Introduction

Cisco IOS[®] Network Address Translation (NAT) software allows access to shared services from multiple MPLS VPNs, even when the devices in the VPNs use IP addresses that overlap. Cisco IOS NAT is VRF-aware and can be configured on provider edge routers within the MPLS network.

Note: MPLS in IOS is supported only with legacy NAT. At this time, there is no support in Cisco IOS for NAT NVI with MPLS.

The deployment of MPLS VPNs is projected to increase rapidly over the next several years. The benefits of a common network infrastructure that permits rapid expansion and flexible connectivity options will undoubtedly drive further growth in services that can be offered to the Internetwork community.

However, barriers to growth still remain. IPv6 and its promise of an IP address space that exceeds the connectivity needs for the foreseeable future is still in the early phases of deployment. Existing networks commonly use private IP addressing schemes as defined within RFC 1918 [\[1\]](#). Network address translation is often used to interconnect networks when address spaces overlap or duplication exists.

Service providers and enterprises that have network application services they want to offer or share with customers and partners will want to minimize any connectivity burden placed on the user of the service. It is desirable, even mandatory, to extend the offering to as many potential users as needed to achieve the desired goals or return. The IP addressing scheme in use must not be a barrier that excludes potential users.

By deploying Cisco IOS NAT within the common MPLS VPN infrastructure, communications service providers can relieve some of the connectivity burden on customers and accelerate their ability to link more shared application services to more consumers of those services.

Benefits from NAT MPLS Integration

NAT integration with MPLS has benefits for both service providers and their enterprise customers. It offers service providers more options to deploy shared services and to provide access to those services. Additional service offerings can be a differentiator over competitors.

For Service Provider	For VPN
More service offerings	Reduced costs
Increased access options	Simpler access
Increased revenue	Addressing flexibility

Enterprise customers seeking to outsource some of their current workload can also benefit from wider offerings by service providers. Shifting the burden of performing any necessary address translation to the service provider network relieves them of a complicated administrative task. Customers may continue to use private addressing, yet maintain access to shared services and the Internet. Consolidating the NAT function within the service provider network may also lower the total cost to enterprise customers since the customer edge routers do not have to perform the NAT function.

Design Considerations

When considering designs that will invoke NAT within the MPLS network, the first step is to determine the service needs from an application point of view. You will need to consider the protocols used and any special client/server communication imposed by the application. Make sure that the necessary support for the protocols employed are supported and handled by Cisco IOS NAT. A list of supported protocols is provided in the document Cisco IOS NAT Application Layer Gateways.

Next, it will be necessary to determine the expected usage of the shared service and the anticipated traffic rate in packets-per-second. NAT is a router CPU-intensive function. Therefore, performance requirements will be a factor in selecting a particular deployment option and to determine the number of NAT devices involved.

Also, consider any security issues and precautions that should be taken. Although MPLS VPNs, by definition, are private and effectively separate traffic, the shared service network is generally common among many VPNs.

Deployment Scenarios

There are two options for NAT deployment within the MPLS provider edge:

- Centralized with egress NAT PEs
- Distributed with ingress NAT PEs

Some advantages to configuring the NAT function at the egress point of the MPLS network nearest to the shared service network include:

- A centralized configuration that promotes simpler service provisioning
- Simplified troubleshooting
- Enhanced operational scalability
- Decreased IP address allocation requirements

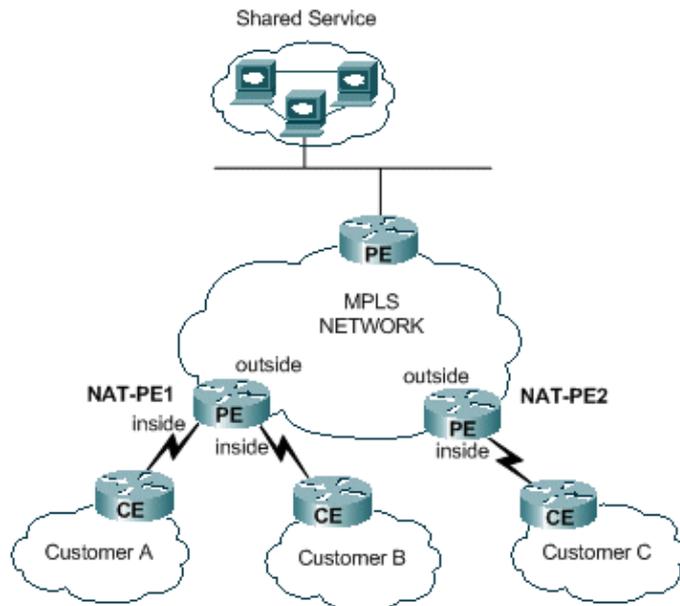

However, the advantages are offset by a reduction in scalability and performance. This is the main tradeoff that must be considered. Of course, the NAT function can also be performed within the customer networks if it is determined that integration of this feature with an MPLS network is not desirable.

Ingress PE NAT

NAT can be configured at the MPLS network ingress PE router as shown in Figure 1. With this design, scalability is maintained to a large extent while performance is optimized by distributing the NAT function

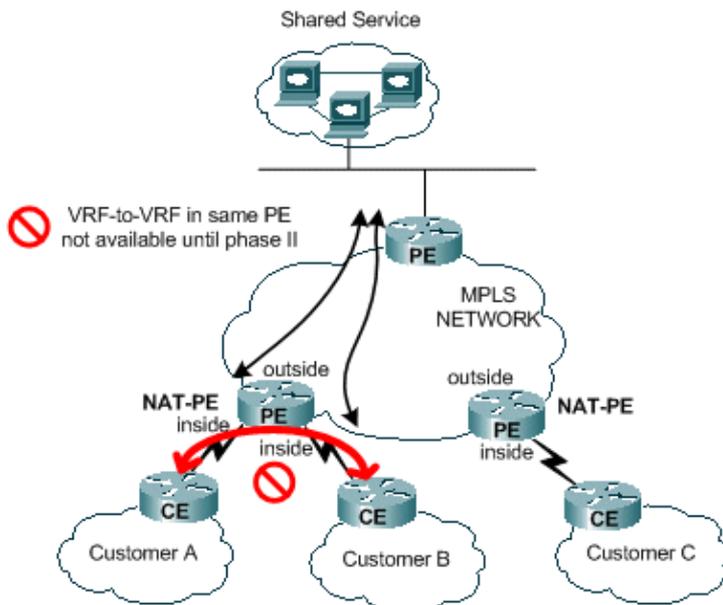

over many edge devices. Each NAT PE handles traffic for sites locally connected to that PE. NAT rules and access control lists or route maps control which packets require translation.

Figure 1: Ingress PE NAT

There is a restriction that prevents NAT between two VRFs while also providing NAT to a shared service as shown in Figure 2. This is due to the requirement to designate interfaces as NAT inside and outside interfaces. Support for connections between VRFs in a single PE is planned for a future Cisco IOS release.

Figure 2: Business to Business

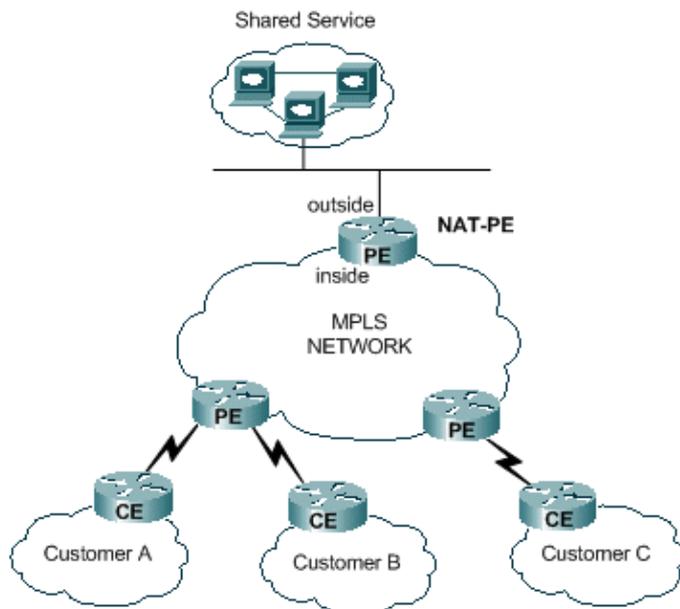

Egress PE NAT

NAT can be configured at the MPLS network egress PE router as shown in Figure 3. With this design, scalability is reduced to some degree since the central PE must maintain routes for all customer networks that access the shared service. The application performance requirements must also be considered so that the traffic does not overburden the router that must translate the IP addresses of the packets. Because NAT occurs

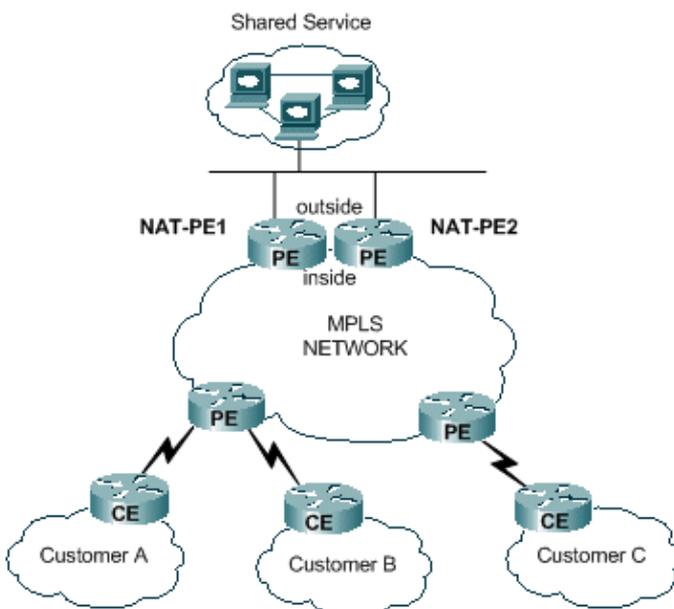

centrally for all customers using this path, IP address pools can be shared; thus, the total number of subnets required is reduced.

Figure 3: Egress PE NAT

Multiple routers could be deployed to increase the scalability of the egress PE NAT design as shown in Figure 4. In this scenario, customer VPNs could be provisioned on a specific NAT router. Network address translation would occur for the aggregate traffic to and from the shared service for that set of VPNs. For example, traffic from the VPNs for Customer A and B could use NAT-PE1, while traffic to and from the VPN for customer C uses NAT-PE2. Each NAT PE would carry traffic only for the specific VPNs defined and only maintain routes back to the sites in those VPNs. Separate NAT address pools could be defined within each of the NAT PE routers so that packets are routed from the shared service network to the proper NAT PE for translation and routing back to the customer VPN.

Figure 4: Multiple Egress PE NAT

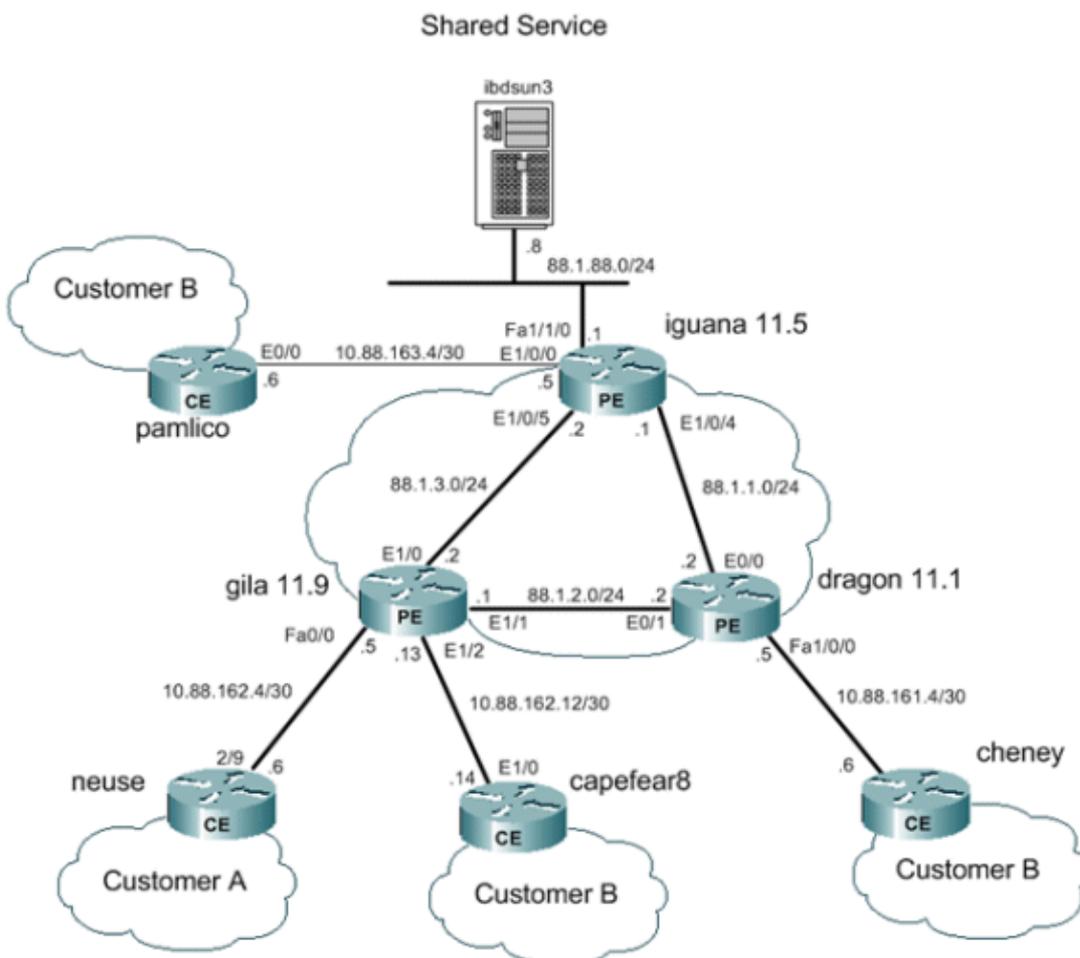

The centralized design does impose a restriction on how the shared service network must be configured. Specifically, use of import/export of MPLS VPN routes between a shared service VPN and customer VPNs is not possible. This is due to the nature of MPLS operation as specified by RFC 2547 [\[4\]](#). When routes are imported and exported using the extended communities and route descriptors, NAT cannot determine the source VPN from the packet coming into the central NAT PE. The usual case is to make the shared service network a generic interface rather than a VRF interface. A route to the shared service network is then added in the central NAT PE for each VRF table associated with a customer VPN needing access to the shared service as part of the provisioning process. This is described in more detail later.

Deployment Options and Configuration Details

This section includes some details related to each of the deployment options. The examples are all taken from the network shown in Figure 5. Refer to this diagram for the rest of this section.

Note: In the network used to illustrate the operation of VRF NAT for this paper, only PE routers are included. There are no core P routers. However, the essential mechanisms can still be seen.

Figure 5: VRF NAT Configuration Example

Egress PE NAT

In this example, the provider edge routers marked **gila** and **dragon** are configured as simple PE routers. The central PE near the shared service LAN (**iguana**) is configured for NAT. A single NAT pool is shared by each customer VPN that needs access to the shared service. The NAT is performed only on packets destined for the shared service host at 88.1.88.8.

Egress PE NAT Data Forwarding

With MPLS, each packet enters the network at an ingress PE and exits the MPLS network at an egress PE. The path of label switching routers traversed from ingress to egress is known as the label switched path (LSP). The LSP is unidirectional. A different LSP is used for return traffic.

When using egress PE NAT, a forwarding equivalence class (FEC) is effectively defined for all traffic from users of the shared service. In other words, all packets destined for the shared service LAN are members of a common FEC. A packet is assigned to a particular FEC just once at the ingress edge of the network and follows the LSP to the egress PE. The FEC is designated in the data packet by adding a particular label.

Packet Flow to Shared Service from VPN

In order for devices in multiple VPNs that have overlapping address schemes to access a shared service host, NAT is required. When NAT is configured at the egress PE, the network address translation table entries will include a VRF identifier to differentiate duplicate addresses and ensure proper routing.

Figure 6: Packets Transmitted to Egress PE NAT

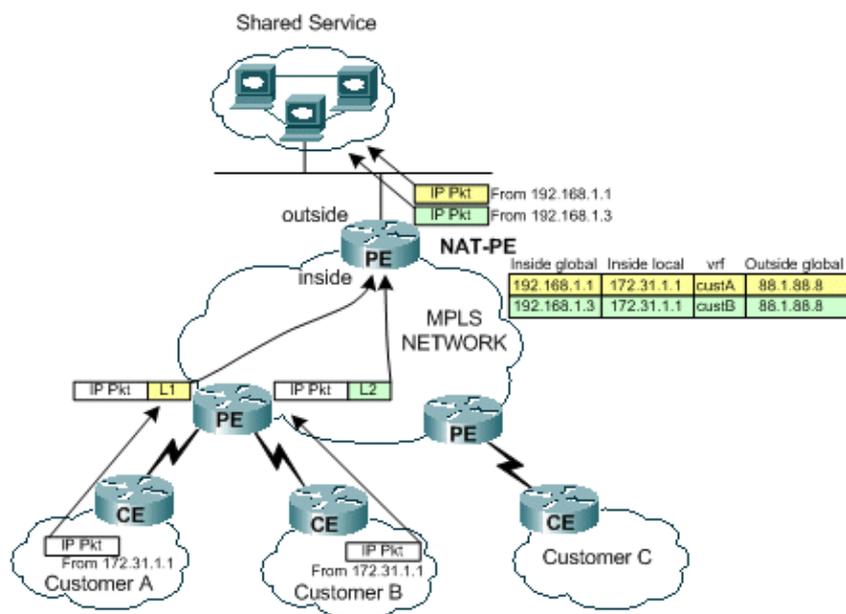

Figure 6 illustrates packets destined for a shared service host from two customer VPNs that have duplicate IP addressing schemes. The figure shows a packet originating at Customer A with a source address of 172.31.1.1 destined for a shared server at 88.1.88.8. Another packet from Customer B with the same source IP address is also sent to the same shared server. When the packets reach the PE router, a layer 3 lookup is done for the destination IP network in the forwarding information base (FIB).

The FIB entry tells the PE router to forward the traffic to the egress PE using a label stack. The bottom label in the stack is assigned by the destination PE router, in this case router **iguana**.

```
iguana#  
show ip cef vrf custA 88.1.88.8  
  
88.1.88.8/32, version 47, epoch 0, cached adjacency 88.1.3.2  
0 packets, 0 bytes  
tag information set  
  local tag: VPN-route-head  
  fast tag rewrite with Et1/0, 88.1.3.2, tags imposed: {24}  
  via 88.1.11.5, 0 dependencies, recursive
```

```

next hop 88.1.3.2, Ethernet1/0 via 88.1.11.5/32
valid cached adjacency
tag rewrite with Et1/0, 88.1.3.2, tags imposed: {24}

iguana# show ip cef vrf custB 88.1.88.8
88.1.88.8/32, version 77, epoch 0, cached adjacency 88.1.3.2
0 packets, 0 bytes
tag information set
  local tag: VPN-route-head
  fast tag rewrite with Et1/0, 88.1.3.2, tags imposed: {28}
via 88.1.11.5, 0 dependencies, recursive
  next hop 88.1.3.2, Ethernet1/0 via 88.1.11.5/32
  valid cached adjacency
  tag rewrite with Et1/0, 88.1.3.2, tags imposed: {28}
iguana#

```

We can see from the display that packets from VRF custA will have a tag value of 24 (0x18) and packets from VRF custB will have a tag value of 28 (0x1C).

In this case, because there are no P routers in our network, there is no additional tag imposed. Had there been core routers, an outside label would have been imposed and the normal process of label swapping would have taken place within the core network until the packet reached the egress PE.

Since the **gila** router is directly connected to the egress PE, we see that the tag is popped before it is ever added:

```

Packet Flow from Shared Service Back to Origin VPN

As packets flow back to devices that have accessed the shared service host, the NAT table is examined prior to routing (packets going from NAT outside interface to inside interface). Because each unique entry includes the corresponding VRF identifier, the packet can be translated and routed appropriately.

Figure 7: Packets Transmitted Back to Shared Service User

As shown in Figure 7, return traffic is first examined by NAT to find a matching translation entry. For example, a packet is sent to destination 192.168.1.1. The NAT table is searched. When the match is found, the appropriate translation is done to the inside local address (172.31.1.1) and then an adjacency lookup is performed using the associated VRF ID from the NAT entry.

```
iguana# show ip cef vrf custA 172.31.1.0
172.31.1.0/24, version 12, epoch 0, cached adjacency 88.1.3.1
0 packets, 0 bytes
tag information set
  local tag: VPN-route-head
  fast tag rewrite with Et1/0/5, 88.1.3.1, tags imposed: {23}
via 88.1.11.9, 0 dependencies, recursive
next hop 88.1.3.1, Ethernet1/0/5 via 88.1.11.9/32
valid cached adjacency
tag rewrite with Et1/0/5, 88.1.3.1, tags imposed: {23}

iguana# show ip cef vrf custB 172.31.1.0
172.31.1.0/24, version 18, epoch 0, cached adjacency 88.1.3.1
0 packets, 0 bytes
tag information set
  local tag: VPN-route-head
  fast tag rewrite with Et1/0/5, 88.1.3.1, tags imposed: {26}
via 88.1.11.9, 0 dependencies, recursive

valid cached adjacency
tag rewrite with Et1/0/5, 88.1.3.1, tags imposed: {26}
iguana#
```

Label 23 (0x17) is used for traffic destined for 172.31.1.0/24 in VRF custA and label 26 (0x1A) is used for packets destined for 172.31.1.0/24 in VRF custB.

This is seen in the echo reply packets sent from router **iguana**:

```
To custA:

```

Router **dragon** would have a configuration very similar to **gila**.

Import/Export of Route Targets Not Permitted

When the shared service network is configured as a VRF instance itself, central NAT at the egress PE is not possible. This is because the incoming packets cannot be distinguished and only one route back to the originating subnet is present at the egress PE NAT.

Note: The displays that follow are meant to illustrate the result of an invalid configuration.

The sample network was configured so that the shared service network was defined as a VRF instance (VRF name = sserver). Now, a display of the CEF table on the ingress PE shows this:

```

gila# show ip cef vrf custA 88.1.88.0
88.1.88.0/24, version 45, epoch 0, cached adjacency 88.1.3.2
0 packets, 0 bytes
tag information set
  local tag: VPN-route-head
  fast tag rewrite with Et1/0, 88.1.3.2, tags imposed: {24}
via 88.1.11.5, 0 dependencies, recursive
  next hop 88.1.3.2, Ethernet1/0 via 88.1.11.5/32
  valid cached adjacency
  tag rewrite with Et1/0, 88.1.3.2, tags imposed: {24}
gila#

gila# show ip cef vrf custB 88.1.88.0
88.1.88.0/24, version 71, epoch 0, cached adjacency 88.1.3.2
0 packets, 0 bytes
tag information set
  local tag: VPN-route-head
  fast tag rewrite with Et1/0, 88.1.3.2, tags imposed: {24}
via 88.1.11.5, 0 dependencies, recursive

```

```

next hop 88.1.3.2, Ethernet1/0 via 88.1.11.5/32
valid cached adjacency
tag rewrite with Et1/0, 88.1.3.2, tags imposed: {24}
gila#

```

```

iguana#
show tag-switching forwarding vrftags 24
Local   Outgoing   Prefix           Bytes tag   Outgoing   Next Hop
tag     tag or VC   or Tunnel Id     switched   interface
24     Aggregate  88.1.88.0/24[V]  10988
iguana#

```

Note: Notice how the tag value *24* is imposed for both VRF *custA* and VRF *custB*.

This display shows the routing table for the shared service VRF instance *sserver* :

```

iguana#
show ip route vrf sserver 172.31.1.1
Routing entry for 172.31.1.0/24
  Known via "bgp 65002", distance 200, metric 0, type internal
  Last update from 88.1.11.9 1d01h ago
  Routing Descriptor Blocks:
    * 88.1.11.9 (Default-IP-Routing-Table), from 88.1.11.9, 1d01h ago
      Route metric is 0, traffic share count is 1
      AS Hops 0

```

Note: Only one route is present for the destination network from the egress PE router *s* (**iguana**) perspective.

Therefore, traffic from multiple customer VPNs could not be distinguished and return traffic could not reach the appropriate VPN. **In the case where the shared service must be defined as a VRF instance, the NAT function must be moved to the ingress PE.**

Ingress PE NAT

In this example, the provider edge routers marked **gila** and **dragon** are configured for NAT. A NAT pool is defined for each attached customer VPN that needs access to the shared service. The appropriate pool is used for each of the customer network addresses that are NATed. The NAT is performed only on packets destined for the shared service host at 88.1.88.8.

```

ip nat pool SSPOOL1 192.168.1.1 192.168.1.254 prefix-length 24
ip nat pool SSPOOL2 192.168.2.1 192.168.2.254 prefix-length 24
ip nat inside source list 181 pool SSPOOL1 vrf custA overload
ip nat inside source list 181 pool SSPOOL2 vrf custB overload

```

Note: In this scenario, shared pools are not supported. If the shared service LAN (at the egress PE) is connected through a generic interface, then the NAT pool may be shared.

A ping sourced from a duplicate address (172.31.1.1) within each of the networks attached to **neuse** and **capefear8** results in these NAT entries:

From **gila**:

```

gila#
show ip nat translations

```

These displays show the routing information for each of the locally attached VPNs for customer A and customer B:

```

gila# show ip route vrf custA
Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
       D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       I - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default, U - per-user static route, o - ODR
       P - periodic downloaded static route

```

Gateway of last resort is 88.1.11.1 to network 0.0.0.0

```
172.18.0.0/32 is subnetted, 2 subnets
B    172.18.60.179 [200/0] via 88.1.11.1, 00:03:59
B    172.18.60.176 [200/0] via 88.1.11.1, 00:03:59
172.31.0.0/24 is subnetted, 1 subnets
S    172.31.1.0 [1/0] via 10.88.162.6, FastEthernet0/0
10.0.0.0/8 is variably subnetted, 5 subnets, 2 masks
B    10.88.0.0/20 [200/0] via 88.1.11.1, 00:03:59
B    10.88.32.0/20 [200/0] via 88.1.11.1, 00:03:59

```

Router **dragon** would have a configuration very similar to **gila**.

Packets Arriving at Central PE after Ingress PE NAT

The traces below illustrate the requirement for unique NAT pools when the destination shared service network is configured as a VRF instance. Again, refer to the diagram in Figure 5. The packets shown below were captured as they entered the MPLS IP interface e1/0/5 at router **iguana**.

Echo from Customer A VPN

Here, we see an echo request coming from source IP address 172.31.1.1 in VRF custA. The source address has been translated to 192.168.1.1 as specified by the NAT configuration:

```

ip nat pool SSP00L1 192.168.1.1 192.168.1.254 prefix-length 24
ip nat inside source list 181 pool SSP00L1 vrf custA overload

DLC: ----- DLC Header -----

Echo Reply to Customer B VPN

Here, we see an echo reply going back to the destination IP address 192.168.1.1 in VRF custB. The destination address is translated to 172.31.1.1 by the ingress PE NAT function.

```

To VRF custB:
DLC: ----- DLC Header -----
DLC:
DLC: Frame 12 arrived at 09:15:49.6635; frame size is 118 (0076 hex) bytes.
DLC: Destination = Station 0090BF9C6C1C
DLC: Source       = Station 005054D92A25
DLC: Ethertype    = 8847 (MPLS)
DLC:
MPLS: ----- MPLS Label Stack -----
MPLS:
MPLS: Label Value           = 0001D
MPLS: Reserved For Experimental Use = 0
MPLS: Stack Value           = 1 (Bottom of Stack)
MPLS: Time to Live          = 254 (hops)
MPLS:
IP: ----- IP Header -----
IP:
IP: Version = 4, header length = 20 bytes
IP: Type of service = 00
IP:      000. .... = routine

ICMP: Identifier = 4173
ICMP: Sequence number = 4212
ICMP: [72 bytes of data]
ICMP:
ICMP: [Normal end of "ICMP header".]

```

Note: In the return packets, the MPLS label values are included and differ: *001A* for VRF custA and *001D* for VRF custB.

Echo from Customer A VPN Destination Is a Generic Interface

This next set of packets show the difference when the interface to the shared service LAN is a generic interface and not part of a VRF instance. Here, the configuration has been changed to use a common pool for both local VPNs with overlapping IP addresses.

```

ip nat pool SSPOOL1 192.168.1.1 192.168.1.254 prefix-length 24
ip nat inside source list 181 pool SSPOOL1 vrf custA overload
ip nat inside source list 181 pool SSPOOL1 vrf custB overload

DLC: ----- DLC Header -----
DLC:
DLC: Frame 1 arrived at 09:39:19.6580; frame size is 118 (0076 hex)
      bytes.
DLC: Destination = Station 005054D92A25
DLC: Source       = Station 0090BF9C6C1C
DLC: Ethertype    = 8847 (MPLS)
DLC:

ICMP: [72 bytes of data]
ICMP:
ICMP: [Normal end of "ICMP header".]

```

Echo from Customer B VPN Destination Is a Generic Interface

Here, we see an echo request coming from source IP address 172.31.1.1 in VRF custB. The source address was translated to 192.168.1.3 (from common pool SSPOOL1) as specified by the NAT configuration:

```

ip nat pool SSPOOL1 192.168.1.1 192.168.1.254 prefix-length 24
ip nat inside source list 181 pool SSPOOL1 vrf custA overload
ip nat inside source list 181 pool SSPOOL1 vrf custB overload

DLC: ----- DLC Header -----
DLC:
DLC: Frame 11 arrived at 09:39:26.4971; frame size is 118 (0076 hex)
      bytes.
DLC: Destination = Station 005054D92A25
DLC: Source      = Station 0090BF9C6C1C
DLC: Ethertype   = 8847 (MPLS)
DLC:
MPLS: ----- MPLS Label Stack -----
MPLS:
MPLS: Label Value           = 0001F
MPLS: Reserved For Experimental Use = 0
MPLS: Stack Value           = 1 (Bottom of Stack)
MPLS: Time to Live          = 254 (hops)
MPLS:
IP: ----- IP Header -----
IP:
IP: Version = 4, header length = 20 bytes
IP: Type of service = 00
IP:      000. .... = routine
IP:      ...0 .... = normal delay
IP:      .... 0... = normal throughput
IP:      .... .0.. = normal reliability
IP:      .... ..0. = ECT bit - transport protocol will ignore the CE
      bit
IP:      .... ...0 = CE bit - no congestion
IP: Total length = 100 bytes
IP: Identification = 75
IP: Flags        = 0X
IP:      .0.. .... = may fragment
IP:      ..0. .... = last fragment
IP: Fragment offset = 0 bytes
IP: Time to live    = 254 seconds/hops
IP: Protocol       = 1 (ICMP)
IP: Header checksum = 4A99 (correct)

```

```

IP: Source address      = [192.168.1.3]
IP: Destination address = [88.1.88.8]
IP: No options
IP:
ICMP: ----- ICMP header -----
ICMP:
ICMP: Type = 8 (Echo)
ICMP: Code = 0
ICMP: Checksum = 5783 (correct)
ICMP: Identifier = 4237
ICMP: Sequence number = 977
ICMP: [72 bytes of data]
ICMP:
ICMP: [Normal end of "ICMP header".]

```

Note: When the interface at the egress PE is a generic interface (not a VRF instance), the labels imposed are different. In this case, *0x19* and *0x1F*.

Echo Reply to Customer A VPN Destination Is a Generic Interface

Next, we see an echo reply going back to the destination IP address 192.168.1.1 in VRF custA. The destination address is translated to 172.31.1.1 by the ingress PE NAT function.

```

DLC: ----- DLC Header -----
DLC:
DLC: Frame 2 arrived at 09:39:19.6621; frame size is 114 (0072 hex)
      bytes.
DLC: Destination = Station 0090BF9C6C1C
DLC: Source      = Station 005054D92A25
DLC: Ethertype   = 0800 (IP)
DLC:
IP: ----- IP Header -----
IP:
IP: Version = 4, header length = 20 bytes
IP: Type of service = 00
IP:    000. .... = routine
IP:    ...0 .... = normal delay
IP:    .... 0... = normal throughput
IP:    .... .0.. = normal reliability
IP:    .... ..0. = ECT bit - transport protocol will ignore the CE
      bit
IP:    .... ...0 = CE bit - no congestion
IP: Total length = 100 bytes
IP: Identification = 54387
IP: Flags        = 4X
IP:    .1.. .... = don't fragment
IP:    ..0. .... = last fragment
IP: Fragment offset = 0 bytes
IP: Time to live   = 254 seconds/hops
IP: Protocol      = 1 (ICMP)
IP: Header checksum = 3672 (correct)
IP: Source address = [88.1.88.8]
IP: Destination address = [192.168.1.1]
IP: No options
IP:
ICMP: ----- ICMP header -----
ICMP:
ICMP: Type = 0 (Echo reply)
ICMP: Code = 0
ICMP: Checksum = 1105 (correct)
ICMP: Identifier = 874
ICMP: Sequence number = 3727
ICMP: [72 bytes of data]
ICMP:

```

```
ICMP: [Normal end of "ICMP header".]
```

Echo Reply to Customer B VPN Destination Is a Generic Interface

Here, we see an echo reply going back to the destination IP address 192.168.1.3 in VRF custB. The destination address is translated to 172.31.1.1 by the ingress PE NAT function.

```
DLC: ----- DLC Header -----
DLC:
DLC: Frame 12 arrived at 09:39:26.4978; frame size is 114 (0072 hex)
      bytes.
DLC: Destination = Station 0090BF9C6C1C
DLC: Source       = Station 005054D92A25
DLC: Ethertype   = 0800 (IP)
DLC:
IP: ----- IP Header -----
IP:
IP: Version = 4, header length = 20 bytes
IP: Type of service = 00
IP:      000. .... = routine
IP:      ...0 .... = normal delay
IP:      .... 0... = normal throughput
IP:      .... .0.. = normal reliability
IP:      .... ..0. = ECT bit - transport protocol will ignore the CE
      bit
IP:      .... ...0 = CE bit - no congestion
IP: Total length = 100 bytes
IP: Identification = 61227
IP: Flags        = 4X
IP:      .1.. .... = don't fragment
IP:      ..0. .... = last fragment
IP: Fragment offset = 0 bytes
IP: Time to live = 254 seconds/hops
IP: Protocol      = 1 (ICMP)
IP: Header checksum = 1BB8 (correct)
IP: Source address = [88.1.88.8]
IP: Destination address = [192.168.1.3]
IP: No options
IP:
ICMP: ----- ICMP header -----
ICMP:
ICMP: Type = 0 (Echo reply)
ICMP: Code = 0
ICMP: Checksum = 5F83 (correct)
ICMP: Identifier = 4237
ICMP: Sequence number = 977
ICMP: [72 bytes of data]
ICMP:
ICMP: [Normal end of "ICMP header".]
```

Note: Since the replies are destined to a global address, no VRF labels are imposed.

With the exit interface to the shared service LAN segment defined as a generic interface, a common pool is permitted. The pings result in these NAT entries in router **gila**:

```
gila# show ip nat translations
Pro Inside global      Inside local      Outside local      Outside global

Service Example

An example of a shared virtual IP PBX service is shown in Figure 8. This illustrates a variant to the ingress and egress examples described earlier.

In this design, the shared VoIP service is front-ended by a set of routers that perform the NAT function. These routers have multiple VRF interfaces using a feature known as VRF-Lite. The traffic then flows to the shared Cisco CallManager cluster. Firewall services are also provided on a per-company basis. Inter-company calls must pass through the firewall, while intra-company calls are handled across the customer VPN using the company's internal addressing scheme.

Figure 8: Managed Virtual PBX Service Example

Availability

Cisco IOS NAT support for MPLS VPNs is available in Cisco IOS release 12.2(13)T and is available for all platforms that support MPLS and can run this early deployment release train.

Conclusion

Cisco IOS NAT has features to permit scalable deployment of shared services today. Cisco continues to develop NAT application level gateway (ALG) support for protocols important to customers. Performance improvements and hardware acceleration for translation functions will ensure that NAT and ALGs provide acceptable solutions for some time to come. All relevant standards activities and community actions are being monitored by Cisco. As other standards are developed, their use will be evaluated based on customer desires, requirements, and application.
