AAA on Cisco IOS Routers

**Note**

From version 4.17, though Cisco Security Manager continues to support IOS features/functionality, it does not support any bug fixes or enhancements.

Authentication, authorization, and accounting (AAA) network security services provide the primary framework through which you set up access control on your Cisco IOS router. Use the AAA policy in Security Manager to enable AAA functionality on Cisco IOS routers and to configure default AAA settings. The default settings that you define in this policy can be used in other policies, such as HTTP and line access (console and VTY) policies. Enabling AAA functionality is a prerequisite for any device policy that makes use of AAA, including NAC, SDP, and 802.1x.

For more information about AAA, see:

- [Supported Authorization Types, page 63-2](#)
- [Supported Accounting Types, page 63-3](#)
- [Understanding Method Lists, page 63-3](#)

To configure a AAA policy, see:

- [Defining AAA Services, page 63-4](#)

Related Topics

- [Understanding AAA Server and Server Group Objects, page 6-27](#)
- [Line Access on Cisco IOS Routers, page 63-35](#)

Supported Authorization Types

AAA authorization enables you to limit the services available to an authenticated user. Security Manager supports the following types of authorization:

- **Network**—Authorizes various types of network connections, such as PPP, SLIP, and ARAP.
- **EXEC**—Authorizes the launching of EXEC (CLI) sessions.
- **Command**—Authorizes the use of all EXEC mode commands that are associated with specific privilege levels.

When authorization is enabled, the router uses information retrieved from the user's profile to configure the user session. The profiles are located either in the local user database or on a security server. Users are granted access to a requested service only if the profile allows it.

Related Topics

- [Understanding Method Lists, page 63-3](#)
- [Defining AAA Services, page 63-4](#)
- [AAA on Cisco IOS Routers, page 63-2](#)

Supported Accounting Types

AAA accounting enables you to track the services the users are accessing and the amount of network resources that they are consuming. Security Manager supports the following accounting types:

- **Connection**—Records information about all outbound connections made from this device, such as Telnet, local-area transport (LAT), TN3270, packet assembler/disassembler (PAD), and rlogin connections.

For example, a RADIUS connection accounting record for an outbound Telnet connection includes such information as the port and IP address of the network access server (NAS), the start and end times of the connection, the identity of the user, and the number of packets that were transmitted during the session.

- **EXEC**—Records information about user EXEC (CLI) sessions on the devices, including the username, date, start and stop times, and the IP address of the NAS. For dial-in users, the record includes the telephone number from which the call originated.
- **Command**—Records information about the EXEC commands executed on the device by users with specific privilege levels. Each command accounting record includes a list of the commands executed for that privilege level, the date and time each command was executed, and the name of the user who executed it.

For each accounting type, you can choose whether you want to generate an accounting record at the start and end of each user session or only at the end.

When AAA accounting is enabled, the router sends accounting records of user activity to the TACACS+ or RADIUS security server. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server. This data can later be analyzed for network management, client billing, and auditing purposes.

Related Topics

- [Supported Accounting Types, page 63-3](#)
- [Understanding Method Lists, page 63-3](#)
- [Defining AAA Services, page 63-4](#)
- [AAA on Cisco IOS Routers, page 63-2](#)

Understanding Method Lists

A method list is a sequential list describing the methods to use to perform a particular AAA function. In Security Manager, you define method lists by selecting AAA server groups, which are reusable objects that typically contain one or more AAA servers running the same protocol, such as RADIUS or TACACS+. Method lists enable you to designate one or more security protocols to be used for each AAA function, thus ensuring a backup system if the initial method fails.

**Note**

Security Manager also contains predefined AAA server group objects for using the enable password or a local database. See [Predefined AAA Authentication Server Groups, page 6-30](#).

For each AAA function, the device initially uses the first method defined in the list. If that method fails to respond, the device selects the next method in the list. This process continues until there is successful communication with a listed method, or all methods defined in the method list are exhausted.

**Note**

The device attempts to communicate with the next listed method only when there is no response from the previous method. If the AAA service fails at any point in this cycle—meaning that the security server or local username database responds by denying the user access or services—the process stops and no other methods are attempted.

- [Supported Authorization Types, page 63-2](#)
- [Supported Accounting Types, page 63-3](#)
- [Defining AAA Services, page 63-4](#)
- [AAA on Cisco IOS Routers, page 63-2](#)

Defining AAA Services

To define AAA services on a Cisco IOS router, you must first enable AAA functionality on the router. After you do this, you can define the kind of functionality (authentication, authorization, and accounting) that you want the device to implement. You must define a method list for each function, including lists for each type of authorization and accounting that you enable.

For example, if you want to configure EXEC authorization and command authorization, you must define one method list for EXEC authorization and other method lists for each privilege level on which command authorization is performed.

**Note**

If you use RADIUS for authentication, you must use the same RADIUS server group for authorization as well.

Related Topics

- [Understanding Method Lists, page 63-3](#)
- [AAA on Cisco IOS Routers, page 63-2](#)
- [Understanding AAA Server and Server Group Objects, page 6-27](#)

Step 1

Do one of the following:

- (Device view) Select **Platform > Device Admin > AAA** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > AAA** from the Policy Type selector. Select an existing policy or create a new one.

The AAA page is displayed. See [AAA Policy Page, page 63-6](#) for a description of the fields on this page.

- Step 2** Define which login authentication methods to use on users who access the device:
- On the Authentication tab (see [AAA Page—Authentication Tab, page 63-6](#)), select the **Enable Device Login Authentication** check box.
 - Enter the names of one or more AAA server group objects (up to four) in the Prioritized Method List field, or click **Select** select the object from a list or to create a new one. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used.

Note If you select None as a method, it must appear as the last method in the list.

- Step 3** (Optional) In the Maximum Number of Attempts field, define the maximum number of unsuccessful authentication attempts to allow before a user is locked out.

- Step 4** (Optional) Define which authorization methods to use on users who have been successfully authenticated:

- Click the **Authorization** tab on the AAA page. See [Table 63-3 on page 63-8](#) for a description of the fields on this tab.
- Define method lists for one or more of the following types of authorization:
 - Network
 - EXEC
 - Command—Click the **Add** button to display the Command Authorization dialog box (see [Command Authorization Dialog Box, page 63-10](#)). From here, you can select a privilege level and the method list to apply to it.

For more information about these authorization types, see [Supported Authorization Types, page 63-2](#).

Note RADIUS uses the same server for authentication and authorization. Therefore, if you use define a RADIUS method list for authentication, you must define the same method list for authorization.

- Step 5** (Optional) Define which accounting methods to use on the activities performed by users:

- Click the **Accounting** tab on the AAA page. See [Table 63-5 on page 63-11](#) for a description of the fields on this tab.
- Define method lists for one or more of the following types of accounting:
 - Connection
 - EXEC
 - Command—Click the **Add** button to display the Command Accounting dialog box (see [Command Accounting Dialog Box, page 63-13](#)). From here, you can select a privilege level and the method list to apply to it.

For more information about these accounting types, see [Supported Accounting Types, page 63-3](#).

- For each accounting type defined above, select a value from the Accounting Process Notices list. This defines when to create an accounting record, at the beginning and end of the user process or only at the end.

- d. For each accounting type defined above, select the **Enable broadcast to multiple servers** check box if you want accounting information sent simultaneously to the first server in each AAA server group defined in the method list.

AAA Policy Page

Use the AAA page to define the default authentication, authorization, and accounting methods to use on the router. You do this by configuring method lists, which define which methods to use and the sequence in which to use them.

Note

You can use the method lists defined in this policy as default settings when you configure AAA on the router's console port and VTY lines. See [Console Policy Page, page 63-42](#) and [VTY Policy Page, page 63-50](#).

Navigation Path

- (Device view) Select **Platform > Device Admin > AAA** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > AAA** from the Policy Type selector. Right-click **AAA** to create a policy, or select an existing policy from the Shared Policy selector.

Field Reference

Table 63-2 AAA Page—Authentication Tab

Element	Description
Enable Device Login Authentication	<p>When selected, enables the authentication of all users when they log in to the device, using the methods defined in the method list.</p> <p>When deselected, authentication is not performed.</p>
Prioritized Method List	<p>Defines a sequential list of methods to be queried when authenticating a user. Enter the names of one or more AAA server group objects (up to four), or click Select to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the Create button to create it.</p> <p>The device tries initially to authenticate users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received.</p> <p>Supported methods include Line, Local, Kerberos, LDAP, RADIUS, TACACS+, and None.</p> <p>Note If you select None as a method, it must appear as the last method in the list.</p>
Maximum Number of Attempts	<p>The maximum number of unsuccessful authentication attempts before a user is locked out. This feature is disabled by default. Valid values range from 1 to 65535.</p> <p>Note From the standpoint of the user, there is no distinction between a normal authentication failure and an authentication failure due to being locked out. The system administrator has to explicitly clear the status of a locked-out user using clear commands.</p>

AAA Page—Authorization Tab

Use the Authorization tab of the AAA page to define the type of authorization services to enable on the device and the methods to use for each type. Security Manager supports the following types of authorization:

- Network—Authorizes various types of network connections, such as PPP.
- EXEC—Authorizes the launching of EXEC sessions.
- Command—Authorizes the use of all EXEC mode commands that are associated with specific privilege levels.

Note You can use the method lists defined in this policy on the console and VTY lines that are used to communicate with the device. See [Console Policy Page, page 63-42](#) and [VTY Line Dialog Box—Authentication Tab, page 63-55](#).

Navigation Path

Go to the [AAA Policy Page, page 63-6](#), then click the **Authorization** tab.

Element	Description
Prioritized Method List	<p>Defines a sequential list of methods to be queried when authorizing a user. Enter the names of one or more AAA server group objects (up to four), or click Select to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the Create button to create it.</p> <p>The device tries initially to authorize users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received.</p> <p>Supported methods include LDAP, RADIUS, TACACS+, Local, and None.</p> <p>Note RADIUS uses the same server for authentication and authorization. Therefore, if you use define a RADIUS method list for authentication, you must define the same method list for authorization.</p> <p>Note If you select None as a method, it must appear as the last method in the list.</p>
EXEC Authorization settings	
Enable CLI/EXEC Operations Authorization	<p>When selected, this type of authorization determines whether the user is permitted to open an EXEC (CLI) session, using the methods defined in the method list.</p> <p>When deselected, EXEC authorization is not performed.</p>
Prioritized Method List	<p>Defines a sequential list of methods to be queried when authorizing a user. Enter the names of one or more AAA server group objects (up to four), or click Select to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the Create button to create it.</p> <p>The device tries initially to authorize users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received.</p>
Command Authorization settings	
Privilege Level	The privilege level to which the command authorization definition applies.
Prioritized Method List	The method list to use when authorizing users with this privilege level.
Add button	Opens the Command Authorization Dialog Box, page 63-10 . From here you can configure a command authorization definition.
Edit button	Opens the Command Authorization Dialog Box, page 63-10 . From here you can edit the command authorization definition.
Delete button	Deletes the selected command authorization definitions from the table.

Command Authorization Dialog Box

Use the Command Authorization dialog box to define which methods to use when authorizing the EXEC commands that are associated with a given privilege level. This enables you to authorize all commands associated with a specific privilege level, from 0 to 15.

Navigation Path

From the [AAA Page—Authorization Tab, page 63-8](#), click the **Add** button beneath the Command Authorization table.

Related Topics

- [Defining AAA Services, page 63-4](#)
- [Supported Authorization Types, page 63-2](#)
- [Understanding Method Lists, page 63-3](#)

Field Reference

Table 63-4 *Command Authorization Dialog Box*

Element	Description
Privilege Level	The privilege level for which you want to define a command accounting list. Valid values range from 0 to 15.
Prioritized Method List	<p>Defines a sequential list of methods to be used when authorizing a user. Enter the names of one or more AAA server group objects (up to four), or click Select to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the Create button to create it.</p> <p>The device tries initially to authorize users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received.</p> <p>Supported methods include TACACS+, Local, and None.</p> <p>Note If you select None as a method, it must appear as the last method in the list.</p>

AAA Page—Accounting Tab

Use the Accounting tab of the AAA page to define the type of accounting services to enable on the device and the methods to use for each type. Security Manager supports the following types of accounting:

- **Connection**—Records information about all outbound connections made from this device.
- **EXEC**—Records information about user EXEC sessions on the devices, including the username, date, start and stop times, and the IP address.
- **Command**—Records information about the EXEC commands executed on the device by users with specific privilege levels.

In addition, you use the Accounting page to determine when accounting records should be generated and whether they should be broadcast to more than one AAA server.

**Note**

You can use the method lists defined in this policy on the console and VTY lines that are used to communicate with the device. See [Console Policy Page, page 63-42](#) and [VTY Line Dialog Box—Authentication Tab, page 63-55](#).

Navigation Path

Go to the [AAA Policy Page, page 63-6](#), then click the **Accounting** tab.

Related Topics

- [Defining AAA Services, page 63-4](#)

Table 63-5 AAA Page—Accounting Tab

Element	Description
Connection Accounting settings	
Enable Connection Accounting	<p>When selected, enables the recording of information about outbound connections (such as Telnet) made over this device, using the methods defined in the method list.</p> <p>When deselected, connection accounting is not performed.</p>
Generate Accounting Records for	<p>Defines when the device sends an accounting notice to the accounting server:</p> <ul style="list-style-type: none"> • Start and Stop—Generates accounting records at the beginning and the end of the user process. The user process begins regardless of whether the accounting server receives the “start” accounting record. • Stop Only—Generates an accounting record at the end of the user process only. • None—Disables this type of accounting.
Prioritized Method List	<p>Defines a sequential list of methods to be queried when creating connection accounting records for a user. Enter the names of one or more AAA server group objects (up to 10 for IOS 12.4(22)T+, otherwise up to four), or click Select to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the Create button to create it.</p> <p>Supported methods include LDAP, RADIUS, and TACACS+.</p>

Table 63-5 AAA Page—Accounting Tab (continued)

Element	Description
Enable Broadcast to Multiple Servers	<p>When selected, enables the sending of accounting records to multiple AAA servers. Accounting records are sent simultaneously to the first server in each AAA server group defined in the method list. If the first server is unavailable, failover occurs using the backup servers defined within that group.</p> <p>When deselected, accounting records are sent only to the first server in the first AAA server group defined in the method list.</p>
EXEC Accounting Settings	
Enable CLI/EXEC Operations Accounting	<p>When selected, enables the recording of basic information about user EXEC sessions, using the methods defined in the method list.</p> <p>When deselected, EXEC accounting is not performed.</p>
Generate Accounting Records for	See description Table 43-7 on page 43-17 .
Prioritized Method List	Defines a sequential list of methods to be queried when creating connection accounting records for a user. Enter the names of one or more AAA server group objects (up to 10 for IOS 12.4(22)T+, otherwise up to four), or click Select to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the Create button to create it.
Enable Broadcast to Multiple Servers	When selected, enables the sending of accounting records to multiple AAA servers. Accounting records are sent simultaneously to the first server in each AAA server group defined in the method list. If the first server is unavailable, failover occurs using the backup servers defined within that group.
Command Accounting settings	
Privilege Level	The privilege level to which the command authorization definition applies.
Generate Accounting Records for	The points in the process where the device sends an accounting notice to the accounting server.
Enable Broadcast	Whether accounting records are broadcast to multiple servers simultaneously.
Prioritized Method List	The method list to use when authorizing users with this privilege level.
Add button	Opens the Command Accounting Dialog Box, page 63-13 . From here you can configure a command accounting definition.
Edit button	Opens the Command Accounting Dialog Box, page 63-13 . From here you can edit the command accounting definition.
Delete button	Deletes the selected command accounting definitions from the table.

Command Accounting Dialog Box

Use the Command Accounting dialog box to define which methods to use when recording information about the EXEC commands that are executed for a given privilege level. Each accounting record includes a list of the commands executed for that privilege level, as well as the date and time each command was executed, and the name of the user who executed it.

Navigation Path

From the [AAA Page—Accounting Tab, page 63-10](#), click the **Add** button beneath the Command Accounting table.

User Accounts and Device Credentials on Cisco IOS Routers

Accounts and credential policies define the contact information for accessing the router, including the privilege level provided to each user account. You can configure as many user accounts as required. However, the user account that Security Manager uses to connect to the router is always the one configured in the Device Properties page.

Additionally, you use device access policies to define the enable or enable secret password required to access privileged EXEC mode. This is the mode required to make any configuration changes on the router.

Note

If you use this policy to define a password, be careful later not to unassign this policy without assigning a replacement policy before your next deployment. If you deploy a device access policy that removes this password and the device contains a different type of password not known to Security Manager, such as a line console password, you will not be able to configure this device in the future. This is because the device reverts to this unknown password if Security Manager removes the enable password that it had previously configured.

Related Topics

- [Defining Accounts and Credential Policies, page 63-14](#)

Defining Accounts and Credential Policies

This procedure describes how to define a device access policy on a Cisco IOS router. If the username that you configured on the Device Properties page to connect to the router (see [Viewing or Changing Device Properties, page 3-40](#)) matches one of the user accounts you defined in this policy, Security Manager updates the device credentials according to your policy definition.

If you change the password for the user defined in the device properties, which Security Manager uses to deploy configurations to the device, or change the enable password, Security Manager uses the existing credentials defined in the device properties to log into the device and deploy changes. After successful deployment, the device properties are then changed to use your new settings. For more information on credentials in device properties, see [Device Credentials Page, page 3-45](#).

Note

You can discover encrypted passwords, but any password you enter must be in clear text. If you discover an encrypted password and then modify it, the password is saved as clear text.

Related Topics

- [User Accounts and Device Credentials on Cisco IOS Routers, page 63-14](#)

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > Accounts and Credentials** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Accounts and Credentials** from the Policy Type selector. Select an existing policy or create a new one.

The Accounts and Credentials page is displayed. See [Table 63-7 on page 63-16](#) for a description of the fields on this page.

Step 2 Enter the password for switching to privileged EXEC mode on the router:

- a. Select **Enable Password** or **Enable Secret Password**. The Enable Secret Password option offers better security than the Enable Password option by storing the password using MD5 encryption. This option is useful in environments in which the password crosses the network or is stored on a TFTP server.

Note After you set an enable secret password, you can switch to an enable password only if the enable secret is disabled or an older version of Cisco IOS software is being used, such as when running an older rxboot image.

- b. Enter a password, then enter it again in the Confirm field. The password that you enter must be in clear text. If you are configuring the enable secret password, the password is encrypted on deployment.

Step 3 (Optional) Select the **Enable Password Encryption Service** check box to encrypt all passwords on the device. This includes, for example, the enable password, username passwords, authentication key passwords, console and VTY line access passwords, and BGP neighbor passwords.

We recommend using this feature to help prevent unauthorized individuals from viewing the passwords in your configuration file.

Note This option does not provide a high level of security and should not be used as a substitute for additional network security measures.

Step 4 To define new user accounts for the router:

- a. Click the **Add** button under the table to display the User Accounts dialog box.
- b. Enter the details for the new user. See [Table 63-8 on page 63-18](#) for a description of the available fields.
- c. Click **OK** to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the User Accounts table.

Note To edit a user account, select it from the User Accounts table, then click **Edit**. To remove a user account, select it, then click **Delete**.

**Caution**

While deleting a user account, Cisco Security Manager times out and deployment fails. To avoid this, you can set up Security Manager to download despite an error. Enable **Allow Download on Error** in **Tools > Administrator > Deployments** in the Configuration Manager.

Accounts and Credentials Policy Page

Use the Accounts and Credentials page to define the enable password or enable secret password assigned to the router. In addition, you can define a list of usernames that can be used to access the router.

For more information, see [Defining Accounts and Credential Policies, page 63-14](#).

Navigation Path

- (Device view) Select **Platform > Device Admin > Accounts and Credentials** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Accounts and Credentials** from the Policy Type selector. Right-click **Accounts and Credentials** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- [User Accounts and Device Credentials on Cisco IOS Routers, page 63-14](#)

- [Table Columns and Column Heading Features, page 1-49](#)
- [Filtering Tables, page 1-48](#)

Field Reference

Table 63-7 *Accounts and Credentials Page*

Element	Description
Enable Secret Password	<p>The enable secret password for entering privileged EXEC mode on the router. This option offers better security than the Enable Password option.</p> <p>The enable secret password can contain between 1-25 alphanumeric characters. The first character must be a letter. Spaces are allowed, but leading spaces are ignored. Question marks are also allowed.</p> <p>Note You can discover an encrypted password, but any password you enter must be in clear text. If you modify an encrypted password, it is saved as clear text.</p> <p>Note After you set an enable secret password, you can switch to an enable password only if the enable secret is disabled or an older version of Cisco IOS software is being used, such as when running an older rxboot image.</p>

Table 63-7 Accounts and Credentials Page (continued)

Element	Description
Enable Password	<p>The enable password for entering privileged EXEC mode on the router. The enable password can contain between 1-25 alphanumeric characters. The first character must be a letter. Spaces are allowed, but leading spaces are ignored. Question marks are also allowed.</p> <p>Note You must enter the password in clear text.</p>
Enable Password Encryption Service	<p>When selected, encrypts all passwords on the device, including the enable password (which is otherwise saved in clear text).</p> <p>For example, use this option to encrypt username passwords, authentication key passwords, console and VTY line access passwords, and BGP neighbor passwords. This command is primarily used for keeping unauthorized individuals from viewing your passwords in your configuration file.</p> <p>When deselected, device passwords are stored unencrypted in the configuration file.</p> <p>Note This option does not provide a high level of network security. You should also take additional network security measures.</p>
User Accounts Table	
Username	The username that can be used to access the router. The username must be a single word up to 64 characters in length. Spaces and quotation marks are not allowed.
Encryption	Indicates whether password information for the user is encrypted using MD5 encryption.
Privilege Level	The privilege level assigned to the user.
Add button	Opens the User Account Dialog Box, page 63-17 . From here you can define a user account.
Edit button	Opens the User Account Dialog Box, page 63-17 . From here you can edit the selected user.
Delete button	Deletes the selected user accounts from the table.

User Account Dialog Box

Employ the User Account dialog box to define a username and password combination that can be used by Security Manager to access the router. You can also define the privilege level of the user account, which determines whether you can configure all commands on this router or only a subset of them.

Note

Remember—there may be additional user accounts defined on the router using other methods, such as the CLI.

Navigation Path

Go to the [Accounts and Credentials Policy Page, page 63-16](#), then click the **Add** or **Edit** button beneath the table.

Related Topics

Field Reference**Table 63-8** *User Account Dialog Box*

Element	Description
Username	The username for accessing the router.
Password	The password for accessing the router with this user account. Note You can discover an encrypted password, but any password you enter must be in clear text.
Confirm	Confirms the password for this user account.
Encrypt password using MD5	When selected, uses MD5 encryption to encrypt the password for this user account. This is the default. When deselected, the password is sent to the router unencrypted.
Privilege Level	The privilege level assigned to the user account. Valid values range from 0 to 15: <ul style="list-style-type: none"> • 0—Grants access to these commands only: disable, enable, exit, help, and logout. • 1—Enables nonprivileged access to the router (normal EXEC-mode use privileges). • 15—Enables privileged access to the router (traditional enable privileges). Note Levels 2-14 are not normally used in a default configuration, but custom configurations can be created by moving commands that are normally at level 15 to a lower level and commands that are normally at level 1 to a higher level. You can configure the privilege levels of commands using the CLI or by defining a FlexConfig.

Bridging on Cisco IOS Routers

Bridging policies enable you to perform transparent bridging (as specified in RFC 1286) on selected interfaces that you have configured to function as a bridge group. Security Manager supports integrated routing and bridging, which makes it possible to route a specific protocol between routed interfaces and bridge groups, or route a specific protocol between bridge groups. Local or unroutable traffic can be bridged among the bridged interfaces in the same bridge group, while routable traffic can be routed to other routed interfaces or bridge groups, as shown in [Figure 63-1](#).

Using integrated routing and bridging, you can:

- Switch packets from a bridged interface to a routed interface.
- Switch packets from a routed interface to a bridged interface.

- Switch packets within the same bridge group.

Figure 63-1 *Transparent Bridging*

Related Topics

- [Defining Bridge Groups, page 63-20](#)
- [Bridge-Group Virtual Interfaces, page 63-19](#)

Bridge-Group Virtual Interfaces

Because bridging takes place at the data link layer and routing takes place at the network layer, they have different protocol configuration models. With IP, for example, bridge group interfaces belong to the same network and have a collective IP network address. In contrast, each routed interface represents a distinct network and has its own IP network address. Integrated routing and bridging uses the concept of a bridge-group virtual interface (BVI) to enable these interfaces to exchange packets for a given protocol. As shown in [Figure 63-2](#), the interface number assigned to the BVI corresponds to the bridge group that the BVI represents. This number serves as the link between the virtual interface and the bridge group.

Figure 63-2 *Bridge-Group Virtual Interface*

When you enable routing for a given protocol on the BVI, packets coming from a routed interface that are destined for a host in a bridged domain are routed to the BVI and then forwarded to the corresponding bridged interface. All traffic routed to the BVI is forwarded to the corresponding bridge group as bridged traffic. All routable traffic received on a bridged interface is routed to other routed interfaces as if it is coming directly from the BVI.

**Note**

BVI interfaces are configured using the Interfaces policy. See [Defining Basic Router Interface Settings, page 62-4](#). The BVI interface must have a corresponding bridge group with the same number; otherwise, deployment will fail.

**Note**

When the bridge group contains more than two interfaces, add a BVI interface to the group to help prevent unicast flooding, which is a potential security issue.

Related Topics

- [Defining Bridge Groups, page 63-20](#)
- [Bridging on Cisco IOS Routers, page 63-18](#)

Defining Bridge Groups

You define a bridge group by selecting the L3 interfaces that are part of the bridge group and assigning the group a number. All bridge groups in Security Manager perform integrated routing and bridging on IP traffic only and use the standard Spanning Tree Protocol (IEEE 802.1D).

**Note**

Use CLI commands or FlexConfigs to bridge other protocols, such as AppleTalk or IPX, and to use other spanning tree protocols, such as VLAN-Bridge. Concurrent routing and bridging is not supported.

Related Topics

- [Bridging on Cisco IOS Routers, page 63-18](#)
- [Bridge-Group Virtual Interfaces, page 63-19](#)

Step 1

Do one of the following:

- (Device view) Select **Platform > Device Admin > Bridging** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Bridging** from the Policy Type selector. Select an existing policy or create a new one.

The Bridging page is displayed. See [Table 63-9 on page 63-21](#) for a description of the fields on this page.

Step 2

Click the **Add** button under the table to display the Bridge Group dialog box. See [Table 63-10 on page 63-22](#) for a description of the fields in this dialog box. From here you can define a bridge group.

Step 3

Enter a number to identify the bridge group.

Step 4

Enter the names of the interfaces and interface roles that are part of the bridge group, or click **Select** to select an interface role or to create a new one. For more information, see [Specifying Interfaces During Policy Definition, page 6-76](#).

You can select most Layer 3 interfaces, except X.25 and Integrated Services Digital Network (ISDN) bridged interfaces and certain types of logical interfaces (such as loopback, tunnel, null, and BVI). Each interface can be included in only one bridge group.

You can select a LAN subinterface only if the parent interface is configured with Inter-Switch Link (ISL) or 802.1Q encapsulation.

Step 5 Click **OK** to save your definitions locally on the client and close the dialog box. The bridge group is displayed in the table on the Bridging page.

Note To edit a bridge group, select it from the Groups table, then click **Edit**. To remove a bridge group, select it, then click **Delete**.

Bridging Policy Page

Use the Bridging page to define bridge groups that can perform integrated routing and bridging on the router. For more information, see [Defining Bridge Groups, page 63-20](#).

Navigation Path

- (Device view) Select **Platform > Device Admin > Bridging** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Bridging** from the Policy Type selector. Right-click **Bridging** to create a policy, or select an existing policy from the Shared Policy selector.

- [Filtering Tables, page 1-48](#)

Field Reference

Table 63-9 *Bridging Page*

Element	Description
Group Number	The number that identifies the bridge group.
Group Interfaces	The interfaces and interface roles that are included in the bridge group.
Add button	Opens the Bridge Group Dialog Box, page 63-21 . From here you can define a bridge group.
Edit button	Opens the Bridge Group Dialog Box, page 63-21 . From here you can edit the bridge group.
Delete button	Deletes the selected bridge groups from the table.

Bridge Group Dialog Box

Use the Bridge Group dialog box to define bridge groups on the router. Each bridge group can contain multiple Layer 3 interfaces of various types, including serial interfaces.

Note All bridge groups use the standard Spanning Tree Protocol (IEEE 802.1D). Use CLI commands or FlexConfigs to bridge other protocols, such as AppleTalk or IPX, and to use other spanning tree protocols, such as VLAN-Bridge.

Navigation Path

Go to the [Bridging Policy Page, page 63-21](#), then click the **Add** or **Edit** button beneath the table.

Element	Description
Group Number	The number assigned to the bridge group. Valid values range from 1 to 255.
Group Interfaces	<p>The interfaces that are included in the bridge group. Enter the name of one or more interfaces and interface roles, or click Select to select them. If the object that you want is not listed, click the Create button to create it.</p> <p>You can select most Layer 3 interfaces, including serial interfaces, provided the serial interface is configured with high-level data link control (HDLC) or Frame Relay encapsulation. Each interface can belong to only one bridge group.</p> <p>You can select a LAN subinterface only if the parent interface is configured with Inter-Switch Link (ISL) or 802.1Q encapsulation.</p> <p>Note Certain types of interfaces, such as loopback, tunnel, null, and BVI, cannot be bridged.</p> <p>Note Make sure that your bridge group does not prevent Security Manager from communicating with the device.</p>

Time Zone Settings on Cisco IOS Routers

The local time on a Cisco IOS router is typically set using the clock set command in the CLI command or by dynamically deriving the time from an NTP server. You can adjust these time settings by defining the time zone in which the router resides and the start and end dates of Daylight Saving Time (DST) in that time zone.

Related Topics

- [Defining Time Zone and DST Settings, page 63-22](#)
- [NTP on Cisco IOS Routers, page 63-96](#)

Defining Time Zone and DST Settings

Security Manager enables you to define the time zone in which a Cisco IOS router is located. You can also define the start and end dates for Daylight Saving Time (DST).

Related Topics

- [Defining NTP Servers, page 63-97](#)
- [Time Zone Settings on Cisco IOS Routers, page 63-22](#)

-
- Step 1** Do one of the following:
- (Device view) Select **Platform > Device Admin > Clock** from the Policy selector.
 - (Policy view) Select **Router Platform > Device Admin > Clock** from the Policy Type selector. Select an existing policy or create a new one.
- The Clock page is displayed. See [Table 63-11 on page 63-24](#) for a description of the fields on this page.
- Step 2** Select the time zone in which the router is located. Time zones are listed according the number of hours behind or ahead of Greenwich Mean Time (GMT).
- Step 3** (Optional) Select the method for determining the start and end dates for DST:
- Set by Date—Select this option when DST starts and ends on fixed dates. Continue with [Step 4](#).
 - Set by Day—Select this option when DST starts and ends on days whose specific dates vary from year to year. Continue with [Step 5](#).
 - None—Select this option when DST is not used.
- Step 4** (When Set by Date is selected) Define the fixed dates when DST starts and ends:
- a. Under Start, click the calendar icon, then click the appropriate date.
 - b. Select the hour and minute from the displayed lists.
 - c. Repeat steps a and b to configure the end date and time.
- Step 5** (When Set by Day is selected) Select the **Specify Recurring Time** check box if you want to define a DST period *other* than the default, which is the period used throughout most of the United States.
- Step 6** (When Specify Recurring Time is selected) Define the start and end of DST:
- a. Under Start, select the month when DST begins.
 - b. Select the week of the month (1, 2, 3, 4, first, or last).
 - c. Select the day of the week.
 - d. Select the hour and minute from the displayed lists. For example, if DST begins at 1:00 a.m. on the last Sunday of each March, select March, last, Sunday, 1, and 00.
 - e. Repeat Steps a through d to configure the end date and time.
-

Clock Policy Page

Use the Clock page to configure the time zone in which the router is located and the settings for Daylight Saving Time (DST). For more information, see [Time Zone Settings on Cisco IOS Routers, page 63-22](#).

**Tip**

You can configure the local time on the router by defining an NTP policy or by configuring the **clock set** command using the CLI.

Navigation Path

- (Device view) Select **Platform > Device Admin > Clock** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Clock** from the Policy Type selector. Right-click **Clock** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- [NTP Policy Page, page 63-98](#)

Field Reference**Table 63-11** Clock Page

Element	Description
Device Time Zone	<p>The time zone in which the router is located, expressed in relation to GMT (Greenwich Mean Time), also known as UTC (Coordinated Universal Time).</p> <p> Caution If you want to use the Command Line Interface (CLI) to configure the time zone on the router, you must use the required Time Zone acronym provided in the Cisco IOS Configuration Fundamentals Command Reference document. If you use any other format for the time zone and then use Security Manager to discover the router, Security Manager will not discover the time zone CLI.</p>
Daylight Savings Time (Summer Time)	<p>The type of DST to apply to the local time on the router:</p> <ul style="list-style-type: none"> • Set by Date—Enables you to define the exact date and time when DST begins and ends. • Set by Day—Enables you to define the relative recurring date and time when DST begins and ends. For example, you can use this option when DST begins the last Sunday of March and ends the last Sunday of October. • None—Daylight savings time is not used.
Additional Set by Date fields	
Start	<p>The date and time when DST begins:</p> <ul style="list-style-type: none"> • Date—Click the calendar icon to select the start date. • Hour—Select the start hour. • Minute—Select the start minute.
End	<p>The date and time when DST ends:</p> <ul style="list-style-type: none"> • Date—Click the calendar icon to select the end date. • Hour—Select the end hour. • Minute—Select the end minute. <p>Note Cisco IOS Software supports dates up to and including December 31st, 2035.</p>
Additional Set by Day fields	

Table 63-11 Clock Page (continued)

Element	Description
Specify Recurring Time	When selected, the router implements DST according to the dates and times specified in this policy. When deselected, the router implements DST according to the schedule used throughout most of the United States.
Start	The relative date and time when daylight savings time begins: <ul style="list-style-type: none"> • Month—Select the month. • Week—Select the week of the month (1, 2, 3, 4, first, or last). • Weekday—Select the day of the week. • Hour—Select the hour. • Minute—Select the minute. For example, if DST begins at 1:00 a.m. on the last Sunday of each March, select March, last, Sunday, 1, and 00.
End	The relative date and time when daylight savings time ends: <ul style="list-style-type: none"> • Month—Select the month. • Week—Select the week of the month (1, 2, 3, 4, first, or last). • Weekday—Select the day of the week. • Hour—Select the hour. • Minute—Select the minute.

CPU Utilization Settings on Cisco IOS Routers

The CPU policy configures settings relating to CPU utilization. This policy provides you with methods for monitoring CPU resources and tracking processes that exceed a predetermined level of utilization.

Note

The CPU policy is supported on routers running Cisco IOS Software Release 12.3(14)T or later.

Related Topics

- [Defining CPU Utilization Settings, page 63-25](#)

Defining CPU Utilization Settings

You can use Security Manager to modify the following default CPU utilization settings:

- The size of the CPU history table.
- The size of the extended CPU load history table.
- Whether to enable the automatic CPU Hog profiling.

In addition, you can optionally define:

- The CPU utilization level that causes a process to be included in the history table.

- The types of CPU utilization thresholds to enable. For each type of threshold, you can determine the threshold values that trigger notifications.

Related Topics

- [CPU Utilization Settings on Cisco IOS Routers, page 63-25](#)
- [Logging on Cisco IOS Routers, page 65-1](#)

-
- Step 1** Do one of the following:
- (Device view) Select **Platform > Device Admin > CPU** from the Policy selector.
 - (Policy view) Select **Router Platform > Device Admin > CPU** from the Policy Type selector. Select an existing policy or create a new one.
- The CPU page is displayed.
- Step 2** (Optional) Define the CPU utilization settings of the router, as required. See [Table 63-12 on page 63-26](#) for a description of the available fields.
-

CPU Policy Page

Use the CPU page to configure settings related to router CPU utilization, including the thresholds for sending log messages, the size of the CPU history table, and whether to enable automatic CPU Hog profiling.

For more information, see [Defining CPU Utilization Settings, page 63-25](#).

Navigation Path

- (Device view) Select **Platform > Device Access > CPU** from the Policy selector.
- (Policy view) Select **Router Platform > Device Access > CPU** from the Policy Type selector. Right-click **CPU** to create a policy, or select an existing policy from the Shared Policy selector.

This is the default.</p> <p>When deselected, automatic CPU Hog profiling is disabled.</p> <p>This feature predicts when a process could hog the CPU and begins profiling that process.</p> <p>Note To view the CPU Hog profile data, use the show processes cpu autoprofile hog command in the CLI.</p>

HTTP and HTTPS on Cisco IOS Routers

Security Manager enables you to configure HTTP and HTTPS over Secure Socket Layer (known as HTTP over SSL or HTTPS) server functionality on Cisco IOS routers. This feature provides SSL version 3.0 support for the HTTP 1.1 server.

A secure HTTP connection means that data sent to and received from an HTTP server are encrypted before being sent out over the internet. HTTP with SSL encryption provides a secure connection to allow such functions as configuring a router from a web browser.

In addition to providing access to the device via the Cisco web browser user interface, HTTP and HTTPS are used by device management applications, such as the Cisco Router and Security Device Manager (SDM), to communicate with the device.

Related Topics

- [Defining HTTP Policies, page 63-29](#)

Defining HTTP Policies

When you define an HTTP policy, you can:

- Enable and disable HTTP and SSL functionality on the router.
- Specify the ports used by each protocol.
- Optionally define a standard, numbered ACL that restricts access to the device using these protocols.

In addition, you can define the methods of AAA authentication and authorization methods to perform on users.

You must use caution when defining an HTTP policy, as your settings may affect communication between Security Manager (as well as other management applications that use these protocols) and the device.

**Note**

As a general rule, Cisco IOS routers that have been discovered by Security Manager already have HTTPS enabled because Security Manager uses SSL as the default protocol for communicating with them. See [Setting Up SSL on Cisco IOS Routers, page 2-4](#).

Before You Begin

- Enable AAA services on the router. See [Defining AAA Services, page 63-4](#).

Related Topics

- [HTTP and HTTPS on Cisco IOS Routers, page 63-28](#)

Step 1

Do one of the following:

- (Device view) Select **Platform > Device Admin > Device Access > HTTP** from the Policy selector, then click the **Setup** tab in the work area.
- (Policy view) Select **Router Platform > Device Admin > Device Access > HTTP** from the Policy Type selector. Select an existing policy or create a new one.

The HTTP Setup tab is displayed. See [Table 63-13 on page 63-32](#) for a description of the fields on this tab.

Step 2

Select the check boxes to enable HTTP and SSL (HTTPS) server functionality on the router.

**Note**

If SSL is disabled (or if the HTTP policy as a whole is unassigned), Security Manager cannot communicate with the device after deployment unless you change the transport protocol for this device to SSH. This setting can be found in Device Properties. See [Managing Device Communication Settings and Certificates, page 9-4](#).

**Tip**

We recommend that you disable HTTP when SSL is enabled. This is required to ensure only secure connections to the server.

Step 3

(Optional) Modify the default ports used by HTTP (80) and HTTPS (443).

- Step 4** (Optional) In the Allow Connection From field, enter the name of the standard, numbered ACL object that specifies which addresses can use HTTP and HTTPS on this device, or click **Select** to select the ACL object from a list or to create a new one. Use this option to restrict access to these protocols. For more information about creating standard ACL objects, see [Creating Standard Access Control List Objects, page 6-56](#)

Note Make sure that the ACL you select permits the Security Manager server; otherwise, communication with the device is lost.

- Step 5** (Optional) On the AAA tab, modify the default type of authentication to perform on users who attempt to access the device using HTTP or HTTPS. Options include AAA, Enable Password (default), Local Database, and TACACS.

If you select AAA, continue with [Step 6](#); otherwise, continue with [Step 8](#).

Note The TACACS option applies only to devices using an IOS software version prior to 12.3(8).

See [Table 63-14 on page 63-33](#) for a description of the fields on the AAA tab.

- Step 6** Select the authentication method to perform on users:

- If you want to use the default AAA login authentication methods defined in the device's AAA policy (see [Defining AAA Services, page 63-4](#)), do *not* select the Enable Device Login Authentication check box. Continue with [Step 7](#).
- If you want to define a method list especially for this policy, do the following:
 - a. Select the **Enable Device Login Authentication** check box.
 - b. Under Prioritized Method List, enter the names of the AAA server groups to use for authentication, or click **Select** to select the AAA server groups from a list or to create new ones. Use the up and down arrows in the selector to define the order in which you want to apply these authentication methods.

Note Make sure that Security Manager users are defined on the AAA servers; otherwise communication with the device is lost.

- Step 7** Select the authorization method to perform on users who use HTTP or HTTPS to begin an EXEC session:

- If you want to use the default AAA authorization methods defined in the device's AAA policy, do *not* select the Enable CLI/EXEC Operations Authorization check box. Continue with [Step 8](#).
- If you want to define a method list especially for this policy, select the **Enable CLI/EXEC Operations Authorization** check box, then define the method list.

Note If you leave this option deselected, make sure that EXEC authorization is enabled in the router's AAA policy. Otherwise, you will be unable to connect to the device via HTTP or HTTPS (SSL). This applies to Security Manager as well as other applications, such as SDM. See [Defining AAA Services, page 63-4](#).

- Step 8** (Optional) Create command authorization definitions for specific privilege levels:
- Click the **Add** button under the Command Authorization Override table. The Command Authorization Override dialog box is displayed. See [Table 63-15 on page 63-34](#) for a description of the fields in this dialog box.
 - Configure the command authorization definition as required.
 - Click **OK**. The dialog box closes and the authorization method is displayed in the Command Authorization Override table.
 - Repeat [a.](#) through [c.](#) to create additional command authorization definitions.
-

HTTP Policy Page

Use the HTTP page to configure HTTP and HTTPS access on the router. You can configure HTTP policies on a Cisco IOS router from the following tabs on the HTTP policy page:

- [HTTP Page—Setup Tab, page 63-31](#)
- [HTTP Page—AAA Tab, page 63-32](#)

For more information, see [HTTP and HTTPS on Cisco IOS Routers, page 63-28](#).

Navigation Path

- (Device view) Select **Platform > Device Admin > Device Access > HTTP** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Device Access > HTTP** from the Policy Type selector. Right-click **HTTP** to create a policy, or select an existing policy from the Shared Policy selector.

HTTP Page—Setup Tab

Use the Setup tab of the HTTP page to enable HTTP and HTTP over Secure Socket Layer (HTTP over SSL or HTTPS) on the router. You can optionally limit access to these protocols to the addresses defined in an access control list.

Note

As a general rule, Cisco IOS routers that have been discovered by Security Manager already have HTTPS enabled because Security Manager uses SSL as the default protocol for communicating with them. See [Setting Up SSL on Cisco IOS Routers, page 2-4](#).

Navigation Path

Go to the [HTTP Policy Page, page 63-31](#), then click the **Setup** tab.

Field Reference**Table 63-13 HTTP Page—Setup Tab**

Element	Description
Enable HTTP	When selected, an HTTP server is enabled on the router. When deselected, HTTP is disabled on the router. This is the default for devices that were not discovered.
HTTP Port	The port number to use for HTTP. Valid values are 80 or any value from 1024 to 65535. The default is 80.
Enable SSL	When selected, a secure HTTP server (HTTP over SSL or HTTPS) is enabled on the router. When deselected, HTTPS is disabled. This is the default for devices that were not discovered. Note If SSL is disabled (or if the HTTP policy as a whole is unassigned), Security Manager cannot communicate with the device after deployment unless you change the transport protocol for this device to SSH. This setting can be found in Device Properties. Note We recommend that you disable HTTP when SSL is enabled. This is required to ensure only secure connections to the server.
SSL Port	The port number to use for HTTPS. Valid values are 443 or any value from 1025 to 65535. The default is 443.
Allow Connection From	The name of the standard numbered ACL that restricts use of HTTP and HTTPS on this device. Enter the name of an ACL object, or click Select to select it. If the object that you want is not listed, click the Create button to create it. Note If you define an ACL, make sure that it includes the Security Manager server. Otherwise, Security Manager cannot communicate with this device using SSL.

HTTP Page—AAA Tab

Use the AAA tab of the HTTP page to define the authentication and authorization methods to perform on users who attempt to access the router using HTTP or HTTPS.

Navigation Path

Go to the [HTTP Policy Page, page 63-31](#), then click the **AAA** tab.

Related Topics

Field Reference

Table 63-14 HTTP Page—AAA Tab

Element	Description
Authenticate Using	<p>The type of authentication to use:</p> <ul style="list-style-type: none"> • AAA—Performs AAA login authentication. • Enable Password—Uses the enable password configured on the router. This is the default. • Local Database—Uses the local username database configured on the router. • TACACS—Uses the TACACS or XTACACS server configured on the router. Applies only to devices using an IOS software version prior to 12.3(8) or 12.3(8)T.
Login Authentication settings	
Enable Device Login Authentication	<p>Applies only when AAA is selected as the authentication method.</p> <p>When selected, authentication is based on the methods defined in the Prioritized Method List field.</p> <p>When deselected, the default authentication list defined in the router's AAA policy is used. See AAA Page—Authentication Tab, page 63-6.</p>
Prioritized Method List	<p>Applies only when the Enable Device Login Authentication check box is selected.</p> <p>Defines a sequential list of methods to be queried when authenticating a user. Enter the names of one or more AAA server group objects (up to four), or click Select to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the Create button to create it.</p> <p>The device tries initially to authenticate users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received.</p> <p>Note If you select None as a method, it must appear as the last method in the list.</p>
EXEC Authorization settings	
Enable CLI/EXEC Operations Authorization	<p>Applies only when AAA is selected as the authentication method.</p> <p>When selected, EXEC authorization is based on the methods defined in the Prioritized Method List field. This type of authorization determines whether the user is permitted to open an EXEC (CLI) session.</p> <p>When deselected, the default EXEC authorization list defined in the router's AAA policy is used. See AAA Page—Authorization Tab, page 63-8.</p> <p>Note If you leave this option deselected, make sure that EXEC authorization is enabled in the router's AAA policy. Otherwise, you will be unable to connect to the device via HTTP or HTTPS (SSL). This applies to Security Manager as well as other applications, such as SDM and the device's web interface.</p>

Table 63-14 HTTP Page—AAA Tab (continued)

Element	Description
Prioritized Method List	<p>Applies only when the Enable CLI/EXEC Operations Authorization check box is selected.</p> <p>Defines a sequential list of methods to be queried when authorizing a user to open an EXEC (CLI) session. Enter the names of one or more AAA server group objects (up to four), or click Select to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the Create button to create it.</p> <p>The device tries initially to authorize users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received.</p> <p>Note If you select None as a method, it must appear as the last method in the list.</p>
Command Authorization settings	
Privilege Level	The privilege level to which the command authorization definition applies.
Prioritized Method List	The method list to use when authorizing users with this privilege level.
Add button	Opens the Command Authorization Override Dialog Box, page 63-34 . From here you can configure a command authorization definition.
Edit button	Opens the Command Authorization Override Dialog Box, page 63-34 . From here you can edit the command authorization definition.
Delete button	Deletes the selected command authorization definitions from the table.

Command Authorization Override Dialog Box

Use the Command Authorization Override dialog box to define which methods to use when authorizing the EXEC commands that are associated with a given privilege. This enables you to authorize all commands associated with a specific privilege level, from 0 to 15.

Navigation Path

From the [HTTP Page—AAA Tab, page 63-32](#), click the **Add** button beneath the Command Authorization Override table.

If that method fails to respond, the device tries the next method, and so on, until a response is received.</p> <p>Supported methods include TACACS+, Local, and None.</p> <p>Note If you select None as a method, it must appear as the last method in the list.</p>

Line Access on Cisco IOS Routers

Security Manager enables you to configure command line access (also called EXEC access) to a router using the following methods:

- Console port—Physical connection via a standard RS232 cable for local access. For more information, see:
 - [Defining Console Port Setup Parameters, page 63-35](#)
 - [Defining Console Port AAA Settings, page 63-37](#)
- VTY lines—Virtual terminal lines for remote access, typically using protocols such as Telnet, SSH, or rlogin. For more information, see:
 - [Defining VTY Line Setup Parameters, page 63-38](#)
 - [Defining VTY Line AAA Settings, page 63-40](#)

After you configure and deploy these policies, you can use these lines to communicate with individual devices directly when you want to configure or diagnose them using the CLI.

Defining Console Port Setup Parameters

The console port on a router is generally used for local system access by an administrator with physical access to the device. By default, the console port is set up as follows:

- All permitted users have privileged access to the router, including all configuration commands (privilege level 15).
- The line is disconnected after 10 minutes without user input.
- Incoming connections are not permitted.
- Outgoing connections support Telnet only.

In addition to modifying any of the default settings, you can optionally define the following settings:

- The password for accessing the console.
- Whether to disable all EXEC sessions on the console.

- Incoming and outgoing ACLs that restrict the connections that are permitted on the console.
- Whether VRF connections are permitted on the console.

Related Topics

- [Line Access on Cisco IOS Routers, page 63-35](#)

-
- Step 1** Do one of the following:
- (Device view) Select **Platform > Device Admin > Device Access > Line Access > Console** from the Policy selector, then click the **Setup** tab in the work area.
 - (Policy view) Select **Router Platform > Device Admin > Device Access > Line Access > Console** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Setup** tab.

The Console Setup tab is displayed. See [Table 63-16 on page 63-42](#) for a description of the fields on this tab.

- Step 2** (Optional) Enter the password for accessing the console port, then enter it again in the Confirm field.
- Step 3** (Optional) Modify the default (15) granted to users of the console port. See [Console Page—Authorization Tab, page 63-45](#).
- Step 4** (Optional) Select the **Disable all the EXEC sessions to the router via this line** check box to prevent any incoming connections via the console.

Note Selecting this option blocks all access to the device via the console port.

- Step 5** (Optional) Modify the default timeout after which the line is disconnected if no user input is detected.

Note Setting this value to 0 disables the timeout. Disabling the timeout could compromise the security of your network.

- Step 6** (Optional) Specify which protocols can be used for outbound connections on the console port:
- All—All supported protocols are permitted.
 - None—No protocols are permitted.
 - Protocol—Enables one or more of the following protocols: SSH, Telnet, and rlogin.

Note You must configure AAA authentication on devices where the console port permits the SSH and rlogin protocols. See [Defining Console Port AAA Settings, page 63-37](#).

- Step 7** (Optional) Enter the names of ACLs that restrict incoming and outgoing connections between the device and the addresses in these lists, or click **Select** to select the ACL object or to create a new one. At the top of the selector, in the Type field, select the ACL type as either Standard or Extended.
- Step 8** (Optional) Click the **AAA** tab to define authentication, authorization, and accounting settings for the console port. See [Defining Console Port AAA Settings, page 63-37](#).
-

Defining Console Port AAA Settings

By default, authentication, authorization, and accounting are not performed on the console port. When you configure one or more of these access control options, you can either make use of the default method lists defined in the device's AAA policy or define a custom method list containing one or more AAA methods.

Related Topics

- [Defining Console Port Setup Parameters, page 63-35](#)
- [Line Access on Cisco IOS Routers, page 63-35](#)

-
- Step 1** Do one of the following:
- (Device view) Select **Platform > Device Admin > Device Access > Line Access > Console** from the Policy selector, then click the **Authentication** tab in the work area.
 - (Policy view) Select **Router Platform > Device Admin > Device Access > Line Access > Console** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Authentication** tab.

The Console Authentication tab is displayed.

- Step 2** (Optional) Select the authentication method to perform on users who attempt to access the console line. See [Table 63-17 on page 63-45](#) for a description of the fields on the Authentication tab.

Note If you select local authentication, preview the full configuration before deployment to make sure that the **aaa new-model** command is not configured by another policy (for example, by configuring a method list in the AAA policy) or is already configured on the device itself.

- Step 3** (Optional) On the Authorization tab, select the authorization method to perform on users who access the console line and begin an EXEC session.

See [Table 63-18 on page 63-46](#) for a description of the fields on the Authorization tab.

Note RADIUS uses the same server for authentication and authorization. Therefore, if you use define a RADIUS method list for authentication, you must define the same method list for authorization.

- Step 4** (Optional) Create command authorization definitions for specific privilege levels:
- a. Click the **Add** button under the Commands Authorization table. The Command Authorization dialog box is displayed. See [Table 63-26 on page 63-61](#) for details.
 - b. Configure the command authorization definition as required.
 - c. Click **OK**. The dialog box closes and the authorization method is displayed in the Commands Authorization table.
 - d. Repeat **a.** through **c.** to create additional command authorization definitions.

- Step 5** (Optional) On the Accounting tab, select the EXEC and connection accounting methods to perform on users who access the console line.

See [Table 63-19 on page 63-47](#) for a description of the fields on this tab.

- Step 6** (Optional) Create command accounting definitions for specific privilege levels:
- Click the **Add** button under the Commands Accounting table. The [Command Accounting Dialog Box—Line Access, page 63-61](#) is displayed.
 - Configure the command accounting definition as required.
 - Click **OK**. The dialog box closes and the accounting method is displayed in the Commands Accounting table.
 - Repeat [a.](#) through [c.](#) to create additional command accounting definitions.
-

Defining VTY Line Setup Parameters

All Cisco IOS routers are configured by default with five VTY lines (labeled 0-4) that have the following settings:

- All permitted users have privileged access to the router, including all configuration commands (privilege level 15).
- VTY lines are disconnected after 10 minutes without user input.
- Incoming connections are not permitted.
- Outgoing connections support Telnet only.

You can use Security Manager to modify the default settings on these five VTY lines or to configure additional lines (up to a maximum of 16). In addition, you can optionally configure the following settings on each line:

- The password for accessing the line.
- Whether to disable all EXEC sessions on the line.
- Incoming and outgoing ACLs that restrict the connections that are permitted on the line.
- Whether VRF connections are permitted on the line.

Defining Groups of VTY Lines

You can configure multiple VTY lines as a contiguous group, which enables you to define identical settings for all the lines in the group with one procedure. All the lines within the group must fall within one of two ranges, 0-4 or 6-15. The group cannot overlap these two ranges.

The rules for configuring VTY line 5 are as follows. Line 5 can be part of the same definition as lines 0-4 only when there are no lines configured above line 5. If there are lines configured above line 5, you cannot include line 5 in the definition for lines 0-4, even if their configurations are the same. Line 5 *can* be included in the definition of the lines above line 5 if their configurations are the same.

For example, if lines 0-5 all share one configuration and lines 6-9 have a different configuration, you need to create three definitions—one definition for lines 0-4, a second definition for line 5, and a third definition for lines 6-9.

Note

When you configure VTY lines, bear in mind that users are assigned a line at random when they connect to the device.

**Note**

You can create only one definition per VTY line. An error is displayed if you create a VTY line definition that overlaps an existing definition.

**Note**

If you use Security Manager to configure the default VTY lines (0-4), your definition overrides the default settings on the device. If you later delete this definition from Security Manager, the input protocol settings are retained and the other default settings are restored. This ensures that you always have VTY lines available for remote access to the device.

**Note**

You can use the CLI or FlexConfigs to configure additional VTY lines on devices that support more than 16 lines.

Related Topics

- [Line Access on Cisco IOS Routers, page 63-35](#)

-
- Step 1** Do one of the following:
- (Device view) Select **Platform > Device Admin > Device Access > Line Access > VTY** from the Policy selector.
 - (Policy view) Select **Router Platform > Device Admin > Device Access > Line Access > VTY** from the Policy Type selector. Select an existing policy or create a new one.
- The VTY page is displayed. See [Table 63-20 on page 63-50](#) for a description of the fields on this page.
- Step 2** Click the **Add** button beneath the Lines table, or select a line definition and then click the **Edit** button. The Setup tab of the VTY Lines dialog box is displayed. See [Table 63-21 on page 63-51](#) for a description of the fields on this tab.
- Step 3** Enter the relative line number of the VTY line. If you are configuring a group of VTY lines, enter the first and last numbers of the group in the fields provided.
- Step 4** (Optional) Enter the password for accessing the console line, then enter it again in the Confirm field.
- Step 5** (Optional) Modify the default Privilege (15) granted to users of this VTY line (or group of lines).
- Step 6** (Optional) Select the **Disable all the EXEC sessions to the router via this line** check box to prevent any incoming connections over this VTY line (or group of lines).
- Step 7** (Optional) Modify the default timeout after which the line is disconnected if no user input is detected.

**Note**

Setting this value to 0 to disables the timeout. Disabling the timeout could cause abandoned sessions to block available VTY lines. It can also compromise the security of your network.

- Step 8** (Optional) Specify which protocols can be used for inbound and outbound connections on this VTY line (or group of lines):
- All—All supported protocols are permitted.
 - None—No protocols are permitted.
 - Protocol—Enables one or more of the following protocols: SSH, Telnet, and rlogin.

**Caution**

Setting the inbound connections setting to None might prevent Security Manager from connecting to the device after deployment.

**Note**

You must configure AAA authentication when the VTY line permits the SSH and rlogin protocols. See [Defining VTY Line AAA Settings, page 63-40](#).

- Step 9** (Optional) Enter the names of ACLs that restrict incoming and outgoing connections between the device and the addresses in these lists, or click **Select** to select an ACL object from a list or to create a new one. You can choose from standard or extended ACLs.

**Tip**

Defining an inbound ACL is a good way to reserve a VTY line for administrative access only.

- Step 10** (Optional) Click the **AAA** tab to define authentication, authorization, and accounting settings for this VTY line (or group of lines). See [Defining VTY Line AAA Settings, page 63-40](#).

- Step 11** Click **OK** to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the Lines table.

**Note**

To remove a VTY line definition, select it, then click **Delete**. If you delete a VTY line from an IOS device, any subsequent lines are also deleted. For example, if the device contains lines 0-9 and you delete line 5, lines 6-9 are deleted as well. If you delete the definition for lines 0-4 from Security Manager, the router retains the inbound protocol definition and restores the other default settings for these lines on the device. This ensures that five VTY lines are always available.

Defining VTY Line AAA Settings

By default, authentication, authorization, and accounting are not performed on VTY lines. When you configure one or more of these access control options, you can either make use of the default method lists defined in the device's AAA policy or define a custom method list containing one or more AAA methods.

Before You Begin

- Define the basic parameters of the VTY line or group of VTY lines. See [Defining VTY Line Setup Parameters, page 63-38](#).

Related Topics

- [Defining VTY Line Setup Parameters, page 63-38](#)
- [Line Access on Cisco IOS Routers, page 63-35](#)

- Step 1** Do one of the following:
- (Device view) Select **Platform > Device Admin > Device Access > Line Access > VTY** from the Policy selector.

- (Policy view) Select **Router Platform > Device Admin > Device Access > Line Access > VTY** from the Policy Type selector. Select an existing policy or create a new one.

The VTY page is displayed. See [Table 63-20 on page 63-50](#) for a description of the fields on this page.

Step 2 Select a VTY line definition in the Lines tables, click the **Edit** button to display the VTY Line dialog box, then click the **Authentication** tab.

Step 3 (Optional) Select the authentication method to perform on users who attempt to access the VTY line.

See [Table 63-23 on page 63-55](#) for a description of the fields on this tab.

Note If you select local authentication, preview the full configuration before deployment to make sure that the **aaa new-model** command is not configured by another policy (for example, by configuring a method list in the AAA policy) or is already configured on the device itself.

Step 4 (Optional) On the Authorization tab, select the authorization method to perform on users who access the VTY line and begin an EXEC session.

See [Table 63-24 on page 63-56](#) for a description of the fields on the Authorization tab.

Note RADIUS uses the same server for authentication and authorization. Therefore, if you use define a RADIUS method list for authentication, you must define the same method list for authorization.

Step 5 (Optional) Create command authorization definitions for specific privilege levels:

- a. Click the **Add** button under the Commands Authorization table. The [Command Authorization Dialog Box—Line Access, page 63-60](#) is displayed.
- b. Configure the command authorization definition as required.
- c. Click **OK**. The dialog box closes and the authorization method is displayed in the Commands Authorization table.
- d. Repeat [a.](#) through [c.](#) to create additional command authorization definitions.

Step 6 (Optional) On the Accounting tab, select the EXEC and connection accounting methods to perform on users who attempt to access the VTY line.

See [Table 63-25 on page 63-58](#) for a description of the fields on the Accounting tab.

Step 7 (Optional) Create command accounting definitions for specific privilege levels:

- a. Click the **Add** button under the Commands Accounting table. The [Command Accounting Dialog Box—Line Access, page 63-61](#) is displayed.
 - b. Configure the command accounting definition as required.
 - c. Click **OK**. The dialog box closes and the accounting method is displayed in the Commands Accounting table.
 - d. Repeat [a.](#) through [c.](#) to create additional command accounting definitions.
-

Console Policy Page

Use the Console page to configure access to the router over the console port. You can configure console policies on a Cisco IOS router from the following tabs on the Console policy page:

- [Console Page—Setup Tab, page 63-42](#)
- [Console Page—Authentication Tab, page 63-44](#)
- [Console Page—Authorization Tab, page 63-45](#)
- [Console Page—Accounting Tab, page 63-47](#)

For more information, see [Line Access on Cisco IOS Routers, page 63-35](#).

Navigation Path

- (Device view) Select **Platform > Device Admin > Device Access > Line Access > Console** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Device Access > Line Access > Console** from the Policy Type selector. Right-click **Console** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- [VTY Policy Page, page 63-50](#)

Console Page—Setup Tab

Use the Setup tab of the Console page to define the basic parameters of the console port. This includes the password for accessing the port, the privilege level assigned to users, the protocols that are permitted, and the ACLs that limit access.

Navigation Path

Go to the [Console Policy Page, page 63-42](#), then click the **Setup** tab.

Field Reference

Table 63-16 Console Page—Setup Tab

Element	Description
Password	<p>The password for accessing the console port.</p> <p>The password is case sensitive and can contain up to 80 alphanumeric characters. The first character cannot be a number. Spaces are not allowed.</p> <p>Enter the password again in the Confirm field.</p>

Table 63-16 Console Page—Setup Tab (continued)

Element	Description
Privilege Level	<p>The privilege level assigned to users connected to the console port. Valid values range from 0 to 15:</p> <ul style="list-style-type: none"> • 0—Grants access to these commands only: disable, enable, exit, help, and logout. • 1—Enables nonprivileged access to the router (normal EXEC-mode use privileges). • 15—Enables privileged access to the router (traditional enable privileges). <p>Note Levels 2-14 are not normally used in a default configuration, but custom configurations can be created by moving commands that are normally at level 15 to a lower level and commands that are normally at level 1 to a higher level. You can configure the privilege levels of commands using the CLI or by defining a FlexConfig.</p> <p>Note If you do not define a value, level 1 is assigned by default. This value does not appear in the device configuration.</p>
Disable all the EXEC sessions to the router via this line	<p>When selected, disables EXEC sessions over this line. Select this option when you want to allow only an outgoing connection on the console. This option is useful for keeping the console port free from unsolicited incoming data that can tie up the line.</p> <p>When deselected, EXEC sessions are enabled on the console port. This is the default.</p> <p>Note Selecting this option blocks all access to the device via the console port.</p>
Exec Timeout	<p>The amount of time (in seconds) that the EXEC command interpreter waits to detect user input on the console port. If no input is detected, the line is disconnected. Valid values range from 0 to 2147483. The default is 600 (10 minutes). Setting the value to 0 disables the timeout.</p> <p>Note Although the timeout is defined in seconds, it appears in the CLI in the format [mm ss].</p>

Table 63-16 Console Page—Setup Tab (continued)

Element	Description
Output Protocols	<p>The protocols that you can use for outgoing connections on the console port:</p> <ul style="list-style-type: none"> All—All supported protocols are permitted. Supported protocols include LAT, MOP, NASI, PAD, rlogin, SSH, Telnet, and V.120. None—No protocols are permitted. This makes the port unusable by outgoing connections. Protocol—Enables one or more of the following protocols: <ul style="list-style-type: none"> SSH—Secure Shell protocol. Telnet—Standard TCP/IP terminal emulation protocol. rlogin—UNIX rlogin protocol. <p>Note SSH and rlogin require that you configure AAA authentication. See Console Page—Authentication Tab, page 63-44.</p> <p>Note Not all IOS Software Versions support rlogin as an output protocol.</p>
Inbound Access List	The name of the ACL object that restricts incoming connections on the console port. Enter the name of the ACL object, or click Select to select it. If the object that you want is not listed, click the Create button to create it.
Permit VRF Interface Connections	Applies only when an inbound ACL is defined on the console port. When selected, accepts incoming connections from interfaces that belong to a VRF. When deselected, rejects incoming connections from interfaces that belong to a VRF.
Outbound Access List	The name of the ACL object that restricts outgoing connections on the console port. Enter the name of an ACL object, or click Select to select it. If the object that you want is not listed, click the Create button to create it.

Console Page—Authentication Tab

Use the Authentication tab of the Console page to define the AAA authentication methods to perform on users who attempt to access the console port.

Navigation Path

Go to the [Console Policy Page, page 63-42](#), then click the **Authentication** tab.

Authorize EXEC Operations Using	<p>The authorization method that determines whether a user is allowed to run an EXEC session:</p> <ul style="list-style-type: none"> • None—Authorization is not performed. This is the default. • AAA Policy Default List—Uses the default authorization method list that is defined in the device’s AAA policy. See AAA Page—Authorization Tab, page 63-8. • Custom Method List—Uses the authorization methods specified in the EXEC Method List field.
Prioritized Method List	<p>Applies only when Custom Method List is selected as the EXEC method.</p> <p>Defines a sequential list of methods to be queried when authorizing a user. Enter the names of one or more AAA server group objects (up to four), or click Select to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the Create button to create it.</p> <p>The device tries initially to authorize users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received.</p> <p>Note If you select None as a method, it must appear as the last method in the list.</p> <p>Note RADIUS uses the same server for authentication and authorization. Therefore, if you use define a RADIUS method list for authentication, you must define the same method list for authorization.</p>
Command Authorization settings	
Privilege Level	The privilege level to which the command authorization definition applies.
Prioritized Method List	The method list to use when authorizing users with this privilege level.
Add button	Opens the Command Authorization Dialog Box—Line Access, page 63-60 . From here you can configure a command authorization definition.

Table 63-18 Console Page—Authorization Tab (continued)

Element	Description
Edit button	Opens the Command Authorization Dialog Box—Line Access , page 63-60. From here you can edit the command authorization definition.
Delete button	Deletes the selected command authorization definitions from the table.

Console Page—Accounting Tab

Use the Accounting tab of the Console page to define the EXEC, connection, and command accounting methods to perform on users who access the console port.

Note

You must enable AAA services on the router to use this feature; otherwise, deployment will fail. See [Defining AAA Services](#), page 63-4.

Navigation Path

Go to the [Console Policy Page](#), page 63-42, then click the **Accounting** tab.

Command Accounting settings	
Privilege Level	The privilege level to which the command authorization definition applies.
Generate Accounting Records for	The points in the process where the device sends an accounting notice to the accounting server.
Enable Broadcast	Whether accounting records are broadcast to multiple servers simultaneously.
Prioritized Method List	The method list to use when authorizing users with this privilege level.

Table 63-19 Console Page—Accounting Tab (continued)

Element	Description
Add button	Opens the Command Accounting Dialog Box—Line Access, page 63-61 . From here you can configure a command accounting definition.
Edit button	Opens the Command Accounting Dialog Box—Line Access, page 63-61 . From here you can edit the command accounting definition.
Delete button	Deletes the selected command accounting definitions from the table.

VTY Policy Page

Use the VTY page to configure up to 16 VTY lines for remote access to the router. In addition to configuring individual lines, you can configure a group of lines that share the same definition.

For more information, see [Line Access on Cisco IOS Routers, page 63-35](#).

Navigation Path

- (Device view) Select **Platform > Device Admin > Device Access > Line Access > VTY** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Device Access > Line Access > VTY** from the Policy Type selector. Right-click **VTY** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

Field Reference

Table 63-20 VTY Lines Page

Element	Description
Line	The relative line number of the VTY line. This field may also contain multiple VTY lines configured as a contiguous group.
Line/Line Group Parameters	
Input Protocols	The protocols that you can use for incoming connections on the VTY line.
Output Protocols	The protocols that you can use for outgoing connections on the VTY line.
Privilege Level	The privilege level assigned to users.
Exec Timeout	The amount of time the EXEC command interpreter waits until user input is detected.
Inbound ACL	The ACL used to limit inbound traffic.

Table 63-20 VTY Lines Page (continued)

Element	Description
Outbound ACL	The ACL used to limit outbound traffic.
Authentication	The type of AAA authentication used.
Authorization	The types of AAA authorization used.
Accounting	The types of AAA accounting used.
VTY Line Page Buttons	
Add button	Opens the VTY Line Dialog Box, page 63-51 . From here you can define a VTY line or line group.
Edit button	Opens the VTY Line Dialog Box, page 63-51 . From here you can edit the VTY line or line group.
Delete button	Deletes the selected VTY lines from the table. If you delete a VTY line from an IOS device, any subsequent lines are also deleted. For example, if the device contains lines 0-9 and you delete line 5, lines 6-9 are deleted as well. Note If you delete any of the default VTY lines (0-4) on the device, the input protocol settings are retained and the other default settings are restored. This helps prevent you from cutting off remote access to the device.

VTY Line Dialog Box

Use the VTY Line dialog box to configure one or more VTY lines (up to 16) that enable remote users to access the router. When you configure a VTY line, you can define the type of authentication and authorization to perform on users who access the lines.

Navigation Path

Go to the [VTY Policy Page, page 63-50](#), then click the **Add** or **Edit** button beneath the table.

Field Reference

Table 63-22 VTY Line Dialog Box—Setup Tab

Element	Description
Starting VTY Line Number	<p>The relative line number of the VTY line. If you are configuring a group of VTY lines, enter the number of the first line in the group. Valid values range from 0 to 15.</p> <p>Note Although different routers support a different number of VTY lines (from four to several thousand), Security Manager supports a maximum of 16 lines per device. You cannot configure the same line number more than once.</p>
Ending VTY Line Number	<p>Applies only when configuring a group of lines.</p> <p>The relative line number of the last VTY line in the group.</p> <p>Note When you configure a group of lines, all the lines in the group must fall within one of two ranges, 0-4 or 6-15.</p>

Table 63-22 VTY Line Dialog Box—Setup Tab (continued)

Element	Description
Password	<p>The password for accessing this VTY line.</p> <p>The password is case sensitive and can contain up to 80 alphanumeric characters. The first character cannot be a number. Spaces are not allowed.</p> <p>Enter the password again in the Confirm field.</p>
Privilege Level	<p>The privilege level assigned to users on this VTY line. Valid values range from 0 to 15:</p> <ul style="list-style-type: none"> • 0—Grants access to these commands only: disable, enable, exit, help, and logout. • 1—Enables nonprivileged access to the router (normal EXEC-mode use privileges). • 15—Enables privileged access to the router (traditional enable privileges). <p>Note Levels 2-14 are not normally used in a default configuration, but custom configurations can be created by moving commands that are normally at level 15 to a lower level and commands that are normally at level 1 to a higher level. You can configure the privilege levels of commands using the CLI or by defining a FlexConfig.</p> <p>Note If you do not define a value, level 1 is assigned by default. This value does not appear in the device configuration.</p>
Disable all the EXEC sessions to the router via this line	<p>When selected, EXEC sessions are disabled over this line. Select this option when you want to allow only an outgoing connection on this line. This option is useful for keeping a particular line free from unsolicited incoming data that can tie up the line.</p> <p>When deselected, EXEC sessions are enabled over this line. This is the default.</p>
Exec Timeout	<p>The amount of time (in seconds) that the EXEC command interpreter waits to detect user input on the line. If no input is detected, the line is disconnected. Valid values range from 0 to 2147483. The default is 600 (10 minutes). Setting the value to 0 disables the timeout.</p> <p>Note Although the timeout is defined in seconds, it appears in the CLI in the format [mm ss].</p>

Table 63-22 VTY Line Dialog Box—Setup Tab (continued)

Element	Description
Input Protocols	<p>The protocols that you can use for incoming connections on this line:</p> <ul style="list-style-type: none"> • All—All supported protocols are permitted. Supported protocols include LAT, MOP, NASI, PAD, rlogin, SSH, Telnet, and V.120. • None—No protocols are permitted. This makes the port unusable by incoming SSH, Telnet, and rlogin connections. <p>Note Setting the input protocols setting to None might prevent Security Manager from connecting to the device after deployment. The device can still be managed using SSL, if SSL is enabled in the HTTP policy. See HTTP Page—Setup Tab, page 63-31.</p> <ul style="list-style-type: none"> • Protocol—Enables one or more of the following protocols: <ul style="list-style-type: none"> – SSH—Secure Shell protocol. – Telnet—Standard TCP/IP terminal emulation protocol. – rlogin—UNIX rlogin protocol. <p>Note SSH and rlogin require that you configure AAA authentication. See VTY Line Dialog Box—Authentication Tab, page 63-55.</p> <p>Note Not all IOS Software Versions support rlogin as an input protocol.</p>
Output Protocols	<p>The protocols that you can use for outgoing connections on this line:</p> <ul style="list-style-type: none"> • All—All supported protocols are permitted. Supported protocols include LAT, MOP, NASI, PAD, rlogin, SSH, Telnet, and V.120. • None—No protocols are permitted. This makes the port unusable by outgoing connections. • Protocol—Enables one or more of the following protocols: <ul style="list-style-type: none"> – SSH—Secure Shell protocol. – Telnet—Standard TCP/IP terminal emulation protocol. – rlogin—UNIX rlogin protocol. <p>Note SSH and rlogin require that you configure AAA authentication. See VTY Line Dialog Box—Authentication Tab, page 63-55.</p> <p>Note Not all IOS Software Versions support rlogin as an output protocol.</p>
Inbound Access List	<p>The name of the ACL object that restricts incoming connections on this line. Enter the name of the ACL object, or click Select to select it. If the object that you want is not listed, click the Create button to create it.</p>
Permit VRF Interface Connections	<p>Applies only when an inbound ACL is defined on this line.</p> <p>When selected, accepts incoming connections from interfaces that belong to a VRF. When deselected, rejects incoming connections from interfaces that belong to a VRF.</p>

Table 63-22 VTY Line Dialog Box—Setup Tab (continued)

Element	Description
Outbound Access List	The name of the ACL object that restricts outgoing connections on this line. Enter the name of the ACL object, or click Select to select it. If the object that you want is not listed, click the Create button to create it.

VTY Line Dialog Box—Authentication Tab

Use the Authentication tab of the VTY Line dialog box to define the authentication methods to perform on users who attempt to access the selected VTY line or group of lines.

Navigation Path

Go to the [VTY Line Dialog Box](#), page 63-51, then click the **Authentication** tab.

Field Reference**Table 63-26 Command Authorization Dialog Box—Line Access**

Element	Description
Privilege Level	The privilege level for which you want to define a command authorization list. Valid values range from 0 to 15. Note If you do not define a value, level 1 is assigned by default. This value does not appear in the device configuration.
AAA Policy Default List	Select this option to apply the default authorization list defined in the device's AAA policy to the EXEC commands associated with this privilege level. See Command Accounting Dialog Box, page 63-13 .
Custom Method List	Select this option to define an authorization method list for this privilege level.
Prioritized Method List	Applies only when the Custom Method List option is selected. Defines a sequential list of methods to be queried when authorizing a user. Enter the names of one or more AAA server group objects (up to four), or click Select to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the Create button to create it. The device tries initially to authorize users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. Note If you select None as a method, it must appear as the last method in the list.

Command Accounting Dialog Box—Line Access

Use the Command Accounting dialog box to define which methods to use when recording information about the EXEC commands that are executed for a given privilege. Each accounting record includes a list of the commands executed for that privilege level, as well as the date and time each command was executed, and the name of the user who executed it.

Navigation Path

From the [Console Page—Accounting Tab, page 63-47](#) or the [VTY Line Dialog Box—Accounting Tab, page 63-57](#), click the **Add** button beneath the Command Accounting table.

Related Topics

Field Reference

Table 63-27 Command Accounting Dialog Box—Line Access

Element	Description
Privilege Level	<p>The privilege level for which you want to define a command accounting list. Valid values range from 0 to 15.</p> <p>Note If you do not define a value, level 1 is assigned by default. This value does not appear in the device configuration.</p>
AAA Policy Default List	Select this option to apply the default accounting list defined in the device's AAA policy to the EXEC commands executed for this privilege level.
Custom Method List	Select this option to define an accounting method list for this privilege level.
Generate Accounting Records for	<p>Applies only when Custom Method List is selected.</p> <p>Defines when the device sends an accounting notice to the accounting server:</p> <ul style="list-style-type: none"> • Start and Stop—Generates accounting records at the beginning and the end of the user process. The user process begins regardless of whether the accounting server receives the “start” accounting record. This is the default. • Stop Only—Generates an accounting record at the end of the user process only. • None—No accounting records are generated.
Prioritized Method List	<p>Applies only when the Custom Method List option is selected.</p> <p>Defines a sequential list of accounting methods to be used when creating accounting records for a user. Enter the names of one or more AAA server group objects (up to four), or click Select to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the Create button to create it.</p> <p>The device tries initially to perform accounting using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received.</p> <p>Note If you select None as a method, it must appear as the last method in the list.</p>
Enable Broadcast to Multiple Servers	<p>Applies only when Custom Method List is selected.</p> <p>When selected, enables the sending of accounting records to multiple AAA servers. Accounting records are sent simultaneously to the first server in each AAA server group defined in the method list. If the first server is unavailable, failover occurs using the backup servers defined within that group.</p> <p>When deselected, accounting records are sent only to the first server in the first AAA server group defined in the method list.</p>

Optional SSH Settings on Cisco IOS Routers

Secure Shell (SSH) is an application and a protocol that uses encryption to provide secure communication between a client and server. You can use SSH to connect remotely to a Cisco IOS router over a VTY line and establish an EXEC session. SSH is the recommended replacement for other protocols, such as Telnet and rlogin, in environments where security is a concern.

All Cisco IOS routers are required to have SSH configured before they can be added to Security Manager. This is because Security Manager uses SSH (in addition to SSL) to communicate with them. The SSH policy provides a way to modify selected default settings and configure selected optional settings.

Related Topics

- [Defining Optional SSH Settings, page 63-63](#)
- [Chapter 2, “Preparing Devices for Management”](#)
- [Setting Up SSH, page 2-5](#)

Defining Optional SSH Settings

SSH is configured by default with the following settings:

- Both SSH version 1 and SSH version 2 are supported.
- The negotiation phase is terminated if not completed successfully after 120 seconds.
- The router tries 3 times to authenticate SSH clients before disconnecting.

You can use Security Manager to modify these default settings and optionally configure the following settings:

- The source interface for SSH packets.
- The name of the RSA key pair to use.
- Whether to regenerate the key during the next deployment.

Before You Begin

- Make sure that SSH is enabled on the router. See [Chapter 2, “Preparing Devices for Management”](#).
- Make sure that the VTY lines on the router allow inbound SSH traffic. See [Defining VTY Line Setup Parameters, page 63-38](#).
- Make sure that a hostname and domain name are configured on the router (unless you plan to use a different RSA key pair). You can use the CLI or the Hostname policy in Security Manager for this purpose. See [Hostnames and Domain Names on Cisco IOS Routers, page 63-77](#).

Related Topics

- [Optional SSH Settings on Cisco IOS Routers, page 63-63](#)
- [Setting Up SSH, page 2-5](#)

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > Device Access > Secure Shell** from the Policy selector.

- (Policy view) Select **Router Platform > Device Admin > Device Access > Secure Shell** from the Policy Type selector. Select an existing policy or create a new one.

The Secure Shell page is displayed. See [Table 63-28 on page 63-65](#) for a description of the fields on this page.

Step 2 (Optional) Modify the following default settings:

- The version of SSH to support.
- The timeout for completing the negotiation phase of the SSH connection.
- The number of times to attempt authentication of the SSH client.

Step 3 (Optional) In the Source Interface field, enter the name of the interface or interface role whose address should be used as the source interface for all SSH packets sent to SSH clients, or click **Select** to select an interface role object from a list or to create a new one. The source interface must have an IP address.

If you do not enter a value in this field, the address of the closest interface to the destination is used.

Step 4 (Optional) Enter the name of the RSA key pair to use for SSH connections. If you do not enter a value in this field, the router uses the key pair that is based on the hostname and domain name.

Tip Use the CLI command `show crypto key mypubkey rsa` to display the names and values of each key pair configured on the device.

Step 5 (Optional) Select the **Regenerate Key During Deployment** check box if you want the router to regenerate the RSA key pair used for SSH. This option is useful if you believe that the secrecy of the keys might be compromised. Enter the size of the modulus to use to regenerate the keys.

Note You must remember to return to this policy after deployment to deselect the check box. If you do not do this, a new key is generated during each deployment.

Note This option requires interaction with the device during deployment. Therefore, you should use it only when deploying to live devices, not when deploying to a file.

Note A key pair must already exist on the device *before* you select this option; otherwise, deployment will fail. (This will typically be the case, since IOS routers must have SSH enabled to be added to Security Manager.)

Secure Shell Policy Page

Use the Secure Shell page to change the default SSH settings on the router and to define additional optional settings, if required.

For more information, see [Optional SSH Settings on Cisco IOS Routers, page 63-63](#).

**Note**

You must configure SSH on the device using CLI commands before adding the device to Security Manager. This is because Security Manager uses SSH (as well as SSL) to communicate with Cisco IOS routers. For more information, see [Setting Up SSH, page 2-5](#).

Navigation Path

- (Device view) Select **Platform > Device Admin > Device Access > Secure Shell** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Device Access > Secure Shell** from the Policy Type selector. Right-click **Secure Shell** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- [Chapter 2, “Preparing Devices for Management”](#)
- [VTY Policy Page, page 63-50](#)
- [Console Policy Page, page 63-42](#)

Field Reference**Table 63-28 Secure Shell Page**

Element	Description
SSH Version	The version of SSH to use when connecting to the router: <ul style="list-style-type: none"> • 1 and 2—SSH version 1 and SSH version 2. This is the default. • 1—SSH version 1 only. • 2—SSH version 2 only.
Timeout	The amount of time the router should wait for the SSH client to respond during the negotiation phase before disconnecting. The default value (and the maximum) is 120 seconds. <p>Note After negotiation finishes and the EXEC session begins, the timeout configured for the VTY line applies. See VTY Line Dialog Box—Setup Tab, page 63-52.</p>
Authentication Retries	The number of times the router attempts to authenticate SSH clients. Valid values range from 0 to 5. The default is 3.
Source Interface	The source address for all SSH packets sent to the SSH client. <p>If you do not define a value in this field, the address of the closest interface to the destination (that is, the output interface through which SSH packets are sent) is used.</p> <p>Enter the name of an interface or interface role, or click Select to select the object from a list or to create a new one.</p>

Table 63-28 Secure Shell Page (continued)

Element	Description
RSA Key Pair	<p>The name of the RSA key pair to use for SSH connections.</p> <p>If you do not enter a value, the router uses the RSA key pair generated from its hostname and domain name. This is the default.</p> <p>Tip Use the CLI command show crypto key mypubkey rsa to display the names and values of each key pair configured on the device. These are the valid names that can be entered in this field.</p>
Regenerate Key During Deployment	<p>When selected, regenerates the RSA key pair on the router during the next deployment. This option is useful if you are concerned that the secrecy of the keys might be compromised.</p> <p>When deselected, a new key pair is not generated.</p> <p>Note This check box is <i>not</i> deselected automatically after deployment. If you do not return to this policy to deselect the check box, the key is regenerated each time you deploy.</p> <p>Note This option requires interaction with the device during deployment. Therefore, you should use it only when deploying to live devices, not when deploying to a file.</p> <p>Note A key pair must already exist on the device <i>before</i> you select this option; otherwise, deployment will fail. (This will typically be the case, since IOS routers must have SSH enabled in order to be added to Security Manager.)</p>
Modulus Size	<p>Applies only when the Regenerate Key check box is selected.</p> <p>The size of the modulus used to generate a new key pair. A larger modulus is more secure but takes longer to generate. Valid values range from 360 to 2048 bits. The default is 1024 bits.</p>

SNMP on Cisco IOS Routers

Simple Network Management Protocol (SNMP) defines a standard way for network management stations or workstations to monitor the health and status of many types of devices, including switches, routers, and firewall devices. It comprises a protocol, a database-structure specification, and a set of management data objects. Each SNMP device or member is part of a *community*, which determines the access that each device has (read-only or read-write).

SNMP obtains information from the managed device through a Management Information Base (MIB). The MIB is a database of code blocks called MIB objects, each of which controls one specific function. The MIB object comprises MIB variables, which define the MIB object name, description, default value, and so forth. MIB objects are structured hierarchically in a MIB tree.

SNMP policies enable you to configure the behavior of the SNMP agent running on the router. The agent sends unsolicited information back to the SNMP host as events occur. These unsolicited messages, which are generated in response to significant, predetermined events on the router, are called traps.

The following topics describe the tasks you perform to create SNMP policies on Cisco IOS routers:

- [Defining SNMP Agent Properties, page 63-67](#)

- [Enabling SNMP Traps, page 63-68](#)

Defining SNMP Agent Properties

When you define the properties of the SNMP agent, you must define the community string and community string type, as well as the address and properties of the SNMP host that receives the traps.

SNMP community strings are embedded passwords to MIBs, which store data about the router's operation and are meant to be available to authenticated remote users. Two types of community strings exist: "public" community strings, which provide read-only access to all objects in the MIB (except community strings themselves), and "private" community strings, which provide read-write access to all objects in the MIB (except community strings).

SNMP hosts receive the traps generated by the router. You must define the address, password, and port number for accessing the SNMP host, as well as the SNMP version being used. Security Manager supports SNMP version 1, version 2c (also called "community-based SNMP") and version 3, which offers authentication and encryption.

Related Topics

- [SNMP on Cisco IOS Routers, page 63-66](#)

-
- Step 1** Do one of the following:
- (Device view) Select **Platform > Device Admin > Device Access > SNMP** from the Policy selector.
 - (Policy view) Select **Router Platform > Device Admin > Device Access > SNMP** from the Policy Type selector. Select an existing policy or create a new one.
- The SNMP page is displayed. See [Table 63-29 on page 63-69](#) for a description of the fields on this page.
- Step 2** Define the community string needed to access the MIB:
- a. Under Permissions, click **Add** to display the Permission dialog box.
 - b. Define the string. See [Table 63-30 on page 63-70](#) for a description of the available fields.
 - c. Click **OK** to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the Permissions table.
-  **Note** A warning is displayed if you attempt to edit or delete a community string that is in use by an SNMP host. If you continue with the operation, the device creates a private, read-only string that matches the definition for the host in the Trap Receiver table.
-
- Step 3** Define the SNMP host that receives the traps generated by the SNMP agent:
- a. Under Trap Receiver, click **Add** to display the Trap Receiver dialog box.
 - b. Define the host. See [Table 63-31 on page 63-71](#) for a description of the available fields.
 - c. Click **OK** to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the Trap Receiver table.
- Step 4** Under SNMP Server Properties, enter the location and contact information for the administrator responsible for routers configured with this SNMP policy.

This definition, which is text-only and does not affect the operation of the router, provides useful information to the manager of the SNMP host when the manager investigates a particular trap.

- Step 5** Click **Configure Traps** to display the SNMP Traps dialog box, which is used to select which traps to enable on the router. For more information, see [Enabling SNMP Traps, page 63-68](#).
-

Enabling SNMP Traps

The router immediately sends notifications, also called SNMP traps, to the designated SNMP host (management station) when a defined condition occurs, such as a link up, link down, or a syslog event.

To enable SNMP traps, select the check box next to each relevant trap. Certain check boxes activate multiple, related traps.

Note Each trap that you enable consumes system resources. To lessen the impact on system performance, select only those traps that you need for network monitoring.

Related Topics

- [SNMP on Cisco IOS Routers, page 63-66](#)
-

- Step 1** Open the SNMP page for defining SNMP server policies on Cisco IOS routers, as described in [Defining SNMP Agent Properties, page 63-67](#).

- Step 2** On the SNMP page, click **Configure Traps**. The SNMP Traps dialog box is displayed.

- Step 3** Select the check box next to each type of trap to enable. The traps are divided into the following four categories:

- Standard SNMP traps (for example, Authentication, Cold Start, and Warm Start).
- ISAKMP traps (related to Phase 1 of the IPsec process).
- IPsec traps (related to Phase 2 of the IPsec process).
- Other traps (includes syslog messages, protocol-related notifications, and CPU usage warnings).

See [Table 63-32 on page 63-73](#) for a description of the available traps.

Note You must add command-line interface (CLI) commands to fully implement the IP multicast and CPU traps. One method available for entering these commands is by using FlexConfigs. See [Chapter 7, “Managing FlexConfigs”](#).

Tip Click **Select All** to enable all traps displayed in the dialog box or **Deselect All** to disable all the traps.

- Step 4** Click **OK** to save your definitions locally on the client and close the dialog box.

Tip To configure SNMP traps not included in this dialog box, define a FlexConfig. See [Chapter 7, “Managing FlexConfigs”](#) for more information.

SNMP Policy Page

Use the SNMP page to configure the parameters necessary to send traps from the router to a designated SNMP host. These traps are unsolicited messages that notify the SNMP host of important events occurring on the router.

For more information, see [Defining SNMP Agent Properties, page 63-67](#).

Navigation Path

- (Device view) Select **Platform > Device Admin > Device Access > SNMP** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Device Access > SNMP** from the Policy Type selector. Right-click **SNMP** to create a policy, or select an existing policy from the Shared Policy selector.

Field Reference

Table 63-31 *Trap Receiver Dialog Box*

Element	Description
Host IP Address	The IP address of the SNMP host receiving the traps generated by the router. Enter an IP address or the name of a network/host object, or click Select to select the object from a list or to create a new one.
SNMP Version	The version of SNMP to use—version 1, version 2c, or version 3.
Community String	Applies only when version 1 or version 2c is selected. The password required to access the SNMP host. Enter the string again in the Confirm field. Note We recommend that you use one of the strings defined in the Permissions table as the password to the SNMP host. You may, however, enter a different password. String length ranges from 1 to 128 characters. Your entry does not appear in the Permissions table and is read-only.

Table 63-31 Trap Receiver Dialog Box (continued)

Element	Description
User Name	<p>Applies only when version 3 is selected.</p> <p>The password required to access the SNMP host. Enter the string again in the Confirm field.</p> <p>Note We recommend that you use one of the strings defined in the Permissions table as the password to the SNMP host. You may, however, enter a different password. String length ranges from 1 to 128 characters. Your entry does not appear in the Permissions table and is read-only.</p>
SNMPv3 Security	<p>Applies only when version 3 is selected.</p> <p>The level of security to apply to SNMP traffic:</p> <ul style="list-style-type: none"> • No MD5, No DES—No packet authentication. • MD5 (auth)—MD5 authentication, but no encryption. • DES (priv)—MD5 authentication and DES encryption.
UDP Port	<p>The port number for the SNMP host. The default is 162. Valid values range from 0 to 65535.</p>

SNMP Traps Dialog Box

Use the SNMP Traps dialog box to select the events in the router that should generate SNMP traps. To lessen possible degradation of system performance, select only those traps that are needed for network monitoring purposes.

Tip

You can configure SNMP traps not included in this dialog box by defining FlexConfigs. For more information, see [Understanding FlexConfig Policies and Policy Objects, page 7-2](#).

Navigation Path

Go to the [SNMP Policy Page, page 63-69](#), then click **Configure Traps**.

Table 63-32 SNMP Traps Dialog Box

Element	Description
Standard SNMP Traps	<p>Enables or disables standard SNMP traps. Options are:</p> <ul style="list-style-type: none"> • Cold start—Sends a trap when the router reinitializes in a way that could change the configuration of the SNMP agent (or any other trap-receiving entity). • Warm start—Sends a trap when the router reinitializes in a way that does not change the configuration of the SNMP agent (or any other trap-receiving entity). • Authentication—Sends a trap if an SNMP request from the SNMP host fails because of an invalid community string.
IPsec Traps	<p>Enables or disables individual IPsec-related traps. Options are:</p> <ul style="list-style-type: none"> • Cryptomap—Sends a trap when a crypto map entry is added to, or removed from, the device's crypto map set. Additionally, this option sends a trap when a crypto map set is attached to, or detached from, an active interface. • Too Many SAs—Sends a trap if an attempt is made to create a security association (SA) when there is insufficient memory on the device. • Tunnel—Sends a trap when an IPsec Phase 2 tunnel becomes active or inactive. <p>For more information, see Understanding IPsec Proposals for Site-to-Site VPNs, page 26-19.</p>
ISAKMP Traps	<p>Enables or disables individual Internet Security Association and Key Exchange Protocol (ISAKMP) traps. Options are:</p> <ul style="list-style-type: none"> • Policy—Sends a trap when an ISAKMP policy is created or deleted. • Tunnel—Sends a trap when a Phase 1 IKE tunnel becomes active or inactive. <p>For more information, see Understanding IKE, page 26-5.</p>

Table 63-32 *SNMP Traps Dialog Box (continued)*

Element	Description
Other Traps	<p>Enables or disables additional SNMP traps. Options are:</p> <ul style="list-style-type: none"> • Syslog—Sends syslog messages to the SNMP host. • TTY—Sends Cisco-specific notifications when a Transmission Control Protocol (TCP) connection closes. • BGP—Sends notifications when Border Gateway Protocol (BGP) state changes occur. See BGP Routing on Cisco IOS Routers, page 67-1. • IP Multicast—(Applicable to multicast routers only) Sends a trap if the router fails to receive a defined number of heartbeat packets from heartbeat sources within a defined time interval. If you select IP Multicast, you must also manually configure the ip multicast heartbeat command on the device to configure the multicast address and heartbeat limits. You can use FlexConfigs to do this. • CPU—Sends a trap when CPU usage rises and remains above an upper threshold or falls and remains below a lower threshold. If you select CPU, you must also manually configure the process cpu threshold type command on the device to configure the thresholds. You can use FlexConfigs to do this. • HSRP—Sends Hot Standby Routing Protocol (HSRP) notifications.
Select All button	Enables all the SNMP traps displayed in the dialog box.
Deselect All button	Disables all the SNMP traps displayed in the dialog box.

DNS on Cisco IOS Routers

The Domain Name System (DNS) is a distributed database in which you can map hostnames to IP addresses through the DNS protocol from a DNS server. Each unique IP address can have an associated hostname. DNS is what makes it possible to connect to hosts without having to know the 32-bit IP address of that host. The DNS server takes the provided hostname and translates it into the appropriate IP address.

In addition to the translation provided by remote DNS servers, you can configure Cisco IOS routers with a local host table containing static mappings of hosts to IP addresses. When commands such as connect, telnet, and ping are used, the router checks this host table before querying the DNS servers, which speeds the translation process.

By default, the DNS feature is enabled on all Cisco IOS routers.

Related Topics

- [Defining DNS Policies, page 63-75](#)

Defining DNS Policies

When you define a DNS policy in Security Manager, you can specify the remote DNS servers used by the router for hostname-to-address translations. In addition, you can define a static host table that contains local translations used exclusively by this device. Having selected addresses in this type of cache can speed the translation process by eliminating the need to query the DNS servers.

Related Topics

- [DNS on Cisco IOS Routers, page 63-74](#)

-
- Step 1** Do one of the following:
- (Device view) Select **Platform > Device Admin > DNS** from the Policy selector.
 - (Policy view) Select **Router Platform > Device Admin > DNS** from the Policy Type selector. Select an existing policy or create a new one.

The DNS page is displayed. See [Table 63-33 on page 63-76](#) for a description of the fields on this page.

- Step 2** In the Servers field, enter the addresses of the DNS servers (up to 6) that can perform hostname-to-address translations for the router. You can use a combination of addresses and network/host objects, or click **Select** to display a selector. For more information, see [Specifying IP Addresses During Policy Definition, page 6-87](#).

Tip If the network you want is not listed in the selector, click the **Create** button or the **Edit** button in the selector to display the [Add or Edit Network/Host Dialog Box, page 6-83](#). From here you can create a network/host object to use in the policy.

- Step 3** (Optional) In the Hosts field, enter the static host mappings that you want to define in the router's host table:
- a. Click **Add** to display the [IP Host Dialog Box, page 63-76](#).
 - b. Enter the hostname to translate.
 - c. Enter up to three addresses or network/host objects, or click **Select** to display a selector. These are the addresses to which the router translates the hostname.
 - d. Click **OK**. The mapping is displayed in the Hosts field on the DNS page.
 - e. Repeat **a.** through **d.** to add more hosts to the host table.

Note To edit a host mapping, select the definition from the Hosts field, then click **Edit**. To remove a host mapping, select it, then click **Delete**.

- Step 4** (Optional) Deselect the **Domain Lookup** check box to disable DNS functionality on the router.
-

DNS Policy Page

Use the DNS policy page to define the local IP host table and the Domain Name System (DNS) servers that the router should use for translating hostnames to IP addresses. You can also prevent the router from performing DNS lookups by disabling the DNS feature.

Navigation Path

- (Device view) Select **Platform > Device Admin > DNS** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > DNS** from the Policy Type selector. Right-click **DNS** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- [DNS on Cisco IOS Routers, page 63-74](#)

Field Reference

Table 63-33 DNS Page

Element	Description
Servers	The DNS servers used by the router to perform DNS lookups. Enter one or more addresses or network/host objects, or click Select to select an object from a list or to create a new one. You can define a maximum of six DNS servers.
Hosts	<p>The local host table configured on the router. When a user types in a hostname, the router checks this table first before querying the DNS servers defined in the Servers field.</p> <p>Click Add to display the IP Host Dialog Box, page 63-76. From here you can define a hostname and the IP addresses to associate with that hostname.</p> <p>Note To edit an entry in the host table, select it, then click Edit. To remove an entry, select it, then click Delete.</p>
Domain Lookup	<p>When selected, the router performs lookups on the defined DNS servers. This is the default.</p> <p>When deselected, lookups on remote DNS servers are disabled.</p>

IP Host Dialog Box

Use the IP Host dialog box to configure the host table on the router. This is the table of static, local mappings that the router uses to translate hostnames to IP addresses. If the router does not find the required entry in the host table, it queries the DNS servers that are defined on the DNS page.

Navigation Path

Go to the [DNS Policy Page, page 63-76](#), then click **Add** under Hosts.

Related Topics

- [DNS on Cisco IOS Routers, page 63-74](#)

Field Reference**Table 63-34** IP Host Dialog Box

Element	Description
Host Name	The hostname to include in the router's local host table.
Addresses	The addresses to associate with the hostname. Enter one or more addresses or network/host objects, or click Select to select an object from a list or to create a new object. You can define a maximum of three addresses per hostname.

Hostnames and Domain Names on Cisco IOS Routers

The Hostname policy configures the hostname and domain name of the selected router. After you deploy this policy, any changes that you made to the hostname and domain name are reflected in the Device Properties page (see [Viewing or Changing Device Properties, page 3-40](#)).

Related Topics

- [Defining Hostname Policies, page 63-77](#)

Defining Hostname Policies

When you define a hostname policy, Security Manager updates the hostname and domain name fields in the Device Properties dialog box after deployment. See [Viewing or Changing Device Properties, page 3-40](#).

Related Topics

- [Hostnames and Domain Names on Cisco IOS Routers, page 63-77](#)

-
- Step 1** Do one of the following:
- (Device view) Select **Platform > Device Admin > Hostname** from the Policy selector.
 - (Policy view) Select **Router Platform > Device Admin > Hostname** from the Policy Type selector. Select an existing policy or create a new one.
- The Hostname page is displayed. See [Table 63-35 on page 63-78](#) for a description of the fields on this page.
- Step 2** Enter the hostname for the router. Names must start with a letter, end with a letter or digit, and include only letters, digits, and hyphens. The maximum length is 63 characters.
- Step 3** Enter the domain name for the router. The router uses this domain name for RSA key generation and in policies when you do not enter the fully-qualified domain name.
-

Hostname Policy Page

Use the Hostname page to define the hostname and domain name assigned to the router. For more information, see [Defining Hostname Policies, page 63-77](#).

Navigation Path

- (Device view) Select **Platform > Device Admin > Hostname** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Hostname** from the Policy Type selector. Right-click **Hostname** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- [Hostnames and Domain Names on Cisco IOS Routers, page 63-77](#)

Field Reference

Table 63-35 Hostname Page

Element	Description
Host Name	The hostname of the router. Names must start with a letter, end with a letter or digit, and include only letters, digits, and hyphens. The maximum length is 63 characters.
Domain Name	The default domain name of the router. The maximum length is 63 characters. The router uses this domain name for RSA key generation and in policies when you do not enter the fully-qualified domain name (FQDN).

Memory Settings on Cisco IOS Routers

The Memory policy configures settings relating to router memory. This policy provides you with methods for monitoring memory consumption, including the ability to generate notification messages when available memory drops below predefined thresholds.

Note

The Memory policy is supported on routers running Cisco IOS Software Release 12.3(14)T or later.

Related Topics

- [Defining Router Memory Settings, page 63-78](#)

Defining Router Memory Settings

You can use Security Manager to modify the following default memory settings:

- The number of hours that the router maintains the log of memory consumption.
- Whether to enable the Memory Allocation Lite feature.
- The amount of memory to reserve for critical system log messages.

In addition, you can define:

- The lower thresholds for processor and I/O memory. Log messages are sent when available memory drops below these thresholds.
- The types of sanity checks to perform.

Related Topics

- [Memory Settings on Cisco IOS Routers, page 63-78](#)
- [Logging on Cisco IOS Routers, page 65-1](#)

-
- Step 1** Do one of the following:
- (Device view) Select **Platform > Device Admin > Memory** from the Policy selector.
 - (Policy view) Select **Router Platform > Device Admin > Memory** from the Policy Type selector. Select an existing policy or create a new one.
- The Memory page is displayed.
- Step 2** (Optional) Define the memory settings of the router, as required. See [Table 63-36 on page 63-80](#) for a description of the available fields.
-

Memory Policy Page

Use the Memory page to define settings related to router memory, including:

- The amount of time to retain the memory log.
- The thresholds for available processor and I/O memory.
- The amount of memory reserved for critical log messages.
- Whether to perform sanity checks on buffers and queues.
- Whether to enable the “memory-allocation lite” feature.

For more information, see [Defining Router Memory Settings, page 63-78](#).

Navigation Path

- (Device view) Select **Platform > Device Admin > Memory** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Memory** from the Policy Type selector. Right-click **Memory** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- [Memory Settings on Cisco IOS Routers, page 63-78](#)

- [Syslog Logging Setup Policy Page, page 65-7](#)
- [Syslog Servers Policy Page, page 65-10](#)

Field Reference

Table 63-36 Memory Page

Element	Description
Maintain Memory Log	<p>The number of hours that the router should maintain the log containing the history of memory consumption on the device. Valid values range from 12 to 72 hours. The default is 24 (1 day).</p> <p>Note The memory log is enabled by default and cannot be disabled.</p>
Processor Threshold	<p>The processor memory threshold in kilobytes. When available processor memory falls below this threshold, a notification message is triggered. Valid values range from 1 to 4294967295 kilobytes (4096 gigabytes).</p> <p>Note Another notification message is generated when available free memory rises to 5% above the threshold.</p>
I/O Threshold	<p>The I/O memory threshold in kilobytes. When available processor memory falls below this threshold, a notification message is triggered. Valid values range from 1 to 4294967295 kilobytes (4096 gigabytes).</p> <p>Note Another notification message is generated when available free memory rises to 5% above the threshold.</p>
Memory Allocation Lite	<p>When selected, the “memory-allocation lite” (malloc_lite) feature on the router is enabled. This feature avoids excessive memory allocation overhead for situations where less than 128 bytes are required. This is the default.</p> <p>When deselected, the “memory-allocation lite” feature is disabled.</p> <p>Note This feature is supported for processor memory pools only.</p>
Memory Region For Critical Notifications	<p>The amount of memory (in kilobytes) reserved for critical system log messages. Valid values range from 1 to 4294967295 kilobytes (4096 gigabytes), but the value you specify cannot exceed 25% of total memory.</p> <p>This option reserves a region of memory on the router so that the router can issue critical system log messages even when system resources are overloaded.</p>
Perform Sanity Checks	<p>The types of sanity checks to perform:</p> <ul style="list-style-type: none"> • Buffer—When selected, performs sanity checks on all buffers. Sanity checks are performed when a packet buffer is allocated and when the packet buffer is returned to the buffer pool. • Queue—When selected, performs sanity checks on all queues. • All—When selected, performs sanity checks on all buffers and queues. <p>Note Enabling any of these options may result in a slight degradation of router performance.</p>

Secure Device Provisioning on Cisco IOS Routers

Secure Device Provisioning (SDP) offers an integrated solution for streamlining VPN and network security deployment. SDP (previously called Easy Secure Device Deployment, or EzSDD) enables remote-site users to securely bootstrap their VPN device through an easy-to-use web interface, thereby easing the deployment burden, lowering costs, and shortening the network development cycle. For example, a telecommuter or small branch office user can remove a new device from its shipping package, plug it in, open a simple web management interface, and establish VPN connectivity, all within a period of just a few minutes.

For more information about SDP, see *Setting Up Secure Device Provisioning (SDP) for Enrollment in a PKI*, which can be found in *Cisco IOS Security Configuration Guide, Release 12.4T*.

Note

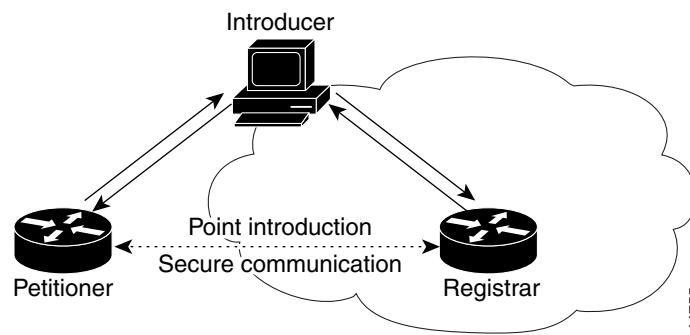

SDP requires Cisco IOS Software Release 12.3(8)T or later. Attempting to deploy this policy to a router running an earlier version could result in deployment failure. You also cannot configure the policy on NO-VPN router models (those that do not allow VPN configurations, such as the 3845 NOVPN).

Trusted Transitive Introduction (TTI) is the protocol that acts as the primary mechanism for implementing SDP. As shown in [Figure 63-3](#), TTI comprises the following three entities:

- **Introducer**—A mutually trusted device that introduces the petitioner to the registrar. Introducers can be end users who use SDP to deploy VPN devices associated with themselves to the PKI network, or an administrator/management system that uses SDP to deploy many VPN devices to the PKI network. This latter type is known as an administrative introducer. For more information, see [Configuring a AAA Server Group for Administrative Introducers, page 63-84](#).
- **Petitioner**—A remote-site device that is joined to the secure domain. The petitioner serves web pages to the introducer and receives the bootstrap configuration from the introducer's web browser. The petitioner component is enabled by default on all Cisco IOS devices.
- **Registrar**—A server that authorizes the petitioner by communicating directly with an authentication, authorization, and accounting (AAA) server to verify user credentials, permit or deny enrollment, and retrieve user-specific configuration information.

Use the SDP policy in Security Manager to configure the router as a registrar.

Figure 63-3 Secure Device Provisioning

For more information about Secure Device Provisioning, see:

- [Contents of Bootstrap Configuration, page 63-82](#)
- [Secure Device Provisioning Workflow, page 63-82](#)

- [Defining Secure Device Provisioning Policies, page 63-83](#)

Contents of Bootstrap Configuration

The bootstrap configuration provided by SDP typically does the following:

- Sets the petitioner's hostname.
- Synchronizes the petitioner's system clock with the registrar.
- Sets the petitioner's trustpoint.
- Sets the petitioner's authentication and authorization mechanism.
- Pushes the CA certificate.
- Enrolls the petitioner with the PKI server.
- Sets other VPN configurations, such as the configuration required to establish a management tunnel.
- Sets Cisco Networking Services (CNS) configuration.
- Sets the petitioner's DHCP pool.

Related Topics

- [Secure Device Provisioning Workflow, page 63-82](#)
- [Secure Device Provisioning on Cisco IOS Routers, page 63-81](#)

Secure Device Provisioning Workflow

The following illustrates the steps required to use SDP to register a remote-site device in a secure network:

1. Unpack the router and connect the power, LAN, and WAN cables.
2. Turn on a computer (introducer) that is assigned an IP address from the DHCP server on the router, open a web browser, and go to the petitioner URL (<http://device/ezsdd/welcome>) on the router. The router responds with a registration page (also called the local login dialog box).
3. Enter the username and password, then click **OK**. On the welcome page, enter the URL for the registrar. The following actions occur:
 - a. The browser opens an HTTPS-secured session to the central-site registrar, which verifies the username with the AAA server and returns the appropriate bootstrap configuration to the browser.
 - b. The browser feeds the bootstrap configuration to the remote-site router, configuring PKI trustpoint enrollment and IPsec VPN connectivity, and provisioning system attributes and other information.
 - c. You are notified that bootstrap configuration is complete.

Related Topics

- [Contents of Bootstrap Configuration, page 63-82](#)
- [Secure Device Provisioning on Cisco IOS Routers, page 63-81](#)

Defining Secure Device Provisioning Policies

The petitioner component is automatically enabled on all Cisco IOS routers. The SDP policy in Security Manager enables the registrar. To define an SDP policy you must define:

- The AAA server group containing the AAA server that the registrar uses to authenticate and authorize the introducer.
- The CA server to which the petitioner enrolls during the bootstrap process.
- The location of the introduction page that is displayed after authorization was performed.
- The location of the bootstrap configuration to be provided to the petitioner.

Related Topics

- [Secure Device Provisioning Workflow, page 63-82](#)
- [Configuring a AAA Server Group for Administrative Introducers, page 63-84](#)
- [Secure Device Provisioning on Cisco IOS Routers, page 63-81](#)

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > Secure Device Provisioning** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Secure Device Provisioning** from the Policy Type selector. Select an existing policy or create a new one.

The Secure Device Provisioning page is displayed. See [Table 63-37 on page 63-85](#) for a description of the fields on this page.

Step 2 Under Introducer Authentication, enter the name of the AAA server group containing the relevant AAA server, or click **Select** to select it from a list or to create a new object.

The selected AAA server determines whether the username and password supplied by the introducer represent an authorized user. The AAA server must use TACACS+, RADIUS, or be local.

Note Each AAA server in the selected group must be configured to communicate with an interface that exists on the router; otherwise, validation fails. If you want to configure a different AAA server group for authenticating and authorizing administrative introducers, see [Configuring a AAA Server Group for Administrative Introducers, page 63-84](#).

Step 3 Under Petitioner Authentication, define the CA server that authenticates the identity of the petitioner by doing one of the following:

- Select **Local CA Server**, then enter the local CA name in the field provided. If you have already configured the CA server locally on the registrar, a trustpoint is generated automatically.

Note If you have not configured the router as the CA server, enter the command **Crypto pki server [name]** using the CLI or FlexConfigs. This command is mandatory when you deploy an SDP policy configured with a local CA server.

- Select Remote CA Server, then enter the name of a PKI enrollment object, or click **Select** to select it from a list or to create a new object.

The PKI enrollment object defines the external CA server used in the SDP policy.

Step 4 Select the source of the introduction page that is displayed after you log in to the registrar. The introduction page indicates whether authorization was successfully completed and contains a button for completing the process of obtaining the bootstrap configuration.

If you do not select the default welcome page, you must enter the URL required to access a different welcome page that you prepared elsewhere.

Step 5 Select the source of the bootstrap configuration provided to the petitioner to implement its first-time configuration:

- If the source of the bootstrap configuration is a non-Security Manager URL, enter the URL and also the username and password for accessing the URL, if required.
- If the source of the configuration file is a Security Manager URL:
 - Enter the name of a FlexConfig, or click **Select** to select it from a list or to create a new object. The FlexConfig contains the device commands required to retrieve the appropriate bootstrap configuration. For more information, see [Add or Edit FlexConfig Dialog Box, page 7-30](#).
 - Enter the device name formula required by the FlexConfig to derive the device name of the petitioner from the username submitted by the introducer. (The two names typically have a fixed relationship.) The default formula is \$n, which uses the introducer name to determine the device name.

The device name determines which bootstrap configuration the petitioner should receive. The resulting URL contains the name of the FlexConfig you selected, as well as the parameters and formula you defined.
 - Enter a username and password for accessing the Security Manager server containing the FlexConfig. The password can contain alphanumeric characters, but cannot consist of a single digit.

Configuring a AAA Server Group for Administrative Introducers

Administrative introducers are administrators or management systems that introduce many devices to the PKI network. You can configure a AAA server group for authenticating and authorizing administrative introducers by appending the following FlexConfig to the configuration of the router:

```
aaa new-model
radius-server host 1.2.3.4 auth-port 1645 acct-port 1646 key key
aaa group server radius default-radius-group2
server 1.2.3.4 auth-port 1645 acct-port 1646
exit
aaa authentication login CSM_SDP2 group default-radius-group2
crypto provisioning registrar
administrator authentication list CSM_SDP2
administrator authorization list CSM_SDP2
exit
```

This FlexConfig serves two functions—it configures the AAA server group to use and it associates this server group with the SDP crypto.

For more information about administrative introducers, see *Administrative Secure Device Provisioning Introducer* on Cisco.com at this URL:

http://www.cisco.com/en/US/docs/ios/12_3t/12_3t14/feature/guide/gtadintr.html

Secure Device Provisioning Policy Page

Secure Device Provisioning (SDP) policies (formerly known as Easy Secure Device Deployment or EzSDD) enable you to configure a Cisco IOS router as a *registrar*. This is the SDP component that retrieves bootstrap configurations for *petitioners*, which are remote-site devices that are enrolling in the network security infrastructure. These devices use the bootstrap configuration for first-time configuration purposes. The registrar also verifies the identity of the *introducer*, which is the user who introduces the petitioner to the registrar.

For more information, see [Defining Secure Device Provisioning Policies, page 63-83](#).

Navigation Path

- (Device view) Select **Platform > Device Admin > Secure Device Provisioning** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Secure Device Provisioning** from the Policy Type selector. Create a new policy or select an existing one.

Table 63-37 Secure Device Provisioning Page (continued)

Element	Description
Bootstrap Configuration	<p>The source of the bootstrap configuration to provide to the petitioner for first-time configuration:</p> <ul style="list-style-type: none"> • Non-Security Manager URL—Used when the bootstrap configuration is located externally to Security Manager. Enter its location in the URL field. <p>If required, enter a username and password to access the server containing the bootstrap configuration.</p> <ul style="list-style-type: none"> • Security Manager URL—Used when Security Manager is providing the bootstrap configuration. Enter information in the following fields: <ul style="list-style-type: none"> – FlexConfig—The FlexConfig that contains the basic CLI structure required to create the bootstrap configuration. Enter the name of a FlexConfig object, or click Select to display a selector. <p>After selecting the FlexConfig, you must enter a username and password to access the Security Manager server that contains the FlexConfig.</p> – Device name formula—The formula required by Security Manager to determine the device name of the petitioner from the username that the introducer supplied. <p>Typically a fixed relationship exists between the username and the device name, which enables a formula like this to be established. The default formula is \$n, which uses the introducer name to determine the device name. The device name is required to determine the configuration file that the petitioner should receive.</p> <p>If required, enter a username and password to access the server containing the bootstrap configuration. The password can contain alphanumeric characters, but cannot consist of a single digit.</p>

DHCP on Cisco IOS Routers

In Security Manager, certain security features, such as Easy VPN and 802.1x, require Dynamic Host Configuration Protocol (DHCP) client/server configuration. DHCP is widely used in LAN environments to dynamically assign host IP addresses from a centralized server, which significantly reduces the overhead of administering IP addresses.

DHCP servers assign and manage IP addresses from specified address pools within a router to DHCP clients. If the DHCP server cannot satisfy a DHCP request from its own database, it can forward the request to one or more secondary DHCP servers defined by the network administrator.

Security Manager enables you to configure a Cisco IOS device as a DHCP server for clients (hosts) that are connected to the device's inside interface. When you configure a DHCP server, you use IP pools (a range of IP addresses reserved for a DHCP server). The IP pools you select determine the range of IP

addresses the server can use. These addresses are provided to client devices for a defined period of time called a lease. When this lease expires, the address is returned to the address pool, enabling the DHCP server to assign it to a different device.

For more information about DHCP, see:

- [Understanding DHCP Database Agents, page 63-88](#)
- [Understanding DHCP Relay Agents, page 63-88](#)
- [Understanding DHCP Option 82, page 63-89](#)
- [Understanding Secured ARP, page 63-89](#)

To configure a DHCP policy, see:

- [Defining DHCP Policies, page 63-90](#)
- [Defining DHCP Address Pools, page 63-91](#)

Understanding DHCP Database Agents

A DHCP database agent is any external host—for example, an FTP, TFTP, or RCP server—that stores the DHCP bindings database. You can include one or more DHCP database agents in each DHCP policy, as well as configure the interval between database updates to the agent.

Note

If you configure an external DHCP database agent, it is not necessary to define IP address pools, but you may do so. For more information about IP address pools, see [Defining DHCP Address Pools, page 63-91](#).

Related Topics

- [Understanding DHCP Relay Agents, page 63-88](#)
- [Understanding DHCP Option 82, page 63-89](#)
- [Understanding Secured ARP, page 63-89](#)
- [Defining DHCP Policies, page 63-90](#)
- [DHCP on Cisco IOS Routers, page 63-87](#)

Understanding DHCP Relay Agents

A DHCP relay agent is any host that forwards DHCP packets between clients and servers when they do not reside on the same physical subnet. Relay agents receive DHCP messages and then generate a new DHCP message to send on another interface. You can configure a reforwarding policy that determines what the DHCP relay agent should do if a forwarded message already contains relay information.

DHCP relay options in Security Manager include:

- Drop—The relay agent discards messages with existing relay information if Option 82 information is also present.
- Keep—The relay agent retains existing relay information.
- Replace—The relay agent overwrites existing information with its own relay information.

For example, you can have the DHCP relay agent replace the forwarded message with a new relay message. Additionally, you can choose whether to have the relay agent check the validity of relay information contained within forwarded BOOTREPLY messages.

Related Topics

- [Understanding DHCP Database Agents, page 63-88](#)
- [Understanding DHCP Option 82, page 63-89](#)
- [Understanding Secured ARP, page 63-89](#)
- [Defining DHCP Policies, page 63-90](#)
- [DHCP on Cisco IOS Routers, page 63-87](#)

Understanding DHCP Option 82

DHCP option 82 enables the DHCP relay agent to include information about itself and its attached client when it forwards requests from a DHCP client to a DHCP server. The DHCP server can use this information to assign IP addresses, perform access control, and set quality of service (QoS) and security policies for each of its subscribers. When the DHCP option 82 feature is enabled, a subscriber is identified by the switch port through which it connects to the networks, instead of by its MAC address. Multiple hosts on the subscriber LAN can be connected to the same port on the access switch and are uniquely identified. Option 82 also enhances security on access switches by providing the ability to use a user's IP address to locate the port on which a user is attached.

Related Topics

- [Understanding DHCP Database Agents, page 63-88](#)
- [Understanding DHCP Relay Agents, page 63-88](#)
- [Understanding Secured ARP, page 63-89](#)
- [Defining DHCP Policies, page 63-90](#)
- [DHCP on Cisco IOS Routers, page 63-87](#)

Understanding Secured ARP

The DHCP Secure IP Address Assignment feature (also called DHCP Authorized ARP) enables you to secure Address Resolution Protocol (ARP) table entries to DHCP leases in the DHCP database. This feature secures and synchronizes the client's MAC address to the DHCP binding, preventing unauthorized clients or hackers from spoofing the DHCP server and taking over a DHCP lease of an authorized client.

When you enable this feature and the DHCP server assigns an IP address to the DHCP client, the DHCP server adds a secure ARP entry to the ARP table with the assigned IP address and the MAC address of the client. These ARP entries cannot be updated by any other dynamic ARP packets, and they exist in the ARP table for as long as the lease is active.

Secure ARP entries can be deleted only by an explicit termination message from the DHCP client or by the DHCP server when the binding expires. To detect when a client has logged out, Secured ARP sends periodic ARP messages to which only authorized users can respond. Unauthorized responses are blocked at the DHCP server, providing an additional level of security.

Note Secured ARP disables dynamic ARP learning on an interface.

- [Understanding DHCP Database Agents, page 63-88](#)
- [Understanding DHCP Relay Agents, page 63-88](#)
- [Understanding DHCP Option 82, page 63-89](#)
- [Defining DHCP Policies, page 63-90](#)
- [DHCP on Cisco IOS Routers, page 63-87](#)

Defining DHCP Policies

When you configure a DHCP policy, you must define the IP address pools for the server to use to provide addresses to DHCP clients. In addition, you can optionally define the following:

- External DHCP database agent.
- IP ranges to exclude from DHCP.
- DHCP relay parameters.

Note When configuring DHCP on a Cisco IOS router, make sure that the router does not contain an access rule denying Bootstrap Protocol (BootP) traffic. Having such a rule blocks DHCP traffic from being transmitted.

Related Topics

- [DHCP on Cisco IOS Routers, page 63-87](#)

-
- Step 1** Do one of the following:
- (Device view) Select **Platform > Device Admin > Server Access > DHCP** from the Policy selector.
 - (Policy view) Select **Router Platform > Device Admin > Server Access > DHCP** from the Policy Type selector. Select an existing policy or create a new one.
- The DHCP Policy page is displayed. See [Table 63-38 on page 63-92](#) for a description of the fields on this page.
- Step 2** (Optional) Under Databases, click the **Add** button to display the [DHCP Database Dialog Box, page 63-94](#). From here you can define external DHCP database agents. For more information, see [Understanding DHCP Database Agents, page 63-88](#).
- Step 3** (Optional) Under Excluded IPs, enter the IP addresses or address ranges within a DHCP address pool that should not be made available to DHCP clients. You can use a combination of addresses and network/host objects, or click **Select** to display a selector. For more information, see [Specifying IP Addresses During Policy Definition, page 6-87](#).

Tip If the network you want is not listed in the selector, click the **Create** button to display the [Add or Edit Network/Host Dialog Box, page 6-83](#). From here you can create a network/host object.

- Step 4** Under IP Pools, click the **Add** button to display the [IP Pool Dialog Box, page 63-94](#). From here you can define the address pools to be used by the DHCP server. For more information, see [Defining DHCP Address Pools, page 63-91](#).
- Step 5** (Optional) When you use a relay agent to manage requests from DHCP clients located on a different subnet from the DHCP server, define the following DHCP relay options:
- Select the relay agent information reforwarding policy (Drop, Keep, or Replace). DHCP relay agents implement this policy when they receive messages already containing relay information.
 - Select the **Option** check box to enable the insertion of Option 82 data in requests that the relay agent forwards to the DHCP server.
 - Select the **Check** check box to validate DHCP Option 82 reply packets sent by the DHCP server.
When you enable this option, invalid messages are dropped. Valid messages are stripped of the option-82 field before they are forwarded to the DHCP client. When you disable this option, the option-82 field is removed from the packet without being checked first for validity.
See [Understanding DHCP Relay Agents, page 63-88](#) for more information.
-

Defining DHCP Address Pools

When you configure a DHCP policy that does not include an external database agent, you must define at least one IP address pool. This pool contains the addresses that the DHCP server can dynamically assign to DHCP clients. Additionally, you can define the following IP pool-specific options:

- The default routers, DNS servers, WINS servers, and domain used by DHCP clients.
- Whether to use the Secured ARP feature.
- Whether to import information regarding IP pool options from a centralized DHCP server.
- The length of the lease.
- The location of the TFTP server that IP telephony devices require to use addresses from this pool.

Related Topics

- [Defining DHCP Policies, page 63-90](#)
- [DHCP on Cisco IOS Routers, page 63-87](#)

-
- Step 1** On the DHCP page, click the **Create** button under IP Pools. The IP Pool dialog box is displayed.
- Step 2** Define the address pool. See [Table 63-40 on page 63-95](#) for a description of the available fields.
- Step 3** Click **OK** to save your definitions locally on the client and close the dialog box. The IP pool appears in the table displayed under IP Pools on the DHCP page.
- Step 4** Repeat [Step 1](#) through [Step 3](#) to define additional address pools, if required.

Note To edit an IP pool, select it from the table, then click the **Edit** button. To delete an IP pool, select it from the table, then click the **Delete** button. You cannot delete a pool whose addresses have been assigned to DHCP clients.

DHCP Policy Page

Use the DHCP policy page to define a DHCP server policy on the selected router. This includes specifying the address pools used by the DHCP server when assigning addresses to requesting clients.

For more information, see [Defining DHCP Policies, page 63-90](#).

Navigation Path

- (Device view) Select **Platform > Device Admin > Server Access > DHCP** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Server Access > DHCP** from the Policy Type selector. Right-click **DHCP** to create a policy, or select an existing policy from the Shared Policy selector.

Field Reference

Table 63-38 DHCP Policy Page

Element	Description
Databases Table	
Database URL	The URL of the external DHCP database agent.
Timeout	The amount of time to wait (in seconds) for a response from the external DHCP database agent before aborting a database transfer.
Write Delay	The interval (in seconds) between DHCP assignment updates sent to the external DHCP database agent.
Add button	Opens the DHCP Database Dialog Box, page 63-94 . From here you can define a DHCP database agent.
Edit button	Opens the DHCP Database Dialog Box, page 63-94 . From here you can edit the selected DHCP database agent.
Delete button	Deletes the selected DHCP database agents.
Excluded IPs	
Excluded IPs or IP Ranges	The IP addresses or address ranges to exclude from DHCP. These addresses are not assigned by the DHCP server to DHCP clients requesting addresses. Enter one or more network addresses or network/host objects, or click Select to select an object from a list or to create a new object. For more information, see Specifying IP Addresses During Policy Definition, page 6-87 .
IP Pools Table	
Name	The name of the IP pool.
Network	The IP address and subnet mask of the IP pool.

Table 63-38 DHCP Policy Page (continued)

Element	Description
Default Router	The IP addresses of the default routers used by DHCP clients.
DNS Server	The IP addresses of the DNS servers used by DHCP clients.
NetBIOS (WINS) Server	The IP addresses of the Windows Internet Naming Service (WINS) servers used by Microsoft DHCP clients.
Domain Name	The domain name for DHCP clients.
Import All	Indicates whether the remote DHCP server imports certain DHCP options from a centralized DHCP server.
Secured ARP	Indicates whether secured ARP is enabled on this IP pool to help prevent IP spoofing by unauthorized users.
Lease	The duration of the lease for each IP address assigned by the DHCP server from this IP pool.
Option 150	The IP address of the TFTP server required by IP phones for configuration, as defined using DHCP option 150.
Option 66	The IP address of the TFTP server required by IP phones for configuration, as defined using DHCP option 66.
Add button	Opens the IP Pool Dialog Box, page 63-94 . From here you can define a DHCP IP address pool.
Edit button	Opens the IP Pool Dialog Box, page 63-94 . From here you can edit the selected IP pool.
Delete button	Deletes the selected IP pools.
Relay parameters	
Policy	The policy that DHCP relay agents implement when they receive messages already containing relay information: <ul style="list-style-type: none"> • Drop—The relay agent discards messages with existing relay information if option-82 information is also present. • Keep—The relay agent retains existing relay information. • Replace—The relay agent overwrites existing information with its own relay information.
Option	When selected, enables DHCP Option 82 data insertion in message requests forwarded from the DHCP client to the server. DHCP Option 82 provides the DHCP server with both the switch and port ID of the requesting client. This option makes it possible to locate where a user is physically connected to the network and prevent spoofing. See Understanding DHCP Option 82, page 63-89 . When deselected, DHCP Option 82 is disabled.
Check	When selected, DHCP Option 82 reply packets received from the DHCP server are validated. Invalid messages are dropped; valid messages are stripped of the option-82 field before being forwarded to the DHCP client. When deselected, the option-82 field is removed from the packet without being checked first for validity.

DHCP Database Dialog Box

Use the DHCP Database dialog box to define external DHCP database agents that contain the automatic bindings. Each database URL that you define must be unique.

For more information, see [Understanding DHCP Database Agents, page 63-88](#).

Navigation Path

Go to the [DHCP Policy Page, page 63-92](#), then click the **Add** or **Edit** button beneath the Databases table.

- [IP Pool Dialog Box, page 63-94](#)

Field Reference

Table 63-39 *DHCP Database Dialog Box*

Element	Description
Database URL	The URL of the external DHCP database agent containing the automatic bindings. The URL can be in HTTP, FTP, TFTP, or RCP format. Note If you define a URL, it is not necessary to define an IP address pool. However, you may do so.
Timeout	The amount of time (in seconds) the DHCP server should wait for a response from the external DHCP database agent before aborting a database transfer. The default is 300 seconds (5 minutes). Note A value of 0 disables the timeout.
Write Delay	The interval (in seconds) between updates sent from the DHCP server to the external DHCP database agent. The minimum delay is 60 seconds. The default is 300 seconds (5 minutes).

IP Pool Dialog Box

Use the IP Pool dialog box to define one or more address pools, which the DHCP server uses to assign dynamic addresses to DHCP clients. You must define at least one address pool, unless you have defined an external DHCP database agent.

Navigation Path

Go to the [DHCP Policy Page, page 63-92](#), then click the **Add** or **Edit** button beneath the IP Pools table.

Field Reference

Table 63-40 IP Pool Dialog Box

Element	Description
Pool Name	The name of the IP pool.
Network	<p>The IP address and subnet mask of the IP pool. This subnet contains the range of available IP addresses that the DHCP server may assign to clients.</p> <p>Enter an address and mask or the name of a network/host object, or click Select to select an object from a list or to create a new one.</p> <p>Tip You can exclude specific addresses within the range by defining them in the Excluded IPs field. See DHCP Policy Page, page 63-92.</p>
Default Router Addresses	<p>The IP addresses of the default routers for DHCP clients using this IP pool. After a DHCP client is booted, it begins sending packets to this router, which should be located on the same subnet as the client.</p> <p>Enter up to eight (8) network addresses or network/host objects, or click Select to select an object from a list or to create a new one.</p>
DNS Server Addresses	<p>The IP addresses of the DNS servers that DHCP clients using this IP pool should query when they need to correlate hostnames to IP addresses.</p> <p>Enter up to eight (8) network addresses or network/host objects, or click Select to select an object from a list or to create a new one.</p>
NetBIOS (WINS) Server Addresses	<p>The IP addresses of the Windows Internet Naming Service (WINS) servers used by Microsoft DHCP clients to correlate hostnames to IP addresses within a general grouping of networks.</p> <p>Enter up to eight (8) network addresses or network/host objects, or click Select to select an object from a list or to create a new one.</p>
Domain Name	The domain name for DHCP clients using this IP pool. This name places these clients in the general grouping of networks that make up the domain.
Import All	<p>When selected, enables remote DHCP servers to import specific DHCP options (such as the DNS server) from a centralized server. Use this option to enable configuration information to be updated automatically.</p> <p>When deselected, all DHCP options are local to this specific server.</p>
Secured ARP	<p>When selected, enables the DHCP Authorized ARP feature, which limits the leasing of IP addresses to authorized mobile users. This feature helps prevent IP spoofing by unauthorized users. See Understanding Secured ARP, page 63-89.</p> <p>When deselected, the DHCP Authorized ARP feature is disabled.</p> <p>Note This feature also disables dynamic ARP learning on an interface.</p>

Table 63-40 IP Pool Dialog Box (continued)

Element	Description
Lease Never Expires	When selected, the DHCP server permanently assigns IP addresses to its clients. When deselected, addresses are leased for a predefined amount of time, as defined in the Time Length field.
Time Length (DD:HH:MM)	Applies only when the Lease Never Expires check box is deselected. The duration of the lease provided to each IP address assigned from this IP pool (using the format DD:HH:MM). After the lease expires, the assigned IP address is no longer valid and is returned to the pool.
Option 66 (IP Addresses)	The IP address of the TFTP server used to provide configuration files to IP phones. These configuration files define parameters required by IP phones to connect to Cisco CallManager. Enter up to eight (8) network addresses or network/host objects, or click Select to select an object from a list or to create a new one. Note This option is functionally similar to option 150. Either or both options may be used.
Option 150 (IP Addresses)	The IP address of the TFTP server used to provide configuration files to IP phones. These configuration files define parameters required by IP phones to connect to Cisco CallManager. Enter up to eight (8) network addresses or network/host objects, or click Select to select an object from a list or to create a new one. Note This option is functionally similar to option 66. Either or both options may be used.

NTP on Cisco IOS Routers

The Network Time Protocol (NTP) is the standard for time synchronization between network devices. Synchronized time enables you to correlate syslog and other debug output to specific events, which is essential for troubleshooting, fault analysis, and security incident tracking. Time comparisons are not possible without precise time synchronization between the logging, management, and AAA functions occurring in your network.

NTP uses the concept of a stratum to describe how far removed a machine is from an authoritative time source. For example, a stratum 1 time server is directly attached to a radio or atomic clock. NTP then distributes the time from this authoritative time source across the network. A stratum 2 time server synchronizes with a stratum 1 time server; a stratum 3 time server synchronizes with a stratum 2 time server and so on. One NTP transaction per minute is sufficient to synchronize two machines to within a millisecond.

NTP runs over the User Datagram Protocol (UDP) using port 123. Security Manager supports NTP version 3, as defined in RFC 1305.

Defining NTP Servers

This procedure describes how to define the NTP servers that the routers users to synchronize time. After the NTP policy is deployed, the router uses an algorithm (based on factors such as delay, dispersion, and jitter) to determine which NTP server is the most accurate and synchronizes to that one.

At the global level, you can enable MD5 authentication and specify a source address to use on all NTP packets sent from the router.

To add an NTP server to the policy, all you need to do is enter its IP address. In addition, you can optionally define authentication parameters and determine whether a particular server should be preferred over other NTP servers of similar accuracy.

Related Topics

- [NTP on Cisco IOS Routers, page 63-96](#)

-
- Step 1** Do one of the following:
- (Device view) Select **Platform > Device Admin > Server Access > NTP** from the Policy selector.
 - (Policy view) Select **Router Platform > Device Admin > Server Access > NTP** from the Policy Type selector. Select an existing policy or create a new one.

The NTP page is displayed. See [Table 63-41 on page 63-98](#) for a description of the fields on this page.

- Step 2** (Optional) In the Source Interface field, enter the name of the interface or interface role whose address should be used as the source interface for all NTP packets sent from the router, or click **Select** to select an interface role from a list or to create a new one. The source interface must have an IP address.

This option is useful when the NTP server cannot reach the address from which the connection originated (for example, due to a firewall). If you do not enter a value in this field, the address of the outgoing interface is used.

Note You can override this global setting for individual NTP servers, as described in [Step 5](#).

- Step 3** (Optional) Select the **Enable NTP Authentication** check box to authenticate all associations between this router and the NTP servers defined in this policy.
- Step 4** Click the **Add** button under the Servers table to display the NTP Server dialog box. From here you can define an NTP server.
- Step 5** Define an NTP server. See [Table 63-42 on page 63-100](#) for a description of the available fields.
- Step 6** (Optional) Define authentication parameters for this NTP server.

Note If you modify the value of a previously defined authentication key, the change affects all NTP servers that share this key.

Note When you define an authentication key in Security Manager, the value 0 is automatically appended to the end of the CLI command. This value, which represents the default authentication key encryption type, can be modified using the CLI.

- Step 7** Repeat [Step 5](#) and [Step 6](#) to define additional NTP servers.

- Step 8** Click **OK** to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the Servers table.

Note To edit an NTP server, select it from the Servers table, then click **Edit**. To remove an NTP server, select it, then click **Delete**. If the key defined on the server you delete is not defined on a different NTP server, the key is also deleted.

NTP Policy Page

Use the NTP page to define one or more NTP servers that the router can use for time synchronization. This includes enabling authentication, if required, and defining a global source interface for all traffic sent to these servers.

For more information, see [Defining NTP Servers, page 63-97](#).

Navigation Path

- (Device view) Select **Platform > Device Admin > Server Access > NTP** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Server Access > NTP** from the Policy Type selector. Right-click **NTP** to create a policy, or select an existing policy from the Shared Policy selector.

Field Reference

Table 63-41 NTP Page

Element	Description
Source Interface	<p>The source address for all packets sent to an NTP server. This setting might be necessary when the NTP server cannot respond to the address from which the packet originated (for example, due to a firewall). The source interface must have an IP address.</p> <p>If you do not define a value in this field, the address of the outgoing interface is used.</p> <p>Enter the name of an interface or interface role, or click Select to select the object from a list or to create a new one.</p> <p>Note The source interface defined in this field is a global setting that you can override for individual NTP servers. For more information, see NTP Server Dialog Box, page 63-99.</p>

Table 63-41 NTP Page (continued)

Element	Description
Enable NTP Authentication	When selected, enables authentication using MD5 when connecting to an NTP server. When deselected, authentication is disabled.
Servers Table	
IP Address	The IP address of the NTP server.
Source Interface	The source address for all packets sent to this NTP server. This setting overrides the global setting defined at the top of the page.
Preferred	Indicates whether this NTP server is preferred over other NTP servers of similar accuracy. Note By default, preferred servers are listed first in the table.
Key Number	The ID number of the key used for authentication with this NTP server.
Trusted	Indicates whether the authentication key defined for this NTP server is a trusted key.
Add button	Opens the NTP Server Dialog Box, page 63-99 . From here you can define an NTP server.
Edit button	Opens the NTP Server Dialog Box, page 63-99 . From here you can edit the selected NTP server.
Delete button	Deletes the selected NTP server from the table. If the key defined on the server you delete is not defined on a different NTP server, the key is also deleted.

NTP Server Dialog Box

Use the NTP Server dialog box to define the address of an NTP server that the router can use to perform time synchronization. In addition, you can use this dialog box to define a default source interface for NTP packets sent to this server and authentication parameters.

Navigation Path

Go to the [NTP Policy Page, page 63-98](#), then click the **Add** or **Edit** button beneath the table.

Related Topics

- [NTP on Cisco IOS Routers, page 63-96](#)
- [Understanding Interface Role Objects, page 6-73](#)

Field Reference

Table 63-42 NTP Server Dialog Box

Element	Description
IP Address	The IP address of the NTP server. Enter an address or the name of a network/host object, or click Select to select the object from a list or to create a new one.
Source Interface	<p>The source address for all packets sent to this NTP server. This setting might be necessary when the NTP server cannot respond to the address from which the packet originated (for example, due to a firewall). The source interface must have an IP address.</p> <p>If you do not define a value in this field and there is no global setting, the address of the outgoing interface is used.</p> <p>Note This setting overrides the global setting you defined on the NTP Policy Page, page 63-98.</p> <p>Enter the name of an interface or interface role, or click Select to select the object from a list or to create a new one.</p>
Preferred	<p>When selected, this NTP server is preferred over other NTP servers of similar accuracy. If this server is used for synchronization, the time offset used to correct the local clock is calculated from this server only.</p> <p>Note If a different NTP server is significantly more accurate than the preferred server (for example, stratum 2 versus stratum 3), the router synchronizes to the more accurate server.</p> <p>When deselected, this NTP server is not given preference over other NTP servers of similar accuracy. The time offset used to correct the local clock is calculated by taking the combined offset of all NTP servers.</p> <p>We recommend that you configure an NTP server as preferred only when multiple servers have the same stratum and you can rely on the accuracy of the preferred server.</p>
Authentication Key	<p>The MD5 key that is used to authenticate associations with the NTP server.</p> <ul style="list-style-type: none"> Key Number—The ID number of the authentication key. Enter the key number or select a previously defined number from the list. Key Value—An arbitrary string of up to 32 characters that defines the authentication key. Enter the string again in the Confirm field. Trusted—When selected, this key authenticates the identity of systems attempting to synchronize with this server. When deselected, this key is not used for authentication. <p>If you select a key number from the list and then change the key value, you are warned that saving this change affects any other NTP servers using the same authentication key.</p> <p>Note To use authentication, you must enable it from the NTP Policy Page, page 63-98.</p>
