Building Architectures to Solve Business Problems

About Cisco Validated Design (CVD) Program

The CVD program consists of systems and solutions designed, tested, and documented to facilitate faster, more reliable, and more predictable customer deployments. For more information visit www.cisco.com/go/designzone.

ALL DESIGNS, SPECIFICATIONS, STATEMENTS, INFORMATION, AND RECOMMENDATIONS (COLLECTIVELY, "DESIGNS") IN THIS MANUAL ARE PRESENTED "AS IS," WITH ALL FAULTS. CISCO AND ITS SUPPLIERS DISCLAIM ALL WARRANTIES, INCLUDING, WITHOUT LIMITATION, THE WARRANTY OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT OR ARISING FROM A COURSE OF DEALING, USAGE, OR TRADE PRACTICE. IN NO EVENT SHALL CISCO OR ITS SUPPLIERS BE LIABLE FOR ANY INDIRECT, SPECIAL, CONSEQUENTIAL, OR INCIDENTAL DAMAGES, INCLUDING, WITHOUT LIMITATION, LOST PROFITS OR LOSS OR DAMAGE TO DATA ARISING OUT OF THE USE OR INABILITY TO USE THE DESIGNS, EVEN IF CISCO OR ITS SUPPLIERS HAVE BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

THE DESIGNS ARE SUBJECT TO CHANGE WITHOUT NOTICE. USERS ARE SOLELY RESPONSIBLE FOR THEIR APPLICATION OF THE DESIGNS. THE DESIGNS DO NOT CONSTITUTE THE TECHNICAL OR OTHER PROFESSIONAL ADVICE OF CISCO, ITS SUPPLIERS OR PARTNERS. USERS SHOULD CONSULT THEIR OWN TECHNICAL ADVISORS BEFORE IMPLEMENTING THE DESIGNS. RESULTS MAY VARY DEPENDING ON FACTORS NOT TESTED BY CISCO.

CCDE, CCENT, Cisco Eos, Cisco Lumin, Cisco Nexus, Cisco StadiumVision, Cisco TelePresence, Cisco WebEx, the Cisco logo, DCE, and Welcome to the Human Network are trademarks; Changing the Way We Work, Live, Play, and Learn and Cisco Store are service marks; and Access Registrar, Aironet, AsyncOS, Bringing the Meeting To You, Catalyst, CCDA, CCDP, CCIE, CCIP, CCNA, CCNP, CCSP, CCVP, Cisco, the Cisco Certified Internetwork Expert logo, Cisco IOS, Cisco Press, Cisco Systems, Cisco Systems Capital, the Cisco Systems logo, Cisco Unity, Collaboration Without Limitation, EtherFast, EtherSwitch, Event Center, Fast Step, Follow Me Browsing, FormShare, GigaDrive, HomeLink, Internet Quotient, IOS, iPhone, iQuick Study, IronPort, the IronPort logo, LightStream, Linksys, MediaTone, MeetingPlace, MeetingPlace Chime Sound, MGX, Networkers, Networking Academy, Network Registrar, PCNow, PIX, PowerPanels, ProConnect, ScriptShare, SenderBase, SMARTnet, Spectrum Expert, StackWise, The Fastest Way to Increase Your Internet Quotient, TransPath, WebEx, and the WebEx logo are registered trademarks of Cisco Systems, Inc. and/or its affiliates in the United States and certain other countries.

All other trademarks mentioned in this document or website are the property of their respective owners. The use of the word partner does not imply a partnership relationship between Cisco and any other company. (0809R)

Solution Authors

Martin Pueblas

Martin Pueblas, CCIE#2133, CISSP#40844—Technical Leader, CMO Enterprise Solutions Engineering (ESE), Cisco Systems

Martin is the lead system architect of the Cisco SAFE Security Reference Architecture. He is a network security expert with over 17 years of experience in the networking industry. He obtained his CCIE certification in 1996 and CISSP in 2004. Martin joined Cisco in 1998 and has held a variety of technical positions. Started as a Customer Support Engineer in Cisco's Technical Assistance Center (TAC) in Brussels, Belgium. In 1999 moved to the United States where soon became technical leader for the Security Team. Martin's primary job responsibilities included acting as a primary escalation resource for the team and delivering training for the support organization. At the end of 2000, he joined the Advanced Engineering Services team as a Network Design Consultant, where he provided design and security consulting services to large corporations and Service Providers. During this period, Martin has written a variety of technical documents including design guides and white papers that define Cisco's best practices for security and VPNs. Martin joined Cisco's Central Marketing Organization in late 2001, where as a Technical Marketing Engineer, he focused on security and VPN technologies. In late 2004, he joined his current position acting as a security technical leader. As part of his current responsibilities, Martin is leading the development of security solutions for enterprises.

Brian Cox

Brian Cox, CCIE#4836, CWN#73—Technical Leader, CMO Enterprise Solutions Engineering (ESE), Cisco Systems

Brian is a Technical Leader at Cisco, with a primary focus on WLANs and mobility. His current role is network design of service ready architectures providing core services such as security, mobility and unified communications over resilient networks. Brian has authored many technical papers, including multiple Mobility Design Guides, Secure Mobility Design Guides, and a Voice over WLAN Design Guide. He holds a master of engineering degree with a specialization in communications from the Royal Melbourne Institute of Technology

Srinivas Tenneti

Srinivas Tenneti, CCIE#10483—Technical Marketing Engineer, CMO Enterprise Solutions Engineering (ESE), Cisco Systems

Srinivas is a Technical Marketing Engineer for WAN and branch architectures in Cisco's ESE team. Prior to joining the ESE team, Srinivas worked two years in Commercial System Engineering team where he worked on producing design guides, and SE presentations for channel partners and SEs. Before that, he worked for 5 years with other Cisco engineering teams. Srinivas has been at Cisco for 8 years.

Steve Gyurindak

Steve Gyurindak, CCIE#9057, CISSP#61046—Solutions Architect, Enterprise Solutions Engineering (ESE), Cisco Systems

Steve is a solutions architect with over 15 years of industry experience. He joined Cisco in 2000 and worked the first 8 and a half years as a Systems Engineer covering the Service Provider, North Florida/Alabama Commercial, Georgia Enterprise and US Channels sales markets. Steve has been recognized for his work with some of Cisco's most influential customers as well as for his work in South America and Europe. Steve joined ESE in 2009 to lead the development of customer-focused architectures and designs for the Education Market. Steve has a Bachelor of Science degree in Telecommunications from the State University of New York at Buffalo, and is currently pursuing a Master's of Science degree in Network Telecommunications at New York University. In addition to a CCIE in Routing and Switching, Steve holds the following certifications: CISSP, CCNP, CCDP, CCNA, CCDA, MCSE, and MCNE.

Solution Authors

John Strika

John Strika, Technical Marketing Engineer, CMO Enterprise Solutions Engineering (ESE), Cisco Systems

John is a Technical Marketing Engineer in Cisco's Public Sector ESE team, with expertise in the areas of mobility and location-based services. He has coauthored documents on enterprise mobility and Wi-Fi location-based services. As a member of Cisco's Enterprise Architecture Board, he helps maintain Cisco's vision and architectural direction and define Cisco's roadmap for context-aware and presence solutions. Previously, John was Cisco's first mobility consulting systems engineer, responsible for architecting creative wireless solutions for large enterprise customers. His 28 years of experience spans network design and implementation, applications development, facilities planning and management, consulting, and general management. His past roles have included mission-critical telecommunications design and development at AT&T and systems programming and data communications management with Wall Street brokerages and commercial banks. Prior to joining Cisco, Strika was at Telxon Corporation (parent of Cisco's Aironet wireless acquisition) for nine years, reaching the position of Southern Division Vice President of Wireless Technologies and Services. He is a member of the IEEE and has held several Federal Communications Commission licenses in the use and modification of amateur and commercial radio. His educational background is in electrical engineering and computer applications programming from Columbia University and in finance from Fordham University's College of Business Administration, and he holds a masters of communications technology certificate from the American Institute. He was a charter Novell Certified Netware Engineer in the greater New York City area. Always seeking opportunities to use his mobility and advanced communications knowledge to improve public safety as well as the safety of our public servants, John has served in volunteer search and rescue as well as a Reserve Deputy.

Bruce McMurdo

Bruce McMurdo, CCIE# 1537—Technical Leader, CMO Enterprise Solutions Engineering (ESE), Cisco Systems

Bruce has more than 20 years of experience in data networking. He has been employed at Cisco since 1996, working as a network consulting engineer, a wireless LAN product manager, and most recently as a technical leader. Bruce has technical expertise in network virtualization, wireless LANs, and unified communications, and has frequently presented and published on these subjects.

Rahul Kachalia

Rahul Kachalia, CCIE# 11740—Technical Marketing Engineer, CMO Enterprise Solutions Engineering (ESE), Cisco Systems

Rahul is a technical marketing engineer in Cisco's Enterprise Solution Engineering group, helping to create the design guidance that will help build the 21st century school network infrastructure. Rahul has more than 14 years of broad engineering experience, primarily in service provider core and edge focused products and technologies including broadband, MPLS, VPN and managed services. He has led many assurance projects to develop solutions that can deliver design guidance and accelerate deployments from traditional WAN infrastructure to next-generation IP/MPLS managed core networks. In the Enterprise Solution Engineering group he has also worked on designing next-generation unified virtual campus networks for large enterprise customers. In addition to CCIE, Rahul holds CCNP, CCNA, MCSE, MCP, and CNE. He holds a bachelor's degree from Mumbai University, India.

CHAPTER 1

Cisco Service Ready Architecture for Schools Solution Overview

Executive Summary

Cisco is committed to the education environment and understands the varying complexities and business influences that impact the continual operation of critical educational network services. As the network becomes more crucial to the operation of the school district—due to the additional essential services that utilize it—it is important to create an architecture that addresses the growing complexities and criticality of the network. The Cisco Service Ready Architecture for Schools was developed as a guide to assist school leadership in planning for the evolution of the school network. It addresses the current network service requirements, such as safety and security, network availability, and mobility while building a foundation that is ready for the addition of future network services as they develop.

Introduction

The Cisco Service Ready Architecture for Schools is a network roadmap for school districts to utilize to enable 21st century education for students and teachers. This design is built by combining an understanding of the current and future school district network needs with the best technology available, while considering the technical and financial constraints faced by school districts.

Cisco's Service Ready Architecture for Schools is a well designed and validated network architecture that is flexible, adaptive and cost effective to support a wide range of education services. This architecture provides the ability to deliver all of the services required of an enhanced learning environment as well as the ability to collaborate with the other schools, district offices and entities beyond the district.

The Service Ready Architecture for Schools starts with a base network foundation consisting of a district office where a majority of the critical applications reside. Connected through a WAN transport of MetroEthernet, two examples of schools sites are provided. School site 1 consists of a smaller design from those schools with a lower student/teacher ratio. School site 2 is designed for a larger site. Each site can co-exist in a single school district or can be treated as separate modules. Having guidance for two separate sites provides flexibility, modularity and scalability as your school district migrates in size.

The district office and each school site contains the critical technologies, or services, required to achieve the base goals of safety, learning and efficiency. Tested techniques and guidance is provided so that a network IT staff can 'set it and forget it.'

The Service Ready Architecture for Schools takes the guesswork out of designing and configuring a school network. Cisco Certified Internet Engineers (CCIEs) have designed the network foundation, based on listening to the top concerns from superintendents across the globe, and provided guidance on

the key network technologies required to enable and solve those top concerns. The Service Ready Architecture for Schools was placed in a lab and tested using best practice techniques from over 20+ years of network design. The products, features, and configurations have been validated and can be utilized in your network.

Design Guide Structure

Cisco's Service Ready Architecture for schools is broken down into modular, interdependent chapters as shown in [Table 1-1](#). This guide can be read as an extensive network design guide or in chapters to suit a particular technology needed.

Table 1-1 Cisco Service Ready Architecture for Schools Solution Overview

Chapter 3, “Network Foundation Design”	Chapter 8, “Digital Media and Video Surveillance Design”
Chapter 4, “Security Design”	Chapter 9, “Access Layer Security Design”
Chapter 5, “Wireless LAN Design”	Chapter 10, “School Site Design”
Chapter 6, “Context-Aware Services Design”	Chapter 11, “District Office Design”
Chapter 7, “Unified Communications Design”	

Supplement Documents

- *Schools Configuration Files Guide*—Example CLI Configurations from the validated design
- *Schools Netformix DesignXpert Tool*—Netformix Desing Expert Template for Schools SRA

The Service Ready Architecture for Schools network design is a comprehensive validated design based on proven techniques to take the guesswork out of establishing your school network. The techniques and guidance provided in the chapters can be used to design and to be deployed in your network easily with enough room for flexibility and growth. Leveraging the practices given in the Service Ready Architecture can establish critical technologies to enable and solve your top concerns in your school network: security, learning and efficiency.

Today's Education Environment

Schools are facing significant challenges that are creating opportunity and driving transformation of many aspects of the education environment. Technological innovation is not only applied to the learning process, but optimized for school operations to drive building and energy efficiencies, heighten the awareness of, and responsiveness to, safety and security concerns, and improve communications on and off campus.

Technology can provide a powerful platform for the educational needs of the 21st century.

Cisco delivers the best architectural framework—based on years of experience and cutting edge technology—to meet the requirements of the education environment. In forming an architectural framework for education, three key drivers are at the forefront of learning innovation:

- Student performance and assessment remains top of mind. Schools are being held accountable for the success and failure of their students, and their teachers while demands to provide equitable opportunities to all learners drives the need for a pervasive technology platform for access to the experts and resources needed. Governmental influence and accountability continues to drive schools to demonstrate that their students are successfully advancing
- Student expectations are changing and engaging kids is increasingly done best with technology. Social networking, online digital content, customized curriculum, and accessing resources worldwide are required. Schools are transforming into learning centers that support the development of basic skills while developing students that are globally aware, internationally competitive and masterful of 21st century skills and talent.
- Teacher Talent and Staff Development focused on leveraging our best expertise and providing optimal opportunities for students is also best supported with a flexible Communications and Collaboration platform. Developing teachers while enriching their own work environment with technology will lead to the innovative application of collaborative tools to students and their classrooms.
- With school budgets and funding sources tightly monitored, schools strive to improve operational efficiencies. When schools streamline operations and processes, they become more cost effective and create sustainable, on-going savings. Schools increasingly look to the network to support critical operational functionality such as Energy Monitoring and Management, Emergency Paging and Communications and Video Based Surveillance and Video Communications. Smart facilities management creates a school that is not only safer for students, a top issue for schools but also creates cost efficiencies and sustainable funding for many advanced technologies for the classroom.
- The ultimate end result of implementing the proper educational framework is to truly transform the current educational environment to one that promotes learning anywhere, anytime, regardless of the medium. Leveraging technology to eliminate barriers to accessibility is paramount to educators and school staff. Making information easy to access enables students to learn at their own pace and not be constrained to a single method of information delivery. Mechanisms that increase student performance can be realized through technology to assist in the development of 21st century skills. Some of the key initiatives to consider are:
- Smart and flexible learning environments—Classrooms are transforming into dynamic classrooms, which include digital content, on-line assessment, and pervasive access to rich media. Students are increasingly becoming the producers of content and controlling more of their own learning and the physical format of the classroom must change on-the-fly to facilitate the use of advanced technologies. Classroom walls are being “virtually” eliminated by the power of the network to allow for access to resources well beyond the physical school building, to be connected to national and global experts and resources.
- Technology-enabled learning—Information is being delivered in multiple formats, often combining methods of delivery to optimize the learning experience. Students are increasingly becoming the producers of content and a less formal, user-created content library is coming to the forefront in the education community. Students learn and share via video, photo-sharing, blogs, wikis, instant messaging, etc. Additionally, as the learning paradigm is shifting the role of the teacher is changing dramatically and students are developing a much sharper sense of self and audience.
- Social networking and on-line learning—Students are interfacing with each other and their educators more than ever. Another interesting trend is that students are publicly publishing their work more today, which drives a higher expectation for quality in the work they produce. Students who own their learning, retain their knowledge, and can apply it wherever and whenever it is needed.
- Convergence of information and communications—Web 2.0 initiatives continue to drive technology practices in the education community. Unified Communications is becoming more prevalent in schools and leverages the benefits of an IP-based platform to integrate data-rich information with communications, facilitating a higher level of responsiveness and engagement with the extended

community (the district, other schools, parents, etc.). This drive toward convergence has also enhanced the safety and security practices in schools where informed emergency response and threat avoidance are top of mind.

- **Learning communities**—Collaborative environments for both students and teachers are on the rise. Integrating technologies further enhance the experience by providing such utilities as interactive-video, on-demand video feeds, voice and Web collaboration, video to mobile devices, and TelePresence. The flexibility of integrating tasks and robust communications accelerates results for students, teachers, administrators and the community.
- **One-to-one learning**—New, inexpensive devices have provided teachers and students with an environment where everyone has access to a mobile computer, as well as digital content, educational software, and digital authoring tools.
- **Connected real estate**—Converging disparate building networks into a common IP backbone reduces many costly silos consuming hundreds of thousands of dollars each year. Intelligent and energy efficient buildings are a high priority for school districts as energy costs have risen and administrative budgets have been reduced. Connected Real Estate leverages the network to centralize operations and provide a platform that applies intelligence to basic building functions. Integrated video and communications are also a key element in promoting the safety and security of teachers and students. Policing building access or using RFID tagging for the protection of assets is quickly becoming a popular practice, as is the incorporation of IP video surveillance systems and emergency response technologies that are integrated to the entire district's network and the public safety community.
- **Mobility**—One of the largest movements in the education community is the pursuit of anywhere, anytime, continuous access. More education environments are moving toward wireless networks as the network of choice. It allows freedom of movement for students and educators and also enhances safety and security by further augmenting the ability to reach individuals quickly and respond immediately to emergency situations. Furthermore, the use of laptop computers, Netbooks, and mobile devices only seems to increase as time goes on. By integrating the preferred learning technologies with mobile platforms, we can realize flexible learning and an accommodating environment.

CHAPTER 2

Service Ready Architecture for Schools—A Framework for Education

The drivers, key initiatives and requirements of the education environment are evolving beyond the traditional enterprise network. The next generation network architecture for school environments must be built on a technical foundation that takes into consideration the current economic environment as well as other business factors impacting the education market as a whole. The fundamentals of this next generation network must:

- Allow many services to operate seamlessly over a common infrastructure.
- Embed service recognition, awareness, and differentiation into all components.
- Support different voice, video, and data services while ensuring availability, scalability, and security.
- Adapt to network technical innovations that allow for better resiliency and the implementation of new network services.
- Integrate these new services and technical innovations with existing network equipment, protocols, and methods of communication.

The Service Ready Architecture for Schools is a well-designed and validated network architecture that is flexible, adaptive, and cost effective to support a wide range of educational services. This architecture provides the ability to deliver all of the services required of an enhanced learning environment, as well as the ability to collaborate with other schools, district headquarters, and entities beyond the district.

At the heart of the architecture is a robust routing and switching network. Operating on top of this network are all the services used within the school district, such as safety and security systems, voice communications, video surveillance, etc. The architecture has been designed around both school operations and technical considerations.

Architectural Design Considerations

This architecture utilizes key technologies that address the safety and security, connected real estate, and multi-service requirements of the modern educational network. The architecture is constructed in a manner that allows these technologies to work seamlessly together.

- High availability—The high availability technologies used in the Service Ready Architecture for Schools allow network equipment to eliminate the effects of any unplanned link or network failures by understanding the typology of the infrastructure and using that information to immediately

re-route network traffic without the need to re-learn (reconverge) the network. The use of this technology allows critical services such as voice and video communications to remain unaffected by network outages.

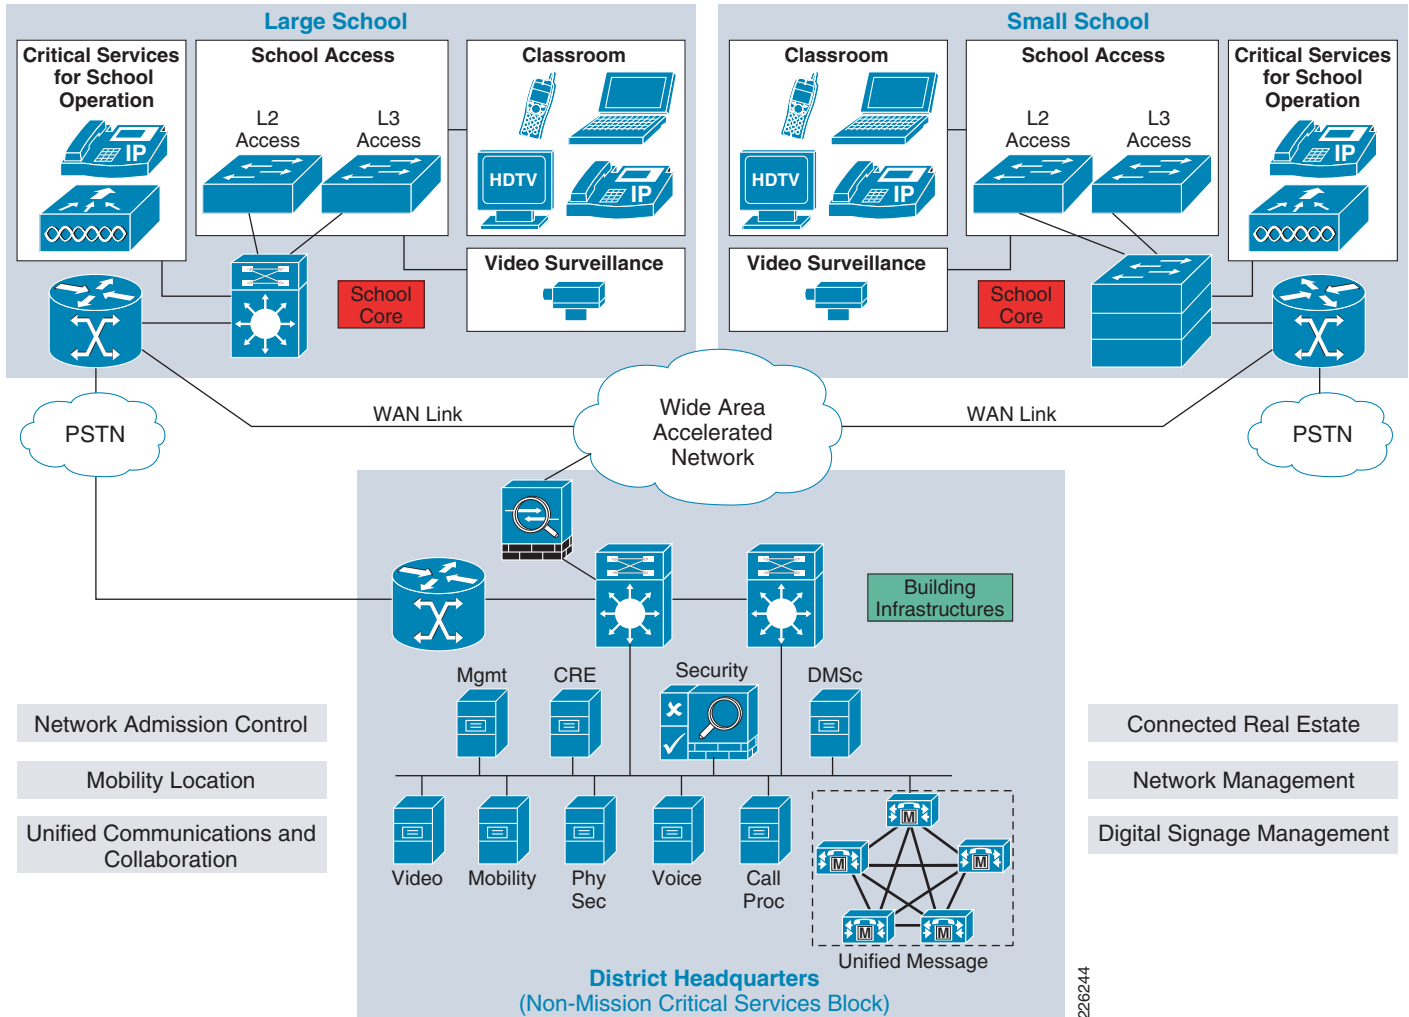

- **Single-fabric multi-service**—This technology gives the network administrator the ability to have many different services or networks share the same infrastructure, yet maintain logically separate networks. As multiple services operate over a single infrastructure, it becomes important to manage traffic based on the service being utilized. In the education environment this is particularly important as schools struggle with allowing student access to the same network used for grading systems, safety and security, and phone conversations.
- **Differentiated services**—Certain network services demand more from the network than others. For example, voice communications do not work if parts of the conversation drop out. Video conferencing is not useful if the picture keeps freezing. Additionally, a teacher's use of the network to enter grades should take precedence over a student surfing the Web. Finally, if there are more traffic demands than the network can handle, the network should be able to decide which traffic is most important. The ability to understand, mark, shape, and limit traffic is embedded into the Service Ready Architecture for Schools.
- **Access layer flexibility**—Employing a hybrid access layer design allows the network administrator to leverage an existing Layer 2 network while giving them the flexibility to implement a routed access layer. Moving the Layer 2/Layer 3 demarcation point to the access switch allows the network administrator to prevent loops without requiring multiple complex Layer 2 technologies, such as spanning tree protocol. Additionally, it provides high availability and eases network troubleshooting and management by leveraging well known Layer-3 troubleshooting tools and technologies.

It is challenging to design architectures for the education environment that include technical innovations and services needed to support the classroom of the future and also create a safe and secure learning environment.

Cisco is committed to making this next generation architecture a reality by providing proven, validated network designs to ease the deployment of these new services. With each design, a deployment model is adopted and guidance provided on how to deploy services and technical innovations that meet the business and technical requirements of the education environment.

Overall Design

An architectural model for the school network is shown in [Figure 2-1](#).

Figure 2-1 Service Ready Architecture for Schools

Cisco's Service Ready Architecture for Schools adopts a mission-critical services model in which services (safety and security, Unified Communications, and mobility) are deployed and managed at the district headquarters, allowing each school to reduce the need for separate services to be operated and maintained by school personnel.

Because many of the services are centrally located within the district office, rather than within each school itself, high network availability must be maintained. However the architecture also uses resilient application service features to maintain mission-critical services within the school in the event of a network failure.

This service model of the architecture allows school districts to maintain a good balance of controlling costs, pooling technical talent, and managing network services to offer a highly resilient, scalable, secure, and flexible network for the 21st century school.

Service Ready Architecture for Schools—Foundational Technologies

The Service Ready Architecture for Schools is the underlying service delivery framework from which all services and technologies flow for the school and district environments. This foundation must have simplified configurations and operations to ease the technical expertise required to support the environment, thus lowering the need for network experts. There is also a need for multiple core/distribution options to scale to the size, bandwidth, and requirements of the school's network to adapt to different size schools and school districts. The technology choices to scale this design and meet future needs include:

- **High availability**—The network must continue operations in the event of a network or service failure.
- **Redundancy**—All critical school services reside within the school to ensure they are not interrupted in the event of a wide area network outage, but the network should be flexible so as to allow non-critical services to be located in the district office to leverage economies of scale and lower total overall cost.
- **Quality of Service (QoS)**—The network must ensure proper prioritization of real-time traffic to enable a media rich network environment supporting voice, video, and data applications.

High Availability

The long-term capability of the network does not require constant hardware or software upgrades. New features and services can be added via in-service software upgrades. The network is highly available through redundancy and modularity and capable of providing an increased level of service not currently realized. Features are upgraded instantly and seamlessly over the network. Cisco can provide nonstop communications with resiliency and redundancy throughout all the layers of the network.

Many elements must be correctly designed and implemented to achieve such a high standard.

- **Network operations and configuration management:**
 - Management tools—Simplify provisioning, configuration management, troubleshooting
 - Management processes—Consistency of processes, minimize service times, etc.
- **Network design and software features:**
 - Redundancy—Paths, devices, servers, power, system components, locations, etc.
 - Resilience—Ability to function when the network is in a degraded state from an attack, misconfiguration, maintenance window, etc.
 - Prioritization and congestion management of traffic (QoS)
 - Security—Harden infrastructure, protect applications and data
- **Hardware and software reliability**—Servers, network devices, end-user systems
- **Circuit reliability**—WAN and LAN circuits
- **Data center and services edge**—Real-time data recovery and data archival capability

For more information, refer to the following URL:

http://www.cisco.com/en/US/docs/solutions/Enterprise/Campus/HA_campus_DG/hacampusdg.html.

Redundancy

- Path redundancy—End-to-end redundant paths are required (see [Figure 2-2](#)) to achieve maximum redundancy. However at the access layer redundant paths to client end systems are typically uncommon. Redundant connections are critical in the data center or services edge where the application servers are located.

Figure 2-2 Second Network Shows End-to-End Redundant Paths

Reliability = 99.938% with Four Hour MTTR (325 Minutes/Year)

Reliability = 99.961% with Four Hour MTTR (204 Minutes/Year)

Reliability = 99.9999% with Four Hour MTTR (30 Seconds/Year)

221673

- Device redundancy—Redundant devices are usually preferred over redundant components within a single device. While redundant components within a single device are valuable, the best availability is usually achieved with completely separate devices (and paths).
- Power redundancy—Power diversity is another area that must be addressed because redundant devices attached to a single power source are vulnerable to simultaneous failure. For example, redundant core switches should have at least two unique power sources. Otherwise, a single power failure brings down both core switches. Alternatively, backup power could be implemented. These types of mundane issues are very important when creating a highly-available system.
- Network design and software features—In a hierarchical network design, the core and distribution layers can re-converge in less than one second after most types of failures. The access layer typically has longer convergence times due to the inherent deficiencies of a flat Layer 2 architecture. Bridging loops, broadcast storms, and slow re-convergence are examples of access layer problems that reduce end-to-end availability. Spanning Tree typically takes up to one minute to recover from a link or system outage, which is far too long to support real-time mission critical applications or provide 99.999 percent availability. There are several design changes and software features that can be implemented to improve availability in the access layer.
- Access-layer design improvements—Currently, there are three different ways to design the access-layer control plane. Although all three of them use the same physical layout, they differ in performance and availability:
 - Traditional multi-tier access layer

This is the traditional design where all access switches run in Layer 2, while distribution switches run in Layer 2 mode when facing the access layer and in Layer 3 mode when facing the core. Cross-connects between distribution switches are usually Layer 2 links. When not optimized, this model is dependent on spanning tree, with all its inherent limitations, to detect and recover from network failures. As mentioned, load balancing of redundant uplinks is not possible because spanning tree usually blocks one uplink. HSRP, VRRP, or GLBP must be used to provide First Hop Routing Protocol redundancy.

While noting the deficiencies of the traditional multi-tier approach, design changes and feature enhancements are available to greatly enhance availability and performance.

The current multi-tier best practice is to create unique VLANs on each access switch as shown in Figure 2-3.

The best practice design offers several benefits. First, a loop-free topology is created. This means spanning tree does not impact re-convergence times. Traffic is load balanced across two active uplinks, achieving maximum throughput and minimum failover times. This loop-free topology also reduces the risk of broadcast storms and unicast flooding.

Figure 2-3 Best Practice Multi-Tier Has Unique VLANs on Each Access Switch

One disadvantage of the best-practice multi-tier design is the requirement to redesign the VLAN and IP addressing scheme—unique IP subnet(s)/VLAN(s) per switch. This can be a significant challenge in large, mature networks. The routed access model discussed below has this same drawback.

- Routed access layer

This design improvement, as the name implies, pushes routing into the access layer switches and creates an end-to-end routed infrastructure. Several important benefits are gained:

- Spanning tree issues are virtually eliminated.
- Re-convergence times for the end-to-end network can be reduced to one second or less.
- Re-convergence times become more predictable with the elimination of spanning-tree.
- Redundant uplinks can be fully utilized.
- HSRP/VRRP is no longer needed to provide host redundancy. This simplifies configuration, management, and troubleshooting.
- Troubleshooting is accomplished using well-known Layer 3 tools, such as Traceroute, Ping, etc.
- Network layout, naming, and VLAN numbering can be standardized across schools.

A drawback to the routed access model is the requirement to have separate IP subnets and VLANs on every access switch. This is in contrast to the traditional multi-tier model where a user VLAN can span several switches. However the convergence times of the routed access layer are much less than that of the flat Layer-2 network.

For more information, refer to the following URL:

<http://www.cisco.com/en/US/docs/solutions/Enterprise/Campus/routed-ex.html>.

- Virtual switch technology

This is a new service enabled by Cisco's Virtual Switching Systems (VSS) technology on the 6500 series and stackwise technology on the 3700 series switches. These features allow two or more distribution switches to be combined into a single virtual switch from a management and data forwarding perspective. Figure 2-4 highlights this technology.

Figure 2-4 Cisco's Virtual Switching Systems

VSS provides several compelling benefits over the traditional multi-tier design and the routed access design:

- Each access switch with redundant uplinks to two distribution switches now appears to be connected to a single switch via a two-port Etherchannel.
- Both links are now forwarding as spanning tree loops have been removed.
- Link failover times are below one second, consistent with Etherchannel capabilities.
- HSRP/VRRP are no longer needed to provide default gateway functionality.
- Unlike the multi-tier or routed access designs, there is no requirement for per-switch VLANs and IP subnets. This is a significant advantage and means the benefits of VSS technology can be gained without a major network reconfiguration.

Quality-of-Service (QoS)

There is some debate in the networking industry about the need to deploy QoS in enterprise architectures because of the ample amounts of bandwidth that make congestion rare. However, during network attacks or a partial outage, this situation can change dramatically. It has been shown that QoS can serve as a vital tool to maintain the performance of priority applications and traffic during a degraded network condition. Reasons why QoS is important in the campus portion of the network include:

- The introduction of 10Gbps (and higher) link speeds is creating greater mismatches between high-speed and low-speed links in the campus. This increases the need to buffer and prioritize traffic.

- Well-known applications ports, like HTTP, are being used by a large number of applications. There is a need to distinguish between high-priority and low-priority traffic using the same port numbers to ensure priority traffic is transmitted.
- Prioritized traffic, such as voice and video, must continue to flow even during a network attack or during a partial failure in the network. Attack traffic often masquerades as legitimate traffic using well-known port numbers. There is a need to distinguish between legitimate and bogus traffic by inspecting data packets more deeply.

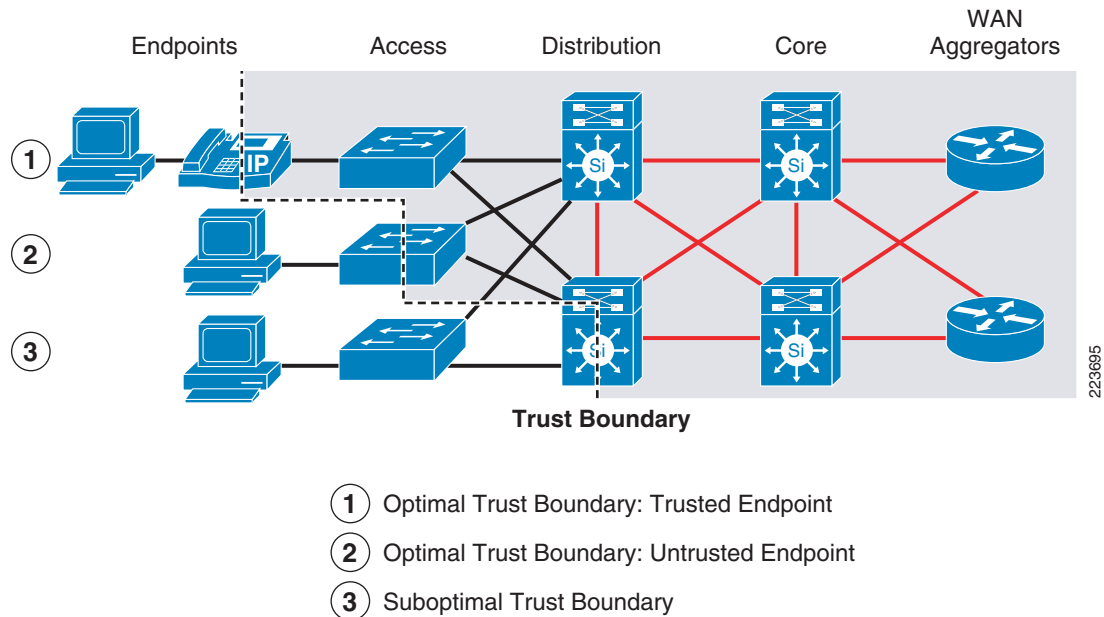

QoS Deployment Guidelines

The following principles should guide QoS deployments:

- Classify and mark traffic as close to the network edge as possible. This is called creating a trust boundary. Traffic crossing the trust boundary is considered trusted and the QoS markings are adhered to in the rest of the network.
- Police/rate-limit traffic as close to the source as possible. It is most efficient to drop unwanted traffic as close to the source as possible, rather than transmitting it further into the network before dropping it.
- Perform QoS functions in hardware rather than software. Software-based QoS functions can easily overwhelm the CPUs of networking devices. High-speed networks require hardware-based QoS functions.

Figure 2-5 summarizes key QoS functions and where they should be performed.

Figure 2-5 QoS Functions

For more information, refer to the following:

http://www.cisco.com/en/US/docs/solutions/Enterprise/WAN_and_MAN/QoS_SRND/QoS-SRND-Book.html

Service Ready Architecture for Schools—Key Services

The adoption of IP technology has led to a change in the learning environment. No longer are networks used solely to provide data communication between computers. IP technology has extended beyond the data network and is now used extensively for voice and video communication as well. Services that are a part of the Service Ready Architecture for Schools are shown in [Figure 2-6](#).

Figure 2-6 Services in the Service Ready Architecture for Schools

Each of these services overlay the IP network and foundational technologies described earlier. While the services shown in [Figure 2-6](#) are just a sample of the myriad of services available, they can be summarized into five key services:

- [Unified Communications](#)
- [Digital Media Systems](#)
- [Mobility](#)
- [Security](#)

Unified Communications

Cisco Unified Communications provide many solutions for schools that wish to take advantage of media-rich unified communications functionality. Each aspect of the total unified communications architecture provides opportunities for enhancing links within the education community. Functionality includes IP telephony, unified client software, presence, instant messaging, unified messaging, rich-media conferencing, mobility solutions, and application development.

- **IP telephony**—At the foundation of the Cisco Unified Communications solution is its proven, industry-leading call processing system, Cisco Unified Communications Manager. This highly available, enterprise-class system delivers call processing, video, mobility, and presence services to IP phones, media processing devices, VoIP gateways, mobile devices, and multimedia applications. The system can scale to one million users across 1000 sites or more or 60,000 users within a single

clustered system. Built-in redundancy keeps service reliable. Cisco also offers several unified communications platforms for small districts. All of these standards-based systems work with an array of third-party phones and dual-mode devices. The systems also provide integration with existing desktop applications such as calendar solutions, E-mail, enterprise resource planning (ERP) systems, and customer relationship management (CRM) software. Cisco unified communications capabilities can also be extended to a variety of mobile phones, including those that run Symbian, Blackberry, and Windows Mobile operating systems.

- **Unified client software**—Cisco offers several rich-media client applications that improve productivity and simplify processes. Available on Microsoft Windows and Mac OS environments, as well as mobile operating systems, these clients support a range of applications, including voice, presence and messaging, unified messaging, video, and conferencing. Communications functionality has also been unified with applications from industry partners. For example, call control and presence can be launched and managed from within Microsoft Outlook through a Cisco Unified Personal Communicator widget or toolbar.
- **Presence and instant messaging**—Cisco presence solutions based on Session Initiation Protocol (SIP) or (SIMPLE) provide SIP presence and proxy services to deliver IM and click-to-call features. Through the presentation of dynamic presence information, presence solutions allow users to check the availability of colleagues in real time, reducing phone tag and improving productivity. Cisco presence and instant messaging solutions work in conjunction with Cisco Unified Communications Manager and support Cisco Unified Personal Communicator, Cisco IP phones, Cisco IP Phone Messenger, IBM Sametime clients, and Microsoft clients.
- **Unified messaging**—Cisco unified messaging solutions easily integrate with existing environments and provide flexible deployment options to meet each organization's individual needs. The broad range of easy-to-manage solutions includes products tailored for small, medium-sized, and very large organizations, with feature-rich functionality aligned intelligently with business requirements.
- **Rich-media conferencing**—Cisco conferencing solutions help remote workers and teams communicate more effectively to save time and reduce costs. Integrated voice, video, and Web conferences can be set up and attended in a single step from IP phones, instant messaging clients, Web browsers, and Microsoft Outlook and IBM Lotus Notes calendars.
- **Mobility solutions**—Cisco Unified Communications extends rich call control and collaboration services to facilitate easy collaboration among mobile workers on campus or on the move. By anchoring communications in the network, Cisco Mobile Unified Communications solutions connect different mobile worker types and workspaces, provide a consistent collaboration experience regardless of location, maintain business continuity and compliance, and take advantage of least-cost routing of mobile communications over the education network. Cisco Mobile Unified Communications solutions support a wide range of popular handheld platforms, enabling workers to communicate quickly and easily using their familiar mobile equipment.
- **Application development**—Schools may operate in unique educational environments that require specialized applications. To meet these needs, Cisco provides a versatile service creation platform, enabling schools and partners to rapidly and easily develop and deliver innovative, media-rich and Web-rich applications. The platform also allows organizations to easily blend unified communications capabilities with existing business process systems.

For more information, refer to the following URL:

http://www.cisco.com/en/US/netsol/ns818/networking_solutions_program_home.html

IP Video Surveillance

Video surveillance systems have proven their value in a wide range of applications. In educational environments, video documentation of critical incidents enhances student safety and better protects valuable assets. However, traditional analog CCTV surveillance systems have many limitations—they are unable to store recorded video in local and remote locations or provide video access to mobile or

remote users. Having recognized the cost savings, productivity improvements, and enhanced communications provided by IP networks, many administrators would like to apply these technology benefits to video surveillance systems.

Network-centric video surveillance components include:

- Cisco Video Surveillance Manager enables education administrators and security personnel to view, manage, and record video locally and remotely using the IP network and a standard Internet browser. Video can be securely accessed anywhere, at any time, enabling faster response, investigation, and resolution of incidents. Video can be recorded and stored locally and off-campus, allowing it to be managed and aggregated with video from multiple locations. VSM interoperates with a wide range of third-party vendor devices and applications such as video analytics, providing a solution that is cost-effective to deploy, fits budgets, and enables new capabilities. As a result, student safety can be enhanced and valuable assets can be better protected through the video documentation of critical incidents.
- Cisco Video Surveillance Media Server—Media Server is a highly scalable and reliable video management platform that manages, replicates, distributes, and archives video streams.
- Cisco Video Surveillance Operations Manager—This Web-based user interface authenticates and manages access to video feeds. It is a centralized administration tool for the management of Media Server hosts, Virtual Matrix hosts, cameras, encoders, and viewers.
- Cisco Video Surveillance Media Virtual Matrix—Virtual Matrix monitors video feeds in command center and other 24-hour monitoring environments. It allows operators to control the video being displayed on multiple local and remote digital monitors.

For more information, refer to the following URL:

http://www.cisco.com/en/US/netsol/ns929/networking_solutions_sub_program_home.html.

Digital Media Systems

The Cisco Digital Media System is a comprehensive suite of digital signage, desktop video, and enterprise TV applications that you can manage centrally:

- Cisco digital signage provides scalable centralized management and publishing of compelling digital media to networked, on-premise digital signage displays. It enables the dissemination of district news and emergency Information to large screens connected to the school's existing network. You can deliver the same content to all signs in the district, such as reminders of testing dates, or deliver different content to different schools. Within the same school, you might display the cafeteria menu on one digital sign and information about an upcoming bond election on signs where parents pick up their children.
- Cisco desktop video gives students access to high-quality and compelling videos on demand (VoDs) and live Webcasts at their desktops. Digital Media can be browsed, searched, and viewed over the network through a unique, easy-to-use Cisco video portal experience—anywhere, anytime.
- Cisco enterprise TV is an interactive application that enables schools to deliver on-demand video and broadcast live TV channels over an IP network to digital displays. On-screen menus and program guides give users access to enterprise TV content and organizations can customize lineups and create their own content libraries. Users can navigate through channel menus and select from on-demand content with a remote control or other remote devices.

Components of Cisco's digital media system include:

- Cisco Digital Media Manager is the central management application for all Cisco Digital Media System products. It is used to manage, schedule, and publish compelling digital media for digital signage, enterprise TV, and desktop video. As an integrated part of the Cisco Digital Media System, this Web-based media management application enables content owners to easily upload, catalogue, edit, package, and publish digital media content for live or on-demand playback.
- Cisco Video Portal allows users to easily browse, search, and view digital media interactively on the desktop. It provides secure login, customizable playlists, search, advanced player controls, full-screen playback, slide synchronization, viewer questions support, and a secure usage-reporting tool. It supports established video formats such as Windows Media, Flash, and MPEG/H.264.
- Cisco Digital Media Players are highly reliable, IP-based hardware endpoints that enable digital signage and Enterprise TV through the ability to play high-definition live and on-demand video, motion graphics, Web, and dynamic content on digital displays. The Digital Media Player hardware options include support for standard-definition and high-definition MPEG-2 and MPEG-4/H.264, Flash, RSS, and other Web formats and dynamic data.
- Cisco LCD Professional Series Displays are an integral part of the Digital Media System (DMS) suite of products and are used to display information. Cisco LCD displays are available in different sizes and models and offer full 1080p resolution.

For more information, refer to the following URL:

http://www.cisco.com/en/US/netsol/ns928/networking_solutions_sub_program_home.html

Mobility

Cisco Mobility and Wireless Solutions for Schools give students and staff the freedom to be anywhere on campus and still perform all the tasks they would normally do on a classroom's wired network. The solutions enable new network connections to PCs, laptops, PDAs, printers, video cameras, videoconferencing units, IP phones, and other devices, making school resources more widely available and improving collaboration among students, teachers, parents, and administrators. Mobility products include:

- Cisco Aironet Access Points connect Wi-Fi devices to networks in a variety of wireless environments. Cisco next generation wireless solutions use 802.11n technology to deliver unprecedented reliability and up to nine times the throughput of 802.11a/b/g networks. Wi-Fi certified for interoperability with a variety of client devices, these access points support robust connectivity for both indoor and outdoor environments.
- Wireless LAN controllers simplify the deployment and operation of wireless networks, helping to ensure smooth performance, enhanced security, and maximum network availability. Cisco wireless LAN controllers communicate with Cisco Aironet access points over any Layer 2 or Layer 3 infrastructure to support system-wide wireless LAN (WLAN) functions, such as:
 - Enhanced security with WLAN policy monitoring and intrusion detection
 - Intelligent radio frequency (RF) management
 - Centralized management
 - QoS
 - Mobility services such as guest access, voice over Wi-Fi, and location services

Cisco wireless LAN controllers support 802.11a/b/g and the IEEE 802.11n draft 2.0 standard, so you can deploy the solution that meets your individual school requirements. From voice and data services to location tracking, Cisco wireless LAN controller products provide the control, scalability, security, and reliability you need to build highly secure, district-wide wireless networks.

Cisco Wireless Location Appliance allows school districts to simultaneously track thousands of devices from within the WLAN infrastructure, bringing the power of a cost-effective, high-resolution location solution to critical applications such as:

- High-value asset tracking
- IT management
- Location-based security

This easy-to-deploy solution smoothly integrates with Cisco WLAN controllers and Cisco lightweight access points to track the physical location of wireless devices to within a few meters. This appliance also records historical location information that can be used for location trending, rapid problem resolution, and RF capacity management.

- Cisco Mobility Services Engine is a solution that creates an open platform for the development and optimization of mobile applications. Designed with extensibility in mind, the platform supports a suite of software that is designed to create and optimize the performance of mobility applications by offering a standardized, open method for bridging network and application intelligence. The Mobility Services Engine allows schools to simplify the deployment of mobility applications across the district and introduces a structured way for partners to develop industry-specific mobility applications.

For more information, refer to the following URL:

http://www.cisco.com/en/US/netsol/ns820/networking_solutions_program_home.html

Security

Cisco security solutions combine multiple security technologies along with embedded security in Cisco routing and switching platforms to protect school network infrastructures. Some of these technologies include:

- Firewall solutions for network security
- A reliable firewall is the hallmark of a secure network. Networks support sensitive, crucial applications and processes and provide a common infrastructure for converged data, voice, and video services; firewall security is a primary concern. Instead of providing only point products that set a base level of security, Cisco embeds firewall security throughout the network and integrates security services in all of its products. Firewall security becomes a transparent, scalable, and manageable aspect of the business infrastructure.
- Cisco NAC Appliance is an easily deployed Network Admission Control (NAC) product that uses the network infrastructure to enforce security policy compliance on all devices seeking to access network computing resources. With NAC Appliance, network administrators can authenticate, authorize, evaluate, and remediate wired, wireless, and remote users and their machines prior to network access. It identifies whether networked devices such as laptops, IP phones, or game consoles are compliant with your network's security policies and repairs any vulnerabilities before permitting access to the network.
- Cisco Secure ACS is a highly scalable, high-performance access policy system that centralizes authentication, user access, and administrator access policy and reduces the administrative and management burden. Cisco Secure ACS is a central point for administering security policy for users and devices accessing the network. Cisco Secure ACS supports multiple and concurrent access scenarios including:
- Device administration—Cisco Secure ACS authenticates network administrators, authorizes commands, and provides an audit trail.

- Remote access—Cisco Secure ACS works with VPN and other remote network access devices to enforce access policies.
- Wireless—Cisco Secure ACS authenticates and authorizes wireless users and hosts and enforces wireless-specific policies.
- 802.1x LAN—Cisco Secure ACS supports dynamic provisioning of VLANs and access control lists (ACLs) on a per user basis and 802.1x with port-based security.
- Network admission control—Cisco Secure ACS communicates with posture and audit servers to enforce admission control policies.

For more information, refer to the following URL:

http://www.cisco.com/en/US/netsol/ns744/networking_solutions_program_home.html

Conclusion

The Cisco Service Ready Architecture for Schools is a network roadmap for school districts to utilize to enable 21st century education for students and teachers. It is built by combining an understanding of the current and future school district network needs with the best technology available, while considering the technical and financial constraints faced by school districts.

To learn more about the Cisco Service Ready Architecture for Schools, refer to the following URL:

<http://www.cisco.com/go/education>

CHAPTER 3

Network Foundation Design

This chapter describes the Schools Service Ready Architecture network design, which is a well designed and tested network architecture that is flexible, and cost effective to support a wide range of educational services. Key features of the Schools SRA include:

- High Availability
- Single Fabric—Multi Services
- Differentiated Services
- Layer 2 and Layer 3 Access

This chapter provides design guidance to build a highly resilient, manageable and cost-effective school network which provides a solid in foundation for seamless integration and operation of applications and network services. The network has been specifically designed to meet the challenges of the education environment.

Building Unified Schools Network Infrastructure

Cisco has years of experience developing high performance, highly available, multi service networks. The key to developing a robust design is applying a proven methodology. The following design principles were applied to develop the School SRA network architecture:

- Hierarchy
 - Clarifies the role of each device in each tier
 - Simpler to deploy, operate, and manage the network
 - Reduces fault domains at every tier
- Modularity
 - Enables growing the network on demand basis
- Resiliency
 - Meet users expectation of network always being available.
- Flexibility
 - Allows intelligent traffic load-sharing by using all network resources

The Unified Schools network is designed to be highly available, and cost effective, while delivering capabilities necessary to enable advanced services, such as IP telephony, video, security, wireless LANs. The network design includes the following key features;

- Hierarchical design with collapsed Core
- Quality-of-service (QoS) to ensure real-time data (telephony, video) are given higher priority
- Application of resilient design principles
- Multi cast
- Routed access
- Redundancy

Hierarchical Network Design

The three-tier hierarchical model (see [Figure 3-1](#)) is the approach typically employed to achieve a high performance, highly available, scalable network design. This design employs the four key design principles of hierarchy, modularity, resiliency and flexibility.

Figure 3-1 *Three-Tier Hierarchical Model*

Each layer in the three-tier hierarchical model has a unique role to perform:

- *Access Layer*—The primary function of an access-layer is to provide network access to the end user. This layer often performs OSI Layer-2 bridge function that interconnects logical Layer-2 broadcast domains and provides isolation to groups of users, applications, and other endpoints. The access-layer interconnects to the distribution layer.
- *Distribution Layer*—Multi-purpose system that interfaces between access layer and core layer. Some of the key function for a distribution layer include the following:
 - Aggregate and terminate Layer-2 broadcast domains
 - Provide intelligent switching, routing, and network access policy function to access the rest of the network.
 - Redundant distribution layer switches provides high availability to the end-user and equal-cost paths to the core. It can provide differentiated services to various class-of-service applications at the edge of network.

- *Core Layer*—The core-layer provides high-speed, scalable, reliable and low-latency connectivity. The core layer aggregates several distribution switches that may be in different buildings. Backbone core routers are a central hub-point that provides transit function to access the internal and external network.

Table 3-1 lists the key functions of each layer.

Table 3-1 Key Functions of Hierarchical Network Layer Devices

Key Function	Access	Distribution	Core
Network Transit	Rest of the network.	Internal and External network	
Intelligent Services	PoE, IEEE 802.1AD, Mobility, AutoQoS, Auto-SmartPort Macro(ASP)	Route optimization Network and System Virtualization Layer-2 Interconnect	
Forwarding Decision	Layer 2/Layer 3		Layer 3
Security Services	CISF, 802.1x, NAC, ACL etc.	CISF, ACL, Route Filter, CoPP etc.	ACL, Route Filter, CoPP etc.
QoS Services	Classification, Marking, Policer and Queueing	Classification, Marking, and Queueing	

To learn more about typical network designs, refer to the following URL:

<http://www.cisco.com/en/US/docs/solutions/Enterprise/Campus/campover.html>

Figure 3-2 illustrates a sample network diagram for a multi-building large school design.

Figure 3-2 Multi Building Large School Network Design

Collapsed Core Network Design

The three-tier hierarchical design maximizes performance, network availability, and the ability to scale the network design. Most school campus' do not grow significantly larger over time, and most school campus' are small enough to be well served by a two-tier hierarchical design, where the core and distribution layers are collapsed into one layer. The primary motivation for the collapsed core design is reducing network cost, while maintaining most of the benefits of the three-tier hierarchical model.

Deploying a collapsed core network results in the distribution layer and core layer functions being implemented in a single device. The collapsed core/distribution device must provide the following:

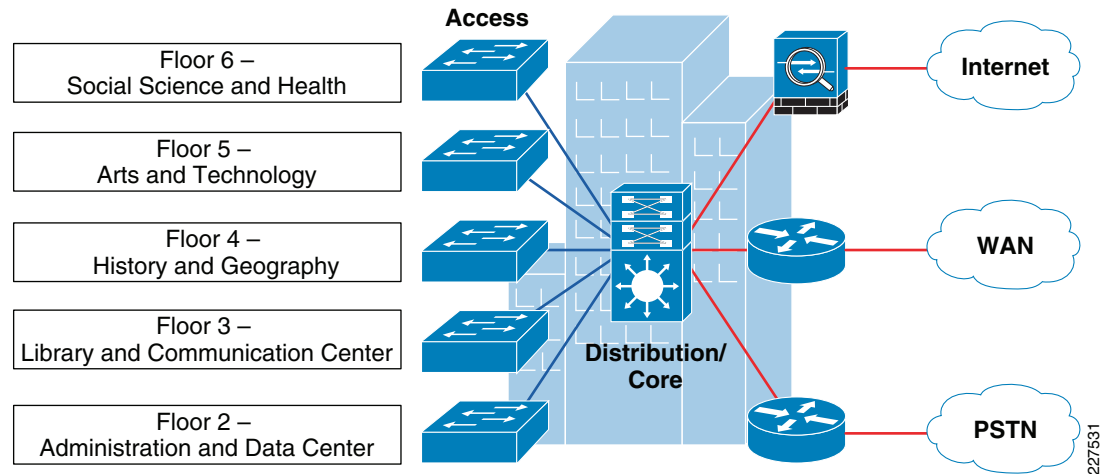

- High speed physical and logical paths connecting to the network
- Layer-2 aggregation and demarcation point
- Define routing and network access policies
- Intelligent network services—QoS, Network virtualization, etc.

Note

If the district office or a school campus has multiple buildings, and is expected to grow over time, then implementing the three-tier hierarchical model is a better choice.

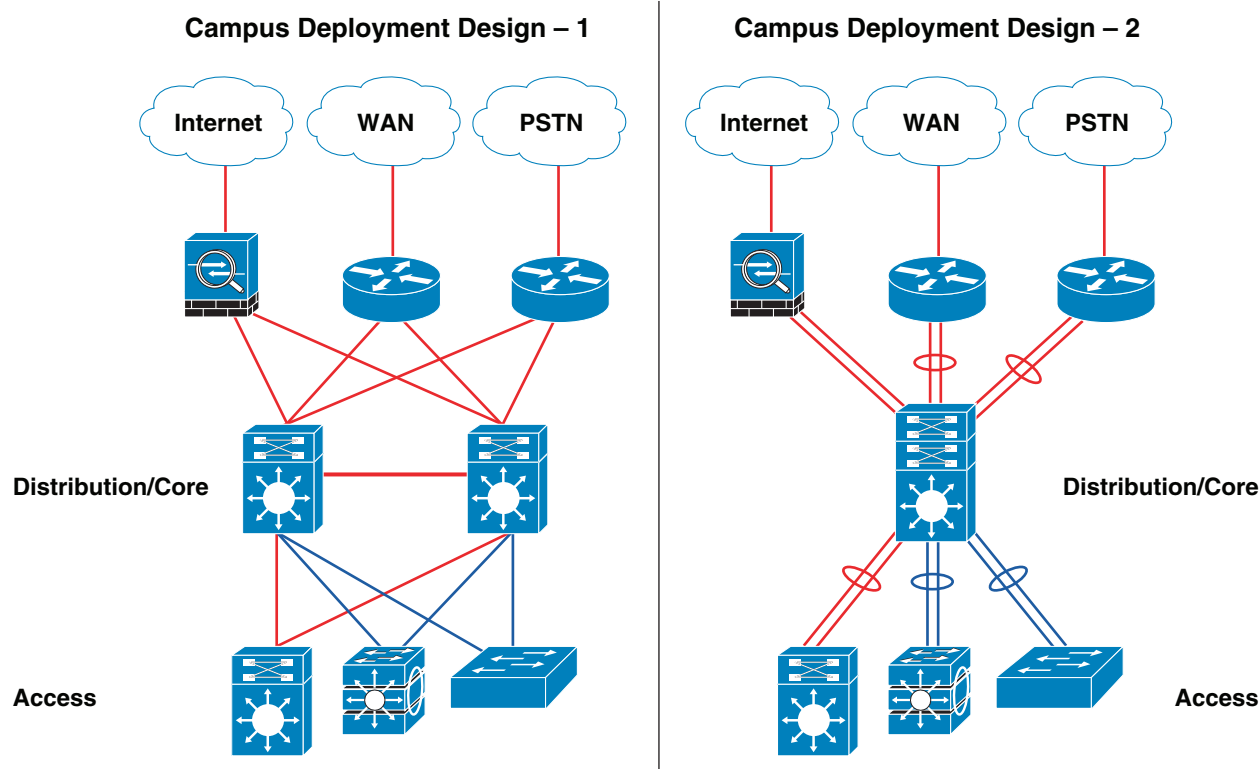

Figure 3-3 illustrates a sample network diagram for a single building school district office.

Figure 3-3 *Collapsed Core School District Office Network Design*

District Office Network Design

If the district office has multiple buildings or the district office site is expected to grow significantly over time, then implementing the three-tier hierarchical model is a good choice. For smaller district office sites that are unlikely to grow significantly, the collapsed core model is more cost effective. The School Service Ready Architecture uses the collapsed core network design in the district office.

The collapsed core network (see [Figure 3-4](#)) may be deployed with redundant core/distribution router, or consolidated core/distribution router.

Figure 3-4 Collapsed Core District Office School Network Models

227532

The redundant design is more complex, because all of the core/distribution functions must be implemented on two routers in a complimentary fashion. To learn more about the redundant designs, refer to *High Availability School Recovery Analysis Design Guide* at the following URL:

http://www.cisco.com/en/US/docs/solutions/Enterprise/Campus/HA_recovery_DG/campusRecovery.html

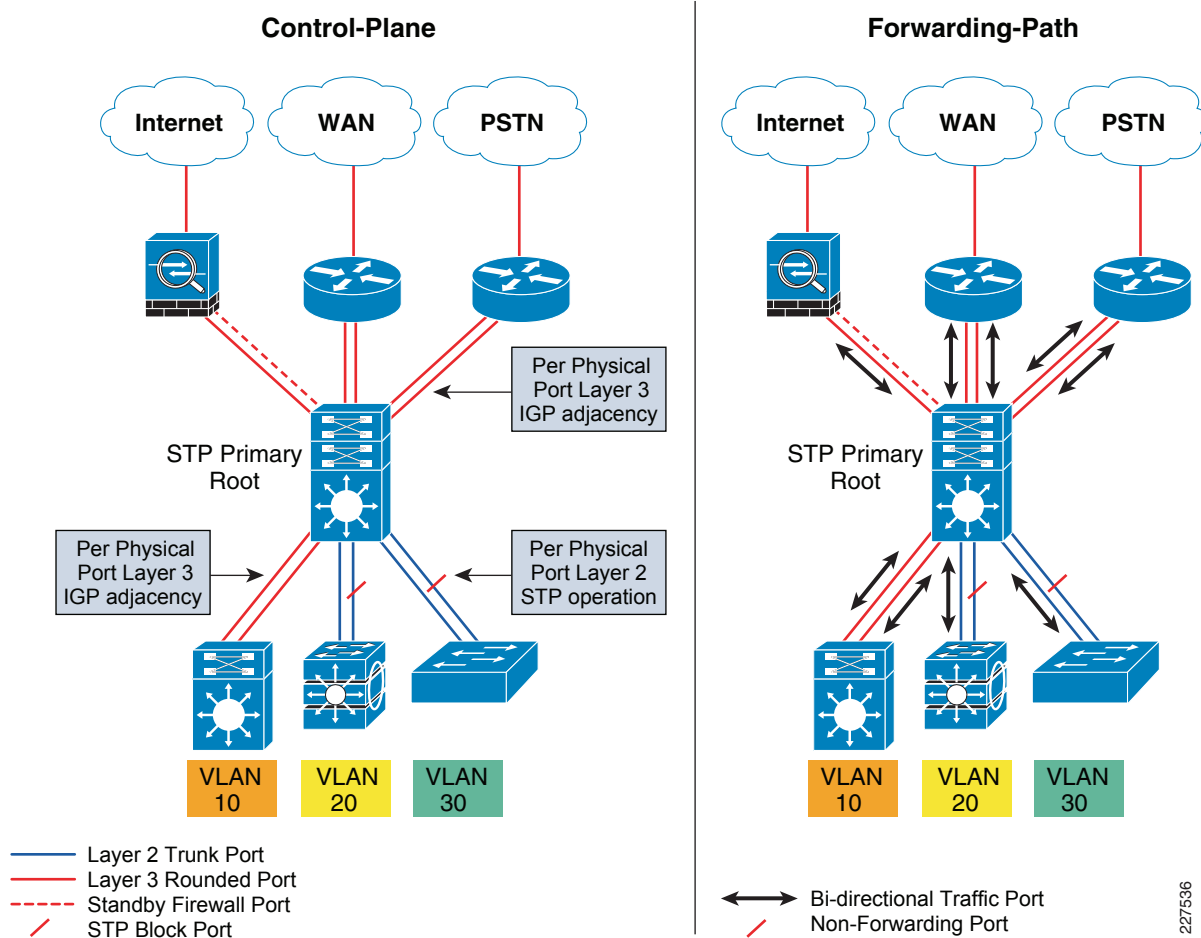

The School SRA district office is designed with a consolidated core/distribution router to maximize performance, while keeping costs affordable (design 2). The consolidated collapsed core model has the following benefits:

- Simplifies network protocols (eases network operations)
- Enables symmetric forwarding paths
- Delivers deterministic network recovery performance

With this design, the default behavior of Layer-2 and Layer-3 network control protocols is to create a redundant view between two systems. The core router builds a ECMP routing topology which results in symmetric forwarding paths beyond the district office.

Default Layer-2 configuration eliminates the need for FHRP, automatically eliminating the asymmetric forwarding behavior which causes unicast flooding in the network. This simplifies the network operation, since there is no need to configure or tune FHRP protocols.

The disadvantage of this Layer-2 network design is that the network is under-utilized. This is due to the way Layer-2 protocols are designed to build loop-free network topologies. When two Layer-2 bridges are directly connected, the STP protocol will block low-priority STP physical port in the forwarding table. [Figure 3-5](#) illustrates the control-plane, and the forwarding-plane for this design.

Figure 3-5 Design Model 2 – Developing Control and Forwarding Paths

This design suffers from two challenges:

- Multiple routing adjacencies between two Layer-3 systems. This configuration doubles the control-plane load between each of the Layer-3 devices. It also uses more system resources like CPU and memory to store redundant dynamic-routing information with different Layer-3 next-hop addresses connected to same router.
- As depicted in [Figure 3-5](#), STP protocol blocks one of the physical ports in the Layer-2 network. Since this design employs point-to-point links between the collapsed core and peer devices, the solution is to tune the network to enable a single control plane, to improve forwarding efficiency and resource utilization. The recommendation is to aggregate all physical ports into a single logical channel-group. This logical aggregated Ethernet bundle interface is known as *EtherChannel*.

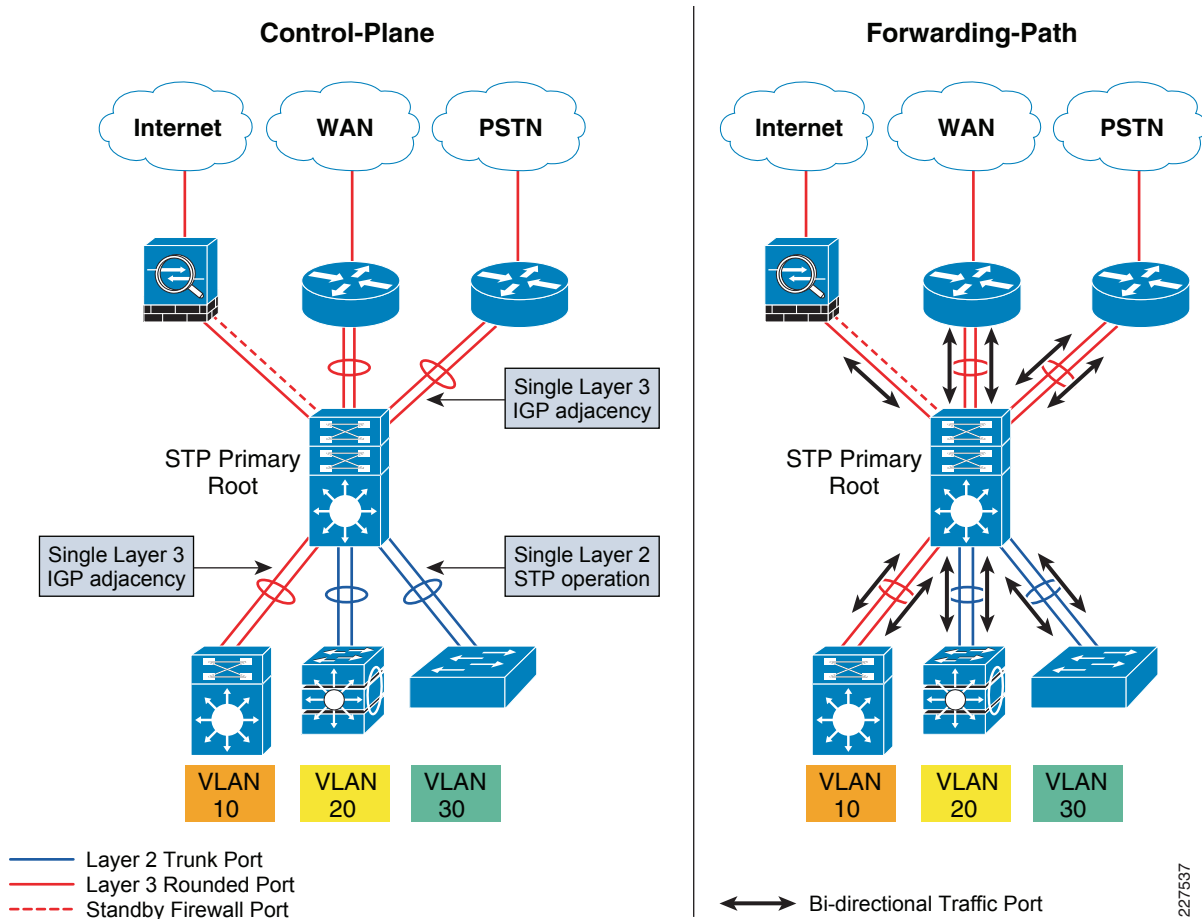

EtherChannel Fundamentals

EtherChannel provides inverse-multiplexing of multiple ports into a single logical port to a single neighbor. This technique increases bandwidth, link efficiency, and resiliency. EtherChannel technology operates on the MAC layer. Upper layer protocols require a single instance to operate over the logical interface. EtherChannel provides efficient network operation and graceful recovery to higher layer protocols during bundle port failure and restoration.

The control-plane depicted in Figure 3-5 builds redundant Layer-2 or Layer-3 network information over each physical links. Each device builds common network prefix entries with a different next-hop path pointing to same next hop device. Implementing EtherChannel results in a network topology with a single destination entry for single next-hops, via the egress logical EtherChannel port. EtherChannel reduces storing redundant network entries in the database and forwarding tables, which automatically improves network convergence times and system resources utilization.

EtherChannel helps improve the overall network stability and availability. Failure of individual physical link will cause network topology recomputation, restoration, and may be rerouted. Such process requires CPU interruption that could impact the overall application performance. EtherChannel significantly simplifies the network response to a individual link failure. If an individual link in EtherChannel fails, the interface will not trigger any network topology changes. All underlying hardware changes remain transparent to higher-layer protocols, thus minimizing impact to network and application performance, and improving network convergence. Figure 3-6 illustrates how enabling EtherChannel in Layer-2 and Layer-3 network simplifies control-plane and forwarding-plane.

Figure 3-6 Design Model 2 – Optimized Control and Forwarding Paths with EtherChannel

Resilient Distributed System

The consolidated core/distribution layer may become a single-point-of-failure (SPOF) in the network. A software upgrade or a route-processor failure may cause network outage for minutes.

The school SRA uses the Cisco Catalyst 4500 with next-generation Supervisor-6E in the consolidated core/distribution layer. It is chosen for its price performance, and the high availability features within the device. The Cisco Catalyst 4500 switch supports redundant supervisor engines and provides Stateful Switchover (SSO) and Non-Stop Forwarding (NSF) capabilities. SSO ensures the Layer-2 and Layer-3 protocol state-machines and network forwarding entries on the standby supervisor engine are maintained, and can quickly assume control-plane responsibilities and gracefully restore the control-plane in the event of a primary supervisor failure. While the control-plane is gracefully recovering, the NSF function continues to switch traffic in hardware.

The Cisco Catalyst 6500 platform is an enterprise-class system providing integrated network services for large scale and high-speed networks. For large, multi building sites, or in situations where future scalability is important, the Catalyst 6500 is a better choice for core/distribution layer switch. The design principles remain the same when deploying a Catalyst 6500.

District Office Access-Layer Edge Services

The access layer is the first tier or edge of the network. It is the layer where end-devices (PCs, printers, cameras, etc.) attach to the school network. It is also the layer where devices that extend the network out one more level are attached; IP phones and wireless access points (APs) are examples of devices that extend the connectivity out from the access switch. The wide variety of devices that can connect and the various services and dynamic configuration mechanisms required, make the access layer the most feature-rich layer of the school network. [Figure 3-7](#) illustrates a district office network deployment with various types of trusted and untrusted endpoints.

Figure 3-7 Access-Layer Trust Boundary and Network Control Services

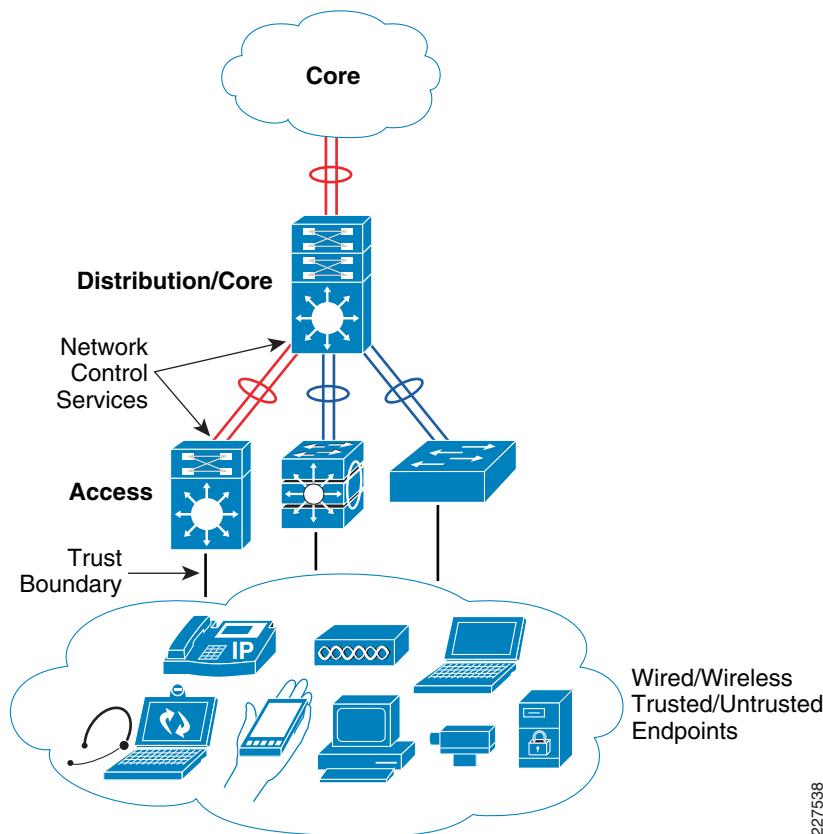

Table 3-2 examples of the types of services and capabilities that need to be defined and supported in the access layer of the network.

Table 3-2 Access-layer Services and Capabilities

Service Requirements	Service Features
Discovery and Configuration Services	802.1AF, CDP, LLDP, LLDP-MED
Integrated Security Services	IBNS (802.1X), CISF – Port-Security, DHCP Snooping, DAI and IPSG
Network Identity and Access	802.1X, MAB, Web-Auth
Application Recognition Services	QoS marking, policing, queueing, deep packet inspection NBAR
Intelligent Network Control Services	PVST+, Rapid PVST+, EIGRP, OSPF, DTP, PAgP/LACP, UDLD, FlexLink, Portfast, UplinkFast, BackboneFast, LoopGuard, BPDUGuard, Port Security, RootGuard
Energy Efficient Services	Power over Ethernet, EnergyWise, Energy efficient systems
Management Services	Auto-SmartPort Macro, Cisco Network Assistant

The access layer provides the intelligent demarcation between the network infrastructure and the computing devices that use the infrastructure. It provides network edge security, QoS, and policy trust boundary. It is the first point of negotiation between the network infrastructure and the end devices seeking access to the network.

A flexible network design, and the demand for mobility are two requirements which drive the access layer design. A flexible network design allows any legitimate device to be connected anywhere in the network (eg IP Phone, printer, video surveillance camera, digital signage, etc). Network users expect to be able to move around their devices (laptops, PDAs, printers, etc) and gain network access wherever necessary.

In order to allow devices to be moved within the school and ensure they associate with the correct network policies and services; the following access services are integrated into the school architecture:

- Ability to physically attach to the network and be associated with or negotiate the correct Layer-1 and Layer-2 network services—PoE, link speed and duplex, subnet (VLAN or SSID)
- Ability to provide device identification and, where needed, perform network access authentication
- Ability for the network to apply the desired QoS policies for the specific user, device or traffic flow (such as RTP streams)
- Ability for the network to apply the desired security policies for the specific user or device
- Ability for the network and device to determine and then register the location of the attaching device
- Ability for the device to negotiate and register the correct end station parameters (such as DHCP), as well as register for any other necessary network services (such as register for Unified Communications presence and call agent services)

The basic steps for deploying edge access switch features are as follows:

-
- Step 1** Configure the baseline switching foundation
 - Step 2** Protect the network infrastructure
 - Step 3** Protect the end devices and their application data flows
 - Step 4** Apply the necessary network policies (QoS) to provide for the required service levels.

Step 5 Create the final template macro to allow for simplified configuration

Design details, explaining how to select the features needed for a given deployment, and how to implement the features is provided in [Chapter 9, “Access Layer Security Design.”](#)

Access-Layer Network Control Services

Properly designing the distribution block ensures the stability of the overall architecture. In the collapsed core model, the access-distribution block includes the access and distribution layers. Each of these layers has specific service and feature requirements. The network control plane choice (i.e., routing or spanning tree protocols) are central to determining how the distribution block fits within the overall architecture. The school SRA includes two designs for configuring the access-distribution block: multi-layer and routed-access. See [Figure 3-8](#).

Figure 3-8 *Access-Distribution Deployment Model*

While both of these designs use the same basic physical topology and cabling plant, there are several key differences:

- Where the Layer-2 and Layer-3 boundaries exist
- How the network redundancy is implemented
- How load-balancing works

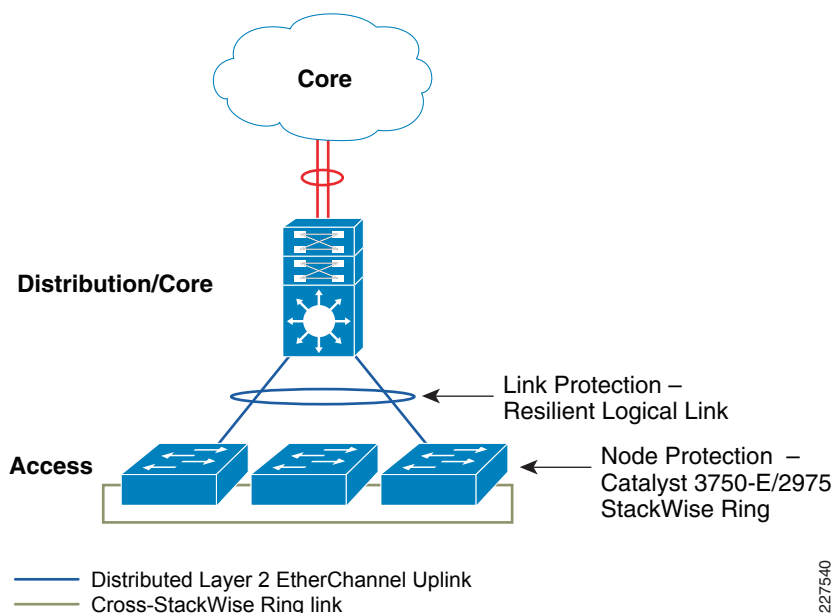

A complete configuration description of each access-distribution block model is provided in “[Logical Multi-Layer Network](#)” section on page 3-28 and the “[Deploying Routed-Access Network](#)” section on page 3-33 of this document.

Resilient Access-Layer Network and System

The access-layer provides endpoint connectivity to the rest of the network. Typical access switches like the Cisco Catalyst 2900 Series and Cisco Catalyst 3500 Series switches becomes single-point-of-failure (SPOF), if the hardware fails or if there is a software upgrade. Disrupting communication to mission critical endpoints (e.g., physical security camera) may be unacceptable.

School SRA is designed with 2 to 4 uplink ports for each access switch, providing link-failure protection. For mission critical endpoints, School SRA employs the Cisco StackWise or StackWise Plus solution in the access. It is designed to physically stack and interconnect multiple Layer-2 or Layer-3 switches using special cables. Stacking multiple switches into a logical ring creates a single unified and resilient access-layer network topology (see Figure 3-9). The Cisco Catalyst 2975 StackWise can be deployed in Layer-2 network domain and the Cisco Catalyst 3750-E StackWise or StackWise Plus is deployed for routed access implementations.

Figure 3-9 Resilient, Scalable and Efficient Access-Layer Network Design

District Office Data Center Network Design

The data center is a central location which houses servers and storage. These resources must be available to users throughout the Schools Service Ready Architecture. The data center may be collocated at the district office, or in a nearby site. Typically, school districts are unable to afford redundant WAN links between the data center and the school sites. This makes the design vulnerable to service outage at the school site, in the event of WAN link failure. The Schools Service Ready Architecture recommends which services should be placed in the centralized data center, and which services should be distributed (i.e., hosted at each school site). The key criteria to consider when making this decision include:

- **Scalability**—The compute capacity and storage capacity of the centralized data center must be sufficient to handle peak loads.
- **Network Load**—The overall network design, from data center to School Site must have enough capacity to carry the anticipated traffic (data and control traffic) to ensure good application performance.

- Redundancy—A WAN link failure will result in service outage between data center and the School Site. This can impact network data services and can expose security issue.
- Synchronization—Some applications which are hosted locally will require content synchronization with a centralized server. This can often be scheduled for off hours, to avoid adding traffic to WAN links during normal working hours.

Table 3-3 provides a sample list of centralized and distributed servers.

Table 3-3 Sample List of Centralized and Distribution Servers

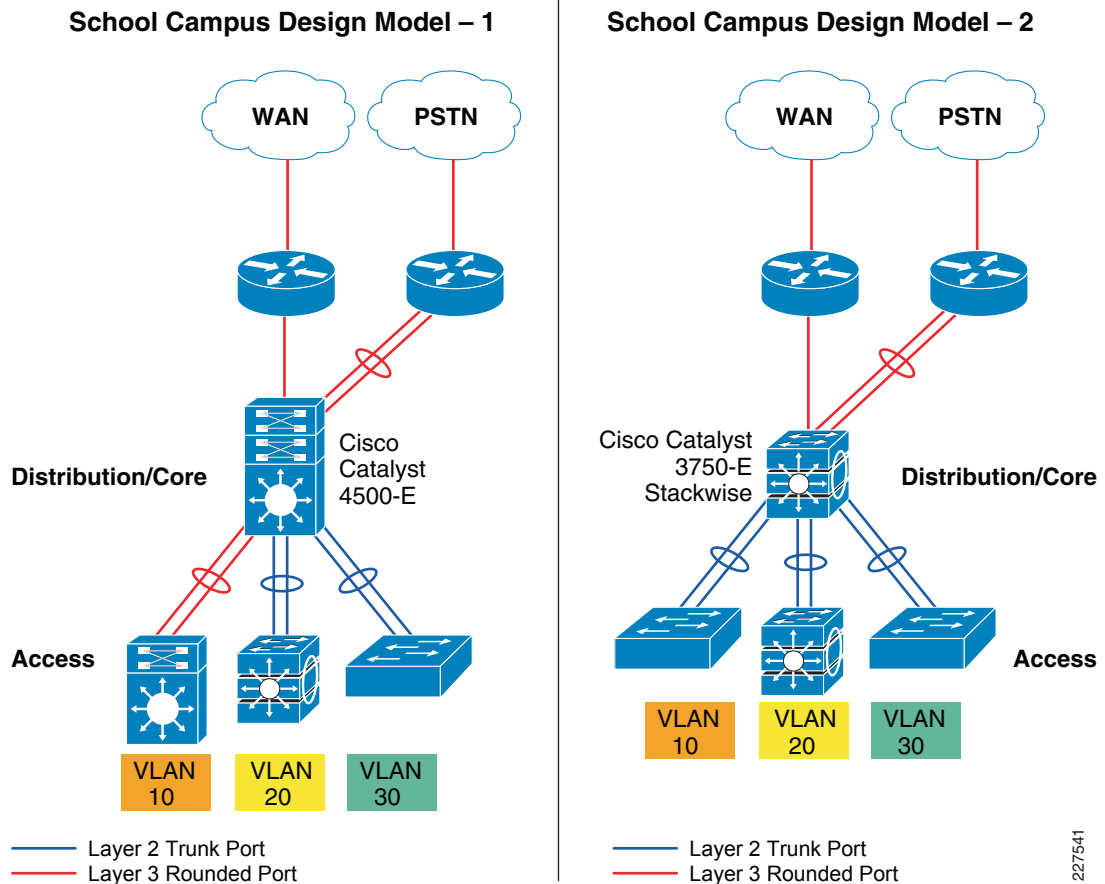

Data Center Model	Server Function	Deployment Location
Centralized	Database server(i.e., Oracle, Sybase, etc)	District Office Data Center
	Cisco Unified Call Manager	
	Cisco Presence Server	
	Cisco Digital Media Manager (DMM)	
	E-mail Messaging Server	
Distributed	Hosted services – Web, FTP, DHCP, DNS, NTP	District Office and School Data Center
	Access-Control – Cisco Access Control Server	
	Cisco Video Surveillance Operation Management	
	Media Storage Server	

School Site Network Design

The School Service Ready Architecture includes two school site designs. One for larger schools, and another for medium to smaller schools. The typical school site is a single building with a limited population which makes the collapsed core network design a suitable choice.

School Collapsed Core Network Design

The key criteria to consider when designing a school network are the network size, bandwidth capacity and high-availability requirements. The School Service Ready Architecture includes two models: one for smaller schools and another for larger schools. Both designs offer high capacity, performance, and availability. Figure 3-10 illustrates the two school network design models.

Figure 3-10 Collapsed Core School Network Models

Design Model - 1 is for a larger school site. The network design is the same as the district office network design, with the same performance capabilities, scalability options, and high availability features.

Design Model - 2 is for a medium to small school site. The primary difference is the use of the Cisco Catalyst 3750-E Stack Wise Plus switch in the collapsed core/distribution layer. The 3750-E Stack Wise Plus deploys up to nine 3750-E switches in a ring topology as a single virtual switch. Each chassis replicates the control functions, and provides packet forwarding. If the master switch fails, another switch will quickly assume the control plane 'master' function. This results in a cost effective, high performance, scalable solution, with built in resiliency.

- **Performance**—Provides wire-rate network connection to access switches
- **Scalable**—May deploy up to 9 switches in a stack to aggregate a reasonable number of access switches
- **High Availability**—Stack provides a virtual switch, with distributed control plane, delivering subsecond system failure recovery times

The Cisco 3750-E StackWise Plus delivers high performance routing and switching capability and robust IOS feature support. The control-plane and forwarding paths functions for the Cisco 3750-E StackWise Plus in the collapsed core network design remain the same. However, the switching architecture of the Cisco 3750-E StackWise differs significantly from the high-end distributed and modular switch platforms like Cisco Catalyst 4500 and 6500 Series switches. For more information about the Cisco 3750-E StackWise architecture, refer to the following URL:

http://www.cisco.com/en/US/partner/prod/collateral/switches/ps5718/ps5023/prod_white_paper09186a00801b096a_ps7077_Products_White_Paper.html

School Access-Layer Design

The access-layer network designate the school site is the same as at the district office. The same devices are available, and the same design choices may be deployed to achieve a high performance, secure and resilient access layer. To simplify the overall system design, and network operations, it is recommended to use consistent design and platform selections in the access-layer role, at the district office and school sites. This will allow a common configuration template and simplify operations and troubleshooting procedures.

Deploying Schools Foundation Services

The two-tier hierarchical design delivers a *reliable and resilient, scalable, and manageable* foundation network design. This subsection provides design and deployment guidelines for the school core layer, and access-distribution block.

The access-distribution block, as described in the “[District Office Data Center Network Design](#)” section on page 3-12, uses a combination of Layer-2 and Layer-3 switching to provide a balance of policy and access controls, availability, and flexibility in subnet allocation and VLAN usage. Deployment guidelines are provided to implement multi-layer, and routed access designs in the access-distribution block.

Implementing EtherChannel in School Network

Etherchannel is used throughout the network design, and the implementation guidelines are the same for multi-layer, and routed-access models, and in the WAN edge design. As recommended in the “[EtherChannel Fundamentals](#)” section on page 3-7, there should be single logical point-to-point EtherChannel deployed between collapsed core and access-layer. The EtherChannel configuration on each end of the link in the access-distribution block must be consistent to prevent a link bundling problem. EtherChannels use link bundling protocols to dynamically bundle physical interfaces into a logical interface.

The following are the benefits of building EtherChannel in dynamic mode:

- Ensure link aggregation parameters consistency and compatibility between switches.
- Ensure compliance with aggregation requirements.
- Dynamically react to runtime changes and failures on local and remote Etherchannel systems
- Detect and remove unidirectional links and multi-drop connections from the Etherchannel bundle.

EtherChannels can be deployed in dynamic or static modes. Both EtherChannel modes can coexist in a single system; however, the protocols (PagP, LACP) can not interoperate with each other.

- *Cisco proprietary link aggregation*—Cisco's implementation of Port Aggregation group Protocol (PAgP) is supported on all the Cisco Catalyst platforms. The PAgP protocol is not supported when the Cisco Catalyst 2975 or 3750 Series switches are deployed in StackWise mode. The PAgP protocol can operate in the different channel-group modes shown in [Table 3-4](#) to initialize link bundling process.

Table 3-4 Cisco's Proprietary PAgP Channel-Group Mode

	Distribution	Access-switch and WAN Edge	EtherChannel State
channel-group mode	auto	auto	Non-Operational
	desirable (recommended)	desirable (recommended)	Operational State
	desirable	auto	
	auto	desirable	

- *IEEE 802.3ad link aggregation*—Link Aggregation Control Protocol (LACP) is based on IEEE 802.3ad specification to operate in vendor-independent network environment. LACP link bundling protocol is developed with same goal as Cisco's PAgP. Cisco Catalyst switches in StackWise mode must use LACP to dynamically bundle. LACP can operate in the following different channel-group modes to initialize the link bundling process. See [Table 3-5](#).

Table 3-5 IEEE 802.3ad LACP channel-group mode

	Distribution	Access-switch and WAN Edge	EtherChannel State
channel-group mode	passive	passive	Non-Operational
	active (recommended)	active (recommended)	Operational State
	active	passive	
	passive	active	

- *Static Mode*—Each system statically bundles selected physical ports into a logical port-channel. In static mode, Etherchannel consistency check is not performed between two switches, which may lead to network protocol instability or network outage due to mis-configuration. This mode is not recommended and should only be considered when EtherChannel is required but side of the link does not support PAgP or LACP link aggregation protocol.

Figure 3-11 Implementing EtherChannel in District Office School Network

The following sample configuration shows how to build Layer-2 and Layer-3 EtherChannel configuration and bundling physical ports into appropriate logical EtherChannel-group:

```
cr24-4507-DO#config t
Enter configuration commands, one per line. End with CNTL/Z.
cr24-4507-DO(config)#interface Port-channel1
cr24-4507-DO(config-if)# description Connected to cr24-3750ME-DO
cr24-4507-DO(config-if)#
cr24-4507-DO(config-if)#interface Port-channel11
cr24-4507-DO(config-if)# description Connected to cr24-2960-DO
cr24-4507-DO(config-if)# switchport
cr24-4507-DO(config-if)#
cr24-4507-DO(config-if)#interface Port-channel16
cr24-4507-DO(config-if)# description Connected to cr25-3750s-DO
cr24-4507-DO(config-if)# switchport
cr24-4507-DO(config-if)#
cr24-4507-DO(config-if)#interface range Gig 3/3 , Gig 4/3
cr24-4507-DO(config-if-range)# description Connected to cr24-3750ME-DO
cr24-4507-DO(config-if-range)# channel-protocol pagp
cr24-4507-DO(config-if-range)# channel-group 1 mode desirable
cr24-4507-DO(config-if-range)#
cr24-4507-DO(config-if-range)#interface range Gig 1/1 , Gig 2/1
cr24-4507-DO(config-if-range)# description Connected to cr24-2960-DO
cr24-4507-DO(config-if-range)# channel-protocol pagp
cr24-4507-DO(config-if-range)# channel-group 11 mode desirable
cr24-4507-DO(config-if-range)#
cr24-4507-DO(config-if-range)#interface range Gig 1/6 , Gig 2/6
cr24-4507-DO(config-if-range)#description Connected to cr26-3750s-DO
cr24-4507-DO(config-if-range)# channel-protocol lacp
cr24-4507-DO(config-if-range)# channel-group 16 mode active
```

Enabling EtherChannel on each switch endpoint will automatically form a logical connection and can be verified using following CLI command:

```
cr24-4507-DO#show etherchannel summary | inc Po
Group Port-channel Protocol Ports
1      Po1 (RU)          PAgP   Gi3/3 (P)  Gi4/3 (P)
11     Po11 (SU)         PAgP   Gi1/1 (P)  Gi2/1 (P)
16     Po16 (SU)         LACP   Gi1/6 (P)  Gi2/6 (P)
```

EtherChannel Load Balancing

EtherChannel load-sharing is based on a polymorphic algorithm. On per protocol basis, load sharing is done based on source XOR destination address or port from Layer 2 to 4 header and ports. For higher granularity and optimal utilization of each member-link port, an EtherChannel can intelligently load-share egress traffic using different algorithms. EtherChannel load balancing method support varies on Cisco Catalyst platforms. [Table 3-6](#) summarizes the currently supported EtherChannel load-balancing methods.

Table 3-6 *EtherChannel Load Balancing Support Matrix*

Packet Type	Classification Layer	Load Balancing Mechanic	Supported Cisco Catalyst Platform
Non-IP	Layer 2	src-dst-mac	29xx, 35xx, 3750, 4500
IP		src-mac	
		dst-mac	
		src-dst-mac	
IP	Layer 3	src-ip	
		dst-ip	
		src-dst-ip	
IP	Layer 4	src-port	4500
		dst-port	
		src-dst-port	

EtherChannel load-balancing mechanisms function on a per-system basis. By default, EtherChannel will use the hash computation algorithm. The network administrator can globally configure the load balancing mechanism. In Cisco Catalyst platforms, EtherChannel load balancing is performed in hardware and it cannot perform per-packet-based load balancing among different member links within EtherChannel. Bandwidth utilization of each member-link may not be equal in default load balancing mode. The Ether Channel load balancing method should be changed to source and destination IP address based throughout the district office and school network for the following reasons:

- One cannot optimize load balancing using hash tuning in a general network deployment model. This is due to variations in application deployment and usage patterns.
- EtherChannel does not take into account the bandwidth of each flow. Instead, it relies on the statistical probability that the load is equally distributed across the links of the port-channel group, given a large number of flows of relatively equal bandwidths. However, this may not always be true. Tuning the load-balancing to source-and-destination IP address allows for statistically-superior load-distribution. When loads are balanced in this manner, packets belonging to a single flow will retain their packet order. See [Figure 3-12](#).

Figure 3-12 EtherChannel Load-Balance Method

The following output provides sample configuration guideline for changing the default **port-channel load-balance** setting to **source-destination-ip** based. Aside from Layer-2 or Layer-3 EtherChannel mode, similar configuration must be applied on each system in the access-distribution block and WAN edge.

```
cr24-4507-DO(config)#port-channel load-balance src-dst-ip
cr24-4507-DO#show etherchannel load-balance
EtherChannel Load-Balancing Configuration:
    src-dst-ip
EtherChannel Load-Balancing Addresses Used Per-Protocol:
Non-IP: Source XOR Destination MAC address
IPv4: Source XOR Destination IP address
IPv6: Source XOR Destination IP address
```

The following additional EtherChannel design and configuration must be taken into consideration for an optimal EtherChannel design:

- Enable single EtherChannel between access-layer and distribution system. Enabling more than a single Ether Channel in a collapsed core network design imposes the same limitations as discussed in non-EtherChannel scenario in [Figure 3-5](#).
- For optimal load sharing and hashing computation, it is recommended to bundle the number of physical ports in powers of 2 (i.e., 2, 4, and 8).
- EtherChannel is a logical interface in Cisco Catalyst platform. EtherChannel scalability in collapsed core and distribution must be taken into account. The Cisco Catalyst 4500 can support up to 64 EtherChannels, whereas the Cisco Catalyst 3750 StackWise can support up to 48 EtherChannels per-system.

Deploying Core Network Layer

This section provides implementation and best practice guidelines for deploying the core-layer in both the district office and school site. Proper design of the core network layer ensures reachability, transparency and availability. This section focuses on building a unicast routing topology.

Routing Protocol

Enabling routing in the school network is a simple task. However, the network physical layout must be carefully planned and designed to ensure flexible, stable and efficient routing. Developing a hierarchical network addressing scheme enables a stable, efficient and scalable design.

- *Hierarchical network addressing*—Structured IP network addressing in school LAN/WAN network is a must to make network scalable, stable.
- *Routing protocol*—Cisco IOS supports wide range of Interior Gateway Protocol (IGP). It is recommended to deploy a single choice of routing protocol across the school infrastructure. This solution guide does not recommended any particular IGP to deploy in the school architecture as it significantly varies based on different network infrastructure. However it will provide some key points to be considered when selecting unicast routing protocol.
- *Hierarchical routing domain*—Routing protocols must be designed in a hierarchical model that allows network to scale and operate with greater stability. Building routing boundaries and summarizing the network addresses minimizes topology size and synchronization procedure, which improves the overall network resource utilization and reconvergence.

Routing Protocol Selection Criteria

- *Efficient address allocation*—Hierarchical addressing enables efficient use of address space, since groups are contiguous.
- *Improves routing efficiency*—Using contiguous ip addresses enables efficient route summarization. Route summarization simplifies the routing database, and computations during topology changes. This reduces the network bandwidth used by the routing protocol, and improves routing protocol performance by reducing network convergence time.
- *Improves system performance*—Hierarchical, contiguous ip addressing reduces router memory usage by eliminating dis-contiguous and non-summarized route entries. It saves on CPU cycles needed to compute the routing database during topology changes. This contributes to a more stable routing network, and simplifies the task of network operations and management.

Cisco IOS supports many Interior Gateway Protocols (IGP), including EIGRP and OSPF, either of which are suitable for large network deployments. While OSPF is capable of greater scale, it is also more complex, and hence more difficult to configure, operate and manage. The Schools Service Ready Architecture is designed and validated using EIGRP, since it is a stable, high performance, efficient protocol, which is simple to implement and manage. The same design principles apply whether using EIGRP or OSPF.

Table 3-7 lists some of the EIGRP and OSPF side-by-side feature comparison information.

Table 3-7 *EIGRP and OSPF feature comparison chart*

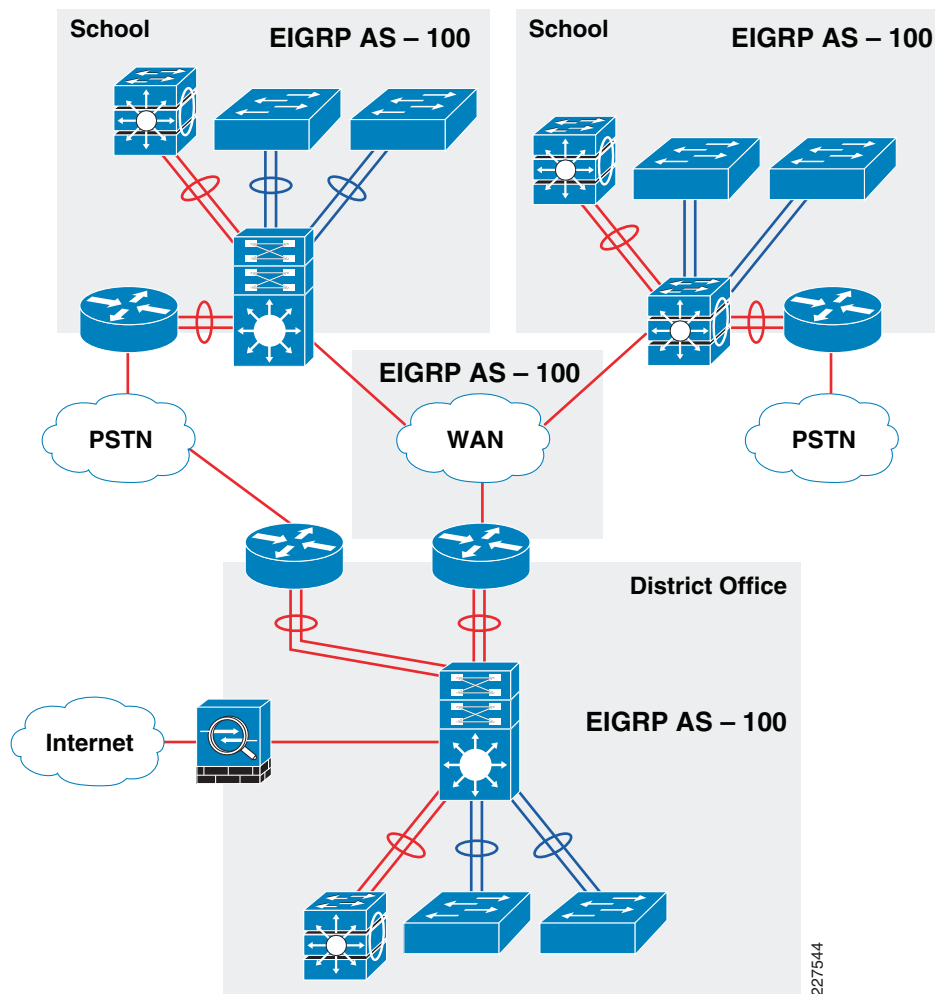

Feature	EIGRP	OSPF
Classless Routing	Both routing protocols support classless routing that allows to partition networks into VLSM.	
Loop Prevention	Built-in mechanic to prevent routing loop in network.	

Table 3-7 *EIGRP and OSPF feature comparison chart (continued)*

Robust metric	Aggregated link Bandwidth + Delay	Aggregated link Bandwidth
Efficient routing	Partial update	
Multi-access routing adjacency	Full-mesh	Hub-n-spoke
Hierarchical Routing	No. All routers considered in backbone. Non-backbone or routers in non-transit path can be deployed in Stub role.	OSPF area is divided in multiple routing domains. Backbone area maintains complete summarized network topology; non-backbone area can be transit or non-transit OSPF routers.
Network convergence	Both routing protocol offers rapid network recovery during link failure.	
Graceful-Restart Support	Yes	Yes. Cisco and IETF based
Route Summarization	Flexibility to manual summarized on any routing node.	Can only be performed on ABR or ASBR
Load-Balancing	Support equal and un-equal cost load balancing	Equal-cost path only.
Standard	Cisco proprietary	IETF standard

Designing End-to-End EIGRP Routing Domain

EIGRP is a balanced hybrid routing protocol that builds neighbor adjacency and a flat routing topology on a per-autonomous-system (AS) basis. The LAN/WAN infrastructure of School Service Ready Architecture should be deployed in a single EIGRP AS to prevent route redistribution, loops, and other problems that may occur due to misconfiguration. See [Figure 3-13](#).

Figure 3-13 End-to-End EIGRP Routing Design in School Architecture

Implementing EIGRP Routing

The district office is the central hub in the network. Each school site is connected to the district office over the WAN infrastructure. The district office network includes the Internet gateway and provides access to the central data-center. Since both the school sites, and district office networks use the collapsed core design, the routing configuration of the core routers is the same.

The following is a sample configuration to enable EIGRP routing process at the edge of the district office collapsed core network. EIGRP is enabled in the school site network with the same configuration:

```
cr24-4507-DO(config)#interface Loopback0
cr24-4507-DO(config-if)# ip address 10.125.100.1 255.255.255.255

cr24-4507-DO(config-if)#interface Port-channel1
cr24-4507-DO(config-if)# description Connected to cr24-3750ME-DO
cr24-4507-DO(config-if)#no switchport
cr24-4507-DO(config-if)# ip address 10.125.32.4 255.255.255.254

cr24-4507-DO(config-if)#interface Port-channel2
cr24-4507-DO(config-if)# description Connected to cr24-2851-DO
cr24-4507-DO(config-if)#no switchport
cr24-4507-DO(config-if)# ip address 10.125.32.6 255.255.255.254
```

```

cr24-4507-DO(config)#interface Vlan200
cr24-4507-DO(config-if)# description Connected to cr24_ASA_Inside_Port
cr24-4507-DO(config-if)# ip address 10.125.33.9 255.255.255.0

EIGRP Adjacency Protection

Implementing summarization in the EIGRP routing process automatically enables EIGRP routing process on each interface that is summarized. By default, the router transmits and accept EIGRP hello messages from remote device to form an adjacency on all EIGRP enabled interfaces. This behavior needs to be modified to ensure a secure, efficient and stable routing design:

- *System efficiency*—There is no need to send EIGRP hellos on an interface where there is no trusted EIGRP neighbor. In a large network, sending EIGRP hello messages periodically to such interfaces consumes unnecessary CPU resource. EIGRP route processing should only be enabled on interfaces where trusted network devices are connected. All other interfaces can be suppressed in passive mode. The following configuration shows how to automatically disable EIGRP processing on all the Layer-3 interfaces and only enable on the trusted interface. This design principle must be applied on each EIGRP router, including distribution and core routers:

```

cr24-4507-DO(config)#router eigrp 100
cr24-4507-DO(config-router)# network 10.125.0.0 0.0.255.255
cr24-4507-DO(config-router)# passive-interface default
cr24-4507-DO(config-router)# no passive-interface Port-channel1
cr24-4507-DO(config-router)# no passive-interface Port-channel2
cr24-4507-DO(config-router)# no passive-interface Vlan200

cr24-3560r-DO#show ip eigrp interface
EIGRP-IPv4:(100) interfaces for process 100

Po2 1	0/04	0/1	50	0				

```

cr24-4507-DO#show ip protocols | inc Passive|Vlan
Passive Interface(s):
  Vlan1
  Vlan101
  Vlan102

```

```
Vlan103
Vlan104
```

- *Network Security*—Sending unnecessary EIGRP Hello messages opens a security vulnerability in two ways. An attacker can detect EIGRP operation and send flood of EIGRP hello messages to destabilize the network. Or an attacker could establish a “fake” EIGRP adjacency and advertise a best metric default-route into the network to black hole and compromise all critical traffic. Each EIGRP system should implement MD5 authentication, and each EIGRP neighbor should validate MD5 authentication is enabled on adjacent systems. This provides a secure method of transmitting and receiving routing information between devices in the network. Following is a sample configuration to enable EIGRP neighbor authentication using MD5:

– Distribution

```
cr24-4507-DO(config)#key chain eigrp-key
cr24-4507-DO(config-keychain)# key 1
cr24-4507-DO(config-keychain-key)# key-string <password>

cr24-4507-DO(config)#interface Port-channel1
cr24-4507-DO(config-if)# description Connected to cr24-3750ME-DO
cr24-4507-DO(config-if)# ip authentication mode eigrp 100 md5
cr24-4507-DO(config-if)# ip authentication key-chain eigrp 100 eigrp-key
```

– WAN Aggregation

```
cr24-3750ME-DO(config)#key chain eigrp-key
cr24-3750ME -DO(config-keychain)# key 1
cr24-3750ME -DO(config-keychain-key)# key-string <password>

cr24-3750ME -DO(config)#interface Port-channel1
cr24-3750ME -DO(config-if)# description Connected to cr24-4507-DO
cr24-3750ME -DO(config-if)# ip authentication mode eigrp 100 md5
cr24-3750ME -DO(config-if)# ip authentication key-chain eigrp 100 eigrp-key
```

- *System Stability*—As mentioned in Table 8, EIGRP allows network administrator to summarize multiple individual and contiguous networks into a single summarized network before advertising to neighbors. Route summarization improves performance, stability, and convergence times, and it makes the network easier to manage operate and troubleshoot.

EIGRP provides the flexibility to summarize at any point in the network. Proper design requires determining which routers will serve as Aggregators, and advertise summarized network information to peers. Routers which connect multiple access devices, or connect to the WAN edge should be made Aggregators. [Figure 3-14](#) provides an example Schools SRA network with route aggregator devices identified with the direction of route summarization illustrated.

Figure 3-14 Route Aggregator and Summary Route Advertisement Direction

The following sample configuration shows EIGRP route summarization. In this example, the entire access-layer network is summarized into a single classless network and advertised to the WAN edge, the ASA firewall and the PSTN gateway:

- Distribution

```
cr24-4507-DO(config)#interface Port-channel1
cr24-4507-DO(config-if)# description Connected to cr24-3750ME-DO
cr24-4507-DO(config-if)# ip summary-address eigrp 100 10.125.0.0 255.255.0.0

cr24-4507-DO(config-if)#interface Port-channel2
cr24-4507-DO(config-if)# description Connected to cr24-2851-DO
cr24-4507-DO(config-if)# ip summary-address eigrp 100 10.125.0.0 255.255.0.0

cr24-4507-DO(config-if)#interface Vlan200
cr24-4507-DO(config-if)# description Connected to cr24_ASA_Inside_Port
cr24-4507-DO(config-if)# ip summary-address eigrp 100 10.125.0.0 255.255.0.0

cr24-4507-DO#show ip protocols | inc Address|10.125.0.0
Address Family Protocol EIGRP-IPv4:(100)
Address Summarization:
  10.125.0.0/16 for Port-channel1, Vlan200, Port-channel2
```

- WAN Aggregation

Verifying district office EIGRP summarized route status at WAN aggregation layer as follows:

```

cr24-3750ME-DO#show ip route 10.125.0.0 255.255.0.0
Routing entry for 10.125.0.0/16
  Known via "eigrp 100", distance 90, metric 1792, type internal
  Redistributing via eigrp 100
  Last update from 10.125.32.4 on Port-channel1, 1d04h ago
  Routing Descriptor Blocks:
    * 10.125.32.4, from 10.125.32.4, 1d04h ago, via Port-channel1
      Route metric is 1792, traffic share count is 1
      Total delay is 20 microseconds, minimum bandwidth is 2000000 Kbit
      Reliability 255/255, minimum MTU 1500 bytes
      Loading 1/255, Hops 1

```

Tuning EIGRP Protocol Timers

EIGRP uses Hello messages to form adjacencies and determine if neighbors are alive. EIGRP adjacency is declared down if it fails to receive Hello messages within the Hold down timer interval. All the prefixes discovered from a dead neighbor are removed from the routing table. By default, EIGRP transmits a Hello message every 5 seconds to notify neighbors that it is still alive. The EIGRP hold-down timer gets reset each time the router receives a EIGRP Hello message. Default EIGRP adjacency Hold-down timer is 15 seconds.

Lowering EIGRP hello and hold-down timer intervals improves network convergence times (i.e. time to detect and respond to an outage). For Schools SRA design it is recommended to use the default EIGRP Hello and Hold timer values for the following reasons:

- **EtherChannel Benefits**—EIGRP operates over the Layer-3 EtherChannel. In the event of a single member-link failure condition, layer 2 will respond more quickly than the routing protocol, and switchover traffic from the impacted link to an alternate member link. EIGRP routing is not impacted by individual link member and no change in the routing table is required. Thus reducing the EIGRP timers will not result in quicker convergence, and may adversely impact system stability.
- **High-Availability**—The Cisco Catalyst 4500, 37xx (non-Stack Wise) and 35xx series layer 3 switches support Stateful-Switch Over (SSO) which enables a backup supervisor to gracefully assume the active role while maintaining adjacency with neighbors, during a supervisor failure condition. The backup supervisor requires sufficient time to detect a failure and initiate graceful recovery with neighbors. Implementing aggressive timers may abruptly terminate adjacency and cause network outage before a stateful switch over is accomplished. Thus, default EIGRP Hello and Hold timers are recommended on Cisco Catalyst 4500, 37xx (non-Stackwise) and 35xx Series Layer-3 platforms.

Deploying Multi-Layer Network

Multilayer design is one of the two access-distribution block designs included in the Schools Service Ready Architecture. This section provides implementation and best practices guidelines the multi-layer design. The deployment and configuration guidelines for the multi-layer access-distribution block are the same for both district office and school site networks.

Spanning-Tree in Multilayer Network

Spanning Tree (STP) is a Layer-2 protocol that prevents logical loops in switched networks with redundant links. The School SRA design uses Etherchannel (point-to-point logical Layer-2 bundle) connection between access-layer and distribution switch which inherently simplifies the STP topology and operation. In this design, the STP operation is done on a logical port, therefore, it will be assigned automatically in forwarding state.

Over the years, the STP protocols have evolved into the following versions:

- Per-VLAN Spanning Tree Plus (PVST+)—Provides a separate 802.1D STP for each active VLAN in the network.
- IEEE 802.1w – Rapid PVST+—Provides an instance of RSTP (802.1w) per VLAN. It is easy to implement, proven in large scale networks that support up to 3000 logical ports and greatly improves network restoration time.
- IEEE 802.1s – MST—Provides up to 16 instances of RSTP (802.1w) and combines many VLANs with the same physical and logical topology into a common RSTP instance.

Following is the example configuration to enable STP protocol in multi-layer network:

Distribution

```
cr24-4507-DO(config)#spanning-tree mode rapid-pvst

cr24-4507-DO#show spanning-tree summary | inc mode
Switch is in rapid-pvst mode
```

Access-Layer Switch

```
cr24-2960-DO(config)#spanning-tree mode rapid-pvst
```

Default STP parameters optimize the network for packet forwarding. Best practice design includes hardening STP parameters in the access and distribution switch to protect against STP misconfiguration, or malicious user by deploying spanning-tree toolkit in the access-distribution block. See [Figure 3-15](#).

Figure 3-15 Hardening Spanning-Tree Toolkit in Multi-Layer Network

The following is the configuration deploys spanning-tree toolkit in the access-distribution block:

Distribution

```
cr24-4507-DO(config)#spanning-tree vlan 1-4094 root primary
cr24-4507-DO(config)#interface range Gig 1/1 - 2 , Gig 2/1 - 2
cr24-4507-DO(config)#spanning-tree guard root
```

Access

```
cr26-2975-DO(config)#interface GigabitEthernet1/0/1
cr26-2975-DO(config-if)#description CONNECTED TO UNTRUSTED-PC
cr26-2975-DO(config-if)#spanning-tree bpduguard enable
```

Other STP Toolkit Consideration

When the access-distribution block multi-layer design is deployed using the recommended best practices, it automatically minimizes the need for deploying the following additional spanning-tree toolkit technologies:

- UplinkFast—Improves the network convergence time by providing direct access to the root switch link failure. UplinkFast is not necessary in this design, because there is no alternate STP path and RSTP protocol natively includes rapid recovery mechanism.
- Backbone Fast—Provides rapid convergence from indirect Layer-2 link failures in a redundant distribution switch configuration. This feature is not necessary for the same reason as stated for UplinkFast.
- LoopGuard—Protects Layer-2 networks from loops that occur due to any malfunction that prevents normal BPDU forwarding. A STP loop is created when a blocking port in a redundant topology erroneously transitions to the forwarding state. This usually happens because one of the ports in a physically redundant topology (not necessarily the blocking port) stopped receiving BPDUs. Because there is single point-to-point STP forwarding port in this design, enabling Loopguard does not provide any additional benefit. UDLD protocol must be implemented to prevent STP loop that may occur in the network due to network malfunction, mis-wiring, etc.

Logical Multi-Layer Network

VLAN assignment can have a significant impact on network performance and stability. There are three basic ways to assign VLANs within the access-distribution block.

Flat Logical Network Design

Spanning a single VLAN across multiple access-layer switches is much simpler with a single collapsed core-distribution device versus a design with redundant distribution devices. The flat multi-layer design has a single VLAN across multiple access devices, as shown in [See Figure 3-16](#).

Figure 3-16 Multi-Layer Flat Network design

A flat multi-layer network deployment introduces the following challenges:

- **Scalability**—Spanning the same VLAN in different access-layer switches will create a large Layer-2 broadcast domain that dynamically discovers and populates MAC address entries for endpoints that may not need to communicate. In a large network, this may become a scalability issue (i.e. memory required to hold large CAM table).
- **Performance**—In a large network, spanning a large number of broadcast domains will impact the performance of all network devices in the access-distribution block, because the switch will have to process many more broadcast packets such as ARP.
- **Security**—The flat multi-layer design widens the fault domain which increases possible attacks to a larger number of users. The number of users is not necessarily due to the number switches spanned and applications during DoS or viruses attack.

Segmented Logical Network Design

Best practice design includes identifying meaningful groups within the user community, and assigning a unique VLAN to each group. These groups may be departments, user groups, or any other logical grouping of users. Enabling a unique VLAN for each group will segment the network and build a logical network structure. All network communication between groups will pass through the routing and forwarding policies defined at the distribution layer. See [Figure 3-17](#).

Figure 3-17 Multi-Layer Segmented Network Design

A segmented VLAN design is the solution to the challenges described in the flat network design. VLAN segmentation improves the scalability, performance, and security of the network.

Hybrid Logical Network Design

The segmented logical network design improves scalability, performance and security, and addresses the challenges of a flat network design. In real world deployments, there is usually a need for some users or applications to communicate with all users (eg system administrator). The hybrid network design is the segmented design, with the addition of a exceptional VLAN which spans the entire access-distribution block. See [Figure 3-18](#).

Figure 3-18 Multi-Layer Hybrid Network Design

Cisco recommends the segmented VLAN network design and optionally hybrid network for centralized users or applications that requires distributed function across the access-layer network.

Following are the sample VLAN configuration steps in the access and the distribution layer switches.

Distribution

VLAN Trunking Protocol (VTP) is a Cisco proprietary Layer 2-messaging protocol that manages the addition, deletion, and renaming of VLANs on a network-wide basis. Cisco's VTP simplifies administration in a switched network. VTP can be configured in three modes: server, client, and transparent. Set the VTP domain name and change the mode to the transparent mode as follows:

```
cr24-4507-DO(config)#vtp domain District-Office
cr24-4507-DO(config)#vtp mode transparent

cr24-4507-DO(config)#vlan 10
cr24-4507-DO(config-vlan)#name cr24-3750-Admin-Dept
cr24-4507-DO(config-vlan)#vlan 20
cr24-4507-DO(config-vlan)#name cr24-3560-Library-Dept
cr24-4507-DO(config-vlan)#vlan 30
cr24-4507-DO(config-vlan)#name cr24-2960-Arts-Dept
```

Access

Set VTP domain name and change the mode to the transparent mode as follows:

```
cr24-3750-DO(config)#vtp domain District-Office
cr24-3750-DO(config)#vtp mode transparent

cr24-3750-DO(config)#vlan 10
cr24-3750-DO(config-vlan)#name cr24-3750-Admin-Dept
```

Implementing Layer 2 Trunk

In a typical network design, a single access switch will have more than one VLAN, for example a Data VLAN and a Voice VLAN. The network connection between Distribution and Access device is a trunk. VLANs tag their traffic to maintain separation between VLANs across the trunk. By default on Cisco Catalyst switches, the native VLAN on each layer 2 trunk port is VLAN 1, and cannot be disabled or removed from VLAN database. The native VLAN remains active on all access switches layer 2 ports.

There are two choices for encapsulating the tagged VLAN traffic on the trunk: IEEE 802.1Q or Cisco ISL. It is recommended to implement trunk encapsulation in static mode instead of negotiating mode, to improve the rapid link bring-up performance. Not all Cisco Catalyst platforms support ISL encapsulation; therefore IEEE 802.1Q is recommended, and validated in the access and distribution switches.

Enabling the Layer-2 trunk on a port-channel, automatically enables communication for all of the active VLANs between the access and distribution. This means an access-switch which has implemented, for example, VLANs 10 to 15, will receive flood traffic destined for VLANs 20 to 25, which are implemented on another access switch. RPVST+, using logical ports, operates on a per-VLAN basis to load balance traffic. In a large network, it is important to limit traffic on Layer-2 trunk ports to only the assigned VLANs, to ensure efficient and secure network performance. Allowing only assigned VLANs on a trunk port automatically filters rest.

The default native VLAN must be properly configured to avoid several security risks—Attack, worm and virus or data theft. Any malicious traffic originated in VLAN 1 will span across the access-layer network. With a VLAN-hopping attack it is possible to attack a system which does not reside in VLAN 1. Best practice to mitigate this security risk is to implement a unused and unique VLAN ID as a native VLAN on the Layer-2 trunk between the access and distribution switch. For example, configure VLAN

802 in the access-switch and in the distribution switch. Then change the default native VLAN setting in both the switches. Thereafter, VLAN 802 must not be used anywhere for any purpose in the same access-distribution block.

Following is the configuration example to implement Layer-2 trunk, filter VLAN list and configure the native-VLAN to prevent attacks on port channel interface. When the following configurations are applied on port-channel interface (i.e., Port-Channel 11), they are automatically inherited on each bundled member-link (i.e., Gig1/1 and Gig2/1):

Distribution

```
cr24-4507-DO(config)#vlan 802
cr24-4507-DO(config-vlan)#name Admin-Hopping-VLAN

cr24-4507-DO(config)#interface Port-channel 11
cr24-4507-DO(config-if)# description Connected to cr24-3750-DO
cr24-4507-DO(config-if)# switchport
cr24-4507-DO(config-if)# switchport mode trunk
cr24-4507-DO(config-if)# switchport trunk allowed vlan 101-110,900
cr24-4507-DO(config-if)# switchport trunk native vlan 802
```

```
cr24-4507-DO#show interface port-channel 11 trunk
```

Port	Mode	Encapsulation	Status	Native vlan
Po11	on	802.1q	trunking	802

cr24-3750-DO(config-if)# switchport mode trunk
cr24-3750-DO(config-if)# switchport trunk allowed vlan 101-110,900
cr24-3750-DO(config-if)# switchport trunk native vlan 802
```

Unidirectional Link Detection

UDLD is a Layer 2 protocol that works with the Layer 1 features to determine the physical status of a link. At Layer 1, auto-negotiation takes care of physical signaling and fault detection. UDLD performs tasks that auto-negotiation cannot perform, such as detecting the identity of neighbors and shutting down

misconnected ports. When both auto-negotiation and UDLD are enabled, Layer 1 and Layer 2 detection works together to prevent physical and logical unidirectional connections and the malfunctioning of other protocols.

Copper media ports use Ethernet link pulse as a link monitoring tool and are not susceptible to unidirectional link problems. Because one-way communication is possible in fiber-optic environments, mismatched transmit/receive pairs can cause a link up/up condition even though bidirectional upper-layer protocol communication has not been established. When such physical connection errors occur, it can cause loops or traffic black holes. UDLD functions transparently on Layer-2 or Layer-3 physical ports. UDLD operates in one of two modes:

- Normal mode—If bidirectional UDLD protocol state information times out; it is assumed there is no-fault in the network, and no further action is taken. The port state for UDLD is marked as undetermined. The port behaves according to its STP state.
- Aggressive mode—If bidirectional UDLD protocol state information times out, UDLD will attempt to reestablish the state of the port, if it detects the link on the port is operational. Failure to reestablish communication with UDLD neighbor will force the port into the err-disable state. That must be manually recovered by user or the switch can be configured for auto recovery within specified interval of time.

Following is the configuration example to implement UDLD protocol:

Distribution

```
cr24-4507-DO(config)#interface range Gig 1/2 , Gig 2/2
cr24-4507-DO(config-int)#udld port
```

```
cr24-4507-DO#show udld neighbor
```

Port	Device Name	Device ID	Port ID	Neighbor State
Gi1/2	FOC1318Y06V	1	Gi1/0/49	Bidirectional
Gi2/2	FOC1318Y06J	1	Gi3/0/49	Bidirectional

Access

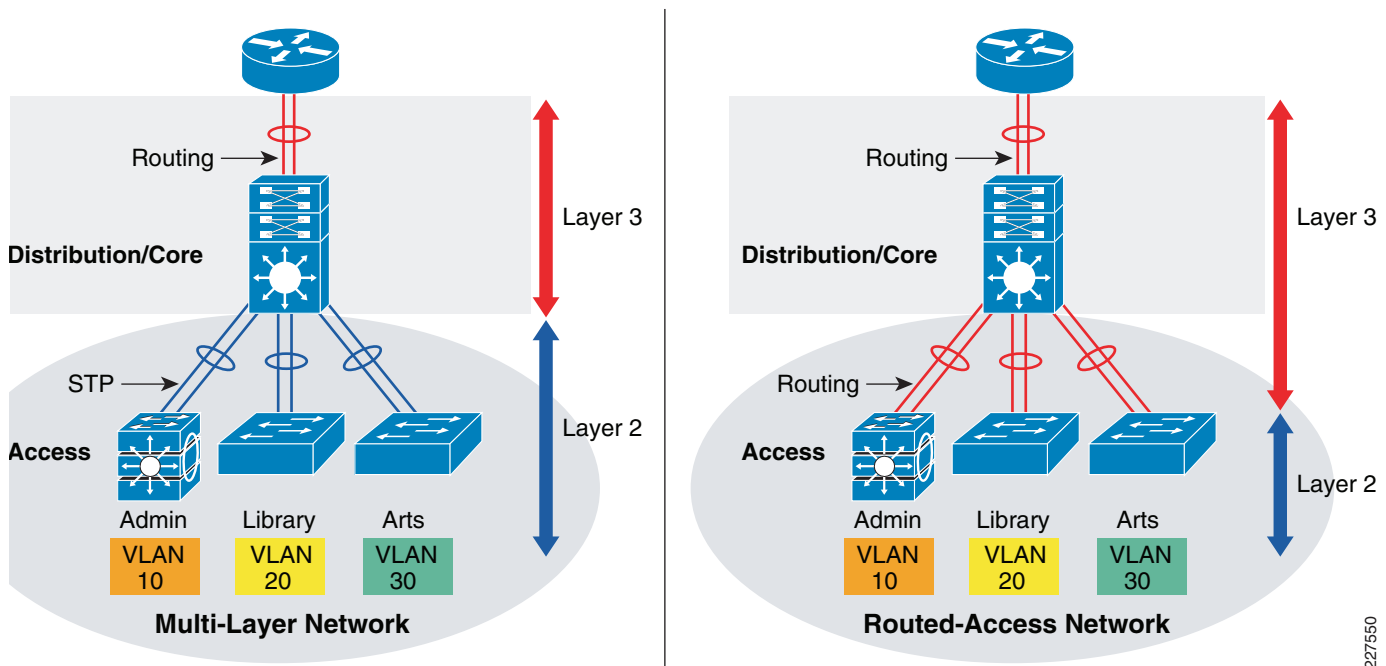

```
cr26-2975-DO(config)#interface Gig 1/0/49 , Gig 3/0/49
cr26-2975-DO(config-if)#description Connected to cr24-4507-DO
cr26-2975-DO(config-if)#udld port
```

```
cr26-2975-DO#show udld neighbor
```

Port	Device Name	Device ID	Port ID	Neighbor State
Gi1/0/49	FOX1216G8LT	1	Gi1/2	Bidirectional
Gi3/0/49	FOX1216G8LT	1	Gi2/2	Bidirectional

Deploying Routed-Access Network

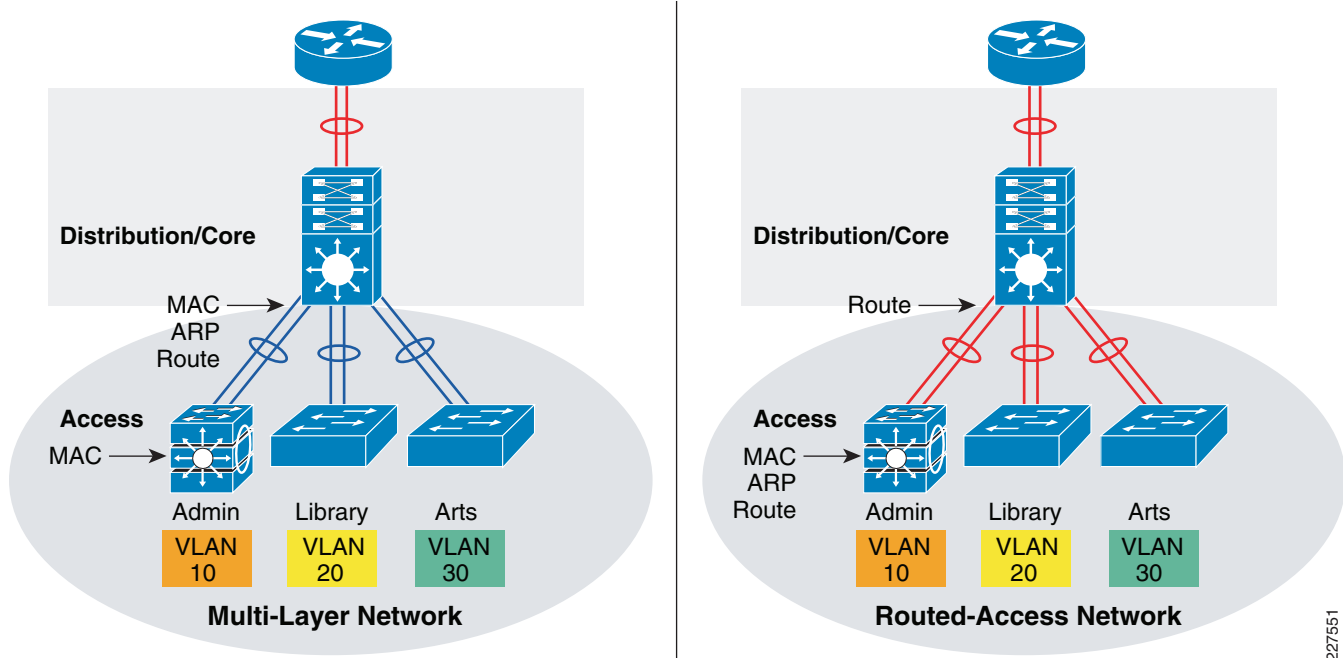

This section provides implementation and best practices guidelines to deploy routed-access in the access-distribution block. The routed access design moves the boundary between Layer 2 and Layer 3 from the distribution layer to the access layer as seen in [Figure 3-19](#).

Figure 3-19 Control Function in Multi-Layer and Routed-Access Network Design

Routing in the access-layer simplifies configuration, optimizes distribution performance, and improves end-to-end troubleshooting tools. Implementing routing in the access-layer replaces Layer-2 trunk configuration with single point-to-point Layer-3 interface in distribution layer. Placing Layer-3 function one tier down on access-switches, changes the multilayer network topology and forwarding path. Implementing Layer-3 function in the access-switch does not require a physical or logical link reconfiguration; the same EtherChannel in access-distribution block can be used.

At the network edge, Layer-3 access-switches provides an IP gateway and become the Layer-2 demarcation point to locally connected endpoints that could be logically segmented into multiple VLANs. Following are the benefits of implementing routed-access in the access-distribution block:

- Eliminates the need to implement STP and the STP toolkit in the distribution layer. As a best practice, STP toolkit must be hardened at the access-layer.
- Shrinks the Layer-2 fault domain, which minimizes the number of endpoints affected by a DoS/DDoS attack.
- Improves Layer-3 uplink bandwidth efficiency by suppressing Layer-2 broadcasts at the access edge port.
- Improves performance by reducing resource utilization in collapsed core-distribution layer. In a large multilayer network, the aggregation layer may consume more CPU cycles due to the large number of MAC and ARP discovery and processing and storing required for each end-station. Routed-access reduces the load of this Layer-2 processing and storage in the distribution layer, by moving the load to layer-3 access-switches. [Figure 3-20](#) illustrates where Layer-2 and Layer-3 forwarding entry processing and storage takes place when access-distribution block is implemented as multi-layer versus routed-access network.

Figure 3-20 Forwarding entry development in multi-tier network

While the routed access design is appropriate for many school networks it is not suitable for all environments. Routed access does not allow a VLAN to span multiple access switches. Refer to following URL for detailed design guidance for the routed access distribution block design:

<http://www.cisco.com/en/US/docs/solutions/Enterprise/Campus/routed-ex.html>

Implementing EIGRP Routing in Access-Distribution Block

The School Service Ready Architecture uses EIGRP routing protocol, and all the devices in the LAN and WAN sub-networks are deployed in a single AS. This subsection focuses on implementing EIGRP in the access-distribution block. All the deployment and configuration guidelines in this section are the same for deploying in the district office or school site network.

Following is the example configuration to enable basic EIGRP routing in the distribution layer and in the access layer:

Distribution

```
cr24-4507-DO(config)#interface Port-channel13
cr24-4507-DO(config-if)# description Connected to cr24-3560r-DO
cr24-4507-DO(config-if)#no switchport
cr24-4507-DO(config-if)# ip address 10.125.32.0 255.255.255.254
```

```
cr24-4507-DO(config)#router eigrp 100
cr24-4507-DO(config-router)# no auto-summary
cr24-4507-DO(config-router)# eigrp router-id 10.125.100.1
cr24-4507-DO(config-router)# network 10.125.0.0 0.0.255.255
```

```
cr24-4507-DO#show ip eigrp neighbor port-channel 13
```

```
EIGRP-IPv4:(100) neighbors for process 100
```

H	Address	Interface	Hold (sec)	Uptime	SRTT (ms)	RTO	Q	Seq Cnt	Num
3	10.125.32.1	Po13	14	00:02:14	2		200	0	385

Access

```

cr24-3560r-DO(config)#interface Loopback0
cr24-3560r-DO(config-if)# ip address 10.125.100.4 255.255.255.255
cr24-3560r-DO(config-if)#
cr24-3560r-DO(config-if)#interface Port-channel1
cr24-3560r-DO(config-if)# description Connected to cr24-4507-DO
cr24-3560r-DO(config-if)# no switchport

Building EIGRP Network Boundary

EIGRP creates and maintains a single flat routing network topology between EIGRP peers. Building a single routing domain enables complete network visibility and reach ability between all of the elements within the network.(access, distribution, core, data center, WAN, etc)

In a tiered design, the access layer always has a single physical or logical forwarding path to the distribution layer. The access switch will build a forwarding topology pointing to same distribution switch as a single Layer-3 next-hop. Since the distribution switch provides a gateway function to the access switch, the routing design can be optimized with the following two techniques to improve performance and network convergence in the access-distribution block:

- Deploy Layer 3 access-switch in EIGRP stub mode
- Summarize network view to Layer-3 access-switch for intelligent routing function

Deploy Layer 3 Access-Switch in EIGRP Stub Mode

The Layer-3 access switch can be deployed to announce itself as a stub router that acts as a non-transit router and does not connect any other Layer-3 stub or non-stub routers. Announcing itself as a non-transit stub Layer-3 router is one way to notify the distribution router that it should not include the Layer-3 access switch in the EIGRP topology recomputation process. This optimized recomputation process will prevent unnecessary EIGRP network queries, which reduces network traffic, and simplifies the route computation.

As illustrated in [Figure 3-21](#), implementing EIGRP stub function in the access switches, greatly reduces the number of EIGRP network queries.

Figure 3-21 EIGRP Query Path with and without Stub Implementation

EIGRP stub router in Layer-3 access-switch can announce routes to a distribution-layer router with great flexibility.

EIGRP stub router can be deployed to announce routes dynamically discovered or statically configured. Best practice design is to deploy EIGRP stub router to announce locally learned routes to aggregation layer.

Following is the example configuration to enable EIGRP stub routing in the Layer-3 access-switch, no configuration changes are required in distribution system:

Access

Stub Peer Advertising (CONNECTED) Routes Suppressing queries

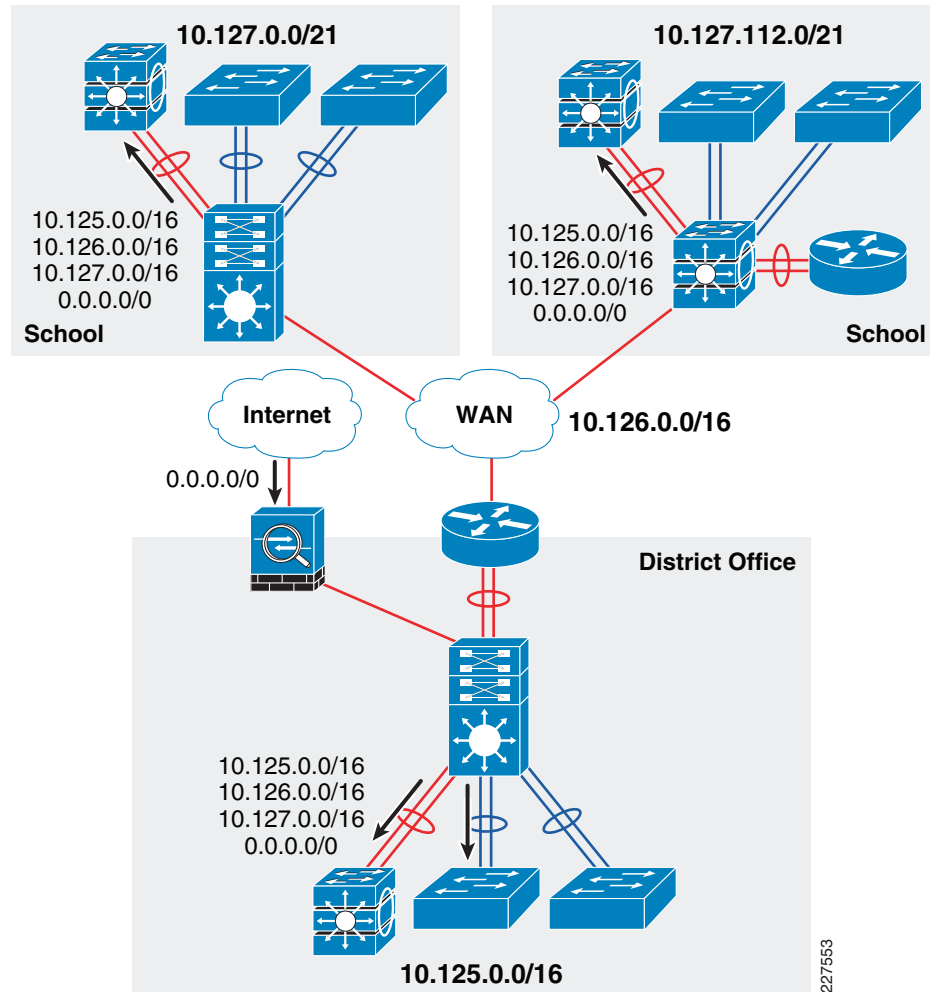

Summarizing Stub Routed-Access Network

Enabling the EIGRP stub function on the access switch does not change the distribution router behavior of forwarding the full EIGRP topology table. The Distribution router must be configured to advertise summarized routes that do not compromise end-to-end reach ability, and help access switches maintain minimal routing information. In a network with a well designed IP addressing scheme, the aggregation system can advertise summarized routes in a classless address configuration, that reduce individual network advertisements, improve network scalability and network convergence. The distribution router must have full network topology information to ensure efficient reachability paths. Therefore, it is recommended to summarize at the distribution router, and not summarize at the access-layer.

Route summarization must be implemented on the distribution layer of district office and each school site network. This includes devices such as the WAN aggregation in the district office. The distribution router must advertise the following summarized network information to Layer 3 access-switch:

- *Local Network*—Distribution router can be implemented in hybrid access-distribution configuration that interconnects several multi-layer or routed-access enabled access-layer switches. Independent of route origination source (connected or dynamic route) and network size within the access-distribution block, the distribution router in district office and school site network must advertise a single, concise and summarized Layer 3 network to each Layer 3 access-switch and to core devices.
- *Remote Network*—Summarized network will be propagated dynamically across the network. Single summarization of all remote networks may be advertised to local Layer 3 access-switches, since it improves bandwidth efficiency. During a network outage, Layer 3 access-switch may drop traffic at the network edge instead of transmitting it to the distribution router to black hole traffic.
- *WAN Network*—Announcing a single summarized WAN network provides flexibility to troubleshoot and verify network availability.
- *Default Network*—When Layer 3 access-switch receives un-known destination traffic from the edge that does not match any of the above mentioned summarized networks, then it is sent to the distribution router to make a forwarding decision. The distribution router performs a forwarding table lookup and may forward to appropriate path or black hole the traffic. In a typical school environment, a default route is announced by an Internet edge system, to forward all internet traffic. Distribution router must propagate this default route to the Layer 3 access-switch.

Figure 3-22 illustrates a summarized EIGRP network advertisement, by route aggregation system, that provides end-to-end internal and external network reachability.

Figure 3-22 End-to-End Routed-Access Network

Following is configuration example to deploy summarized and filtered Layer-3 network information to Layer-3 access-switch.

```

EIGRP Adjacency Protection

EIGRP adjacency protection guidelines discussed earlier for the core network, apply equally to routed access in the access-distribution block. The two challenges, system efficiency, and network security also apply equally to the routed access design, and the same solution is applied:

- System efficiency—EIGRP hello transmission must be blocked on an interface where there are no trusted EIGRP neighbors, to reduce CPU utilization and prevent network attacks. EIGRP routing process should only be enabled on interfaces where trusted school devices are connected. All other interfaces can be suppressed in passive mode.

Following is the example configuration on Layer-3 access-switch that advertises networks enabled on SVI interfaces; however, keeps them in passive mode and explicitly allows EIGRP function on uplink port-channel to distribution router. Same configuration principle must be applied on each EIGRP router including distribution and core routers:

```

cr24-3560r-DO(config)#router eigrp 100
cr24-3560r-DO(config-router)# network 10.125.0.0 0.0.255.255
cr24-3560r-DO(config-router)# passive-interface default

cr24-3560r-DO(config-if)# ip authentication key-chain eigrp 100 eigrp-key
```

Tuning EIGRP Protocol Timers

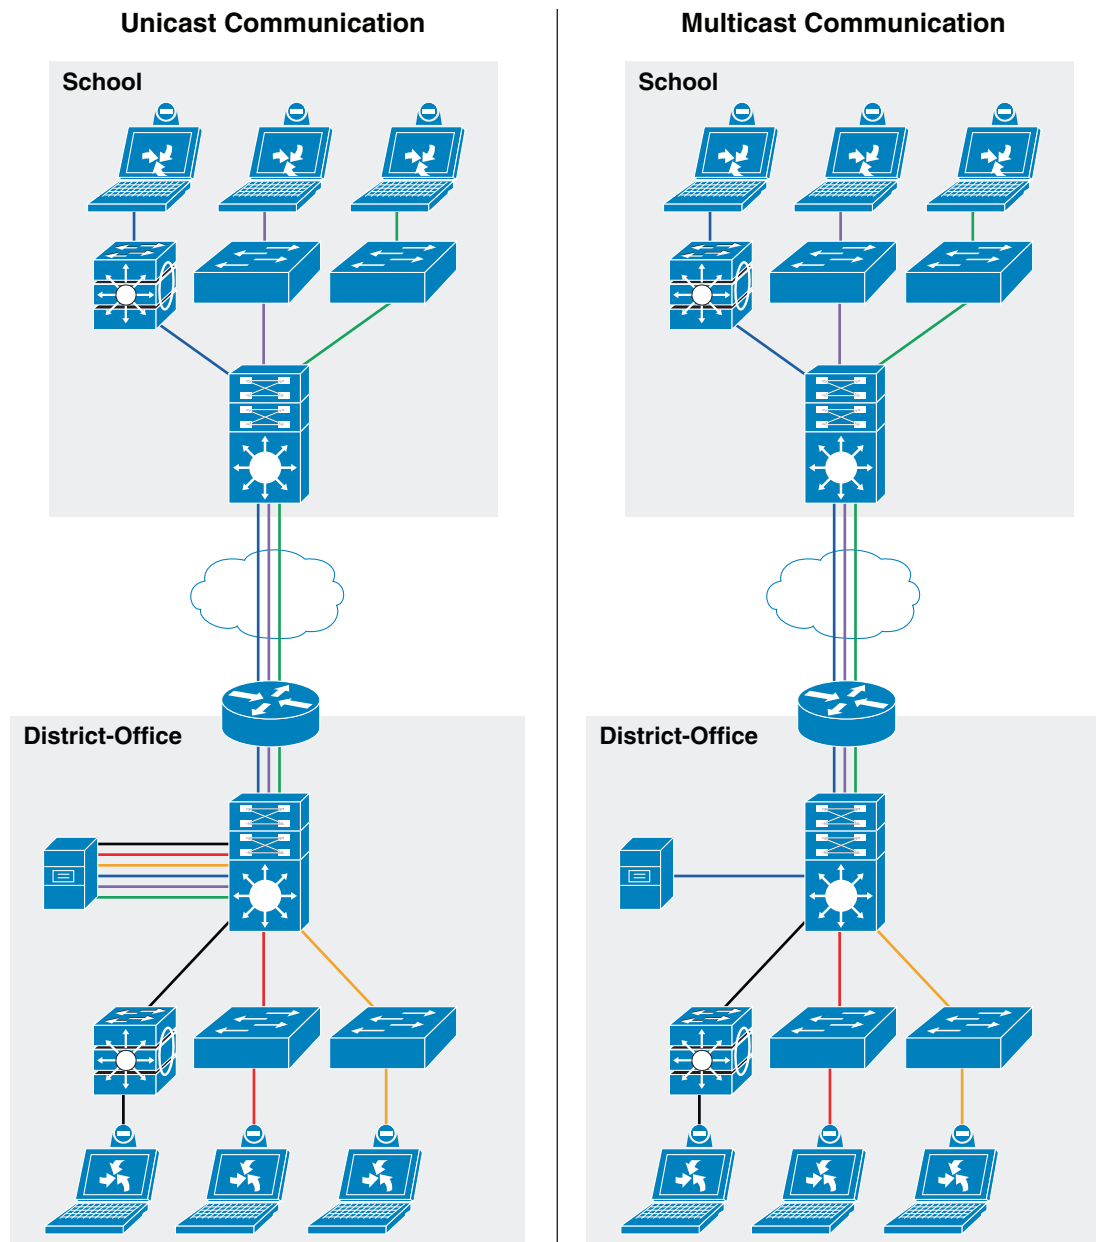

EIGRP protocol functions the same in routed-access as it does in the core network. It is highly recommended to retain default EIGRP hello and hold timers on distribution and Layer 3 access-switch and rely on EtherChannel and SSO-based recovery mechanisms, that offers sub-second network convergence, during individual link or supervisor failure scenarios.

Deploying Multicast in School Network

Communications in a IP network can be:

- Unicast—One source sends a message to one destination
- Broadcast—One source sends a message to all destinations
- Multicast—One source sends a message to a subset of destinations

IP multicast allows a source to transmit a message as a group transmission to a subset of hosts on the network. Many collaboration applications, such as video conferencing, distance learning, software distribution, utilize multicast techniques. IP multicast improves network bandwidth utilization, by reducing unnecessary duplicate traffic. Multicast improves efficiency by reducing data processing on the source server, and sending a single flow into the network. Multicast packets are replicated in the network where paths diverge, by Protocol Independent Multicast (PIM) enabled routers, and other supporting multicast protocols. See [Figure 3-23](#).

Figure 3-23 Unicast versus Multicast Communication in School Network

227554

Multicast IP Addressing

The Internet Assigned Numbers Authority (IANA) controls the assignment of IP multicast addresses. A range of class D address space is assigned for IP multicast applications. All multicast group addresses fall in the range of 224.0.0.0 through 239.255.255.255. In IP multicast packets, the destination IP address is in the multicast group range, while the source IP address is always in the unicast address range. The multicast IP address space is further divided into several pools for well-known multicast network protocols, and inter-domain multicast communications as shown in [Table 3-8](#).

Table 3-8 Multicast Address Range Assignments

Application	Address Range
Reserved – Link Local Network Protocols	224.0.0.0/24
Globally Scope – Group communication between organization and Internet	224.0.1.0 – 238.255.255.255
Source Specific Multicast (SSM) – PIM extension for one-to-many unidirectional multicast communication	232.0.0.0/8
GLOP – Inter-domain Multicast group assignment with reserved global Autonomous System (AS)	233.0.0.0/8
Limited Scope – Administratively scope address that remains constrained within local organization or AS. Commonly deployed in enterprise, education and other organization.	239.0.0.0/8

For the Schools SRA network design, the multicast IP addresses must be selected from the Limited Scope pool (239.0.0.0/8).

Multicast Routing Design

Each device between a multicast source and receiver must enable dynamic multicast. The technique for creating a multicast forwarding table is different than unicast routing and switching techniques. Multicast requires Multicast Routing Protocol (MRP) and Dynamic Group Membership (DGM) to enable communication.

Multicast Routing Protocol

IP multicast delivers source traffic to multiple receivers using the least amount of network resources, without placing additional burden on the source or the receivers. Multicast packet replication in the network is performed by Cisco routers and switches enabled with Protocol Independent Multicast (PIM) and other multicast routing protocols.

The network must build a packet distribution tree that specifies a unique forwarding path between the source subnet and each multicast group members subnet. A primary goal for the tree is to ensure that only one copy of each packet is forwarded on each branch of the tree. The two basic types of multicast distribution trees are source trees and shared trees:

- **Source trees**—The simplest form of a multicast distribution tree is a source tree, with the source at the root and the receivers at the branches. Because this tree uses the shortest path through the network, it is also referred to as a shortest path tree (SPT).
- **Shared trees**—A shared tree uses a single common root placed at a chosen point in the network. This shared root is called a Rendezvous Point (RP).

PIM protocol has two modes which support both types of multicast distribution trees:

- **Dense Mode**—This mode assumes that most routers in the network will distribute multicast traffic to each multicast group. PIM-DM builds distribution trees by initially flooding the entire network and then pruning back the small number of paths without receivers.
- **Sparse Mode**—This mode assumes that relatively few routers in the network will be involved in each multicast group. The hosts belonging to the group are usually widely dispersed, as would be the case for most multicast over the WAN. PIM-SM begins with an empty distribution tree and adds branches only as the result of explicit IGMP requests to join.

It is recommended to deploy multicast in PIM-SM in the Schools SRA. All the recommended platforms in this design support PIM-SM mode on physical or logical (SVI and EtherChannel) interfaces.

Dynamic Group Membership

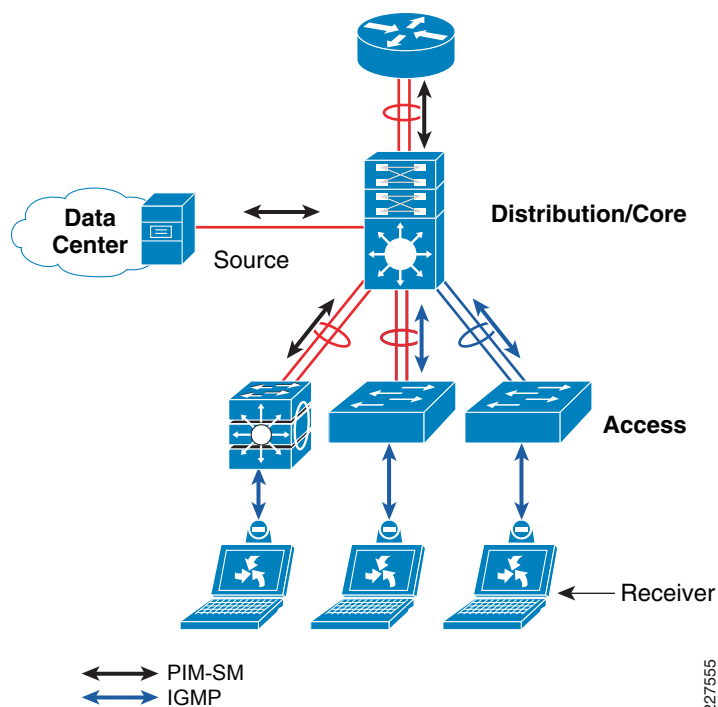

Multicast receiver registration and deletion is done via Internet Group Management Protocol (IGMP) signaling. IGMP operates between a multicast receiver in the access-layer and a collapsed core router at the distribution layer in the district office or the school site.

In a multi-layer design, the layer 3 boundary is at the distribution switch. Multi-layer access-switches do not run PIM, and therefore flood the traffic on all ports. This multi-layer access-switch limitation is solved by using IGMP snooping feature, which is enabled by default. Best practice is to not disable IGMP snooping feature.

In a routed-access network design, the Layer-3 boundary is at the access-layer and IGMP communication is between receiver and access-switch. Along with unicast routing protocol, PIM-SM must be enabled on the Layer 3 access-switch to communicate with RP in the network.

Figure 3-24 demonstrates multicast source and receiver registration procedure and how shared-tree is dynamically developed for multicast data delivery.

Figure 3-24 Multicast Source and Receiver Registration Procedure

Deploying PIM-SM

Multicast data delivery in the network is “connection-oriented”. Multicast communication does not get triggered by data, instead it requires a registration procedure to detect the source and receiver and develop the path. Multicast registration procedure is handled by PIM protocol in the network, and when PIM is deployed in Sparse-Mode registration process is handled by RP.

PIM-SM Rendezvous Point

PIM-SM distributes information about active sources by forwarding data packets on the shared tree. Because PIM-SM uses shared trees initially, it requires the use of a RP. It is recommended to deploy the RP close to the multicast source (collapsed core-distribution router in the district office is a good choice). Multicast sources centrally deployed in district office will register themselves with the RP and then data is forwarded down the shared tree to the receivers that could be located anywhere in the network.

PIM-SM supports RP deployment in the following three different modes in the network:

- **Static**—As the name implies, RP must be statically identified and configured on each PIM router in the network. RP load-balancing and redundancy can be achieved using Anycast RP.
- **Auto-RP**—Dynamic method to discover and announce RP in the network. Auto-RP implementation is beneficial when there are multiple RPs and groups that often change in the network. To prevent network reconfiguration during change, RP mapping agent router must be designated in the network to receive RP group announcements and arbitrate conflicts. This capability is part of PIM version 1 specification.
- **BootStrap Router (BSR)**—Performs same task as Auto-RP but different mechanism. This capability is part of PIM version 2 specification. Auto-RP and BSR cannot coexist or interoperate in the same network.

In a small to mid-size multicast network, static RP configuration is best overall, due primarily to the amount of administrative overhead that Auto-RP or BSR introduce. Static RP implementation offers same RP redundancy and load sharing and a simple ACL can be applied to deploy RP without compromising multicast network security. See [Figure 3-25](#).

The diagram illustrates a PIM-SM network topology. At the top, there are two PIM-SM routers connected to a central WAN cloud. Each of these routers is also connected to a PIM-SM RP (Rendezvous Point) located in the middle. The PIM-SM RP is connected to a Data Center Source. Below the PIM-SM RP, there is another PIM-SM router connected to it. The entire network is connected via a central WAN cloud.

Distribution - RP

Layer 3 Access

School Core

227556

Upon successful PIM-SM RP implementation throughout the school network, PIM-SM must be enabled on Layer-3 edge and core network-facing ports. The following sample configuration provides a simple PIM-SM implementation guideline to be implemented on every intermediate Layer-3 systems between receiver and source:

Distribution - RP

```
! District Office - Access Network

10.125.11.1      Vlan11v2/S      0      30     1      10.125.11.1
```

Implementing IGMP

By default the Layer-2 access-switch will dynamically detect IGMP hosts and multicast-capable Layer-3 routers in the network. The IGMP snooping and multicast router detection functions on a per VLAN basis, and is globally enabled by default for all the VLANs. The IGMP configuration can be validated using the show command on the Layer-2 access-switch:

```
cr24-2960-DO#show ip igmp snooping
Global IGMP Snooping configuration:
-----
IGMP snooping           : Enabled
IGMPv3 snooping (minimal) : Enabled
Report suppression      : Enabled
TCN solicit query       : Disabled
TCN flood query count    : 2
Robustness variable     : 2
Last member query count  : 2
Last member query interval : 1000

cr24-2960-DO#show ip igmp snooping mrouter
Vlan    ports
-----  -
101     Po1(dynamic)
102     Po1(dynamic)

cr24-2960-DO#show ip igmp snooping group
Vlan    GroupType    Version    Port List
-----  -
101     239.192.51.1igmp    v2        Fa0/1, Po1
101     239.192.51.2igmp    v2        Fa0/2, Po1
```

Multicast routing function changes when the access-switch is deployed in routed-access mode. PIM operation is performed at the access layer, therefore multicast router detection process is eliminated. The following output from a Layer-3 switch verifies that the local multicast ports are in router mode, and provide a snooped Layer-2 uplink port-channel which is connected to the collapsed core router, for multicast routing:

```
cr24-3560r-DO#show ip igmp snooping mrouter
Vlan    ports
-----  -
11      Router
12      Router

cr24-3560r-DO#show ip igmp membership | inc Channel|Vl

```

Multicast Security—Preventing Rogue Source

This section provides basic multicast security configuration guidelines to prevent an unauthorized host in the network from acting like a rogue source in the network and sending multicast traffic.

In a PIM-SM network, an unwanted traffic source can be controlled with the pim accept-register command. When the source traffic hits the first-hop router, the first-hop router (DR) creates (S,G) state and sends a PIM Source Register message to the RP. If the source is not listed in the accept-register filter list (configured on the RP), then the RP rejects the Register and sends back an immediate Register-Stop

message to the DR. The drawback with this method of source-filtering is that the pim accept-register command on the RP, PIM-SM (S,G) state is still created on the source's first-hop router. This can result in traffic reaching receivers local to the source and located between the source and the RP. Furthermore, the pim accept-register command works on the control plane of the RP, which could be used to overload the RP with “fake” register messages, and possibly cause a DoS condition.

Best practice is to apply the pim accept-register command on the RP in addition to other edge-filtering methods, such as simple data plane ACLs on all DRs and on all ingress points into the network. While ingress ACLs on the DR are sufficient in a perfectly configured and operated network, best practice includes configuring the pim accept-register command on the RP in the district office as a secondary security mechanism in case of misconfiguration on the edge routers.

Following is the sample configuration with a simple ACL which has been applied to the RP to filter only on the source address. It is also possible to filter the source and the group with the use of an extended ACL on the RP:

Distribution-RP

```
cr24-4507-DO(config)#ip access-list extended PERMIT-SOURCES
cr24-4507-DO(config-ext-nacl)# permit ip 10.125.31.80 0.0.0.15 239.192.0.0 0.0.255.255

cr24-4507-DO(config)#ip pim accept-register list PERMIT-SOURCES
```

Multicast Security—Preventing Rogue RP

Any router can be misconfigured or maliciously advertise itself as a multicast RP in the network, with the valid multicast group address. With a static RP configuration, each PIM-enabled router in the network can be configured to use the static RP for the multicast source and ignore any Auto-RP or BSR multicast router announcement.

Following is the sample configuration that must be applied to each PIM-enabled router in the district office and school sites, to accept PIM announcements only from the static RP and ignore dynamic multicast group announcement from any other RP:

Distribution-RP

```
cr24-4507-DO(config)#ip access-list standard Allowed_MCAST_Groups
cr24-4507-DO(config-std-nacl)# permit 224.0.1.39
cr24-4507-DO(config-std-nacl)# permit 224.0.1.40
cr24-4507-DO(config-std-nacl)# permit 239.192.0.0 0.0.255.255

cr24-4507-DO(config)#ip pim rp-address 10.125.100.100 Allowed_MCAST_Groups override

cr24-4507-DO#show ip pim rp mapping
PIM Group-to-RP Mappings
Acl: Allowed_MCAST_Groups, Static-Override
RP: 10.125.100.100 (?)
```

Deploying QoS in School Network

IP networks forward traffic on a best-effort basis by default. The routing protocol forwards packets over the best path, but offers no guarantee of delivery. This model works well for TCP-based data applications that adapt gracefully to variations in latency, jitter, and loss. The Schools Service Ready Architecture is a multi-service network design which supports voice and video as well as data traffic on a single network. Real time applications (such as voice, video) require packets delivered with in specified loss, delay and jitter parameters. Quality-of-Service (QoS) is a collection of features which allows the network to dedicate network resources for higher priority real time applications, while reserving sufficient network resources to service lower priority traffic. QoS accomplishes this by providing differentiated services, depending on the traffic type. For a detailed discussion of QoS, refer to the Enterprise QoS SRND at the following URL:

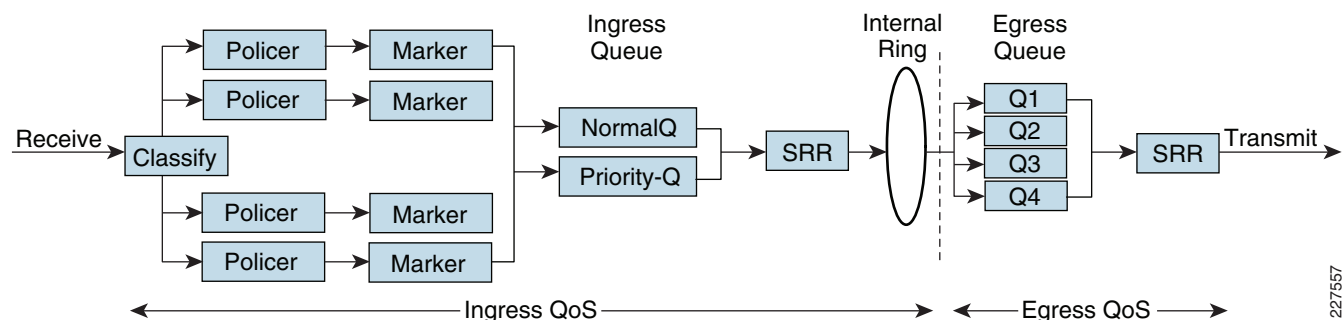

http://www.cisco.com/en/US/docs/solutions/Enterprise/WAN_and_MAN/QoS_SRND/QoS-SRND-Book.html

While design principles are common, QoS implementation varies between fixed-configuration switches and the modular switching platforms like the Cisco Catalyst 4500/6500. This section discusses the internal switching architecture and the differentiated QoS structure on a per-hop-basis.

QoS in Catalyst Fixed Configuration Switches

The QoS implementation in Cisco Catalyst 2960, 2975, 3560G, 3560-E, 3750G and 3750-E Series switches is similar. There is no difference in ingress or egress packet classification, marking, queuing and scheduling implementation among these Catalyst platforms. The Cisco Catalyst switches allow users to create a policy-map by classifying incoming traffic (Layer 2 to Layer 4). Catalyst switches allow attaching the policy-map to an individual physical port or to logical interfaces (SVI or port-channel). This creates a common QoS policy which may be used in multiple networks. To prevent switch fabric and egress physical port congestion, the ingress QoS policing structure can strictly filter excessive traffic at the network edge. All ingress traffic from edge ports passes through the switch fabric and congestion may occur at the egress ports. Congestion in access-layer switch can be prevented by tuning queuing scheduler and Weighted Tail Drop (WTD) drop parameters. See Figure 3-26.

Figure 3-26 Fixed Configuration Catalyst QoS Architecture

The main difference between these platforms is the switching capacity which ranges from 1G to 10G. The switching architecture and some of the internal QoS structure differs between these switches also. Following are some important differences to consider when selecting the access switch:

- The Catalyst 2960 and 2975 do not support multilayer switching and do not support per-VLAN or per-port/per-VLAN policies.

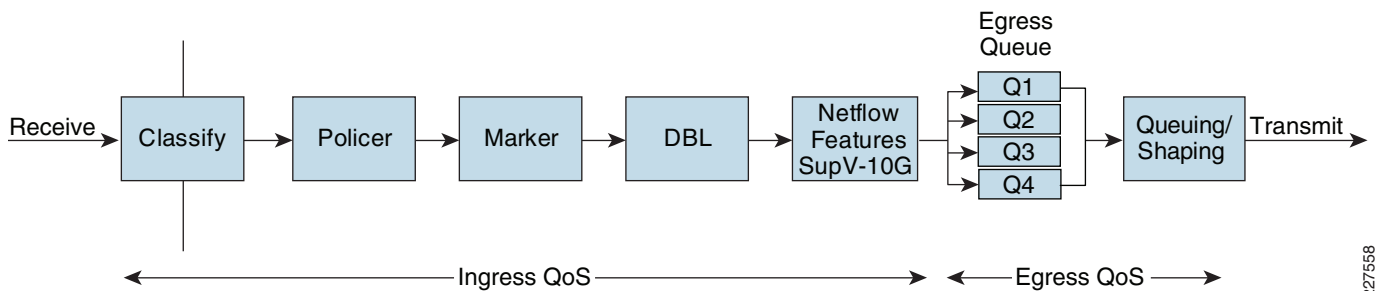

- The Catalyst 2960 and 2975 can police to a minimum rate of 1 Mbps; all other switches within this product family can police to a minimum rate of 8 kbps.
- Only the Catalyst 3650-E and 3750-E support IPv6 QoS.
- Only the Catalyst 3650-E and 3750-E support policing on 10 Gigabit Ethernet interfaces.
- Only the Catalyst 3650-E and 3750-E support SRR shaping weights on 10 Gigabit Ethernet interfaces

QoS in Cisco Modular Switches

Cisco Catalyst 4500 and 6500 are high density, resilient switches for large scale networks. The School Service Ready Architecture uses the Cisco Catalyst 4500 in the district office and larger school site designs, hence all the QoS recommendations in this section will be based on 4500 architecture. Cisco Catalyst 4500 Series platform are widely deployed with classic and next-generation supervisors.

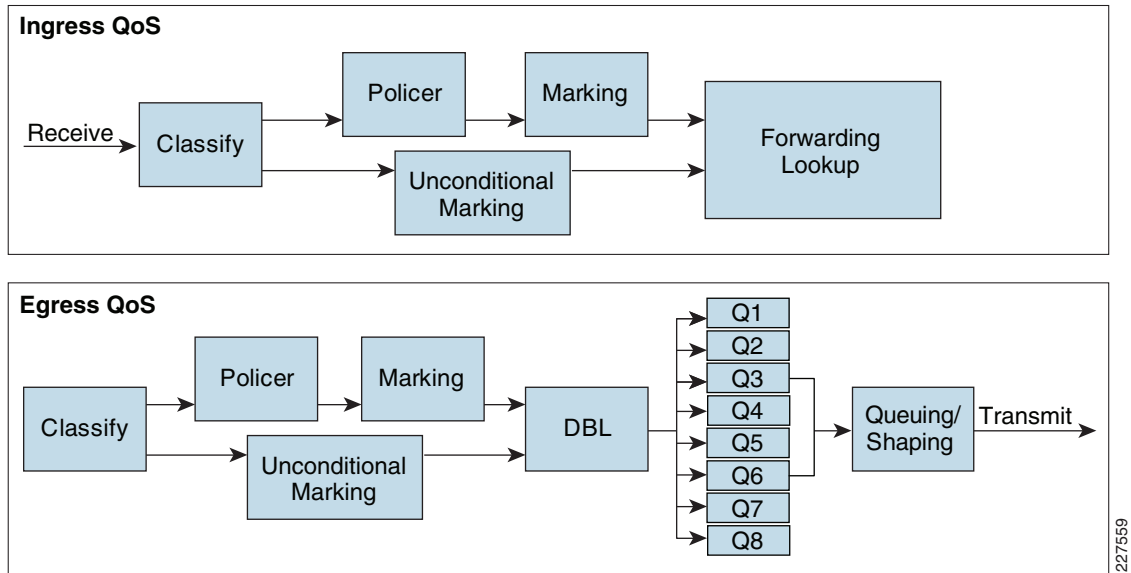

The classification function in the classic supervisor module is based on incoming DSCP or CoS setting in the pack, which was assigned by the access-layer switch. Catalyst 4500 with classic supervisor performs ingress and egress QoS function based on internal mapping table that performs DSCP, ToS, or CoS interworking. Classic supervisor relies on trust model configuration; redirection of ingress traffic to an appropriate queue is based on the trust model defined on the edge port. See [Figure 3-27](#).

Figure 3-27 Catalyst 4500 – Classic Supervisor QoS Architecture

The Cisco Catalyst 4500 with next generation Sup-6E (see [Figure 3-28](#)) is designed to offer better differentiated and preferential QoS services for various class-of-service traffic. New QoS capabilities in the Sup-6E enable administrators to take advantage of hardware-based intelligent classification and take action to optimize application performance and network availability. The QoS implementation in Sup-6E supports Modular QoS CLI (MQC) as implemented in IOS-based routers that overall enhances QoS capabilities and eases implementation and operations. Following are some of the key QoS features which differentiate the Sup-6E versus classic supervisors:

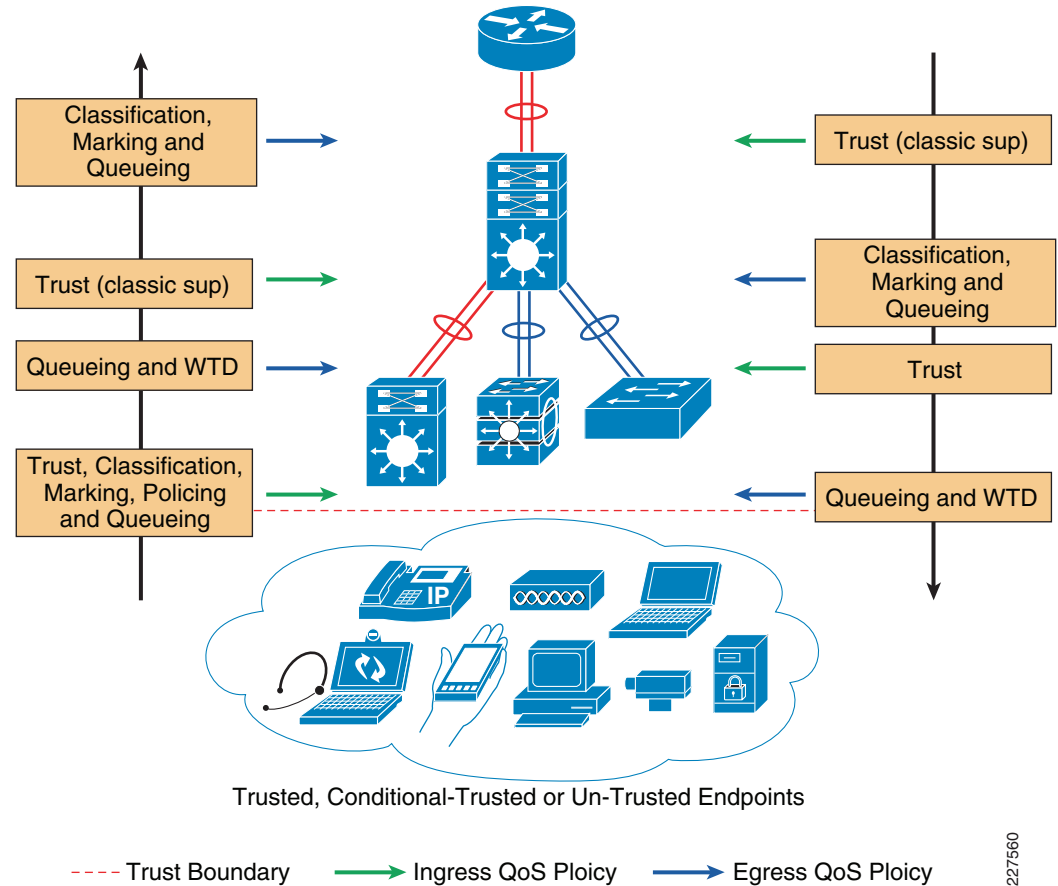

- *Trust and Table-Map*—MQC based QoS implementation offers a number of implementation and operational benefits over classic supervisors that rely on Trust model and internal Table-map as a tool to classify and mark ingress traffic.
- *Internal DSCP*—The queue placement in Sup-6E is simplified by leveraging the MQC capabilities to explicitly map DSCP or CoS traffic in hard-coded egress Queue structure,. For example, DSCP 46 can be classified with ACL and can be matched in PQ class-map of an MQC in Sup-6E.
- *Sequential vs Parallel Classification*—With MQC-based QoS classification, the Sup-6E provides sequential classification rather than parallel. Sequential classification method allows the network administrator to classify traffic at egress based on the ingress markings.

Figure 3-28 Catalyst 4500 – Supervisor 6-E QoS Architecture

QoS Framework

QoS needs to be designed and implemented considering the entire network. This includes defining trust points, and determining which policies to enforce at each device within the network. Developing the trust model, guides policy implementations for each device.

Figure 3-29 depicts QoS trust model that guides QoS policy implementation in the district office and school site networks.

Figure 3-29 School QoS Framework

227560

The devices (routers, switches) within the internal network are managed by the system administrator, and hence are classified as trusted devices. Access-layer switches communicate with devices that are beyond the network boundary and within the internal network domain. QoS trust boundary at the access-layer communicates with various devices that could be deployed in different trust models (Trusted, Conditional-Trusted, or Un-Trusted). This section discusses the QoS policies for the traffic that traverses access-switch QoS trust boundary. The QoS function is unidirectional; it provides flexibility to set different QoS policies for traffic entering the network versus traffic that is exiting the network. See [Figure 3-30](#).

Figure 3-30 School Network Edge QoS Boundary

QoS Trust Boundary

The access-switch provides the entry point to the network for end devices. The access-switch must decide whether to accept the QoS markings from each endpoint, or whether to change them. This is determined by the QoS policies, and the trust model with which the endpoint is deployed.

End devices are classified into one of three different trust models; each with its own unique security and QoS policies to access the network:

- *Untrusted*—An unmanaged device that does not pass through the network security policies. For example, student-owned PC or network printer. Packets with 802.1p or DSCP marking set by untrusted endpoints are reset to default by the access-layer switch at the edge. Otherwise, it is possible for an unsecured user to take away network bandwidth that may impact network availability and security for other users.
- *Trusted*—Devices that pass through network access security policies and are managed by network administrator. For example, secure PC or IP endpoints (i.e., servers, cameras, DMP, wireless access points, VoIP/video conferencing gateways, etc). Even when these devices are network administrator maintained and secured, QoS policies must still be enforced to classify traffic and assign it to the appropriate queue to provide bandwidth assurance and proper treatment during network congestion.
- *Conditionally-Trusted*—A single physical connection with one trusted endpoint and an indirect untrusted endpoint must be deployed as conditionally-trusted model. The trusted endpoints are still managed by the network administrator, but it is possible that the untrusted user behind the endpoint may or may not be secure. For example, Cisco Unified IP Phone + PC. These deployment scenarios require hybrid QoS policy that intelligently distinguishes and applies different QoS policy to the trusted and untrusted endpoints that are connected to the same port.

Deploying QoS

The ingress QoS policy at the access-switches needs to be established, since this is the trust boundary, where traffic enters the network. The following ingress QoS techniques are applied to provide appropriate service treatment and prevent network congestion:

- *Trust*—After classifying the endpoint the trust settings must be explicitly set by a network administrator. By default, Catalyst switches set each port in untrusted mode when QoS is enabled.

- *Classification*—IETF standard has defined a set of application classes and provides recommended DSCP settings. This classification determines the priority the traffic will receive in the network. Using the IETF standard, simplifies the classification process and improves application and network performance.
- *Policing*—To prevent network congestion, the access-layer switch limits the amount of inbound traffic up to its maximum setting. Additional policing can be applied for known applications, to ensure the bandwidth of an egress queue is not completely consumed by one application.
- *Marking*—Based on trust model, classification, and policer settings the QoS marking is set at the edge before approved traffic enters through the access-layer switching fabric. Marking traffic with the appropriate DSCP value is important to ensure traffic is mapped to the appropriate internal queue, and treated with the appropriate priority.
- *Queueing*—To provide differentiated services internally in the Catalyst switching fabric, all approved traffic is queued into priority or non-priority ingress queue. Ingress queueing architecture assures real-time applications, like VoIP traffic, are given appropriate priority (eg transmitted before data traffic).

Implementing QoS Trust Mode

By default, QoS is disabled on all Catalyst switches and must be explicitly enabled in global configuration mode. The QoS configuration is the same for a multilayer or routed-access deployment. The following sample QoS configuration must be enabled on all the access-layer switches deployed in district office and school sites.

```
cr24-2960-DO(config)#mls qos
cr24-2960-DO#show mls qos
QoS is enabled
QoS ip packet dscp rewrite is enabled
```

Upon enabling QoS in the Catalyst switches, all physical ports are assigned untrusted mode. The network administrator must explicitly enable the trust settings on the physical port where trusted or conditionally trusted endpoints are connected. The Catalyst switches can trust the ingress packets based on 802.1P (CoS-based), ToS (ip-prec-based) or DSCP (DSCP-based) values. Best practice is to deploy DSCP-based trust mode on all the trusted and conditionally-trusted endpoints. This offers a higher level of classification and marking granularity than other methods. The following sample DSCP-based trust configuration must be enabled on the access-switch ports connecting to trusted or conditionally-trusted endpoints.

Access (Multilayer or Routed-Access)

Trusted Port

```
cr24-2960-DO(config)#interface FastEthernet0/5
cr24-2960-DO(config-if)# description CONNECTED TO IPVS 2500 - CAMERA
cr24-2960-DO(config-if)# mls qos trust dscp

cr24-2960-DO#show mls qos interface f0/5
FastEthernet0/5
trust state: trust dscp
trust mode: trust dscp
trust enabled flag: ena
COS override: dis
default COS: 0
DSCP Mutation Map: Default DSCP Mutation Map
Trust device: none
qos mode: port-based
```

Conditionally-Trusted Port

```
cr24-2960-DO(config)#interface FastEthernet0/3
cr24-2960-DO(config-if)# description CONNECTED TO PHONE
cr24-2960-DO(config-if)# mls qos trust device cisco-phone
cr24-2960-DO(config-if)# mls qos trust dscp
```

```
cr24-2960-DO#show mls qos interface f0/3
FastEthernet0/3
trust state: trust dscp
trust mode: trust dscp
trust enabled flag: ena
COS override: dis
default COS: 0
DSCP Mutation Map: Default DSCP Mutation Map
Trust device: cisco-phone
qos mode: port-based
```

UnTrusted Port

As described earlier, the default trust mode is *untrusted* when globally enabling QoS function. Without explicit trust configuration on Fas0/1 port, the following **show** command verifies current trust state and mode:

```
cr24-2960-DO#show mls qos interface f0/1
FastEthernet0/1
trust state: not trusted
trust mode: not trusted
trust enabled flag: ena
COS override: dis
default COS: 0
DSCP Mutation Map: Default DSCP Mutation Map
Trust device: none
qos mode: port-based
```

Implementing QoS Classification

When creating QoS classification policies, the network administrator needs to consider what applications are present at the access edge (in the ingress direction) and whether these applications are sourced from trusted or untrusted endpoints. If PC endpoints are secured and centrally administered, then endpoint PCs may be considered trusted endpoints. In most deployments, this is not the case, thus PCs are considered untrusted endpoints for the remainder of this document.

Not every application class, as defined in the Cisco-modified RFC 4594-based model, is present in the ingress direction at the access edge; therefore, it is not necessary to provision the following application classes at the access-layer:

- *Network Control*—It is assumed that access-layer switch will not transmit or receive network control traffic from endpoints; hence this class is not implemented.
- *Broadcast Video*—Broadcast video and multimedia streaming server are centrally deployed at the district office and multicast traffic is originated from trusted data center servers and is unidirectional to school site endpoints (and should not be sourced from school endpoints).
- *Operation, Administration and Management*—Primarily generated by network devices (routers, switches) and collected by management stations which are typically deployed in the trusted data center network, or a network control center.

All applications present at the access edge need to be assigned a classification, as shown in Figure 34. Voice traffic is primarily sourced from Cisco IP telephony devices residing in the voice VLAN (VVLAN). These are trusted devices, or conditionally trusted, if users also attach PC's, etc to the same port. Voice communication may also be sourced from PC's with soft-phone applications, like Cisco Unified Personal Communicator (CUPC). Since such applications share the same UDP port range as multimedia conferencing traffic (UDP/RTP ports 16384-32767) this soft-phone VoIP traffic is indistinguishable, and should be classified with multimedia conferencing streams. See Figure 3-31.

Figure 3-31 QoS Classes

Application	PHB	Application Examples	Present at Campus Access-Edge (Ingress)?	Trust Boundary
Network Control	CS6	EIGRP, OSPF, HSRP, IKE		
VoIP	EF	Cisco IP Phone	Yes	Trusted
Broadcast Video		Cisco IPVS, Enterprise TV		
Realtime Interactive	CS4	Cisco TelePresence	Yes	Trusted
Multimedia Conferencing	AF4	Cisco CUPC, WebEx	Yes	Untrusted
Multimedia Streaming	AF3	Cisco DMS, IP/TV		
Signaling	CS3	SCCP, SIP, H.323	Yes	Trusted
Transactional Data	AF2	ERP Apps, CRM Apps	Yes	Untrusted
OAM	CS2	SNMP, SSH, Syslog		
Bulk Data	AF1	Email, FTP, Backup	Yes	Untrusted
Best Effort	DF	Default Class	Yes	Untrusted
Scavenger	CS1	YouTube, Gaming, P2P	Yes	Untrusted

227562

MQC offers scalability and flexibility in configuring QoS to classify all 8 application classes by using match statements or an extended access-list to match the exact value or range of Layer-4 known ports that each application uses to communicate on the network. The following sample configuration creates an extended access-list for each application and then applies it under class-map configuration mode.

```
cr24-3560r-DO(config)#ip access-list extended MULTIMEDIA-CONFERENCING

cr24-3560r-DO(config-cmap)# match access-group name SCAVENGER

```

Implementing Ingress Policer

It is important to limit how much bandwidth each class may use at the ingress to the access-layer for two primary reasons:

- **Bandwidth Bottleneck**—To prevent network congestion, each physical port at trust boundary must be rate-limited. The rate-limit value may differ based on several factors—end-to-end network bandwidth capacity, end-station, and application performance capacities, etc.
- **Bandwidth Security**—Well-known applications like Cisco IP telephony, use a fixed amount of bandwidth per device, based on codec. It is important to police high-priority application traffic which is assigned to the high-priority queue, otherwise it could consume too much overall network bandwidth and impact other application performance.

In addition to policing, the rate-limit function also provides the ability to take different actions on the excess incoming traffic which exceeds the established limits. The exceed-action for each class must be carefully designed based on the nature of application to provide best effort service based on network bandwidth availability. [Table 3-9](#) provides best practice policing guidelines for different classes to be implemented for trusted and conditional-trusted endpoints at the network edge.

Table 3-9 Best Practice Policing Guidelines

Application	Policing Rate	Conform-Action	Exceed-Action
VoIP Signaling	<32 kbps	Pass	Drop
VoIP Bearer	<128 kbps	Pass	Drop
Multimedia Conferencing	<5Mbps ¹	Pass	Drop
Signaling	<32 kbps	Pass	Drop
Transactional Data	<10 Mbps ¹	Pass	Remark to CS1
Bulk Data	<10 Mbps ¹	Pass	Remark to CS1
Best Effort	<10 Mbps ¹	Pass	Remark to CS1
Scavenger	<10 Mbps ¹	Pass	Drop

1. Rate varies based on several factors as defined earlier. This table depicts sample rate-limiting values.

As described in the “[QoS in Catalyst Fixed Configuration Switches](#)” section on page 3-50, the policer capabilities differ in Cisco Catalyst switching platforms. When deploying policer policies on the access-layer switches the following platform limitations must be taken into consideration:

- The Catalyst 2960 and 2975 can only police to a minimum rate of 1 Mbps; all other platforms within this switch-product family can police to a minimum rate of 8 kbps.
- Only the Cisco Catalyst 3650-E and 3750-E support policing on 10 Gigabit Ethernet interfaces.

The following sample configuration shows how to deploy policing for multiple classes on trusted and conditionally-trusted ingress ports in access-layer switches.

Trusted or Conditionally-Trusted Port

```
cr24-3560r-DO(config)#policy-map Phone+PC-Policy
cr24-3560r-DO(config-pmap)# class VVLAN-VOIP
cr24-3560r-DO(config-pmap-c)# police 128000 8000 exceed-action drop
cr24-3560r-DO(config-pmap-c)# class VVLAN-SIGNALING
cr24-3560r-DO(config-pmap-c)# police 32000 8000 exceed-action drop
cr24-3560r-DO(config-pmap-c)# class MULTIMEDIA-CONFERENCING
cr24-3560r-DO(config-pmap-c)# police 5000000 8000 exceed-action drop
cr24-3560r-DO(config-pmap-c)# class SIGNALING
cr24-3560r-DO(config-pmap-c)# police 32000 8000 exceed-action drop
cr24-3560r-DO(config-pmap-c)# class TRANSACTIONAL-DATA
cr24-3560r-DO(config-pmap-c)# police 10000000 8000 exceed-action policed-dscp-transmit
cr24-3560r-DO(config-pmap-c)# class BULK-DATA
cr24-3560r-DO(config-pmap-c)# police 10000000 8000 exceed-action policed-dscp-transmit
cr24-3560r-DO(config-pmap-c)# class SCAVENGER
cr24-3560r-DO(config-pmap-c)# police 10000000 8000 exceed-action drop
cr24-3560r-DO(config-pmap-c)# class DEFAULT
cr24-3560r-DO(config-pmap-c)# police 10000000 8000 exceed-action policed-dscp-transmit
```

All ingress traffic (default class) from untrusted endpoint must be policed without explicit classification that requires differentiated services. The following sample configuration shows how to deploy policing on untrusted ingress ports in access-layer switches:

UnTrusted Port

```
cr24-3560r-DO(config)#policy-map UnTrusted-PC-Policy
cr24-3560r-DO(config-pmap)# class class-default
cr24-3560r-DO(config-pmap-c)# police 10000000 8000 exceed-action drop
```

Implementing Ingress Marking

Accurate DSCP marking of ingress traffic at the access-layer switch is critical to ensure proper QoS service treatment as traffic traverses through the network. All classified and policed traffic must be explicitly marked using the policy-map configuration based on an 8-class QoS model as shown in [Figure 3-31](#).

Best practice is to use an explicit marking command (**set dscp**) even for trusted application classes (like VVLAN-VOIP and VVLAN-SIGNALING), rather than a trust policy-map action. A trust statement in a policy map requires multiple hardware entries, while the use of an explicit (seemingly redundant) marking command, improves the hardware efficiency.

The following sample configuration shows how to implement explicit marking for multiple classes on trusted and conditionally-trusted ingress ports in access-layer switches:

Trusted or Conditionally-Trusted Port

```
cr24-3560r-DO(config)#policy-map Phone+PC-Policy
cr24-3560r-DO(config-pmap)# class VVLAN-VOIP
cr24-3560r-DO(config-pmap-c)# set dscp ef
cr24-3560r-DO(config-pmap-c)# class VVLAN-SIGNALING
cr24-3560r-DO(config-pmap-c)# set dscp cs3
cr24-3560r-DO(config-pmap-c)# class MULTIMEDIA-CONFERENCING
cr24-3560r-DO(config-pmap-c)# set dscp af41
```

```

cr24-3560r-DO(config-pmap-c)# class SIGNALING
cr24-3560r-DO(config-pmap-c)# set dscp cs3
cr24-3560r-DO(config-pmap-c)# class TRANSACTIONAL-DATA
cr24-3560r-DO(config-pmap-c)# set dscp af21
cr24-3560r-DO(config-pmap-c)# class BULK-DATA
cr24-3560r-DO(config-pmap-c)# set dscp af11
cr24-3560r-DO(config-pmap-c)# class SCAVENGER
cr24-3560r-DO(config-pmap-c)# set dscp cs1
cr24-3560r-DO(config-pmap-c)# class DEFAULT
cr24-3560r-DO(config-pmap-c)# set dscp default

```

All ingress traffic (default class) from an untrusted endpoint must be marked without a explicit classification. The following sample configuration shows how to implement explicit DSCP marking:

Untrusted Port

```

cr24-3560r-DO(config)#policy-map UnTrusted-PC-Policy
cr24-3560r-DO(config-pmap)# class class-default
cr24-3560r-DO(config-pmap-c)# set dscp default

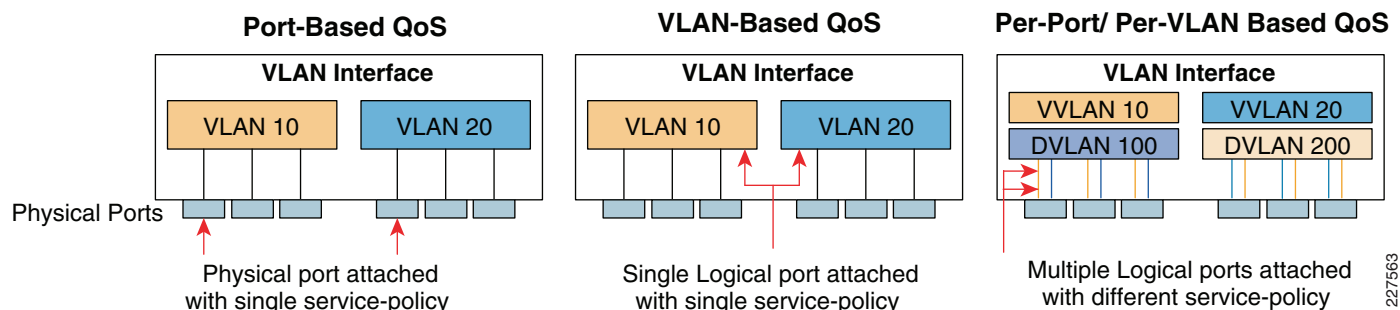

```

Applying Ingress Policies

After creating a complete policy-map with all the QoS policies defined, the service-policy must be applied on the edge interface of the access-layer to enforce the QoS configuration. Cisco Catalyst switches offer three simplified methods to apply service-policies. Depending on the deployment model, any of these methods may be used:

- **Port-based QoS**—Applying service-policy on a per physical port basis will force traffic to pass-through the QoS policies before entering the network. Port-based QoS functions on a per-physical port basis even if the port is associated with a logical VLAN.
- **VLAN-based QoS**—Applying service-policy on per VLAN basis requires the policy-map to be attached to a logical Layer-3 SVI interface. Every physical port associated with the VLAN will require an extra configuration to enforce the QoS policies defined on a logical interface.
- **Per-Port/Per-VLAN-based QoS**—Not supported on all the Catalyst platforms and the configuration commands are platform-specific. Per-port/per-VLAN-based QoS creates a nested hierarchical policy-map that operates on a trunk interface. A different policy-map can be applied on each logical SVI interface that is associated to a single physical port.

Figure 3-32 Depicts All Three QoS Implementation Method

The following sample configuration shows how to deploy port-based QoS on the access-layer switches:

```

cr24-3560r-DO(config)#interface fastethernet0/4
cr24-3560r-DO(config-if)# description CONNECTED TO PHONE+PC

```

```

cr24-3560r-DO(config-if)# service-policy input Phone+PC-Policy

cr24-3560r-DO#show policy-map interface f0/4 | inc Service|Class
Service-policy input: Phone+PC-Policy
Class-map: VVLAN-VOIP (match-all)
Class-map: VVLAN-SIGNALING (match-all)

Class-map: SIGNALING (match-all)
Class-map: TRANSACTIONAL-DATA (match-all)
Class-map: BULK-DATA (match-all)
Class-map: SCAVENGER (match-all)
Class-map: DEFAULT (match-all)
Class-map: class-default (match-any)

```

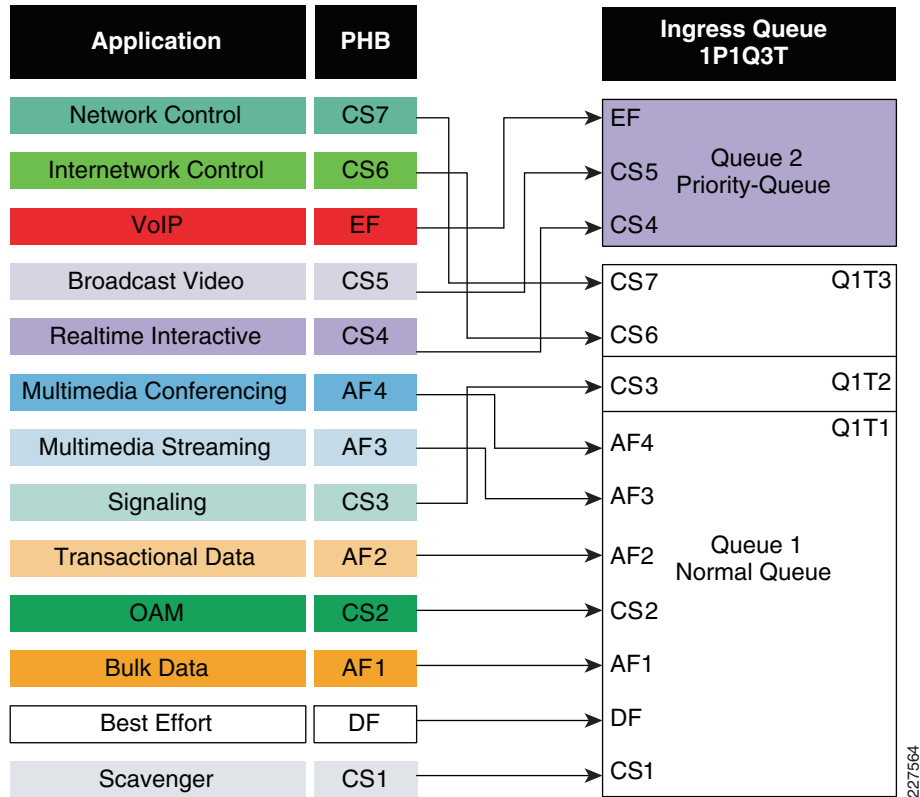

Applying Ingress Queueing

Fixed configuration Cisco Catalyst switches (29xx and 3xxx) not only offer differentiated services on the network ports but also internally on the switching fabric. After enabling QoS and attaching inbound policies on the physical ports, all the packets that meet the specified policy are forwarded to the switching fabric for egress switching. The aggregate bandwidth from all edge ports may exceed switching fabric bandwidth and cause internal congestion.

These platforms support two internal ingress queues: normal queue and priority queue. The ingress queue inspects the DSCP value on each incoming frame and assigns it to either the normal or priority queue. High priority traffic, like DSCP EF marked packets, are placed in the priority queue and switched before processing the normal queue.

The Catalyst 3750-E family of switches supports the weighted tail drop (WTD) congestion avoidance mechanism. WTD is implemented on queues to manage the queue length. WTD drops packets from the queue, based on dscp value, and the associated threshold. If the threshold is exceeded for a given internal DSCP value, the switch drops the packet. Each queue has three threshold values. The internal DSCP determines which of the three threshold values is applied to the frame. Two of the three thresholds are configurable (explicit) and one is not (implicit). This last threshold corresponds to the tail of the queue (100 percent limit).

[Figure 3-33](#) depicts how different class-of-service applications are mapped to the Ingress Queue structure (1P1Q3T) and how each queue is assigned a different WTD threshold.

Figure 3-33 *Ingress Queueing*

The DSCP marked packets in the policy-map must be assigned to the appropriate queue and each queue must be configured with the recommended WTD threshold as defined in Figure 3-33. The following ingress queue configuration must be enabled in global configuration mode on every access-layer switch.

```
cr25-3750-DO(config)#mls qos srr-queue input priority-queue 2 bandwidth 30
! Q2 is enabled as a strict-priority ingress queue with 30% BW

cr25-3750-DO(config)#mls qos srr-queue input bandwidth 70 30
! Q1 is assigned 70% BW via SRR shared weights
! Q1 SRR shared weight is ignored (as it has been configured as a PQ)

cr25-3750-DO(config)#mls qos srr-queue input threshold 1 80 90
! Q1 thresholds are configured at 80% (Q1T1) and 90% (Q1T2)
! Q1T3 is implicitly set at 100% (the tail of the queue)
! Q2 thresholds are all set (by default) to 100% (the tail of Q2)

! This section configures ingress DSCP-to-Queue Mappings

Deploying Egress QoS

The QoS implementation for egress traffic toward the network edge on access-layer switches is much simpler than the ingress traffic QoS. The egress QoS implementation provides optimal queueing policies for each class and sets the drop thresholds to prevent network congestion and application performance impact. Cisco Catalyst switches support 4 hardware queues that are assigned the following policies:

- Real-time queue (to support a RFC 3246 EF PHB service)
- Guaranteed bandwidth queue (to support RFC 2597 AF PHB services)
- Default queue (to support a RFC 2474 DF service)
- Bandwidth constrained queue (to support a RFC 3662 scavenger service)

As a best practice each physical or logical link must diversify bandwidth assignment to map with hardware queues:

- Real-time queue should not exceed 33% of the link's bandwidth.
- Default queue should be at least 25% of the link's bandwidth.
- Bulk/scavenger queue should not exceed 5% of the link's bandwidth.

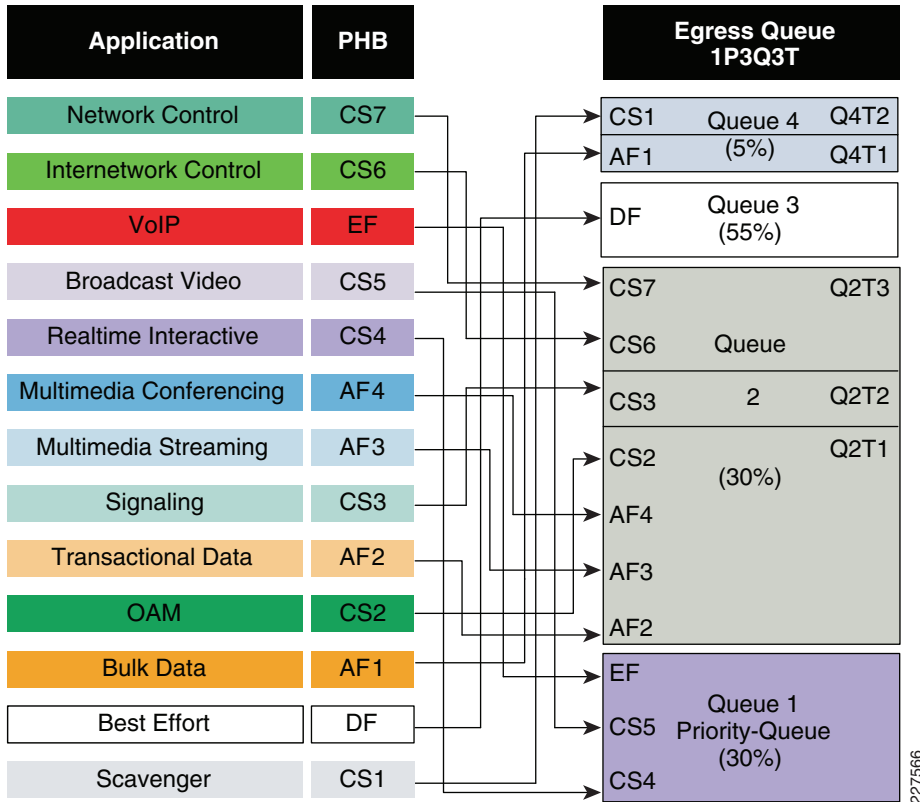

Figure 3-34 shows best practice egress queue bandwidth allocation for each class.

Figure 3-34 Egress QoS

Given these minimum queuing requirements and bandwidth allocation recommendations, the following application classes can be mapped to the respective queues:

- *Realtime Queue*—Voice, broadcast video, and realtime interactive may be mapped to the realtime queue (per RFC 4594).
- *Guaranteed Queue*—Network/internetwork control, signaling, network management, multimedia conferencing, multimedia streaming, and transactional data can be mapped to the guaranteed bandwidth queue. Congestion avoidance mechanisms (i.e., selective dropping tools), such as WRED, can be enabled on this class. If configurable drop thresholds are supported on the platform, these may be enabled to provide intra-queue QoS to these application classes, in the respective order they are listed (such that control plane protocols receive the highest level of QoS within a given queue).
- *Scavenger/Bulk Queue*—Bulk data and scavenger traffic can be mapped to the bandwidth-constrained queue and congestion avoidance mechanisms can be enabled on this class. If configurable drop thresholds are supported on the platform, these may be enabled to provide inter-queue QoS to drop scavenger traffic ahead of bulk data.
- *Default Queue*—Best effort traffic can be mapped to the default queue; congestion avoidance mechanisms can be enabled on this class.

The egress queueing is designed to map traffic, based on DSCP value, to four egress queues, as shown above. The egress QoS model for a platform that supports DSCP-to-queue mapping with a 1P3Q8T queuing structure is depicted in [Figure 3-35](#).

Figure 3-35 Access-Layer 1P3Q3T Egress Queue Model

DSCP marked packets are assigned to the appropriate queue and each queue is configured with appropriate WTD threshold as defined in Figure 3-35. Egress queueing is the same on network edge port as well as on uplink connected to internal network, and it is independent of trust mode. The following egress queue configuration in global configuration mode, must be enabled on every access-layer switch in the network.

```
! This section configures explicit WTD thresholds on Q2 and Q4
cr25-3750-DO(config)#mls qos queue-set output 1 threshold 2 80 90 100 100

Deploying Network Core QoS

All connections between internal network devices that are deployed within the network domain boundary are classified as trusted devices and follow the same QoS best practices recommended in the previous section. Ingress and egress core QoS policies are simpler than those applied at the network edge, See [Figure 3-36](#).

Figure 3-36 School Network Core QoS Boundary

The core network devices are considered trusted and rely on the access-switch to properly mark DSCP values. The core network is deployed to ensure consistent differentiated QoS service across the network. This ensures there is no service quality degradation for high-priority traffic, such as IP telephony or video.

The QoS implementation at the District Office and Larger School Site differ from the Smaller School Site, due to different platforms used as the collapsed core router (Catalyst 4500 vs Catalyst 3750 StackWise).

Deploying District Office or Large School Site Ingress QoS

The district office collapsed core is deployed with Cisco Catalyst 4500 with Supervisor-6E, whereas the Larger School Site collapsed core is deployed with Cisco Catalyst 4500 with either Supervisor-6E or Supervisor-V. The Supervisor-6E product has a redesigned QoS implementation which matches Cisco IOS routers. No ingress QoS configuration is required, since QoS is enabled by default, and all ports are considered trusted.

The Cisco Catalyst 4500 with Supervisor-V requires ingress QoS configuration similar to trusted endpoints in the access-layer. Following is a sample configuration which enables QoS in the Catalyst 4500 with Supervisor-V:

```
cr35-4507-SS1(config)#qos
! Enables QoS function in the switch

cr35-4507-SS1#show qos
QoS is enabled globally
IP header DSCP rewrite is enabled
```

After QoS is globally enabled, all interfaces are in the untrusted mode by default. QoS trust settings must be set on each Layer 2 or Layer 3 port that is physically connected to another device within the network trust boundary. When Cisco Catalyst 4500 is deployed in EtherChannel mode, the QoS trust settings must be applied to every physical member-link and logical port-channel interface. Best practice is to enable trust DSCP settings on each physical and logical interface that connects to another internal trusted device (e.g., access-layer switches in wiring closet or data-center, a router, wireless LAN controller (WLC)).

```
cr35-4507-SS1(config)#interface range Po11 , Gi1/2 , Gi2/2
cr35-4507-SS1(config-if-range)#description Connected to cr35-2960-SS1
cr35-4507-SS1(config-if-range)#qos trust dscp

cr35-4507-SS1#show qos interface Port-channel 11
QoS is enabled globally
Port QoS is enabled
Administrative Port Trust State: 'dscp'
Operational Port Trust State: 'dscp'
Trust device: none
Default DSCP: 0 Default CoS: 0
```

Additional ingress QoS techniques (such as classification, marking, and policing) are not required at the collapsed core layer since these functions are already performed by the access-layer switches. The architecture of Catalyst 4500 with classic or next-generation Supervisor do not need ingress queueing since all of the forwarding decisions are made centrally on the supervisor. There are no additional QoS configurations required at the collapsed core-layer system.

Deploying Small School Site Ingress QoS

The Smaller School Site is deployed using Cisco Catalyst 3750-E StackWise as the collapsed core switch. The QoS implementation remains the same whether deployed as 3750-E StackWise or as a standalone switch. By default, QoS is disabled on the 3750-E switch. Following is a sample configuration to enable QoS in global configuration mode:

```
cr36-3750s-SS100(config)#mls qos
! Enables QoS function in the switch

cr36-3750s-SS100#show mls qos
```

```
QoS is enabled
QoS ip packet dscp rewrite is enabled
```

After QoS is globally enabled, all interfaces are in the untrusted mode by default. QoS trust settings must be set on each Layer 2 or Layer 3 port that is physically connected to another device within the network trust boundary. When Cisco Catalyst 3750-E StackWise Plus is deployed in EtherChannel mode, the QoS trust settings must be applied to every physical member-link. Best practice is to enable trust DSCP settings on each physical and logical interface that connects to another internal trusted device (e.g., access-layer switches in wiring closet or data-center, a router, wireless LAN controller (WLC)).

```
cr36-3750s-SS100(config)#int range gi1/0/49 , gi3/0/49
cr36-3750s-SS100(config-if-range)# description Connected to cr36-2960-SS100
cr36-3750s-SS100(config-if-range)#mls qos trust dscp

cr36-3750s-SS100#show mls qos interface Gi1/0/49
GigabitEthernet1/0/49
trust state: trust dscp
trust mode: trust dscp
trust enabled flag: ena
COS override: dis
default COS: 0
DSCP Mutation Map: Default DSCP Mutation Map
Trust device: none
qos mode: port-based
```

Additional ingress QoS techniques (such as classification, marking, and policing) are not required at the collapsed core layer since these functions are already performed by the access-layer switches. The ingress queueing and DSCP-Ingress-Queue function in 3750-E StackWise Plus must be enabled to allow differentiation between normal versus high-priority traffic. The ingress queueing configuration is consistent with the implementation at the access-edge. Following is a sample configuration for the ingress queues of the Catalyst 3750-E StackWise collapsed core switch:

```
cr36-3750-SS100(config)#mls qos srr-queue input priority-queue 2 bandwidth 30
! Q2 is enabled as a strict-priority ingress queue with 30% BW

cr36-3750-SS100(config)#mls qos srr-queue input bandwidth 70 30
! Q1 is assigned 70% BW via SRR shared weights
! Q1 SRR shared weight is ignored (as it has been configured as a PQ)

cr36-3750-SS100(config)#mls qos srr-queue input threshold 1 80 90
! Q1 thresholds are configured at 80% (Q1T1) and 90% (Q1T2)
! Q1T3 is implicitly set at 100% (the tail of the queue)
! Q2 thresholds are all set (by default) to 100% (the tail of Q2)

! This section configures ingress DSCP-to-Queue Mappings
cr36-3750-SS100(config)# mls qos srr-queue input dscp-map queue 1 threshold 1 0 8 10 12 14

```

Deploying District Office Egress QoS

The district office is deployed with Cisco Catalyst 4500 with Supervisor-6E as the collapsed core router. Egress QoS from the collapsed core router provides optimized queueing and drop thresholds to drop excess low-priority traffic and protect high-priority traffic.

The Supervisor-6E supports up to 8 traffic classes for QoS mapping. It also supports a platform-specific congestion avoidance algorithm to provide Active Queue Management (AQM) with Dynamic Buffer Limiting (DBL). DBL tracks the queue length for each traffic flow in the switch. When the queue length of a flow exceeds its limit, DBL drops packets or sets the Explicit Congestion Notification (ECN) bit in the TCP packet header. With 8 egress (1P7Q1T) queues and DBL capability in the Sup-6E, the bandwidth distribution for each class changes, as shown in [Figure 3-37](#).

Figure 3-37 District Office School Network

Implementing QoS policies on Sup-6E-based Catalyst 4500 platform follows IOS (MQC)-model. The egress QoS implementation bundles the queueing and policing functions on EtherChannel based networks. To provide low-latency for high priority traffic, all lower priority traffic must wait until the priority-queue is empty. Best practice includes implementing a policer along with the priority-queue to provide more fair treatment for all traffic.

The following sample configuration shows how to create an 8-class egress queueing model and protect from high-priority traffic consuming more bandwidth than global policies allow. The egress QoS service-policy must be applied to all the physical EtherChannel member-links connected to different service-blocks (i.e., WAN edge, data center, access-layer switches, etc).

EtherChannel is an aggregated logical bundle interface that does not perform queueing and relies on individual member-links to queue egress traffic. The policer to rate-limit priority class traffic must be implemented on EtherChannel and not on individual member-links since it governs the aggregate egress traffic limits. The following additional policy-map must be created to classify priority-queue class traffic and rate-limit the traffic to 30% of egress link capacity:

```

cr24-4507-DO(config)#class-map match-any PRIORITY-QUEUE
cr24-4507-DO(config-cmap)# match dscp ef
cr24-4507-DO(config-cmap)# match dscp cs5

cr24-4507-DO(config)#interface range Port-Channel 1 , Port-channel 11 - 17
cr24-4507-DO(config-if-range)#service-policy output PQ-POLICER

```

Deploying Large School Site Egress QoS

The large school site is deployed with Cisco Catalyst 4500 and either Supervisor-6E or Supervisor-V as the collapsed core router. If the larger school site network is deployed with Sup-6E, then the configuration is the same as described in the previous section.

The QoS deployment and implementation guidelines differ when the Cisco Catalyst 4500 is deployed with the classic Supervisor-V module. The SupV supervisor can have up to four egress queues like the Cisco Catalyst 29xx and 35xx/37xx Series switches. Before forwarding egress traffic, each packet must be internally classified and placed in the appropriate egress-queue. Placing traffic into different class-of-service queues, will offer traffic prioritization and guaranteed bandwidth to the network. The following sample configuration shows how to implement egress QoS on the Catalyst 4500 with Supervisor-V:

```
cr35-4507-SS1(config)#qos db1
! DBL is globally enabled
cr35-4507-SS1(config)#no qos db1 dscp-based 32
cr35-4507-SS1(config)#no qos db1 dscp-based 40
cr35-4507-SS1(config)#no qos db1 dscp-based 46
! DBL is explicitly disabled on DSCP CS4, CS5 and EF
! as these DSCP values are assigned to the PQ
! and as such should never experience congestion avoidance drops
cr35-4507-SS1(config)#qos db1 exceed-action ecn

Deploying Small School Site Egress QoS

Collapsed Core – Catalyst 3750-E StackWise Plus

The small school site is deployed with Cisco Catalyst 3750-E StackWise as the collapsed core router.

The Catalyst 3750-E can have up to four egress queues. Before forwarding egress traffic, each packet is placed in the appropriate egress-queue as shown in [Figure 3-35](#). The Catalyst 3750-E switch supports Shaped Round Robin (SRR) packet schedule service which can be deployed in two different modes:

- *Shaped*—To provide guaranteed bandwidth, the shaped egress queue reserves some of the bandwidth of the port for each queue. Traffic load exceeding the shape parameter gets dropped. The queue cannot take advantage of excess bandwidth capacity when other queues are not using their bandwidth allocations.
- *Shared*—Shared mode also provides guaranteed bandwidth for each queue; however, it allows the flexibility of using excess bandwidth when there is any available.

The following sample configuration shows how to implement egress QoS on the Catalyst 3750-E:

```

! This section configures explicit WTD thresholds on Q2 and Q4
cr36-3750s-SS100(config)#mls qos queue-set output 1 threshold 2 80 90 100 100
! Q2T1 is set to 80%; Q2T2 is set to 90%

```

```

cr36-3750s-SS100(config)#mls qos queue-set output 1 threshold 4 60 100 100 100
! Q4T1 is set to 60%; all other thresholds for Q4 remain at 100%

```

Building a Resilient Network

The Schools Service Ready Architecture is a high performance, resilient and scalable network design. A network outage may be caused by the system, human error, or natural disaster. The Schools SRA is designed to minimize the impact of a failure regardless of the cause. Network outages may be either planned or unplanned.

- *Planned Outage*—Planned network outage occurs when a portion of the network is taken out of service as part of a scheduled event (e.g., a software upgrade).
- *Unplanned Outage*—Any unscheduled network outage is considered an unplanned outage. Such outages may be caused by internal faults in the network, or devices due to hardware or software malfunctions.

The network is designed to recover from most unplanned outages in less than a second (milliseconds). In many situations, the user will not even notice the outage occurred. If the outage lasts longer (several seconds), then the user will notice the lack of application responsiveness. The network is designed to minimize the overall impact of an unplanned network outage, and gracefully adjust and recover from many outage conditions. Figure 3-38 shows an example of a real-time VoIP application and user impact depending on duration of outage event.

Figure 3-38 VoIP User Impact for Minor and Major Network Outage

Several techniques are used to make the network design more resilient. Deploying redundant devices and redundant connections between devices, enables the network to recover from fault conditions. Identifying critical versus non critical applications, and network resources optimizes cost performance, by focusing on the most important elements of the network design. The resiliency of a system design is often categorized as follows:

- **Network Resiliency**—Provides redundancy during physical link outages (e.g., fiber cut, bad transceivers, incorrect cabling, etc).
- **Device Resiliency**—Protects network during device outage triggered by hardware or software (e.g. software crash, non-responsive supervisor, etc).
- **Operational Resiliency**—Capabilities which provide network availability even during planned network outage conditions - (e.g., ISSU features which enable software upgrades while device is operating).

Figure 3-39 Resiliency Deployment Strategy

227570

The high availability framework is based upon the three resiliency categories described in the previous section. [Figure 3-40](#) shows which technologies are implemented to achieve each category of resiliency.

Figure 3-40 High-Availability Categories and Technologies

Resilient Goal	Network Service Availability		
Resilient Strategies	Network Resiliency	Device Resiliency	Operational Resiliency
Resilient Technologies	EtherChannel UDLD IP Event Dampening	NSF/SSO Stack Wise	ISSU

227571

Redundant Hardware Components

Redundant hardware implementations vary between fixed configuration and modular Cisco Catalyst switches. Selective deployment of redundant hardware is an important element of the Schools SRA design which delivers device resiliency.

Redundant hardware component for device resiliency varies between fixed configuration and modular Cisco Catalyst switches. To protect against common network faults or resets, all critical district office and school campus network devices must be deployed with similar device resiliency configuration. This subsection provides a basic redundant hardware deployment guideline at the access-layer and collapsed core switching platforms in the campus network.

Redundant Power System

Redundant power supplies protect the device from power outage or power supply failure. Protecting the power is not only important for the network device, but also the endpoints that rely on power delivery over the Ethernet network. Redundant power supplies are deployed differently depending on the switch type:

- *Modular Switch*—Dual power supplies can be deployed in the modular switching platforms like the Cisco Catalyst 4500-E. By default, the Cisco Catalyst 4500 power supply operates in 1+1 redundant mode (both power supplies are active).
- *Fixed configuration switch*—Fixed configuration switches are deployed with internal power supplies and they may also use Cisco RPS 2300 external power supply. A single Cisco RPS 2300 power supply has modular power supplies and fans to deliver power to multiple switches. Deploying internal and external power-supplies provides a redundant power solution for fixed configuration switches.

Redundant Network Connectivity

Redundant network connections protect the system from failure due to cable or transceiver faults. Redundant network connections attached to a single fixed configuration switch or network module in the Cisco Catalyst 4500 switch do not protect against internal device hardware or software fault.

Best practice design is to deploy redundant network modules within the Catalyst 4500 switch and the Cisco 3750-E StackWise Plus solution in the small school site collapsed core network. Deploying the 3750-E StackWise Plus in critical access-layer switches in the data center network and in the district office is also best practice. Connecting redundant paths to different hardware elements provides both network and device resiliency.

Figure 3-41 Redundant Network Connectivity

227572

Redundant Control-Plane

The processing software operation is different in standalone or StackWise fixed configuration switches, and on a supervisor module of a modular switch. Network communication and forwarding operations can be disrupted when the processing unit fails, causing a network outage. Network recovery techniques vary based on the different platforms.

The standalone and non-stackable fixed configuration switches like the Cisco Catalyst 2960 or 3560-E feature power redundancy and network resiliency support; however they do not protect against a processing unit failure. During a processing unit failure event, all endpoints attached to the switch are impacted and network recovery time is undeterministic.

Device resiliency in Cisco StackWise and modular switching platforms provides 1+1 redundancy with enterprise-class high availability and deterministic network recovery time.

Cisco StackWise

Cisco Catalyst 2975 and Catalyst 3750-E switches can be deployed in StackWise mode using a special stack cable. Up to nine switches can be integrated into a single stack that delivers distributed forwarding architecture and unified single control and management plane. Device level redundancy in StackWise mode is achieved via stacking multiple switches using the Cisco StackWise technology. One switch from the stack is selected automatically to serve as the master, which manages the centralized control-plane process. Cisco StackWise solution provides 1:N redundancy. In the event of a active master-switch outage, a new master is selected automatically. See [Figure 3-42](#).

Figure 3-42 Cisco Stack Wise Switching Architecture

Since Cisco StackWise enables up to 9 switches to appear as one logical switch, it has centralized management and control functions. Most Layer 2 and Layer 3 functions are centrally performed, however Layer-2 topology development is distributed (i.e., each switch performs the function independently). [Table 3-12](#) lists network protocol functions and identifies which are centralized and which are distributed.

Table 3-12 Cisco StackWise Centralized and Distributed Control-Plane

Protocols		Function
Layer 2 Protocols	MAC Table	Distributed
	Spanning-Tree Protocol	Distributed
	CDP	Centralized
	VLAN Database	Centralized
	EtherChannel - LACP	Centralized
Layer 3 Protocols	Layer 3 Management	Centralized
	Layer 3 Routing	Centralized

Cisco StackWise solution offers network and device resiliency with distributed forwarding. In the event of a master switch outage, Non-Stop Forwarding (NSF) enables packet forwarding to continue based on current state information, while a new master switch is selected. New master switch selection is

accomplished in the range of 700 to 1000 milliseconds; the amount of time to reestablish the control-plane and develop distributed forwarding will vary depending on the size and complexity of the network.

Following is a best practice to reduce Layer-3 disruption in the event of a master switch outage: Determine the master switch with the higher switch priority, and isolate the uplink Layer-3 EtherChannel bundle path by using physical ports from member switches (i.e. don't use the master switches ports for Etherchannel uplinks). With NSF capabilities enabled, this design decreases network downtime during a master-switch outage.

An understanding of SSO and StackWise components and failover events associated with NSF provides significant insight in designing a network that enables supervisor redundancy. The following subsection uses the above concepts and principles to identify the design parameters, and applies them to develop a best-practice hierarchical network with the highest availability.

Cisco Modular Switch

The Cisco Catalyst 4500 modular switch supports redundant supervisors, and Stateful Switch Over (SSO). When deployed along with NSF, the 4500 provides a enterprise-class highly available system with network and device resiliency.

SSO is a Cisco IOS service used to synchronize critical forwarding and protocol state information between redundant supervisors configured in a single chassis. With SSO enabled, one supervisor in the system assumes the role of *active* and the other supervisor becomes the *hot-standby*. Each is ready to backup the other, thus providing 1:1 hot redundancy to protect from a control-plane outage. Since both supervisors are active, the system benefits by using the physical ports from both supervisors during normal operation. SSO synchronizes system services such as DHCP snooping, Switched Port Analyzer (SPAN), security access control lists (ACLs), and QoS policies so ensure the switch provides the same level of protection and service after a supervisor failover event.

NSF enables packets to continue to be forwarded using existing routing table information, during switchover. NSF also provides graceful restart to the routing protocol such that during the failover, the routing protocol remains aware of the change and does not react by resetting its adjacency. If the routing protocol were to react to the failure event, and alter routing path information, the effectiveness of stateful switch over would be diminished.

Operational Resiliency Strategy

Designing the network to recover from unplanned outages is important. It is also important to consider how to minimize the disruption caused by planned outages. These planned outages can be due to standard operational processes, configuration changes, software and hardware upgrades, etc.

The same redundant components which mitigate the impact of unplanned outages can also be used to minimize the disruption caused by planned outages. The ability to upgrade individual devices without taking them out of service is enabled by having internal component redundancy (such as with power supplies, and supervisors) complemented with the system software capabilities. Two primary mechanisms exist to upgrade software in a live network:

- Full-image In-Service Software Upgrade (ISSU) on the Cisco Catalyst 4500 leverages dual supervisors to allow for a full, in-place Cisco IOS upgrade. This leverages the NSF/SSO capabilities of the switch and provides for less than 200 msec of traffic loss during a full Cisco IOS upgrade.
- Network and device level redundancy, along with the necessary software control mechanisms, guarantee controlled and fast recovery of all data flows following a fault condition, and provide the ability to manage the fault tolerant infrastructure during planned outage events.

Validating operational resiliency is beyond the scope of this design guide, refer to CCO documentation for deployment guidelines.

Deploying High Availability in School Network

Many of the design features of the Schools Service Ready Architecture which were described in [“Deploying Schools Foundation Services” section on page 3-15](#), contribute to the network high availability capabilities. This section focuses on how to implement additional features which complete the Schools SRA high availability design.

Network Resiliency

Etherchannel and UDLD are two design features which are included in the network foundation services, which contribute to network resiliency.

Implementing IP Event Dampening

Poor signaling or a loose connection may cause continuous port-flap (port alternates between active state and inactive state). A single interface flapping can impact the stability and availability of the network. Route summarization is one technique which mitigates the impact of a flapping port. Summarization isolates the fault domain with a new metric announcement by the aggregator and thereby hides the local networks fault within the domain.

A best practice to mitigate local network domain instability due to port-flap, is implementing IP Event Dampening on all layer 3 interfaces. Each time the Layer-3 interface flaps the IP dampening tracks and records the flap event. Upon multiple flaps, a logical penalty is assigned to the port and suppresses link status notification to IP routing until the port becomes stable. IP event dampening is a local function and does not have a signaling mechanism to communicate with a remote system. It can be implemented on each individual physical or logical Layer-3 interface: physical ports, SVI or port-channels. Following is an example configuration to implement IP Event Dampening:

Distribution/Core

```
cr24-4507-DO(config)#int range Port1 , Gig5/6 , Gig6/6 , Vlan 101 - 110
cr24-4507-DO(config-if-range)#dampening
```

```
cr24-4507-DO#show interface dampening | be Port
Port-channell Connected to cr24-3750ME-DO
Flaps Penalty Supp ReuseTm HalfL ReuseV SuppV MaxSTm MaxP Restart
0 0 FALSE 0 5 1000 2000 20
16000 0
```

The following output illustrates how the IP event dampening keeps track of port flaps and makes a decision to notify IP routing process based on interface suppression status:

```
cr24-4507-DO#debug dampening interface
cr24-4507-DO#show logging | inc EvD|IF-EvD
```

```
12:32:03.274: EvD(GigabitEthernet5/6): charge penalty 1000, new accum. penalty 1000, flap
count 2
12:32:03.274: EvD(GigabitEthernet5/6): accum. penalty 1000, not suppressed
12:32:03.274: IF-EvD(GigabitEthernet5/6): update IP Routing state to DOWN, interface is
not suppressed
```

```
cr24-4507-DO#show interface dampening | be 5/6
Flaps Penalty Supp ReuseTm HalfL ReuseV SuppV MaxSTm MaxP Restart
2 0 FALSE 0 5 1000 2000 20 16000
0
```

In a multilayer access-distribution design, the Layer-2 and Layer-3 demarcation is at the collapsed core-distribution device. IP event dampening is enabled on per-logical VLAN (SVI) interface basis on the collapsed core device. IP event dampening becomes more effective when each access-layer switch is deployed with a unique set of Layer-2 VLANs.

Assigning unique VLANs on each access-layer switch also helps IP event dampening to isolate the problem and prevent network faults triggered in a multilayer network. The following output illustrates how IP event dampening keeps track of individual logical VLAN networks associated to same Layer-2 physical trunk ports. When a Layer-2 trunk port flaps, the state of SVI also flaps, and forces dampening to track and penalize unstable interfaces:

```
12:58:41.332: EvD(Vlan101): charge penalty 1000, new accum. penalty 2627, flap count 3
12:58:41.332: EvD(Vlan101): accum. penalty 2627, now suppressed with a reuse intervals of
7
12:58:41.332: IF-EvD(Vlan101): update IP Routing state to DOWN, interface is suppressed
```

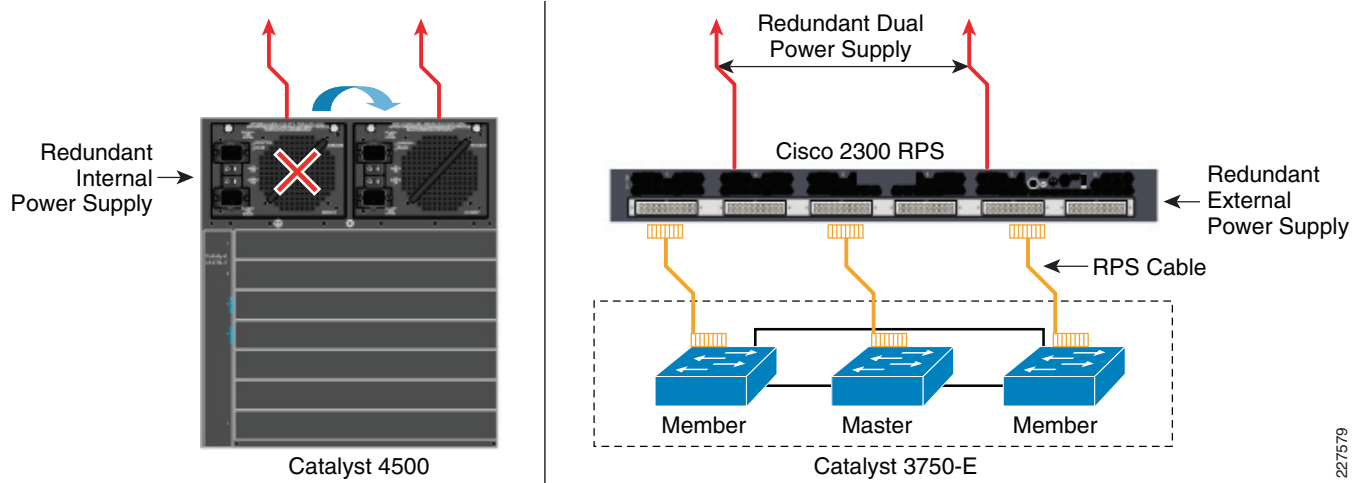

```
cr24-4507-DO#show interface dampening
Vlan101 Connected to cr24_2960_Dept_1_VLAN
Flaps Penalty Supp ReuseTm HalfL ReuseV SuppV MaxSTm MaxP Restart
3 71 FALSE 0 5 1000 2000 20 16000
0
```

Device Resiliency

As described earlier, redundant hardware is an important technique for achieving device resiliency. The Schools SRA network design applies hardware redundancy considering the cost / performance tradeoffs.

Implementing Redundant Power Supply

Redundant power supplies can prevent a system outage due to power outage, power supply or fan hardware failure. All Cisco Catalyst switching platforms supports robust 1+1 redundant power capabilities that can be deployed with internal or external power source management. See [Figure 3-43](#).

Figure 3-43 Cisco Catalyst Internal and External Power Redundancy Option**Catalyst 4500—Redundant Internal Power Supply**

The Cisco Catalyst 4500 provides power to internal hardware components and external devices like IP phones. All the power is provided by the internal power supply. Dual-power supplies in the Catalyst 4500 can operate in one of two different modes:

- **Redundant Mode**—By default, Catalyst 4500 power supply operates in redundant mode offering 1+1 redundant option. The system determines power capacity and number of power supplies required based on the power required for all internal and external power components. Both power supplies must have sufficient power to support all the installed modules and operate in 1+1 redundant mode.

```
cr24-4507-D0(config)#power redundancy-mode redundant
```

```
cr24-4507-D0#show power supplies
Power supplies needed by system      :1
Power supplies currently available   :2
```

- **Combined Mode**—If the system power requirement exceeds the capacity of a single power supply, then both power supplies can be combined to increase the capacity. In this mode, the power system does not provide 1+1 power redundancy. The following global configuration will enable power supplies to operate in combined mode:

```
cr24-4507-D0(config)#power redundancy-mode combined
```

```
cr24-4507-D0#show power supplies
Power supplies needed by system:2
Power supplies currently available:2
```

Catalyst 29xx and 3xxx – Redundant External Power Supply with RPS

Cisco Redundant Power Supply (RPS) 2300 provides up to 6 RPS ports to provide backup power to critical access-layer switches in the school network. Additional power resiliency can be added by deploying dual-power supply to backup to two devices simultaneously. The Cisco RPS 2300 can be provisioned through the Cisco 3750-E or 3560-E Series switches using the enable mode CLI:

```
cr36-3750s-ss100#power rps <switch id> name CiscoRPS
cr36-3750s-ss100#power rps <switch id> port <rps port id> active
```

Implementing Redundant Control Plane System

The collapsed core device in the district office and school sites (Catalyst 4500 or 3750-E StackWise) is deployed with redundant supervisor, or StackWise Plus to enable graceful recovery from switch hardware outage. Any access-switch which is deemed critical may be deployed as StackWise Plus to improve device resiliency. The implementation for each switch is different, and is discussed separately in the sections which follow.

Resilient Cisco StackWise

Cisco Catalyst 2975 supports StackWise, and is used when a resilient layer-2 access switch is required. Cisco Catalyst 3750-E supports StackWise, and is used when a resilient layer 2 or layer 3 access switch is required. Cisco 3750-E StackWise Plus is deployed for the collapsed core in the small school site network.

StackWise switch provisioning is done dynamically by the StackWise protocol. Cisco IOS automatically adjusts the interface addressing and its associated configuration based on the number of provisioned switches in the stack.

```
cr26-2975-DO#show run | inc provision
```

```
switch 1 provision ws-c2975gs-48ps-1
switch 2 provision ws-c2975gs-48ps-1
switch 3 provision ws-c2975gs-48ps-1
```

Master Switch Election

The centralized control-plane and management plane is managed by the master switch in the stack. By default, the master switch selection within the ring is performed dynamically by negotiating several parameters and capabilities between each switch within the stack. Each StackWise-capable switch is by default configured with priority 1.

```
cr26-3750r-DO#show switch
```

```
Switch/Stack Mac Address : 0023.eb7b.e580
```

Switch#	Role	Mac Address	Priority	H/W Version	Current State
* 1	Member	0023.eb7b.e580	1	0	Ready
2	Master	0026.5284.ec80	1	0	Ready
3	Member	0025.eb7b.e680	1	0	Ready

As described in previous section, the Cisco StackWise architecture is not SSO-capable. This means all the centralized Layer-3 functions must be reestablished with the neighbor switch during a master-switch outage. To minimize the control-plane impact and improve network convergence the Layer 3 up links should be diverse, originating from member switches, instead of the master switch. The default switch priority must be increased manually after identifying the master switch and switch number. The new switch priority becomes effective after switch reset.

```
cr26-3750r-DO(config)#switch 2 priority 15
```

```
Changing the Switch Priority of Switch Number 2 to 15
```

```
cr26-3750r-DO#show switch
```

```
Switch/Stack Mac Address : 0026.5284.ec80
```

Switch#	Role	Mac Address	Priority	H/W Version	Current State
1	Member	0023.eb7b.e580	1	0	Ready
* 2	Master	0026.5284.ec80	15	0	Ready
3	Member	0025.eb7b.e680	1	0	Ready

StackWise Layer 3 MAC Management

To provide a single unified logical network view in the network, the MAC addresses of Layer-3 interfaces on the StackWise (physical, logical, SVIs, port channel) are derived from the Ethernet MAC address pool of the master switch in the stack. All the Layer-3 communication from the StackWise switch to the endpoints (like IP phone, PC, servers and core network system) is based on the MAC address pool of the master switch.

```
cr26-3750r-DO#show switch
```

```
Switch/Stack Mac Address : 0026.5284.ec80
```

Switch#	Role	Mac Address	Priority	H/W Version	Current State
1	Member	0023.eb7b.e580	1	0	Ready

```
* 2 Master 0026.5284.ec80      15          0          Ready
   3Member0025.eb7b.e680      1          0          Ready
```

```
cr26-3750r-DO#show version
. . .
Base ethernet MAC Address      : 00:26:52:84:EC:80
. . .
```

After a master-switch outage, the new master switch in the stack assigns new MAC addresses to all Layer-3 interfaces, from the local MAC address pool. Once the new MAC address is assigned, it will force the switch to generate a gratuitous ARP in the network to make sure no other system is using the same MAC address. The default timer to retain the MAC address from the failed master switch is four minutes. While the new MAC address is not assigned on Layer-3 interface and not being propagated and updated in the network, the traffic will blackhole in the network.

```
cr26-3750r-DO#reload slot 2
Proceed with reload? [confirm]
Switch 2 reloading...
```

```
cr26-3750r-DO#show switch
Switch/Stack Mac Address : 0023.eb7b.e580
```

Switch#	Role	Mac Address	Priority	H/W Version	Current State
* 1	Master	0023.eb7b.e580	1		Ready
2	Member	000.0000.0000	0	1	Removed
3	Member	0025.eb7b.e680	1	1	Ready

To prevent this network instability, the old MAC address assignments on Layer-3 interfaces can be retained even after the master switch fails. The new active master switch can continue to use the MAC addresses assigned by the old master switch, which prevents ARP and routing outages in the network. The default **stack-mac timer** settings must be changed in Cisco Catalyst 2975 and 3750-E StackWise switch mode using the global configuration CLI mode as shown below:

```
cr26-3750r-DO(config)#stack-mac persistent timer 0
```

```
cr26-3750r-DO#show switch
Switch/Stack Mac Address : 0026.5284.ec80
Mac persistency wait time: Indefinite
```

Switch#	Role	Mac Address	Priority	H/W Version	Current State
1	Member	0023.eb7b.e580	1		Ready
* 2	Master	0026.5284.ec80	15		Ready
3	Member	0025.eb7b.e680	1		Ready

Non-Stop Forwarding (NSF)

The Cisco Catalyst 3750-E switch in StackWise mode is not SSO-capable. When the master switch fails, the new master switch is required to reform the Layer-3 adjacencies with the neighbors in the network. The forwarding architecture in StackWise switch is designed to provide non-stop forwarding during the master switch outage using NSF technology. Each 3750-E switch in the stack maintains distributed Layer-3 FIB from the old master switch and continues to forward upstream traffic, until they are updated by the new master in the stack ring.

To enable NSF capability, explicit configuration must be enabled under the routing process. NSF-aware feature is enabled by default on all Layer-3 Ethernet switches to function in helper mode to perform graceful recovery during NSF-capable Cisco 3750-E master switch outage. NSF-capable system can also operate in NSF aware role:

NSF Capable Layer-3 Switch

```
cr36-3750s-SS100(config)#router eigrp 100
cr36-3750s-SS100(config-router)#nsf
```

```
cr36-3750s-SS100#show ip protocols | inc NSF
*** IP Routing is NSF aware ***
  EIGRP NSF-aware route hold timer is 240
  EIGRP NSF enabled
    NSF signal timer is 20s
    NSF converge timer is 120s
```

NSF-Aware Layer-3 Switch

```
cr24-3560r-DO#show ip protocols | inc NSF
*** IP Routing is NSF aware ***
  EIGRP NSF-aware route hold timer is 240
```

NSF Timers

As depicted in the above **show** commands, the default NSF-aware system hold timer is 240 seconds. Lowering the timer value may abruptly terminate graceful recovery, causing network instability. Best practice is to use the default NSF hold timer, unless it is observed that NSF recovery takes longer than 240 seconds.

600 seconds after a graceful-recovery starts on a NSF-aware system, NSF clears the route stale marking and resumes using the synchronized routing database.

```
! NSF Aware received graceful-restart message from new master switch
11:56:15.365: %DUAL-5-NBRCHANGE: EIGRP-IPv4:(100) 100: Neighbor 10.125.32.3
(Port-channel15) is resync: peer graceful-restart
11:56:15.365: EIGRP: NSF: AS100, NSF or GR initiated by 10.125.32.3 at 00:00:00, flags 0x4

! NSF route hold timer expires and searches and removes all stale route entries
received graceful-restart message from new master switch
12:00:15.392: EIGRP: NSF: AS100. route hold timer expiry
12:00:15.392: DUAL: Search for outdated routes from 10.125.32.3
```

Resilient Cisco Catalyst 4500

A modular switching platform like the Cisco Catalyst 4500 is fully NSF/SSO-capable, providing 1+1 control plane redundancy. In the Catalyst 4500, all the intelligent Layer-2 and Layer-3 functions are performed centrally on the supervisor module. Deploying redundant supervisor in SSO mode in same system will allow the primary supervisor to fully synchronize the adjacencies, forwarding, configuration, counters, and more information on redundant hot-standby supervisor.

The Cisco Catalyst 4500 ports are independent of the supervisor state. Because of this hardware design, during a supervisor switchover, the ports connected to the failed supervisor do not go down. Because paths and ports are not down, hardware keeps forwarding the packet to a valid next-hop while supervisor switchover is occurring.

The configuration and implementation guidelines for implementing NSF/SSO on the Cisco Catalyst 4500 are the same for district office and school site network designs.

Increasing Supervisor Uplink Port Availability

There are restrictions on which supervisor uplink ports can be actively configured. Multiple ports can be simultaneously active on the supervisor. However Cisco IOS Release 12.2(25)SG or later is required for concurrent use of both 10G and 1G. The Schools SRA uses the 1G interface to connect to the Cisco 3750-MetroE WAN aggregation switch. To use 10G port in 1G mode with redundancy, the following configuration must be applied on collapsed core Catalyst 4500 switch:

```
cr24-4507-DO(config)#hw-module uplink mode shared-backplane
cr24-4507-DO(config)#hw-module module 3 port-group 1 select gigabitethernet
cr24-4507-DO(config)#hw-module module 4 port-group 1 select gigabitethernet

cr24-4507-DO#show hw-module uplink
Active uplink mode configuration is Shared-backplane
```

Stateful Switchover (SSO)

SSO redundancy mode in the Cisco Catalyst 4500 supervisor is turned on by default starting with Cisco IOS Release 12.2(20)EWA. To provide 1+1 redundancy, all the technical specifications between active and standby supervisor must be identical. Also note that the Cisco Catalyst 4507R and 4510R are the only models that support supervisor redundancy. SSO is supported on all supervisors running IOS except Sup II-Plus-TS. The NSF-awareness feature is supported by all the supervisors supporting EIGRP, OSPF, IS-IS, and BGP routing protocols, while the NSF-capable feature is supported only on supervisors IV, V, and V-10G. NSF/SSO on Catalyst 4500 requires a minimum boot ROM version and must be the same on both supervisors. For additional details on hardware requirements, refer to the Release Notes at the following URL:

<http://www.cisco.com/en/US/docs/switches/lan/catalyst4500/12.2/53SG/configuration/NSFwSSO.html#wp1135767>

```
cr24-4507-DO(config)#redundancy
cr24-4507-DO(config-red)# mode sso
cr24-4507-DO(config-red)# main-cpu
cr24-4507-DO(config-r-mc)# auto-sync standard

cr24-4507-DO#show module | inc Chassis | 6-E | SSO
Chassis Type : WS-C4507R-E
```

```

3      6  Sup 6-E 10GE (X2), 1000BaseX (SFP)      WS-X45-SUP6-E      JAE1132SXQ3
4      6  Sup 6-E 10GE (X2), 1000BaseX (SFP)      WS-X45-SUP6-E      JAE1132SXRQ

3  Active Supervisor      SSOActive
4  Standby Supervisor     SSOStandby hot

```

The active supervisor dynamically detects the secondary supervisor installed in the same chassis and initiates several SSO dependency configuration checks. If the SSO dependency check fails, then the standby supervisor falls back into RPR mode. For example, IOS release mismatch between two supervisors may not allow SSO to synchronize.

If the SSO dependency configuration checks successfully pass, then SSO communication between both supervisors goes through several synchronization states before it transitions to hot-standby state as illustrated in the following output:

```

cr24-4507-DO#show redundancy states
my state = 13 -ACTIVE
peer state = 8  -STANDBY HOT
. . .

Redundancy Mode (Operational) = Stateful Switchover
Redundancy Mode (Configured)  = Stateful Switchover
Redundancy State               = Stateful Switchover
  Maintenance Mode = Disabled
  Manual Swact = enabled
  Communications = Up
. . .

```

All the state-machines and dynamic information of SSO-capable protocols are automatically synchronized to the standby supervisor module without any additional operational requirement. The hot-standby supervisor takes over the ownership of control-plane process when the active supervisor outage or removal from the chassis is detected.

Non-Stop Forwarding (NSF)

All the state-machines and dynamic information of SSO-capable protocols are automatically synchronized to the standby supervisor module. The hot-standby supervisor takes over the ownership of control-plane process if the active supervisor suffers an outage or is removed from the chassis.

NSF-Capable Layer 3 Switch

```

  EIGRP NSF-aware route hold timer is 240

```

WAN Design

In the Schools Service Ready Architecture, the school sites are connected to the district office over Wide Area Network (WAN) links. This section discusses how to design and deploy the WAN for Schools SRA. The primary components of WAN architecture are as follows:

- WAN technology
- Bandwidth capacity planning
- WAN IP addressing structure
- Routing
- QoS

WAN Technologies

There are several WAN technologies available today to provide WAN services, such as MPLS/VPN, Internet, and Metro Ethernet. MPLS/VPN provides Layer-2 or Layer-3 VPN services. It provides the capability for an IP network infrastructure that delivers private network services over a shared network infrastructure. To learn more about deploying MPLS/VPN, refer to the following URL:

http://www.cisco.com/en/US/solutions/ns340/ns414/ns742/ns817/landing_overall_wan.html

Internet service is the least expensive and easiest to deploy. Deploying a VPN service over the Internet requires an overlay VPN network such as DMVPN to provide secure VPN service.

Metro Ethernet is one of the fastest growing transport technologies in the telecommunications industry. The Schools SRA design uses Metro Ethernet service as the WAN transport between school sites, and the district office.

Figure 3-44 depicts the WAN technologies available today.

Figure 3-44 **WAN technologies**

Metro Ethernet offers several distinct advantages for the Schools SRA WAN design:

- Low latency and delay variation—Make it the best solution for video, voice and data
- Low Cost—Carrier Ethernet brings the cost model of Ethernet to the WAN
- Performance, QoS and Suitability for Convergence—Ethernet networks inherently require less processing to operate and manage and operate at higher bandwidth than other technologies
- Scalability, Ubiquity and Reachability—Global availability of standardized services independent of physical access type dramatically reduce complexity and cost

Types of Metro Ethernet Services

Metro Ethernet typically offers two popular services:

- E-line, which is also known as Ethernet Virtual Private Line (EVPL), provides a point-to-point service.
- E-LAN provides multi-point or any-to-any connectivity.

EVPL, like Frame Relay, provides for multiplexing multiple point-to-point connections over a single physical link. In the case of Frame Relay, the access link is a serial interface to a Frame Relay switch with individual data-link connection identifiers (DLCIs) identifying the multiple virtual circuits or connections. In the case of EVPL, the physical link is Ethernet, typically FastEthernet or Gigabit Ethernet, and the multiple circuits are identified as VLANs through an 802.1q trunk.

E-LAN is also known as Virtual Private LAN Services (VPLS). One of its major advantages is any to any connectivity within the metro area, which allows flexibility. It passes 802.q trunks across the SP network known as Q-in-Q. [Figure 3-45](#) shows the difference between these services.

Figure 3-45 Different Services Available

Service Deployed in the Design

Schools SRA design uses E-line with point-to-point service to connect school sites to the district office. Each school site has a 100 Mbps Metro point-to-point connection to the service provider Network. As mentioned in the previous section, each circuit is represented by a VLAN using dot1q trunk. [Figure 3-46](#) illustrates how this is implemented.

Figure 3-46 *EVPN Service Used in School WAN Architecture*

Following is a sample configuration of the WAN interface at the district office:

```
interface GigabitEthernet1/1/1
description Connected to SP-MPLS-Core-cr24-6500-1
switchport trunk native vlan 801
switchport trunk allowed vlan 501-550
switchport mode trunk
logging event trunk-status
load-interval 30
carrier-delay msec 0
priority-queue out
mls qos trust dscp
spanning-tree portfast trunk
spanning-tree bpdupfilter enable
spanning-tree guard root
service-policy output School-1to50-Parent-Policy-Map
hold-queue 2000 in
hold-queue 2000 out
```

In the above configuration, the link is carrying 50 VLANs, which are connected to 50 school sites.

Bandwidth Capacity

Planning sufficient bandwidth capacity is a critical component of the overall WAN design. Application performance depends largely on guaranteed level of bandwidth at school sites and the district office. This section discusses the general WAN bandwidth capacity planning steps, and how this has been implemented in the School SRA.

Planning

The School district must purchase the MetroE service from the local Service Provider. The amount of bandwidth capacity at each school, and at the district office must be sufficient to meet the anticipated network load, and some margin for peak usage, and to allow future growth. The bandwidth is shared based on the four-class QoS model, for optimal service delivery, as described in the [“Deploying QoS in](#)

[School Network” section on page 3-50](#). Logical bandwidth assignment to each circuit must be symmetric at the school and at the district office. A mismatch in bandwidth capacity will force traffic drop in the SP core due to in-consistent bandwidth SLAs.

The WAN bandwidth capacity may vary between school sites, but the design principles and implementation (bandwidth sharing, routing, QoS, multicast) are the same.

**Note**

The district office WAN router is an aggregator that logically connects to multiple schools over a single media. The School SRA district office WAN device is the Cisco 3750ME. The media type connecting to the Metro WAN MUST be GigE, since the 3750ME does not negotiate to lower speeds.

Calculating the optimum guaranteed bandwidth required at the district office is done by considering the following factors:

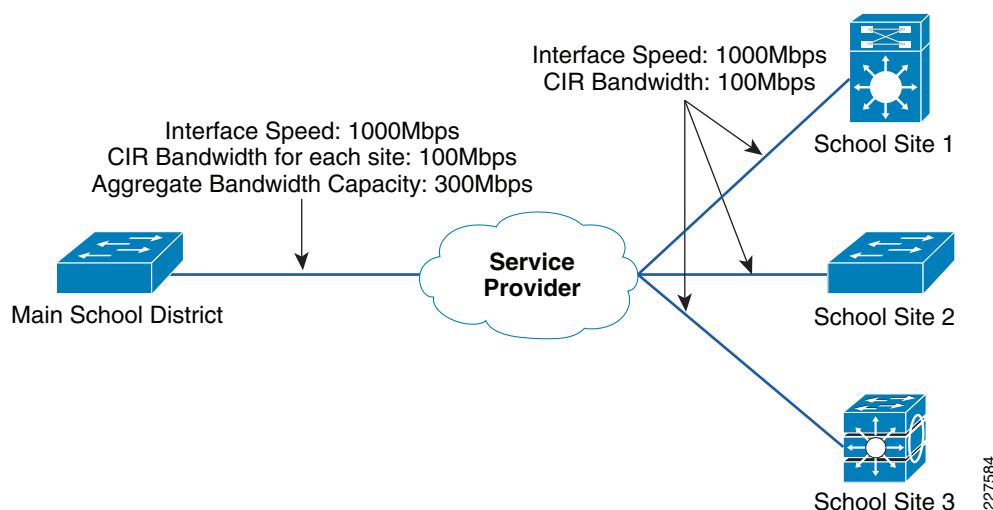

- Number of school sites.
- Bandwidth required at each location.
- Platform scalability limits, mainly, at district office.

To describe how much bandwidth is required at each school site, we use two terms, CIR, Interface speed.

- CIR—Committed bandwidth that is guaranteed from the service provider, based on the logical connection.
- Interface speed—The interface speed is actual Ethernet handoff, which is 1Gbps for both school sites and district office.

For example, let us consider a scenario where there are three school sites, and one district office. The CIR required at each school site is 100Mbps, and since there are three school sites, the district office needs three virtual circuits each having a CIR of 100Mbps, which also means that the aggregate bandwidth at district office is 300Mbps. [Figure 3-47](#) illustrates this point.

Figure 3-47 Bandwidth Capacity Panning for Three School Sites

Similarly, if the CIR required at each school site is 100Mbps, and if there are 100 school sites, then the bandwidth required at the district office is 10Gbps. To support an aggregate CIR bandwidth of 10Gbps at district office, we need to think about scalability limits on the WAN aggregation box.

If the aggregated logical connection speed to the schools exceed the media capacity on 3750-ME, which is the WAN aggregator for our design, then there are two design options:

1. Migrate to Modular a switching platform (such as Catalyst 6500)—Migrating to a modular switching platform in the WAN aggregation tier enables higher bandwidth, capacity, and may reduce operational and management complexities.
2. Deploy another 3750-ME —Deploying another 3750-ME is the simplest way to scale the WAN capacity. Deploying another set of 3750-ME does not change any WAN design principles, and except for VLAN and IP address, all the configurations can be replicated to the secondary system.

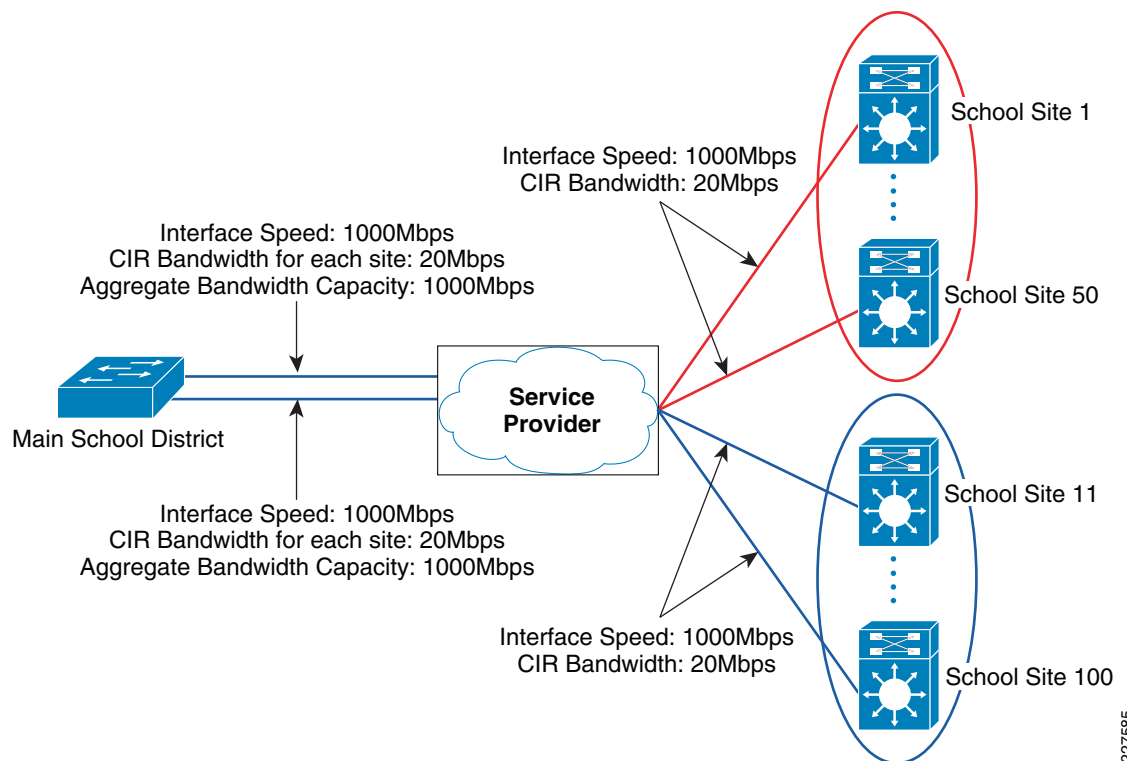

Implementation

This section describes how the WAN is implemented in the Schools SRA reference design, which was validated in the lab:

- The district office has dual WAN connections, and each connection is 1Gbps.
- On each WAN connection there are 50 Virtual circuits, each with CIR of 20Mbps.
- The school sites have 1Gbps connection, and CIR value of 20Mbps on each circuit.

Figure 3-48 shows how this design is validated with 100 school sites.

Figure 3-48 Bandwidth Capacity Planning for 100 School Sites

227585

IP Address Aggregation

This section describes how to aggregate IP address space at the school sites, and the district office on the WAN interface.

As explained in the previous section, all the school sites are connected to the district office using point-to-point links, which means that every school site should be on a different IP subnet. It is common for customers to deploy using /30 subnet for each school site. This uses up to four addresses for each subnet. Best practice recommendation is to use /31 subnets. This approach only uses two addresses in each link. The following configuration shows how to deploy this at a school site or district office:

School site	District office
<pre> interface Vlan501 description Connected to cr24-3750ME-DO dampening ip address 10.126.0.1 255.255.255.254 no ip redirects no ip unreachablees ip authentication mode eigrp 100 md5 ip authentication key-chain eigrp 100 eigrp-key ip pim sparse-mode ip summary-address eigrp 100 10.127.0.0 255.255.248.0 5 load-interval 30 </pre>	<pre> interface Vlan501 description Connected to cr35-4507-SS1 dampening ip address 10.126.0.0 255.255.255.254 no ip redirects no ip unreachablees ip authentication mode eigrp 100 md5 ip authentication key-chain eigrp 100 eigrp-key ip pim sparse-mode ip summary-address eigrp 100 10.124.0.0 255.252.0.0 5 load-interval 30 hold-queue 2000 in hold-queue 2000 out </pre>

Routing for WAN Connections

This section discusses how to implement routing on the WAN interfaces. The key consideration when designing the routing protocol is summarization.

- Summarization on network boundaries is very important to design as it prevents unnecessary routing updates to flow across the WAN interface, when there is a link-state change in the network. For example, let us consider a school district where there are subnets in the following range:

```

10.127.0.0/26
10.127.0.64/26
10.127.0.128/26
.
.
.
10.127.7.64/26

```

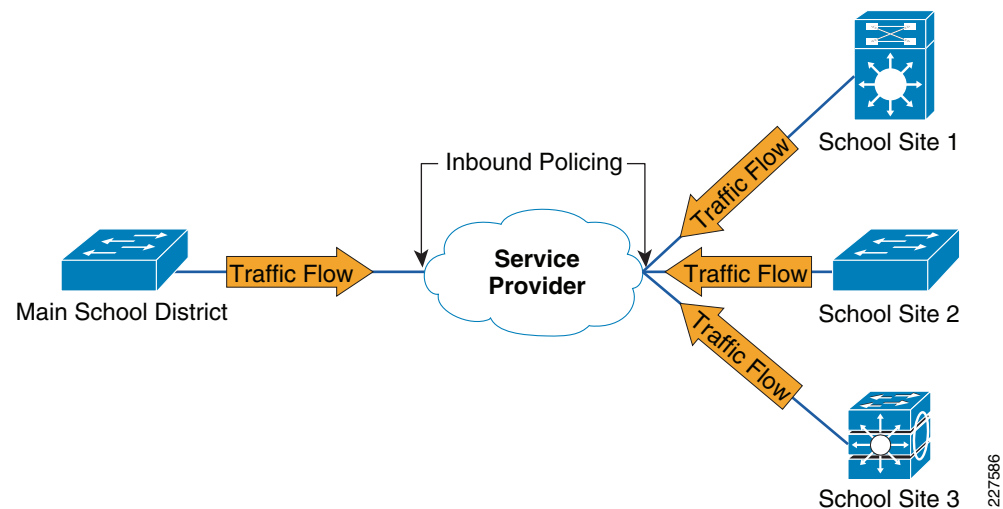

Since the above subnets belong to a particular school district, they could be summarized as 10.127.0.0/21. The following configuration shows how to perform summarization on the WAN interface, which is Vlan501 in this example:

School site	District office
<pre> interface Vlan501 description Connected to cr24-3750ME-DO dampening ip address 10.126.0.1 255.255.255.254 no ip redirects no ip unreachableables ip authentication mode eigrp 100 md5 ip authentication key-chain eigrp 100 eigrp-key ip pim sparse-mode ip summary-address eigrp 100 10.127.0.0 255.255.248.0 5 load-interval 30 </pre>	<pre> interface Vlan501 description Connected to cr35-4507-SS1 dampening ip address 10.126.0.0 255.255.255.254 no ip redirects no ip unreachableables ip authentication mode eigrp 100 md5 ip authentication key-chain eigrp 100 eigrp-key ip pim sparse-mode ip summary-address eigrp 100 10.124.0.0 255.252.0.0 5 load-interval 30 hold-queue 2000 in hold-queue 2000 out </pre>

WAN QoS Design

QoS design is particularly important when using Ethernet as the WAN, since the router or switch on the WAN edge might believe they have complete line rate available to transmit. If the WAN device transmits at full line rate into the WAN, the Service Provider network will drop packets exceeding the CIR (i.e. the committed rate agreed to with Service Provider). [Figure 3-49](#) shows what may happen without a proper QoS design.

Figure 3-49 Policing at Service provider due to lack of proper QoS at district office, and school sites

Proper QoS policies implemented at the district office and school site will prevent packets from being dropped at service provider network.

WAN QoS Policy at District Office

The district office has several point to point circuits; one connecting to each school site. The QoS policy at the district office has the following objectives:

- The aggregate traffic going out to the school site does not exceed the school site CIR (20Mbps for the lab testbed).
- All the traffic going out is put into four classes.

To accomplish the above objectives, Hierarchical Class Based Weighted Fair Queuing (HCBWFQ) is implemented. To learn more about HCBWFQ, refer *Ethernet Access for Next Generation Metro and Wide Area Networks Design Guide* at the following URL:

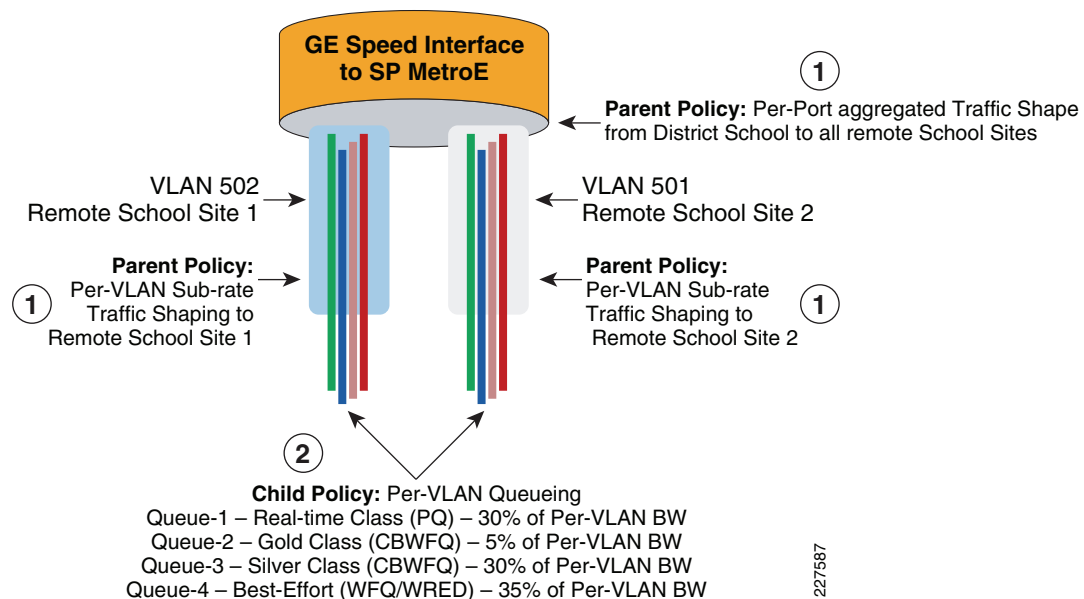

http://www.cisco.com/en/US/docs/solutions/Enterprise/WAN_and_MAN/Ethernet_Access_for_NG_MAN_WAN_V3.1_external.html

Implementing HCWFQ requires the following two policies:

- Parent policy that defines the aggregate shape rate
- Child policy that enables queuing within the shaped rate.

Figure 3-50 shows the representation of hierarchical policy.

Figure 3-50 Hierarchical policy implementation at District office

The following table shows how these classes are defined:

Class	Queuing type	Bandwidth Allocation
REAL_TIME	LLQ	30%
GOLD	CBWFQ	5%
SILVER	CBWFQ	30%
DEFAULT	CBWFQ	35%

Following is the configuration of the QoS policy at the district office. This configuration is for one VLAN:

```
class-map match-all School_Site1 <-This class map would match the traffic going to a
school site
description cr2-4507-SS1
```

```

match vlan 501

policy-map School-Child-Policy-Map <- This is child policy
  class REAL_TIME
    priority
    police cir percent 30 conform-action set-cos-transmit 5 exceed-action drop
  violate-action drop
  class GOLD
    bandwidth percent 5
    set cos 3
  class SILVER
    bandwidth percent 30
    set cos 2
  class class-default
    bandwidth percent 35
    set cos 0
!
```

Following is the configuration of the parent policy, which shapes to 20Mbps for each school site in this example:

```

Policy Map School-1to50-Parent-Policy-Map <-This is parent policy map
  Class School_Site1
    shape average 20000000 (bits/sec)
    service-policy School-Child-Policy-Map <-This is child policy map
```

After defining the policies, they are applied to WAN interfaces. The following example shows the configuration of Metro switch on its WAN interface:

```

interface GigabitEthernet1/1/1
description Connected to SP-MPLS-Core-cr24-6500-1
switchport trunk native vlan 801
switchport trunk allowed vlan 501-550
switchport mode trunk
logging event trunk-status
load-interval 30
carrier-delay msec 0
priority-queue out
mls qos trust dscp
spanning-tree portfast trunk
spanning-tree bpdupfilter enable
spanning-tree guard root
max-reserved-bandwidth 100
service-policy output School-1to50-Parent-Policy-Map <-The policy-map
hold-queue 2000 in
hold-queue 2000 out
```

After completing the QoS policy at district office, we need to define the QoS policy at school sites.

WAN QoS Policy at School Site

The objectives at the school sites are similar to the one at the district office, which is:

- Ensure that 20Mbps is the maximum aggregate traffic leaving the WAN device.
- Ingress traffic is queued in four classes.

The school site implementation is different from the district office (due to lack of HCBWFQ support). The following configuration shows how to implement the QoS policy without HCBWFQ.

The first step is to queue the ingress traffic in the four queues. The following table shows the queues, and the bandwidth allocated for each:

The first step is to queue the ingress traffic in the four queues. The following table shows the queues, and the bandwidth allocated for it:

Class	Queuing type	Bandwidth Allocation
REAL_TIME	Per-class	6mbps
GOLD	Per-class	1mbps
SILVER	Per-class	7mbps
DEFAULT	Per-class	6mbps

Following is the configuration of egress interface on the school-site:

```
interface GigabitEthernet1/1
description Connected to MetroE-Core-cr25-6500-1
switchport trunk encapsulation dot1q
switchport trunk native vlan 801
switchport trunk allowed vlan 501
switchport mode trunk
logging event link-status
load-interval 30
carrier-delay msec 0
qos trust dscp
udld port disable
tx-queue 1
    bandwidth 1 mbps
tx-queue 2
    bandwidth 7 mbps
tx-queue 3
    bandwidth 6 mbps
    priority high
tx-queue 4
    bandwidth 6 mbps
no cdp enable
spanning-tree portfast trunk
spanning-tree bpduguard enable
spanning-tree guard root
service-policy output WAN-EGRESS-PARENT
```

The above configuration ensures that each class of traffic is queued as per the table shown above. However, the “bandwidth” would only ensure the minimum amount of bandwidth available. It does not control the upper threshold, which needs to be 20Mbps in our example. Therefore, to make sure that the traffic on the egress interface does not exceed 20Mbps, we have a WAN-EGRESS-PARENT policy that polices the traffic to 20Mbps. Following is the configuration of the WAN egress policy:

```
cr35-4507-SS1#show policy-map WAN-EGRESS-PARENT
Policy Map WAN-EGRESS-PARENT
Class class-default
    police 20 mbps 1000 byte conform-action transmit exceed-action drop
    service-policy WAN-EGRESS-CHILD
cr35-4507-SS1#
```

CHAPTER 4

Security Design

Introduction

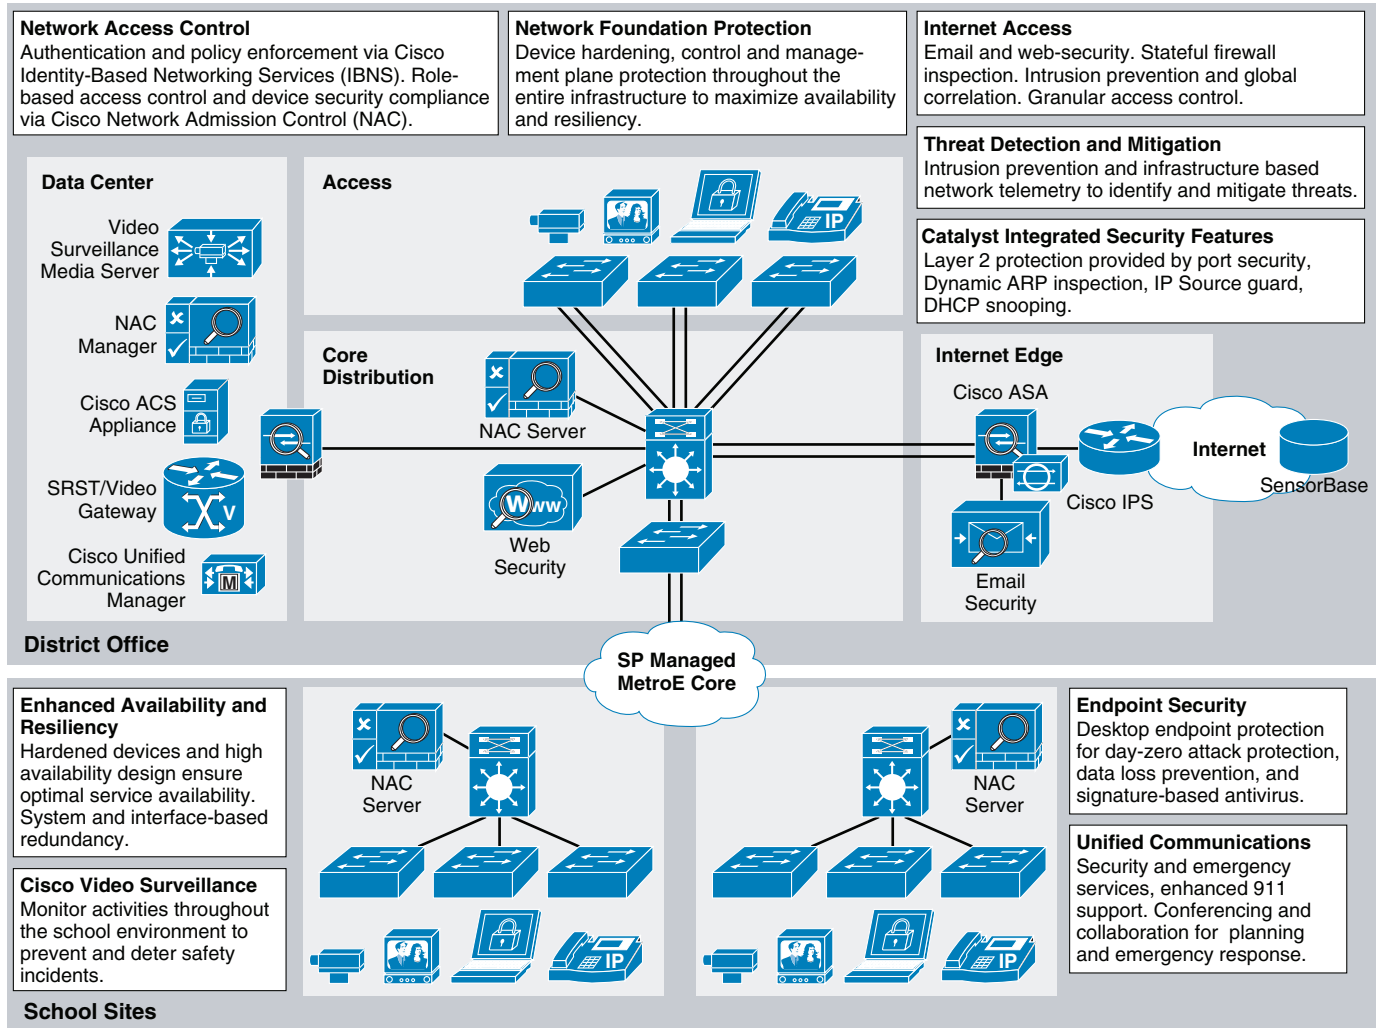

The Cisco Service Ready Architecture (SRA) for Schools solution is designed with security to provide a safe online environment for teaching and learning. Following the proven guidelines of the Cisco SAFE Security architecture, a series of security technologies and products are strategically deployed throughout the solution to protect minors from harmful and inappropriate content, to guarantee the confidentiality of student, staff and faculty private data, and to ensure the availability and integrity of the systems and data.

Protecting the infrastructure and keeping students and staff safe requires the implementation of security controls capable of mitigating both well-known and new forms of threats. Common threats to school environments include:

- *Service disruption*—Disruption of the administrative infrastructure and learning resources such as computer labs caused by botnets, worms, malware, adware, spyware, viruses, DoS attacks.
- *Harmful or inappropriate content*—Pornography, adult, aggressive, offensive and other type of content that could put the physical and psychological well being of minors at risk.
- *Network abuse*—Peer-to-peer file sharing and instant messaging abuse, use of non-approved applications by students, staff, and faculty.
- *Unauthorized access*—Intrusions, unauthorized users, escalation of privileges, and unauthorized access to learning and administrative resources.
- *Data loss*—Theft or leakage of student, staff and faculty private data from servers, endpoints, and while in transit, or as a result of spyware, malware, key-loggers, viruses, etc.

The solution design follows a defense-in-depth approach, whereby multiple layers of protection are built into the architecture. Different security products and technologies are combined together for enhanced security visibility and control. [Figure 4-1](#) illustrates the security design and its product positioning.

Figure 4-1 SRA Security Design

The security design focuses on the following key areas:

- **Network Foundation Protection (NFP)**— Ensuring the availability and integrity of the network infrastructure, protecting the control and management planes.
- **Internet Perimeter Protection**— Ensuring safe Internet connectivity, and protecting internal resources and users from malware, viruses, and other malicious software. Protecting students and staff from harmful and inappropriate content. Enforcing E-mail and web browsing policies.
- **Network Access Security and Control**—Securing the access edges. Enforcing authentication and role-based access for students, staff and faculty residing at school sites and district office. Ensuring systems are up-to-date and in compliance with the school's network security policies.
- **Network Endpoint Protection**—Protecting students, staff and faculty from harmful and inappropriate content. Enforcing E-mail and web browsing policies.

The design guidelines and best practices for each focus area are discussed next. For more detailed information, refer to the *Cisco SAFE Reference Guide* at the following URL:

http://www.cisco.com/en/US/docs/solutions/Enterprise/Security/SAFE_RG/SAFE_rg.html

227420

Network Foundation Protection

School networks are built with routers, switches, and other network devices that keep the applications and services running. Therefore, properly securing these network devices is critical for continued operation.

The SRA solution protects the network infrastructure by implementing the Cisco SAFE best practices for the following areas:

- Infrastructure device access
 - Restrict management device access to authorized parties and for the authorized ports and protocols.
 - Enforce Authentication, Authorization and Accounting (AAA) with TACACS+ or RADIUS to authenticate access.
 - Authorize actions and log all administrative access.
 - Display legal notification banners.
 - Ensure confidentiality by using secure protocols like SSH and HTTPS.
 - Enforce idle and session timeouts.
 - Disable unused access lines.
- Routing infrastructure
 - Restrict routing protocol membership by enabling MD5 neighbor authentication and disabling default interface membership.
 - Enforce route filters to ensure that only legitimate networks are advertised, and networks that are not supposed to be propagated are never advertised.
 - Log status changes of neighbor sessions to identify connectivity problems and DoS attempts on routers.
- *Device resiliency and survivability*
 - Disable unnecessary services, implement control plane policing (CoPP).
 - Enable traffic storm control.
 - Implement topological, system and module redundancy for the resiliency and survivability of routers and switches and to ensure network availability.
 - Keep local device statistics.
- Network telemetry
 - Enable NTP time synchronization.
 - Collect system status and event information with SNMP, Syslog, TACACS+/RADIUS accounting.
 - Monitor CPU and memory usage on critical systems.
- Network policy enforcement
 - Implement access edge filtering.
 - Enforce IP spoofing protection with access control lists (ACLs), Unicast Reverse Path Forwarding (uRPF) and IP Source Guard.
- Switching infrastructure

- Implement a hierarchical design, segmenting the LAN into multiple IP subnets or VLANs to reduce the size of broadcast domains.
- Protect the Spanning Tree Protocol (STP) domain with BPDU Guard, STP Root Guard.
- Use Per-VLAN Spanning Tree to reduce the scope of possible damage.
- Disable VLAN dynamic trunk negotiation on user ports.
- Disable unused ports and put them into an unused VLAN.
- Enable Traffic Storm Control.
- Implement Catalyst Infrastructure Security Features (CISF) including port security, Dynamic ARP Inspection, and DHCP snooping.
- Use a dedicated VLAN ID for all trunk ports.
- Explicitly configure trunking on infrastructure ports.
- Use all tagged mode for the native VLAN on trunks and drop untagged frames.
- Network management
 - Ensure the secure management of all devices and hosts within the school network architecture.
 - Authenticate, authorize and keep record of all administrative access.
 - If possible, implement a separate out-of-band (OOB) management network (hardware or VLAN-based) to manage systems local at the District Office.
 - Secure the OOB by enforcing access controls, using dedicated management interfaces or VRFs.
 - Provide secure in-band management access for systems residing at the school sites by deploying firewalls and ACLs to enforce access controls, using Network Address Translation (NAT) to hide management addresses, and use secure protocols like SSH and HTTPS.
 - Ensure time synchronization by using NTP. Secure servers and other endpoint with endpoint protection software and operating system (OS) hardening best practices.

Configurations are shown in the design chapters. For more detailed information on the NFP best practices, refer to “Chapter 2, Network Foundation Protection” of the *Cisco SAFE Reference Guide* at the following URL:

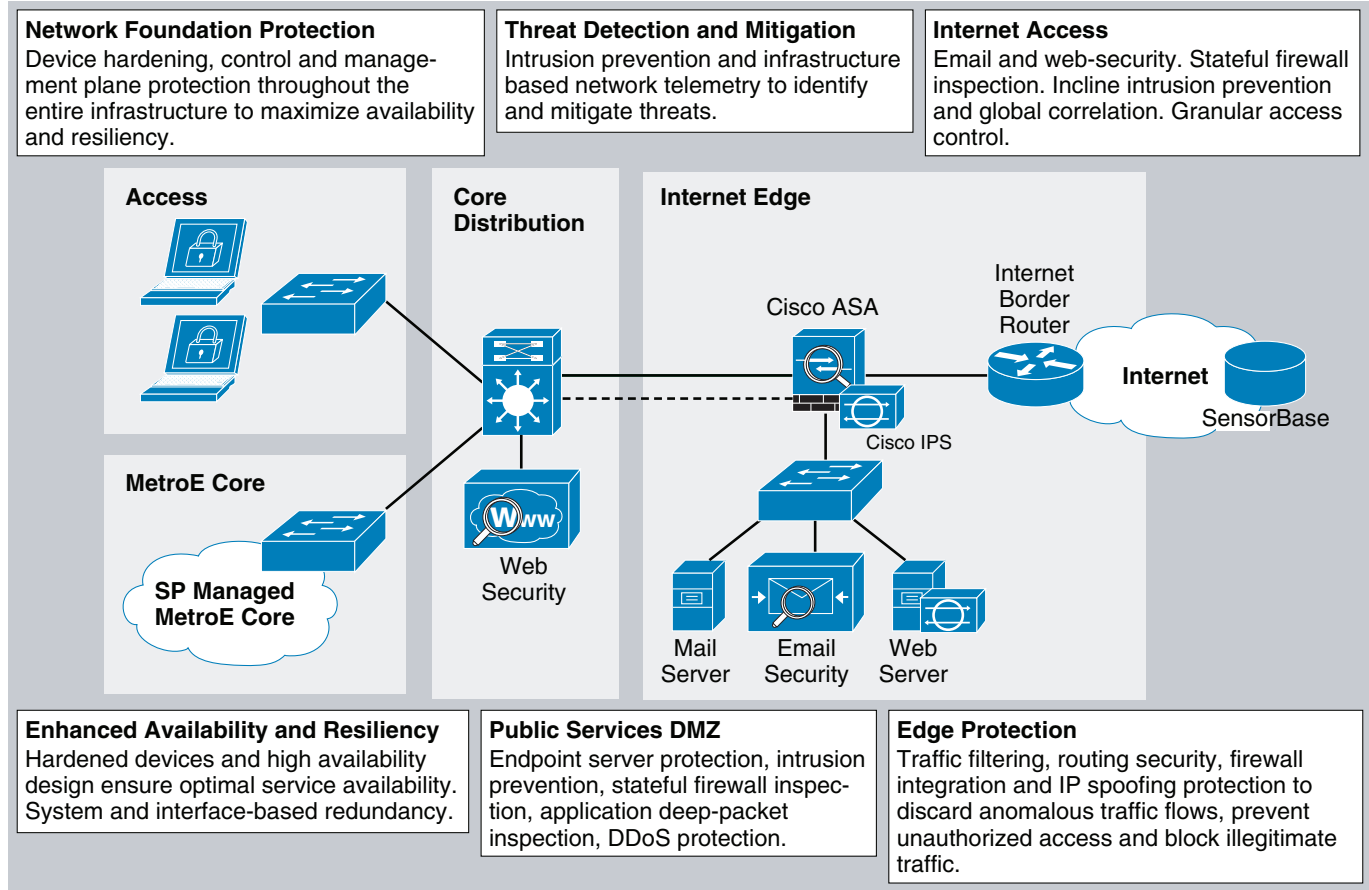

http://www.cisco.com/en/US/docs/solutions/Enterprise/Security/SAFE_RG/chap2.html

Internet Perimeter Protection

The school architecture assumes the existence of a centralized Internet connection at the district office, serving students, staff and faculty residing at all school premises. Common services typically provided include E-mail for staff and faculty, Internet browsing for everyone, and a school web portal accessible over the Internet. Other services may also be provided using the same infrastructure.

The network infrastructure that provides Internet connectivity is defined as the Internet perimeter, illustrated in [Figure 4-2](#).

Figure 4-2 Internet Perimeter

The primary functions of the Internet perimeter is to allow for safe and secure access to students, staff, and faculty, and to provide public services without compromising the confidentiality, integrity, and availability of school resources and data. To that end, the Internet perimeter incorporates the following security functions:

- **Internet Border Router**—This is the Internet gateway responsible for routing traffic between the school and the Internet. The Internet border router may be administered by school personnel or may be managed by the Internet service provider (ISP). The router provides the first line of protection against external threats and should be hardened using the Network Foundation Protection (NFP) best practices.
- **Internet Firewall**—A Cisco Adaptive Security Appliance provides Stateful access control and deep packet inspection to protect the school resources and data from unauthorized access and disclosure. The security appliance is configured to prevent incoming access from the Internet, to protect the school web portal and other Internet public services, and to control student, staff and faculty traffic bound to the Internet. The security appliance may also implement an Advanced Inspection and Prevention Security Services Module (AIP SSM) for enhanced threat detection and mitigation. This IPS module may be configured either in inline or promiscuous mode. The security appliance may also provide secure remote access to faculty, staff, and students in the form of IPSec or SSL VPN.
- **Public Services DMZ**—The Internet school web portal, mail server, and other public-facing services may be placed on a demilitarized zone (DMZ) for security and control purposes. The DMZ acts as a middle stage between the Internet and school's private resources, preventing external users from directly accessing any internal servers and data. The Internet firewall is responsible for restricting

incoming access to the public services and by limiting outbound access from DMZ resources out to the Internet. Systems residing on the DMZ are hardened with endpoint protection software (i.e., Cisco Security Agent) and operating system (OS) hardening best practices.

- *E-mail Security*—A Cisco Ironport C Series E-mail Security Appliance (ESA) is deployed at the DMZ to inspect incoming and outgoing E-mails and eliminate threats such as E-mail spam, viruses, and worms. The ESA appliance also offers E-mail encryption to ensure the confidentiality of messages, and data loss prevention (DLP) to detect the inappropriate transport of sensitive information.
- *Web Security*—A Cisco IronPort S Series Web Security Appliance (WSA) is deployed at the distribution switches to inspect HTTP and HTTPS traffic bound to the Internet. This system enforces URL-filtering policies to block access to websites containing content that may be harmful or inappropriate for minors or that are known to be the source of spyware, botnets, or other type of malware. The WSA is also responsible for the monitoring of Layer-4 traffic for rogue activity and infected systems.

The following subsections describe the design guidelines for implementing the security functions.

**Note**

For implementation details on Remote Access VPN, IPS, CSA, and Internet border router hardening, refer to the *Cisco SAFE Reference Guide* at the following URL:

http://www.cisco.com/en/US/docs/solutions/Enterprise/Security/SAFE_RG/SAFE_rg.html. Firewall and web security configurations can be found in [Chapter 11, “District Office Design.”](#)

Internet Border Router Guidelines

The Internet border router provides connectivity to the Internet via one or more Internet service providers. The router act as the first line of defense against unauthorized access, DDoS, and other external threats. Access control lists (ACLs), uRPF, and other filtering mechanisms may be implemented for anti-spoofing and to block invalid packets. NetFlow, Syslog, and SNMP may be used to gain visibility on traffic flows, network activity and system status. In addition, the Internet border router should be secured. This includes restricting and controlling administrative access, protecting the management and control planes, and securing the dynamic exchange of routing information.

[Chapter 11, “District Office Design”](#) provides an example of Internet edge ACL. For more information on how to configure the Internet border router, refer to “Internet Edge” chapter of the *Cisco SAFE Reference Guide* at the following URL:

http://www.cisco.com/en/US/docs/solutions/Enterprise/Security/SAFE_RG/SAFE_rg.html.

Internet Firewall Guidelines

The Cisco Adaptive Security Appliance (Cisco ASA) deployed at the Internet perimeter is responsible for protecting the school’s internal resources and data from external threats by preventing incoming access from the Internet; protecting public resources served by the DMZ by restricting incoming access to the public services and by limiting outbound access from DMZ resources out to the Internet; and controlling user’s Internet-bound traffic.

To that end, the security appliance is configured to enforce access policies, keep track of connection status, and inspect packet payloads following these guidelines:

- Deny any connection attempts originating from the Internet to internal resources and subnets.

- Allow outbound Internet HTTP/HTTPS access for students, staff and faculty residing at any of the school premises.
- Allow outbound Internet SSL access for administrative updates, SensorBase, IPS signature updates, etc.
- Allow students, staff and faculty access to DMZ services such as school web portal, E-mail, and domain name resolution (HTTP, SMTP, POP, IMAP, and DNS).
- Restrict inbound Internet access to the DMZ for the necessary protocols and servers (HTTP to Web server, SMTP to Mail Transfer Agent, DNS to DNS server, etc.).
- Restrict connections initiated from DMZ to the only necessary protocols and sources (DNS from DNS server and mail server, SMTP from mail server, SSL for Cisco IronPort ESA).
- Enable stateful inspection for the used protocols to ensure returning traffic is dynamically allowed by the firewall.
- Implement Network Address Translation (NAT) and Port Address Translation (PAT) to shield the internal address space from the Internet.

Figure 4-3 illustrates the protocols and ports explicitly allowed by the Cisco ASA.

Figure 4-3 Allowed Protocols and Ports

Note

Allowed Protocols and Ports does not include any management traffic destined to the firewall. Whenever available, a dedicated management interface should be used. In case the firewall is managed in-band, identify the protocols and ports required prior to configuring the firewall ACLs.

In addition, the Cisco ASA should be hardened following the NFP best practices. This includes restricting and controlling administrative access, securing the dynamic exchange of routing information with MD5 authentication, and enabling firewall network telemetry with SNMP, syslog, and NetFlow.

In the school design, higher availability is achieved by using redundant physical interfaces. This represents the most cost-effective solution for high availability. As an alternative, a pair of firewall appliances could be deployed in stateful failover, as discussed in [Chapter 11, “District Office Design.”](#)

E-mail Security Guidelines

The Cisco Ironport C Series E-mail Security Appliance (ESA) deployed at the DMZ is responsible for inspecting E-mails and eliminating threats such as E-mail spam, viruses and worms. The ESA can be described as a firewall and threat monitoring system for Simple Mail Transfer Protocol (SMTP) traffic (TCP port 25). Logically speaking, the ESA acts as a Mail Transfer Agent (MTA) within the E-mail delivery chain, as illustrated in [Figure 4-4](#). Upon reception, E-mails are evaluated using a reputation score mechanism based on the SensorBase network. The SensorBase network is an extensive network

that monitors global E-mail and web traffic for anomalies, viruses, malware and other and abnormal behavior. The network is composed of Cisco IronPort appliances, Cisco ASA and IPS appliances installed in more than 100,000 organizations worldwide, providing a large and diverse sample of Internet traffic patterns. By leveraging the SensorBase Network, messages originating from domain names or servers known to be the source of spam or malware, and therefore with a low reputation score, are automatically dropped or quarantined by preconfigured reputation filters. Optionally, the school may choose to implement some of the other functions offered by the ESA appliance, including anti-virus protection with virus outbreak filters and embedded anti-virus engines (Sophos and McAfee), encryption to ensure the confidentiality of messages, and data loss prevention (DLP) for E-mail to detect inappropriate transport of sensitive information.

Figure 4-4 E-mail Delivery Chain

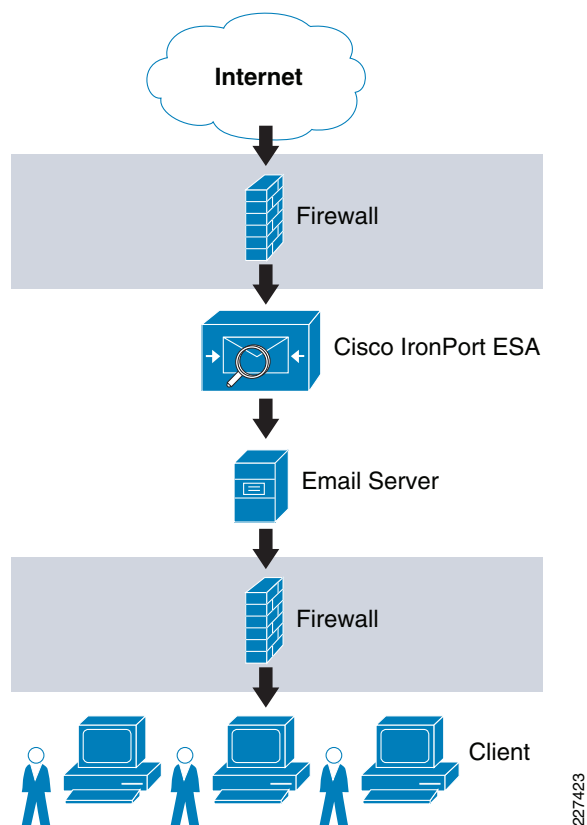

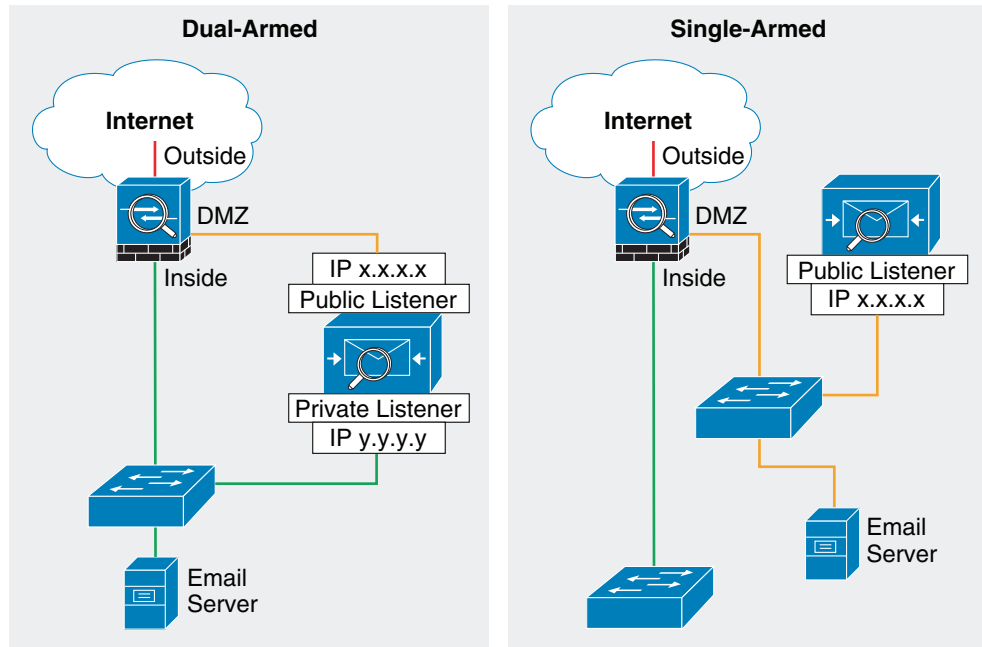

Figure 4-4 shows a logical implementation of a DMZ hosting the E-mail server and ESA appliance. This can be implemented physically by either using a single firewall or two firewalls in sandwich.

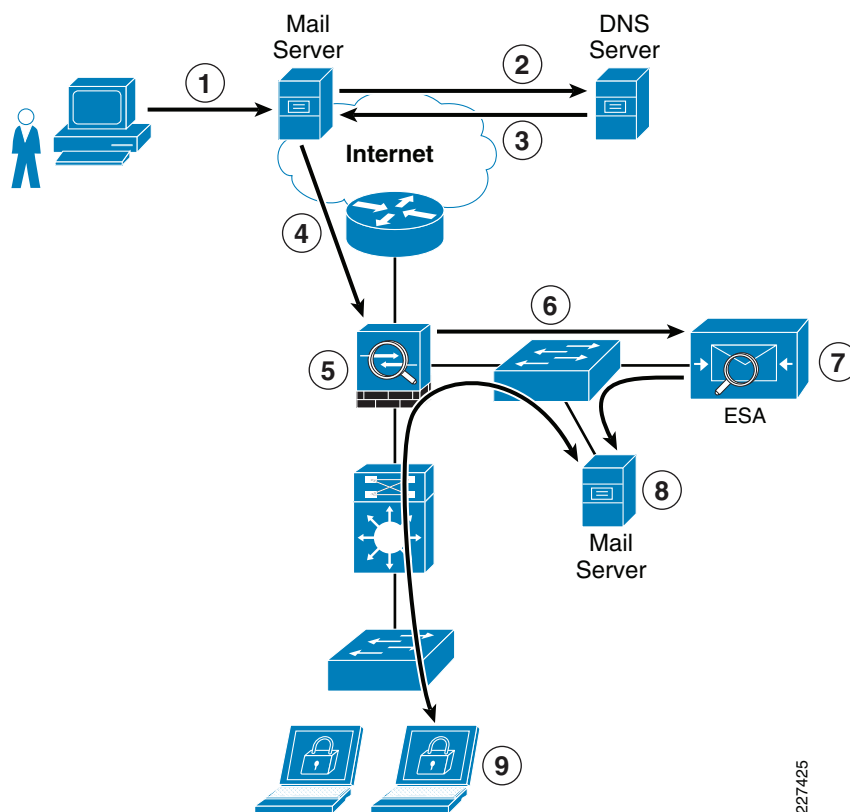

Figure 4-5 Common ESA Deployments

There are multiple deployment approaches for the security appliance depending on the number of interfaces used (see [Figure 4-5](#)):

- *Dual-armed configuration*—Two physical interfaces used to serve a public mail listener and a private mail listener, each one configured with a separate logical IP address. The public listener receives E-mail from the Internet and directs messages to the internal E-mail servers; while the private listener receives E-mail from the internal servers and directs messages to the Internet. The public listener interface may connect to the DMZ; while the private listener interface may connect to the inside of the firewall.
- *One-armed configuration*—A single ESA interface configured with a single IP address and used for both incoming and outgoing E-mail. A public mail listener is configured to receive and relay E-mail on that interface. The best practice is to connect the ESA interface to the DMZ where the E-mail server resides.

For simplicity, the school architecture implements the ESA with a single interface. In addition, using a single interface leaves other data interfaces available for redundancy.

[Figure 4-6](#) illustrates the logical location of the ESA within the E-mail flow chain.

Figure 4-6 Typical Data Flow for Inbound E-mail Traffic

227425

The following steps explain what is taking place in [Figure 4-6](#):

-
- Step 1** Sender sends an E-mail to xyz@domain X.
 - Step 2** What's the IP address of domain X?
 - Step 3** It's a.b.c.d (public IP address of ESA).
 - Step 4** E-mail server sends message to a.b.c.d using SMTP.
 - Step 5** Firewall permits incoming SMTP connection to the ESA, and translates its public IP address.
 - Step 6** ESA performs a DNS query on sender domain and checks the received IP address in its reputation database, and drops, quarantines E-mail based on policy.
 - Step 7** ESA forwards E-mail to preconfigured inbound E-mail server.
 - Step 8** E-mail server stores E-mail for retrieval by receiver.
 - Step 9** Receiver retrieves E-mail from server using POP or IMAP.
-

The Internet firewall should be configured to allow communications to and from the Cisco IronPort ESA. Protocols and ports to be allowed vary depending on the services configured on the appliance. For details, refer to the *Cisco IronPort User's Guide* at the following URL:
<http://www.ironport.com/support/>

The following are some of the most common services required:

- Outbound SMTP (TCP/25) from ESA to any Internet destination

- Inbound SMTP (TCP/25) to ESA from any Internet destination
- Outbound HTTP (TCP/80) from ESA to **downloads.ironport.com** and **updates.ironport.com**
- Outbound SSL (TCP/443) from ESA to **updates-static.ironport.com** and **phonehome.senderbase.org**
- Inbound and Outbound DNS (TCP and UDP port 53)
- Inbound IMAP (TCP/143), POP (TCP/110), SMTP (TCP/25) to E-mail server from any internal client

In addition, if the ESA is managed in-band, appropriate firewall rules need to be configured to allow traffic such as SSH, NTP, and syslog.

The Cisco IronPort ESA appliance functions as a SMTP gateway, also known as a mail exchange (MX). The following are the key deployment guidelines:

- Ensure that the ESA appliance is both accessible via the public Internet and is the first hop in the E-mail infrastructure. If you allow another MTA to sit at your network's perimeter and handle all external connections, then the ESA appliance will not be able to determine the sender's IP address. The sender's IP address is needed to identify and distinguish senders in the Mail Flow Monitor, to query the SensorBase Reputation Service for the sender's SensorBase Reputation Service Score (SBRS), and to improve the efficacy of the anti-spam and virus outbreak filters features.
- Features like Cisco IronPort Anti-Spam, Virus Outbreak Filters, McAfee Antivirus and Sophos Anti-Virus require the ESA appliance to be registered in DNS. To that end, create an A record that maps the appliance's hostname to its public IP address, and an MX record that maps the public domain to the appliance's hostname. Specify a priority for the MX record to advertise the ESA appliance as the primary (or backup during testing) MTA for the domain. A static address translation entry needs to be defined for the ESA public IP address on the Internet firewall if NAT is configured.
- Add to the Recipient Access Table (RAT) all the local domains for which the ESA appliance will accept mail. Inbound E-mail destined to domains not listed in RAT will be rejected. External E-mail servers connect directly to the ESA appliance to transmit E-mail for the local domains, and the ESA appliance relays the mail to the appropriate groupware servers (for example, Exchange™, Groupwise™, and Domino™) via SMTP routes.
- For each private listener, configure the Host Access Table (HAT) to indicate the hosts that will be allowed to send E-mails. The ESA appliance accepts outbound E-mail based on the settings of the HAT table. Configuration includes the definition of Sender Groups associating groups or users, upon which mail policies can be applied. Policies include Mail Flow Policies and Reputation Filtering. Mail Flow Policies are a way of expressing a group of HAT parameters (access rule, followed by rate limit parameters and custom SMTP codes and responses). Reputation Filtering allows the classification of E-mail senders and to restrict E-mail access based on sender's trustworthiness as determined by the IronPort SensorBase Reputation Service.
- Define SMTP routes to direct E-mail to appropriate internal mail servers.
- If an out-of-band (OOB) management network is available, use a separate interface for administration.

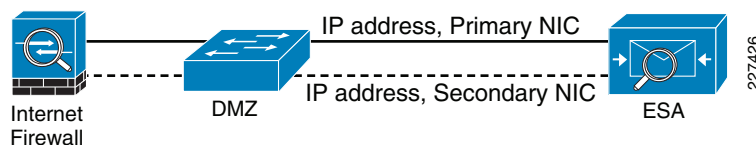

A failure on the ESA appliance may cause service outage, therefore a redundant design is recommended. There are multiple ways to implement redundancy:

- *IronPort NIC Pairing*—Redundancy at the network interface card level by teaming two of the Ethernet interfaces on the ESA appliance. If the primary interface fails, the IP addresses and MAC address are assumed by the secondary.
- *Multiple MTAs*—Consists in adding a second ESA appliance or MTA with an equal cost secondary MX record.

- *Load Balancer*—A load balancer such as Cisco ACE Application Control Engine (ACE) load-balances traffic across multiple ESA appliances.

IronPort NIC pairing is the most cost-effective solution (see Figure 4-7), because it does not require the implementation of multiple ESA appliances and other hardware. It does not, however, provide redundancy in case of chassis failure.

Figure 4-7 Cisco IronPort ESA NIC Pairing

For more information on how to configure ESA, refer to the *Cisco SAFE Reference Guide* (http://www.cisco.com/en/US/docs/solutions/Enterprise/Security/SAFE_RG/SAFE_rg.html) and *IronPort ESA User's Guide* (<http://www.ironport.com/support/>).

Web Security Guidelines

The school architecture implements a Cisco IronPort S Series Web Security Appliance (WSA) to block access to sites with content that may be harmful or inappropriate for minors, and to protect the schools from web-based malware and spyware.

Cisco IronPort WSA's protection relies in two independent services:

- *Web Proxy*—This provides URL filtering, web reputation filters, and optionally anti-malware services. The URL filtering capability defines the handling of each web transaction based on the URL category of the HTTP requests. Leveraging the SensorBase network, the web reputation filters analyze the web server behavior and characteristics to identify suspicious activity and protect against URL-based malware. The anti-malware service leverages anti-malware scanning engines such as Webroot and McAfee to monitor for malware activity.
- *Layer 4 Traffic Monitoring (L4TM)*—Service configured to monitor all Layer-4 traffic for rogue activity and to detect infected clients.

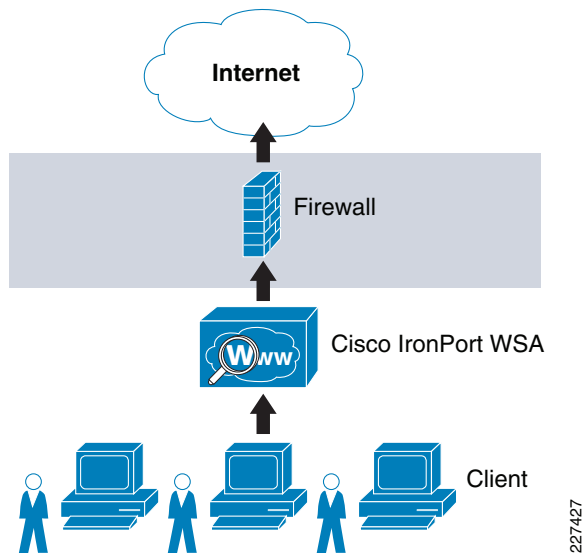

Note

The SensorBase network is an extensive network that monitors global E-mail and web traffic for anomalies, viruses, malware, and other abnormal behavior. The network is composed of the Cisco IronPort appliances, Cisco ASA, and Cisco IPS appliances and modules installed in more than 100,000 organizations worldwide, providing a large and diverse sample of Internet traffic patterns.

As the school design assumes a centralized Internet connection, the WSA is implemented at the distribution layer of the district office network. This allows the inspection and enforcement of web access policies to all students, staff, and faculty residing at any of the school premises. Logically, the WSA sits in the path between web users and the Internet, as shown in Figure 4-8.

Figure 4-8 Cisco IronPort WSA

There are two deployment modes for the Web Proxy service:

- *Explicit Forward Proxy*—Client applications, such as web browsers, are aware of the Web Proxy and must be configured to point to the WSA. The web browsers can be either configured manually or by using Proxy Auto Configuration (PAC) files. The manual configuration does not allow for redundancy, while the use of PAC files allows the definition of multiple WSAs for redundancy and load balancing. If supported by the browser, the Web Proxy Autodiscovery Protocol (WPAD) can be used to automate the deployment of PAC files. WPAD allows the browser to determine the location of the PAC file using DHCP and DNS lookups.
- *Transparent Proxy*—Client applications are unaware of the Web Proxy and do not have to be configured to connect to the proxy. This mode requires the implementation of a Web Cache Communications Protocol (WCCP) enable device or a Layer-4 load balancer in order to intercept and redirect traffic to the WSA. Both deployment options provide for redundancy and load balancing.

Explicit forward proxy mode requires the school to have control over the configuration of the endpoints, which may not be always possible. For example, the school may allow students, staff and faculty to use personal laptops, smart-phones and other devices outside the school's administration. Transparent proxy mode, on the other hand, provides a transparent integration of WSA without requiring any configuration control over the endpoints. It also eliminates the possibility of users reconfiguring their web browsers to bypass the appliance without knowledge of the administrators. For these reasons, the school architecture implements transparent proxy with WCCP. In this configuration, the Cisco ASA at the Internet perimeter is leveraged as a WCCP server while the WSA act as a WCCP Traffic Processing Entity.

Note

It is recommended to enable both the Layer-4 traffic monitor and transparent proxy during the initial System Setup Wizard. Either of these services can be disabled or reconfigured after initial setup from the web interface. If you do not enable one of the features in the System Setup Wizard and then need to enable it later, you must run the System Setup Wizard again, losing all configurations added to the appliance.

The Cisco ASA uses WCCP version 2, which has a built-in failover and load balancing mechanism. Per WCCPv2 specification, multiple appliances (up to 32 entities) can be configured as part of the same service group. HTTP and HTTPS traffic is load-balanced across the active appliances based on source and destination IP addresses. The server (Cisco ASA) monitors the availability of each appliance in the group, and can identify appliance failures within 30 seconds. After failure, traffic is redirected across the remaining active appliances. In the case no appliances are active, WCCP takes the entire service group offline and subsequent requests bypass redirection. In addition, WCCPv2 supports MD5 authentication for the communications between WCCP server and WSA appliances.

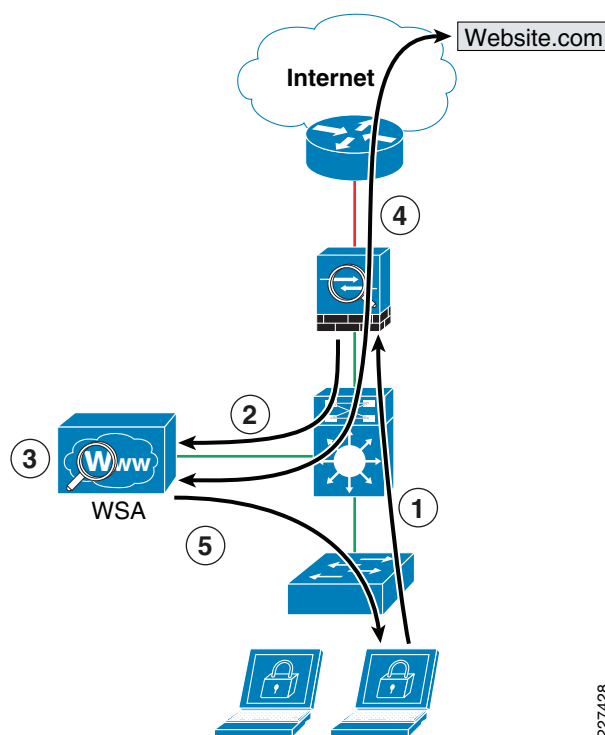

**Note**

In the event the entire service group fails, WCCP automatically bypasses redirection, allowing users to browse the Internet without the Web controls. In case it is desired to handle a group failure by blocking all traffic, an outbound ACL may be configured on the Cisco ASA outside interface to permit HTTP/HTTPS traffic originated from the WSA appliance itself and to block any direct requests from clients. The ACL may also have to be configured to permit HTTP/HTTPS access from IPS and other systems requiring such access.

WCCPv2 supports Generic Route Encapsulation (GRE) and Layer-2-based redirection; however, the Cisco ASA only supports GRE. In addition, WCCP is supported only on the ingress of an interface. The only topology supported is one where both clients and WSA are reachable from the same interface, and where the WSA can directly communicate with the clients without going through the Cisco ASA. For these reasons, the WSA appliance is deployed at the inside segment of the Cisco ASA.

Figure 4-9 illustrates the how WCCP redirection works in conjunction with Cisco ASA.

Figure 4-9 WCCP Redirection

The following steps describe what takes place in Figure 4-9:

-
- | | |
|---------------|---|
| Step 1 | Client's browser requests connection to http://website.com . |
| Step 2 | Cisco ASA intercepts and redirects HTTP requests over GRE. |
| Step 3 | If content not present in local cache, WSA performs a DNS query on destination domain and checks the received IP address against URL and reputation rules, and allows/denies request accordingly. |
| Step 4 | WSA fetches content from destination web site. |
| Step 5 | Content is inspected and then delivered directly to the requesting client. |
-

The WSA appliance may also be configured to control and block peer-to-peer file-sharing and Internet applications such as AOL Messenger, BitTorrent, Skype, Kazaa, etc. The way WSA handles these applications depends on the TCP port used for transport:

- *Port 80*—Applications that use HTTP tunneling on port 80 can be handled by enforcing access policies within the web proxy configuration. Application access may be restricted based on applications, URL categories, and objects. Applications are recognized and blocked based on their user agent pattern, and by the use of regular expressions. The user may also specify categories of URL to block, including the predefined *chat* and *peer-to-peer* categories. Custom URL categories may also be defined. Peer-to-peer access may also be filtered based on object and MIME Multipurpose Internet Mail Extensions (MIME) types.
- *Ports other than 80*—Applications using ports other than 80 can be handled with the L4TM feature. L4TM block access to a specific application by preventing access to the server or block of IP addresses to which the client application must connect.

**Note**

In the school design, the Cisco ASA is configured to allow only permitted ports (HTTP and HTTPS), so any connection attempts on other ports should be blocked by the firewall.

**Note**

The Cisco IPS appliances and modules, and the Cisco ASA (using the modular policy framework), may also be used to block peer-to-peer file sharing and Internet applications.

The following are the guidelines for implementing a Cisco IronPort WSA appliance with WCCP on a Cisco ASA:

- Deploy WSA on the inside of the firewall so that the WSA can communicate with the clients without going through the firewall.
- Implement MD5 authentication to protect the communications between the Cisco ASA and the WSA(s).
- Configure a redirect-list on the firewall to indicate what traffic needs to be redirected. Make sure the WSA is always excluded from redirection.
- Ingress ACL on the firewall takes precedence over WCCP redirection, so make sure the ingress ACL is configured to allow HTTP and HTTPS traffic from clients and the WSA itself.
- In an existing proxy environment, deploy the WSA downstream from the existing proxy servers (closer to the clients).
- Cisco ASA does not support WCCP IP source address spoofing, therefore any upstream authentication or access controls based on client IP addresses are not supported. Without IP address spoofing, requests originating from a client are sourced with the IP address of the Web Proxy, and not the one of the client.

- TCP intercept, authorization, URL filtering, inspect engines, and IPS features do not apply to redirected flows of traffic served by the WSA cache. Content requested by the WSA is still subject to all the configured features on the firewall.
- Configure WSA access policies to block access to applications (AOL Messenger, Yahoo Messenger, BitTorrent, Kazaa, etc) and URL categories not allowed by the school's Internet access policies.
- If an out-of-band (OOB) management network is available, use a separate interface for administration.

**Note**

WCCP, firewall, and other stateful features usually require traffic symmetry, whereby is traffic in both directions should flow through the same stateful device. The school architecture is designed with a single Internet path ensuring traffic symmetry. Care should be taken when implementing active-active firewall pairs as they may introduce asymmetric paths.

The Layer-4 Traffic Monitor (L4TM) service is deployed independently from the Web Proxy functionality, and its mission is to monitor network traffic for rogue activity and for any attempts to bypass port 80. L4TM works by listening to all UDP and TCP traffic and by matching domain names and IP addresses against entries in its own database tables to determine whether to allow incoming and outgoing traffic. The L4TM internal database is continuously updated with matched results for IP addresses and domain names. Additionally, the database table receives periodic updates from the IronPort update server (<https://update-manifests.ironport.com>).

The following are the key guidelines when deploying the L4 Traffic Monitor:

- *Determine physical connection*—L4TM requires traffic to be directed to the WSA for monitoring. This can be done by connecting a physical network tap, configuring SPAN port mirroring on a switch, or using a hub. Network taps forward packets in hardware, while SPAN port mirroring is generally done in software. On the other hand, SPAN port mirroring can be easily reconfigured, providing further flexibility.
- *Location*—Deploy L4TM in the network where it can see as much traffic as possible before getting out to the Internet through the firewall. It is important that the L4TM be logically connected after the proxy ports and before any device that performs network address translation (NAT) on client IP addresses.
- *Action setting*—The default setting for the L4TM is monitor only. Optionally you may configure the L4TM to monitor and block suspicious traffic. TCP connections are reset with the generating of TCP resets, while UDP sessions are tear down with ICMP unreachable. The use of L4TM blocking requires that the L4TM and the Web Proxy to be placed on the same network so that all clients are accessible on routes that are configured for data traffic.

In the school architecture, L4TM is deployed by setting a SPAN session on the distribution switch to replicate all TCP and UDP traffic on the links connecting to the inside interface of the firewall. Using SPAN provides greater flexibility, and inspecting the firewall's inside links ensures traffic is monitored before NAT and before being sent out the Internet. The L4TM deployment is shown in [Figure 4-10](#).

Figure 4-10 L4TM Deployment

L4TM action is set to monitor only. Because the Internet firewall is configured to block any traffic bound to the Internet other than HTTP and HTTPS, there is no additional benefit in using L4TM blocking. If active mitigation is required, consider implementing a Cisco IPS module or appliance in in-line mode. When deployed in inline mode, the Cisco IPS is placed in the traffic path and is capable of stopping malicious traffic before it reaches the intended target. In addition, the Cisco IPS provides multiple configurable response actions including blocking the malicious packet only, blocking the entire session, or blocking any traffic coming from the offending system.

Configuration steps and examples are included in [Chapter 11, “District Office Design.”](#)

Network Access Security and Control

Some of the most vulnerable points of the network are the access edges where students, staff and faculty connect to the network. With the proliferation of wireless networks, increased use of laptops and smart mobile devices, the school administration cannot simply rely on physical controls hoping to prevent unauthorized systems from being plugged into the ports of the access switches. Protection should be rather embedded into the network infrastructure, leveraging the native security features available in switches and routers. Furthermore, the network infrastructure should also provide dynamic identity or role-based access controls for all systems attempting to gain access.

Implementing role-based access controls for users and devices help reduce the potential loss of sensitive information by enabling schools to verify a user or device identity, privilege level, and security policy compliance before granting network access. Security policy compliance could consist of requiring antivirus software, OS updates or patches. Unauthorized, or noncompliant devices can be placed in a quarantine area where remediation can occur prior to gaining access to the network.

The Schools SRA achieves access security and control by using the following technologies:

- Catalyst Integrated Security Features (CISF)
- Cisco NAC Appliance
- Cisco Identity-Based Network Networking Services (IBNS)

The CISF is a set of native security features available on Cisco Catalyst Switches and designed to protect the access infrastructure and users from spoofing, man-in-the-middle, DoS and other network-based attacks. CISF includes features such as private VLANs, port security, DHCP snooping, IP Source Guard, secure Address Resolution Protocol (ARP) detection, and dynamic ARP inspection (DAI). CISF features are considered to be part of a security baseline and should be deployed on all access ports.

In addition to using the CISF features to secure the access ports, access control solutions like IBNS or NAC appliance may be deployed to control who can access the network and ensure endpoint compliance with the schools security policies.

The Cisco IBNS solution is a set of Cisco IOS software services designed to enable secure user and host access to enterprise networks powered by Cisco Catalyst switches and wireless LANs. It provides standards-based network access control at the access layer by using the 802.1X protocol to secure the physical ports where end users connect. 802.1X is an IEEE standard for media-level (Layer 2) access control, offering the capability to permit or deny network connectivity based on the identity of the end user or device enabling enterprise policy enforcement of all users and hosts, whether managed or unmanaged. In addition to holistic access-control provided by 802.1X, IBNS also offers device-specific access-control through MAC-Authentication Bypass (MAB) and user-based access-control through Web-Auth.

The Cisco Network Admission Control (NAC) Appliance uses the network infrastructure to enforce security policy compliance on all devices seeking to access network computing resources. With NAC Appliance, network administrators can authenticate, authorize, evaluate, and remediate wired, wireless, and remote users and their machines prior to network access. It identifies whether networked devices such as laptops, IP phones, or game consoles are compliant with your network's security policies and repairs any vulnerability before permitting access to the network. Noncompliant machines are redirected into a quarantine area, where remediation occurs at the discretion of the administrator.

The choice of which access control solution to use depends on the security goals and the direction of the network design. For networks using or moving towards 802.1x-based wired or wireless access and interested in identity-based access control, Cisco IBNS solution should be considered. For networks requiring role-based access control using posture assessments to ensure security compliance, Cisco NAC Appliance should be considered.

The Catalyst Integrated Security Features (CISF), and the Cisco Identity-Based Networking Services (IBNS) and NAC Appliance access control solutions are discussed in [Chapter 9, “Access Layer Security Design.”](#)

Endpoint Protection

Servers, desktop computers, laptops, printers, and IP phones are examples of the diverse network endpoints commonly present in School environments. The great variety in hardware types, operating systems, and applications represents a clear challenge to security. In addition, students and staff may bring laptops and other portable devices that could also be used outside the school's premises, potentially introducing viruses, worms, spyware, and other type of malware.

Properly securing the endpoints requires not only adoption of the appropriate technical controls but also end-user awareness. While this document focuses on the implementation of the technical controls, the school's security strategy must include security awareness campaigns and programs. Students and staff must be continuously educated on current threats, use best practices, and the security measures needed for keeping endpoints up-to-date with the latest updates, patches, and fixes.

Following the best practices of Cisco SAFE, the school architecture implements a range of security controls designed to protect the endpoints. These include host-based Cisco IPS, network-based intrusion prevention systems, and web and E-mail traffic security.

As Cisco host-based IPS, the architecture leverages the Cisco Security Agent (CSA). CSA takes a proactive and preventative approach, using behavior-based security to focus on preventing malicious activity on the host. Malicious activity is detected and blocked, independent of the type of malware, spyware, adware, or virus affecting the host.

Once deployed on an endpoint, whenever an application attempts an operation, the agent checks the operation against the application's security policy—making a real-time allow or deny decision on the continuation of that operation and determining whether logging the operation request is appropriate. Security policies are collections of rules that IT or security administrators assign to protect servers and desktops, either individually or organization-wide. CSA provides defense-in-depth protection against spyware and adware by combining security policies that implement distributed firewall, operating system lockdown and integrity assurance, malicious mobile code protection, and audit-event collection capabilities in default policies for servers and desktops.

CSAs are centrally managed with the CSA Management Center (CSA-MC), which in the Cisco SAFE design is placed in a secure segment in the data center. The Management Center (MC) also provides centralized reporting and global correlation.

For complete details about deploying CSA in a network, refer to the *Rapid Deployment Guide for Cisco Security Agent 6.0 for Desktops* at the following URL:

http://www.cisco.com/en/US/prod/collateral/vpndevc/ps5707/ps5057/deployment_guide_c07-501928.htm

Internet Perimeter Security

Internet Border Router

Whether the Internet border router is managed by the school or the ISP, it must be hardened following the best practices listed in the Network Foundation Protection section. This includes restricting and controlling administrative access, protecting the management and control planes, and securing the dynamic exchange of routing information. In addition, the Internet border router may be leveraged as the first layer of protection against outside threats. To that end, edge ACLs, uRPF and other filtering mechanisms may be implemented for anti-spoofing and to block invalid packets.

The following configuration snippet illustrates the structure of an edge ACL applied to the upstream interface of the Internet border router. The ACL is designed to block invalid packets and to protect the infrastructure IP addresses from the Internet. The configuration assumes the school is assigned the 198.133.219.0/24 address block, and that the upstream link is configured in the 64.104.10.0/24 subnet.

```

```

**Note**

The 64.104.0.0/16 and 198.133.219.0/24 address blocks used in the examples here provided are reserved for the exclusive use of Cisco Systems, Inc.

Internet Firewall

The mission of the Internet firewall is to protect the school's internal resources and data from external threats, secure the public services provided by the DMZ, and to control user's traffic to the Internet. The Schools Service Ready architecture uses a Cisco ASA appliance as illustrated in [Figure 4-11](#).

Figure 4-11 Internet Edge Firewall

The Cisco ASA is implemented with three interface groups, each one representing a distinct security domain:

- *Inside*—The Inside is the interface connecting to the core/distribution switch that faces the interior of the network where internal users and resources reside.
- *Outside*—Interface connecting to the Internet border router. The router may be managed either by the school or a service provider.
- *Demilitarized Zone (DMZ)*—The DMZ hosts school services that are accessible over the Internet. These services may include a web portal and E-mail services.

The Internet firewall acts as the primary gateway to the Internet; Therefore, its deployment should be carefully planned. The following are key aspects to be considered when implementing the firewall:

- Firewall Hardening and Monitoring
- Network Address Translation (NAT)
- Firewall Access Policies
- Firewall Redundancy
- Routing

Firewall Hardening and Monitoring

The Cisco ASA should be hardened in a similar fashion as the infrastructure routers and switches. According to the Cisco SAFE security best practices, the following is a summary of the measures to be taken:

- Implement dedicated management interfaces to the OOB management network.
- Present legal notification for all access attempts.
- Use HTTPS and SSH for device access. Limit access to known IP addresses used for administrative access.
- Configure AAA for role-based access control and logging. Use a local fallback account in case AAA server is unreachable.
- Use NTP to synchronize the time.
- Use syslog or SNMP to keep track of system status, traffic statistics, and device access information.
- Authenticate routing neighbors and log neighbor changes.
- Implement firewall access policies (explained in the Firewall Access Policies).

The Cisco ASA 5510 and higher appliance models come with a dedicated management interface that should be used whenever possible. Using a dedicated management interface keeps the management plane of the firewall isolated from threats originating from the data plane. The management interface should connect to the OOB management network, if one is available.

The following is an example of the configuration of a dedicated management interface.

```
interface Management0/0
 nameif management
 security-level 100
 ip address 172.26.160.225 255.255.252.0
 management-only
!
```

**Note**

Any physical interface or logical sub-interface can be configured as a management-only interface using the **management-only** command.

It is recommended that a legal notification banner is presented on all interactive sessions to ensure that users are notified of the security policy being enforced and to which they are subject. The notification banner should be written in consultation with your legal advisors.

The following example displays the banner after the user logs in:

```
banner motd UNAUTHORIZED ACCESS TO THIS DEVICE IS PROHIBITED.
banner motd You must have explicit, authorized permission to access or configure this
device.
banner motd Unauthorized attempts and actions to access or use this system may result in
civil and/or criminal penalties.
banner motd All activities performed on this device are logged and monitored.
```

Management access to the firewall should be restricted to SSH and HTTPS. SSH is needed for CLI access and HTTPS is needed for the firewall GUI-based management tools such as CSM and ADSM. Additionally, this access should only be permitted for users authorized to access the firewalls for management purposes.

The following ASA configuration fragment illustrates the configuration needed to generate a 768 RSA key pair and enabling SSH and HTTPS access for devices located in the management subnet.

```
! Generate RSA key pair with a key modulus of 768 bits
```

```
crypto key generate rsa modulus 768
! Save the RSA keys to persistent flash memory
write memory
! enable HTTPS
http server enable
! restrict HTTPS access to the firewall to permitted management stations
http <CSM/ADSM-IP-address> 255.255.255.255 management
! restrict SSH access to the firewall to well-known administrative systems
ssh <admin-host-IP-address> 255.255.255.255 management
! Configure a timeout value for SSH access to 5 minutes
ssh timeout 5
```

Administrative users accessing the firewalls for management must be authenticated, authorized, and access should be logged using AAA. The following ASA configuration fragment illustrates the AAA configurations needed to authenticate, authorize, and log user access to the firewall:

```
aaa-server tacacs-servers protocol tacacs+
  reactivation-mode timed
aaa-server tacacs-servers host <ACS-Server>
  key <secure-key>
aaa authentication ssh console tacacs-servers LOCAL
aaa authentication serial console tacacs-servers LOCAL
aaa authentication enable console tacacs-servers LOCAL
aaa authentication http console tacacs-servers LOCAL
aaa authorization command tacacs-servers LOCAL
aaa accounting ssh console tacacs-servers
aaa accounting serial console tacacs-servers
aaa accounting command tacacs-servers
aaa accounting enable console tacacs-servers
aaa authorization exec authentication-server
! define local username and password for local authentication fallback
username admin password <secure-password> encrypted privilege 15
```

As with the other infrastructure devices in the network, it is important to synchronize the time on the firewall protecting the management module using NTP.

The following configuration fragment illustrates the NTP configuration needed on an ASA to enable NTP to an NTP server located in the management network:

```
ntp authentication-key 10 md5 *
ntp authenticate
ntp trusted-key 10
ntp server <NTP-Server-address> source management
```

Syslog and SNMP can be used to keep track of system status, device access, and session activity. NetFlow Security Event Logging (NSEL), now supported on all Cisco ASA models, may also be used for the monitoring and reporting of session activity. The following configuration fragment illustrates the configuration of Syslog.

```
logging trap informational
logging host management <Syslog-Server-address>
logging enable
```

The routing protocol running between the Internet firewall and the core/distribution should be secured. The following ASA configuration fragment illustrates the use of EIGRP MD5 authentication to authenticate the peering session between the inside firewall interface and the core/distribution switch:

```
interface Redundant1
  nameif inside
  security-level 100
  ip address 10.125.33.10 255.255.255.0
  authentication key eigrp 100 <removed> key-id 1
```

```
authentication mode eigrp 100 md5
```

Network Address Translation (NAT)

NAT is required because the school typically gets a limited number of public IP addresses. In addition, NAT helps shield the school's internal address space from reconnaissance and another malicious activity.

The following illustrates the NAT configuration:

```
! Static translation for servers residing at DMZ
static (dmz,outside) 198.133.219.10 10.25.34.10 netmask 255.255.255.255
static (dmz,outside) 198.133.219.11 10.25.34.11 netmask 255.255.255.255
static (dmz,outside) 198.133.219.12 10.25.34.12 netmask 255.255.255.255
static (dmz,outside) 198.133.219.13 10.25.34.13 netmask 255.255.255.255
!
! Dynamic Port Address Translation (PAT) for inside hosts going to the Internet
global (outside) 10 interface
nat (inside) 10 10.0.0.0 255.0.0.0
!
Static translation for inside hosts going to the DMZ and vice-versa. The inside IP addresses are visible
to the DMZ.

static (inside,dmz) 10.0.0.0 10.0.0.0 netmask 255.0.0.0
```

Firewall Access Policies

As previously explained, the Internet firewall should be configured to:

- Protect school internal resources and data from external threats by preventing incoming access from the Internet.
- Protect public resources served by the DMZ by restricting incoming access to the public services and by limiting outbound access from DMZ resources out to the Internet.
- Control user's Internet-bound traffic.

Enforcing such policies requires the deployment of ACLs governing what traffic is allowed or prevented from transiting between interfaces. By default, the Cisco ASA appliance allows traffic from higher to lower security level interfaces (i.e., from inside to outside). However, due to the sensitivity of school environments, the school administration may opt to override the default rules with more stringent rules indicating exactly what ports and protocols are permitted.

It should also be noted that, as the Cisco ASA inspects traffic, it is able to recognize packets belonging to already established sessions. The stateful inspection engine of the firewall dynamically allows the returning traffic. Therefore, the firewall ACLs should be constructed to match traffic in the direction in which it is being initiated. In our sample configurations, ACLs are applied in the ingress direction.

The following are the guidelines and configuration examples of ACLs controlling access and traffic flows:

- Ingress Inside

Allow Internet access to student, staff and faculty residing at all school premises for the allowed ports and protocols. This typically includes HTTP and HTTPS access.

```
access-list Outbound extended permit tcp 10.0.0.0 255.0.0.0 any eq http
access-list Outbound extended permit tcp 10.0.0.0 255.0.0.0 any eq https
```

Allow students, staff, and faculty access to DMZ services such as school web portal, E-mail, and domain name resolution (HTTP, HTTPS, SMTP, POP, IMAP, and DNS). Note that the previous entries in the ACL already permit HTTP and HTTPS traffic.

```
! Allow DNS queries to DNS server
access-list Outbound extended permit udp 10.0.0.0 255.0.0.0 host 10.25.34.13 eq domain
! Allow SMTP, POP3 and IMAP access to DMZ mail server
access-list Outbound extended permit tcp 10.0.0.0 255.0.0.0 host 10.25.34.12 eq smtp
access-list Outbound extended permit tcp 10.0.0.0 255.0.0.0 host 10.25.34.12 eq pop3
access-list Outbound extended permit tcp 10.0.0.0 255.0.0.0 host 10.25.34.12 eq imap4
! Apply ACL to inside interface
access-group Outbound in interface inside
```

- Ingress DMZ

Restrict connections initiated from DMZ to the only necessary protocols and sources. This typically includes DNS queries and zone transfer from DNS server, SMTP from E-mail server, HTTP/SSL access from the Cisco IronPort ESA for updates, Sensorbase, etc.

```
! Allow DNS queries and zone transfer from DNS server
access-list DMZ extended permit udp host 10.25.34.13 any eq domain
access-list DMZ extended permit tcp host 10.25.34.13 any eq domain
!
! Allow SMTP from Cisco IronPort ESA
access-list DMZ extended permit tcp host 10.25.34.11 any eq smtp
!
! Allow update and SensorBase access to Cisco IronPort ESA
access-list DMZ extended permit tcp host 10.25.34.11 any eq http
access-list DMZ extended permit tcp host 10.25.34.11 any eq https
!
! Apply ACL to DMZ interface
access-group DMZ in interface dmz
```

- Ingress Outside

Inbound Internet access should be restricted to the public services provided at the DMZ such as SMTP, Web, and DNS. Any connection attempts to internal resources and subnets from the Internet should be blocked. ACLs should be constructed using the servers' global IP addresses.

```
! Allow DNS queries and zone transfer to DNS server
access-list Inbound extended permit udp any host 198.133.219.13 eq domain
access-list Inbound extended permit tcp any host 198.133.219.13 eq domain
!
! Allow SMTP to Cisco IronPort ESA
access-list Inbound extended permit tcp any host 198.133.219.11 eq smtp
!
! Allow HTTP/HTTPS access to school public web portal
access-list Inbound extended permit tcp any host 198.133.219.10 eq http
access-list Inbound extended permit tcp any host 198.133.219.10 eq https
!
! Apply ACL to outside interface
access-group Inbound in interface outside
```

Firewall Redundancy

The Internet perimeter of the school architecture uses a single Cisco ASA appliance configured with redundant interfaces. The use of redundant interfaces makes the design resilient to link level failures, representing an affordable option for high availability. In cases where chassis redundancy is desirable, the school may consider deploying a pair of Cisco ASA appliances configured for stateful failover. Both

active/active and active/standby failover modes are supported. While stateful failover protects against chassis failures, it requires the deployment of two identical Cisco ASA appliances and the adjustment of the topologies around the firewalls, so its deployment should be carefully planned.

This guide explains the use of redundant interfaces. For information on how to configure stateful failover, refer to the *Cisco ASA 5500 Series Adaptive Security Appliances Configuration Guides* at the following URL:

http://www.cisco.com/en/US/products/ps6120/products_installation_and_configuration_guides_list.html

A Cisco ASA redundant interface is a logical interface that pairs two physical interfaces, called active and standby interfaces. Under normal operation the active interface is the only one passing traffic. The active interface uses the IP address defined at the redundant interface, and the MAC address of the first physical interface associated with the redundant interface. When the active interface fails, the standby interface becomes active and starts passing traffic. The same IP address and MAC address are maintained so that traffic is not disrupted. Figure 4-12 illustrates the concept of redundant interface.

Figure 4-12 Cisco ASA Redundant Interface

The configuration of a redundant interface consists in the configuration of the physical interface parameters and the logical redundant interface. Physical parameters such as media type, duplex, and speed are still configured within the physical interface. IP address, interface name, routing protocols, security level are configured as part of the redundant interface. The following configuration example corresponds to Figure 4-12.

```
! Physical interface and Ethernet parameters
interface GigabitEthernet0/0
description Connected to cr24-4507-DO
no nameif
no security-level
no ip address
!
interface GigabitEthernet0/1
description backup to cr24-4507-DO
no nameif
no security-level
no ip address
!
! Defines logical redundant interface associated with physical interfaces. Configures IP
and logical interface parameters.
interface Redundant1

Routing

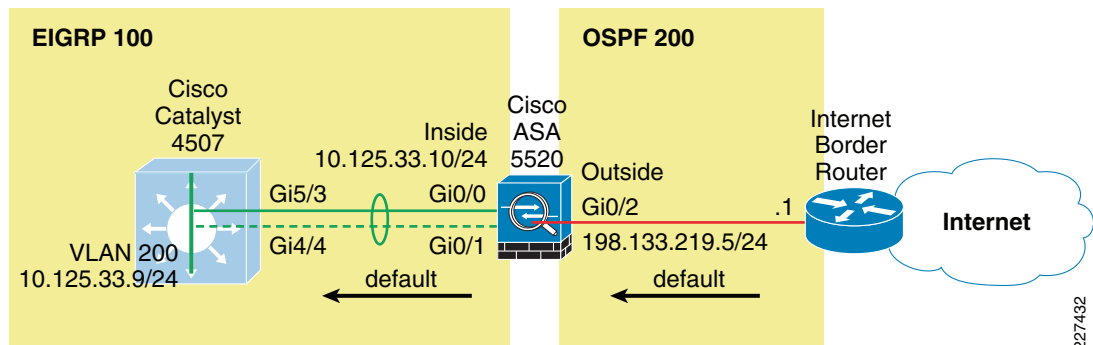

An interior gateway protocol, EIGRP in our configuration examples, is used for dynamic routing. The Internet firewall may participate in routing by learning the internal routes and by injecting a default route pointing to the Internet. The default route should be removed dynamically if the Internet connection becomes unavailable.

As part of the school architecture, two different approaches were validated for the injection of the default route:

- *OSPF*—The Cisco ASA appliance learns the default route from the Internet border router using OSPF. The default route is then redistributed into EIGRP, and from there propagated into the rest of the internal network.
- *Static Route*—The Cisco ASA appliance is configured with a static default route pointing to the Internet gateway. Object tracking is configured to dynamically remove the default route when the Internet connection becomes unavailable. The default route is redistributed into EIGRP, and from there propagated into the rest of the internal network.

Injecting a default route with OSPF requires the configuration of an OSPF process between the Cisco ASA and the Internet border router, as illustrated in [Figure 4-13](#). If the router is managed by the ISP, the configuration will require coordination with the service provider. This scenario also requires the default route to be propagated over OSPF. The actual default route may originate from the Internet border router itself or somewhere in the ISP network.

Figure 4-13 Cisco ASA OSPF

The following are the guidelines for using OSPF for the injection of a default route:

- Whenever possible, use MD5 authentication to secure the routing session between the Cisco ASA and the Internet border router.
- Since NAT is configured on the Cisco ASA and the inside address space is not visible outside the firewall, there is no need to redistribute routes from the internal EIGRP into OSPF.
- Route redistribution from OSPF into the internal EIGRP should be limited to the default route only. No other routes should be propagated into EIGRP.

The following configuration snippet illustrates the routing configuration of the Cisco ASA appliance. The configuration includes the route redistribution from OSPF into EIGRP with the enforcement of a route-map allowing only the injection of the default route. MD5 authentication is used for OSPF, and the logging of neighbor status changes is enabled.

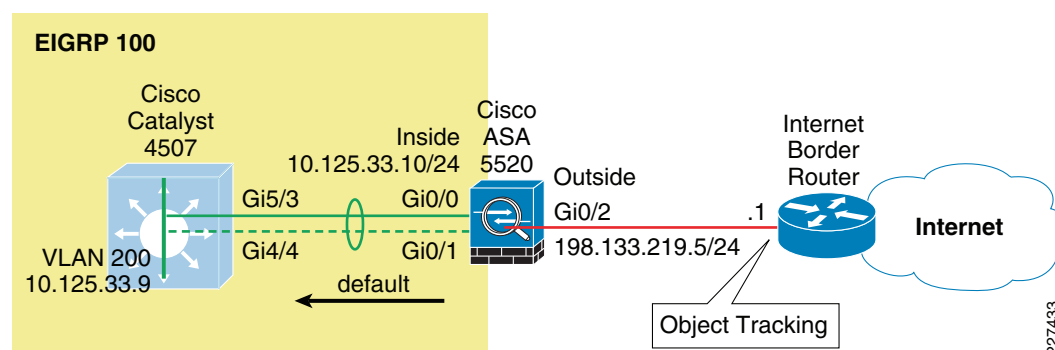

```
! Permit default only
access-list Inbound-Routes standard permit host 0.0.0.0
!
interface GigabitEthernet0/2
  ospf message-digest-key 1 md5 <removed>
  ospf authentication message-digest
!
route-map Inbound-EIGRP permit 10
  match ip address Inbound-Routes
!
router eigrp 100
  no auto-summary
  network 10.125.33.0 255.255.255.0
  passive-interface default
  no passive-interface inside
  redistribute ospf 200 metric 1000000 2000 255 1 1500 route-map Inbound-EIGRP
!
router ospf 200
  network 198.133.219.0 255.255.255.0 area 100
  area 100 authentication message-digest
  log-adj-changes
!
```

**Note**

The **hello-interval** and **dead-interval** OSPF timers can be adjusted to detect topological changes faster.

The other validated alternative for the default route injection is the definition of a static default route, which then can be redistributed into the internal EIGRP process. This is shown in [Figure 4-14](#). This option does not require the configuration of the Internet border router.

Figure 4-14 Cisco ASA Static Route

It is highly recommended to use object tracking so the default route is removed when the Internet connection becomes unavailable. Without object tracking, the default route will be removed only if the outside interface of the appliance goes down. So there is a possibility that the default route may remain in the routing table even if the Internet border router becomes unavailable. To avoid that problem, the static default route can be configured with object tracking. This consists in associating the default route

with a monitoring target. The Cisco ASA appliance monitors the target using ICMP echo requests. If an echo reply is not received within a specified time period, the object is considered down and the associated default route is removed from the routing table.

The monitoring target needs to be carefully selected. First, pick one that can receive and respond to ICMP echo requests sent by the Cisco ASA. Second, it is better to use a persistent network object. In the configuration example below the Cisco ASA monitors the IP address of the next hop gateway, which helps identifying if the Internet gateway goes down, but it will not help if the connection is lost upstream. If available, you may want to monitor a persistent network object located somewhere in the ISP network. Static route tracking can also be configured for default routes obtained through DHCP or PPPoE.

In the following configuration the IP address of the next hop gateway (198.133.219.1) is used as the monitoring target. The static default route is then redistributed into EIGRP.

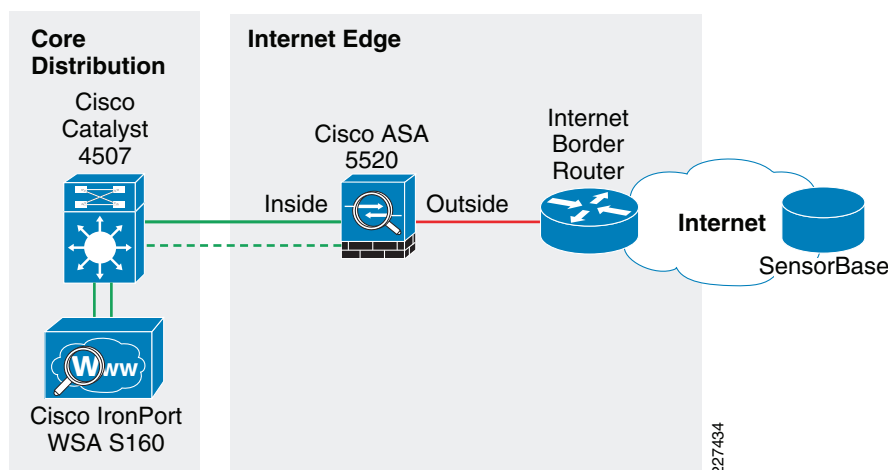

```
router eigrp 100
  no auto-summary
  network 10.125.33.0 255.255.255.0
  passive-interface default
  no passive-interface inside
  redistribute static metric 1000000 2000 255 1 1500
!
route outside 0.0.0.0 0.0.0.0 198.133.219.1 1 track 10
!
sla monitor 1
  type echo protocol ipIcmpEcho 198.133.219.1 interface outside
sla monitor schedule 1 life forever start-time now
!
track 10 rtr 1 reachability
```

**Note**

The *frequency* and *timeout* parameters of object tracking can be adjusted to detect topological changes faster.

Web Security

The Schools Service Ready Architecture implements a Cisco IronPort WSA at the core/distribution layer of the district office, as illustrated in [Figure 4-15](#). The WSA is located at the inside of the Cisco ASA acting as the Internet firewall. That ensures that clients and WSA are reachable over the same inside interface of the firewall, and that the WSA can communicate with them without going through the firewall. At the same time, deploying the WSA at the core/distribution layer gives complete visibility to the WSA on the traffic before getting out to the Internet through the firewall.

Figure 4-15 WSA Deployment

Following subsections describe the guidelines for the WSA configuration and deployment.

Initial System Setup Wizard

The WSA provides a browser-based system setup wizard that must be executed the first time the appliance is installed. The System Setup Wizard guides the user through initial system configuration such as network and security settings. It is critical to note that some of the initial settings cannot be changed afterwards without resetting the appliance's configuration to its factory defaults. Therefore, care should be taken in choosing the right configuration options. Plan not only for the features to be implemented immediately, but also for what that might be required in the future.

The following are some guidelines when running the System Setup Wizard:

- *Deployment Options*—Step 2 of the wizard gives the user the options to enable only L4 Traffic Monitoring, enable only Secure Web Proxy, or enable both functions. Select enable both Secure Web Proxy and L4 Traffic Monitor if you plan to use both functions.
- *Proxy Mode*—If the Secure Web Proxy function has been enabled, Step 2 of the wizard requires the user to choose between Forward and Transparent mode. It should be noted that a WSA appliance initially configured in Transparent mode can still be configured as a Forward Web Proxy, per contrary, the Transparent Web Proxy function is not available if the appliance is configured in Forward mode. Therefore, select Forward mode only if you certain that the Transparent mode will never be required.

Note

The deployment and proxy mode options cannot be changed after the initial configuration without resetting the WSA appliance to its factory defaults. Plan your configuration carefully.

Interface and Network Configuration

The following need to be configured as part of the initial setup of the WSA appliance:

-
- Step 1** Configuring network interfaces
 - Step 2** Adding routes

- Step 3** Configuring DNS
- Step 4** Setting time
- Step 5** Working with upstream proxy (if present)

These settings are configured as part of an initial setup using the System Setup Wizard, but can be later modified by using the WSA Web-based GUI.

Configuring Network Interfaces

Independently from the model, all Cisco IronPort WSA appliances are equipped with six Ethernet interfaces as shown in [Figure 4-16](#).

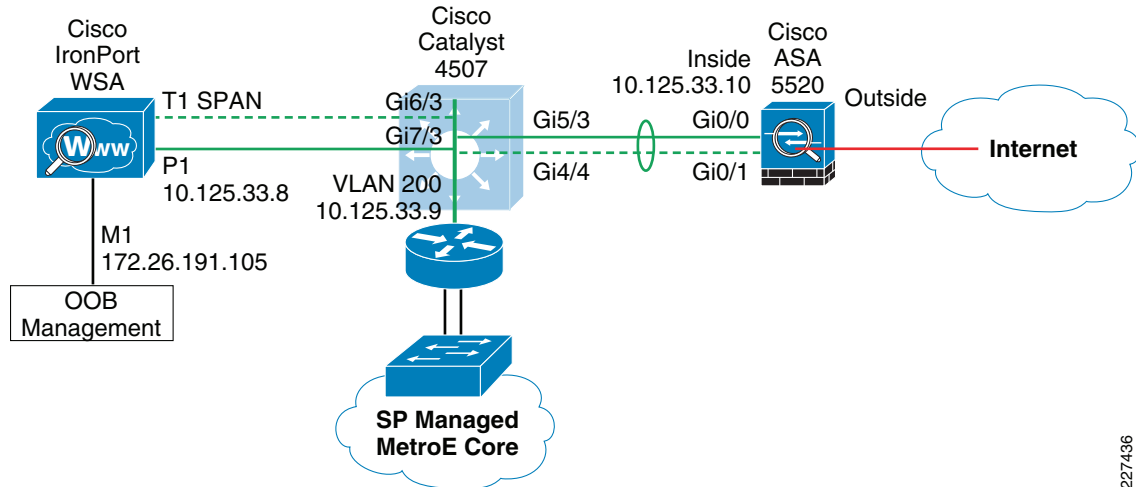

Figure 4-16 WSA Interfaces

The WSA interfaces are grouped for the following functions:

- *Management*—Interfaces M1 and M2 are out-of-band (OOB) management interfaces. However, only M1 is enabled. In the school architecture, interface M1 connects to the out-of-band management network. Interface M1 can optionally be used to handle data traffic in case the school does not have an out-of-band management network.
- *Web Proxy*—Interfaces P1 and P2 are Web Proxy interfaces used for data traffic. Only the P1 interface is used in the school architecture. P1 connects to the inside subnet of the firewall.
- *L4 Traffic Monitor (L4TM)*—T1 and T2 are the L4TM interfaces. The school design uses only the T1 interfaces. The T1 interface connects to a core/distribution switch port configured as the destination of the SPAN session used to capture traffic bound to the Internet.

[Figure 4-17](#) illustrates the network topology around the WSA used in the Cisco validation lab.

Figure 4-17 WSA Network Topology

227436

Figure 4-18 illustrate the IP address and hostname configurations for the interfaces used. In this case, an out-of-band management network is used; therefore the M1 port is configured with an IP address in the management subnet. In addition, the WSA is configured to maintain a separate routing instance for the M1 management interface. This allows the definition of a default route for management traffic separate from the default route used for data traffic.

Figure 4-18 WSA Interface Configuration**Interfaces**

227437

Adding Routes

A default route is defined for management traffic pointing to the OOB management default gateway (172.26.191.1). A separate default route is defined for the data traffic pointing to the inside IP address of the firewall (10.125.33.10). As all internal networks are reachable throughout the core/distribution switch, a route to 10.0.0.0/8 is defined pointing to the switch IP address (10.125.33.9) to allow the WSA to communicate with the clients directly without having to go to the firewall first. These settings are illustrated in Figure 4-19.

Figure 4-19 WSA Route Configuration**Routes**

227438

Configuring DNS

The initial setup requires the configuration of a host name for the WSA appliance, and listing the DNS servers. [Figure 4-20](#) shows the DNS configuration.

Figure 4-20 WSA DNS Configuration**DNS**

DNS Server Settings

DNS Servers: Use these DNS Servers:

227440

Working with Upstream Proxies

If Internet access is provided by an upstream proxy, then the WSA must be configured to use the proxy for component updates and system upgrades. This is illustrated in [Figure 4-22](#) and [Figure 4-23](#).

227442

WCCP Transparent Web Proxy

The configuration of the WCCP Transparent Web Proxy includes the following:

-
- Step 1** Defining WSA WCCP Service Group
 - Step 2** Enabling WSA Transparent Redirection
 - Step 3** Enabling WCCP redirection on the Cisco ASA
 - Step 4** Enabling WSA HTTPS scanning
 - Step 5** Working with upstream proxy (if present)
-

Defining WSA WCCP Service Group

Web Proxy settings are configured as part of an initial setup using the System Setup Wizard and can be later modified with the WSA Web-based GUI. The Web Proxy setting include the following:

- *HTTP Ports to Proxy*—List the ports to be proxied. Default is 80 and 3128.
- *Caching*—Defines whether or not the WSA should cache response and requests. Caching helps reduce latency and the load on the Internet links. Default is enabled.
- *IP Spoofing* — Defines whether or not the Web Proxy should spoof IP addresses when forwarding requests to upstream proxies and servers. The Cisco ASA does not support source address spoofing.

Figure 4-24 illustrates the Web Proxy settings.

Figure 4-24 WSA Proxy Settings

227443

Enabling WSA Transparent Redirection

Configuring WCCP Transparent Redirection requires the definition of a WCCP service profile in the WSA. If redirecting HTTP and HTTPS, define a dynamic service ID to be used with the Cisco ASA. Use MD5 authentication to protect the WCCP communication between the WSA and Cisco ASA.

Figure 4-25 shows an example.

Figure 4-25 WSA Transparent Proxy

227444

Enabling WCCP Redirection on Cisco ASA

The configuration of WCCP on the Cisco ASA appliance requires:

- A group-list indicating the IP addresses of the appliances member of the service group. In the example provided below the group-list is called **wsa-farm**.
- A redirect-list indicating the ports and subnets of traffic to be redirected. In the example, the ACL named proxylist is configured to redirect any HTTP and HTTPS traffic coming from the 10.0.0.0/8 subnet. It is critical to ensure traffic from the WSA(s) bypasses redirection. To that end, add an entry to the redirect-list explicitly denying traffic sourced from the WSA(s).
- WCCP service indicating the service ID. Make sure you use the same ID as defined on the WSAs. Use a password for MD5 authentication.
- Enabling WCCP redirection on an interface. Apply the WCCP service on the inside interface of the Cisco ASA.

Cisco ASA WCCP configuration example:

```
! Group-list defining the IP addresses of all WSAs
access-list wsa-farm extended permit ip host 10.125.33.8 any
!
! Redirect-list defining what ports and hosts/subnets should be redirected
access-list proxylist extended deny ip host 10.125.33.8 any
access-list proxylist extended permit tcp 10.0.0.0 255.0.0.0 any eq www
access-list proxylist extended permit tcp 10.0.0.0 255.0.0.0 any eq https
!
! WCCP service
wccp 10 redirect-list proxylist group-list wsa-farm password cisco
!
! Applies WCCP on an interface
wccp interface inside 10 redirect in
```

The WCCP connection status and configuration can be monitored on the Cisco ASA with the **show wccp** command. An example is provided below:

```
cr26-asa5520-do# show wccp

Global WCCP information:
  Router information:
    Router Identifier:          198.133.219.5

227445

Working with Upstream Proxies

In case Internet traffic is handled by one or more upstream proxies, follow these guidelines:

- Add an Upstream Proxy Group
- Define a routing policy to direct traffic to the upstream proxies

The Upstream Proxy Group lists the IP addresses or domain names of the proxies to be used for traffic sent to the Internet. When multiple proxies are available, the WSA can be configured for failover or load balancing.

The following are the options available:

- *None (failover)*—The first proxy in the list is used. If one proxy cannot be reached, the Web Proxy attempts to connect to the next one in the list.
- *Fewest connections*—Transactions are directed to the proxy servicing the fewest number of connections.
- *Hash-based*—Requests are distributed using a hash function. The function uses the proxy ID and URL as inputs so that requests for the same URL are always directed to the same upstream proxy.
- *Least recently used*—Transactions are directed to the proxy that least recently received a transaction if all proxies are currently active.
- *Round robin*—The Web Proxy cycles transactions equally among all proxies in the group in the listed order.

[Figure 4-27](#) illustrates the upstream proxy group configuration. Two upstream proxies are used, and transactions are forwarded to the proxy servicing the fewest number of connections.

Figure 4-27 WSA Upstream Proxy Group**Edit Upstream Proxy Group**

Proxy Group			
Name: <input type="text" value="Upstream-Lab_proxy"/>			
Proxy Servers:	Proxy Address	Port	Reconnection Attempts ? <input type="button" value="Add Row"/>
	<input type="text" value="64.102.255.40"/>	<input type="text" value="80"/>	<input type="text" value="2"/> <input type="button" value="Delete"/>
	<input type="text" value="128.107.241.169"/>	<input type="text" value="80"/>	<input type="text" value="2"/> <input type="button" value="Delete"/>
	<i>hostname or IP address</i> <i>Any number great than 0.</i>		
Load Balancing ? <input type="button" value="Fewest Connections"/>			
Failure Handling: <i>Specify how to handle requests if all proxies in this group fail.</i>			
<input checked="" type="radio"/> Connect directly to destination host <input type="radio"/> Drop requests			

227446

Next, a routing rule needs to be defined to indicate when and how to direct transactions to the upstream proxy group. Use the Global Routing Policy if all traffic is to be handled by the upstream proxies. If no proxies are present, then leave the routing destination of the Global Routing Policy configured as **Direct Connection**. Figure 4-28 presents an example where all traffic is directed to the proxies in the Upstream-Lab_proxy group.

Figure 4-28 WSA Routing Policies**Routing Policies**

Routing Definitions			
<input type="button" value="Add Policy..."/>			
Order	Members	Routing Destination	Delete
	Global Routing Policy	Upstream-Lab_proxy 64.102.255.40:80, 128.107.241.169:80	

227447

Web Access Policies

The access policies define how the Web Proxy handles HTTP requests and decrypted HTTPS connections for network users. By configuring access policies the school can control what Internet applications (instant messaging clients, peer-to-peer file-sharing, web browsers, Internet phone services, etc.) and URL categories students, staff and faculty may access. In addition, access policies can be used to block file downloads based on file characteristics, such as file size and file type.

The WSA comes with a default Global Policy that applies to all users. However, multiple policies can be defined when different policies need to be applied to different group of users. Figure 4-29 shows the global policy.

Figure 4-29 Global Access Policy**Access Policies**

Policies						
Add Policy...						
Order	Group	Applications	URL Categories	Objects	Web Reputation and Anti-Malware Filtering	Delete
	Global Policy Identity: All	Allow: FTP over HTTP, HTTP Allow: Ports 8080, 21,...	Redirect: 0 Monitor: 52 Block: 1 Allow: 0	Object Max Size: None	(enabled)	

227448

URL categories corresponding to content inappropriate for minors should be blocked in compliance with the school's Internet access policies. [Figure 4-30](#) provides an example on how the "Adult/Sexually Explicit" category is blocked.

Figure 4-30 URL Categories**Access Policies: URL Categories: Global Policy**

☺ Adult/Explicit & Sexual		

227449

Layer-4 Traffic Monitoring

(L4TM)

L4TM can be implemented in the school environment to identify rogue traffic across all network ports and detect malware attempts to bypass port 80. Additionally, L4TM is capable of identifying internal clients with malware and that attempt to phone-home across non-standard ports and protocols.

Implementing L4TM requires the following:

-
- Step 1** Configuring L4TM interfaces
 - Step 2** Configuring WSA L4TM global settings
 - Step 3** Configuring traffic monitoring
-

Configuring L4TM Interfaces

The wiring type depends on how traffic is directed to the WSA appliance. Network taps and SPAN can be either configured in simplex or duplex mode. If using a hub, only duplex mode can be used. The wiring type configuration is typically done during the initial setup as described earlier in this chapter. [Figure 4-31](#) show the wiring options.

Figure 4-31 L4TM Wiring Type

L4 Traffic Monitor Wiring:	<input checked="" type="radio"/> Duplex TAP: T1 (In/Out) <input type="radio"/> Simplex TAP: T1 (In) and T2 (Out)
----------------------------	---

227450

Configuring WSA L4TM Global Settings

The ports to be monitored can be specified in the L4TM Global Settings. Options are:

- *All ports*—Monitors all 65535 TCP ports for rogue activity.
- *All ports except proxy ports*—Monitors all TCP ports except HTTP and HTTPS proxy ports.

Note

The Cisco ASA in the Internet perimeter is configured to allow only permitted ports, so any connection attempts on rogue ports should be blocked by the firewall.

Figure 4-32 shows the options.

Figure 4-32 L4TM Global Settings

Edit L4 Traffic Monitor Global Settings

L4 Traffic Monitor Global Settings	
<input checked="" type="checkbox"/> Enable L4 Traffic Monitor	
Traffic Monitored On:	<input checked="" type="radio"/> All Ports <input type="radio"/> All Ports Except Web Ports (HTTP/HTTPS)

227451

Configuring Traffic Monitoring

While a hub or a network tap could be used, using SPAN port mirroring provides the greatest flexibility. SPAN allows the monitoring of port traffic based on VLANs or source interfaces and it can easily be reconfigured.

The following is a configuration example of SPAN to replicate traffic:

```
! Enables port mirroring on the switch ports connecting to the firewall inside interfaces
monitor session 10 source interface Gi4/4
monitor session 10 source interface Gi5/3
!
! Sets the interface connecting to the WSA as the destination
monitor session 10 destination interface Gi6/3
```

The SPAN configuration can be seen on the switch with the **show monitor session** command.

Activity monitored by the L4TM feature can be seen in the L4 Traffic Monitor page of the WSA web-based GUI. Figure 4-33 shows client activity with a website known to be the source of malware.

Figure 4-33 L4 Traffic Monitor

L4 Traffic Monitor

227452

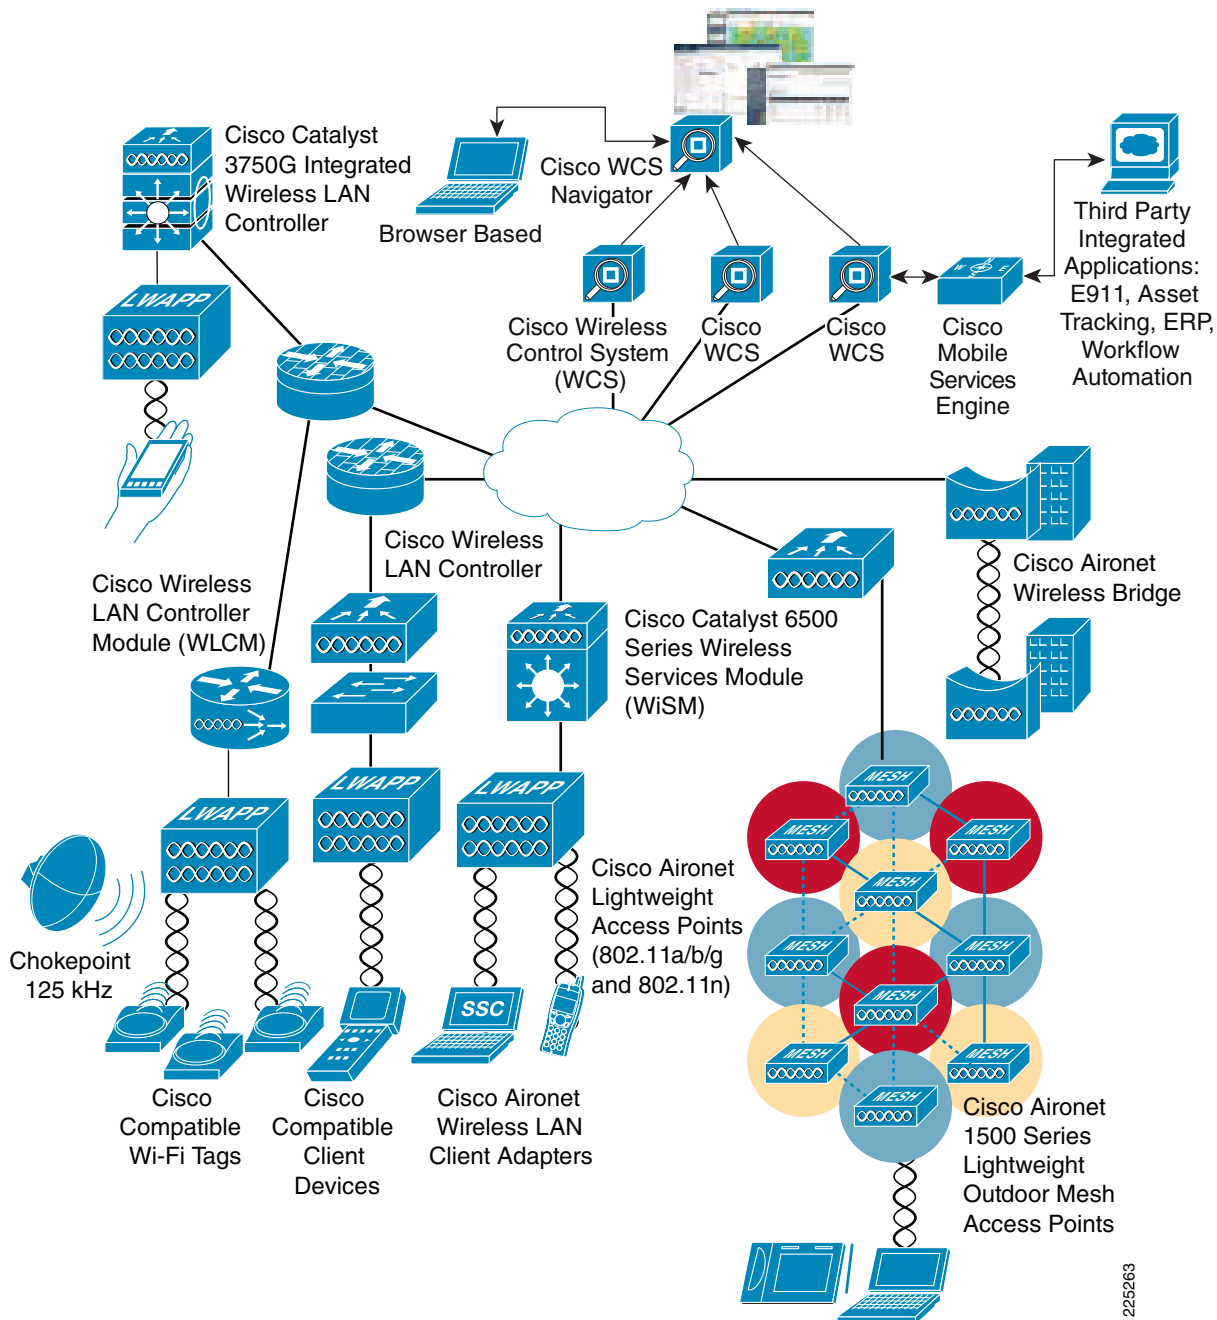

CHAPTER 5

Wireless LAN Design

Cisco Unified Wireless Network Architecture

WLANs in the schools have emerged as one of the most effective means for connecting to a network, given the mobility of students and staff. The Cisco Unified Wireless Network (CUWN) is a unified wired and wireless network solution that addresses the wireless network security, deployment, management, and control aspects of deploying a wireless network. It combines the best elements of wireless and wired networking to deliver secure, scalable wireless networks with a low total cost of ownership.

[Figure 5-1](#) shows a high-level topology of the CUWN architecture, which includes Lightweight Access Point Protocol (LWAPP) access points (LAPs), mesh LWAPP APs (MAPs), the Wireless Control System (WCS), and the Wireless LAN Controller (WLC); alternate WLC platforms include the Wireless LAN Controller Module (WLCM) or Wireless Services Module (WiSM). The Cisco Access Control Server (ACS) and its Authentication, Authorization, and Accounting (AAA) features complete the solution by providing RADIUS services in support of wireless user authentication and authorization.

Figure 5-1 Cisco Unified Wireless Network Architecture Overview

The CUWN network is composed of two key elements: Wireless LAN Controllers (WLCs) and Access Points (APs). These form the core of the Wireless LAN system, where the APs provide the radio connection between wireless clients and the network, and the WLCs provide network.

Figure 5-2 illustrates one of the primary features of the architecture: how Lightweight Access Point Protocol (LWAPP) or Control and Provisioning of Wireless Access Points (CAPWAP) access points (LAPs) use the LWAPP/CAPWAP protocol to communicate with and tunnel traffic to a WLC.

**Note**

CUWN is migrating from the LWAPP protocol to CAPWAP, and the WLC software version in the Schools SRA uses CAPWAP. The fundamentals of the architecture and operation are the same. Documents discussing the LWAPP architecture operation and behavior are still valid for CAPWAP, apart from the UDP port numbers. For the purposes of this document and other documents referring to LWAPP, the Cisco CAPWAP implementation can be considered as a superset of LWAPP features and behavior.

Figure 5-2 *LAP and WLC Connection*

LWAPP/CAPWAP has three primary functions:

- Control and management of the LAP
- Tunneling of WLAN client traffic to the WLC
- Collection of 802.11 data for the management of the Cisco Unified Wireless System

LWAPP Features

The easier a system is to deploy and manage, the easier it will be to manage the security associated with that system. Early implementers of WLAN systems that used “fat” APs (autonomous or intelligent APs) found that the implementation and configuration of such APs was the equivalent of deploying and managing hundreds of individual firewalls, each requiring constant attention to ensure correct firmware, configuration, and safeguarding. Even worse, APs are often deployed in physically unsecured areas where theft of an AP could result in someone accessing its configuration to gain information to aid in some other form of malicious activity.

LWAPP addresses deployment, configuration, and physical security issues by doing the following:

- Removing direct user interaction and management of the AP. Instead, the AP is managed by the WLC through its LWAPP connection. This moves the configuration and firmware functions to the WLC, which can be further centralized through the use of the WCS.
- Having the AP download its configuration from the WLC, and be automatically updated when configuration changes occur on the WLC.
- Having the AP synchronize its firmware with its WLC, ensuring that the AP is always running the correct software version.

- Storing sensitive configuration data at the WLC, and storing only IP address information on the AP. In this way, if the AP is physically compromised, there is no configuration information resident in NVRAM that can be used to perform further malicious activity.
- Mutually authenticating LAPs to WLCs, and AES encrypting the LWAPP control channel.

In addition to the improvements in physical security, firmware, and configuration management offered by LWAPP, the tunneling of WLAN traffic in an LWAPP-based architecture improves the ease of deployment without compromising the overall security of the solution. LAPs that support multiple WLAN VLANs can be deployed on access-layer switches without requiring dot1q trunking or adding additional client subnets at the access switches. All WLAN client traffic is tunneled to centralized locations (where the WLC resides), making it simpler to implement enterprise-wide WLAN access and security policies.

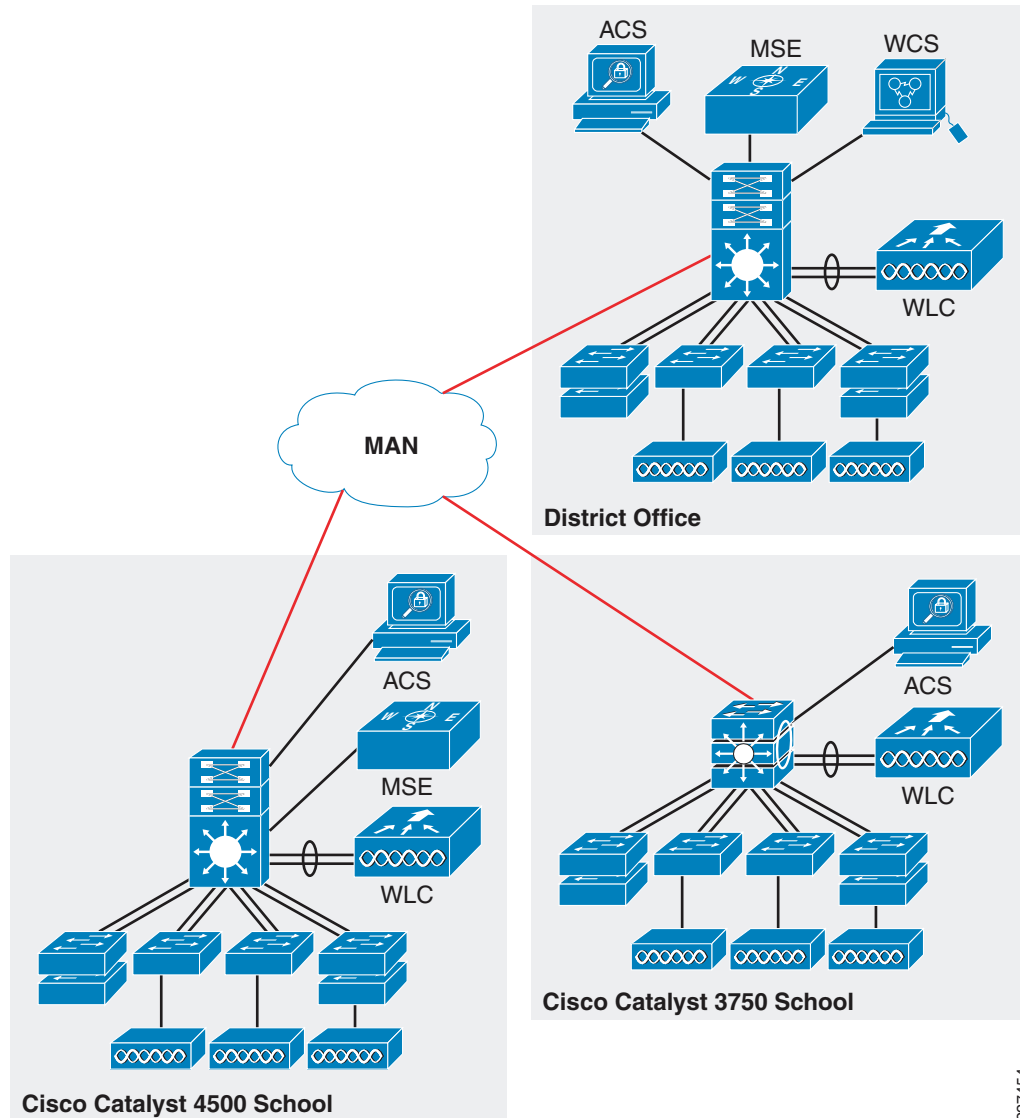

Schools SRA Architecture

Figure 5-3 shows a simple schematic of the CUWN integration into the schools SRA. The key features of the CUWN integration is the use of a WLC at each school, with the management function (WCS) located at the district office. If context-aware services are implemented, the Cisco Mobility Services Engine (MSE) may be placed at the school; for smaller schools, an MSE at the district office may provide a centralized service.

The standalone WLCs used in this design support AP capacities from 12 to 250 APs per WLC, and multiple WLCs may be deployed at the same school if more than 250 APs are required or if a load sharing or higher availability WLAN solution is required. An alternate higher availability solution is to use a WLC at the district office as a backup WLC for the school's WLCs. This is known as an N+1 solution, where a district office WLC maintains sufficient capacity to support the APs of any individual school site.

A similar principle to N+1 is used to provide high availability for the AAA service provided by the Cisco ACS server. Each school will have a local ACS server to provide AAA services, and use the district office ACS server as its secondary AAA server.

Figure 5-3 High level view of the CUWN SRA Integration

Management

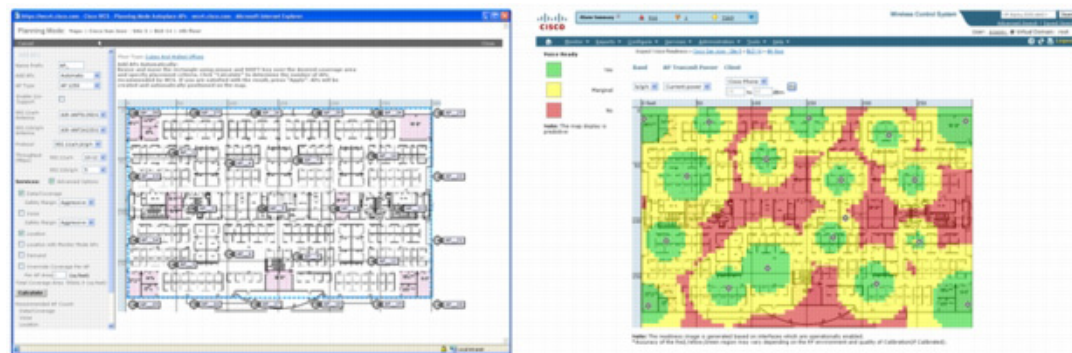

Each of the WLCs has both a CLI and web interface to provide WLAN configuration and management features, but for a complete lifecycle management solution, the Cisco Wireless Control System (WCS) is needed. The WCS supports the delivery of high-performance applications and mission-critical solutions that simplify business operations and improve productivity. This comprehensive platform scales to meet the needs of small, midsize, and large-scale wireless LANs across local, remote, national, and international locations. The WCS gives IT managers immediate access to the tools they need, when they need them, to more efficiently implement and maintain new or expanding WLANs—all from a centralized location requiring minimal IT staffing. Operational costs are significantly reduced through the Cisco WCS's intuitive GUI, simplified ease-of-use, and built-in tools that deliver improved IT

efficiency, lowered IT training costs, and minimized IT staffing requirements, even as the network grows. Cisco WCS lowers operational costs by incorporating the full breadth of management requirements, from radio frequency, to controllers services, and into a single unified platform.

The Cisco WCS scales to manage hundreds of Cisco wireless LAN controllers, which in turn can manage thousands of Cisco Aironet® access points including the next-generation Cisco Aironet 1140 and 1250 Series 802.11n access points. For large-scale indoor and outdoor deployments, Cisco WCS Navigator can be included to simultaneously support up to 20 Cisco WCS platforms and 30,000 Cisco access points. Adding mobility services such as context-aware software and adaptive wireless intrusion prevention systems (wIPS) is simplified through Cisco WCS integration with the Cisco MSE.

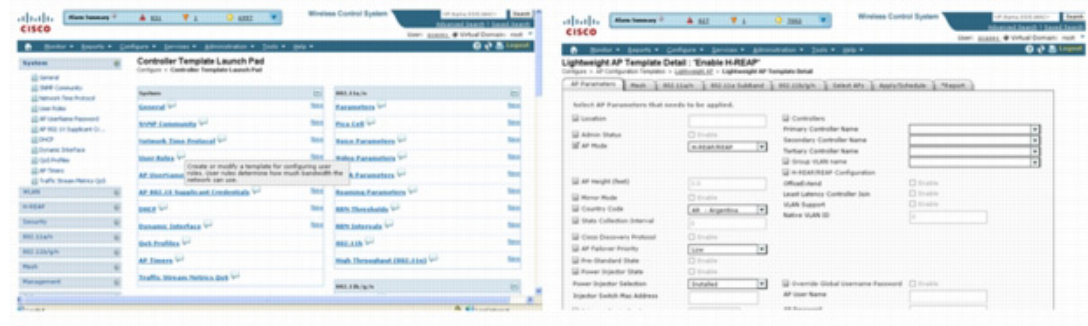

Designing a wireless LAN that effectively supports business-critical data, voice, and video services is simplified with the Cisco WCS suite of built-in planning and design tools. [Figure 5-4](#) shows an example of the simplified Wireless LAN Planning and Design Cisco WCS planning and design tools simplify the process of defining access point placement and determining access point coverage areas for standard and irregularly shaped buildings. These tools give IT administrators clear visibility into the radio frequency (RF) environment. They make it easier to visualize the ideal RF environment, anticipate future coverage needs, and assess wireless LAN behavior. They help IT administrators reduce, and in many cases eliminate, improper RF designs and coverage problems that can lead to end-user trouble tickets. Specialized Cisco WCS planning tools enable real-time assessment of the WLAN's readiness to support voice-over-WLAN (VoWLAN) and context-aware (location) services. VoWLAN services support single and dual-mode Wi-Fi-enabled phones. Context-aware services use Cisco's patent pending "RF fingerprinting" technology to locate, track, and manage Wi-Fi-enabled devices and their contextual information in conjunction with Cisco MSE.

Figure 5-4 WCS planning tools

Getting the WLAN up and running quickly and cost-effectively to meet end-user needs is streamlined with the broad array of Cisco WCS integrated configuration templates. These easy-to-use templates and deployment tools help IT managers provision and configure the wireless LAN to expressly deliver the services that their business requires. [Figure 5-5](#) shows an example of the Flexible Deployment Tools and Configuration Templates available through an easy-to-use interface, make it simple to apply common configurations across one or more wireless LAN controllers, regardless of their location in the network—whether on the same LAN as Cisco WCS, on separate routed subnets, or across a wide-area connection. At the click of a button, IT administrators can streamline even the most complex controller configurations, updates, and scheduling across the entire wireless network. Auto-provisioning access points is just as simple, with easy-to-use templates that support customized configuration of single or multiple access points.

Figure 5-5 **WCS Deployment Templates**

Cisco WCS is the ideal management platform for monitoring the entire WLAN to maintain robust performance and deliver an optimal wireless experience to mobile end users. Cisco WCS centralized interface makes it easy to access information where it is needed, when it is needed, on demand or as scheduled. [Figure 5-6](#) shows an example of the Customizable Dashboard and Easy-to-Use Web-Based Interface Cisco WCS easy-to-use graphical displays serve as a starting point for maintenance, security, troubleshooting, and future capacity planning activities. Quick access to actionable data about healthy and unhealthy events occurring on the network is available from a variety of entry points, making Cisco WCS vital to ongoing network operations. The ever-present alarm summary in the Cisco WCS simplifies access to critical information, faults, and alarms based on their severity. Detecting, locating, and containing unauthorized (rogue) devices is fully supported when location services are enabled. [Figure 5-7](#) shows an example of the Ever-Present Alarm Summary and Simplified Rogue Device Detection and Location.

Figure 5-6 **WCS Monitoring Dashboard**

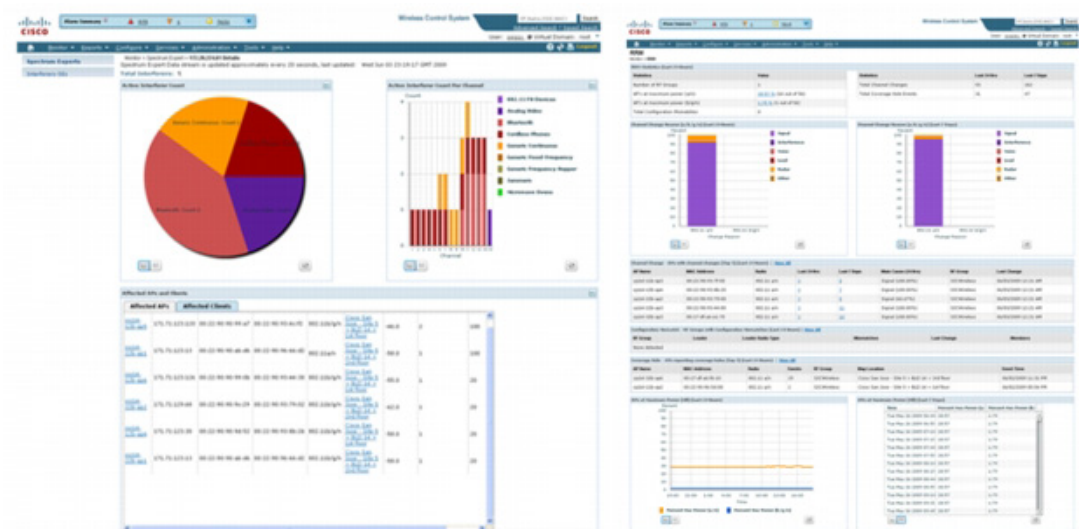

Figure 5-7 WCS Alarm Panels

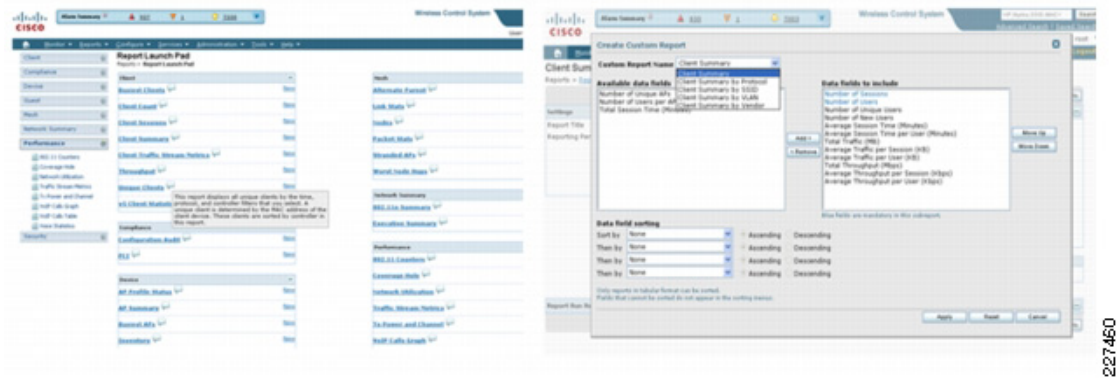

The integrated workflow and expansive array of troubleshooting tools in the Cisco WCS help IT administrators quickly identify, isolate, and resolve problems across all components of the Cisco Unified Wireless Network. Cisco WCS supports rapid troubleshooting of any size WLAN with minimal IT staffing. Figure 5-8 shows an example of the Integrated Workflows and Troubleshooting Tools. Cisco WCS makes it easy to quickly assess service disruptions, receive notices about performance degradation, research resolutions, and take action to remedy nonoptimal situations. Integrated workflows support seamless linkage between all tools, alarms, alerts, searches, and reports for all infrastructure components and client devices. A variety of tools work together to help IT administrators understand the operational nuances occurring on the WLAN and discover nonoptimal events occurring outside baseline parameters such as client connection or roaming problems. The ever-present search tool in Cisco WCS facilitates cross-network access to real-time and historic information about devices and assets located anywhere in the wireless network. A built-in client troubleshooting tool provides a step-by-step method to analyze problems for all client devices. Cisco CleanAir supports finding, classifying, and correlating sources of interference from Wi-Fi and non-Wi-Fi sources such as Bluetooth devices and cordless phones.

Figure 5-8 WCS Troubleshooting Tools

Cisco WCS includes customizable reporting that assists IT teams in more effectively managing, maintaining, and evolving the wireless LAN to meet ongoing business and operations requirements. Flexible reports provide access to the right data, at the right time, in a format to meet any requirement. [Figure 5-9](#) shows an example of the Customizable Reports Meet Any Requirement. An extensive variety of reports is available to help IT managers stay on top of network trends, maintain network control, audit operations, and quickly address changing business and end-user requirements. Reports are customizable based on user-defined parameters. Detailed analysis of what is going on, where and when in the network, as well as capacity planning, is simplified by collecting data from several reports and analyzing trends to understand how the WLAN has changed over time. Understanding WLAN trends makes it easier to plan for future enhancements and growth.

Figure 5-9 WCS Customizable Reports

Connection to the Schools SRA Network

[Figure 5-10](#) and [Figure 5-11](#) show the school switch to WLC physical connection in more detail, a key feature in of the WLC interface is its direct connection to the core distribution switch via a port channel interface. This uses multiple Gigabit Ethernet connections from the WLC to the core/distribution switch. These Gigabit Ethernet connections are to different line cards on switches or line card to ensure that a single switch or line card failure does not result in the loss of the WLC connection to the school network. The switch feature to achieve this is the same switch feature used for the Ether Channel connections between switches in the Schools SRA. The WLC feature is called *link aggregation* (LAG). LAG is disabled by default on the WLC and requires a WLC reboot to be enabled. This allows the WLC to use the same port channel configuration as the access switches when connecting to the core/distribution switch.

Figure 5-10 4500 School Switch WLC Physical Connection

227461

Figure 5-11 750 School Switch WLC Physical Connection

227462

The WLC connects to the switch via a 802.1Q trunk connection, as shown in [Figure 5-12](#), and multiple SVIs need to be configured on the switch to support the CUWN implementation. The key SVIs are an SVI for the management and AP manager interface of the WLC, and the SVIs for each of the different WLANs implemented on the WLC; there is not always a one-to-one relationship between SVIs and WLANs, but in most simple WLAN deployments this is the case.

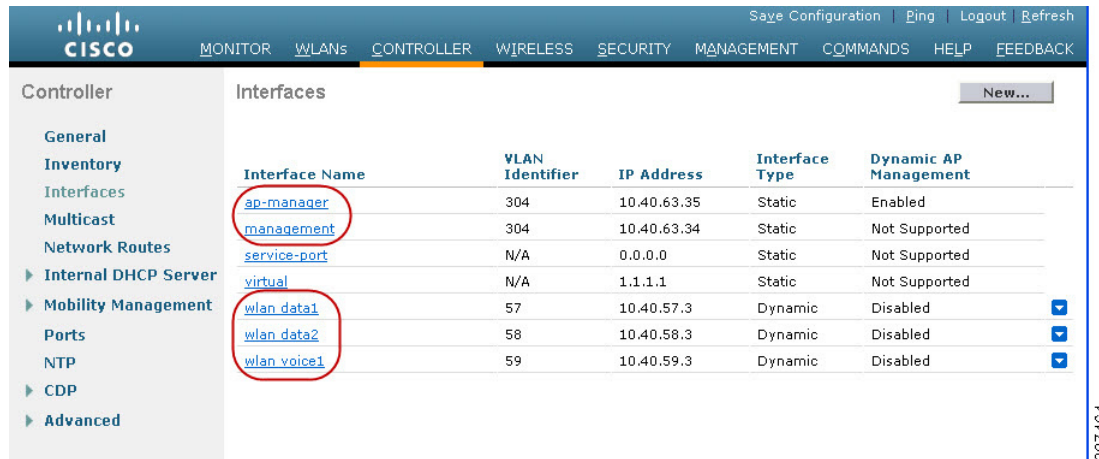

Figure 5-12 Switch WLC Layer-2 Connection

227463

[Figure 5-13](#) shows an example of the interface configuration summary on school WLC. The key interfaces of interest are *ap-manger*, *manager*, and *wlan data1*, *wlan data2*, and *wlan voice1* interfaces.

The server port is an out-of-band management interface not used in this design guide. The virtual interface and its interface address are used to assist in the provisioning of seamless mobility. The virtual interface is assigned an address during the initial configuration of the WLC and this address is typically 1.1.1.1 for all controllers.

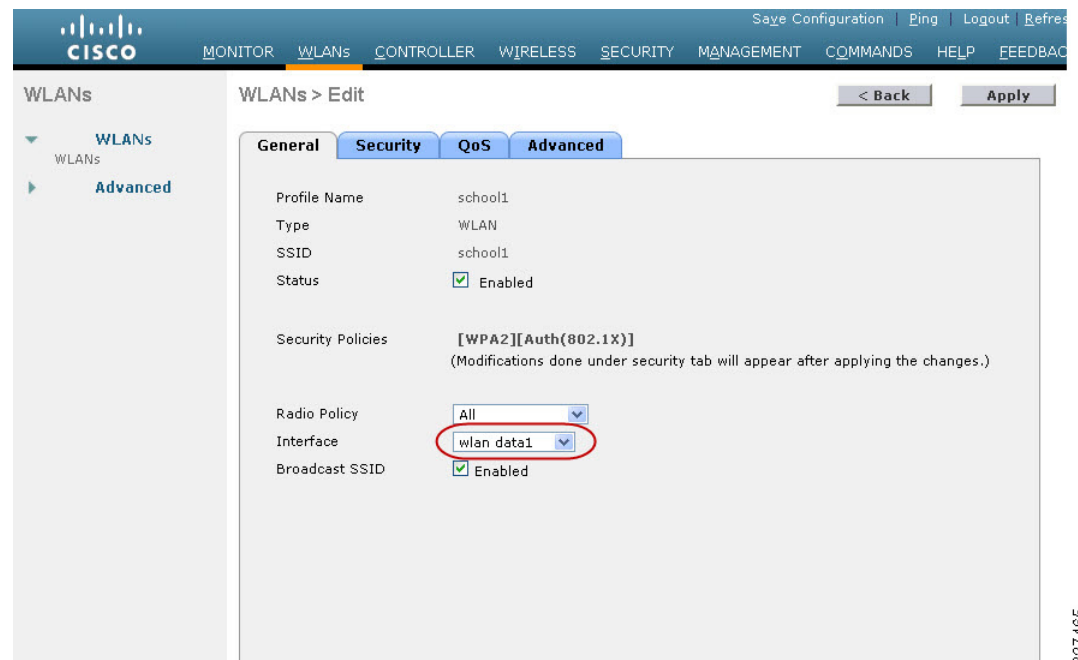

Figure 5-13 WLC Interface Example

Interface Name	VLAN Identifier	IP Address	Interface Type	Dynamic AP Management
ap-manager	304	10.40.63.35	Static	Enabled
management	304	10.40.63.34	Static	Not Supported
service-port	N/A	0.0.0.0	Static	Not Supported
virtual	N/A	1.1.1.1	Static	Not Supported
wlan_data1	57	10.40.57.3	Dynamic	Disabled
wlan_data2	58	10.40.58.3	Dynamic	Disabled
wlan_voice1	59	10.40.59.3	Dynamic	Disabled

Figure 5-14 shows the mapping of a particular WLAN SSID to a defined interface. A WLAN can be mapped to the management interface (this is normally not recommended), or any dynamic interface.

RF Groups and Mobility Groups

Part of a WLCs role is to manage the RF network in its area, and to provide mobility services to WLCs in its network. To define the area of the RF network that you are interested in managing, use an RF group name; to define the mobility services domain, use a mobility group. The details of RF groups and mobility groups are beyond the scope of this design guide, but the key point for the design is that the RF network area and the mobility services domain will typically be a single school campus, and only WLCs that are at the same school should have the same RF group name or mobility group name. Figure 5-15 shows an example of the RF and mobility group configuration on the controllers. Each school campus can be given a different RF group and mobility group as the WLCs are different schools and are not expected to be in the same RF group or mobility group.

Figure 5-15 Mobility Groups and RF Groups Example

The screenshot shows the Cisco WLC configuration interface. The left sidebar lists various configuration categories: General, Inventory, Interfaces, Multicast, Network Routes, Internal DHCP Server, Mobility Management (selected), Ports, NTP, CDP, and Advanced. The main area displays the 'General' configuration for the selected controller. The 'Default Mobility Domain Name' and 'RF Group Name' fields are both set to 'School1wlc' and are circled in red. Other settings include Name (S1WLC), 802.3x Flow Control Mode (Disabled), LAG Mode on next reboot (Enabled), Broadcast Forwarding (Disabled), Aggressive Load Balancing (Disabled), Over The Air Provisioning of AP (Disabled), AP Fallback (Enabled), Apple Talk Bridging (Disabled), Fast SSID change (Disabled), User Idle Timeout (300), ARP Timeout (300), Web Radius Authentication (PAP), 802.3 Bridging (Disabled), Operating Environment (Commercial), and Internal Temp Alarm Limits (0 to 65 C).

A school with only one WLC will have a mobility group with only its own details in the mobility group. If there is more than one WLC at the school, then the mobility group configuration will contain both WLCs.

Figure 5-16 shows the single WLAN example and Figure 5-17 shows a multiple WLC example. If there is only one WLC, the mobility group information is automatically populated. Additional WLCs must have the MAC address and management IP address added manually.

Figure 5-16 **Mobility Groups for a Single WLC**

The screenshot shows the Cisco WLC GUI with the 'CONTROLLER' tab selected. The left sidebar shows the 'Mobility Management' section expanded, with 'Mobility Groups' selected. The main content area is titled 'Static Mobility Group Members' and shows a table for the 'Local Mobility Group' 'School1wlc'. The table has five columns: MAC Address, IP Address, Group Name, Multicast IP, and Status. One entry is listed with MAC Address 00:0b:85:40:23:a0, IP Address 10.40.63.34, Group Name School1wlc, Multicast IP 0.0.0.0, and Status Up. The 'Group Name' and 'Status' columns are circled in red.

MAC Address	IP Address	Group Name	Multicast IP	Status
00:0b:85:40:23:a0	10.40.63.34	School1wlc	0.0.0.0	Up

Figure 5-17 **Mobility Groups for a Multiple WLCs**

The screenshot shows the Cisco WLC GUI with the 'CONTROLLER' tab selected. The left sidebar shows the 'Mobility Management' section expanded, with 'Mobility Groups' selected. The main content area is titled 'Static Mobility Group Members' and shows a table for the 'Local Mobility Group' 'School1wlc'. The table has five columns: MAC Address, IP Address, Group Name, Multicast IP, and Status. Two entries are listed: one with MAC Address 00:0b:85:40:23:a0, IP Address 10.40.63.34, Group Name School1wlc, Multicast IP 0.0.0.0, and Status Up; and another with MAC Address 00:0b:85:40:80:00, IP Address 10.40.79.34, Group Name School1wlc, Multicast IP 0.0.0.0, and Status Up. The 'Group Name' and 'Status' columns are circled in red.

MAC Address	IP Address	Group Name	Multicast IP	Status
00:0b:85:40:23:a0	10.40.63.34	School1wlc	0.0.0.0	Up
00:0b:85:40:80:00	10.40.79.34	School1wlc	0.0.0.0	Up

Example WLAN Configurations

In a typical school WLAN environment, it is expected that there be multiple WLANs (SSIDs) serving different purposes and different client groups. This section addresses the examples of what would be considered typical WLAN examples.

- A secured data WLAN network that uses 802.1X/EAP to provide AAA functionality and dynamically generated per-user, per-session encryption key.
- A secured VoWLAN network that also uses 802.1X/EAP to provide AAA functionality and optimized for voice.

- An open unencrypted WLAN for access to a WLAN network for unmanaged clients such as student laptops, iPod, and iPhones.

For ease of administration and support for users who visit multiple schools, the WLAN SSIDs should be the same for each school in the district. In addition, the SSIDs should be broadcast and have meaningful names.

Secured Staff WLAN

Figure 5-18 shows the general WLAN configuration tab for the secured data WLAN network. The key point shown are the security policy that has been set under the security tab and the WLC interface that the WLAN has been mapped to. The security configuration recommended is to use WPA2 with 802.1X+CCKM. Most WLAN should now support WPA2, and CCKM has been added to 802.1X as it provides a faster roaming for WLAN clients. This is for clients that support CCKM, while using the AAA features of 802.1X/AP to secure the WLAN connection.

Figure 5-18 General Configuration for Secured WLAN

The screenshot shows the Cisco WLAN configuration interface. The top navigation bar includes links for MONITOR, WLANs, CONTROLLER, WIRELESS, SECURITY, MANAGEMENT, COMMANDS, HELP, and FEEDBACK. The left sidebar shows a tree view with 'WLANs' expanded, containing 'WLANs' and 'Advanced'. The main content area is titled 'WLANs > Edit' and has tabs for General, Security, QoS, and Advanced. The General tab is active, showing the following configuration:

Profile Name	school1
Type	WLAN
SSID	school1
Status	<input checked="" type="checkbox"/> Enabled
Security Policies	[WPA2][Auth(802.1X + CCKM)] (Modifications done under security tab will appear after applying the changes.)
Radio Policy	All
Interface	wlan_data1
Broadcast SSID	<input checked="" type="checkbox"/> Enabled

Buttons for '< Back' and 'Apply' are visible at the top right of the configuration area.

Figure 5-19 shows the QoS configuration for the secured data WLAN; in this case, the QoS profile is set to *Silver*, which is best effort setting. The WMM policy is set to disabled, as disabled WMM is the equivalent of best effort. The primary role of WMM is to give higher priority to voice and video traffic over the WLAN. Unless the school is planning to deliver interactive voice and video applications to their WLAN data clients, WMM can remain disabled.

Note

802.11n standard requires WMM be enabled and, therefore, WMM must be enabled on all WLANs in the 802.11n deployments. In this case, the WMM policy would be set to allowed.

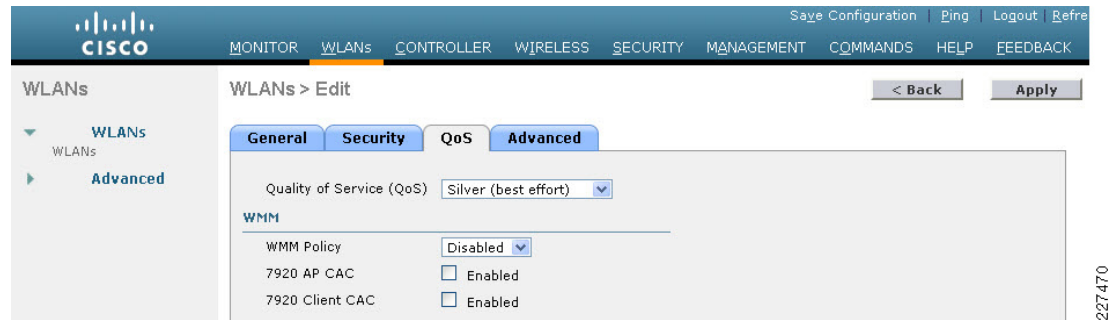

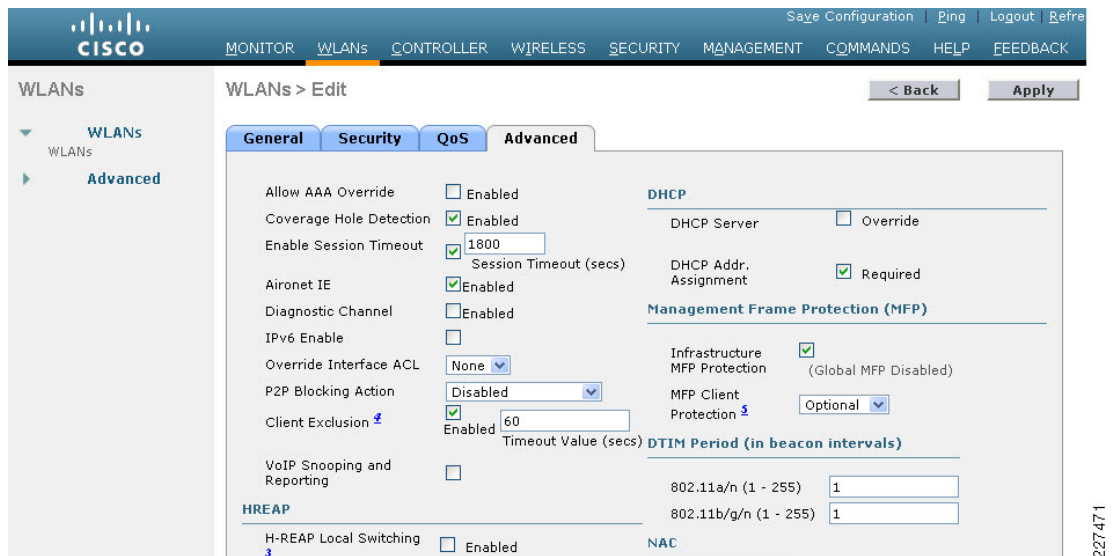

Figure 5-19 Secured Staff WLAN QoS

Figure 5-20 shows the secured data WLAN advanced configuration. The only change from the default settings on the tab is enabling the DHCP address assignment required feature. Typically, WLAN mobile clients use DHCP, and any statically configured client runs the risk of introducing an address duplication issue.

Figure 5-20 Secured Staff Advanced Configuration

Secured VoWLAN

Figure 5-21 shows the General Tab of the voice over WLAN (VoWLAN). The primary difference between this WLAN and the secured data WLAN is that the security policy is WPA with CCKM, because this is the optimum security configuration for the Cisco 7921G and 7925G. The other difference is that the radio policy has been set for 802.11a only.

The use of 802.11a for the VoWLAN will depend on a number of factors, but the Cisco 7921G and 7925G are dual-band phones, and can use both bands but do not roam between bands. This means that once the handset associates with a network in one band, it will not leave that band while call quality is maintained. Keeping the VoWLAN handsets in the 802.11a band will ensure that the 2.4GHz band remains available for other client devices. Whether this is a viable option for a school depends on the required call capacity of the school's WLAN and the type of AP network that has been deployed.

Figure 5-21 VoWLAN General Configuration

Radio Policy 802.11a only

Interface wlan voice1

Broadcast SSID ☒ Enabled

Figure 5-22 shows the QoS Tab for the VoWLAN. In this WLAN configuration, WMM is required (both the 7921G and 7921G) support WMM, and WMM will give voice traffic priority over other WLAN traffic on the network. The QoS profile is set to *Platinum* to ensure that the QoS classification is appropriate for voice. The QoS profile controls the maximum classification value for both the WLAN frames and LWAPP packets.

Figure 5-22 VoWLAN QoS Configuration

WLANs > Edit

General Security QoS Advanced

Quality of Service (QoS) Platinum (voice)

WMM

WMM Policy Required

7920 AP CAC ☒ Enabled

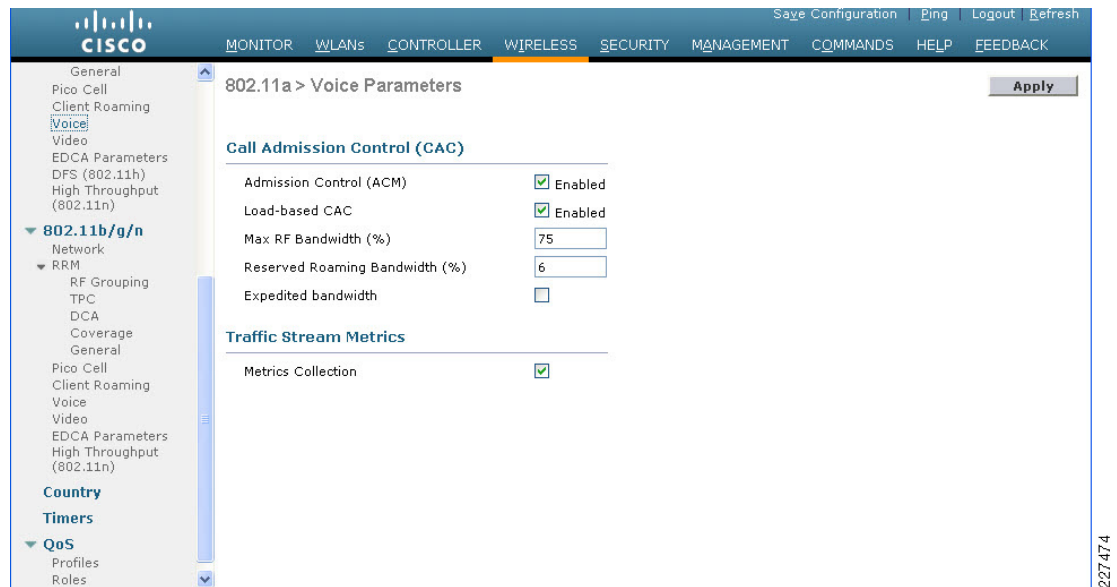

7920 Client CAC ☒ Enabled

The Advanced Tab for the VoWLAN is the secured data WLAN. There is an option for VoIP snooping and reporting, but this option pertains only to a particular type of SIP and is not applicable to the Cisco 7921G and 7925G handsets.

To protect VoIP call quality, the WLC can perform call admission control (CAC) to prevent VoWLAN calls being added to an access point that cannot take any additional VoWLAN calls without compromising call quality. An example of the CAC configuration page is shown in Figure 5-23.

**Note**

There is a separate CAC page for each RF band.

Figure 5-23 VoWLAN Call Admission Control

The CUWN prioritizes traffic based upon the QoS profiles applied to each WLAN, but it does not change the IP QoS classification (DSCP) of the client traffic carried by the CUWN. This means that client traffic that leaves the CUWN may need to be reclassified based upon the network policy. There are two ways of achieving this.

1. Applying policy at each of the network SVIs that connect the WLC to the network.
2. Learning the QoS policy that was applied within the CUWN as this should be in alignment with the network policy.

The second method is preferable as it requires less configuration and maintenance of the policy; the policy only needs to be maintained upon WLCs, and not open the WLCs and the connected switch. To achieve this, the Wired Protocol in the QoS profiles (Platinum, Gold, Silver, and Bronze) must be set to 802.1p and all other settings may remain as default. This configures the WLC to set the 802.1p marking of the frames sent from the WLC to reflect QoS policy on that WLAN. For example, the IP packet was from a Platinum WLAN and had a DSCP value of EF, the WLC would use a CoS value of 5 in the frame header. If the same packet had been on a Silver WLAN, the CoS value would be 0. Therefore, if the WLC is connected to switch network that is configured to trust CoS and maintains a translation table between CoS and DSCP for its network, the translation between CUWN policy and network policy will occur automatically. See [Figure 5-24](#).

For a further information on WLAN QoS, refer to the *Voice over WLAN Design Guide* at the following URL:

<http://www.cisco.com/en/US/docs/solutions/Enterprise/Mobility/vowlan/41dg/vowlan41dg-book.html>

Figure 5-24 Controller QoS Profiles

Figure 5-24 shows the Cisco Wireless LAN Controller (WLC) configuration page for "Edit QoS Profile". The page includes a sidebar with navigation options like General, Pico Cell, Client Roaming, Voice, Video, EDCA Parameters, DFS (802.11h), High Throughput (802.11n), 802.11b/g/n, Network, RRM, RF Grouping, TPC, DCA, Coverage, General, Pico Cell, Client Roaming, Voice, Video, EDCA Parameters, High Throughput (802.11n), Country, Timers, QoS, Profiles, and Roles. The main configuration area is titled "Edit QoS Profile" and includes buttons for "< Back", "Apply", and "Reset to defaults". The configuration fields are as follows:

- QoS Profile Name:** platinum
- Description:** For Voice Applications
- Per-User Bandwidth Contracts (k) *:**
 - Average Data Rate: 0
 - Burst Data Rate: 0
 - Average Real-Time Rate: 0
 - Burst Real-Time Rate: 0
- Over the Air QoS:**
 - Maximum RF usage per AP (%): 100
 - Queue Depth: 100
- Wired QoS Protocol:**
 - Protocol Type: 802.1p
 - 802.1p Tag: 6

* The value zero (0) indicates the feature is disabled

Web Authenticated Student Access

In many situations, it is not possible to administer and support the WLANs clients that are required to connect to the network. There can be a wide variety of operating systems, WLAN clients, and user ability to support, and a very limited amount of support resources. In cases like this, a typical solution is to create an open WLAN that does not perform 802.1X/EAP authentication or encryption. This is normally simple enough for all users and all platforms.

To provide some level of access control and audit trail, these WLANs perform a Web-Authentication where all network access—apart from DHCP and DNS—is blocked until the user enters a correct username and password into an authentication web page. This authentication web page will be forced to the WLAN client screen when the client attempts to open any web page. Additional security policy may be applied through filters on the WLC, upstream switch and/or firewall. See [Figure 5-25](#).

Figure 5-25 Student Open WLAN General

Figure 5-25 shows the Cisco Wireless LAN Controller (WLC) configuration page for "Student Open WLAN General". The page includes a sidebar with navigation options like WLANs, WLANS, and Advanced. The main configuration area is titled "WLANs > Edit" and includes buttons for "< Back" and "Apply". The configuration fields are as follows:

- Profile Name:** school1student
- Type:** WLAN
- SSID:** school11student
- Status:** ☒ Enabled
- Security Policies:** Web-Auth
(Modifications done under security tab will appear after applying the changes.)
- Radio Policy:** All
- Interface:** wlan data2
- Broadcast SSID:** ☒ Enabled

Figure 5-26 shows the QoS settings for the Student WLAN. WMM is disabled, and the QoS profile of Bronze. WMM is disabled to prevent WLAN clients on the Student assigning a WMM classification, and the QoS profile of Bronze assigns network priority of less than best effort.

**Note**

802.11n standard requires WMM be enabled and, therefore, WMM must be enabled for all WLANs in a 802.11n deployments. In this case, the WMM policy would be set to allowed.

Figure 5-26 Student WLAN QoS

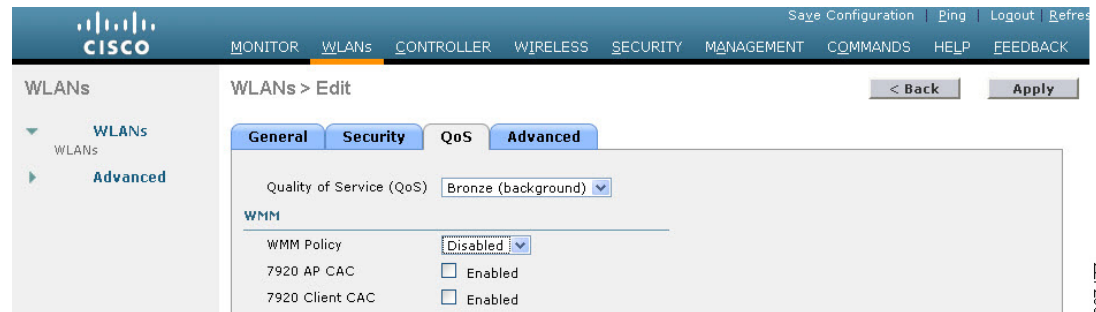

Figure 5-27 shows the security configuration for the student WLAN. Web policy presents a number of web-based controls for network access, the option chosen in the case is authentication. Authentication requires the client to enter username and password through a web page. The web page used can be an internal server provided by the WLC, or to a third-party service.

Figure 5-27 Student WLAN Security

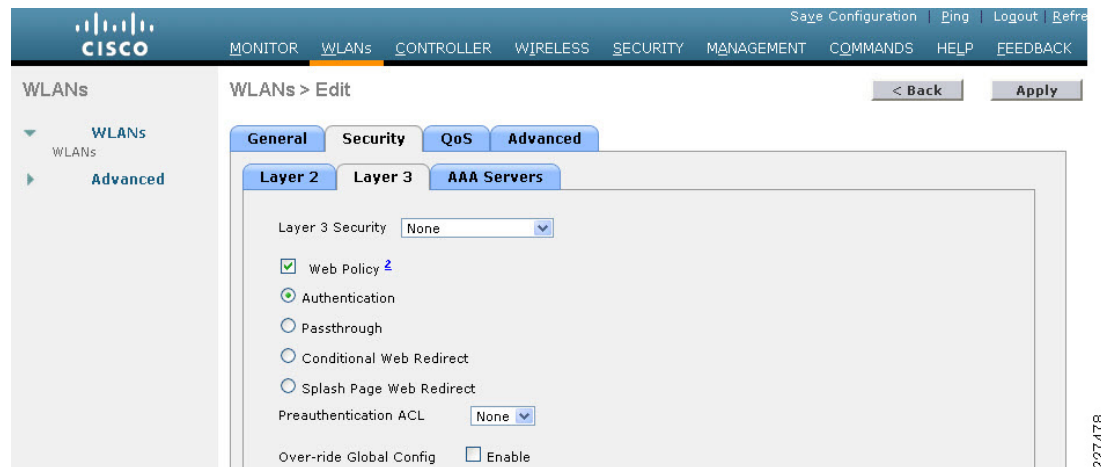

Figure 5-28 shows an example of the internal web page option for web authentication, this allows the creation of a simple web page as shown in Figure 5-29.

The usernames and passwords for authentication can use the Local Net Users database on the WLC or a RADIUS AAA server. The authentication mechanism between the WLC and the RADIUS is PAP.

AP Deployments Considerations

As with any other WLAN deployment, the key design decision are as follows: which areas require coverage and what level of performance is required in those areas with WLAN coverage. The Schools environment introduces an additional challenge to the design considerations due to the structured nature of network use. That is, classes start at particular times and a teacher will often ask the entire class to start an activity at the same time. This is a contrast to a typical enterprise deployment where network

users are much more independent. The structured nature of a school network usage can greatly increase the peaks in load upon the WLAN network. The general guidance for enterprise AP deployments has been 15 to 20 active clients per AP, but the peaks in demand at schools has seen this translate into two APs per class room, where there may be 20 to 30 students in that class room. The number of APs required per class room depends on many factors, including the number of clients, the type of applications, and the expected performance.

AP 1250

The Cisco 1250 Series is a rugged indoor access point designed for challenging RF environments that require the antenna versatility associated with connectorized antennas, a rugged metal enclosure, and a broad operating temperature range. The combined data rates of up to 600 Mbps to provide users with mobile access to high-bandwidth data, voice, and video applications. 802.11n provides reliable and predictable WLAN coverage to improve the end-user experience for both existing 802.11a/b/g clients and new 802.11n clients.

AP 1140

The Cisco 1140 Series Access Point is a business-ready, 802.11n access point designed for simple deployment and energy efficiency. The high-performance platform, which offers at least six times the throughput of existing 802.11a/g networks, prepares the business for the next wave of mobile devices and applications. Designed for sustainability, the Cisco 1140 Series delivers high performance from standard 802.3af PoE while decreasing waste with multi-unit eco-packs and Energy Star certified power supplies. As part of the CUWN, the Cisco 1140 Series provides the industry's lowest total cost of ownership and investment protection by integrating seamlessly with the existing network.

Coverage and Site Surveys

The WLAN coverage requirements can be expected to vary from school to school depending upon their goals and their budget. If the school is simply to try to provide wireless network connectivity in selected classrooms, then simple tactical placement of APs in the selected rooms is likely to be sufficient. If the school is planning to leverage the productivity associated with mobile application and mobile access, then a more strategic approach is required.

If the school is planning to implement mobility solution, they need to examine the expected workflow and movement of the users of these applications to determine the range of coverage required and perform a site survey based on these coverage requirements. If the customer is considering WLAN location-based services as a possibility for future deployments, this should also be taken into account during the site survey process as the density and placement of APs can be substantially different when providing a suitable WLAN platform for location-based services.

Single Band vs Dual Band APs

There are both single-band and dual-band APs available for schools solution. The single-band APs support the 2.4GHz band and the dual-band APs support both the 2.4GHz and 5GHz band. It is a general recommendation that a dual-band solution be deployed.

Number of APs Per Room, Coverage in the School

Single band APs vs Dual Band APs

If your goal is to simply provide WLAN coverage without trying to optimize capacity and performance then a single band AP is an appropriate choice, but in most cases a dual band Access Point is a better long term choice.

The longevity of a WLAN deployment is fundamentally determined by its capacity. A quick look at the dual-band deployment shows that it has twice the capacity of a single-band solution, but a deeper look will reveal that the advantage of a dual-band solution is much greater than an additional radio.

The additional 5GHz radio, of a dual band AP, is able to support a much higher capacity WLAN network as it has access to approximately 7 times the number of non-overlapping channels as the 2.4GHz. In almost all 2.4GHz deployments, APs reusing the three non-overlapping channels interfere with each other and prevent the WLAN deployment from delivering a full WLAN capacity increase when the number of APs is increased. A 5GHz AP is 7 times more likely to be able to deliver additional capacity for the addition of an AP.

Another consideration in the single-band versus dual-band AP discussion is 802.11n performance. 802.11n uses two primary mechanisms to provide data rate improvements over the existing 802.11g and 802.11a standards. The first mechanism changes the modulation, and error correction that can provide a data rate of up to 150Mbps, and the second mechanism is **channel binding** that combines non-overlapping channels to deliver data rates that are multiples of what a single channel could achieve. Channel binding is only available for the 5GHz band, as there is not sufficient channel capacity to support it in an enterprise 2.4GHz deployment.

Deploying a dual-band WLAN system is not a matter of simply replacing the APs in place, the 5GHz band has different power constraints, and has different propagation properties that need to be considered when deciding on AP density and placement. If fiscally possible, a dual-band AP solution should be planned and deployed initially. This will save an expensive rework layer.

For further discussion on 2.4GHz vs 5GHz capacity, refer to the *Voice over WLAN Design Guide* at the following URL:

<http://www.cisco.com/en/US/docs/solutions/Enterprise/Mobility/vowlan/41dg/vowlan41dg-book.html>

Client Considerations

One additional consideration in the single-band versus dual-band AP decision is the client devices that the WLAN network is going to support. Many earlier laptops and mobile devices only supported the 2.4GHz band, and this is still true for many consumer WLAN clients. To take advantage of a dual-band solution a concerted effort needs to be made to ensure that as many clients as possible are also dual-band. For cases where the school is purchasing WLAN clients, they should favor dual-band devices, in recommending WLAN client devices they should point out that the dual-band client devices will have access to a higher performance network. Of course, the first step is having the dual band network in place, for client devices to take advantage of their investment in a higher performance client.

WLC Discovery

CUWN provides auto-discovery functionality for its APs, where an AP upon connection to an appropriately connected network can automatically find and connect to a WLC. The WLC will ensure that the AP is running the appropriate software version, apply the appropriate configuration to that AP, and adjust the radio settings to optimize the AP for its current environment.

Multiple auto-discovery options are available in the CUW:

- Over the air: The APs learn the IP address of WLCs from APs in the area which are currently attached to those WLCs
- DHCP: The APs learn the IP address(es) of the WLCs as part of its DHCP address assignment
- DNS: The APs learn the IP address(es) of the WLCs by querying a well known DNS name CISCO-LWAPP-CONTROLLER.<localdomain.com>
- Staging: Have the AP join a WLC prior to them being deployed, and the APs will attempt to rejoin this WLC when reconnected to the network
- Static Configuration: The APs can be manually configured with the WLC IP address prior to being connected to the networks

Given that the school architecture utilizes a local DNS server for school to ensure survivability the use of the DNS discovery provides the simplest WLC discovery mechanism.

For details about how to configure DHCP discovery, refer to the DHCP OPTION 43 for Lightweight Cisco Aironet Access Points Configuration Example at the following URL:

http://www.cisco.com/en/US/tech/tk722/tk809/technologies_configuration_example09186a00808714fe.shtml

WLC Failover Options

CUWN provides multiple failover options allowing APs to make a choice between WLCs based upon configured priorities. When an AP goes through its discovery process it learns about all of the WLCs in the mobility group, and can prioritize based upon its high availability (HA) configuration or choose an WLC based upon loads.

In network architectures, such as the school SRA, where there is a high-speed WAN/MAN that makes AP failover to a remote WLC—such as the district Office WLC—feasible, APs can be configured to failover to a WLC outside their mobility group. In this scenario, the remote WLC would not be in the Mobility Group that is learned during the AP discovery process, and the IP address of the remote WLC need to be provided in the HA configuration.

This feature allows the district office to become a backup WLC for school sites in an event of an WLC outage at the school. For this to be effective, a common WLAN SSID naming policy for key WLANs needs to be implemented within the school district to ensure that WLAN clients do not have to be reconfigured in the event of an AP failover to the district office WLC. This type of HA configuration is called N+1 where a single district office WLC is able to provide HA at a much lower cost than a traditional 1+1 design which would require additional WLCs at each school. See [Figure 5-30](#).

Figure 5-30 AP High Availability Configuration Example

The screenshot shows the Cisco Wireless LAN Controller (WLC) configuration interface. The top navigation bar includes links for MONITOR, WLANs, CONTROLLER, WIRELESS, SECURITY, MANAGEMENT, COMMANDS, HELP, and FEEDBACK. The left sidebar shows the configuration tree with options like Access Points, Radios, Mesh, HREAP Groups, 802.11a/n, 802.11b/g/n, Country, Timers, and QoS. The main content area is titled 'All APs > Details for AP3.558e.32ae' and features tabs for General, Credentials, Interfaces, High Availability, Inventory, and Advanced. The High Availability tab is active, displaying fields for Primary Controller (S1WLC), Secondary Controller (S2WLC), and Tertiary Controller. The Management IP Address for the Secondary Controller is 10.40.79.34. The AP Failover Priority is set to Low.

AP1142	AIR-LAP1142N-A-K9

CHAPTER 6

Context-Aware Services Design

This chapter focuses on the application of general design best practices for the Cisco Context-Aware Services (CAS) and the Cisco Mobility Services Engine (MSE) when integrating into the Service Ready Architecture for Schools (SRA). It is intended as a guide to producing scalable and functional designs that incorporate CAS, where such inclusion can be seen to provide real-world benefits.

Note that while this chapter attempts to be as comprehensive as is warranted by the subject matter being discussed, it is not intended to be a comprehensive technical guide on Cisco Context-Aware Services, RFID technology, or the Cisco Mobility Services Engine in general. For comprehensive configuration and deployment information, the reader should refer to the in-depth configuration and deployment guides mentioned throughout this chapter.

Introduction

What Are Context-Aware Services?

Context-Aware Services provides the ability to dynamically capture and use contextual information about assets to optimize existing communications flows and organizational processes or facilitate the establishment of new ones. Contextual information can be collected for assets involved in almost any activity or process and this includes not just network endpoint devices (such as laptops and VoIP Phones) and products (such as microscopes and video projectors), but in some cases also the users that are associated with such devices.

In environments where the Cisco Unified Wireless Network has been deployed, Context-Aware Services makes use of embedded 802.11 network interface adapters (radios) in wireless client devices to accumulate contextual information about those assets or the user associated with the asset. For example, the location of a wireless laptop can be calculated via several different approaches or the user name associated with the laptop's user may be collected.

For assets that do not possess embedded wireless interfaces, external active Radio Frequency Identification (RFID) tags and sensors can be used to provide location input and monitor ambient environmental characteristics. Sensor capabilities can be directly embedded into active RFID tags in order to link the data captured (for instance, whether the asset is currently in motion) with the location of the asset. The algorithms used to determine location vary depending on the Radio Frequency (RF) environment and the accuracy required for a specific application.

In some cases, it may be necessary to track an asset with a high degree of accuracy throughout a school, such as when it is necessary to determine where a missing valuable asset is currently located). On the other hand, some applications using context-aware services may only require general indication of whether an asset is in or out of a permissible zone (such as the confines of a chemistry lab area for example).

Context-Aware Services can also provide location and other contextual information for wired devices attached to certain Cisco Catalyst LAN switches. With the correct level of software, switches such as the 2960G, 3560E, 3750E, 3750G, 4500, and 4900 series can become context-aware. Catalyst switches that are context-aware can provide civic location details for wired devices to the Cisco Mobility Services Engine based on pre-configured information specified for each switch port. This information can then be presented to users in a tabular format combined with other contextual information such as user name, device serial number and emergency location identifier numbers (ELINs).

Note

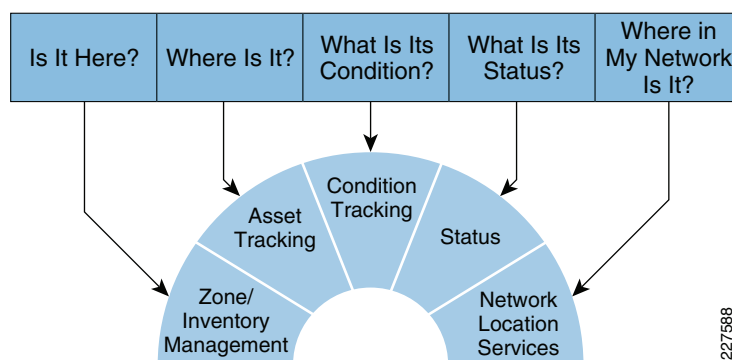

A civic location specifies the civic address and postal information for a physical location using fields such as the number, street or road name, community, and county assigned to residential, commercial, institutional, and industrial buildings (e.g., 31 Main Street, Alpharetta, Georgia 30004). An emergency location identifier number (ELIN) is a number that can be used by the local public safety answering point (PSAP) to look up the geographic location of the caller in a master database known as the automatic location information (ALI) database. The ELIN also allows the PSAP to call back the emergency caller directly in the event the phone call is disconnected.

For a more detailed overview of Context-Aware Services, refer to the following URL:
http://www.cisco.com/en/US/solutions/collateral/ns340/ns394/ns348/ns788/solution_overview_c22-475173.html.

Why Use Context-Aware Services?

The information that can be provided by Context-Aware Services across its application API can generally be classified into five functional categories, as shown in [Figure 6-1](#).

Figure 6-1 Five Functional Categories of Context-Aware Services

Is It Here?—Zone or Inventory Management

Zone or inventory management applications that utilize Cisco Context-Aware Services can define specific zones in which they monitor mobile assets that possess embedded wireless interfaces or have been outfitted with Cisco Compatible Extensions compliant RFID tags. These devices can be tracked and

monitored when they enter and exit both permissible and non-permissible areas. Notifications can be generated when monitored assets stray away into areas where they should not enter. Examples of how zone or inventory management may be used in the school environment include:

- Issuing notifications to administrators or school resource officers when school assets are moved out of authorized areas
- Alerting appropriate parties when persons equipped with RFID-enabled ID badges enter unauthorized areas
- Providing indication to teachers and assistants upon the arrival of an authorized parent or guardian that has arrived to pick-up their children at the end of the day

Further details about zone or inventory management can be found at the following URL:

http://www.cisco.com/en/US/solutions/collateral/ns340/ns394/ns348/ns788/solution_overview_c22-475178.html.

Where Is It?—Asset Tracking

Asset tracking applications that incorporate Context-Aware Services can help locate assets within the school, whether they are connected to wired or wireless infrastructure. In this way, Cisco Context-Aware Services can provide great value to school administrators, teachers, security personnel, or anyone who must quickly and effectively locate and recover missing assets. Examples of how asset tracking may be used in the School environment include:

- Locating wired and wireless portable assets (such as a portable video projector or flat panel display) for class use or faculty presentations
- Locating personnel possessing wireless VoWLAN phones or RFID-enabled badges in both emergency and non-emergency situations
- Identifying the past pattern of movement associated with an asset by enabling the review of archived location history information in both a tabular and a graphical format. Such audit trails can be especially useful when incorporated into security applications that can combine this information with other information sources, such as video surveillance.

Further detail regarding asset tracking can be found at the following URL:

http://www.cisco.com/en/US/solutions/collateral/ns340/ns394/ns348/ns788/solution_overview_c22-475177.html.

What Is Its Condition?—Condition Tracking

Condition tracking applications utilizing Context-Aware Services can monitor select characteristics of an asset's internal or external environment, such as variations in temperature, humidity, pressure, quantity, fluid volume, etc. Any change in these characteristics beyond set thresholds can trigger alerts, notifications, or other application-dependent actions. Examples of how condition tracking may be used in the School environment include:

- Temperature and humidity telemetry passed by RFID tag sensors can be utilized in school food service applications to monitor the temperature of food refrigeration units, guarding against costly spoilage and premature replacement.
- Fluid level sensors placed in combination with RFID tags can be used to monitor critical fluid levels in school maintenance applications, such as fuel oil levels for school generators and remote fuel storage for building heating.

- Indication of excessive or insufficient pressure in systems such as school heating and cooling, school labs (vacuum, air, and various gases), and so on can be passed as telemetry data using properly equipped RFID tag sensors.

What Is Its Status?—Status Monitoring

Applications that monitor changes in user and asset status can use Context-Aware Services to detect status transitions, such as a change from a normal state to one indicating that an extraordinary event has occurred. Examples of how this may apply to the school environment include:

- RFID tags with user push buttons could be used to covertly pass indication of situations where assistance is needed, along with the location of the tag at the time of activation.
- Attempted asset tampering, such as the removal of RFID asset tags themselves or jostling of any type, can trigger status monitoring applications to generate alerts.
- The introduction of new assets into a school location, or any changes in the motion status of existing assets above a certain threshold, can serve as preliminary indication to building energy management systems regarding potential building environmental modifications, such as lighting, zone heating, or zone cooling.

Where Is It in My Network?—Network Location Services

Network location applications interfacing with the Context-Aware Services can help optimize the distribution of both wired and wireless network resources, reduce troubleshooting time, help eliminate waste due to use of network resources by unauthorized “rogue” devices, and help lower the overall total cost of network operation. Examples of how this may apply to the school environment include:

- Location and removal of unauthorized 802.11 wireless devices operating within a school building, which helps reduce the school system's exposure to the introduction of malicious external software as well as its liability to illegal file sharing activities.
- Ongoing tuning of the wireless network by identifying areas where the routine congregation of wireless users is heavier than expected. This may prompt adjustments in wireless network parameters, the number of access points deployed, or the placement of access points.

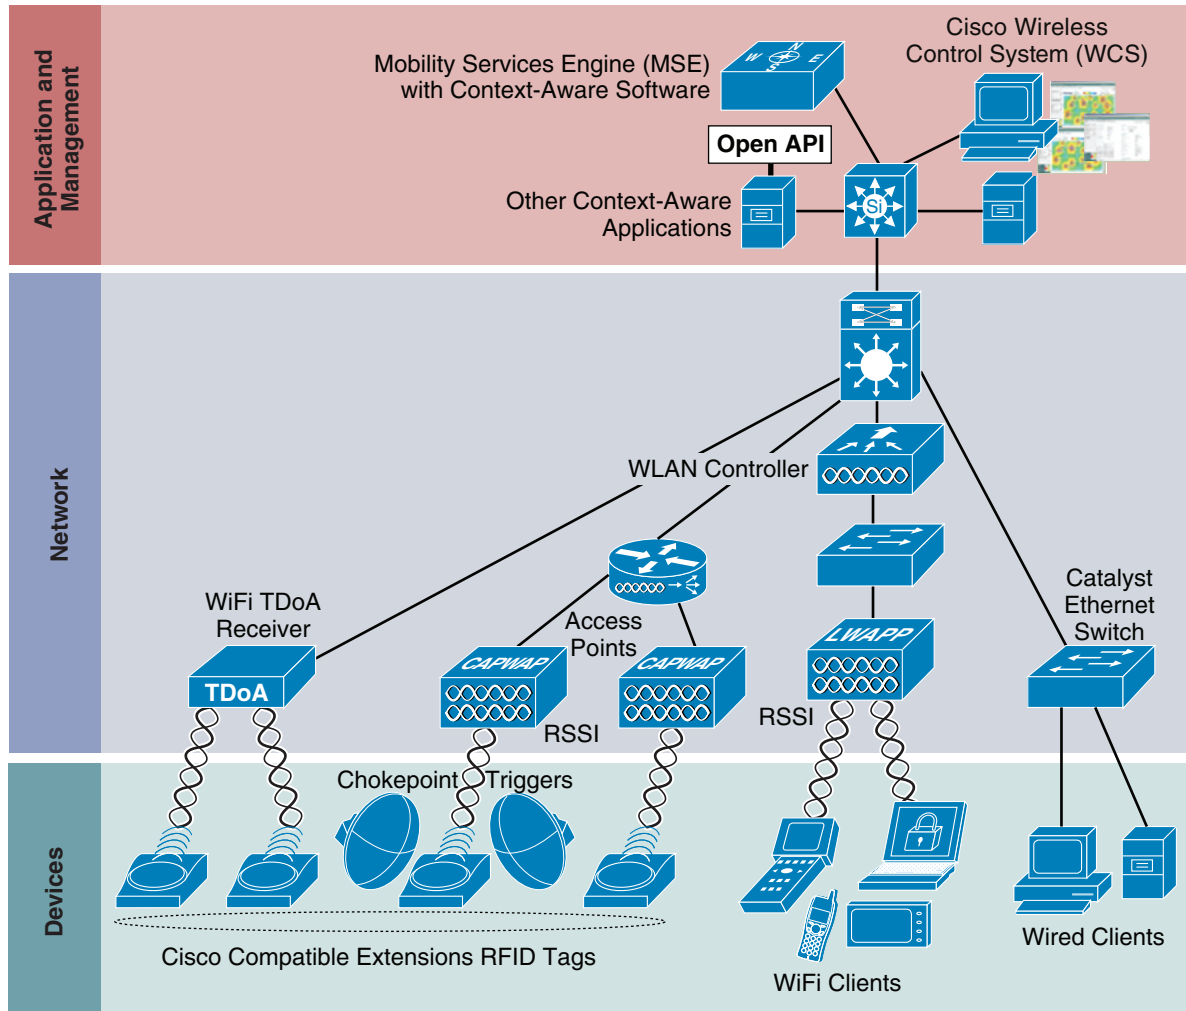

Further detail regarding network location services can be found at the following URL:

http://www.cisco.com/en/US/solutions/collateral/ns340/ns394/ns348/ns788/solution_overview_c02-474514.html.

When combined with other applications constructed to take advantage of the Cisco Context-Aware Services API, Context-Aware Services can serve as an enabler for entirely new application functionality. For example, from their wired or wireless device, a teacher can consult a context-aware enabled application that makes use of such information to determine the location of other faculty team members (such as a nurse or resource school safety resource officer) and initiate contact with the nearest available team member qualified to assist them. Context-aware services enhance the experience of users while at the same time improving their overall efficiency and productivity.

Cisco Context-Aware Components

The components of the Cisco Context-Aware Services are shown in [Figure 6-2](#).

Figure 6-2 Cisco Context-Aware Services Components

227589

Wired and Wireless Client Devices

- Wired or wireless (Wi-Fi) devices—Mobile wireless devices (asset tags, WiFi equipped computers, mobile stations, etc.) that interact with the network and whose location and other contextual parameters can be monitored by Context-Aware Services. Wired devices are generally equipped with an Ethernet interface which is attached to a Cisco Ethernet switch (such as the 2960G, 3560E, 3750E, 3750G, 4500, and 4900 series) that supports context-aware services. In addition, some devices may possess both wired and wireless interfaces. Without context-aware services deployed, if a wired IP speakerphone is originally deployed in a school library, and a librarian moves this phone to classroom 206 across the hall, any location information with regard to this conference phone's whereabouts would need to be manually updated across all concerned systems. With Context-Aware Services and a context-aware Ethernet switch, the location of the phone can be dynamically updated to reflect its new location within seconds after it has been plugged into the wired network jack in classroom 206. Via the Mobility Services Engine's API, this information can be provided to various context-aware applications, including the Cisco Wireless Control System (WCS).

- **Cisco Compatible Extensions RFID Tags**—These RFID tags can be physically attached to assets (regardless of whether the asset itself contains a wired or wireless network interface adapter) and can pass contextual information on behalf of the asset to Cisco Context-Aware Services. Compliance with the Cisco Compatible Extensions program helps ensure that RFID tags comply with predefined information formats such that the contextual information they capture can be made readily available to other Context-Aware Services components, including safety and security applications from Cisco partners. Sensor capabilities can be externally mounted or directly embedded into tags in order to link the data captured (for instance, motion, or temperature data) with the location of the mobile asset. Externally mounted sensors can also be placed in fixed locations, like a refrigerator or a storage room.

For more information about the Cisco Compatible Extensions for RFID Tags program, refer to the following URL: http://www.cisco.com/web/partners/pr46/pr147/ccx_wifi_tags.html.

- **Chokepoint triggers**—Chokepoint triggers (sometimes referred to as Exciters) are an optional component that can greatly enhance asset tag functionality, providing for finer tag location granularity and improved accuracy by localizing tagged assets within multi-floor structures, in presence detection scenarios, or when passing through chokepoint areas, such as entrances and exits. RFID asset tags that enter the proximity of a chokepoint trigger can change their normal behavior based on a set of pre-programmed instructions. RFID tags that have been stimulated by chokepoint triggers in this fashion send notifications and contextual information via the wireless infrastructure to the Cisco Mobility Services Engine.

Cisco Unified Network

This multipurpose network contains the wired and wireless infrastructure required to address converged data, voice, and video requirements, as well as providing the foundation for use of context-aware services.

- **Context-Aware Ethernet switches**—These are Ethernet switches (such as the 2960G, 3560E, 3750E, 3750G, and 4500 series) that support the specification of civic and emergency location identification number (ELIN) location information and the transmission of this information to Cisco Context-Aware Services. This functionality allows for contextual information associated with wired devices to be tracked using Context-Aware software on the Mobility Services Engine. Switches transmit relevant contextual information to the MSE for all of the devices attached to them. This information may include the physical mailing or street address location associated with the attached device (the civic address) as well as other information such as the IP address, MAC address, port, VLAN, and user name. Typically, this information is obtained using switch features such as IEEE 802.1x, Dynamic Host Configuration Protocol (DHCP) snooping, Dynamic Address Resolution Protocol (ARP) Inspection (DAI), and IP Source Guard. Additionally, if the end device runs the Cisco Discovery Protocol or Link Layer Discovery Protocol for Media Endpoint Devices (LLDP-MED), additional information, such as the version number and serial number, can also be sent to the MSE.

Note At this time, serial numbers of attached devices are reported to the MSE Context-Aware Service only if the device supports LLDP-MED.

- **WLAN controllers**—WLAN controllers (and the embedded software residing within them) provide for the aggregation and transfer of device tracking and statistics information for RFID tags, mobile wireless clients, and any rogue devices detected.

- Access points—In addition to their fundamental role in providing access for wireless clients, Cisco Aironet access points provide measurements of received signal strength from both wireless client devices and RFID tags and subsequently forward this information to the Mobility Services Engine via their registered WLAN controller.
- Received Signal Strength Indication (RSSI)—This is a mechanism used to determine device location by carefully considering the measured strength of a radio signal at several points in an indoor environment. Used by the Cisco Mobility Services Engine for WLAN clients, RFID tags, and rogue devices, this algorithm is based on the signal sent from the mobile asset to different access points deployed within the school. RSSI is usually preferred for indoor or low ceiling environments, both of which can result in high degrees of signal reflection.
- Wi-Fi Time Difference of Arrival (TDoA) Receiver—Wi-Fi TDoA receivers are optional components used in very large, open environments to locate assets equipped with RFID tags with greater accuracy and precision than is possible using other techniques.

**Note**

Although useful in extending Context-Aware Services for RFID tagged assets in outdoor venues, the use of TDoA receivers were not included in the Schools SRA design.

For a much more detailed explanation of both RSSI and other wireless location algorithms, refer to the *Wi-Fi Location-Based Services Design Guide 4.1* at the following URL:

<http://www.cisco.com/en/US/docs/solutions/Enterprise/Mobility/wifich2.html#wp1049520>.

Management and Applications

- Cisco Mobility Services Engine (MSE) with Context Aware Services Software—The Cisco Mobility Services platform can host multiple independent services possessing high-level capabilities that can enhance both wireless and wired network infrastructures. One of these is Cisco Context-Aware Services which can capture, store, and analyze contextual information from multiple wired and wireless networks simultaneously. When Context-Aware Services is deployed in accordance with generally accepted best practices, both wired and wireless network infrastructure devices (controllers and switches) may send raw location measurement data, device attachment, and other contextual information to the MSE regarding the presence of any wired clients, wireless clients, RFID tags, or rogue devices. Both wired and wireless network infrastructures communicate with the MSE using the Cisco Network Management Services Protocol (NMSP), which is a Cisco-defined protocol used for secure communication between the MSE and other context-aware network infrastructure components. The MSE sits out of the data path of the wireless LAN and receives data from WLAN controllers and context-aware switches via the use of NMSP.

The location of WLAN clients and RFID tags on the Cisco Mobility Service Engine is calculated by one of two software service modules:

- Cisco Context-Aware Engine for Clients, which handles all context-aware operations involving RSSI location of Wi-Fi clients, rogue clients, and rogue access points. This engine also handles context-aware operations for wired clients.
- Cisco Context-Aware Engine for Tags, which handles all context-aware operations involving TDoA and RSSI location of Cisco Compatible Extensions compliant RFID tags.

Context-Aware Services software, when operating alone on the Cisco MSE, is capable of servicing up to a maximum of 18,000 simultaneously tracked devices per single MSE-3350 appliance and 2,000 simultaneously tracked devices per single MSE-3310 appliance.

Refer to the following data sheet for more information regarding the Cisco 3300 Series Mobility Services Engines

http://www.cisco.com/en/US/prod/collateral/wireless/ps9733/ps9742/data_sheet_c78-475378.html

- **Wireless Control System (WCS)**—The Cisco Wireless Control System is a management platform that also contains a context-aware client application that interacts with the Mobility Services Engine. The primary role of the context-aware client application is to provide access to the contextual information contained on the MSE using the MSE's application programming interface (API). The application can then either present this information to the user directly (such as is seen in a graphical location map or a table of location values) or enable other processes to accomplish relevant tasks using this information that would otherwise be difficult to achieve. The Cisco WCS can also serve in a special secondary role as a control client that possesses the ability to configure MSE operational parameters.

For more detailed information on the Cisco Wireless Control System management server and its capabilities, including its ability to serve as a context-aware application client, refer to the documentation at the following URL:

http://www.cisco.com/en/US/prod/collateral/wireless/ps5755/ps6301/ps6305/product_data_sheet0900aecd802570d0.html.

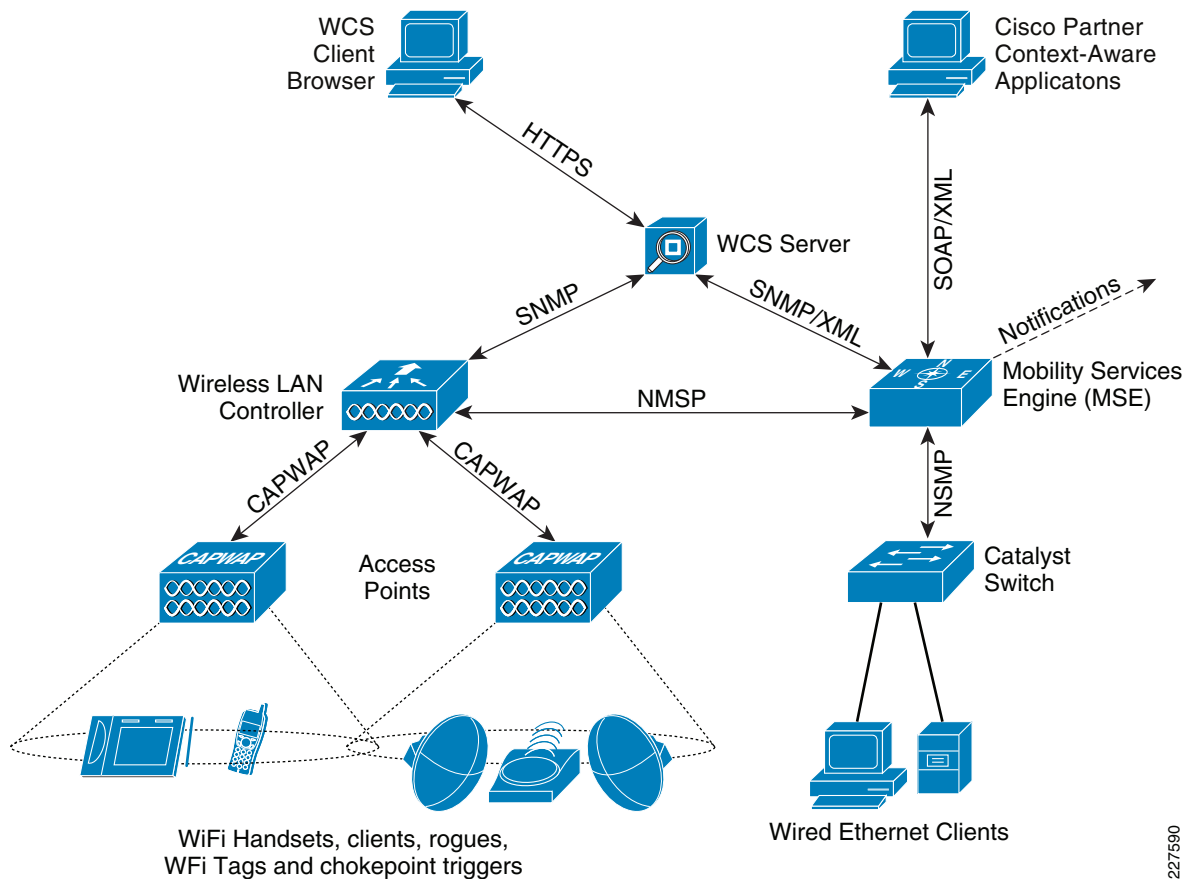

- **Other Context-Aware Applications**—Other context-aware client applications from third party Cisco Technology Development Partners may also access the MSE via its open API, which is based on Simple Object Access Protocol (SOAP) and XML protocol. Access to this API is available to any Cisco technology partner. Context-aware applications developed by Cisco Partners often deliver specifically targeted application functionality that is often not available from other sources.

For more information on the Cisco Context-Aware Services API, refer to the following URL:

<http://developer.cisco.com/web/contextaware/home>.

Context-Aware Component Interaction

Figure 6-3 provides a more detailed illustration of the protocol interaction between the various Context-Aware Service components.

Figure 6-3 Protocol Interaction Between Context-Aware Components

For wireless clients, tags, and rogues, Cisco Aironet access points use the Control and Provisioning of Wireless Access Points (CAPWAP) protocol to forward the RSSI of detected clients, tags, and rogues to the WLAN controller to which they are currently registered. The wireless LAN controller aggregates this information on a per device basis from all registered access points detecting the wireless device's signal. This information is then forwarded to the MSE using the NMSP protocol via an authenticated and encrypted session. The appropriate Context Aware software engine on the MSE then uses the RSSI data received from one or more WLAN controllers to determine the location of the wireless device

**Note**

A rogue access point is any access point that is determined not to be a member of the same mobility group as the WLAN controller to which the detecting access points belong. A rogue client is any client that is currently associated to a rogue access point.

For wireless clients, rogue access points, and rogue clients, the Context-Aware Engine for Clients is used to process the received RSSI information. For operations involving RFID tags, however, the Context-Aware Engine for Tags is used instead. Using Context-Aware Services and the Mobility Services Engine, the Cisco Unified Network can readily detect 802.11 Wi-Fi active RFID tags that are compliant with the Cisco Compatible Extensions for Wi-Fi Tags specification (such as those from AeroScout, WhereNet, G2 Microsystems, and others). Through the MSE and WCS, the location of these RFID tags can then be displayed on WCS floor maps using a yellow tag icon.

**Note**

The Context-Aware Engine for Tags in Cisco Context-Aware Services Release 6.0 only tracks RFID tags that are compliant with the Cisco Compatible Extensions for Wi-Fi Tags specification.

Cisco Compatible Extensions compliant active RFID tags are detected on a Wi-Fi network based on periodic frames¹ that are sent by the tag using a Layer-2 multicast. The delay between these periodic frames can be programmed based on the specific application use case. In most cases, tags are configured to transmit periodic frames every three to five minutes in order to strike an equitable balance between location accuracy and good tag battery life.

RFID tags can also pass tag telemetry information upstream to the MSE as part of the tag message payload. This contextual information (battery status, motion, temperature, pressure, humidity, etc.) is received by access points and collected by WLAN controllers in a similar fashion as that described earlier in this section. WLAN controllers will aggregate telemetry traffic from multiple tags and eliminate any duplicate tag telemetry values that might be received. After the telemetry has been distilled and cleansed of any duplicate information, the WLAN controller passes it to the MSE. The MSE updates its internal databases with this information and in turn makes this information available to application programs.

Properly equipped RFID tags can also indicate the occurrence of a priority event, such as one that might result from the triggering of a tag tamper sensor or the depression of a tag call button. RFID tags indicate that these types of events have occurred via additional information embedded in the tag messages that are sent to the WLAN controller. This information is in turn passed northbound from the WLAN controller to the MSE and the MSE can make this information available to application programs.

Several manufacturer's RFID tags include a secondary on-board magnetic signaling receiver, typically set up to respond to the magnetic field component of a 125 kHz RF carrier. This secondary receiver provides for additional tag functionality when tags enter into areas that are within close proximity to a magnetic signaling transmitter or chokepoint trigger. Chokepoint triggers are proximity communication devices that trigger asset tags to alter their configuration or behavior when the tag enters the chokepoint trigger's area of operation or stimulation zone. This alteration could be as simple as causing the asset tag to transmit its unique MAC address identifier. It could be significantly more complex, including causing the tag to change its internal configuration and status. One of the prime functions of a chokepoint trigger is to stimulate the asset tag such that it provides indication to the system that tag has entered (or exited) the confines of a constricted physical area known as a chokepoint. Typical chokepoints include entrances, exits or other types of physical constrictions that provide passage between connected regions of a facility (such as a corridor or hallway).

**Note**

While chokepoint triggers are electronic devices that are typically deployed within physical chokepoints, it is not unusual to hear the term “chokepoint” used rather loosely to refer to both the physically constricted area and the associated electronic device.

Chokepoint triggers (including a very popular model manufactured by AeroScout Ltd. known as an Exciter) may be connected to the wired infrastructure and are configured using each vendor's configuration software. Once they have been configured, they can either remain connected to the infrastructure full-time for management purposes or can be disconnected and operate in a standalone mode, requiring a source of electrical power but no actual connectivity to the network.

1. These periodic frames are also sometimes referred to as “beacons”. They should not be confused with the 802.11 beacons that are sent by access points.

The chokepoint trigger address information contained in the tag packet provides the MSE with enough information to temporarily override any RSSI or TDoA localization currently in place for the tag and set the current location of the RFID tag to the location of the chokepoint trigger. The size of a chokepoint trigger's stimulation zone, or range, can extend from a radius one foot or less to over twenty feet, dependent upon the vendor and the capabilities of the particular model.

Catalyst switches supporting context-aware services also make use of NMSP to interact with the MSE similar to the manner described earlier for WLAN controllers. A major difference between how WLAN controllers and Catalyst switches interact with context-aware services lies with the method used to determine the location of switch attached wired devices. As explained earlier, localization of wireless devices is performed by the MSE using a signal or time based technique, whereas the location of wired devices is based on information sent to the MSE that originates in the switch configuration. The information recorded by the MSE for the wired device includes the device MAC address, switch MAC address, slot or port, IP address, and user name (if available). This information is sent whenever a device link changes state. Context-aware Cisco Catalyst switches provide the MSE with the latest relevant civic location and emergency location identification number (ELIN) information for all attached IP endpoints. These endpoints may include IP phones, PCs, access points and other devices.

In Release 6.0, all civic and ELIN location information is configured locally at the switch, and shortly after location changes are made using the CLI, they are propagated to the MSE. NMSP is used between the switches and the MSE to maintain synchronization, and alert the switch as to the connection or disconnection of devices.

Additional information regarding civic address location is available from the IETF in the following RFCs:

- DHCP Option for Civic Addresses Configuration Information
<http://www.rfc-editor.org/rfc/rfc4776.txt>
- Revised Civic Location Format for Presence Information Data Format Location Object
<http://www.rfc-editor.org/rfc/rfc5139.txt>

**Note**

Proper validation of certificates between context-aware service components requires the participants to possess sane clocks (clocks whose configured time does not differ from one another by large amounts). In order to facilitate this, it is highly recommended that the clocks in the MSE, WCS, WLAN Controllers, and any context-aware Ethernet switches be synchronized to a common time base using the Network Time Protocol (NTP). The lack of clock sanity amongst context-aware components in the network can cause NMSP sessions to fail if the configured date and time fall outside of the certificate validity period and cause certificate validation to fail.

Network Mobility Services Protocol (NMSP)

The Network Management Service Protocol (NMSP) was designed to define intercommunication between Mobility Service Engines and network access controllers over a switched or routed IP network. An access controller can provide network access for either wired or wireless endpoints. Within the scope of the Schools SRA design, access controllers are represented by WLAN controllers and context-aware Cisco Catalyst Ethernet switches.

NMSP is a two-way protocol that can be run over a connection-oriented or a connectionless transport. WLAN controllers and context-aware switches can use NMSP to communicate with one or more MSEs. NMSP is based upon a bidirectional system of requests and responses between the MSE and the access controllers.

MSP also provides for a keepalive feature that allows either partner in a NMSP session to determine if the adjacent partner is still active and responsive. Should an MSE fail, a WLAN controller or a context-aware Ethernet switch will try to contact another MSE with which to communicate. If the WLAN controller or context-aware Ethernet switch fails, all context-aware services being provided to that WLAN controller or context-aware Ethernet switch are disabled until that WLAN controller or context-aware Ethernet switch once again becomes active and re-establishes its NMSP session.

Note

It is important to understand that the failure of an NMSP session has no direct impact on the ability of a WLAN controller or context-aware capable Ethernet switch to pass normal client session traffic to applications on the network. In other words, a failed NMSP session to a WLAN controller may affect the ability of the MSE to provide updated contextual information on that controller and its resources. But it does not affect the ability of the WLAN clients using that WLAN controller to logon to applications residing on the network. This also applies to wired clients and context-aware Ethernet switches.

NMSP uses Transport Layer Security (TLS) and TCP port 16113 on the WLAN controller or context-aware Ethernet switch. The MSE will initiate the connection to the WLAN controller or context-aware Ethernet switch, although once a secure session has been established between MSE and its session partner, messages may be initiated in either direction. The TCP port (16113) that the controller and mobility services engine communicate over must be open on any firewall that exists between the controller and mobility services engine.

The MSE and the WLAN controller or context-aware Ethernet switch use Echo Request and Echo Response control messages to maintain an active channel of communication so that the data messages can be sent. The Echo Request message is a keepalive mechanism that allows either NMSP session partner to determine if the other partner remains active and responsive. Echo Requests are sent periodically (upon expiration of a heartbeat timer) by the MSE or its session partner to determine the state of the NMSP session. When the Echo Request is sent, a NeighborDeadInterval timer is started. The NeighborDeadInterval timer specifies the minimum time a session partner must wait without having received Echo Responses to its Echo Requests, before the other session partner can be considered non-responsive and the NMSP session is placed in an idle state.

Context-Aware Services in the Schools Service Ready Architecture

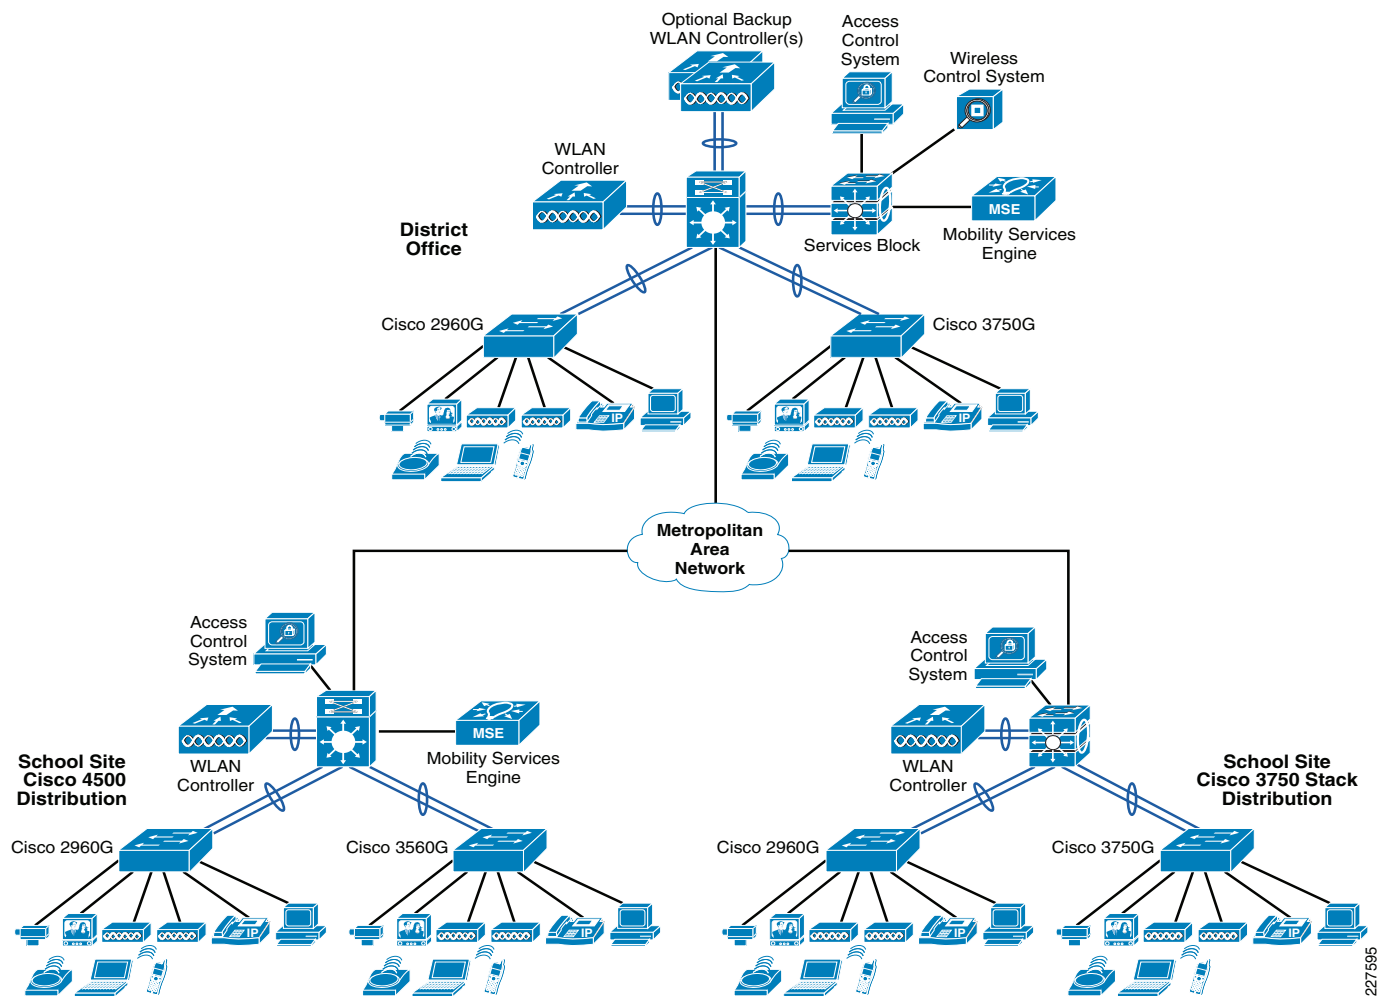

Figure 6-4 provides a high level illustration of the integration of Cisco Context-Aware Services into the Schools Service Ready Architecture. The key points of this integration into a Metropolitan Area Network deployment are:

- The presence of a **centralized management entity** (the wireless control system (WCS))) at the district office. In the case of Context-Aware Services, WCS also serves as a context-aware application client. District and school context-aware users can log into WCS and query the contextual characteristics (such as location) associated with wireless and wired client devices, rogues and asset tags. In some cases, third-party context-aware application servers may also contain context-aware applications that are located in the district office.
- The presence of a **local Mobility Services Engine at larger schools** used to provide Context-Aware Services to individual larger schools, where the anticipated number of total tracked devices is significantly higher (e.g., greater than 500 and most likely 1000 or more). A locally deployed MSE

may also be justified if context-aware services are being utilized for school applications and tasks that are considered mission-critical to the function of the school or the safety and security of students or faculty.

- The option of a centralized Mobility Services Engine with Context Aware software at the district site used to provide the Context-Aware Services to smaller schools where the anticipated number of total tracked devices per school is relatively low (e.g., less than 500).

Figure 6-4 High-Level View of the Schools SRA With Hybrid Context-Aware Services Model

Except for very large or very small school districts, it is our understanding that the majority of School districts addressed by the Schools SRA design will contain a mix of large schools (such as high schools) and smaller schools (such as elementary and intermediate schools). We anticipate that many of the smaller schools in these districts may be well served by the 3750 switch stack used at the distribution layer, whereas larger school designs may be outfitted instead with the 4500 distribution switch. In situations such as this, the context-aware deployment model shown in Figure 4 can be used to provide context-aware services to both types of schools.

Historically, context-aware services and the Cisco Mobility Services Engine (as well as its predecessor, the Cisco Wireless Location Appliance) were designed to be deployed within modern switched LAN environments. In such deployments, FastEthernet speeds and capacity (or better) are typically assumed

to be present throughout the local area network. Due to the lower speeds associated with traditional wide-area networking technologies (such as frame relay, T-1, and so on), context-aware components have not been recommended for deployment across traditional WANs. In fact, if context-aware services are to be deployed in remote sites possessing only traditional WAN connectivity, Cisco Systems has typically always recommended that the MSE be deployed locally along with WLAN controllers and any other components establishing NMSP sessions to the MSE. In addition, designers may wish to break up large WCS network designs into smaller designs to avoid time outs that can occur between WCS and the MSE during synchronization of very large network designs when using low-speed links².

While the cost of local MSE deployment can be very applicable to very large remote sites whose device population can justify it, this is typically not true in the case of smaller sites with lower device populations. Looking at the general case of school districts that might contain a mix of larger and smaller schools, we can easily see that this local versus remote dilemma applies in the case of the Schools SRA design as well.

A key difference (and advantage) of In the Schools SRA design, is that the use of a modern high-speed metropolitan area network (MAN) to interconnect remote schools offers far more bandwidth to each remote site than would be seen with a traditional WAN deployment. In this case, with modern LAN-like speeds available across the metropolitan area network, the concept of deploying an MSE remotely from the other context-aware components begins to resemble the look and feel of a local LAN deployment, and thus becomes much more feasible. Note however, this assumes sufficient bandwidth and infrastructure is in place to assure that FastEthernet-like speeds are available to each school and that proper network protocol identification, classification and QoS are all applied properly to manage congestion in the network.

In the context-aware services model shown in [Figure 6-4](#), we take advantage of high-speed connectivity across the MAN to the remote schools and allow for a centralized MSE to provide context-aware services for smaller schools across the district. We assume here that on their own, a single small school might only have a maximum of 250 to 500 simultaneously tracked devices. An exception to the case made for using a centralized MSE for smaller schools might be for any schools where context-aware services are used for applications that are mission-critical to the safety and security of the school, its students, and the faculty and administration. An example of such an application might be a safety and security application used to ascertain the location of all faculty or students during a school lock-down security event using identification cards that are equipped with RFID technology. This type of application obviously must be available at all times, including any potential network outages, hence the use of a centralized MSE in this case is not an option. Any other supporting applications that are required for such mission-critical deployments of context-aware services should also be deployed locally in this case as well.

Note

Based on our analysis of MAN capacity, traffic flows, classification and QoS, we believe the centralized deployment of an MSE across a modern high speed metropolitan network is a viable concept. Although a great deal of intensive functional testing was performed during the preparation of this chapter, time constraints did not allow us to complete validation of centralized MSE deployments across metropolitan area networks.

Larger schools using a 4500 series Catalyst Ethernet switch for distribution are assumed to possess at least 500 or, more likely, 1000 or more simultaneously tracked wired or wireless devices. While it may be possible to service these larger schools using a centralized MSE, the larger number of clients and the increased amount of traffic placed onto the MAN between controllers, switches, and the MSE in this case can pose more of a challenge, especially when there are large device populations that move frequently and generate location updates on a regular basis. Careful analysis of data traffic and the judicious application of QoS in the network becomes especially important.

2. Or use a locally deployed WCS at each remote site that could optionally be managed by WCS-Navigator at a central site.

At the current time, the most reliable known solution in the case of larger schools with large tracked device populations is to deploy an MSE locally at the school. This MSE can in turn be managed via a remote WCS at the district office. Once again, in cases where context-aware services are regarded as mission critical for the school, other context-aware components (such as third-party context aware application servers or in some cases the WCS as well) should also be deployed locally in order to ensure that the context-aware solution is functional even in the rare case of a prolonged MAN failure.

In school districts where there are many schools with either large tracked device populations or mission-critical context-aware applications, it is important to keep in mind that at this time Cisco officially supports the management of up to five (5) MSE platforms from a single WCS system. While this is not a “hard” limitation on the number of MSE platforms that can be assigned to a single WCS system, it is the limit to which testing has been performed. Therefore, in designs where there may be greater than five large schools equipped with locally deployed MSE platforms, you may wish to consider using additional WCS systems as necessary. In this case, the use of WCS-Navigator (not shown in [Figure 6-4](#)) should be considered at the district office to provide a single interface portal to as many as twenty (20) WCS management systems and their associated Mobility Services Engines. WCS-Navigator is a management aggregation platform that delivers enhanced scalability, manageability, and visibility of large-scale implementations of Cisco WCS and the Cisco Unified Network. WCS-Navigator provides straightforward access to information from multiple Cisco WCS management platforms. A single WCS-Navigator management aggregator can support up to twenty (20) WCS management systems and 30,000 access points.

**Note**

Due to time constraints, scalability testing of WCS-Navigator in the Schools SRA design beyond four WCS systems was not able to be completed. Further information on WCS-Navigator can be found at <http://www.cisco.com/en/US/products/ps7305/index.html>.

Component Capacities

Mobility Services Engine

Each Cisco Mobility Services Engine has a maximum device tracking capacity, defined as the maximum number of active wired and wireless (clients, rogues, and RFID tags) that can be tracked by a single Mobility Services Engine. This is a “hard” limit that is dictated by the licensing purchased for the Context-Aware software as well as the presence of any other applications on the MSE. Once a Mobility Services Engine has reached its maximum tracking capacity, any new devices that the MSE becomes aware of beyond that limit are simply not tracked. It is important to note that while this section discusses the maximum device tracking limits for the MSE, MSE licenses can be purchased supporting device limits significantly lower than those shown here. Refer to the *MSE Licensing and Ordering Guide* (http://www.cisco.com/en/US/prod/collateral/wireless/ps9733/ps9742/data_sheet_c07-473865.html) for more information regarding the various combination of client and RFID tag tracking capacities available for the MSE.

For Release 6.0, the maximum device tracking limits when using only the Context-Aware Services software on the MSE are shown in the following table:

Mobility Service Engine	Maximum Tracked Device Capacity
MSE-3350	18,000
MSE-3310	2,000

If you intend to use the MSE-3350 to deliver other services in addition to Context-Aware, the maximum capacity shown above in Table 2 will likely be reduced. See the *MSE Licensing and Ordering Guide* (http://www.cisco.com/en/US/prod/collateral/wireless/ps9733/ps9742/data_sheet_c07-473865.html) for information on Context-Aware maximum tracked device limits with other co-resident MSE services.

When working within these maximum capacities, it is important to note that further category-specific limits can be instituted at the designer's discretion via the MSE configuration. This allows, for example, a maximum capacity of 2,000 tracked devices on a MSE-3310 to be further limited as 1,000 wired and wireless clients, 500 RFID tags, and 500 rogue access points and clients. Partitioning the maximum tracking capacity of the context-aware software in this manner prevents any single device category from consuming more than its authorized share of the maximum tracking capacity of the system.

In the high-level diagram shown in Figure 6-4, the MSE-3310 might be a good design choice for a locally deployed MSE at our 4500-based school site. Its maximum tracked device capacity of 2000 devices should scale well to a larger school site with an estimated 1000-1250 total tracked devices. This would leave ample MSE capacity in reserve for future growth in tracked devices at this location. Of course, you could deploy with less capacity in reserve should you choose to, and elect to address future tracked device growth at a later date via a hardware addition or upgrade. 4500-based schools that possess or anticipate near-term tracked device needs beyond 2000 devices should consider the MSE-3350 instead.

Except for very small school districts, the MSE-3350 would typically be the best overall choice when considering a centralized deployment using a high-speed metropolitan area network. In this way, it can provide context-aware services for several smaller school sites, each of which might possess an estimated 500 or fewer tracked devices. In very small school districts (e.g., a district containing up to four small schools for example) a centralized MSE-3310 may prove to be even more cost-effective.

WLAN Controllers

WLAN controllers also possess limitations on the maximum number of devices for which the controller will track and aggregate contextual information. In Release 6.0, these limits are shown in Table 6-1.

Table 6-1 Maximum Device Limitation

WLAN Controller	Clients	Tags	Rogue Access Points	Rogue Clients
4404	5000	2500	625	500
4402	2500	1250	625	500
2106	500	256	125	100

Note that these are indeed “hard” limits. In other words, once these limits have been achieved on a WLAN controller, contextual tracking information for any new clients, RFID tags, rogue access points, or rogue clients beyond these limits will be dropped until such time that older entries are pruned from the controller's internal database. The client and tag limits are quite high and should not prove to be easily exceeded for a single school. Unless students are allowed to operate their own unauthorized rogue WiFi equipment during school hours (which is typically not the case as per our understanding), the limitation on the number of rogue devices tracked by a single controller should not be routinely exceeded in a single school.

The Context-Aware System Performance chapter of the *Mobility Services Engine Context Aware Deployment Guide* (http://www.cisco.com/en/US/products/ps9742/products_tech_note09186a00809d1529.shtml#casysper)

f) also points out that a single MSE can support up to 500 total NMSP connections. Keep in mind this includes not only the NMSP sessions to WLAN controllers, but NMSP sessions to any context-aware Ethernet switches conducted from that MSE.

**Note**

Although a single MSE can technically support up to 500 NMSP sessions, scalability testing constraints have only allowed for testing of 100 simulated NMSP connections to a single MSE at this time.

Wireless Control System (WCS)

With regard to the MSE, WCS interacts as a context-aware client and does not track devices itself when used in conjunction with the MSE. Thus, there are no direct constraints on the maximum number of tracked devices imposed by WCS itself.

In addition to established WCS sizing and capacity guidelines for the number of supported controllers and access points (listed in the *System Requirements* section of the *Wireless Control System Configuration Guide*, Release 6.0,

http://www.cisco.com/en/US/docs/wireless/wcs/6.0/configuration/guide/6_0wst.html#wp1061082), there are a few indirect constraints relating to Context-Aware services that you should be aware of:

- To maintain clarity and the speed of its graphical user interface, WCS only displays the first 250 wireless clients, RFID tags, rogue clients, or access points on a single floor map. To view graphical location displays for any of these device categories beyond this limit, filtering (based on MAC address, asset name, asset group, asset category, or controller) should be used to limit the number of devices displayed at once (see the Floor Settings section of the *Wireless Control System Configuration Guide*, Release 6.0, http://www.cisco.com/en/US/docs/wireless/wcs/6.0/configuration/guide/6_0maps.html#wp1210969).
- Currently, a single WCS can manage Context-Aware Services on up to five (5) Mobility Service Engines. While defining more than five MSEs to a single WCS is possible, Cisco Systems has not validated this level of operation.
- Currently, Context-Aware Services on the Mobility Services Engine can be managed by only one Wireless Control System.
- In Release 6.0, WCS supports the creation of up to 124 WCS virtual domains.

Context-Aware Engine for Tags (AeroScout)

The Context-Aware Engine for Tags used in version 6.0.85.0 of the MSE Context-Aware Services software supports network designs containing up to 255 floor maps. A network design typically consists of campus, buildings, and floor maps. Thus, in the Schools SRA, a network design might be used to describe a school district. This limitation could be interpreted as saying that a school district should not contain more than 255 floor maps. If more than 255 floor maps are required, it is necessary to break the school district up into two or more network designs.

Obviously, the degree of restriction here will vary with the number of floors in each school in your district, multiplied by the number of schools. For example, if all schools in a district contain only a single floor, then up to 255 schools could be defined in a single network design before the conditions of this restriction are encountered. If schools each contained three floors however, then only 85 schools could be defined before being subject to this limitation.

Integration with the Schools Service-Ready Architecture

MSE Connection to the Network

Figure 6-5 is an illustration of the rear panel of both the MSE-3350 and the MSE-3310. The Cisco Mobility Services Engine is equipped with two 10/100/1000BASE-T Gigabit Ethernet ports (shown in Figure 6-5 by the solid arrows) that can be used to directly connect the MSE to two different IP networks (dual-homed). This makes it a simple affair, for example, to configure a MSE for service on network A while affording it the capability to be managed out-of-band on network B if the need arises.

In the Schools SRA design, we attach the MSE to the network via a single connection to the NIC0 interface.

Figure 6-5 Rear Panel Illustration of MSE-3350

Note

The dual on-board Ethernet controllers on the MSE are not intended for redundant or simultaneous connections to the same IP network. Any attempt to manually configure the MSE in order to try and establish parallel, load balancing, or redundant Ethernet connections to the same IP network is not recommended or supported at this time.

Clock Synchronization

The Mobility Services Engine, WCS, WLAN controllers, and any switches that support context-aware services use Coordinated Universal Time (UTC)³ in their interaction. Because proper certificate authentication relies on time base consistency between participating components, it is important to ensure that these components are synchronized to a common time base throughout the Schools SRA design. In addition, having components synchronized to a common time source makes troubleshooting much easier, especially when having to look at events occurring within the logs of different network components. And the output of coordinated information by a central source, such as WCS, makes much more sense when the time stamps of all information displayed follow a logical flow and make sense to the user.

Once time and date in each network component has been set initially, time synchronization should be maintained using the Network Time Protocol (NTP). In the Schools SRA design, these components should be synchronized to the local school or district ISR router.

3. For applications such those anticipated in the Schools SRA, Universal Coordinated Time may be considered as equivalent to Greenwich Mean Time (GMT).

NTP Configuration of the Mobility Services Engine

Configuration of the NTP server addresses used by the MSE is handled during installation and the execution of the MSE automatic configuration script. An excerpt of that script is shown below. Detailed information regarding the automatic configuration script can be found in the Automatic Installation Script section

(http://www.cisco.com/en/US/docs/wireless/mse/3350/quick/guide/mse_qsgmain.html#wp1057105) of the Mobility Services Engine Getting Started Guide, http://www.cisco.com/en/US/docs/wireless/mse/3350/quick/guide/mse_qsgmain.html#wp1057105, and in Appendix A (http://www.cisco.com/en/US/products/ps9742/products_tech_note09186a00809d1529.shtml#appena) of the Mobility Services Engine Context Aware Deployment Guide, http://www.cisco.com/en/US/products/ps9742/products_tech_note09186a00809d1529.shtml#appena.

If you choose to enable NTP, the system time will be configured from NTP servers that you select. Otherwise, you will be prompted to enter the current date and time.

NTP is currently disabled.

Configure NTP related parameters? (Y)es/(S)kip/(U)se default (S)kip: Y

Enter whether or not you would like to set up the Network Time Protocol (NTP) for this machine.

If you choose to enable NTP, the system time will be configured from NTP servers that you select. Otherwise, you will be prompted to enter the current date and time.

Enable NTP (yes/no) no : yes

Enter NTP server name or address: <IP address or DNS name of NTP server>

Enter another NTP server IP address (or none) none: none

NTP Configuration of WLAN Controllers

Configuration of the internal clock and the specification of which NTP servers to use for periodic time synchronization can be performed on the WLAN controller using either the web GUI interface or the command line interface.

If you did not configure the system date and time through the configuration wizard when the controller was initially configured, or if you want to change your configuration, you can follow the instructions located in the section entitled Managing the System Date and Time

(<http://www.cisco.com/en/US/docs/wireless/controller/6.0/configuration/guide/c60intf.html>) in the WLAN Controller Configuration Guide 6.0

(<http://www.cisco.com/en/US/docs/wireless/controller/6.0/configuration/guide/c60intf.html#wp1144340>) in order to configure the controller to obtain the date and time from a Network Time Protocol (NTP) server.

NTP Configuration of the Wireless Control System (WCS) Server

Configuration of the internal clock and the specification of which NTP servers to use for periodic time synchronization must be performed on the WCS server using the time and date capabilities of the WCS host operating system in use (either Windows or Linux).

RHEL-Based WCS Server

For a Redhat Linux-based WCS server, login to the host OS as root and use the following procedure to synchronize the internal software clock to the NTP server, synchronize the software clock to the server's hardware clock, and then maintain synchronization by starting the ntpd client daemon:

1. **clock**—Displays the current setting of the software clock.
2. **/etc/init.d stop**—Stops the ntpd client if it is already running.
3. **ntpdate <ntp server name or address>**—Synchronizes the system software clock with the NTP server.
4. **setup**—Brings up a setup utility that allows you to choose to set the time zone (shown in Figure 6-6).
5. **hwclock--systohc**—Writes the software clock settings to the hardware clock.
6. **/etc/init.d/ntpd start**—Starts the ntpd daemon to keep the clock synchronized going forward.⁴

Figure 6-6 RHEL Setup Utility

Note

There are various other approaches that can be used to set the time zone on a Linux system. The reader is encouraged to consult the Redhat documentation for methods involving the use of the TZ variable or symbolic links to the localtime file or a particular time zone file in the system's time zone directory.

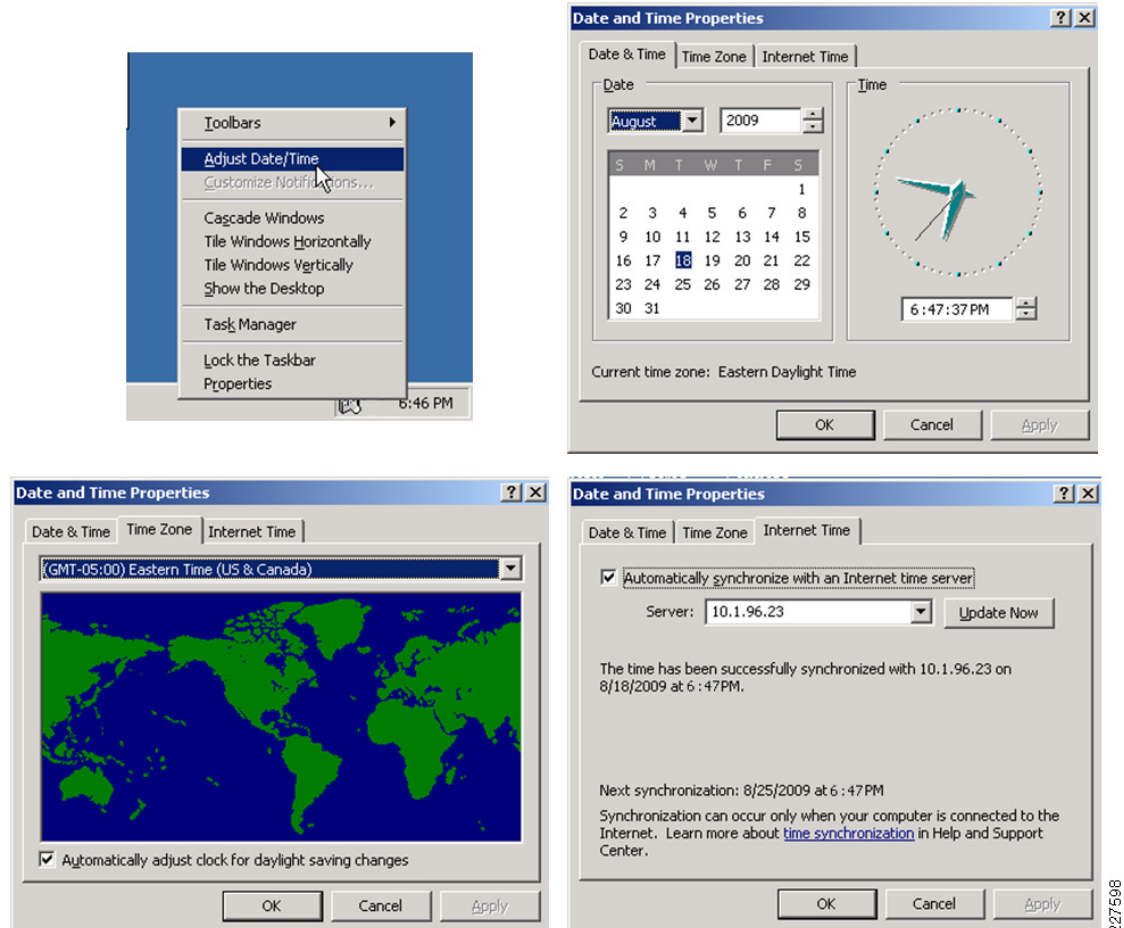

Windows 2003-Based WCS Server

For a WCS server based on the Microsoft Windows 2003 Server OS, use the following procedure to synchronize and maintain the correct system time via the Windows Time service (see Figure 6-7):

1. Check **Settings>Control Panel >Administrative Tools>Services** for the Windows Time service and ensure that it has been started.
2. Right click on the **Task Bar** clock and select **Adjust Date/Time**.
3. Under the **Date & Time** tab, set the current date and clock time to the approximate time of your NTP server.
4. If ntpd does not start as part of your system boot script, you might want to add it using the command **chkconfig --add ntpd**.

4. Set the Time Zone and Daylight Savings time selections appropriately.
5. Select the Internet Time tab, check the box to Automatically Synchronize With An Internet Time Server, type in the DNS name or address of your NTP server, and then Apply.

Figure 6-7 *Setting Time and NTP Server on Windows 2003*

227598

NTP Configuration of Context-Aware Catalyst Ethernet Switches

In order to prevent any issues with authentication and NMSP session initiation, Catalyst Ethernet switches participating in context-aware services should be configured to utilize NTP in order to keep their clocks in synchronization with other context-aware components. NTP is configured similarly amongst the various switch models discussed in this chapter, and the most comprehensive information on how to configure a Catalyst switch as an NTP client can usually be found in the configuration guide for the particular switch model. For example, for the Catalyst 2960G NTP configuration is documented in Configuring NTP section of the Catalyst 2960 Switch Software Configuration Guide (http://www.cisco.com/en/US/docs/switches/lan/catalyst2960/software/release/12.2_50_se/configuration/guide/swadmin.html#wp1053923).

It is good general best practice to ensure time synchronization of all network components when possible. However, from the perspective of context-aware services in the Schools SRA, only those switches that are actually participating in an NMSP session with the MSE require clock synchronization.

Schools SRA Wireless Control System (WCS) Context-Aware Considerations

The Wireless Control System is used for several important configuration tasks relating to context-aware services in the Schools SRA:

- Creation of a School or School District Network Design, which may include campus, building, floor, and outdoor level maps.
- Definition of WCS User Groups, which are used to define what management actions school context-aware users are authorized to perform with regard to network resources.
- Definition of Virtual Domains, which can be used to restrict which network resources school and other users have the ability to manage via WCS.
- Configuration of Mobility Service Engine operating parameters. This represents the next level of MSE setup beyond that performed by the MSE automatic configuration script discussed in section [NTP Configuration of the Mobility Services Engine](#).
- Definition of Context-Aware Conditional Notifications, which defines how applications and parties external to the School might receive notification of specific events pertaining to changes in contextual characteristics associated with clients, tags or rogue devices.

In this section, we discuss only those areas where, in our testing of the Schools SRA design, we made use of significant WCS features relevant to the integration of context-aware services in our design, or where important configuration changes were made that significantly differ from the defaults. This is not meant to serve as a comprehensive configuration guide to all aspects of the WCS and MSE. Readers should refer to the WCS and MSE configuration documents already cited throughout this document (including Context-Aware Services General Best Practice References) for additional information regarding configuration parameters and procedures that, while not discussed in detail here, must still be configured or performed properly.

Creation of a Network Design

Once access points have been installed and have registered with a controller, WCS can be configured to manage the controllers and a network design can be set up. A network design is a representation within WCS of the physical placement of access points and other context-aware components throughout a facility or group of facilities. A hierarchy consisting of a single campus, the buildings that compose that campus, the floors of each building, and any outdoor areas constitutes a single network design.

In the Schools SRA, the choice of whether to configure the school district or each individual school at the campus layer depends to a large part on the on whether the schools in the district each contain a single building, or multiple buildings. If each school is comprised of one building and one building only, then the campus layer of the network design can be the entire school district. On the campus map, each school would be represented by a single building with one or more floors per building. This might be seen where:

- Schools are of more recent vintage and may have been sized accordingly for larger student populations. School temporary or portable outbuildings are not seen in this type of scenario.
- Areas where student population is relatively low, and there is no need for any secondary outbuilding structures at schools to meet student population demands.

In other cases, schools might be composed of multiple buildings, such as:

- An older school which has been expanded via the use of one or more secondary outbuildings. This might also be the case despite the age of the school if the surrounding communities have experienced explosive population growth.

- Larger schools that were architecturally designed to be small campuses, with multiple buildings, outdoor venues and the potential for large student populations. In some areas, this may be seen in high school settings.

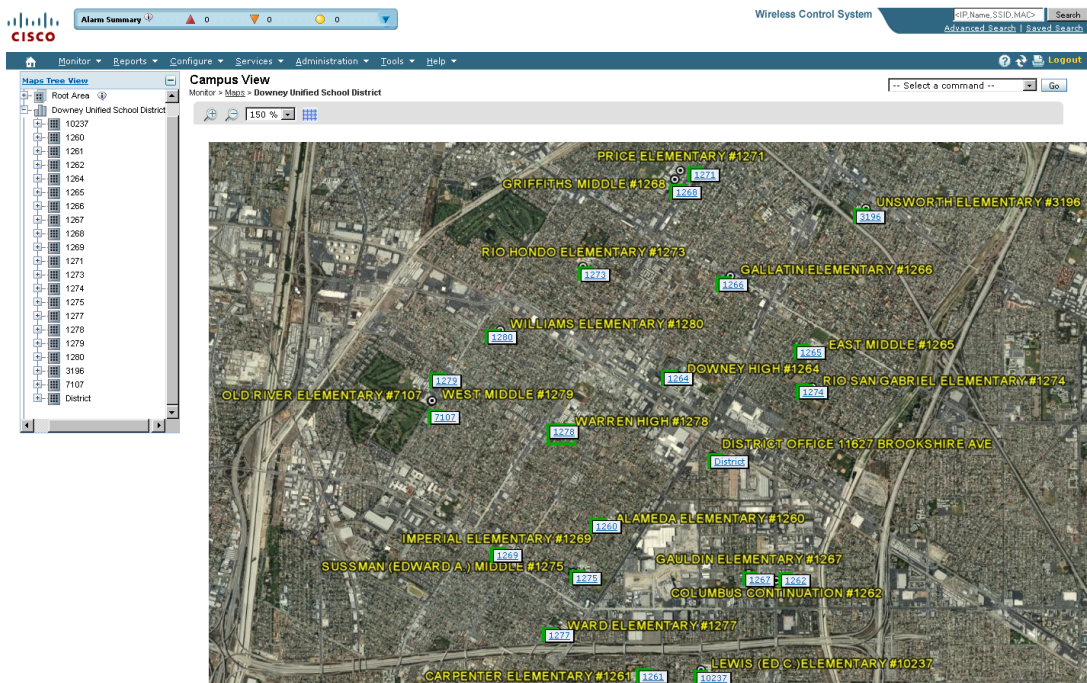

In these scenarios, it makes more sense to define the school as a campus in and of itself if context-services will be deployed in two or more buildings or parts of the school campus.

A step-by-step set of configuration instructions regarding how to configure network designs consisting of campus, building, and floor maps can be found in Chapter 5 of the *Cisco Wireless Control System Configuration Guide*, Release 6.0,

http://www.cisco.com/en/US/docs/wireless/wcs/6.0/configuration/guide/6_0maps.html#wp1203275.

Figure 6-8, Figure 6-9, and Figure 6-10 give an example of what a campus, building, and floor level network design might look like for a school district where all schools are assumed to be comprised of single buildings. In Figure 6-8, we use satellite imagery of the school district area as the backup for the campus map. Clicking on any of the icons takes us to the building map for the school. In this case, we select high school number 1278, which then brings us to Figure 6-9.

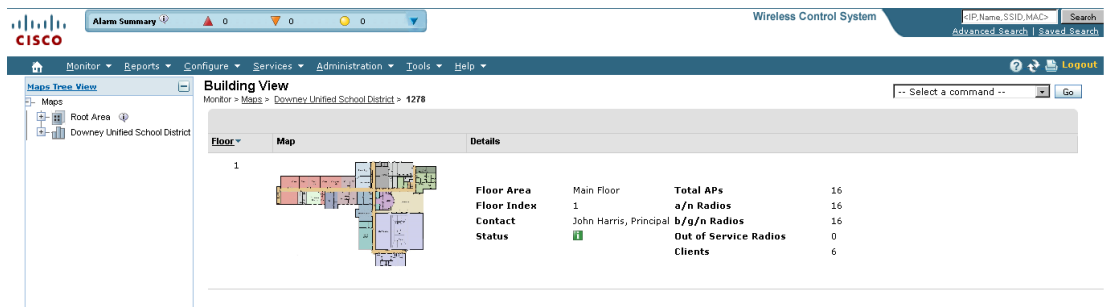

Figure 6-8 Campus Level

The building map shown in Figure 6-9 indicates that this school is composed of a single floor. Clicking directly on the building map takes us to the floor definition shown in Figure 6-10. This is where we would actually see the location of wireless clients, active RFID tags and rogues displayed. Wired devices that are attached to context-aware Ethernet switches are not displayed on floor maps in Release 6.0 of Context-Aware Services.

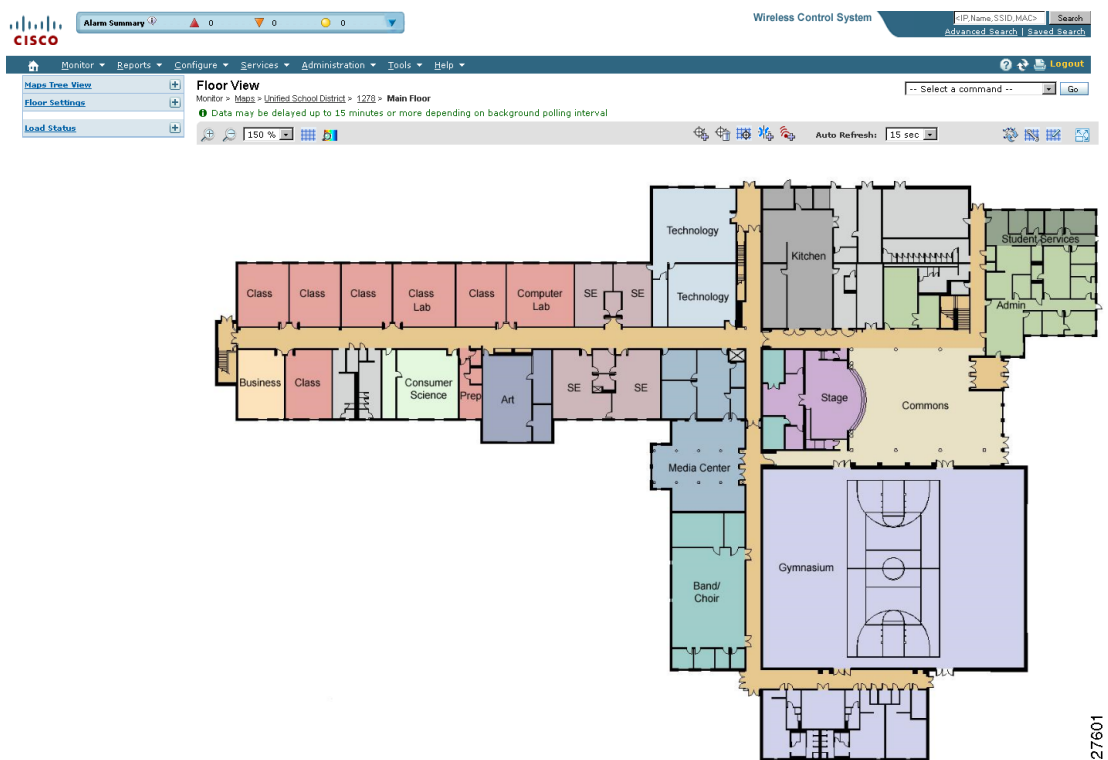

227599

Figure 6-9 Building Level for School #1278

227600

Figure 6-10 Floor Level for School #1278

227601

Note

Network designs are created in WCS, but they are not actually used for device tracking until they are transmitted to the MSE via a process known as network design synchronization. Only after network design synchronization has successfully occurred between WCS and its associated MSE will the network design actually be used by the Context-Aware Engine for Clients and the Context-Aware Engine for Tags. Synchronization of network designs and other components with the MSE is discussed in detail in the chapter entitled “Synchronizing Mobility Services Engines” in the Context-Aware Service Configuration Guide 6.0, http://www.cisco.com/en/US/docs/wireless/mse/3350/6.0/CAS/configuration/guide/msecg_ch3_CAS.html.

WCS Users, User Groups, and Virtual Domains

When installed, WCS provides for a single root user, which will have access to all WCS functions. The password for this root user should be protected and only known by those personnel at the district data center with a true need to know (e.g. those personnel responsible for the installation, maintenance, and detailed administration of WCS). Instead of using the root user password for routine access to WCS, you should create other users and grant them administrative access with privileges assigned as necessary via the use of WCS user groups. Chapter 7 of the *Cisco Wireless Control System Configuration Guide*, Release 6.0 (http://www.cisco.com/en/US/docs/wireless/wcs/6.0/configuration/guide/6_0manag.html) provides comprehensive instructions with regard to the proper procedure for configuring users and group privileges on your WCS server. This chapter also contains a complete listing of the user groups available in WCS as well as the privileges contained in each group.

Common sense should be applied in the assignment of user privileges in the Schools SRA. For example, while only a very small set of key technical personnel should have access to the actual WCS root user ID and password, you may wish to assign the ability to make WCS configuration changes to a somewhat larger audience. This larger group can be assigned as WCS “admin” users or assigned to the “superuser” group. Most school users that are only interested in viewing the information available to them on WCS will not need more than the ability to simply monitor network activity in WCS. For these users, the privileges accorded them by the WCS System Monitoring or Monitor Lite user groups may be all that is required, depending upon the specific WCS monitoring functions you wish to grant those users.

In our validation of the Schools SRA, the custom user-defined group shown in [Figure 6-11](#) was found to be very useful in limiting users to only monitoring context-aware information, as well as some basic WCS alerts and events. Note that the user is not allowed free rein to use any of the monitoring functions provided by WCS. For example, we may wish to allow a librarian in a school to access the context-aware functions listed under the WCS “Maps” function or search for a device by name. But this same school librarian probably has no need to monitor school network security compliance reports, thus we have not enabled access to those reports for this librarian's WCS account. Keep in mind that the requirements of school users in your environment may be different, so it may make sense for you to develop a custom WCS user group that closely fits your needs.

Figure 6-11 Custom User Group to Allow Context-Aware Monitoring

While WCS user groups define the WCS functionality users have been granted, WCS virtual domains allow the network administrator logically partition the WCS management domain and limit management access. In this way, the group of resources that the WCS functionality assigned to a user group may be exercised against is restricted. A WCS virtual domain consists of a set of assigned devices and maps, and restricts a user's scope to only information that is relevant to those devices and maps. Through a assigned virtual domain, users are only able to utilize WCS functionality against a pre-defined subset of the devices managed by WCS.

Users can be assigned one or more virtual domains, however only one assigned virtual domain may be active for a user at WCS login. The user can change the current virtual domain in use by selecting a different permitted virtual domain using the WCS Virtual Domain drop-down menu.

The WCS virtual domain can be used to limit the user's ability to even view certain resources inside WCS that are not contained in their active assigned virtual domain. For example, the Physics department chairman of a high school may have the ability to view the location and other context-aware characteristics of wireless assets due to his WCS user account being assigned to an appropriate user group permitting this level of WCS functionality. But the virtual domain that this department chairman director is assigned may only allow such functionality to be exercised against these assets if they are located within his assigned school. Thus, if the chairman of the physics department for school "A" attempted to use WCS to discover the quantity and location of RFID-tagged equipment in school "B", his assigned virtual domain would not allow access to school B's resources.

Administrative personnel with district-wide responsibilities, on the other hand, would be assigned a virtual domain that includes all resources in the district, including those in each school, and could exercise the functionality assigned to them by their user group against any of these resources. In this way, the virtual domain assignment can be useful in prevent unnecessary inter-school WCS traffic, especially traffic whose nature might be based more upon curiosity rather than actual need.

**Note**

WCS user groups assign what actions a user can take against a resource, whereas WCS virtual domains determine what resources those user group actions can be applied towards.

There are two basic steps necessary to enable the use of virtual domains within WCS:

1. A virtual domain must be created, and the resources that we wish to include assigned to the virtual domain. The process for creating and assigning network resources to the virtual domain is detailed in Chapter 20 Virtual Domains of the WCS Configuration Guide 6.0 (http://www.cisco.com/en/US/docs/wireless/wcs/6.0/configuration/guide/6_0virtual.html#wp104002).
2. The virtual domain must be assigned to the user. The process for assigning a virtual domain to a user is detailed in Chapter 7 Managing WCS User Accounts (http://www.cisco.com/en/US/docs/wireless/wcs/6.0/configuration/guide/6_0manag.html#wp1097733).

**Note**

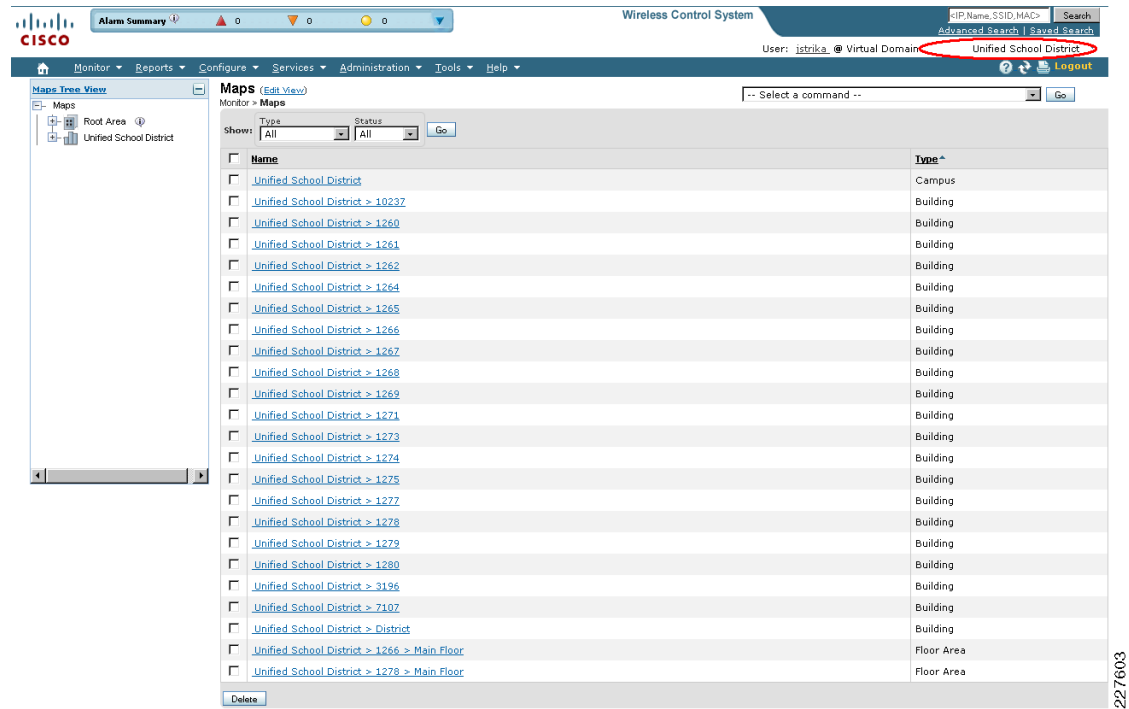

It is important to note that in release 6.0, non-root WCS virtual domain users cannot access WCS functions listed under the Services > Mobility Services main menu heading. This includes wired switch and device location. Refer to Understanding Virtual Domains as a User, WCS Configuration Guide 6.0 (http://www.cisco.com/en/US/docs/wireless/wcs/6.0/configuration/guide/6_0virtual.html#wp1120787) for a complete list of WCS functions that are not available in non-root virtual domains.

In Release 6.0, since wired devices attached to context-aware Ethernet switches are displayed using Services > Mobility Services > Context Aware Service > Wired > Wired Clients, only users that are assigned to the root virtual domain are able to display context-aware information for these devices.

Figure 6-12, Figure 6-13, and Figure 6-14 demonstrate the effectiveness of WCS virtual domains (note that the current virtual domain in use by the logged-in WCS user is highlighted in each figure by the red oval). In Figure 6-12, we can see from the left hand margin that the root virtual domain user can see the entire set of schools comprising the Unified School District, and is capable of applying any of the WCS functionality accorded to them by their WCS user group assignment. This virtual domain setting might

be appropriate, for example, in the case of a person requiring the ability to view and potentially take action upon all resources in the network. An example of a person in a school district that might require such capability could be a school district administrator.

Figure 6-12 Virtual Domain for Entire School District

In contrast, [Figure 6-13](#) and [Figure 6-14](#) each illustrate how the user's view of the school district in WCS can be severely curtailed when a WCS virtual domain is applied. A virtual domain setting such as this might be appropriate for most of the personnel within a school that might only need to work with school resources located in their school only. [Figure 6-13](#) illustrates what a user in High School #1278 would see if they were assigned a WCS virtual domain that limited their resource visibility to only those resources associated with High School #1278.

Figure 6-13 Virtual Domain Limited to High School 1278

In [Figure 6-14](#), we see the results of a WCS virtual domain for a user in Elementary School #1266. Note that a user that is assigned a virtual domain for school 1266 does not have visibility to any resources associated with other schools. All that is visible to the school 1266 user in this case are the buildings and floor maps associated with school 1266.

Figure 6-14 Virtual Domain Limited to Elementary School 1266

Figure 6-15 illustrates the typical result that occurs when a user attempts to view information for resources outside the scope of their assigned virtual domain. In this case, we see the result of a user in school 1266 attempting to access resources in another school, #1278.

Figure 6-15 Virtual Domain Permission Error

Mobility Services NMSP Parameters

WCS 6.0 provides us with several NMSP parameters available that affect various NMSP protocol timing characteristics between the MSE and its session partners. These parameters can be found at **Services > Mobility Services > System > NMSP Parameters**, and apply globally to all NMSP sessions between the selected MSE and any of its WLAN controller or Ethernet switch session partners. Complete configuration information for configuring NMSP session timing parameters, as well as the default values for these parameters, can be found at Configuring Mobility Services Engine Properties section of the *Context-Aware Service Configuration Guide* (http://www.cisco.com/en/US/docs/wireless/mse/3350/6.0/CAS/configuration/guide/msecg_ch4_CAS.html#wp1014368).

When deploying an MSE locally in the school, it is unlikely that these parameters will require changes from the default values, except perhaps in the very largest of schools where there might be several thousand tracked devices, and a large quantity of wireless devices moving about on a regular basis. However, in a centralized deployment, there is more of a chance that network congestion or other factors may cause delays that could cause NMSP session timeouts. While this should be minimized by the appropriate identification and classification of NMSP data flows in the network along with properly defined network QoS, there may be instances where adjustments to NMSP timing is required. In these cases, the NMSP echo interval, neighbor dead interval, and response timeout values can be increased to limit the number of failed echo acknowledgments that may occur, especially in a centralized MSE deployment.

Note

Readers are advised that a tremendous amount of functional validation was performed in association with the content contained in this chapter. However, time constraints limited the degree of performance validation that could be completed for Context-Aware Services across a simulated Metropolitan Area Network (MAN). The deployment of Mobility Services Engines in a centralized fashion across a MAN was not able to be fully validated due to these time constraints. We hope to revisit and validate centralized deployments of context-aware services over a MAN at a future time.

To aid in determining whether echo packets are being dropped, you can use the WCS function **Services > Mobility Services > System > Status > NMSP Connection Status** as shown in [Figure 6-16](#). This WCS menu panel displays all the NMSP session partners for this MSE, along with echo request and response counts. For example, in the figure for the Mobility Services Engine with the hostname MSE1, we see that there are currently two NMSP sessions to two different school WLAN controllers.

Figure 6-16 NMSP Connection Status

We can see in [Figure 6-16](#) that both of the NMSP WLAN controller sessions appear to be functioning properly, as the number of Echo Requests issued is seen to be exactly equal to the number of Echo Responses received. This might not always be the case and small static differences over a long period of time do not necessarily indicate a serious problem. However, sluggish performance combined with a regularly increasing discrepancy in the delta between the number of requests issued and responses received could be indicative of the NMSP session timing out. In a centralized deployment, this may be due to unforeseen levels of congestion or other resource constraint. In this case, raising the response timeout may assist in alleviate the timeouts. Keep in mind, however, that a successful centralized deployment assumes that there is sufficient MAN capacity available to each school and that QoS has been applied appropriately.

[Figure 6-17](#) gives an example of the NMSP Parameter screen that is located at **Services > Mobility Services > System > NMSP Parameters**, which we can use to change the system defaults. In [Figure 6-17](#), the network administrator or network technician has instituted the following changes from the defaults: the echo interval has been raised to 30 seconds, the neighbor dead interval has been raised to 60 seconds, and the response timeout has been raised to 5 seconds.

Figure 6-17 Example of NMSP Parameter Modification

NMSP Parameters		
Echo Interval	30	1 - 120 secs
Neighbor Dead Interval	60	1 - 240 secs
Response Timeout	5	1 - 99999 secs
Retransmit Interval	3	1 - 99999 secs
Maximum Retransmits	5	0 - 99999

Save Cancel

**Note**

Although the NMSP configuration worked well for us in our lab testing, we cannot predict and simulate each and every condition that might occur in a production deployment. Therefore, it is important that you take the time to understand the function of these parameters and especially the fact that they can be adjusted beyond the values illustrated here in order to promote improved NMSP session stability and network performance.

Further information on these NMSP parameters can be found in the Configuring Mobility Services Engine Properties section of the *Context-Aware Service Configuration Guide* (http://www.cisco.com/en/US/docs/wireless/mse/3350/6.0/CAS/configuration/guide/msecg_ch4_CAS.html#wp1014368).

Context-Aware Service Parameters—Tracking

As mentioned earlier, Context-Aware Services can track up to a maximum of 18,000 licensed devices when using the MSE-3350 hardware platform, and up to a maximum of 2,000 licensed devices when using the MSE-3310 platform. The absolute limit on the number of clients or tags that can be tracked is determined by the hardware platform used, the presence of any other applications co-residing on the MSE, and the level of licensing purchased. The WCS tracking parameters configuration panel (located at **Services > Mobility Services > Context Aware Service > Administration > Tracking Parameters**) allows the administrator to pre-determine just how much of the MSE's maximum licensed tracking capacity will be allocated towards the tracking of specific device categories. This is useful in the Schools SRA environment in order to allow the tracking of device categories such as nearby rogue access points and rogue clients, but also limit these categories such that an uncontrolled introduction of rogues is not allowed to consume all of the remaining context-aware tracking capacity on the MSE.

We can use the Context-Aware Service Tracking configuration to:

- Entirely enable or disable the tracking of wired and wireless client stations, asset tags, rogue access points, and rogue clients.

- Set limits on how much MSE tracked device capacity will be allocated to certain device categories. [Figure 6-18](#) provides us with an example of how this can be achieved, where the maximum number of tracked clients and rogue clients/APs are capped at 4,000 devices each. No limit is placed on the number of RFID tags tracked, which in effect means that the maximum number of tags tracked will be allowed to rise until the tag licensing limit is reached (3,000 tags).

Note that any devices that are detected but excluded from tracking due to the enforcement of a tracking limit will be reflected in the “Not Tracked” device count column shown on the right side of the display.

Figure 6-18 Context-Aware Service Tracking Parameters

Tracking Parameters: mse1
 Services > Mobility Services > Context Aware Service > Administration > Tracking Parameters

Tracking Parameters

Network Location Service Elements: Licensed Limit = 12000

Enable	Tracking Parameters	Enable Limiting	Limit Value	Active Value	Not Tracked
<input checked="" type="checkbox"/>	Wired Clients	<input type="checkbox"/>		0	0
<input checked="" type="checkbox"/>	Wireless Clients	<input checked="" type="checkbox"/>	4000	0	0
<input checked="" type="checkbox"/>	Rogue Clients and AccessPoints	<input checked="" type="checkbox"/>	4000	0	0
<input type="checkbox"/>	Exclude Adhoc Rogue APs				

Asset Tracking Elements: Licensed Limit = 3000

Enable	Tracking Parameters	Enable Limiting	Limit Value	Active Value	Not Tracked
<input checked="" type="checkbox"/>	Active RFID Tags	<input type="checkbox"/>		0	0

Note

In Release 6.0, wired client tracking can be enabled or disabled, but imposing a limit on the number of wired clients that are tracked simultaneously is not supported at this time. As a workaround, use switch CLI commands such as the global `nmosp disable` or the interface `nmosp suppress attachment` commands to limit the number of tracked wired clients that are presented to the MSE.

Context-Aware Service Parameters—History

The MSE records and maintains historical location and statistics information for wireless clients, tags, rogue access points, and rogue clients. This information is available for viewing through WCS or via third-party context-aware application clients, and can be very valuable in helping establish patterns of movement for tracked assets and rogues. Historical information can be used for location trending, asset loss investigation, RF capacity management, and facilitation of network problem resolution. Contextual information such as whether an emergency button was depressed or whether an asset tag has moved into close proximity to a chokepoint trigger is also tracked in the history data.

The collection of historical information must be explicitly enabled for each desired category of device (as shown in [Figure 6-19](#)). By default, 30 days of historical data are stored in the MSE.

Figure 6-19 MSE History Parameters**History Parameters**Services > [Mobility Services](#) > Context Aware Service > Administration > **History Parameters****History Parameters**

Archive for days

Prune data starting at hours minutes and also every minutes

Enable History Logging of Location Transitions for

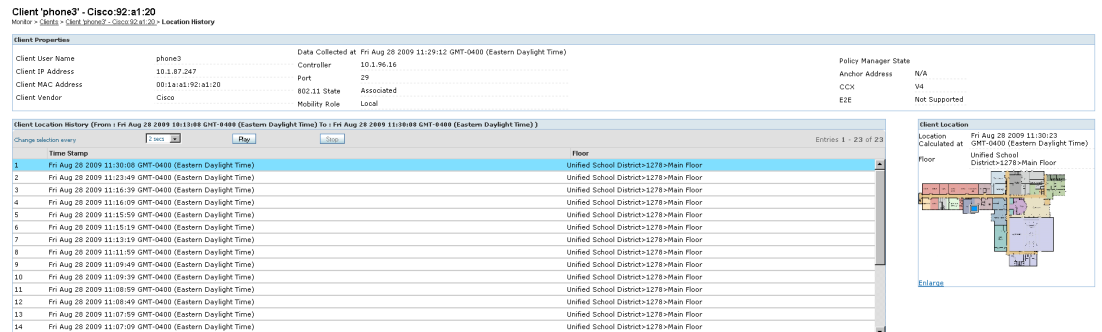

- ☒ Client Stations
- ☒ Asset Tags
- ☐ Rogue Clients and Access Points

227609

There are several variables that can affect how much historical information can be stored by the MSE for the tracked assets in your school or school district. Among these variables are the average number of elements that move, average distance covered every time there is a movement, information transitions, telemetry information from tags, and so on. Depending on these variables as well as the number of items for which you are tracking history information in your school, you may wish to decrease the number of days of historical data to a value below 30 days.

Changes to the default history archive period should be done with careful consideration, since longer history periods typically increase the amount of space consumed by the history database. Users unfamiliar with the way in which Context-Aware Services on the Cisco MSE archives historical information for tracked devices may wish to consult with your Cisco field technical representative or the Cisco Technical Assistance Center

Figure 6-20 illustrates what you can expect to see when recalling the history for a tracked device. Here, we recall the history for a specific WLAN client. As shown in **Figure 6-20**, the focus of the display is the list of past locations recorded for the client. Setting the “change selection time” parameter on the screen and then clicking play displays the various client locations on the small floor map at the right side of the image (this can be enlarged for easier viewing). In this way, you can step back through all of the stored locations for the client within the history database. Obviously, this information could be very useful to school administrators, district and school WLAN engineers, as well as school resource officers and other law enforcement officials that may be looking for information useful in recreating a sequence of events that may have take place in the past.

Figure 6-20 Display of Location History for a WLAN Client in the School

227610

Further information on the procedure to follow when making adjustments to history parameters can be found in the following documents:

- Context Aware Solution Deployment Guide
http://www.cisco.com/en/US/products/ps9742/products_tech_note09186a00809d1529.shtml#rfid

- *Context Aware Service Configuration Guide 6.0*
http://www.cisco.com/en/US/docs/wireless/mse/3350/6.0/CAS/configuration/guide/msecg_ch7_CAS.html#wp1128896

Context Aware Service Parameters—Notifications

Cisco WCS allows you to define certain conditions for tags, WLAN clients, and rogues that cause the MSE to send notifications to application programs that are monitoring specific ports. You can use Cisco WCS to define and enable both conditional notifications and northbound notifications.

Conditional notifications are those notifications that the mobility services engine sends to Cisco WCS and other applications that can receive short, relatively simple messages via SOAP/XML (either HTTP or HTTPS), SMTP, UDP Syslog, or as an SNMP trap. Conditional notifications can be triggered by WLAN clients, tags, or rogue devices. The conditions available include:

- **Missing**—The MSE generates a Missing Asset conditional notification if it has not located the asset for more than a specified number of minutes.
- **In/Out**—The MSE generates an In/Out conditional notification if the asset is found to be inside of, or outside of, a selected area.
- **Distance From Marker**—The MSE generates a Distance From Marker conditional notification if the asset is found to be beyond a specified distance from a designated marker.
- **Battery Level**—The MSE generates a Battery Level conditional notification if the battery level reported by an asset tag is equal to a selected value.
- **Location Change**—The MSE generates a Location Change conditional notification if the asset experiences a change in location.
- **Emergency**—The MSE generates an Emergency conditional notification if a tag button, tamper or detached event is detected.
- **Chokepoint**—The MSE generates a Chokepoint Conditional notification if a tag enters into the proximity of a chokepoint trigger.

Northbound notifications are a special category of notification that is specific to RFID tags only. They define which tag notifications the MSE will send to third-party applications using SOAP/XML.

Northbound notifications can include chokepoint, telemetry, emergency, battery, and tag vendor data. Optionally, the tag's location coordinates can be included within the northbound notifications as well.

An important difference between conditional notifications and northbound notifications is that northbound notifications can contain considerably more information. The information sent in the northbound notification is sent in a pre-defined data format. Details regarding the data format for northbound notifications are available on the Cisco developers support portal at

<http://developer.cisco.com/web/contextaware>.

Note

In Release 6.0, neither conditional nor northbound notifications can be applied to tracked wired devices.

Complete and detailed information regarding how to configure Context-Aware Notifications can be found in the following locations:

- **Configuring Event Notifications** chapter of the Context-Aware Configuration Guide 6.0
http://www.cisco.com/en/US/docs/wireless/mse/3350/6.0/CAS/configuration/guide/msecg_ch6_CAS.html.

- Enabling Notifications and Configuring Notification Parameters section of the Context-Aware Configuration Guide 6.0 (http://www.cisco.com/en/US/docs/wireless/mse/3350/6.0/CAS/configuration/guide/msecg_ch7_CAS.html#wp1129909).
- Context-Aware System Performance section of the Context-Aware Solution Deployment Guide (http://www.cisco.com/en/US/products/ps9742/products_tech_note09186a00809d1529.shtml#casysperf).

Via the menu panel located at **Services > Mobility Services > Context Aware Service > Advanced > Notification Parameters** (Figure 6-21), WCS allows the user to modify several advanced timing parameters pertaining to conditional notifications and northbound notifications. For example, you can limit the rate at which the MSE generates notifications, set a maximum queue size for notifications, and set a retry limit for notifications with in a certain period.

Figure 6-21 Context Aware Advanced Notification Parameters

Advanced

Rate Limit ⓘ	<input type="text" value="0"/>	0 - 9999999 msec
Queue Limit ⓘ	<input type="text" value="18000"/>	1 - 99999
Retry Count ⓘ	<input type="text" value="1"/>	0-60
Refresh Time ⓘ	<input type="text" value="60"/>	0 - 99999 mins
Notifications Dropped ⓘ	<input type="text" value="0"/>	

227/611

Note

Modify advanced notification parameters only when you can reasonably expect the Mobility Services Engine to transmit a large number of notifications or when it is noticed that notifications are being dropped.

- **Rate Limit**—(Pertains to northbound notifications only.) This is the rate in milliseconds at which the MSE generates northbound notifications. A value of 0 (default) means that the Mobility Services Engine generates event notifications as fast as possible. If you are using the northbound notifications system to communicate to a third-party application (such as AeroScout MobileView, for example) in the Schools SRA, it is recommended that you consider how often notifications are expected to be generated and how many total notifications will be requested of the MSE per minute. For example, an exception based notification (such as an emergency notification) is not a normal event and thus it would be extremely unusual to see a great deal of emergency events generated from many schools at the same time. However, a more routine event, such as the chokepoint entry event that would be used in a parent curbside pickup application, could be expected to generate much more traffic during, for example, the hours of 2:00-2:30 PM, when a large number of parents might be expected to pick up children from a suburban school district. In cases such as this where a large number of notifications might be a normal and routine event, it is recommended to increase the rate limit so as to allow the MSE to pace the transmission of notifications (for example, a rate limit value of 200 would slow the rate of notification transmission down to one every 200 msec). The correct notification delay will vary from deployment to deployment depending on the amount of traffic generated.
- **Queue Limit**—Specifies the size of the output notification queue of the MSE. Default queue limit value for the MSE-3350 is 18000 and for the MSE-3310 it is 5,000. The MSE drops any outbound notifications above this limit if the output notification queue size is exceeded. In the School SRA design, if you are using context-aware notifications, it is recommended that you use the Queue Limit parameter in conjunction with the Notifications Dropped counter to avoid any notifications from being dropped. If you notice that the Notifications Dropped counter is greater than zero, you should

consider increasing the Queue Limit parameter to avoid any future increases. Given the relatively large default sizes for this parameter however, it is unlikely that adjustment will be required except in rare cases where very many notifications are generated.

- **Retry Count**—For each matching condition, the retry count specifies the number of times to generate an event notification before the refresh timer expires. The default value is 1. The total number of event notifications transmitted between Refresh Time periods is equal to one plus the value specified for Retry Count. After the value of one plus the Retry Count has been reached, the location appliance skips firing any further northbound notifications for this condition and device for the time period specified by the Refresh Time. Once the Refresh Time has expired, this cycle repeats unless the event has been cleared. Retry count is intended to help ensure (to a limited extent) that notifications reach their intended destination. If notifications are not indicated as being dropped by the Notifications Dropped counter, but are not reliably reaching their destination application, you may wish to increase the number of notifications sent between Refresh Time periods by raising the Retry Count judiciously.

**Note**

The Mobility Service Engine transmits notifications using a “Fire and Forget” technique. Notifications are not retained in any database within the MSE after they are transmitted.

- **Refresh Time**—The wait time in minutes that must pass before an event notification is resent. The default is 60 minutes. Refresh Time and Retry Count are used cooperatively to help limit the number of notifications repeatedly generated for events that have not been cleared. Retry Count limits the number of notifications that are sent by the MSE, while Refresh Time imposes a “waiting period” during which time no further notifications are sent for this event condition and device. If you are noticing that repeated notifications are being generated for the same event, it may be due to the condition not clearing within the refresh time interval. In this case, you may wish to investigate why the triggered condition does not clear and possibly extend the refresh time.
- **Notifications Dropped**—The number of event notifications dropped from the queue since startup. The Notifications Dropped counter should be used in conjunction with the Queue Limit parameter to reduce the number of total dropped notifications.

WLAN Controller and Ethernet Switch Definition and Synchronization

To allow for proper tracking of the devices that may be registered or attached to them, WLAN controllers and context-aware Ethernet switches must be defined to WCS and then synchronized with the Mobility Services Engine.

Detailed information regarding how to add WLAN controller definitions to WCS using the WCS Configure > Controllers menu panel can be found in the section entitled Adding Controllers in the WCS Configuration Guide 6.0

(http://www.cisco.com/en/US/docs/wireless/wcs/6.0/configuration/guide/6_0ctrlcfg.html#wp1041451)

.

Detailed information regarding how to add Ethernet switch definitions to WCS using the WCS Configure > Add Ethernet Switches menu panel can be found in the WCS Configuration Guide 6.0

(http://www.cisco.com/en/US/docs/wireless/wcs/6.0/configuration/guide/6_0ctrlcfg.html#wp1089752)

.

Detailed information regarding how to synchronize the MSE with WLAN controllers and context-aware Ethernet switches using the WCS Services > Mobility Services > Synchronize WCS and MSE(s) menu panel can be found in the Synchronizing Mobility Services Engines chapter of the Context-Aware

Service Configuration Guide 6.0

(http://www.cisco.com/en/US/docs/wireless/mse/3350/6.0/CAS/configuration/guide/msecg_ch3_CAS.html#wp998995).

**Note**

Always ensure that the MSE is synchronized with the primary WLAN controllers it is providing Context-Aware Services for, as well as any backup WLAN controllers in the Schools SRA design. If the MSE is not kept in synchronization with your backup WLAN controllers, Context-Aware Services may not function properly or may not be available at all for WLAN clients and RFID tags in the event of a primary WLAN controller failure.

Wireless Client Context-Aware Considerations

The ability to track WLAN client location using Cisco Context-Aware Services can be useful in a school to locate WLAN clients that are part of our school network (such as authorized 7921G and 7925 VoWLAN phones, laptops, wireless desktops, etc.). Generally speaking, provided that a 802.11 wireless client device has its 802.11 wireless network interface adapter powered on and is sending periodic transmissions (probe requests), these WLAN client devices can be located by Context-Aware Services. Since devices such as portable VoWLAN phones are very often powered on for the entire day and carried on the belt, purse, or pocket of the user, these devices become useful in helping locate not only the device itself but the user to which the device is assigned. As the device becomes larger in size and heavier in weight, we find that the chances of the device being with the assigned user all the time diminishes and thus its usefulness as a way to determine the location of the user diminishes as well.

Tracking WLAN client devices by their wireless network interface adapter works well if the goal is to track the location of the device when it is in operation and use this information to enhance the operation of the device on the network, or its interaction with an application. For example, using WLAN client tracking in the school environment to perform one or more of the following represents a prime example of how this functionality can be put to use in the school environment:

- Determining where wireless users and their portable devices may congregate, allowing for the placement of access points to be further optimized to enhance overall coverage and performance.
- Investigate where a missing device is currently located within the school or district campus. A good example might be when equipment is “borrowed” from one classroom to another (or even from one school to another) without permission.
- Determining the location of users that are known to be visiting guests, and helping ensure that they do not stray into areas that have been explained to be off-limits to them.
- Using the location history of a wireless device to establish a pattern of usage and location in order to clarify past actions, such as any past actions that might relate to safety and security concerns.
- Use the location of wireless LAN clients as a parameter for network troubleshooting and security audits.
- Use the location of wireless printers (or other output devices) as input to an application designed to determine which device is available and most convenient for a particular wireless user depending on the user's location.

Figure 6-22 illustrates how Cisco Context-Aware Services can be used with Cisco WCS to display the current location of school faculty members equipped with Cisco 7925G IP phones, laptops, and PDAs in a sample lab school environment. Note that we have chosen to assign and display the user name associated with each device, rather than the device MAC address. Clicking on any of the blue WLAN client icons shown in Figure 6-22 displays a plethora of information about the client device, including its client properties, association history, connection troubleshooting information, as well as its event history.

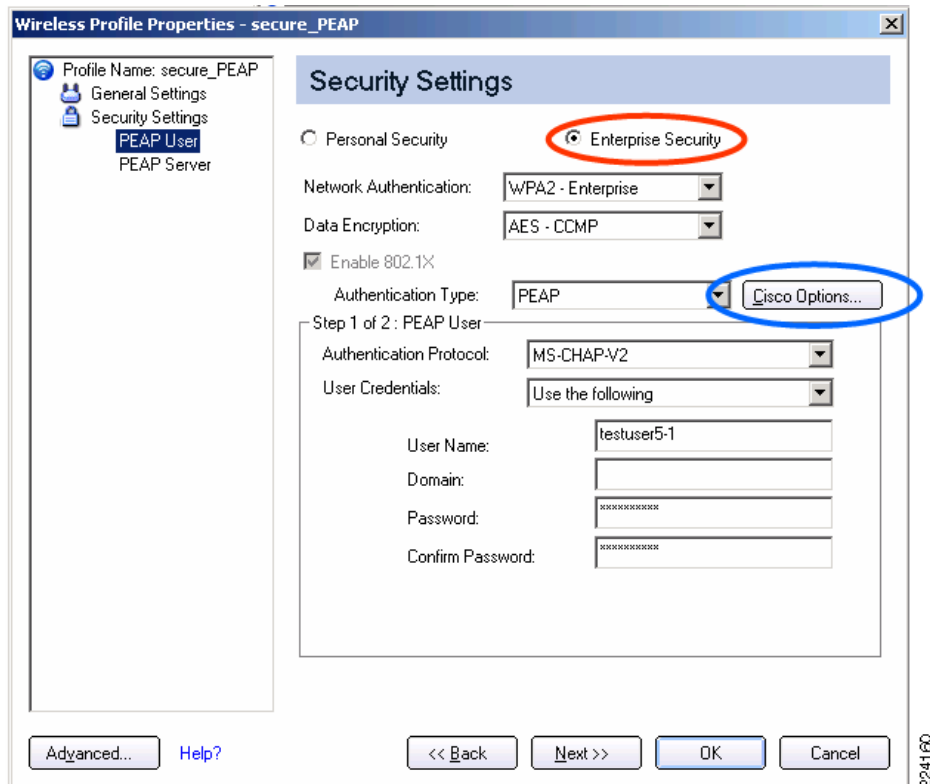

[illegible]

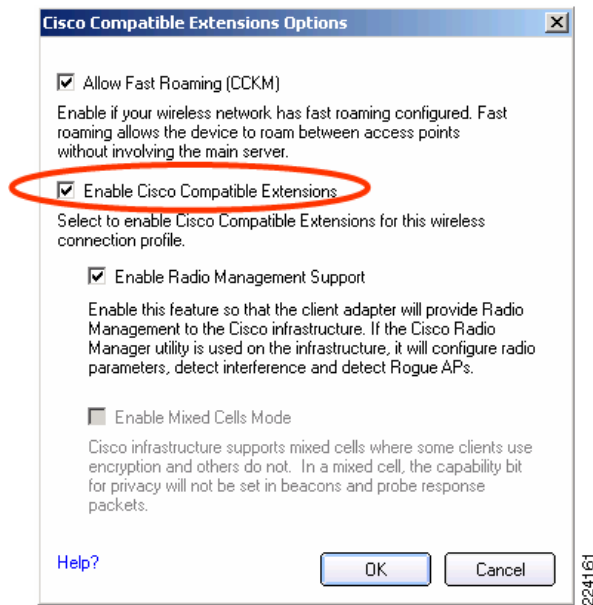

5. Readers interested in the technical details concerning compatibility with the Cisco Compatible Extensions for WLAN Clients specification v2 are referred to the section entitled Tracking Clients, Assets and Rogue Devices in Wi-Fi Location Based Services Design Guide 4.1,
<http://www.cisco.com/en/US/docs/solutions/Enterprise/Mobility/wifich3.html#wp1049277>

Intel® Wi-Fi Clients and ProSet Client Supplicant Context-Aware Considerations

When using clients equipped with the Intel® Wireless WiFi Link 4965AGN, Intel® PRO/Wireless 3945ABG Network Connection, or the Intel® PRO/Wireless 2915ABG Network Connection adapter, it is important to note that the default “Personal Security” settings of the Intel® ProSet Configuration Utility does not include compatibility with the Cisco Compatible Extensions specification. In order to enable compatibility with the Cisco Compatible Extensions specification, the Intel ProSet client supplicant must be used to reconfigure the client for “Enterprise Security” and to enable Cisco Compatible Extensions using the “Cisco Options” (Figure 6-23).

Figure 6-23 Enabling Cisco Compatible Extensions on Intel® ProSet Clients

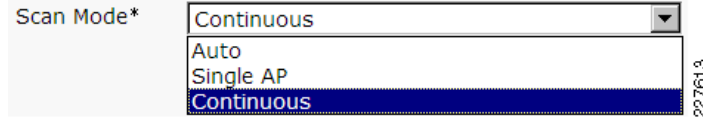

Cisco 7921 and 7925G Context-Aware Considerations

7921G and 7925G Unified IP Wireless Phone users should note that phones that are idle and not currently participating in an active call may not transmit 802.11 Probe Requests with sufficient frequency to ensure that changes in the actual location of the phone user are promptly reflected in the calculated location coordinates provided to the context-aware services software in the MSE. In some cases this can be of concern, especially if the 7921G or 7925G user remains within the primary coverage area of the same access point for long periods of time. In cases where an access point might have a large coverage footprint, a roaming event may not occur very often despite a significant change in user location.

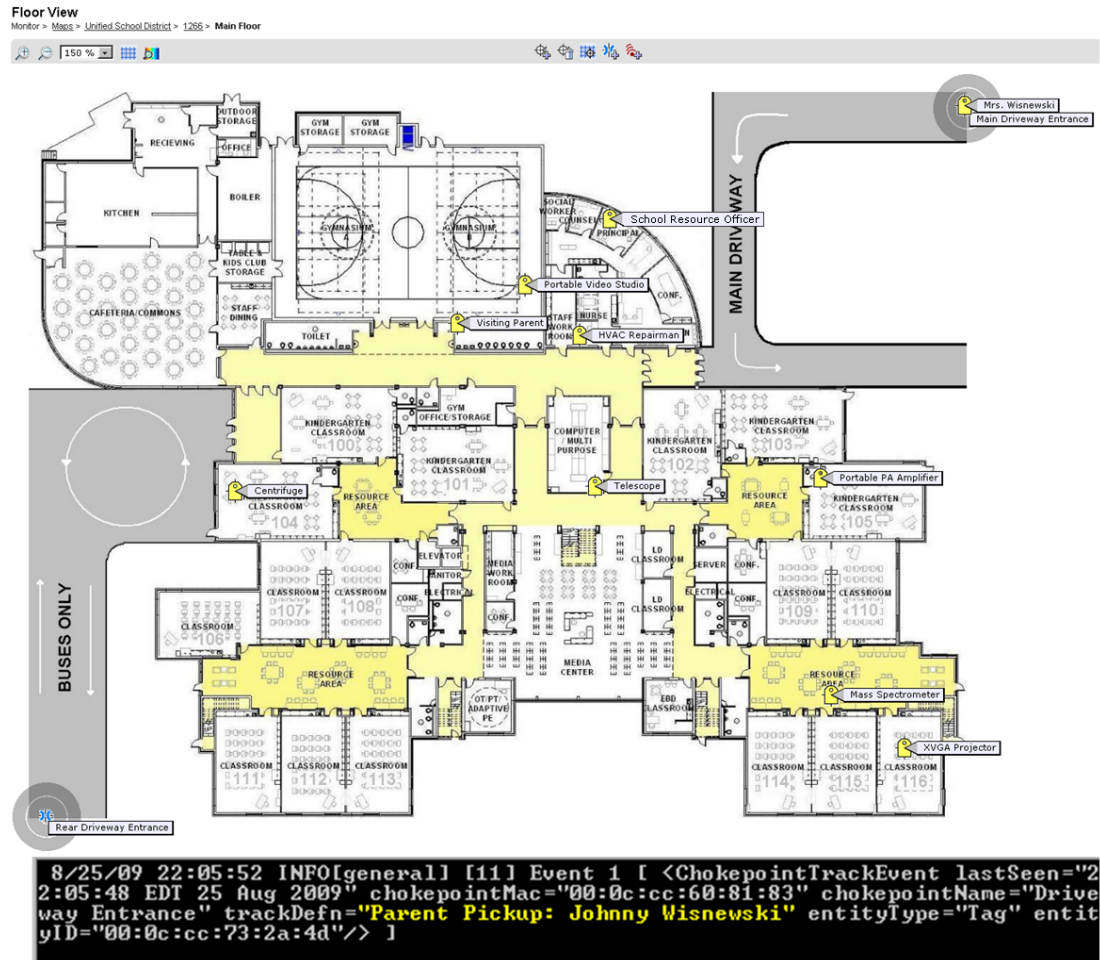

If you experience situations where the location fidelity of a 7921G or 7925G Unified IP Wireless Phone appears to be much better for those users actively participating on a call versus those that are on hook and idle, you may wish to consider changing the scan mode parameter associated with the 7921G or 7925G device in the Cisco Unified Communications Manager. In some cases, improved location fidelity can be achieved by enabling the “continuous” scan mode on the Device=>Phone configuration page of Cisco Unified Communications Manager Administration (shown in [Figure 6-24](#)). Note that scan mode options listed are “auto”, “continuous”, and “single AP”, where auto is the default. “Continuous” scan mode causes the wireless IP phone to issue a probe request approximately every two seconds, whereas “auto” scan mode causes the device to issue probe requests primarily only when the device is engaged on an active call, when roaming, or when preparing to roam. “Single AP” is used in installations where the wireless IP phone is only used in the vicinity of a single access point at all times, as probe requests are issued only when the wireless IP phone is first powered on. “Single AP” mode is not applicable and should not be used in the Schools SRA design.

Figure 6-24 Scan Mode Option in Cisco Unified Communications Manager**Note**

It is recommended that continuous scan mode be used only in situations where the anomaly described here is actually witnessed. This is because a trade-off associated with any increase in the frequency of probe requests transmitted is the potential for reduced 7921G or 7925G battery life. If you do not notice the anomaly described in this section, it is recommended that you leave the CUCM scan mode setting at the “auto” default.

RFID Asset Tag Context-Aware Considerations

Radio Frequency Identification (RFID) has many potential safety and security applications in the education arena. Already used in various enterprise sectors, from the logistics depot that tracks pallets of goods throughout the warehouse, to the motorist with the “EZ-Pass” or “CruiseCard” that no longer needs to search for change at the toll booth, schools can now embrace RFID technology to address a wide realm of challenges.

Figure 6-25 Floor Map Showing Various Uses for RFID Tags and Cisco Context-Aware Services

The illustration in [Figure 6-25](#) provides us with a visual representation of just some of the ways RFID can be used in the Schools SRA in conjunction with Context-Aware Services:

- High value assets (such as projectors, microscopes, telescopes, audio/video equipment, etc.) can be kept safe and secure, since the application of RFID tags to these assets provides school administrators and school resource officers with the ability to locate the assets quickly and efficiently. [Figure 6-25](#) illustrates how the present location of assets equipped in this fashion can be quickly ascertained by a quick check of the school floor map. Here we can see the last known location of a lab centrifuge, microscope, telescope, portable PA system, X VGA projector, and even a mass spectrometer. For buildings containing more than a single floor, database search techniques can be used to search for the desired asset by name or attached RFID tag MAC address.

Figure 6-26 ID Badge with Embedded Active RFID

- Faculty and administrators can wear specially manufactured badges (see [Figure 6-26](#)) that combine a traditional identification card with active RFID technology, allowing them to be located quickly in the event of an emergency. These same devices can also transmit special notifications using a push button sequence, which can be interpreted in various ways by Context-Aware Services, including as a signal that an emergency event is in progress. [Figure 6-25](#) illustrates how a person can be located if they are carrying an RFID-enabled ID card, as seen in the displayed location of the school's resource officer (a law enforcement official), whose location is currently indicated as being inside of the school principal's office. Being able to physically locate the school resource officer using a tool such as this could help in saving precious seconds in the event of a school emergency.
- The whereabouts of school visitors (such as maintenance or repair contractors) can be monitored and alerts triggered to school resource officers and others if these visitors stray into areas that they have no authorization to be in. For example, in [Figure 6-25](#), we see that in our school we have an HVAC repair contractor as well as a visiting parent. In addition to making us aware as to the presence of these visitors, our system can alert us if these personnel access areas that we do not want them to by comparing their current locations to location boundaries we have defined as notification rules. Third-party applications that can access context-aware information from the MSE may perform more advanced tasks as well.
- RFID tag technology can be combined with chokepoint triggers (Exciters) to enable the use of proximity applications. In this fashion, chokepoint triggers can serve many purposes, including stimulating asset tags affixed to assets that might be in the process of being removed from the school building without authorization. This makes it possible to notify school officials or resource officers of such action, so as to act quickly and determine whether such movement is legitimate.

Figure 6-27 *Curbside Congestion at a Typical Urban School*

- The concept of a curbside student receiving application in a suburban school system that notifies student hallway monitors and school faculty assistants when a parent has entered school property, ready to pick up their child at the end of the school day. By issuing the parent an RFID tag that is serialized and known to the context-aware system, safety, security, and efficiency is increased. School personnel are aware that the parent's vehicle has entered school property and is waiting in the queue for their child. Children can be retrieved from waiting areas and classrooms in an efficient manner, and presented to parents that are in queue at the school front entrance. This reduces school curbside congestion (see [Figure 6-27](#)), gets parents and students in and out of the school area quickly, and reduces the amount of pollutants emitted by idling vehicles waiting in line for curbside pickup and drop off.

An RFID tag whose MAC address has been recorded and registered with Context-Aware Services as to being issued to a particular parent and vehicle is shown in [Figure 6-25](#). In [Figure 6-25](#), we see that the arrival of a young student's mother ("Mrs. Wisnewski") is signified by the appearance of an RFID tag assigned this label at the location of the chokepoint trigger installed at the school driveway entrance. Even more importantly, the lower portion of [Figure 6-25](#) provides a conceptual illustration of how Cisco Context-Aware Services can generate a SOAP/XML notification to a receiving application ("Parent Pickup: Johnny Wisnewski"). The receiving application then could be used to trigger visual and audible notification in the school that this child's parent has arrived and that the child should be brought forward and queued for release. As each parent vehicle in a long stream of cars enters the school driveway and takes its place in the queue, school personnel are made aware that the parent is only a few hundred yards away and will soon be at the curbside front door pickup area to pickup their child. This system can help manage this process and drastically increase the ability of limited school resources to dispatch those children to those parents that prefer to drop off and pick up their children each day.

In addition to simply displaying the location of assets, Cisco Context-Aware Services makes other contextual characteristics of the asset and its environment available to applications accessing the MSE via its SOAP/XML API. For instance, if the asset tags used contain on-board temperature sensors, we can also read the current temperature surrounding the asset tag via the MSE. This can be seen in [Figure 6-28](#), where we see from WCS that the ambient temperature surrounding our HVAC repairman is 20 degrees Celsius or a comfortable 68 degree Fahrenheit. Looks like our school air conditioning system is doing its job from what this tag sensor tells us. It is important to note that while WCS is used to view this information in [Figure 6-28](#), any authorized context-aware application that is written to use the MSE SOAP/XML API could have accessed this data as well.

Simply put, RFID technology and Cisco Context Aware Services can help schools improve their overall safety, security, and efficiency.

Cisco Context-Aware Software is designed to function with active RFID asset tags from vendors compliant with the Cisco Compatible Extensions for Wi-Fi Tags specification. A list of current Cisco Compatible Extensions for Wi-Fi Tags compliant vendors can be found at http://www.cisco.com/web/partners/pr46/pr147/ccx_wifi_tags.html. Although all vendor RFID tags compliant with the Cisco Compatible Extensions for Wi-Fi Tags specification share a great deal of functionality in common, the parameter names and means used to configure each brand of tags can differ from vendor to vendor, therefore no set prescribed configuration parameter list would apply to all. That being said, there are several general configuration functions that tag vendors share and although the exact parameter names may differ, it is important that you understand them and use this knowledge accordingly when configuring the particular tags of choice for your installation. More information regarding the configuration procedure for AeroScout tags can be found in the section entitled RFID Tag and WLC Configuration/Tuning in the Cisco MSE Context-Aware Deployment Guide (http://www.cisco.com/en/US/products/ps9742/products_tech_note09186a00809d1529.shtml#rfid-wlc)⁶.

- **RF Channel Configuration**—It is recommended that tags be configured for the standard set of 2.4 Ghz non-overlapping channels, which is typically channels 1, 6, and 11 (this may vary depending on your international regulatory domain).
- **Stationary Transmission Interval**—This is the time between periodic tag transmissions that are normally generated when the tag is stationary and not in motion. It is recommended that this be configured for values between 3 and 5 minutes.

6. Additional information can also be found in the *Wi-Fi Location-Based Services Design Guide 4.1* section entitled Configuring Asset Tags, located at <http://www.cisco.com/en/US/docs/solutions/Enterprise/Mobility/wifich6.html#wp1077248>.

- **Motion Transmission Interval**—(Applies only to tags with motion sensors.) This is the time between periodic tag transmissions generated when the tag and asset is in motion. A recommended initial value is 15 seconds.
- **Number of Tag Message Repetitions**—Some popular RFID tags default to transmitting a single transmission on all defined channels. Tag parameters that control the number of tag message repetitions specify the number of times each transmitted message is repeated, per channel. It is generally recommended that this parameter be set to a value of three. Doing this helps protect against lost tag transmissions due to congestion or interference, which is a primary cause of poor tag location accuracy.
- **Message Repetitions Interval**—The delay between subsequent message repetitions on the same channel. This is often defaulted to 512msec, although in lab testing we have seen some evidence of improved location accuracy when a message repetition interval of 256 msec is used with the default controller value of 2 seconds for NMSP notification interval. This parameter is discussed in more detail the section entitled RFID Tag and WLC Configuration/Tuning of the Cisco MSE Context-Aware Deployment Guide (http://www.cisco.com/en/US/products/ps9742/products_tech_note09186a00809d1529.shtml#rfid-wlc).

This chapter does not detail the steps involved with procedures such as calibration of the Context-Aware Engine for Tags and other deployment procedures. For information on these and other procedures that should be understood prior to deployment, refer to the MSE Context Aware Service Deployment Guide (http://www.cisco.com/en/US/products/ps9742/products_tech_note09186a00809d1529.shtml). In addition, the AeroScout Context-Aware Engine for Tags for the Cisco MSE Users Guide, version 3.2, available from your AeroScout representative or <https://support.aeroscout.com>, is highly recommended.

RFID Tag Chokepoint Trigger Considerations

Chokepoint triggers are proximity communication devices that trigger RFID asset tags to alter their behavior when the tag enters into close range (otherwise known as the stimulation zone) of the chokepoint trigger. This behavioral modification may, for example, cause the RFID tag to immediately transmit its unique identifier (MAC address) or cause the tag to change its internal configuration, depending on how the tag is programmed. A very popular use of the chokepoint trigger is to stimulate the asset tag such that it provides indication to the MSE that the tag has entered or exited a given area, known as a chokepoint. Chokepoints are entry or exit points that provide passage between connected regions. Common chokepoints are entrances and exits such as doorways, hallways, and stairwells.

Note

An Exciter is a registered trademark of AeroScout Ltd., and represent a popular example of a chokepoint trigger.

In schools, chokepoint triggers are useful in causing RFID tags to react quickly when assets are moved past certain points in the school. This could be a microscope with an affixed RFID tag moving past a chokepoint trigger located near a school exit, a faculty member with an RFID badge walking into the school through the front entrance at 7:00 AM, or it could be a parent in the family automobile that has a RFID tag on the front visor coming past a chokepoint trigger located at the entrance of the school property. In all these cases, the chokepoint trigger causes the tag to change its behavior, most likely to immediately transmit its MAC address (as well as the MAC address of the chokepoint trigger that stimulated it) to the MSE via one or more access points that can receive the tag's transmissions. The net result is to cause the MSE to indicate that the current location of the asset and its asset tag is within a known, pre-determined proximity of the chokepoint trigger.

In order to use chokepoint triggers with Cisco Context-Aware Services, they must be properly configured using the appropriate vendor-supplied software utility, defined to WCS, placed on floor maps, and synchronized as part of an updated network design to the MSE. After all of this is complete, the MSE is able to recognize the transmissions generated by asset tags that have been stimulated by specific chokepoint trigger MAC addresses. Based on this information, the MSE can attempt to localize the tag to the proximity of the chokepoint trigger. Applications such as WCS (or third party context-aware applications) may then display the asset tag's location at the chokepoint icon associated with the chokepoint trigger's MAC address.

Various chokepoint trigger specific parameters such as transmission range, IP address, transmission interval, transmission repetitions, and so on are set using vendor-specific utilities. Note that each vendor maintains their set of software tools necessary for configuration of their chokepoint triggers. These software configuration tools are not interoperable between vendors (for example, AeroScout software configuration tools cannot be used to configure WhereNet chokepoint triggers or vice-versa).

The individual configuration of each vendor's chokepoint trigger is beyond the scope of this chapter. Complete and detailed configuration information relating to the specific configuration of each vendor's chokepoint trigger can be found in the appropriate vendor's documentation, which can be obtained from your tag vendor representative.

Rogue Device Context-Aware Considerations

The use of context-aware services for locating clients and RFID tags that we have defined and authorized in the school environment is often what first comes to mind for many of us when we consider this solution. However, another equally important and useful function of context aware services is the ability to detect the location associated with those wireless clients and access points that we have not authorized to operate within our domain. In other words, context-aware services in our schools can help us in locating rogue access points or rogue clients that may have been installed within our school by students, contractors, visitors, vendors, or even faculty or administration members without authorization. Even if an unauthorized access point is innocently installed by a school user that is otherwise authorized to use the school network, the unauthorized and potentially insecure portal provided by such an access point can unnecessarily expose our secure school network to outside intruders.

The Cisco Wireless Control System can use the location capabilities provided by the Cisco Mobility Services Engine and the Cisco Context-Aware Engine for Clients to define the location of unauthorized access points and the wireless clients that may be using these access points, as shown in [Figure 6-29](#). In the figure, we can see icons for both rogue access points as well as rogue clients displayed over their predicted positions on a floor map of an elementary school located within our school district. This capability is very useful both to the local school administrator, as well as the district network administrator and their technical teams. It allows them to determine the location of wireless equipment that may have been brought into the school and used in an attempt to gain unauthorized access to school or district computing resources. In [Figure 6-29](#), the round icon with the “skull and crossbones” logo represents the rogue access point and the rectangular icon with the same logo represents a rogue client that is associated to this rogue access point.

Figure 6-29 Using Context-Aware Services to Perform Location of Rogue Access Points and Clients

Note

In comparison to WLAN clients and RFID tags, it is normal to experience a reduced accuracy when localizing rogue access points and rogue clients. The very nature of “rogue” devices establishes that these devices are not under the control of school administration. Therefore, the configuration of such these rogue devices may not facilitate optimal context-aware location accuracy (for example, they may not be Cisco Compatible Extensions devices, etc.).

As shown in [Figure 6-30](#), clicking on either the rogue access point icon or the rogue client icon reveals additional information and capabilities that can help in further identifying (and even isolating) these devices. This includes the ability to perform switch port tracing with the latest versions of WCS, which allows tracing of rogue access points that have been connected to the switch infrastructure (for more information on switch port tracing, refer to the WCS Configuration Guide 6.0, (http://www.cisco.com/en/US/docs/wireless/wcs/6.0/configuration/guide/6_0_ctrlcfg.html#wp1089752)).

The collection of rogue AP and rogue client information is enabled by default on WLAN controllers. In order to enable the tracking of rogue access points and rogue clients by the context-aware service, it is important to ensure that the collection of rogue information has also been enabled for context-aware services on the MSE. Refer back to [Figure 6-18](#) in this chapter and ensure that the “Rogue Client and Access Points” tracking parameter check box has been enabled under **Mobility Services > Context-Aware Services > Administration > Tracking Parameters**.

**Note**

Be advised that depending on the environment in which your school is located, as well as the number of rogue devices present, the number of rogue devices detected can rise very quickly. Since the size of the rogue device population is typically not under the direct control of school IT staff or local school administration, it is highly advisable that you enable limiting for rogue clients and access points and set a limiting value. This is so that any unforeseen increase in the number of rogue devices detected does not consume all the remaining tracked device capacity on the MSE, thereby depriving the MSE of capacity that might be of more significance to school administration and faculty. This is especially important if the MSE is used to service more than just one school in your district.

In addition to enabling the collection of rogue access point and rogue client information by the context-aware services on the MSE, you must also enable the display rogue device location when displaying floor maps using WCS. This is accomplished via the WCS “Floor Settings” submenu that is displayed on every WCS floor map, as shown in [Figure 6-31](#). Information on how to use the Floor Settings sub-menu for all the categories of device shown here can be found in Chapter Five of the WCS Configuration Guide 6.0,
http://www.cisco.com/en/US/docs/wireless/wcs/6.0/configuration/guide/6_0maps.html#wp1210969.

Figure 6-31 WCS Floor Settings Sub-Menu

Context-Aware Considerations for Wired Device Tracking

As described previously in this chapter, beginning with release 6.0 Cisco Context-Aware Services provides the capability to determine the civic location and emergency line identifiers of devices connected to Cisco Catalyst switches, such as the 2960G, 3560E, 3750E, 3750G, 4500, and 4900 series. As participants in context-aware services, switches are configured with and provide the relevant contextual information for all the IP endpoints attached to them. These endpoints may include IP phones, PCs, host servers, access points, etc. The NMSP protocol is used between the switches and MSE to deliver this contextual information to the MSE. Location information may include the physical location address (also known as the civic address) as well as other information about endpoints such as the IP address, MAC address, port, VLAN, and username. If the end device makes use of the Cisco Discovery Protocol or Link Layer Discovery Protocol (LLDP), additional information, such as the version number and serial number, can also be sent to the MSE.

Note

The use of Context-Aware Services for wired device location is entirely optional. In the School SRA, Context-Aware Services may be deployed for wireless devices, wired devices, or for both.

The district office, large school, and small school design of the Schools SRA provides that in the event of a failure of a switch line card in a 4500 series context-aware Catalyst switch, or a stack member in the 3750 switch stack, NMSP sessions recover from the failure without intervention from the user. For the Schools SRA design, NMSP session recovery time from isolated switch stack member or line card failure was seen to occur in the lab very quickly, and in most cases the recovery time was almost unnoticeable from the perspective of the Mobility Services Engine. Careful examination of the NMSP session status during simulated failures indicated that sessions remained up, intact, and passing NMSP data while stack member or line card hand-off occurred.

While still a relatively new context-aware capability, the inclusion of wired device tracking provides new visibility into the location of wired IP endpoints in your school network. For example, some of the ways that this new exciting capability can be used in the Schools SRA design include:

- Determining the whereabouts of missing IP phones, PCs, and peripheral devices such as printers and network scanners that have disconnected and moved from their originally installed locations to other locations within a school (or moved to another school). Once reconnected to the network, the MSE would be updated with the wired device's new attachment information and any location and/or ELIN information defined for that switch port.
- Keeping track of the location of host computers located in the district data center or in any school. The wired location capabilities contained in release 6.0 of Context-Aware Services make it possible to specify the location of a device down to the room, cubicle, seat, or even rack/slot location (see [Figure 6-32](#)). This can be important in verifying that equipment to be de-commissioned is actually removed from service and sanitized of all student information.

In contrast to the manner in which searches for wireless clients and tags is handled via the **WCS Monitor > Maps**, in Release 6.0 of Context-Aware Services, all wired client searches are handled via the **Services > Mobility Services > Context Aware Services > Wired > Wired Clients** menu panel. Searches using the wired client WCS menu panel are specific to the particular MSE that you have selected.

Hardware and Software Requirements for Wired Device Tracking

As mentioned previously, at the current time wired device tracking is only performed on Catalyst switch hardware such as the 2960G, 3560E, 3750E, 3750G, 4500, and 4900 series. The images used for testing of wired device tracking during the production of this chapter included:

- cat4500e-entservicesk9-mz.122-53.SG.bin
- c3750-ipservicesk9-tar.122-50.SE3.tar

- c3750e-universalk9-tar.122-50.SE3.tar
- c2960-lanbasek9-tar.122-50.SE3.tar

**Note**

Readers should note that cryptography-enabled (k9) switch images are required in order to enable wired device tracking in Catalyst switches.

- You should be aware that including wired device tracking in your design will require additional tracked device licenses on the MSE over and above that required for wireless device tracking alone. This is because wired tracked devices are included in the maximum number of simultaneous devices that can be licensed for tracking by an MSE. For example, a school that would otherwise possess a maximum licensed tracked device requirement of 500 for wireless LAN clients, RFID tags, and rogues might require 750 or more when wired device tracking is considered, depending on the number of switches deployed and whether wired device tracking is enabled for all of them. Be sure to plan appropriately for the number of wired devices that you intend to track when purchasing MSE client tracking licenses for the Cisco Context-Aware Engine for Clients.

In addition to planning appropriately for an increase in MSE tracked device licensing due to the use of wired device tracking, keep in mind that although a single MSE can technically support up to 500 NMSP sessions, scalability testing limits have only allowed Cisco to test up to 100 simulated NMSP connections to a single MSE at this time. Each context-aware switch that is enabled for wired device tracking in your network establishes one NMSP session to the MSE and counts against this limit. Therefore, when enabling many switches for context-aware wired device tracking, it is recommended that you plan for the total number of MSEs that may be required to support the total number of NMSP sessions in your network.

Enabling Context-Aware Wired Device Tracking

In order to track wired devices on Catalyst switch ports, each switch whose devices we wish to track must be configured to enable NMSP and other important parameters, and to contain the appropriate civic address and ELIN location information. In addition, WCS must be configured to be aware of the context-aware switches in the network and to be able to communicate with them. WCS is also used to transmit information about the switches to the Mobility Services Engine via the synchronization process.

A complete, step by step guide to configuring Catalyst switches and WCS for wired device tracking can be found in the Context Aware Service Configuration Guide 6.0

http://www.cisco.com/en/US/docs/wireless/mse/3350/6.0/CAS/configuration/guide/msecg_ch7_CAS.html#wp1224011.

In addition, the following chapters and documents provide valuable and detailed background information concerning the wired device tracking capability of Catalyst switches:

- Configuring LLDP, LLDP-MED, and Wired Location Service in the Catalyst 3750 Switch Software Configuration Guide, 12.2(50)SE
http://www.cisco.com/en/US/docs/switches/lan/catalyst3750/software/release/12.2_50_se/configuration/guide/swlldp.html
- Configuring LLDP, LLDP-MED, and Wired Location Service in the Catalyst 2960 Switch Software Configuration Guide, 12.2(50)SE
http://www.cisco.com/en/US/docs/switches/lan/catalyst2960/software/release/12.2_50_se/configuration/guide/swlldp.html
- Configuring LLDP and LLDP-MED in the Catalyst 4500 Series Switch Software Configuration Guide, 12.2(53)SG
<http://www.cisco.com/en/US/docs/switches/lan/catalyst4500/12.2/53SG/configuration/swlldp.html#wp1097119>

Readers are reminded that:

- NMSP is disabled on switches by default and must be explicitly enabled via the `nmosp enable` global configuration command.
- IP device tracking must be enabled on the switch in order for Context-Aware wired device tracking to function properly. It can be enabled by issuing the `ip device tracking` in global configuration mode on the context-aware switch.
- The civic location identifier in the LLDP-MED TLV is limited to 250 bytes or less. To avoid receiving error messages regarding available buffer space during switch configuration, the total length of all civic location information specified for each civic-location identifier must not exceed 250 bytes.
- In Release 6.0, all wired device client and switch tracking is available only to the root WCS virtual domain user. Because of this, you may wish to limit the use of context-aware wired device tracking to only those users with whom you are comfortable assigning WCS root virtual domain privileges.

NMSP Attachment Notification Interval

After an NMSP session is established between the MSE and a context-aware Catalyst switch, the MSE transmits an Echo Response packet to the switch every echo interval period, which is specified on the MSE (for all NMSP session partners) using the WCS menu entitled **Services > Mobility Services > System > NMSP Parameters**. In addition to Echo Responses, the switch will periodically send attachment notifications to the MSE via the NMSP session. Any link-up or link-down events that are detected by the switch are aggregated during a configurable time interval and sent to the MSE via an attachment notification at the conclusion of that time interval.

This interval is known as the `nmosp attachment notification interval` and is configurable on the switch via the **`nmosp notification interval attachment interval-seconds`** command. The range of values for `interval-seconds` is from 1 to 30 seconds, with 30 seconds being the default. In large networks where there are many NMSP sessions active across the MAN to an MSE and the number of users connecting and disconnecting from the switch is high, configuring **`nmosp attachment notification interval`** to a very short interval can increase the amount of NMSP traffic between switches and the MSE and is not recommended⁷ without carefully understanding the nature of the traffic present in your network.

Civic Address Configuration

The information contained in the Context Aware Service Configuration Guide 6.0 (http://www.cisco.com/en/US/docs/wireless/mse/3350/6.0/CAS/configuration/guide/msecg_ch7_CAS.html#wp1224011) provides the information necessary to configure context-aware switches and the WCS for wired device tracking.

As can be seen in the Context Aware Service Configuration Guide, in release 6.0 of Context-Aware Services all configuration of civic and ELIN location information is performed on each context-aware switch using the switch CLI. Once a switch is configured with the desired civic and ELIN location information, the switch will share all of the configured port information with the MSE when the NMSP session is initially established and will periodically update the MSE if any location updates are performed.

Note

Readers should find the following IETF RFC documents helpful in better understanding the types of values that should be specified for the various civic location fields: RFC 4776 (<http://www.ietf.org/rfc/rfc4776.txt>), RFC 4589 (<http://www.ietf.org/rfc/rfc4589.txt>), and RFC 5139 (<http://www.ietf.org/rfc/rfc5139.txt>).

7. Except for switches that are local to the Mobility Services Engine and need not traverse the MAN.

During the course of our lab testing, we discovered other useful facets of information regarding civic location and ELIN configuration in Catalyst switch IOS releases 12.2-52(SE) and 12.2-53(SG):

- Global Scope of Civic and ELIN location—Civic address or ELIN information must be configured at a global level and then assigned to each switch interface using the appropriate civic or ELIN location identifier. Globally defined civic address parameters (such as the building, county, postal code, floor, and so on) cannot be individually over-ridden at the interface level in release 6.0. If more than one switch port shares the same civic location or ELIN, then the same globally specified civic and ELIN location identifiers can be used on each switch port interface. However, if all ports possess unique civic address characteristics, then uniquely specified global civic address parameters for each port must be used. This can be seen in the following example where three unique civic location identifiers are applied to three different ports (Gi1/0/3 - 1/0/5). The test application server that is being tested on port Gi 1/0/6 is in the same physical location as the device connected to port Gi1/0/5, hence they share civic-location identifier 3.

- Civic location **additional-location-information** subcommand—During the course of our testing we found the **additional-location-information** subcommand useful in adding miscellaneous information about devices that can be displayed on the civic address tab of the WCS wired clients display under “Address Line 2”. In our testing, we made use of this facility to label the rack and position location of various servers and other devices that are deployed in a common location. [Figure 6-35](#) illustrates how the information entered using **additional-location-information** is then displayed on the civic address tab of the WCS wired clients display for the device (indicated by the red arrow). Below the configuration for the switch port, we can see the results of displaying the civic location for the switch interface using the **location civic-location interface interface** command.

- Civic Location **street-group** subcommand—In order to display a value under the street name component on the civic address tab of the WCS wired clients display, we found it was necessary to use the civic location **street-group** subcommand in the switch configuration. If we look again at the left hand portion of [Figure 6-35](#), we can see the street-group is specified as “Brookshire Avenue”. On the right hand of [Figure 6-35](#), we see that this value appears under the civic address tab of the WCS wired clients display under the label “Street”.

Excluding Device Tracking on Select Switch Ports

In the majority of cases, when using context-aware wired device tracking, it is usually acceptable to simply enable NMSP on the switch and allow the attachment status of all ports to be reported to the MSE. In this way, the attachment status and any location or ELIN information specified for each port in the switch is reported and can be accessed from the MSE. However, in some cases, it might be desirable to enable wired device tracking on a switch, but exclude selected switch ports from reporting device attachments to the MSE. A reason for doing this might be to help reduce the number of MSE tracked device licenses required by eliminating the NMSP reporting of device attachments on select ports where not much chance of device migration is expected. Recall that in release 6.0, while it is possible to enable or disable wired device tracking entirely on a per MSE basis, it is not possible to limit the number of wired devices that are tracked in each MSE at this time (i.e., wired device tracking is either on or off). Therefore, any such limiting must be done manually by either disabling NMSP sessions with selected switches entirely (**no nmosp enable**) or disabling only the tracking of select switch ports on a context-aware switch that is otherwise reported device attachments normally.

To disable device tracking for select switch ports on a switch where NMSP has been enabled, the switch interface configuration **nmosp attachment suppress** command should be specified on each switch interface where device tracking is not desired. The nmosp attachment suppress interface command is used to configure the interface to not send any attachment notifications to a Cisco Mobility Services Engine (MSE).

If you are using Location MAC Filtering (**Services > Mobility Services > Context Aware Service > Administration > Filtering Parameters**) to specifically limit or block (by MAC address) tracked wireless clients and tags, be advised that these address filters also apply to wired device clients as well. Make sure that any filtering specifications that you set using Location MAC Filtering are flexible enough to allow tracking of not only your wireless clients and tags, but wired devices as well. Any devices that have been blocked from location tracking as a result of a defined filter will be viewable under the “Blocked MACs” listing on the Filtering Parameters page. Detailed information regarding how to configure Location MAC filtering can be found in Modifying Filtering Parameters section of the Cisco Context-Aware Service Configuration Guide 6.0

(http://www.cisco.com/en/US/docs/wireless/mse/3350/6.0/CAS/configuration/guide/msecg_ch7_CAS.html#wp1100062).

Classification and Marking of NMSP Sessions

A vital component in assuring NMSP session stability and acceptable CAS performance during periods of network congestion is the application of QoS to NMSP data flows between the MSE and any WLAN controllers or context-aware Ethernet switches in the Schools SRA design. Classification, marking and QoS should be applied ideally in both cases of locally deployed as well as centralized MSE implementations, however, it is especially important when using a centralized MSE at the district site and remote WLAN controllers and context-aware Ethernet switches in the schools.

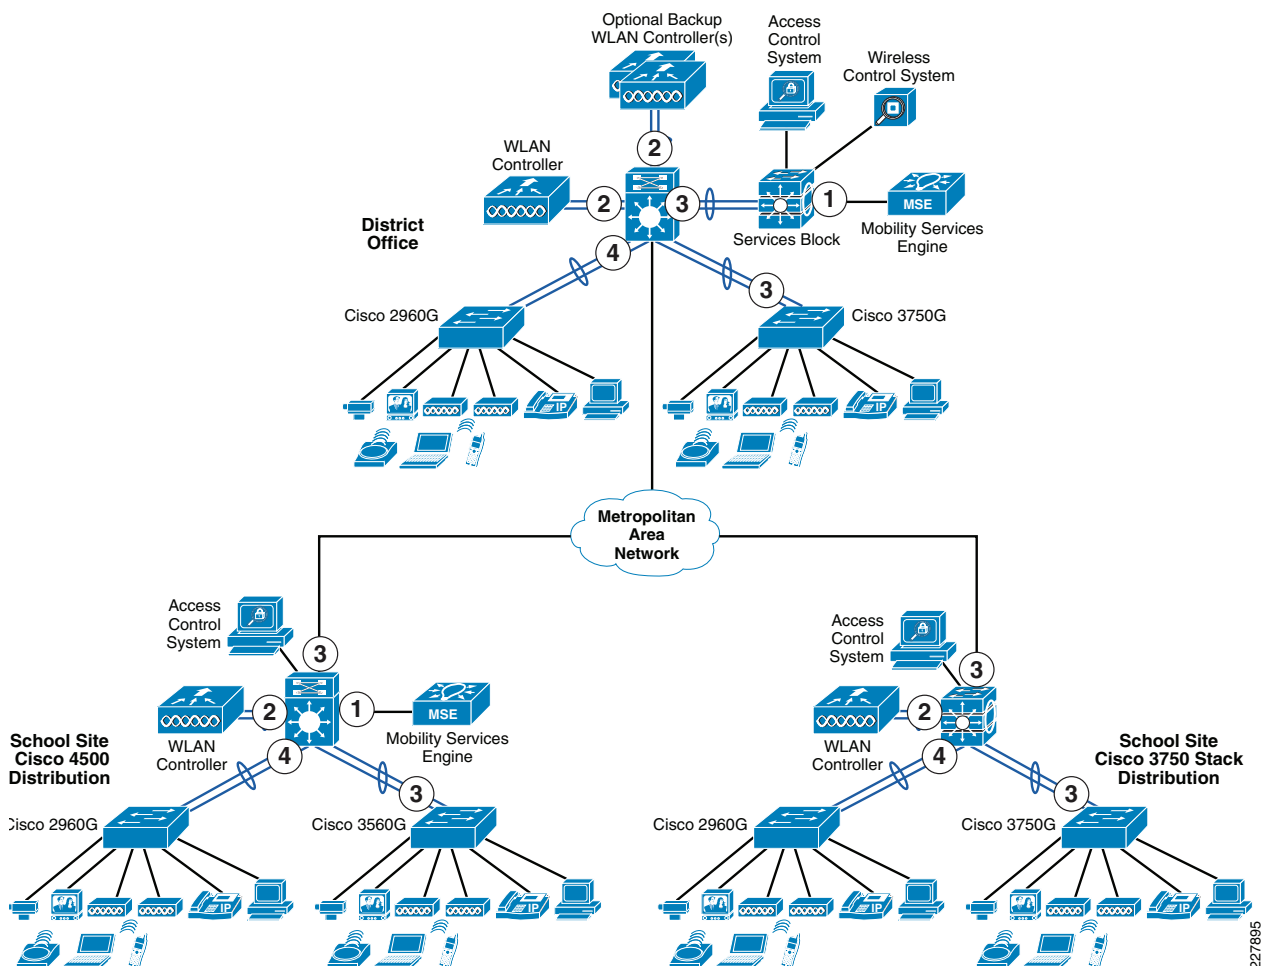

In order to ensure that QoS prioritization can occur properly for NMSP sessions the NMSP data flows must be properly identified, classified and marked as close as possible to their points of origin. This section explains where such marking of NMSP data flows should occur in the network, and how it should be performed.

Figure 6-36 provides an example of where identification, classification and marking of NMSP data flows should occur in the case of the school district design containing:

- A district office with adjoining data center
- A school site that is based on the Catalyst 4500 for distribution
- A school site that is based on the Catalyst 3750 switch stack for distribution.

In Figure 6-36, we have identified several points where classification and remarking needs to occur in order to properly mark NMSP traffic inbound from WLAN controllers and context aware switches, and outbound from Mobility Services Engines. These points are indicated by the yellow and red numbered circles.

Figure 6-36 Points of NMSP Classification and Marking

NMSP Traffic Flows Originating At The MSE

NMSP sessions between the MSE, WLAN controllers and context-aware switches are bi-directional in nature. Here, we are referring simply to that portion of any flow whose source address is that belonging to the Mobility Services Engine. Since the Mobility Services Engine does not mark the DSCP for the NMSP traffic it transmits into the network, all such traffic originating at the MSE will contain the default DSCP marking of 0x00. Left unchanged, when congestion is encountered in the Schools SRA design all NMSP traffic marked in this fashion will be treated with the lowest priority. This increases the probability that NMSP session data will be dropped in the network during periods of congestion. Left unchecked, this can result in NMSP session stability issues, and poor context-aware performance. Clearly, this is not desirable. We can avoid this by classifying and remarking NMSP data appropriately, as described in this section.

Since the MSE currently does not support classification and marking the DSCP value assigned to its traffic, we must make use of the classification and marking capabilities available to us in the Ethernet switch to which the MSE is attached. Thus, where **1** appears in [Figure 6-36](#), we will:

- Define the criteria to select our NMSP traffic
- Define a class-map that will filter NMSP traffic using this criteria
- Define a service-policy to assign our desired DSCP value to the filtered traffic using the class-map
- Apply the service-policy to the port to which the MSE is attached.

Since we know that NMSP traffic will involve TCP port 16113, we can make use of this to identify NMSP traffic and proceed to mark it appropriately.

The following example defines a policy map that will mark NMSP traffic inbound to the network from the MSE as DSCP 0x12 (also referred to as DSCP 18, Assured Forwarding 21), police down to 10 Mbps per 8k burst, and mark down any NMSP traffic exceeding this accordingly using the QoS map.

```
mls qos
!
class-map match-all CAS
  match access-group name NMSP
!
policy-map MSE-Policy
  class CAS
    set dscp af21
    police 10000000 8000 exceed-action policed-dscp-transmit
!
ip access-list extended NMSP
  remark Identify NMSP traffic
  permit tcp any any eq 16113
  permit tcp any eq 16113 any
```

On the switch interface where the MSE is attached, it is imperative that service-policy statement appears to assign the policy map to the interface. For example:

```
interface GigabitEthernet1/0/2
description Mobility Services Engine MSE1
.
.
service-policy input MSE-Policy
```

NMSP Traffic Generated By WLAN Controllers

As was the case with the MSE, NMSP traffic entering the network originating at the WLC is also marked with the default DSCP value of 0x00. Left unchanged, when congestion is encountered in the Schools SRA design all NMSP traffic marked in this fashion will be treated with the lowest priority. Once again, this is not desirable and we shall address it in this section.

Like the MSE, the WLAN controller does not provide us with the ability to mark the NMSP traffic as we see fit, thus we must instead classify and mark this traffic inside the network. In accordance with general best practices, this operation is performed as close in the network as possible to the WLAN controller. Therefore, in [Figure 6-36](#), the points at which this should occur are shown by **2**. Note that traffic coming from both normally active as well as any backup WLAN controllers located in the data center services switch block must be classified and marked.

The method used to accomplish this classification and marking for WLAN controllers is very similar to that presented in the previous section for the MSE. However, since the WLAN controller is attached to the Ethernet switch using an Etherchannel port-channel group, there will be some relevant differences relating to whether the port-channel attachment is to a Catalyst 3750 switch stack or Catalyst 4500 distribution switch.

For example, when using the Catalyst 3750 switch stack in distribution, the following configuration would apply:

```
mls qos
!
class-map match-all CAS
  match access-group name NMSP
!
policy-map CAS-Policy
  class CAS
    set dscp af21
    police 10000000 8000 exceed-action policed-dscp-transmit
!
ip access-list extended NMSP
  remark Identify NMSP traffic
  permit tcp any any eq 16113
  permit tcp any eq 16113 any
```

The 3750 switch stack would also have a port-channel definition that would refer to the two physical Ethernet interfaces comprising the port-channel group.

```
interface Port-channel4
  description EC trunk to school 1266, WLC, interfaces gig1/0/28, 2/0/28
```

It is important to note that the 3750 switch stack does not support the use of a policy-map statement on a port-channel definition. In order to assure that NMSP traffic originating at the WLAN Controller in-bound to the network is properly classified and marked, ensure that a service-policy statement appears on each of the two physical interfaces that comprise the WLAN controller port-channel group in the 3750 switch stack. For example:

```
interface GigabitEthernet1/0/28
  description trunk to school 1266 WLC, port-channel4
  .
  .
  mls qos trust dscp
  channel-group 4 mode on
  service-policy input CAS-Policy
!
interface GigabitEthernet2/0/28
  description trunk to school 1266 WLC, port-channel4
  .
```

```

.
mls qos trust dscp
channel-group 4 mode on
service-policy input CAS-Policy

```

When using the Catalyst 4500 as the distribution switch, the scenario is a bit different. The Catalyst 4500 requires the service-policy to be assigned to the port-channel group used for the WLAN controller, and not the physical interfaces. Thus, our recommended configuration when using a Catalyst 4500 in distribution would be as follows:

```

!
class-map match-all CAS
  match access-group name NMSP
!
policy-map CAS-Policy
  class CAS
    set dscp af21
    police cir 10000000
      conform-action transmit
      exceed-action set-dscp-transmit default
!
ip access-list extended NMSP
  remark Identify NMSP traffic
  permit tcp any any eq 16113
  permit tcp any eq 16113 any
!
interface Port-channel6
  description trunk to district WLC, interfaces gig2/11, gig3/11
  .
  .
  service-policy input CAS-Policy
!
!
interface GigabitEthernet2/11
  description trunk to district WLC, port-channel6
  .
  .
  channel-group 6 mode on
!
interface GigabitEthernet3/11
  description trunk to district WLC, port-channel6
  .
  .
  channel-group 6 mode on
!

```

NMSP Traffic Generated By Context-Aware Switches

As you will recall, specific models of Catalyst switches described earlier in this document (such as the 2960G, 3560, 3750, 4500, 4900 and others) can provide context-aware information to the MSE relating to IP-based attached devices. When this capability is enabled in a context-aware switch, the switch itself participates in an NMSP session with the MSE. This NMSP session is separate and independent of any NMSP sessions that may pass through the switch to or from attached devices (such as the WLAN controllers described earlier, or other downstream context-aware switches).

In order to ensure that the NMSP traffic originating at these switches is treated appropriately in the network during times of congestion, it is important that we properly classify the NMSP data originating at the context-aware switch and destined in-bound to the network for the MSE. Depending on the type of switch used, the exact method we shall use to apply this classification and marking will vary.

Layer-Three Context-Aware Switches

In the case of context-aware Layer-3 switches such as the 3750, 3560 and 4500, we can make use of local policy routing to assign an IP precedence 2 (DSCP 0x10) to NMSP traffic originating from the switch itself. Local policy routing in this fashion is performed internal to the context-aware L3 switch originating the NMSP traffic, and the traffic is marked prior to being introduced into the network. At the locations in [Figure 6-36](#) marked with **3**, we can perform the required classification using a local policy route-map as follows:

```
ip local policy route-map switch-NMSP
!
route-map switch-NMSP permit 10
  match ip address NMSP
  set ip precedence 2
  set ip tos max-throughput
!
ip access-list extended NMSP
  permit tcp any any eq 16113
  permit tcp any eq 16113 any
!
```

Layer Two Context-Aware Switches

However, the use of the Cisco 2960G context-aware layer two (L2) switch in the access layer presents a challenge. Local policy routing is not supported by the L2-only 2960G. Therefore, as a workaround, we must classify and mark the NMSP traffic originating from the 2960G at the next switch upstream to it in the network. In the Schools SRA design, this upstream switch would be the 3750 switch stack or 4500 distribution switch. In [Figure 6-36](#), the points at where this must be performed are indicated by **4**.

Note that in the Schools SRA design, the 2960G access layer switches are attached to the distribution switches using an Etherchannel port-group, in a fashion very similar to that of the WLAN controllers. Therefore, similar techniques can be used to classify and mark the NMSP traffic originating at the 2960G and coming across the Etherchannel link.

Thus, for a 3750 switch stack used in distribution, a **class-map** and **policy-map** can be applied as described previously, and the **service-policy input CAS-Policy** statement applied to the physical interfaces in the 3750 switch stack that comprise the port-channel group to the 2960G switch. Just as for an Etherchannel-attached WLAN controller, a service-policy cannot be applied to the port-channel group definition used for the 2960G.

When using a Catalyst 4500 as the distribution switch with a context-aware 2960G at the access layer, apply the **service-policy input CAS-Policy** statement to the port-channel group definition for the 2960G. This would be done in a similar fashion to that described earlier for a Etherchannel-attached WLAN controller.

Hardware/Software Releases

During any deployment of Context-Aware Services and Cisco Unified Wireless Networks, detailed site surveys should be performed by a Cisco Wireless LAN Specialized Partner with expertise in voice, high speed data, and Context-Aware wireless network deployment. Cisco Systems also offers a complete package of bundled design and deployment services via the Cisco Advanced Services team. Cisco and our Wireless LAN Specialized Partners offer Context-Aware Design and Implementation Services to help you successfully deploy enterprise-class wireless connectivity. These services include the installation and configuration of crucial components such as the Mobility Services Engine (MSE), helping you to take full advantage of the strong security, management, and investment protection features that are built into Cisco Context-Aware components. In addition to planning, design, and implementation, we also offer services based on proven methodologies for operating and optimizing the performance of a Context-Aware Mobility solution, along with its associated technologies and strategies.

**Note**

The importance of a properly performed wireless site survey of your facility cannot be over-emphasized. For more information on Cisco bundled planning, design, and deployment services, refer to http://www.cisco.com/en/US/services/ps2961/ps6899/ps8306/services_overview_context_aware.pdf. To locate a Cisco Wireless LAN Specialized Partner, refer to <http://tools.cisco.com/WWChannels/LOCATR/openAdvanceSearch.do>.

CHAPTER 7

Unified Communications Design

Introduction

While many school networks still use legacy PBX phone systems, many are migrating to the advantages of IP-based voice. Lower in cost, and more flexible and reliable, the Cisco Unified Communications suite of solutions provides great benefits to a school network. Based on years of best practice recommendations, this chapter provides information on the advanced suite of communications, collaboration, and mobility features in the Cisco Unified Communications solution set.

This chapter provides guidance for deploying Cisco Unified Communications. It covers the dial-plan principles recommended for a school district, along with recommended solutions for ensuring communications survivability during a WAN outage, and emergency 911 call capabilities.

School Service Ready Architecture Dial Plan

The CUCM dial plan discussed here is appropriate for deployments supporting up to 100 schools. This dial plan is for a centralized CUCM cluster in the school District Office supporting up to 100 schools over a 100Mbps Metro Ethernet WAN.

Note

This document is based on the UC SRND version 7 that can be accessed at the following URL: http://www.cisco.com/en/US/docs/voice_ip_comm/cucm/srnd/7x/uc7_0.html. The dial plan chapter of the UC SRND is the authoritative source for dial plan guidance and should be referenced for more details and more options than are provided in the example deployment provided in this chapter.

Design Assumptions

The following design aspects and requirements are assumed:

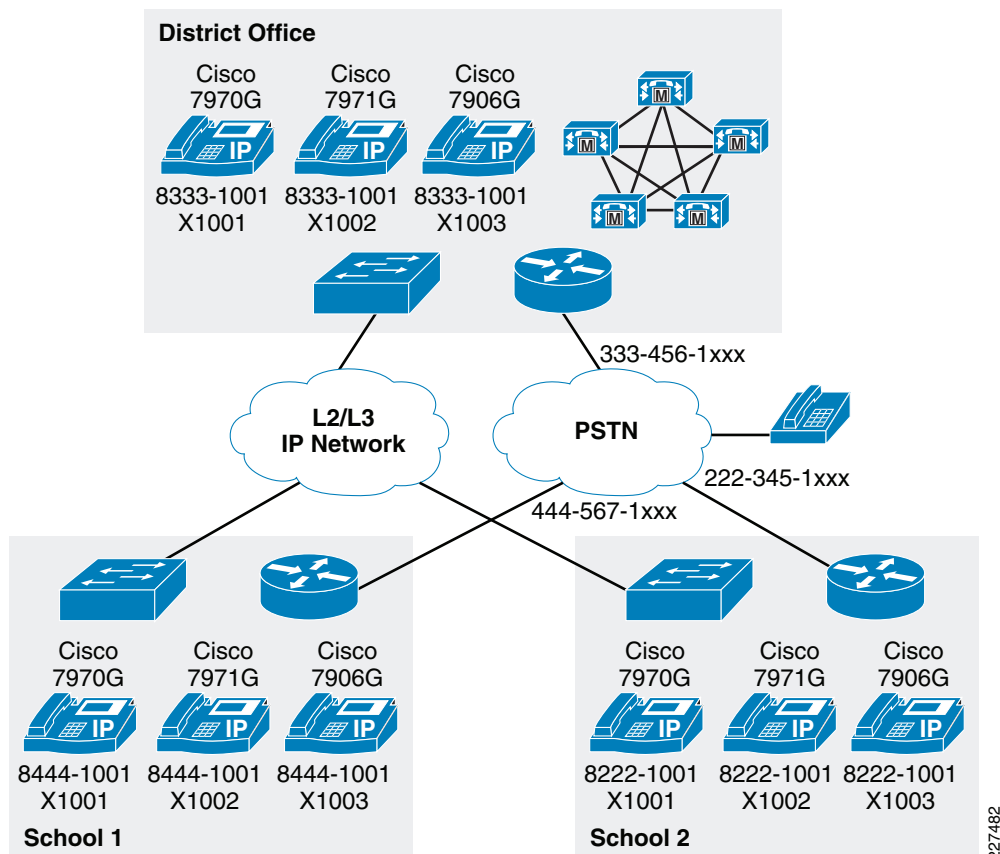

- Connectivity between schools and district office is via hub-and-spoke Metro Ethernet WAN.
- Metro Ethernet provides sufficient bandwidth and low enough latency to support centralization of CUCM at the district office for all sites in the network.
- The network is configured with the appropriate QoS policy to support a voice deployment.
- CUCM provides centralized call control for all sites in the network.
- Call processing redundancy at the district office is provided by a CUCM cluster.

- Access to the PSTN is provided by PSTN gateway functionality running on a Cisco Integrated Services Router (ISR) router at each school and in the district office.
- At the school sites, additional call processing redundancy is provided by SRST in the Cisco ISR at that site. If phones at a remote sites lose connectivity with the CUCM over the WAN link, they can fall back to SRST mode whereby they register with the SRST function in the Cisco ISR router local to that site
- Same site calling; every phone can call any other internal phone at the same site using four-digit extension.
- Inter-site calling; calls between phones in different sites of the same school district use 8 as an access code, followed by a site code, followed by the four-digit extension.
- PSTN gateways at the district office and remote sites provide PSTN connectivity.

Example Deployment

Dial-plan testing was performed on an example network of three sites in a deployment designed to scale up to 100 sites. The example deployment is shown in [Figure 7-1](#).

Figure 7-1 Sample Dial-Plan

In the example deployment, each of the sites has less than 8,000 phones and can therefore use a 4-digit internal extension. The following Direct Inward Dial DID blocks are assumed to have been issued by the local telecoms operator:

- District office DID block 333-456-1000 through 333-456-1799
- School 1 DID block 444-567-1000 through 444-567-1799
- School 2 DID block 222-345-1000 through 222-345-1799

Within each of the three sites, dialing will be by four-digit extension (x1000 through x1799)

Between sites, dialing will use 8 as an access code, followed by a site-code (in the example, this is area code assigned to that sites PSTN gateway), followed by the four-digit extension.

- District office phones dialed from school 1 or school 2 will be dialed as 8-333-1000 through 8-333-1799.
- School 1 phones dialed from district office of school 2 will be dialed as 8-444-1000 through 8-444-1799.
- School 2 phones dialed from district office of school 1 will be dialed as 8-222-1000 through 8-222-1799.

Note

In the example above, each site has a unique area code that is mapped directly to a site code. In a typical deployment, the expectation is to see multiple schools using the same area code; this requires site codes to be assigned by other means.

Note

You must ensure that the on-net access code and site code combination do not overlap with the local abbreviated dialing range at any site. This is accomplished by ensuring that no abbreviated dial extension start with the digit 8.

Variable-Length On-Net Dial Plans with Flat Addressing

This document discusses a dial plan that is appropriate for deployments where the CUCM cluster in the school district office supports up to 100 schools over a 100Mbps Metro Ethernet WAN.

There are two main approaches to a dial plan for internal destinations within an IP Telephony system:

- *Uniform on-net dial plan*—All extensions in a uniform on-net dial plan are reached in a uniform way. Every internal call destination has a unique number of defined length. Uniform on-net dial plans are the easiest to design and configure; however, they become impractical when the number of sites and users increases due to the following reasons:
 - All on-net extension dialing must be globally unique. For example, in a system using an abbreviated 4-digit on-net dial plan, there cannot be an extension 1000 in site A and another extension 1000 in site B. This requirement is very difficult to satisfy in large deployments where the extension is derived from the DID blocks obtained from local telecoms companies.
 - There cannot be any partial overlap between different dial strings. For example, if 9 is used as an off-net access code in a 4-digit abbreviated dial plan (for example, to make PSTN calls), there cannot be any extensions in the 9XXX range. Attempting to do so would create situations where calls are not routed immediately. For example, if a user dialed 9141, the system would have to wait for either more digits (if the user were dialing 91415551234, for example) or the expiration of the inter-digit timeout before routing the call to extension 9141. Likewise, if an operator code is used (for example, 0), the entire 0XXX extension range would have to be excluded from a four-digit uniform dial plan.
 - There cannot be overlapping strings of different length. For example, a system with extensions 1000 and 10000 would force users to wait for the inter-digit timeout when they dial 1000.

- *Variable-length on-net dial plan*—This is where internal destinations are dialed differently within a site than across sites. Typically, this approach uses four or five-digit abbreviated dialing for calls within a site and an on-net access code followed by a site code and the extension for calls across sites.
 - Variable-length on-net dial plans are more scalable and better allow for future expansion or changes to the dial plan. For this reason, variable-length on-net dial plans are used in this design guide.
 - A variable-length on-net dial plan with flat addressing is implemented by defining internal call destinations as unique strings containing an on-net access code, a site code, and the extension (for example, 8-123-1000). Flat addressing places all the directory numbers in the same global partition, thus enabling inter-site calls using the site code. Translation patterns are defined in site-specific partitions (one translation pattern and one partition per site) to enable abbreviated dialing within a site.
- *Alternative to using site codes*—The UC7.x SRND discusses a variant of the flat addressing approach that does not rely on the definition of an on-net numbering plan based on site codes. In this scheme, internal call destinations are defined with their full E.164 number. Intra-site calls use translations patterns to ensure they can still dialed as four-digit numbers. Inter-site calls are dialed using the E.164 number and are then recognized and routed across the IP WAN by Unified CM. This option was not used in this document because the site code approach results in numbers that are shorter and easier to remember; for example, the dial plan could be set up so that every school principal has a non-DID second extension of 7000. With this scheme in place, it is possible to dial the principal at any school by dialing 8, the site code, and 7000. The site code approach is also preferred because many schools do not have E.164 DID numbers assigned to each phone; instead they route calls through an IVR or an operator.

Call Routing

The dial plan in this document is designed with the following structure:

- *Localized Call Ingress*—Accept calls in the local format preferred by the originating users and carriers. Convert called and calling numbers to a globalized format.
- *Globalized Call routing*—Route the calls on-net using global representations of the called and calling numbers.
- *Localized Call Egress*—Deliver the calls to phones or gateways and convert the called and calling numbers from the globalized format to the local format required by the destination user or network.

The benefits of the dial-plan design approach are most compelling when deploying UC across diverse countries and telephony carriers, but as a Cisco UC best practice, the new design approach still has benefits to a smaller network such as that which would be used by a school district. Some of those benefits include the following:

- Dial plan is consistent with Cisco best practice recommendations and scales globally
- Simplified configuration of call routing, especially when considering local egress to the PSTN
- Simplified configuration and enhanced functionality of system functions such as:
 - Automated Alternate Routing (AAR)
 - Emergency Responder (ER) site-specific failover
 - Call Forward Unregistered (CFUR)
 - Tail End Hop Off (TEHO)

- Click-to-dial of E.164 numbers (including the + sign) from soft clients such as Cisco Unified Personal Communicator
- Adaptive call routing for speed dials originating from roaming extension mobility users or roaming devices
- One-touch dialing from phone directory entries, including dual-mode phones
- One-touch dialing from missed and received call lists in IP phone directories

**Note**

The dial plan in this document uses several features introduced in CUCM 7.0.

Localized Call Ingress

Localized call ingress is where the UC system accept calls in the local format preferred by the originating users and carriers and then converts called and calling numbers into 8-digit local phone numbers for CUCM on-cluster numbers, and to the full E.164 format for PSTN numbers.

Using the + Sign on E.164 Numbers

When an external called or calling number is converted to the globalized representation on input, a + sign is used to represent the international dialing access code needed to reach a destination from different countries.

For calls that egress via a PSTN gateway, *localized call egress* will replace the + in a called number with the appropriate off-net access code (as required by the enterprise telephony system) and international access code (as required by the PSTN carrier) relevant for each caller.

Even though the Telephony User Interface (TUI) does not allow for dialing + from the keypad, the missed and received calls directories can contain entries where the number includes a +. On 7911, 7941, 7942, 7945, 7961, 7962, 7965, 7970, 7971, and 7975 phones, if the user dials from those directories, the resulting call into Unified CM will have a called number beginning with +. (7905, 7912, 7940, and 7960 phones do not support storing or displaying the + sign).

This section discusses the following:

- Localized call ingress on IP phones
 - Localized called number on IP phones
 - IP phones called number is a 4-digit local extension
 - IP phones called number is on the external PSTN
 - Localized calling number on IP phones
- Localized call ingress on gateways
 - Localized called number on gateways
 - Localized calling number on gateways

Localized Call Ingress on IP Phones

This section discusses *localized call ingress* on IP phones and Soft phones.

Localized Called Number on IP Phones

If a user dials the full 8-digit directory number of an on-cluster phone line, the called number does not need to be manipulated, and is routed directly. This section will discuss the cases where the called number is one of the following:

- A 4-digit local extension
- A full E.164 PSTN number

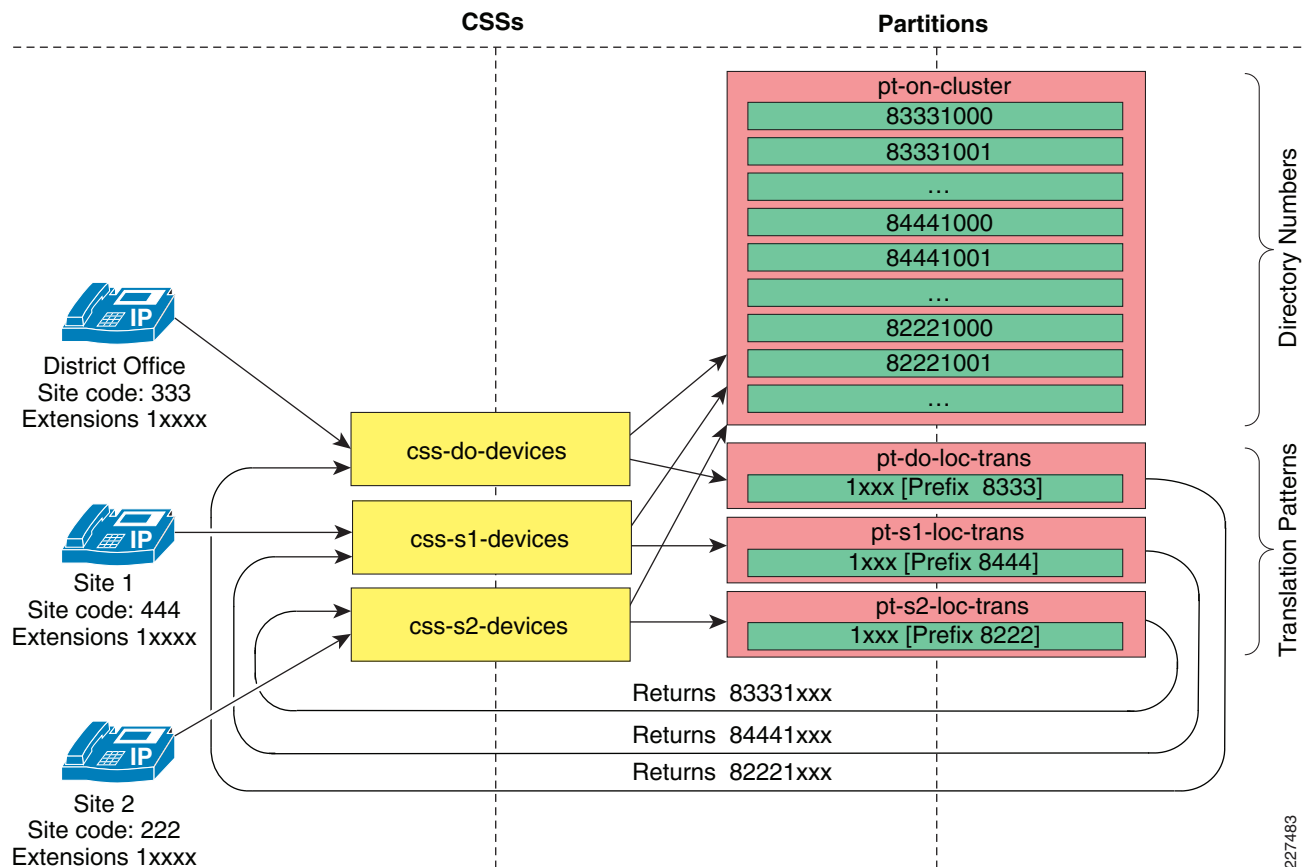

IP Phones Called Number is a 4-digit Local Extension

For on-net destinations, such as calls between two users in the same site, translation patterns are used to derive the globalized on-net form of the destination number. For example, assume two users in the Site 1 use 4-digit abbreviated dialing to call each other. User A calls user B by dialing 1234. A translation pattern specific to this site is configured to recognize any 4-digit string beginning with 1 and to translate the called number to the globalized on-net form of 84441234. The translation pattern is configured as: 1XXX, prefix 8444.

The translation pattern must be site-specific (included in the CSS of only the phones in Site 1) to avoid confusion with extension 1234 at other sites in the system. In the example above, the on-net global form is implemented using an inter-site access code (8) and a site code (444). After the call has been translated into a 8-digit global on-net number, the CSS of the translation pattern is used to direct the call to the destination partition and route pattern.

[Figure 7-2](#) shows an example configuration for intra-site calls within the CUCM cluster used in the sample network.

Figure 7-2 Localized Call Ingress for On-net Calls

To provide connectivity between sites and partitions, the sample network used the following guidelines:

- Place all unique DNs, including the on-net access code 8, in a global partition (named **Internal_pt** in this example).
- Create one partition per site, each containing a translation pattern that expands four-digit numbers into the fully qualified eight-digit number for that site, thus enabling abbreviated dialing within the site.
- For each site, include both the **Internal_pt** partition and the local translation partition in the phone's calling search space. The inclusion of the on-net access code in the DN configured in Unified CM enables you to place all internal extensions in a partition directly accessible by all phones, and at the same time ensures that all call directories on the IP phones are populated with numbers that can be directly redialed.

IP Phones Called Number is on the External PSTN

For calls to numbers on the PSTN, translation patterns should be used to derive the globalized on form of the destination number.

- Add the local area code to any 7-digit PSTN numbers.
- Replace the PSTN access code (for example, 9) and any international dialing access code (eg 011), with a + sign.

With these changes to the called number, the call could be routed or re-routed to any gateway globally, and the gateway would be able to route the call successfully.

Figure 7-3 Localized Call Input; IP Phone Calling Off-net Destination

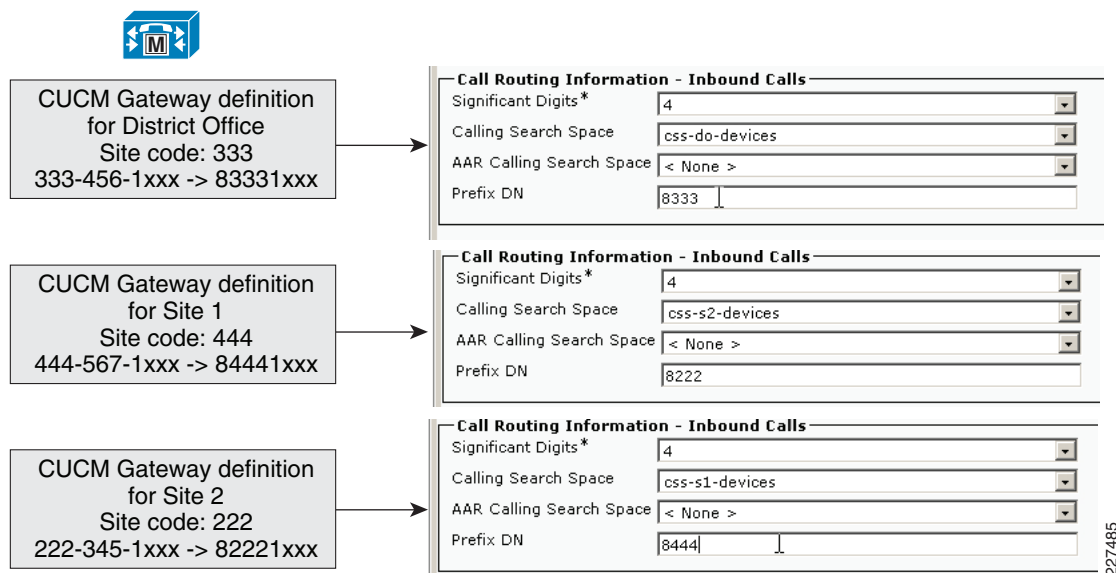

Figure 7-3 shows the following partitions:

- *NANP_Loc2glob*—The system has one translation pattern, used by all sites, to perform the following modifications to called numbers:
 - Remove the PSTN access code of 9 on emergency numbers
 - Replace the PSTN access code of 9 with the + code, on National numbers
 - Replace the PSTN access code and the international dialing access code with the + code on international calls.
- *xx_loc2glob*—Each site has a site-specific partition containing a translation pattern to replace the PSTN access code for 7 digit local dialing with the + code and the NNAP country code of 1, and the local area code for that site.
- *NNAP_pstn_part*—The translation patterns in the other partitions translated numbers into a globalized number. After the call has been translated into a E.162 off-net number, the CSS of the translation pattern is used to direct the call to the *NNAP_pstn_part* partition. The *NNAP_pstn_part* partition is used by all sites, to route globalized called numbers out the appropriate gateway. The Globalized call routing section will detail how the gateways are used for each of the patterns in this partition.
 - There are patterns for each sites local area code so that Tail End Hop Off may be used to route the call to the gateway local to that area code.
 - The +1xxxxxxxxx pattern is for NNAP numbers
 - The +! pattern will route international calls.
 - Emergency numbers (911) should always be routed out the local gateway of the calling phone, when available.

Localized Calling Number on IP Phones

On cluster IP phones are configured with a directory number that is in the global on-net format. In this example the directory number is an 8-digit number that includes the access code, the site number, and the 4-digit extension. This directory number is already in the globalized format and is therefore not changed on ingress. If the call is directed out a gateway, the calling number will be changed by the gateway to a full E.164 number.

Localized Call Ingress on Gateways

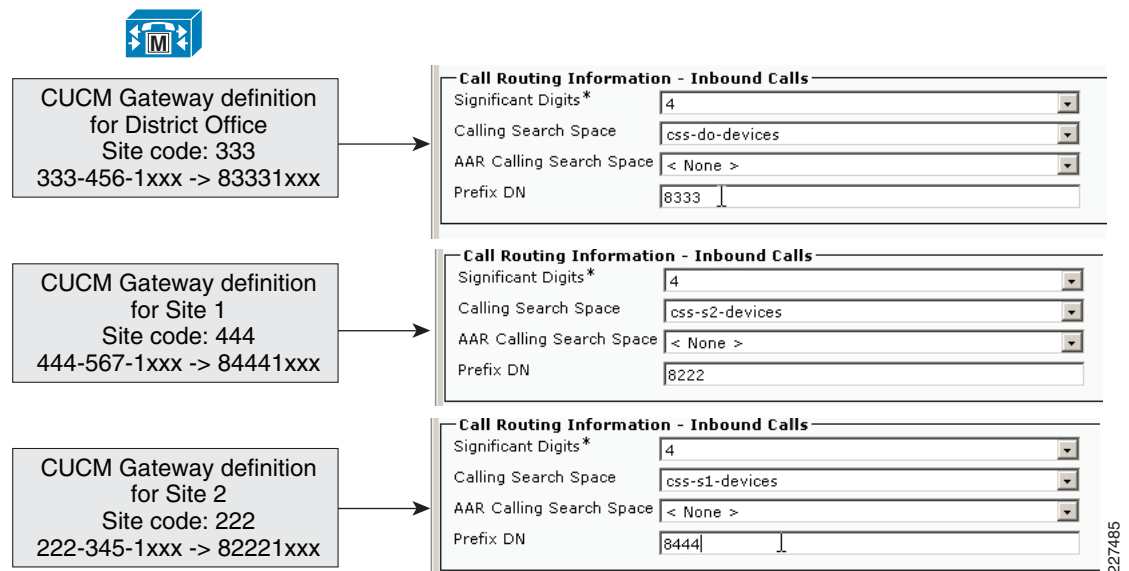

Just as with IP phones discussed previously, we need to localize call ingress on gateways. We accept incoming calls on gateways in the local format of the telephone network to which the gateway is connected, and we convert the called and calling numbers to a globalized format. The global format is later used to route the call within the voice over IP network to its destination.

Localized Called Number on Gateways

Incoming PSTN calls require that the E.164 number be manipulated to obtain the eight-digit internal number in order to reach the destination phone. Within this example dial-plan, this requirement has been implemented by configuring the *Num Digits* and *Prefix Digits* fields within the Gateway Configuration page in Unified CM. These fields strip and then prefix the needed digits.

In [Figure 7-4](#), the *Significant Digits* field maps the last 4 digits of the incoming called DID number to the local 4-digit extension. The *Prefix DN* field adds the inter-site access code (8) and a site code (222).

Figure 7-4 Converting from localized PSTN called DID number format to globalized on-net directory number format

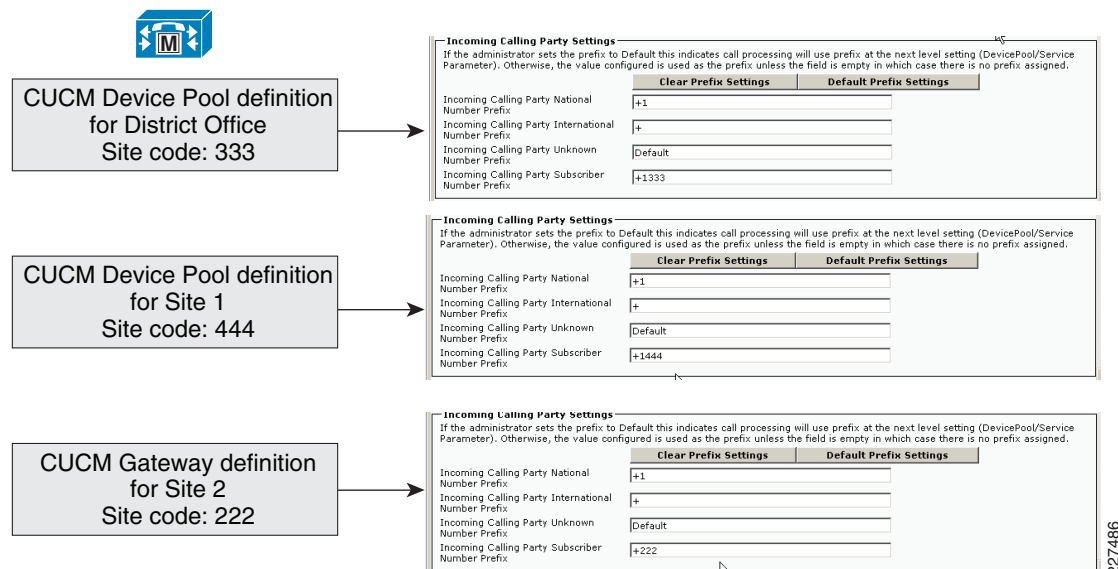

Localized Calling Number on Gateways

Incoming calling party settings can be configured on individual gateways, at the device pool level, or at the service parameter level, in order of precedence. For each numbering type (Subscriber, National, International, or Unknown), Unified CM allows for the appropriate prefix digits to be configured. Digits

can be stripped from and prefixed to the string provided as the incoming party number. The notation takes the form PP:SS, where PP represents the digits to be prefixed and SS represents a quantity of digits to be stripped. The digit stripping operation is performed first on the incoming calling party number, and then the prefix digits are added to the resulting string. For example, if the prefix digits field is configured as +33:1 and the incoming calling party number is 01 58 40 58 58, the resulting string will be +33 1 58 40 58 58.

Figure 7-5 shows the incoming calling-party settings for the gateway at school 2.

Figure 7-5 Localized calling party number on gateways

For the example dial plan above, the following actions are taken:

- Incoming national calls have the area code included in the calling number, and the gateway is configured to add the + and the 1 for North America.
- Incoming international calls have the international country code included in the calling number, and the gateway is configured to just add the +.
- For incoming unknown calls, the gateway is configured to just add the +.
- For incoming subscriber calls, and the gateway is configured to add the + and then the 1 for North America, and then the local area code for that gateway.

Globalized Call Routing

In this section, we assume the calling number has been manipulated into one of the following:

- Globalized to an 8-digit on-net number
- Globalized to an E.164 external number

This section discusses how the call is routed to the appropriate destination.

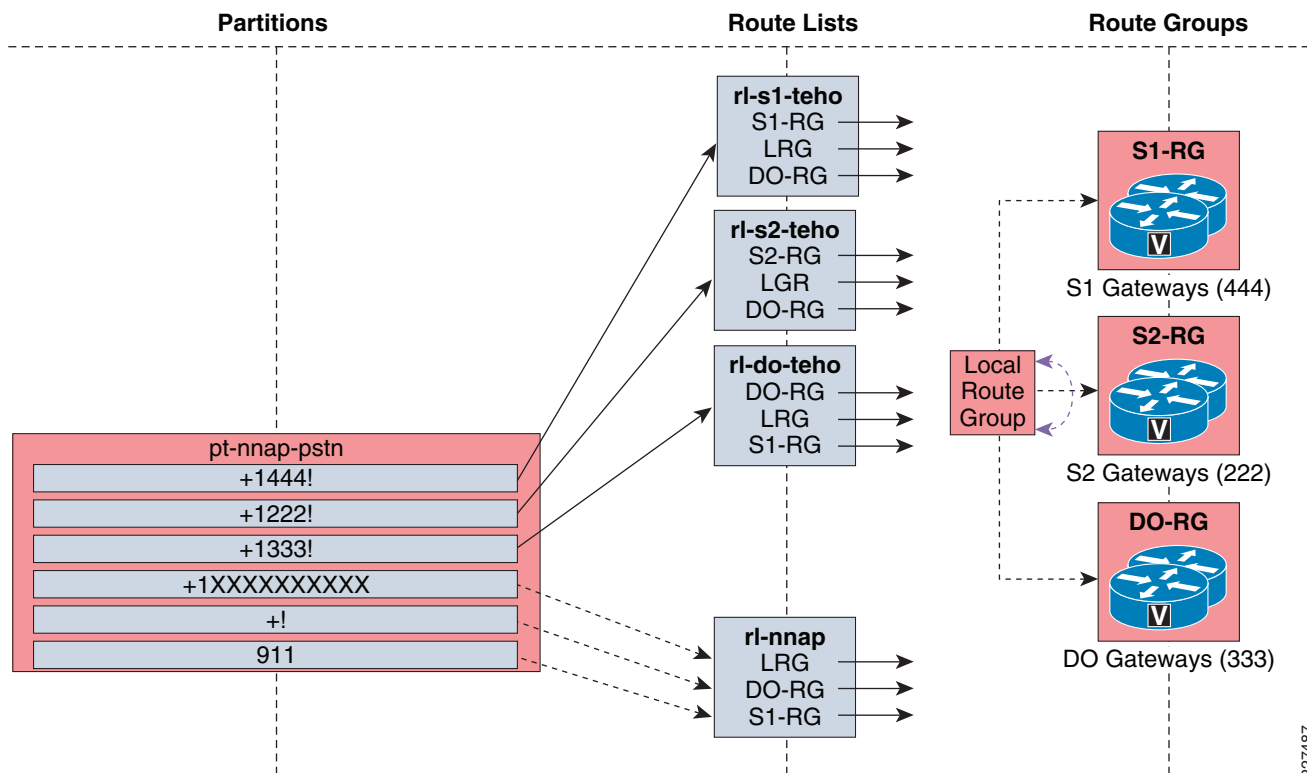

Globalized Call Routing to an 8-digit On-net Number

The sample network is deployed as a single CUCM cluster the CUCM cluster has full knowledge of every 8-digit on-net number, and can route calls directly to the destination phone.

Globalized Call Routing to an E.164 External Number

Where the destination is an external PSTN number, we have to route the call to the appropriate PSTN gateway. Figure 7-6 shows how calls are routed in our example deployment. Route patterns point to route lists that in turn point to egress gateways.

Figure 7-6 Call Routing Example

The following discussion of the dial plan in Figure 7-6 includes the use of local route groups which are discussed further in the section following this one.

The route patterns that include the area code implement Tail End Hop Off (TEHO) by pointing to a route list which is comprised of the following route groups:

- A route group containing the gateways at the local site in which the directly connected gateways are connected.
- A route group containing the local route group which will route calls out a gateway connected to the site the calling phone is dialing from. For more details on local route group, refer to [“Using Local Route Group” section on page 7-12](#).
- A route group containing the gateways at a different site. This provides redundancy in the event that the previous two route groups both point to the gateways at the same site.

The route patterns in Figure 7-6 for national, international, and emergency calls point to a route list that is comprised of the following route groups:

- A route group containing the Local Route Group which will route calls out a gateway connected to the site the calling phone is dialing from. For more details on Local Route Group, refer to “[Using Local Route Group](#)” section on page 7-12.
- A route group containing the gateways at the district office.
- A route group containing the gateways at Site 1. This provides redundancy in the event that the previous two route groups both point to the gateways at the same site.

Other variations are possible in a real deployment. For example, it might be preferable to route some calls out the district office as a first choice, and out the Local route group if the district office gateways are unavailable.

Using Local Route Group

Local Route Group is a Cisco Unified CM 7.0 feature that simplifies the configuration of site-specific routing of off-net calls. Route patterns using the local route group allow for dynamic selection of the egress gateway, based on the device originating the call.

Before local route group route patterns were site specific. For example, before local route groups:

- The 911 route pattern for site 1 would point to site 1's PSTN gateway
- The 911 route pattern for site 2 would point to site 2's PSTN gateway.

With local route groups, a single 911 route pattern can be configured pointing to the *Local Route Group*.

- Phones in sites 1 and 2 will use the PSTN gateway pointed to by the *Local Route Group* field in each sites device pool.
- Phones acquire their local route group from the *Local Route Group* field in the phones' device pool.

Localized Call Egress

Calls are routed to a destination using the global form of the called and the calling numbers. These numbers need to be transformed into the format expected by the telephone network to which the gateway is connected.

Localized Call Egress to an IP Phone

Called Number

In this dial plan, IP phones directory numbers are the same as the globalized on-net number format; no conversion of the called number is required.

Calling Number

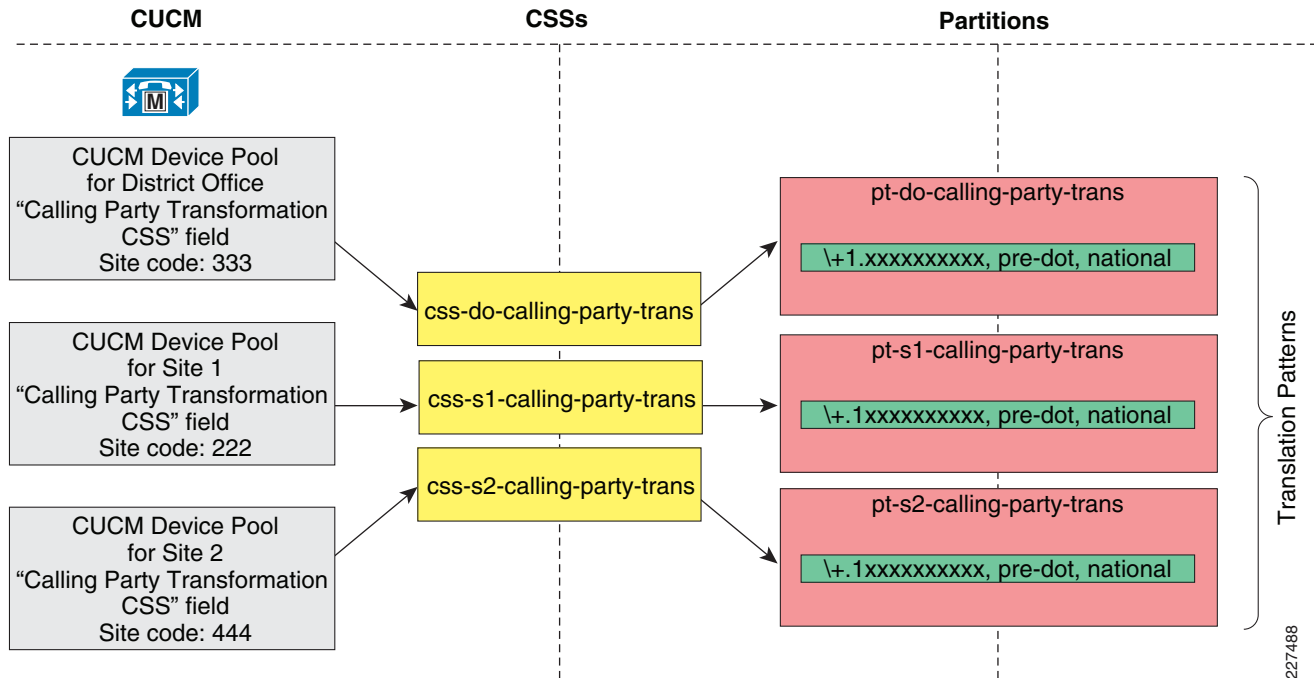

As a call is delivered to a phone, the calling number will be in its global form, which might not be recognizable to the called party. Typically, users prefer to see calls from callers within their country presented with an abbreviated form of the caller's number.

For example, users in the US want to see incoming calls from US callers with a ten-digit national number, without the + sign or the country code (1). If a user whose global phone number is +1 222 345 1234 calls +1 333 456 4000, the called phone would like to receive 222 345 1234 as the calling-party number while the phone is ringing.

To achieve this, the system administrator should configure a calling-party transformation pattern of: +1.!, strip pre-dot. The calling-party transformation pattern is placed in a partition included in the destination phone's calling-party transformation pattern CSS, configured at the device-pool level. As a call from +1 222 345 1234 is offered to the phone, it matches the configured calling-party transformation pattern, which removes the +1 and presents a calling-party number of 222 345 1234 as the call rings.

Figure 7-7 shows how the device pool of the destination phone determines the calling party transformation

Figure 7-7 IP Phone Outgoing Calling-Party Transformation

Note

The calling-party number stored in the missed and received calls directories is left in its globalized form to allow one-touch dialing from the directories without requiring manual editing of the directory's stored number string.

Note

Many phone users are becoming accustomed to the globalized form of PSTN numbers, mainly due to the common use of mobile phones across international boundaries. The system administrator can forgo the configuration of calling-party transformation patterns for phones if displaying the global form of incoming numbers is preferred.

Localized Call Egress to a Gateway

Gateway Called-Party Number Localization

As a call is delivered to a gateway, the called party number must be adapted to the requirements of the PSTN service provider providing the trunk group to which the gateway is connected. Called-party number transformation patterns can be used to change the called-party number digit-string and

numbering type. Typically, a called-party number featuring the gateway's country code should be changed to remove the + sign and the explicit country code, and they should be replaced with the national prefix. Also, the numbering type of the called-party number should be changed to national. If the gateway is connected to a trunk group featuring a specific area, region, or city code, the specific combination of + sign, country code, and local area code usually must be replaced by the applicable local prefix. Also, the numbering type must be adjusted to subscriber.

For example, assume that a call to an external user in site 1's area code (+1 444 555 2222) is routed through a route list featuring a Site 1 gateway (San Francisco) as a first choice and a Site 2 (Chicago) gateway as a second choice. The Site 1 gateway is configured with two called-party transformation patterns:

- +1444.XXXXXXX, strip pre-dot, numbering type: subscriber
- +1.!, strip pre-dot, numbering type: national

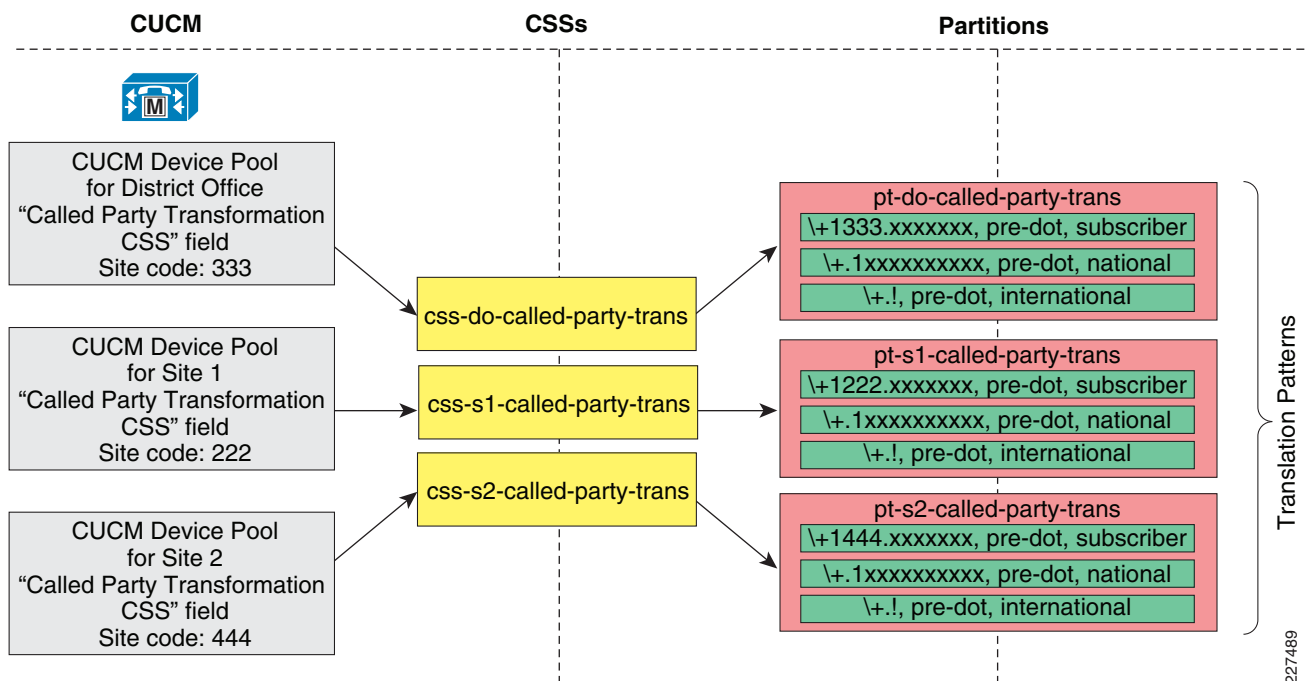

As the call is delivered to the Site 1 gateway, the called-party number matches both of the called-party transformation patterns. However, the first one is a more precise match and is selected to process the called party number. Thus, the resulting transformed number is 5552222, with a called party type set to subscriber.

If the gateway had not been able to process the call (for example, if all ports were busy), the call would have been sent to the Site 2 gateway to egress to the PSTN. The Chicago gateway is configured with the following two called-party transformation patterns:

- +1222.XXXXXXX, strip pre-dot, numbering type: *subscriber*
- +1.!, strip pre-dot, numbering type: *national*

As the call is delivered into the Chicago gateway, the called-party number matches only the second called-party transformation pattern. Therefore, the resulting called-party number offered to the gateway is 4445552222, with a called-party number type set to national.

Figure 7-8 shows how the device pool of the destination gateways determines the calling-party transformation.

Figure 7-8 Gateway Called-Party Transformation

Gateway Calling Party Number Localization

As a call is delivered to a gateway, the calling-party number must be adapted to the requirements of the PSTN service provider providing the trunk group that the gateway is connected to. The calling-party number transformation patterns can be used to change the calling-party number digit-string and numbering type. Typically, a calling-party number featuring the gateway's country code should be changed to remove the + sign and the explicit country code, and they should be replaced with the national prefix. Also, the numbering type of the calling-party number should be changed to *national*. If the gateway is connected to a trunk group featuring a specific area, region, or city code, the specific combination of + sign, country code, and local area code usually must be replaced by the applicable local prefix. Also, the numbering type must be adjusted to *subscriber*.

For example, assume that a call from a Site 1 user (+1 444 567 1234) is routed through a route list featuring a San Francisco gateway as a first choice and a Chicago gateway as a second choice. The San Francisco gateway is configured with two calling-party transformation patterns:

- +1444.XXXXXXX, strip pre-dot, numbering type: *subscriber*
- +1.!, strip pre-dot, numbering type: *national*

As the call is delivered to the Site 1 gateway, the calling-party number matches both calling-party transformation patterns. However, the first one is a more precise match and is selected to process the calling-party number. Thus, the resulting transformed number is 5671234, with a calling-party type set to *subscriber*.

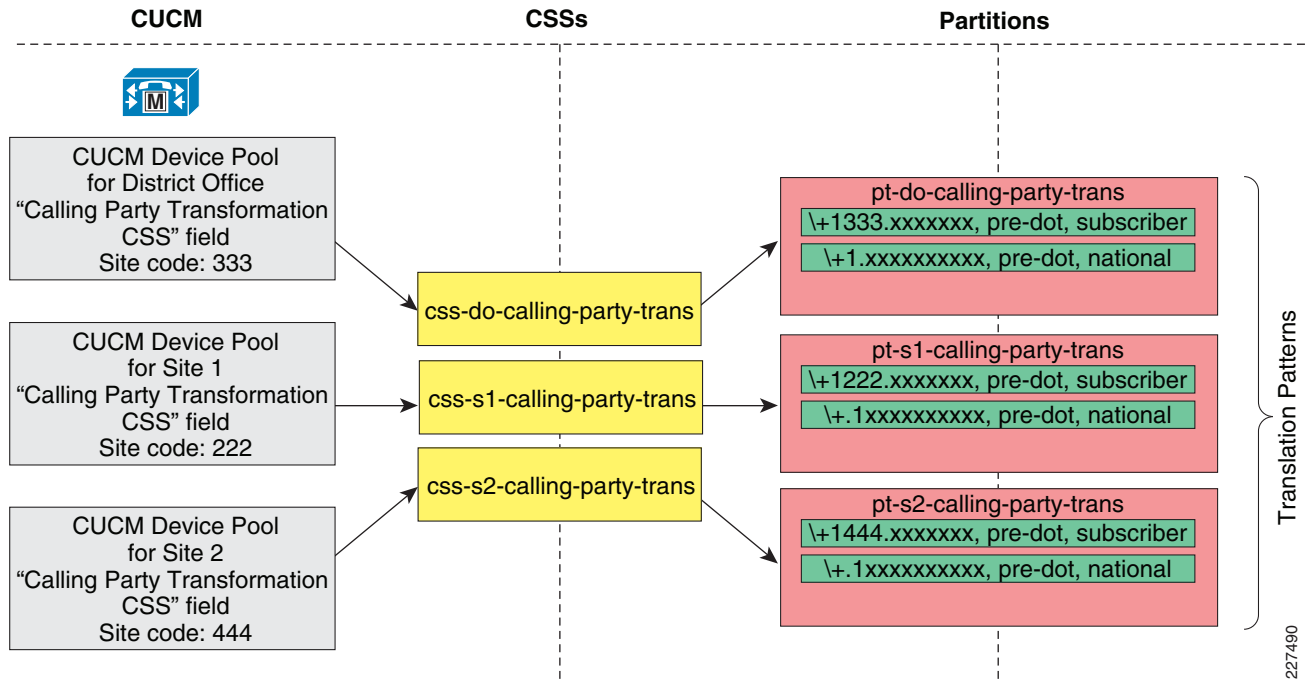

If the gateway had not been able to process the call (for example, if all ports were busy), the call would have been sent to the Site 2 gateway to egress to the PSTN. The Site 2 gateway is configured with the following two calling-party transformation patterns:

- +1222.XXXXXXX, strip pre-dot, numbering type: *subscriber*
- +1.!, strip pre-dot, numbering type: *national*

As the call is delivered into the Chicago gateway, the calling-party number matches only the second calling-party transformation pattern. Therefore, the resulting calling-party number offered to the gateway is 4445671234, with a calling-party number type set to *national*.

Figure 7-9 shows how the device pool of the destination gateways determines the calling-party transformation pattern.

Figure 7-9 Gateway Calling-Party Transformation Pattern

Building Classes of Service for Unified CM with the Line/Device Approach

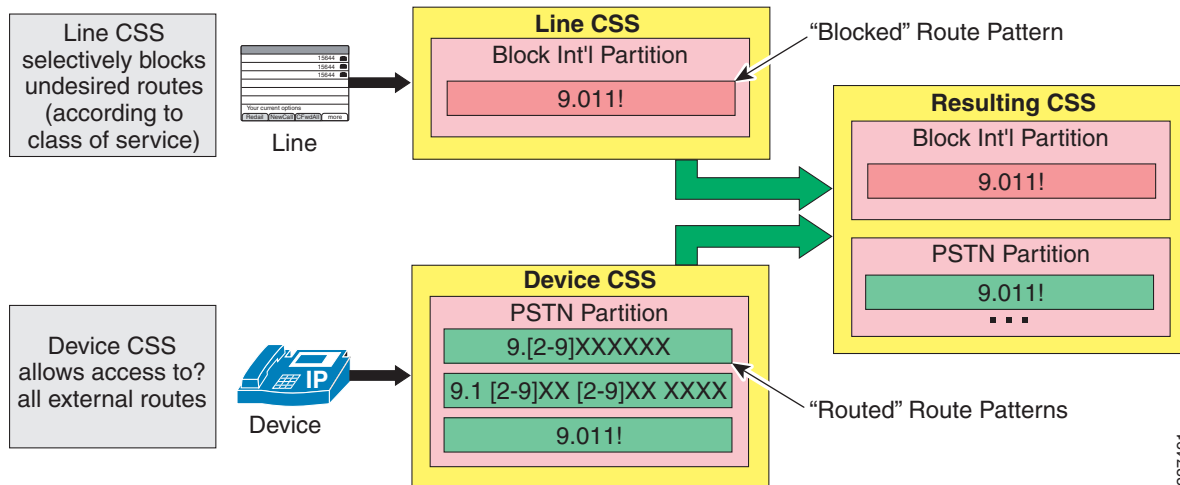

Class-of-Service (CoS) for the Cisco Unified CM refers to the ability to apply call restrictions to certain users and/or phones in the dial plan. The dial plan outlined above allows every IP phone to dial any destination; local, long distance, or international. When it is necessary to dial restrictions to certain phones, this document uses the line/device approach.

The line/device approach works by appending the line CSS to the device CSS on each phone. If the same route pattern appears in two partitions, one contained in the line's calling search space and one contained in the device's calling search space, then the Cisco Unified CM selects the route pattern listed first in the concatenated list of partitions (in this case, the route pattern associated with the line's calling search space).

In the route plan listed above, every phone had a device CSS that allowed it to call any destination. CoS will be applied by defining a line CSS for the restricted lines, that will override the device CSS and deny access to defined call destinations.

To better understand how to apply these rules, consider the example shown in [Figure 7-10](#), where the device calling search space contains a partition with route patterns to all PSTN numbers, including international numbers. The route patterns point to a PSTN gateway via the route list and route group construct.

Figure 7-10 Line/Device Approach

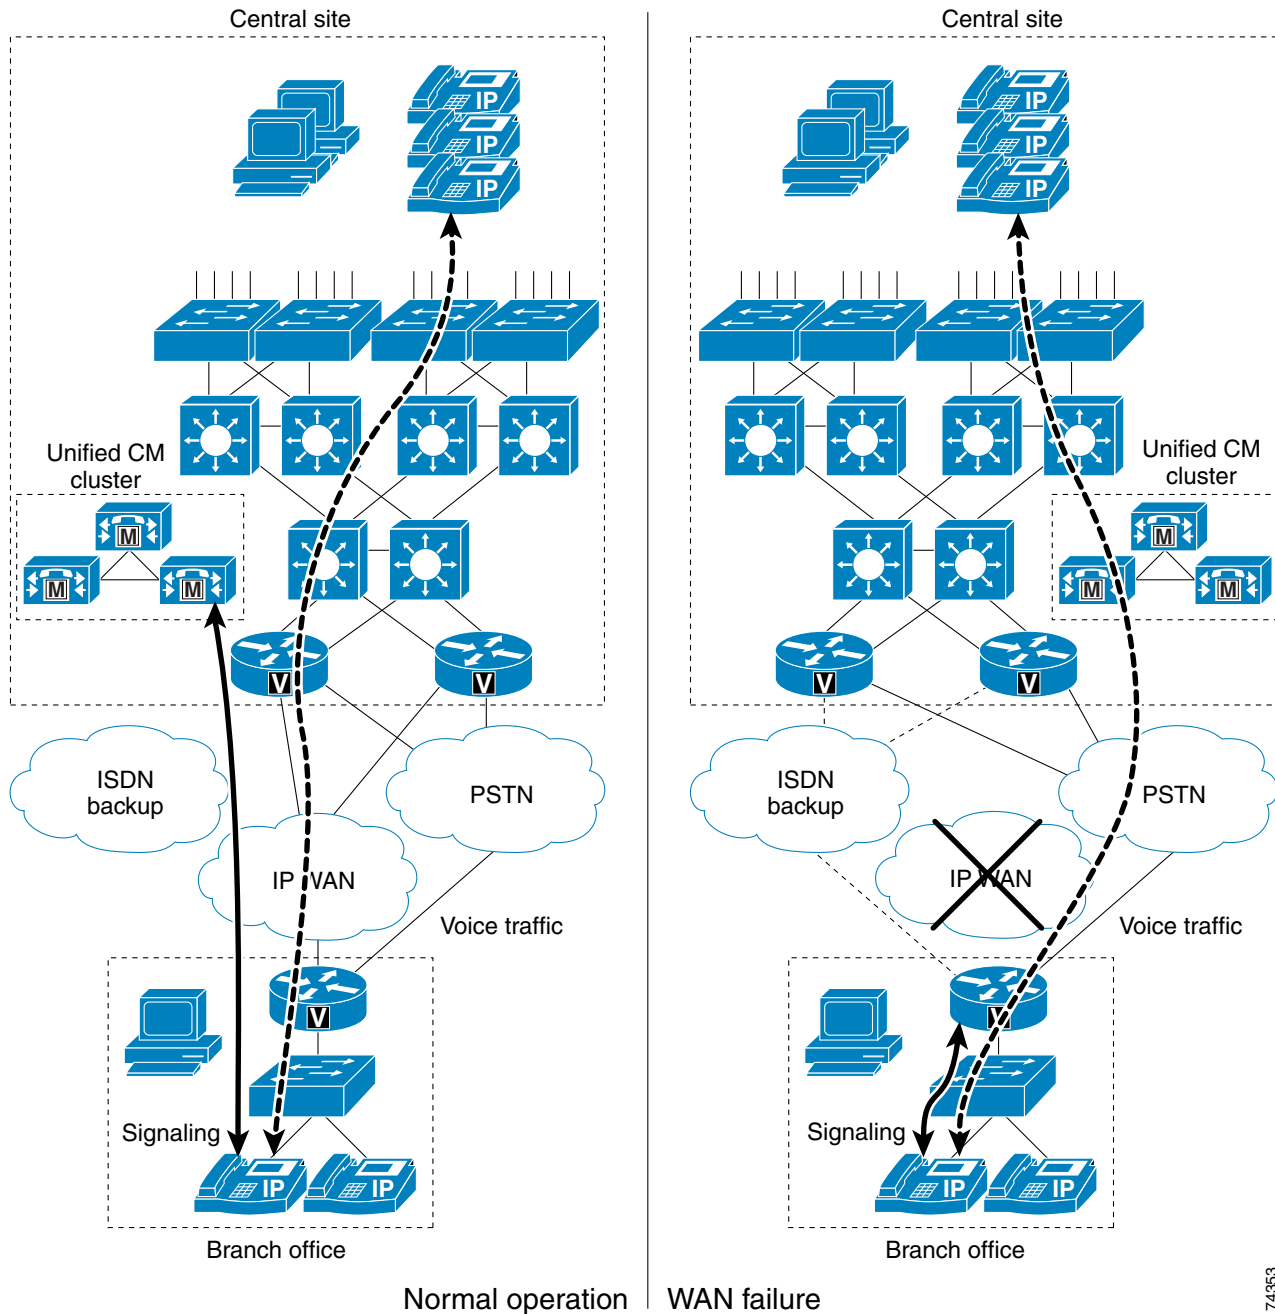

At the same time, the line calling search space contains a partition with a single translation pattern that matches international numbers and that has been configured as a blocked pattern. The resulting calling search space therefore contains two identical patterns matching international numbers, with the blocked pattern in the line calling search space appearing first. The result is that international calls from this line will be blocked.

Survivable Remote Site Telephony (SRST)

When deploying the Cisco Unified Communications across a WAN with the centralized call processing model, additional steps must be taken to ensure that data and voice services at the remote sites are highly available.

The Schools SRA design uses SRST to provide high availability for voice services, by providing a subset of the call processing capabilities within the remote office router and enhancing the IP phones with the ability to "rehome" to the call processing functions in the local router if a WAN failure is detected.

[Figure 7-11](#) illustrates a typical call scenario with SRST.

Figure 7-11 Survivable Remote Site Telephony (SRST)

74353

Under normal operations shown in the left part of [Figure 7-11](#), the branch office connects to the central site via an IP WAN, which carries data traffic, voice traffic, and call signaling. The IP phones at the branch office exchange call signaling information with the Cisco Unified CM cluster at the central site and place their calls across the IP WAN. The branch router or gateway forwards both types of traffic (call signaling and voice) transparently and has no knowledge of the IP phones.

If the WAN link to the branch office fails, or if some other event causes loss of connectivity to the Cisco Unified CM cluster, the branch IP phones reregister with the branch router in SRST mode. The branch router SRST queries the IP phones for their configuration and uses this information to build its own

configuration automatically. The branch IP phones can then make and receive calls either internally or through the PSTN. The phone displays the message “*Unified CM fallback mode*,” and some advanced Unified CM features are unavailable and are grayed out on the phone display.

When WAN connectivity to the central site is reestablished, the branch IP phones automatically reregister with the Unified CM cluster and resume normal operation. The branch SRST router deletes its information about the IP phones and reverts to its standard routing or gateway configuration. Unified CME running in SRST mode at the branch can choose to save the learned phone and line configuration to the running configuration on the Unified CME router by using the auto-provision option. If auto-provision none is configured, none of the auto-provisioned phone or line configuration information is written to the running configuration of the Unified CME router. Therefore, no configuration change is required on Unified CME if the IP phone is replaced and the MAC address changes.

**Note**

When WAN connectivity to the central site is reestablished, or when Unified CM is reachable again, phones in SRST mode with active calls will not immediately re-register to Unified CM until those active calls are terminated.

SRST CUCM Configuration

When communication with the CUCM is lost, the default SRST action is for IP phones to attempt to register to the router listed as their default gateway. In the example deployment used in this guide, the IP phones default gateway is not the ISR router running SRST, so a SRST instance needs to be configured on CUCM to tell the IP phones what router to register with instead when communication with CUCM is lost. The SRST reference is configured to point to the ISR router. This is configured by navigating to **System -> SRST** on CUCM. See [Figure 7-12](#).

Figure 7-12 **Configuring SRST Reference**

Emergency Notification of 911 Calls with Cisco Emergency Responder

Ease of administration for adds, moves, and changes is one of the key advantages of IP telephony technology. To provide for adds, moves, and changes that automatically update 911 information without user intervention, Cisco has developed a product called the Cisco Emergency Responder (Cisco ER).

The Schools SRA design uses Cisco ER to provide the following primary functionality:

- Dynamic association of a phone to an ERL, based on the detected physical location of the phone.
- Dynamic association of the emergency location identification number (ELIN) to the calling phone, for callback purposes. Cisco ER enables the callback to ring the exact phone that initiated the 911 call.
- On-site notification to designated parties (by pager, web page, or phone call) to inform them that there is an emergency call in progress. The pager and web page notifications include the calling-party name and number, the emergency response location (ERL), and the date and time details associated with the call. Phone notification provides the information about the calling number from which the emergency call was placed.

Note

For more information on Cisco ER, refer to the *Unified Communications SRND* and to the Cisco ER product documentation available online at the following URL:

http://www.cisco.com/en/US/products/sw/voicesw/ps842/tsd_products_support_series_home.html

The key functionality of Cisco ER relies on the detection of the phone's location by discovery of the network port (Layer-2 port, such as a Fast Ethernet switched port) from which the phone made the 911 call. The discovery mechanism relies on two main assumptions:

- The wired infrastructure of the enterprise is well established and does not change sporadically.
- The infrastructure is available for Cisco ER to browse; that is, Cisco ER can establish Simple Network Management Protocol (SNMP) sessions to the underlying network infrastructure and can scan the network ports for the discovery of connected phones.

Once the Cisco ER discovers the originating port for the call, it associates the call with the preestablished ERL for the location of that port. This process also yields an association with a preestablished ELIN for the location and the selection of the appropriate egress point to the E911 infrastructure, based on the originating ERL.

The School SRA dial plan is configured so that the system easily recognizes emergency calls, whether an access code (for example, 9) is used or not; the system has been configured to recognize both the strings 911 and 9911. The emergency route patterns have also been explicitly marked with urgent priority so that Unified CM does not wait for the inter-digit timeout (Timer T.302) before routing the call.

Voice Messaging

The Cisco Unified Communications messaging portfolio consists of three main messaging products: Cisco Unity, Cisco Unity Connection, and Cisco Unity Express. Each product fits different requirements, yet each one contains overlapping features and scalability with regard to the others. They also have the ability to interwork with one another using Voice Mail Networking and can also leverage the Cisco Unified Messaging gateway to achieve this in a highly scalable fashion, as discussed later in

this chapter. When considering these products, it helps to think of the messaging types that the products apply to in order to understand the messaging options they include and to determine which options could fit your deployment requirements. The following definitions help define these messaging types:

- *Voicemail-only*—Refers to a telephony voicemail integration where there is no access to the voicemail via any messaging client.
- *Integrated messaging*—Refers to voicemail with telephony access as well as voicemail-only access via a messaging client.
- *Unified messaging*—Refers to voicemail with telephony access as well as voicemail, E-mail, and fax access via a messaging client.

Based on the above messaging types and definitions, the three messaging product options are as follows:

- *Cisco Unity*—This solution option scales to meet the needs of large enterprise organizations and delivers powerful voice, integrated, and unified messaging options that integrate with Microsoft Exchange (including Exchange 2007) and Lotus Domino.
- *Cisco Unity Connection*—This option combines integrated messaging, voice recognition, and call transfer rules into an easy-to-manage system for medium-sized businesses with up to 10,000 users, or it can network up to 5 systems to support larger-sized businesses with up to 50,000 users. For organizations with up to 500 users, Cisco Unity Connection is available as a single-server solution with Cisco Unified Communications Manager Business Edition.
- *Cisco Unity Express*—This option provides cost-effective voice and integrated messaging, automated attendant, and interactive voice response (IVR) capabilities in certain Cisco Integrated Services Routers for small and medium-sized businesses and enterprise branch offices with up to 250 users.

For the Schools SRA test network, Cisco Unity 7.0 for Microsoft Exchange was deployed. Deploying Unity allows for a centralized deployment with the greatest scalability and broadest feature set. The following Unity collaboration capabilities are important in this decision;

- *Unified messaging*—Cisco Unity unified messaging integrates transparently with Microsoft Exchange, allowing you to handle all your messages - E-mail, voice, and fax - through a single inbox using the Outlook E-mail client. Icons provide simple visual descriptions of each message type, and because every message is delivered to one inbox, you can see the number, type, and status of all your communications at a single glance. You also can reply to, forward, and save your messages - regardless of media type - in public or personal Microsoft Outlook folders with just a click of the mouse, decreasing response times and increasing organizational agility and customer service.
- *Mobile access to voice messages*—Cisco Unity unified messaging delivers all-in-one messaging for mobile users. Mobile workers using a Palm Treo or RIM BlackBerry device can simply double-click to play voice messages within their smartphone E-mail applications. The Cisco Unity solution supports a variety of notification options that allow you to customize the way you are notified of new voice messages. Cisco Unity Unified Messaging for Microsoft Exchange users can access their voice messages using Cisco Unified Mobile Communicator, which integrates with Exchange to provide mobile access to messages. Even for users with basic mobile phones, the Cisco Unity solution is optimized to enhance mobile productivity. When you call in from a mobile phone, speech recognition allows for hands-free usage of the system. If a call is dropped because of a less-than-fully reliable mobile phone network, the Interrupted Session Recovery feature resumes, on the next call-in, the session where the call left off, reducing lost time.

**Note**

Unity requires integration with Microsoft Active Directory and Exchange, smaller school districts might opt for a simpler Cisco Unity Connections deployment instead of deploying Unity.

Cisco Unified Personal Communicator 7.0

Cisco Unified Personal Communicator provides a very versatile communications platform to the schools SRA. Cisco Unified Personal Communicator is a Microsoft Windows or Apple Mac application that operates in one of two modes, Desk Phone (CTI control of the user's desk phone for click to call) and Soft Phone (software client operation), and it is supported on Apple Macintosh and Microsoft Windows platforms.

Cisco Unified Personal Communicator integrates the most frequently used communications applications and services into a single desktop software application. Cisco Unified Personal Communicator facilitates streamlined communications from your desktop or laptop computer, including integrated contact lists, click to call, instant messaging, voicemail playback, inbound call notification, and media escalation. By being able to control your communications from a single window, you can communicate more effectively and be more productive.

Figure 7-14 Cisco Unified Personal Communicator

Cisco Unified Personal Communicator Features and Benefits

- *Communication integration*—Take advantage of a single, intuitive interface for voice and video calls, instant messaging, voicemail playback, web conferencing, and integrated directories.
- *Presence*—View real-time availability of other Cisco Unified Personal Communicator and Cisco Unified IP Phone users. You can also display customized messages, set an out-of-office message, and automatically show your availability based on free and busy status on your Microsoft Outlook Calendar.
- *Do not disturb (DND)*—Easily block incoming calls with synchronized DND status from your Cisco Unified Personal Communicator or Cisco Unified IP Phone or use the privacy preference setting to block instant messages when you need additional privacy.
- *Contact list*—Search your corporate directory from one easy-to-use interface to locate contacts quickly and simply click to call. Add your most frequently contacted personal contacts, co-workers, and federated business contacts

- *Media escalation*—Add communication methods during a conversation; for example, you can add video to an audio conversation or add web conferencing or white-boarding to an existing audio or video conversation.
- *Click to call*—Dial from the contact list, using either the integrated softphone or an associated Cisco Unified IP Phone. You can also click to call directly from Microsoft Outlook using an Outlook toolbar.
- *Integrated voice and video calling*—Exchange ideas face-to-face with a coordinated video display on the PC screen and audio conversation with the softphone. You can place video calls using Cisco Unified Personal Communicator, Cisco Unified Video Advantage, or the Cisco Unified IP Phone 7985G, a personal desktop videophone.
- *IP phone association*—Use Cisco Unified Personal Communicator to control your desktop Cisco Unified IP Phone to make, receive, or merge calls.
- *Instant messaging*—Chat in real time using instant messaging with other Cisco Unified Personal Communicator users to save time and reduce phone tag. In addition, enable business-to-business federation between Cisco Unified Presence and Microsoft Live Communications or Microsoft Office Communications server to exchange presence information and instant messages with Microsoft Office Communicator and Cisco Unified Personal Communicator users.
- *Conferencing*—Create voice or video conferencing sessions by simply merging conversation sessions. There is no need to call into a separate conference bridge.
- *Web conferencing*—Launch a Cisco Unified MeetingPlace, Cisco Unified MeetingPlace Express, or Cisco WebEx web conferencing session at a moment's notice to share content, such as a presentation, with others.
- *Voice messages*—Access secure Cisco Unity® or Cisco Unity Connection encrypted voicemail messages - view, play back, sort, and delete messages - all from within the application.
- *Languages supported for both Microsoft Windows and Apple Macintosh desktops include*—Arabic, Chinese (Traditional Chinese and Simplified Chinese), Danish, Dutch, English, French, German, Italian, Japanese, Korean, Portuguese (Brazilian), Spanish, Russian, and Swedish.

Cisco Unified Mobility

Cisco Unified Mobility is natively available with Cisco Unified CM on the school SRA network. Cisco Unified Mobility extends rich call control capabilities of Cisco Unified Communications Manager from a mobile worker's primary workplace desk phone to any location or device of their choosing.

Some of the key benefits of enabling Cisco Unified Mobility capabilities with Cisco Unified Communications Manager include:

- *Single Business Number Reach and Single Business Voicemail*—Cisco Unified Mobility makes it possible for workers to consolidate all their incoming business calls (i.e. incoming business calls to mobile phones, home office phone, or any temporary telework phone) into a single business phone number and immediately receive them wherever they are working. Coworkers, business partners, and customers now only need a single business phone number to reach workers who can be more responsive without additional effort. If mobile workers are unable to answer the call extended to one of the many user-defined alternative phone numbers, they can rely on Cisco Unified Mobility to store the unanswered calls into a single business voicemail on Cisco Unity® or other business voicemail system. Cisco Unified Mobility reduces the burden on workers of having to share multiple phone numbers with business contacts and having to check multiple voicemail boxes at the end of the day.

- *Seamless Transition of Ongoing Extended Communications*—Mobile phones are great when moving from location to location, but when a mobile worker arrives at the office, they would rather take advantage of speakerphone or other IP Phone services on their Cisco Unified IP Phone at their desk. Cisco Unified Mobility provides seamless transition of extended ongoing calls from mobile phones to desk phone and vice versa. This provides workers with the ability to maintain business communications continuity while taking advantage of least cost routing of mobile calls across company's IP communications infrastructure while in the office. Hence they can start the conversation from their mobile phone and seamlessly transition that conversation to a desk phone upon arrival in the office without needing to call back. Similarly they can transition the call seamlessly back to the mobile phone and wander away at will for another appointment.
- *Cisco Mobile Voice Access*—With Cisco Unified Mobility, workers who need to place national or international calls from their mobile phone can use the Cisco Mobile Voice Access line to place the call as if they are placing the call from their business extension on their desk. The worker dials the Cisco Mobile Voice Access line from the mobile phone and places the call on the IP communications network over a tie line. The call is connected and remains in control of Cisco Unified Communications Manager providing the opportunity to reduce mobile communications costs associated with national or international calls placed directly from mobile phone. With Cisco Mobile Voice Access, the person being called sees the caller-id as coming from a desk phone in the office rather than from the personal cell phone that may have actually initiated the call.
- *Access to Mid Call Control Cisco Unified Communications Manager Capabilities*—Cisco Unified Mobility extends key call control features of Cisco Unified Communications Manager (such as hold, resume, transfer, and conferencing) on calls extended to devices and locations of the workers choice. For workers who have become accustomed to such productivity capabilities in the office can now access them while they are away from their desk.
- *Personalized Access Lists*—Mobile workers can access the secure user profile webpage to enter mobile and other alternate phone numbers and create filters that restrict the types of calls that are extended using Cisco Unified Mobility. Cisco Unified Mobility intelligently manages, filters, and routes each call between a worker's business extension and alternate phone numbers based on rules defined by the worker on their profile. Unanswered calls are consolidated into single business voicemail and voice communications resources are only used to extend relevant calls as determined by rules specified by the worker.
- *Web-Based System Administration*—Cisco Unified Mobility provides system administrators with the flexible to define and manage user profiles. System administrators can use the secure Administration Webpage to determine how much control users will have over their profiles and make user profile changes when needed. Users enjoy the advantages of personal choice, while the system administrator retains control over resource use and can provide backup support.

Cisco Unified Mobile Communicator

Cisco Unified Mobile Communicator (see [Figure 7-15](#)) is an easy-to-use software application for mobile handsets that facilitates more effective communications for mobile employees. By extending enterprise communications applications and services to mobile phones and smartphones, Cisco Unified Mobile Communicator streamlines the communication experience, facilitating real-time collaboration across the enterprise. With Cisco Unified Mobile Communicator, you can place and receive calls, access company directory contacts, check presence information, and review voicemail messages, as well as receive Cisco Unified MeetingPlace® notifications and other vital information—all from a single, intuitive interface connected to Cisco Unified Communications.

Figure 7-15 Cisco Unified Mobile Communicator

Using Cisco Unified Mobile Communicator, employees have the Key Features and Benefits available on the mobile cellular phone;

- *Communication integration*—Use one intuitive interface for mobile calls, directory and presence information, voicemail playback, text messaging, and conferencing.
- *Unified contact list*—Search your corporate directory (Active Directory) and personal contacts (Microsoft Outlook) from one easy-to-use interface to locate contacts quickly. Simply select a name to call.
- *Presence*—Find a contact and see whether the person is available to talk-before placing the call. View a person's availability status from the directory on the mobile handset.
- *Select to call*—Dial from the directory by simply selecting a name.
- *Single-business-number reach*—Provide colleagues with a single number to reach you. Supported by Cisco Unified Mobility, calls to your desk phone can be answered from your mobile phone. If you are busy, simply decline or ignore the call and it will be diverted to your office voicemail.
- *Secure text messaging*—Send and receive text messages from colleagues when they are unavailable to talk. A visual list on your mobile handset shows at a glance who is trying to reach you. Incoming messages are conveniently grouped by person, showing the sender, the priority, and a brief subject line, if available.
- *Voice messages*—Access Cisco Unity® voicemail messages to select, view, play back, and delete messages in any order, all from the mobile handset.
- *Conferencing*—Receive notifications of conference calls on your mobile phone from the Cisco Unified MeetingPlace solution. Simply press a button to call the conference bridge.
- *Call logs*—View a list of recent calls on your mobile phone and learn what calls were missed, placed, and received from your mobile phone or your Cisco Unified IP Phone.
- *Security*—Cisco Unified Mobile Communicator is deployed securely behind the enterprise firewall. Cisco Unified Mobile Communicator uses industry-standard, Secure Sockets Layer (SSL) and Transport Layer Security (TLS) encryption to protect transmission of data between handsets and your data center. End users authenticate with existing Lightweight Directory Access Protocol (LDAP) directories. If a mobile handset is lost or stolen, IT staff can remotely deactivate the device and erase sensitive company information.
- *Management*—Simple, Web-based management allows IT staff to manage user activation, configuration, and administration; set system privileges and security; report statistics; and manage devices. The end-user portal allows provisioning, directory management, and configuration of user preferences.

- *Broad operator and device support*—Working simultaneously across multiple networks, mobile operators, and handset platforms, Cisco Unified Mobile Communicator helps ensure end-user choice and delivery of consistent performance at work, at home, and on the road.

CHAPTER 8

Digital Media and Video Surveillance Design

Digital Media System Overview

The schools Service Ready Architecture (SRA) network architecture in combination with the Cisco Digital Media System (DMS) creates an environment which streamlines and automates information flow and process throughout school districts.

The evolution of digital communication in the 21st century education environment is transforming processes and empowering educators to develop and deploy “eye-catching”, compelling, and integrated video content.

- Digital media communication in school systems is an extremely effective tool to deliver dynamic and cost effective subject matter to staff and students.
- Using digital media school systems keeps the education community connected, increases awareness, and integrates with safety and security system notifications.
- Integrating digital media technologies assists teacher's curriculum development and professional development.
- Comprehensive digital video systems transform video delivery processes in individual classrooms; school administrator can create customized, on-demand educational video content or even relay live video feed during national events or local emergencies.

Video Surveillance Overview

Video surveillance has been a key component of safety and security groups for many organizations. As an application, video surveillance has demonstrated its value and benefits countless times by providing real-time monitoring of a facility's environment, people, and assets as well as by recording events for subsequent investigation, proof of compliance, and audit.

For school systems that need to visually monitor or record events video, surveillance has become more important as the number of security risks increases. In addition to video analytics, the value of video surveillance has grown significantly with the introduction of motion, heat, and environmental sensors.

In a typical school environment, several systems are deployed for disparate applications, such as physical access control, fire and smoke detection, and video surveillance. These applications typically do not communicate with each other and require different management and support personnel. As a result, owners and operators suffer from a lack of operational consistency, interoperability, and capabilities that translate into higher capital and operational costs and limit the return on their investment.

Cisco's solution offers software and hardware to support video transmission, monitoring, recording, and management. Cisco video surveillance solutions work in unison with the advanced features and functions of the IP network infrastructure—switches, routers, and other network security devices—to enable secure, policy-based access to live and recorded video.

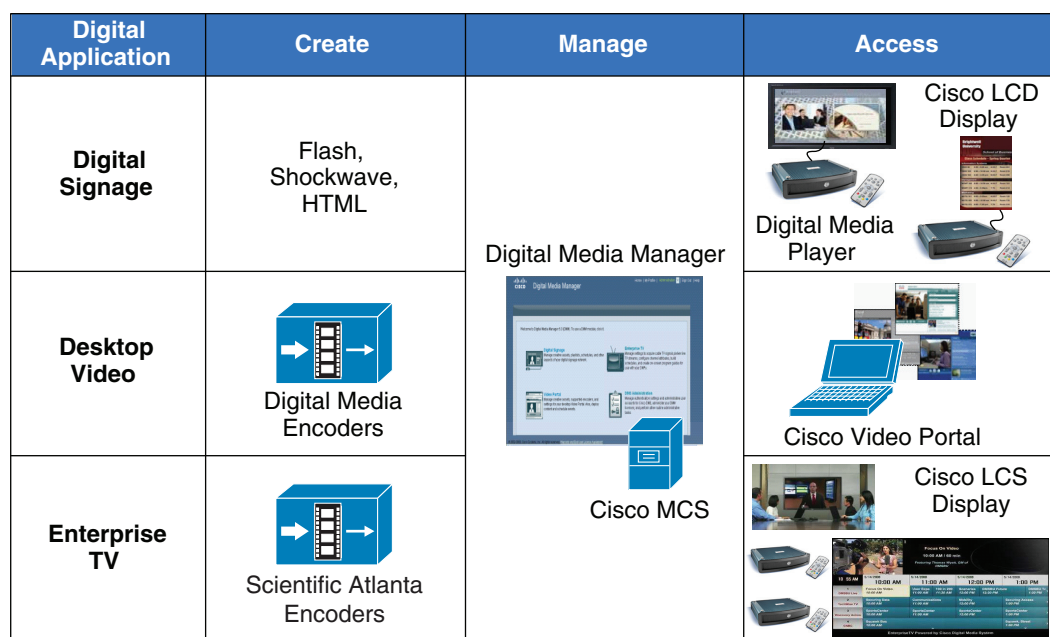

Cisco Digital Media System Architecture

Cisco has developed a comprehensive, scalable, and network-centric DMS architecture that is built on three major digital application components. Each application is specifically designed to address key challenges, regardless of how or where the digital content is designed and developed. The multifunction management and adaptive media system is common to these three applications:

- **Desktop video**—Interactive education training application that allow students to watch instructional videos on-demand or via live streaming. Students can use classroom PCs to navigate a Cisco Video Portal database to securely access relevant training video content.
- **Enterprise TV**—While the targeted users for desktop video applications are individuals or group of students, enterprise TV expands the same video capability to a larger audience and so extends the classroom. Live or on-demand pre-recorded training video can be broadcast in a classroom. In addition to internally developed video material, district and school administration can also enable live educational TV programming like science, discovery, etc.
- **Digital signage**—Enables innovative ways to publish content and information that improves the user experience, allows dynamic updates, and increases campus safety and security. Some of the common digital signage use cases in schools system include announcing school and district news, major events, classroom assignments, PTA meetings, etc.

Figure 8-1 shows a Cisco DMS solution suite that is a set of product and technologies developed to create an end-to-end digital media network. The products are divided into three major functions, create, manage, and access.

Figure 8-1 Cisco DMS Solution Suite

227853

The digital media components in the Cisco DMS solution suite assist schools in deploying digital media solutions at their own pace; e.g., initially deploy digital signage with simple development applications and deploy interactive video solutions in subsequent phases.

The Cisco Digital Media Manager (DMM) is a Web-based application that simplifies deploying all three digital media applications in schools.

DMS Solution for Schools

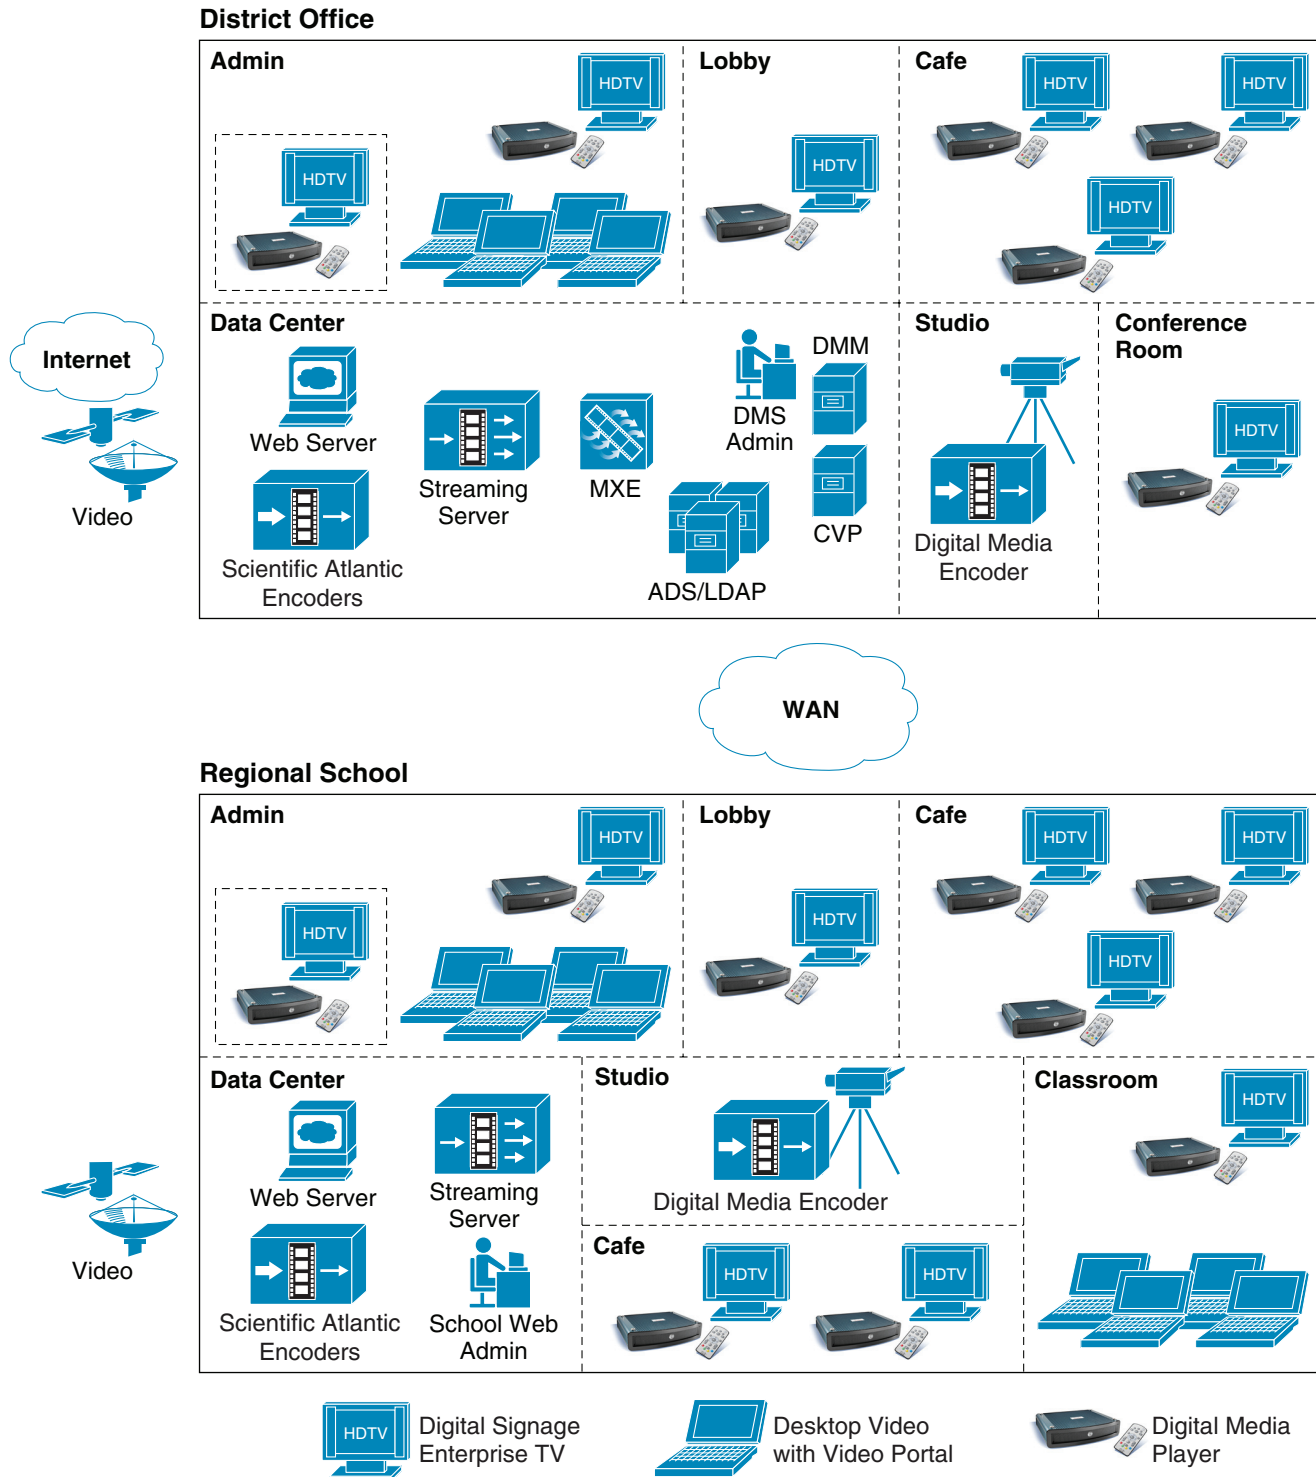

DMS solutions in schools have proven valuable in overcoming key challenges in the development of next-generation education delivery processes. DMS provides the flexibility to develop training content that can be accessed by students anytime, and anywhere. Cisco DMS relies on a resilient, scalable, and reliable network infrastructure for seamless end-to-end content delivery.

Figure 8-2 shows an end-to-end digital media reference model with all three applications enabling a unified digital network service for the school district.

The following are some of the key benefits of this DMS design model:

- Centralized management at the district office providing consistent publishing policies, security, scalability, and reduced operational and maintenance cost.
- Distributed storage and media access points enabling district office and schools to use centrally developed content with reduced bandwidth capacity and increased availability during network instability.
- In large-scale video networks, the Cisco Application and Content Network Services (ACNS) or WAN optimization appliances can be deployed to increase media performance and reduce expensive WAN bandwidth requirements.

Figure 8-2 End-to-End Reference DMS Solution in School Network Architecture

The following section provides an overview of various deployment scenarios, device components, communication, and network requirements for digital media applications in schools. For a detailed digital media design and implementation guide, refer to:

http://www.cisco.com/en/US/docs/solutions/Enterprise/Video/DMS_DG/DMS_dg.html

Desktop Video Application Overview

Students, teachers, and administrative staff can watch live or pre-recorded video events from their personal computers at any location and at any time. The Cisco DMS Digital Video application empowers faculty to extend the classroom audience to remote locations by broadcasting live or recording training sessions available as video on-demand (VoD).

Cisco Desktop Video applications offer several benefits:

- Customizable interface with program guide and search window.
- Students can create a personalized video playlist.
- Questions and comments can be made during live video broadcast events.
- Restrict video content access based on Active Directory or LDAP authentication and privilege.
- Wide format support—Adobe Flash, Windows Media, H.264, QuickTime, etc.
- Player Controls—Synchronized slides, advanced video and controls, etc.

Desktop Video Components

As one of the integrated components of the Cisco DMS solution suite, the digital video application uses common video development, management, and publishing components. In combination, external authentication servers can provide secure, on-demand video content and live video broadcast services to the desktop or on Cisco LCD TVs deployed in different physical locations.

The Cisco DMS solution suite consists of:

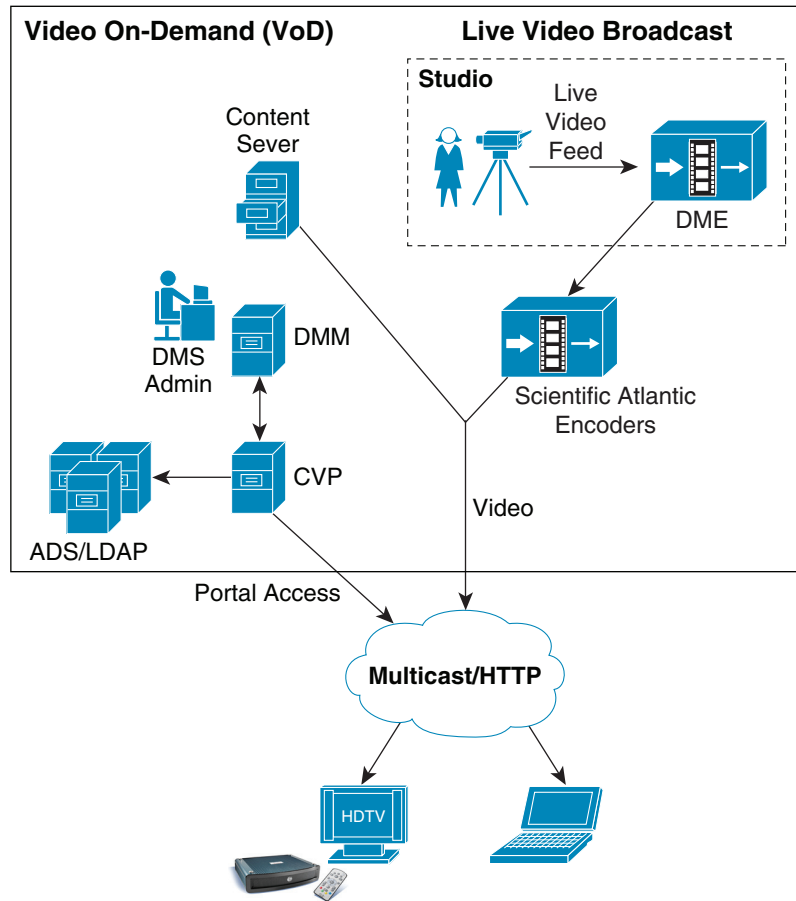

- Digital Media Manager (DMM)—Centralized management appliance in district office governs the content and communicates with local or remotely deployed critical desktop video components, e.g., CVP, HTTP server etc.
- Digital Media Encoder (DME)—Single or multi-channel media encoder receives live analog/digital feed from cameras or television service providers and transports over the IP network to the streaming server.
- Streaming Server—Provides stream splitting capabilities, allowing many clients to view a single live stream from DME or pre-recorded source (replay)
- Cisco Video Portal (CVP)—Web-based video navigation engine provides access to users after successful authentication with Active Directory or LDAP server.
- Web Server/Content Repository—Stores all VoDs referenced by Video Portal server. User triggers VoD request to access video content through CVP and the request gets redirected to pull video file from the content repository to the requested user.

Publishing Live and Video On-Demand Content

A critical feature of the Cisco Digital Media System for Cisco Desktop Video is its ability to simplify the publishing of live and on-demand digital media files to the Cisco Video Portal (CVP). On-demand video content can be uploaded from the developer's computer directly to the DMM server for staging and previewing prior to deployment. This staging capability includes the addition of an approval process within the content workflow to help ensure that school branding, publishing policies, and messaging are properly incorporated in the content. Post approval process, the content can be moved or deployed to the Cisco Video Portal using secure file transmission.

The Cisco DMM works in conjunction with Cisco Digital Media Encoders (DME) to create and deploy live content to the Cisco Video Portal. The Cisco DMM first manages the Cisco DME to set up their encoding profiles, defining the bit rate, format, and media type. The Cisco DMM also defines the port that the Cisco Digital Media Encoders will stream from, so that the streaming servers can pull the stream to their live publishing points. These publishing points are then deployed to the Cisco Video Portal through the Cisco Digital Media Manager deployment process. The same workflow defined for the on-demand digital media content is applied to live events, providing a consistent, easy-to-use process for all types of deployments. Figure 8-3 shows a schematic of Cisco DMM video management.

Figure 8-3 VoD and Live Video Broadcast Using Digital Video Application

Enterprise TV Application Overview

The Enterprise TV (ETV) application brings standard or high-definition television network channels into IP-based networks. Deploying Scientific Atlanta encoders in a video head-end role performs the interworking function that transforms video source from television service provider to an IP based video delivery within the campus network. When the ETV module is enabled in Cisco DMM appliance, the school administrator can program the channel guide information to be broadcast in different physical locations, e.g., channel number, name, port number, etc. To improve the user experience in navigating video channels, ETV Electronic Program Guide (EPG) can be programmed to provide information on channel lineup, and current and future programming information, which is similar to television service

provided programming guide. To watch the live video channels, users can use Cisco DMP and remote control to navigate and access the channel. Video delivery over IP networks can be unicast or multicast, depending on how IP/multicast is designed in campus network.

With larger displays in key physical locations, the ETV application becomes the primary communications interface in the district targeting large audiences. For example, live or VoD broadcast for education training, demonstrations, meetings, etc., targeting all the students in a classroom, or live news, etc.

Enterprise TV Components

To broadcast school developed VoD or live video through ETV, the core Cisco DMS components used in the desktop video application can be leveraged to integrate ETV in the network. The primary difference between ETV and desktop video in this case would be Digital Media Player (DMP) instead of a PC as an access end point for a large screen display targeting a larger audience. To broadcast television network channels in the campus network, the Scientific Atlanta encoder must be integrated along with other ETV components. It is recommended to deploy distributed television service in local campus and not forward non-critical video traffic over the WAN infrastructure.

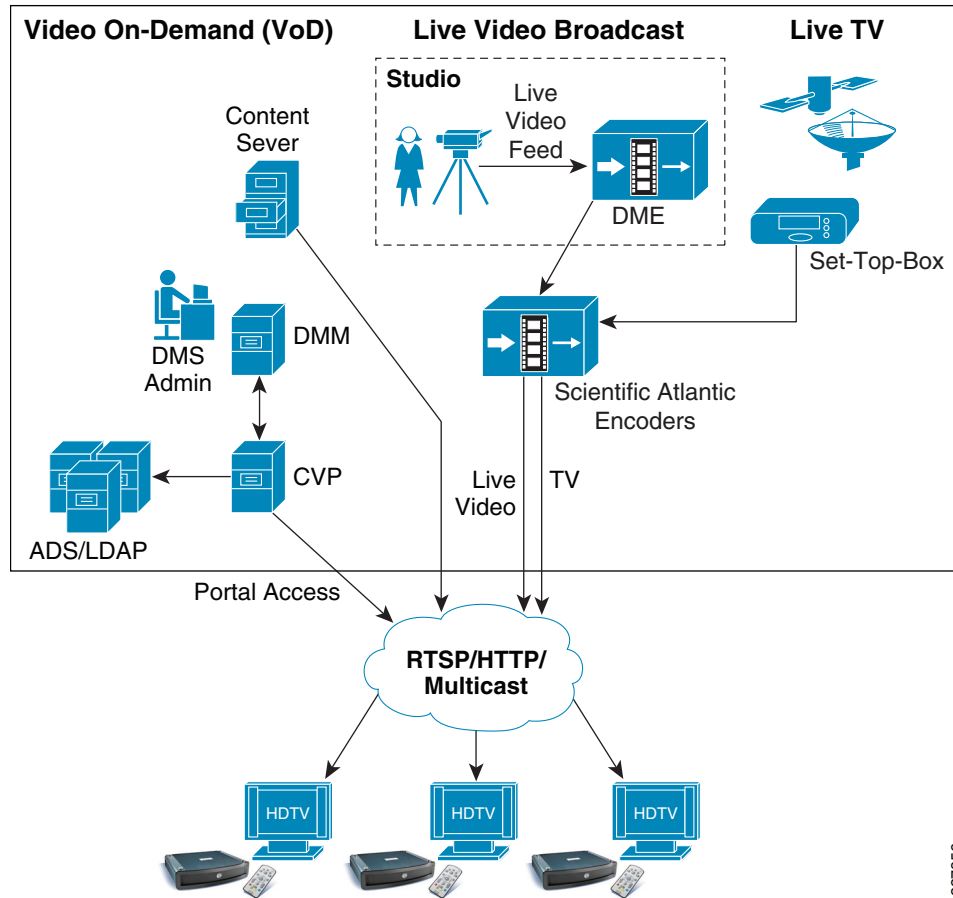

- Scientific Atlanta Encoder—An encoder system that provides interworking function between analog or digital television service provider and IP network. Encodes live video input and transforms into MPEG-2 or MPEG-4 multicast stream.
- Cisco Digital Media Player (DMP)—Key media access end point that connects to Cisco LCD TV for large size displays. DMP provides capabilities to decode multi-format graphics and stream video content received over unicast or multicast IP network.

Broadcasting Live TV or Video On-Demand Content

The communication flow between the DMP and the DMM and Video Portal function is similar to desktop video applications. Proper planning, technologies, and equipment must be deployed in campus network for successful live television video delivery. When designing the playlist in Cisco Enterprise TV module, the school administrator must understand that it can support up to 99 live and on-demand video channels broadcast in the campus network. The DMM administrator in the district office can use the DMM-ETV software module to create customized TV navigation interfaces, such as adding school logo and skins, programming video channel assignments, and configuring specific video channel assignment to DMP deployed in specific campus location. [Figure 8-4](#) shows a schematic of the Enterprise TV video architecture.

District and school architects must understand the codec type required for publishing video in the campus network. Deployed digital encoders must follow the MPEG2 standard specification to stream the video. It is recommended to deploy Scientific Atlanta 9032SD or 9050HD encoder to stream live video stream to DMP for Enterprise TV application.

Figure 8-4 Live Video Broadcast and VoD Using Enterprise TV Application

Digital Signage Application Overview

Cisco's Digital Signage solution is a comprehensive solution for the publishing of dynamic and on-demand signage using digital media displays deployed locally or regionally in schools over an IP network. The key benefits of digital signage over traditional static signs in school are that the digital content can be exchanged and updated more dynamically, using digital media tools to make the content more relevant and interactive. Publishing school messages, local announcements, or emergency alerts through Cisco digital signage becomes more effective and with better investment return compared to traditional models.

The Cisco digital signage application is a Web-based media management and publishing application that creates a playlist with a set of content that is required to be published to a single or group of DMPs in a network. The digital signage application use standard HTTP protocols to communicate with centrally deployed DMM in the district office data center and single or distributed Web servers to pull and publish the real-time information to display on large Cisco LCD TVs. With flexible user administration, the DMM administrator is empowered to create groups of users with different privileges who can develop, publish, and manage the signage content; e.g., user group like school Web admin, IT admin, and security admin can create content assets, control display properties, etc.

Digital Signage Components

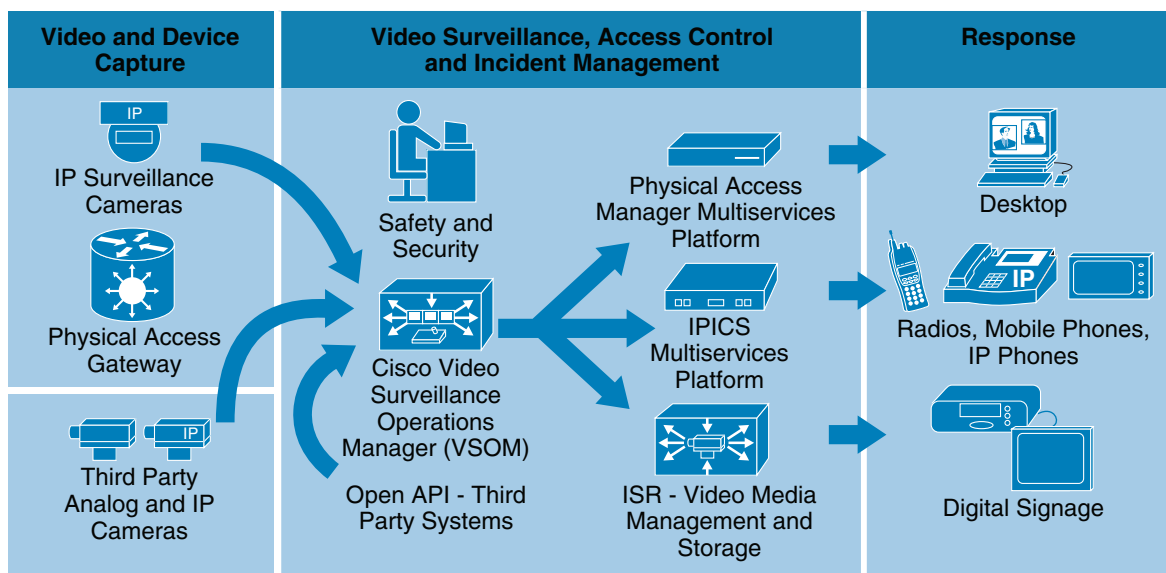

The requirements of the integrated digital media components depend on which content needs to be published through a signage module. The Cisco digital signage application provides the flexibility for the DMM administrator or school Web administrator to develop multi-functional, integrated content that can play key messages, stream VoD files from a content server, and keep connected with external information. For example, schools can publish a single Adobe flash file that is composed of static text information, embedded with education short VoD stream and live news information with RSS feed. The basic digital signage components are:

- **Digital Media Manager (DMM)**—Centralized management appliance in district office governs the content and communicate with local or remotely deployed critical desktop video components, e.g., CVP, HTTP server, etc.
- **Cisco Digital Media Player (DMP)**—The Cisco DMP is a highly reliable IP-based hardware endpoint for video decoding and playback of digital media content—including high-definition live broadcasts and VoD, Flash animations, text tickers, and other Web content—across digital displays. DMP is a critical component of the digital signage and ETV applications allow for the networking of digital displays and the broadcasting of live and on-demand media. The current DMP portfolio includes the Cisco DMP 4305G for standard signage and ETV and the Cisco DMP 4400G for high-end signage and ETV.
- **Cisco LCD Professional Series**—For an end-to-end Cisco digital media solution, the Cisco LCD professional series displays is a high definition LCD display that can be centrally managed through DMM.
- **Web Server/Content Repository**—Stores all HTML, VoDs, flash files referenced by HTTP server or Video Portal server. Multiple files can be played on same DMP; based on Web application design, the program triggers the content request and it is pulled by DMP from a source server.

Video Surveillance System Architecture

The Cisco Video Surveillance solution relies on an IP network infrastructure to link all components. The design of a highly available hierarchical network has been proven and tested for many years and allows applications to converge on an intelligent and resilient infrastructure.

[Figure 8-5](#) shows the main components of the Cisco Physical Security solution, including video surveillance, physical access control, incident response and integration with third-party systems.

Figure 8-5 Cisco Physical Security Components

Some of the benefits of Cisco's Video Surveillance solution include the following:

- Access to video at any time from any network location, enabling real-time incident response and investigation.
- Transfer of control and monitoring to any other point in the network in an emergency situation.
- Ability to manage devices and alarms from a centralized location.
- Ability for products from various vendors to interoperate in the same network.
- An open, standards-based infrastructure that enables the deployment and control of new security applications.

The main components of the Cisco Video Surveillance solution include the following:

- **Cisco Video Surveillance Media Server**—The core component of the network-centric Video Surveillance Manager solution. This software manages, stores, and delivers video from a wide range of cameras and encoders over an IP network
- **Cisco Video Surveillance Operations Manager**—The Operations Manager authenticates and manages access to video feeds. It is a centralized administration tool for management of Media Servers, Virtual Matrixes, cameras, encoders, and viewers and for viewing network-based video.
- **Cisco Video Surveillance IP Cameras**—The high-resolution digital cameras are designed for superior performance in a wide variety of environments.
- **Cisco Video Surveillance Virtual Matrix**—The Virtual Matrix monitors video feeds in command center and other 24-hour monitoring environments. It allows operators to control the video being displayed on multiple local and remote monitors.
- **Cisco Video Surveillance Encoding Server**—This all-in-one appliance encodes, distributes, manages, and archives digital video feeds for analog cameras. Each server encodes up to 64 channels and provides up to 12 TB of storage.
- **Cisco Video Surveillance Storage System**—This complementary component allows the Media Server's internal storage to be expanded with direct attached storage (DAS) and storage area networks (SANs). The Storage System allows video to be secured and accessed locally or remotely.

The following subsections describe the components used for this solution.

Cisco Video Surveillance Media Server

The Cisco Video Surveillance Media Server (VSMS) is the core component in the Cisco Video Surveillance Manager solution and performs the following networked video surveillance system functions:

- Collection and routing of video from a wide range of third-party cameras and video encoders over an IP network
- Event-tagging and recording of video for review and archival purposes
- Secure local, remote, and redundant video archive capabilities

In [Figure 8-6](#), the Media Server is responsible for receiving video streams from different IP cameras and encoders and replicating them as necessary to different viewers.

Figure 8-6 Video Surveillance Media Server (VSMS)

By using the power and advanced capabilities of today's IP networks, the Media Server software allows third-party applications, additional users, cameras, and storage to be added over time. This system flexibility and scalability supports the following:

- Hundreds of simultaneous users viewing live or recorded video
- Standard video compression algorithms such as MJPEG, MPEG-2, MPEG-4, and H.264 simultaneously via a single Media Server
- Conservation of storage using events and loop-based archival options
- Integration with other security applications

Cisco Video Surveillance Operations Manager

Working in conjunction with the Cisco Video Surveillance Media Server, the Cisco Video Surveillance Operations Manager (VSOM) enables organizations to quickly and effectively configure, manage, and view video streams throughout the enterprise. [Figure 8-7](#) shows the Operations Manager main screen, which is accessed through a Web browser.

Figure 8-7 Video Surveillance Operations Manager

The Operations Manager meets the diverse needs of administrators, systems integrators, and operators by providing the following:

- Multiple Web-based consoles to configure, manage, display, and control video throughout a customer's IP network.
- The ability to manage a large number of Cisco Video Surveillance Media Servers, Cisco Video Surveillance Virtual Matrixes, cameras and users.
- Customizable interface, ideal for branded application delivery.
- Encoder and camera administration.
- Scheduled and event-based video recording.
- Interface to Media Server and Virtual Matrix software for pushing predefined views to multiple monitors.
- User and role management.
- Live and archived video views.
- Friendly user interface for PTZ controls and presets, digital zoom, and instant replay.
- Event setup and event notifications.
- “Record Now” feature while viewing live video

Cisco Video Surveillance IP Cameras

Cisco 2500 Series Video Surveillance IP Camera

The Cisco 2500 Series Video Surveillance IP camera is a high resolution standard-definition, feature-rich digital camera designed for secure performance in a wide variety of environments. The camera supports MPEG-4 and MJPEG compressions with up to 30 frames per second.

Contact closure and two-way audio allow integration with microphones, speakers, and access control systems. By providing wired and wireless models, the Cisco 2500 IP camera provides an ideal platform for integration and operation as an independent device or as part of the Cisco Video Surveillance network. [Figure 8-8](#) shows both the wired and wireless models of the 2500 IP Camera.

Figure 8-8 Cisco 2500 Series IP Cameras

The 2500 Series IP camera provides the following features:

- The camera employs powerful digital imaging technology, allowing it to capture high-quality images in a wide variety of indoor and outdoor lighting conditions. It uses a progressive scan image-sensor with global electronic shuttering to ensure natural color rendition, and minimal motion blurring.
- The wireless IP camera model supports 1X2 Multiple Input Multiple Output (MIMO) communication, which provides better data throughput and higher link range than single antenna designs. The wireless IP camera offers strong wireless security using Wi-Fi Protected Access (WPA)/WPA2 and supports various network protocols for 802.1x authentication.
- Power over Ethernet (PoE) 802.3af or DC power through an optional external power supply.
- Support for the Cisco Media API, an open, standards-based interface that allows integration with compatible video surveillance management systems.
- Support for 802.1x authentication on both the wired and wireless models.

Cisco 4000 Series Video Surveillance IP Camera

The Cisco Video Surveillance 4000 Series IP Cameras employ true high-definition (HD) video and H.264 compression, streaming up to 30 frames per second at 1080p (1920 x 1080) resolution. The Cisco 4000 IP Camera series also supports contact closure and two-way audio allow integration with microphones, speakers, and access control systems.

The Cisco 4000 Series includes two models: the CIVS-IPC-4300 and CIVS-IPC-4500. These cameras have identical feature sets, with the exception of the additional digital signal processor capabilities specifically designed to support real-time video analytics at the edge on the CIVS-IPC-4500. On this model, applications and end users have the option to run multiple analytics packages without compromising video streaming performance on the camera.

Figure 8-9 shows a Cisco 4000 IP Camera with an optional DC Auto Iris Lens.

Figure 8-9 Cisco 4000 Series IP Camera

The 4000 Series IP camera provides the following features:

- True high-definition video—The camera streams crisp and clear 1080p (1920 x 1080) video at 30 frames per second while maintaining surprisingly low network bandwidth.
- Progressive scan video—The camera captures each frame at its entire resolution using progressive scan rather than interlaced video capture, which captures each field of video.
- Embedded security and networking—The camera provides hardware-based Advanced Encryption Standard (AES).
- IP Multicast for enhanced bandwidth management.
- Event notification—The camera can examine designated areas for activity and notify users or other applications when it detects activity that exceeds a predefined sensitivity and threshold.
- True day/night functionality that includes an infrared (IR) filter that automatically switches to night mode in low light scenes.
- The camera supports Power-over-Ethernet (PoE) 802.3af, 12 VDC or 24 VAC power through an optional external power supply.
- The camera can be installed with a fixed mount or with an optional external pan/tilt mount and motorized zoom lens.

For more information, see the *Physical Safety for Schools Application Deployment Guide*:

http://www.cisco.com/en/US/docs/solutions/Verticals/Education/safe_sec_ed_dg.html

Deploying Digital Signage in School Campus

To ensure a successful digital media deployment, network, display, and management planning must be done prior to deploying digital signage in the schools network. A well-planned digital signage network design provides flexibility to incrementally deploy desktop video and ETV digital media applications without making major infrastructure changes. As described earlier, digital signage uses standard HTTP protocols to pull and publish the signage content on displays. Network bandwidth consumption for digital signs varies widely as it depends on playlist and content types. This document provides the best practices to design and configure the digital signage with content developed with rich text, flash, and animation and located on distributed Web servers to increase network efficiency.

Centralized Management Model

Cisco DMM is highly scalable appliance server that can be deployed centrally in district office location to manage up to 1000 DMPs deployed in local and regional school campus network. Cisco DMP deployed in local district offices or remote regional schools can communicate with centralized DMM

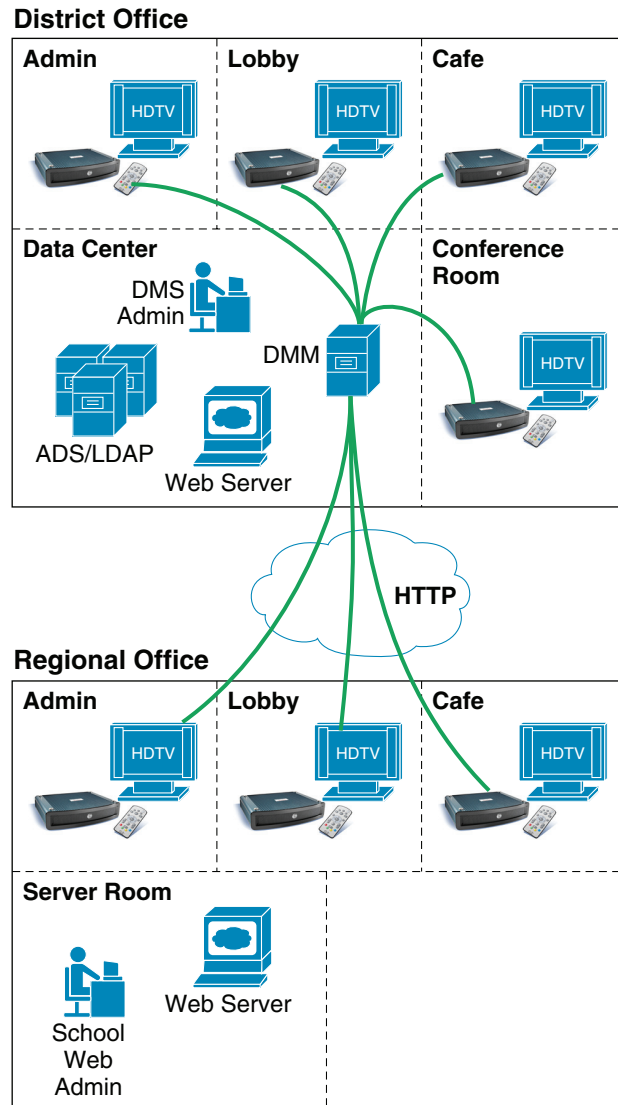

over LAN and WAN network using standard HTTP as the control protocol to receive Web or content server re-direction information to display content. Deploying DMM in a centralized location allows the DMM administrators in district offices to manage all registered DMP in various ways:

- Add and archive digital content and assign metadata and keywords.
- Create and manage play lists, ticker alerts, messages, closed captions, and promotional interstitials.
- Preview digital signage content and manage approval workflow.
- Ability to pre-configure the playlist and schedule for instant and future deployments.
- Take WAN optimization solution advantage and provide tight integration with Cisco ACNS and Cisco Content Engines.
- Manage user administrator accounts and permissions.

Centralizing DMP management and publishing signage content centrally at a district office allows the DMM administrator to advertise consistent information and messaging throughout the network. To minimize WAN network utilization, the school administrator must leverage internal storage or their local Web server to store and advertise the local, regional, and department news and information. However the district office and Internet news must be communicated over the WAN.

The network architect must consider integrating enterprise-class Cisco Application and Content Networking System (ACNS) that uses caching technology and offers higher scalability and reliable video delivery solution at the schools to improve end user experience and application response time. When integrated with the Cisco Wide-Area Application Services (WAAS) solution, it helps in optimizing WAN bandwidth utilization significantly with local redirection and high data compression over the WAN.

[Figure 8-10](#) is a validated design to integrate digital signage with centralized management in the district office with distributed DMP in a large-scale school network.

Figure 8-10 Centralized DMM with Distributed DMP in School SRA

Distributed Content Storage Model

Digital signage content is typically wrapped with HTML or Adobe Flash applications that provide greater flexibility for a Web administrator to display more types of content from various sources on a single page. When deploying large numbers of DMPs with rich and static digital signage content, the unicast communication between DMP and the distributed content server may waste network bandwidth by retrieving the same content for continuous display. Hence it becomes important for the network architect to understand the content distribution and network level requirements to optimally deploy signage application in a campus network.

Depending on DMP scalability, overall network capacity, and the bandwidth allocation for digital signage application, Cisco DMS offers the following three distributed content storage solutions for Cisco DMP to pull and display the static content from the local network instead of downloading all of it through the WAN network:

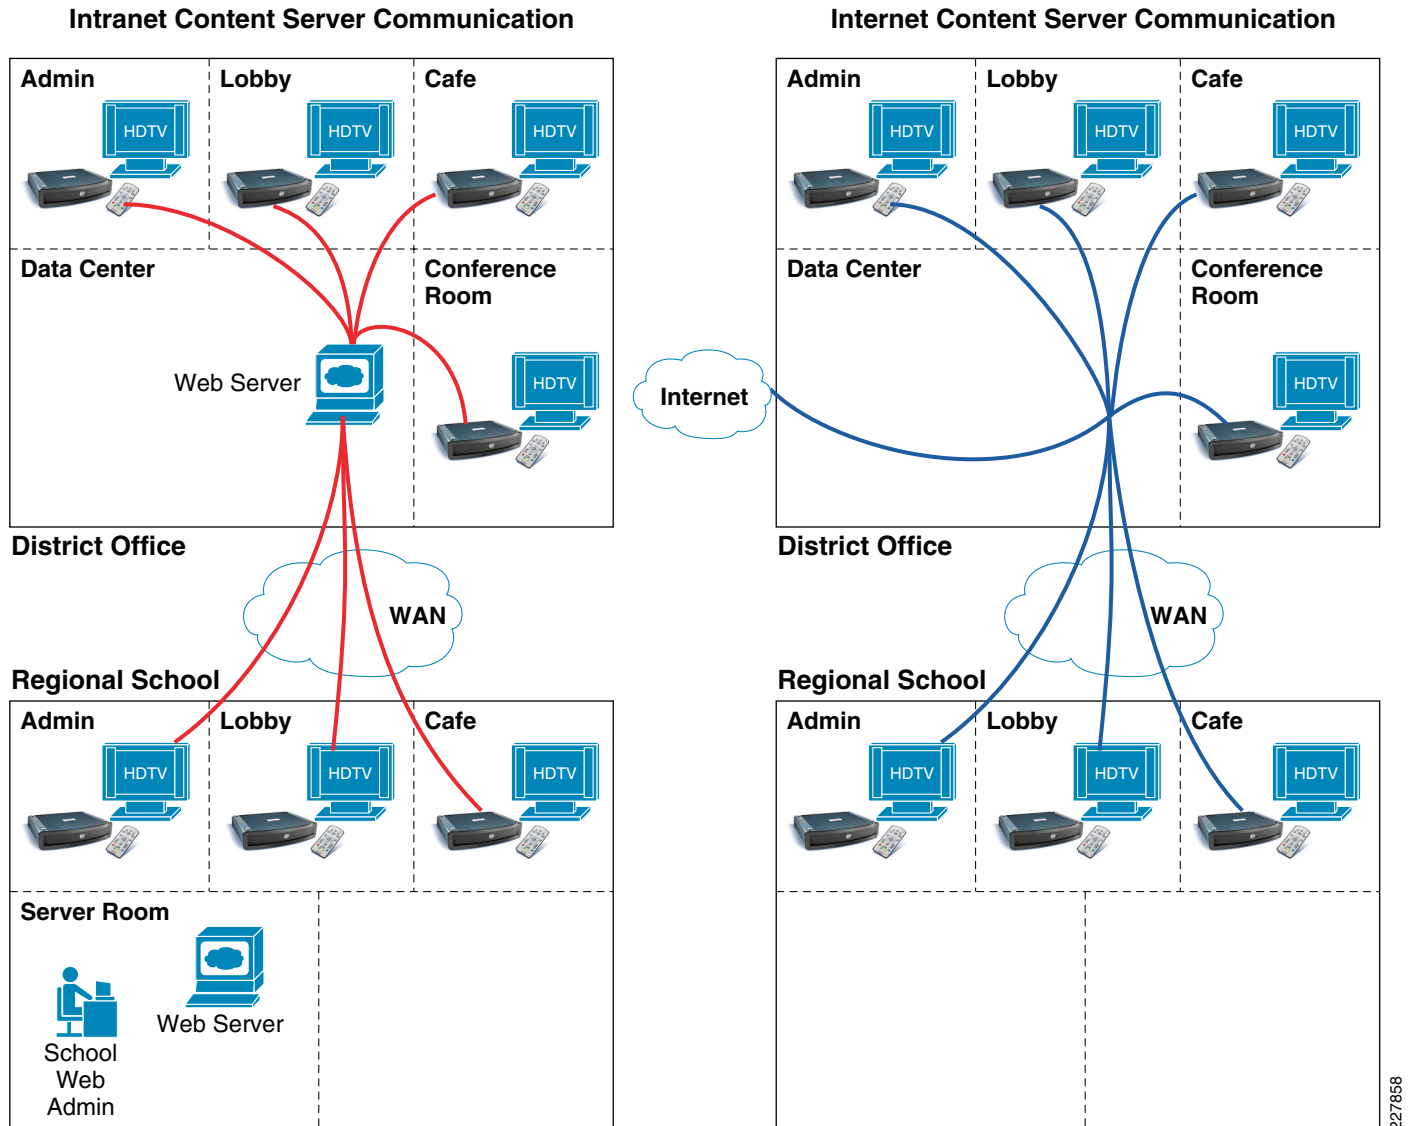

- **Cisco DMS-Content Distribution (CD)**—Is an ideal solution for a small-scale school network with few Cisco DMPs. Cisco DMM can push the static HTML or flash content via FTP or SFTP protocol to Cisco DMM on internal storage or to external storage device like USB drive and redirect Cisco DMP to access internal storage. This solution helps to minimize WAN bandwidth utilization.
- **Local Content Server (Web or CIFS)**—Storing the digital media content on a single local content server, like HTTP or CIFS sever, gives the network administrator more flexibility and management of the content distribution solution. The Web administrator can dynamically add, modify, and store the updated HTML or Flash file on a centralized server for Cisco DMP to retrieve and display. On the next HTTP request from DMP, the refreshed copy is displayed automatically. This solution provides more flexibility compared to Cisco DMS-CD solution, as it can dynamically update content without updating and managing content on each individual Cisco DMP.
- **Cisco ACNS**—Highly scalable and intelligent large size video content distribution to remote locations. Hierarchical content distribution system at district office and school sites distributes single copy of pre-recorded video to ACNS edge at the schools. To increase WAN network efficiency, Cisco ACNS leverages the caching technology and provides unicast VoD delivery in local LAN networks to end users instead of downloading one copy for each user over the WAN network.

SRA Validated Content Distribution Model

To provide a simplified, scalable, and cost-effective content distribution and management solution in SRA architecture, it is recommended to leverage local Web or CIFS servers in the district office and schools to store and publish local digital signage content. Cisco DMM can be programmed to re-direct local DMPs to a local Web server and remote DMPs to pull the content from a local Web server. Such distributed content storage design minimizes the critical WAN bandwidth usage to publish local information. However, the WAN network may still be utilized to access global signage information, such as county or state level education and emergency news that can be broadcast by Web server from district office, and similarly real-time news ticker from the Internet can be embedded in major content that provides constant world-wide news updates.

School network architects and Web administrators must perform pre-deployment exercise to assess the type of local versus distributed content (text/graphics/VoD/RSS) embedded in signage and the number of DMPs to be deployed in schools. This assessment provides WAN bandwidth guidelines to integrate digital signage in schools. As described earlier, Cisco WAN optimization solution like ACNS and WAAS must be integrated in the network if it demands higher WAN bandwidth. [Figure 8-11](#) depicts the unicast communication flow between Cisco DMP deployed across the network and Web servers located in intranet and Internet domains.

Figure 8-11 Distributed Content Server Communication

Implementing Network Services for Digital Signage

Prior to integrating digital signage applications, the network architect must make network services ready with the best practices for resilient and seamless operation and integration. Building the network as a highly-available platform is a foundational requirement for applications like IP telephony and digital media solutions as they demand constant bandwidth and network availability. Deploying centralized DMM with a distributed content server spans the digital communication beyond the campus boundary; hence it is recommended to deploy digital media solutions based on these network design principles:

- Low latency—Deploy the high-speed campus network that offers lower latency for real-time applications like voice and video.

- High availability—To increase network resiliency it is recommended to deploy the network with redundant modules, systems, and power supplies offering non-stop communication and sub-second network recovery during minor or major network failure events.
- QoS—Enhance user experience and content quality with robust QoS policies at the campus network edge.
- Confidentiality—Protect digital media end points, appliances, and data with centralized authentication and encryption.

This section provides access layer design and configuration guidelines to deploy Cisco DMP at the campus network edge and DMM in a centralized data center in a district office. For more information on design and implementation guideline for building a strong and resilient core and foundational campus network, refer to the following URL:

http://www.cisco.com/en/US/docs/solutions/Verticals/Education/SRA_Schools/school_sra_campus_dg.pdf

Deploying Cisco DMP in the Access Layer Network

Cisco DMP is a school managed and trusted end point in the campus access layer, hence the network administrator must apply the common security and QoS policy for DMP as defined for other trusted end-points like IP phones. In a typical deployment scenario, a single access layer switch may be connected to several other trusted and un-trusted end-points, hence it becomes an important task for administrator to provide secure and suitable network services.

Cisco access layer switches provides the flexibility to deploy Cisco DMP in two different modes, manual deployment and plug-and-play Auto Smartport (ASP) macro.

Manual Deployment

School administrator must manually implement the following three major network services to successfully integrate DMP in the network:

- Assigning unique Layer 2 VLAN
- Implement network edge security
- Implement network edge QoS

Assigning Unique Layer 2 VLAN

To provide secured and simplified digital signage communication, the DMP must be assigned a unique broadcast domain. De-coupling DMP with other trusted and un-trusted end points makes DMP more secure during any attacks and is easier to manage and troubleshoot. When single access layer connects to multiple DMPs, then all the DMPs can be assigned on the same Layer 2 VLAN. Like any other logical network partition design, it is recommended to use unique Layer 2 VLAN for DMP that are physically deployed on different Cisco access layer switches. [Figure 8-12](#) provides recommended Cisco DMP Layer 2 segmentation guidelines in the access-layer:

Figure 8-12 Cisco DMP-Layer 2 VLAN Segmentation

Cisco DMP cannot transmit or receive 802.1Q tagged frames, hence it is recommended to change default switchport mode from dynamic to access mode. The following is a sample configuration to enable VLAN in the database and apply VLAN on the DMP physical port:

2960

```
cr24-2960-DO(config-if)#interface FastEthernet0/7
cr24-2960-DO(config-if)# description CONNECTED TO LOBBY DMP
cr24-2960-DO(config-if)# switchport mode access
cr24-2960-DO(config-if)# spanning-tree portfast
cr24-2960-DO(config-if)# switchport access vlan 10
```

3750

```
cr25-3750-DO(config-if)#interface range GigabitEthernet 1/0/1 - 3
cr25-3750-DO(config-if-range)# switchport mode access
cr25-3750-DO(config-if-range)# spanning-tree portfast
cr25-3750-DO(config-if-range)# switchport access vlan 20
```

For flexible and scalable DMP deployment, it is recommended that the DMP edge port be in Layer 2 mode even when the access layer switch is deployed in a multilayer or routed access network design.

Implement Network Edge Security

Cisco DMP player is an extremely silent system and it requires communication with certain critical systems in the network, such as an IP gateway, Cisco DMM, Web servers, SNM, and NTP. To display the digital signage content and synchronize with management servers, Cisco DMP receives more data from the network than transmitting to the network.

Cisco Catalyst integrated security feature must be deployed on the physical port to protect DMP from being attacked by viruses or unauthorized hosts. Based on the protocol and data communication characteristics of Cisco DMP, it is recommended to apply the following set of security configurations to protect the network and the DMP from unknown traffic floods and attacks:

Access

```
interface FastEthernet0/7
! Block transmitting all unknown unicast traffic
switchport block unicast
! Enable port-security on this port
switchport port-security
! Default, allow single-host to access this port
switchport port-security maximum 1
! Block receiving BPDU from this port
spanning-tree bpduguard enable
```

Implement Network Edge QoS

It is important to implement differential service treatment for digital media applications over non-critical network traffic in the network. Depending on the digital media applications and the distributed content, appropriate QoS services must be implemented at the network edge that connects media end-points and in the data center where typically centralized management and content servers are deployed. As described earlier, the Cisco DMP primarily use standard HTTP protocol to communicate with centralized DMM management server and the distributed Web server to publish the digital signage content.

By default, HTTP packets between digital media end-points are set with default DSCP values and rely on intermediate network devices to classify the traffic and provide advanced QoS techniques to protect the digital media communication between DMP and other back end systems. Since the communication and publish content is delivered using HTTP protocol, it becomes challenging to distinguish between HTTP control traffic versus digital content in the campus network. Following RFC 4594 QoS deployment guidelines, the unicast control plane communication between Cisco DMM and DMP system can be classified as signaling traffic and must be marked an appropriate DSCP value and assigned a proper queue. [Figure 8-13](#) provides QoS references to deploy digital media application in a campus network:

Figure 8-13 Digital Signage QoS Reference Chart

Application Class	PHB	Admission Control	Congestion Management and Congestion Avoidance	Cisco Video Applications
VoIP Telephony	EF	Required	Priority Queue (PQ)	
Broadcast Video	CS5	Required	Optional (PQ)	Cisco DMS (Live Streams)/Enterprise TV/IPVS
Realtime Interactive	CS4	Required	Optional (PQ)	Cisco TelePresence
Multimedia Conferencing	AF4	Required	BW Queue + DSCP WRED	Cisco CUPC/CUVA/CI IP Phone 7985G
Multimedia Streaming	AF3	Recommended	BW Queue + DSCP WRED	Cisco DMS (VoDs)
Network Control	CS6		BW Queue	
Call-Signaling	CS3*		BW Queue	DMM/DMP Control Traffic
OAM	CS2		BW Queue	
Transactional Data	AF2		BW Queue + DSCP WRED	Cisco WebEx/CU MeetingPlace
Bulk Data	AF1		BW Queue + DSCP WRED	
Best Effort	DF		Default Queue + RED	
Scavenger	CS1		Min BW Queue (Deferential)	YouTube/Xbox Live/iTunes/BitTorrent/etc.

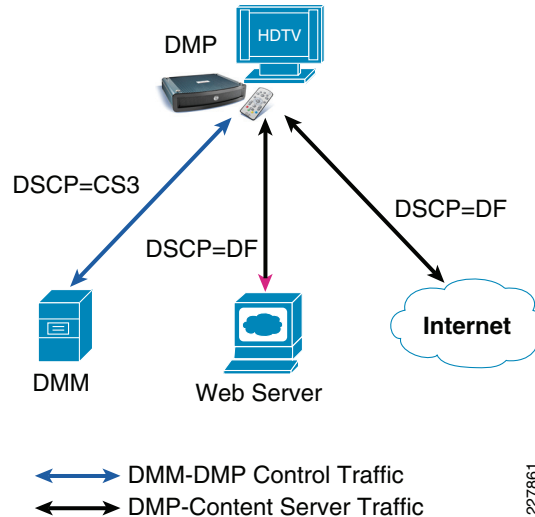

*Cisco classification method slightly differs from RFC 4594. CS3 and CS5 definition are interchanged.

227860

Applying Ingress QoS Policy on DMP and DMM Port

Network QoS policies must be set at the campus access edge to mark recommended DSCP bit for control or management traffic between DMM and DMP. HTML or Flash based digital signage content can remain in same best-effort class. The control traffic can be identified from digital signage content based on TCP flow between Cisco DMM and DMP. [Figure 8-14](#) provides QoS marking guidelines between Cisco DMP, Cisco DMM appliance, and content server:

Figure 8-14 QoS Marking Between Digital Signage Components

Based on TCP and static Cisco DMM and DMP player information, the following configuration guideline must be implement QoS policy on access layer switches that connect to Cisco DMP and Cisco DMM in a centralized data center:

```
! Classify DMP and DMM HTTP traffic with extended ACL
ip access-list extended DMS-SIGNALING
remark DMM-DMP-MGMT
permit tcp host <DMP-IP-Address> host <DMM-IP-Address>
permit tcp host <DMM-IP-Address> host <DMP-IP-Address>
!
class-map DMS-SIGNALING
match access-group name DMS-SIGNALING
!
policy-map DMS-Policy
class DMS-SIGNALING
set dscp cs3 ? Explicit mark DSCP CS3
!
interface FastEthernet0/7
description CONNECTED TO LOBBY DMP
mls qos trust dscp
service-policy input DMS-Policy?Apply ingress service-policy
!

interface FastEthernet0/10
description CONNECTED TO Cisco DMM Appliance
mls qos trust dscp
service-policy input DMS-Policy?Apply ingress service-policy

cr24-3560r-DO#show mls qos interface fas0/7 | inc policy-map|dscp
Attached policy-map for Ingress: DMS-Policy
trust state: trust dscp
```

```
trust mode: trust dscp
```

Additional ingress QoS policies, such as policers, can be implemented on access switches if the network administrator is concerned about securing the restricting ports to consume higher bandwidth.

Applying Egress QoS Policy on DMP and DMM Port

Ingress QoS policy helps the network to distinguish between HTTP control and digital media content traffic within the campus backbone. Similar QoS techniques are required to provide differential services between control and digital media content traffic exiting the port connected to Cisco DMP and DMM appliance on the access layer switches. For global egress policy for trusted and un-trusted device, it is recommended to share the egress bandwidth to each hardware queue and enable prioritization for the low-latency traffic:

```
cr24-3560r-DO(config)#interface FastEthernet0/7
cr24-3560r-DO(config-if)# srr-queue bandwidth share 1 30 35 5 ? Enable BW share
cr24-3560r-DO(config)#priority-queue out? Enable Priority-Queueing

cr24-3560r-DO#show mls qos interface fast0/7 queueing
FastEthernet0/7
Egress Priority Queue : enabled
Shaped queue weights (absolute) : 25 0 0 0
Shared queue weights : 1 30 35 5
The port bandwidth limit : 100 (Operational Bandwidth:100.0)
The port is mapped to qset : 1
```

To deploy QoS in a school campus network design, refer to the following URL:

http://www.cisco.com/en/US/docs/solutions/Verticals/Education/SRA_Schools/SchoolSRA_QoS_sba.pdf

Auto Smartport Macro Deployment

Cisco access layer switches provide a zero-touch or plug-n-play type network provisioning solution by dynamically detecting connected end-points and automatically applying best practices and recommended configurations. Cisco Auto Smartport macro helps network architects to reduce the number of challenges in implementation when deploying complex configurations. Cisco validated design comprehensively validates multiple set of tools and technologies to solve the critical business problems. Cisco Auto Smartport leverages validated and recommended network configuration and parameters that dynamically provision the network without any user intervention. Implementing recommended and validated configuration parameters helps school network administrators to automatically provide network and device security and optimize application performance.

Cisco Auto Smartport leverages several Layer 2 protocol techniques to dynamically detect the end-point platform that intelligently triggers the function and applies the configuration from pre-defined recommended templates. To further increase operational efficiency, Cisco Auto Smartport removes all dynamically applied configurations when the device is un-plugged or removed from the network. The following is the list of Layer 2 technologies and end-point types that Cisco Auto Smartport macros use to dynamically apply configurations:

- Layer 2 Technologies
 - Cisco Discovery Protocol (CDP)
 - IEEE AB - LLDP
 - 802.1x
 - MAC-Authentication Bypass (MAB)

- Layer 2 Source MAC address
- Ethernet OUI
- Supported End-Point Platforms
 - IP Phones—Cisco and Avaya IP Phone
 - Wireless Access-Points—Cisco AP 11xx series
 - IP Video Surveillance—Cisco IPVS 25xx and 4xxx series camera
 - Digital Media Player—Cisco DMP 4x00 series players

This section focuses on providing guidelines for the basic configuration needed to enable Cisco Auto Smartport to dynamically provision Cisco DMP in the network.

Cisco Auto Smartport macro leverages a simple shell function to execute the pre-defined configuration template embedded in the switch for each type of supported end-point. Cisco DMP configuration gets executed dynamically based on the port event triggers. The following output provides the Auto Smartport event trigger and dynamic configuration guideline when it detects Cisco DMP on the physical port:

```
cr26-3750#show shell functions CISCO_DMP_AUTO_SMARTPORT

function CISCO_DMP_AUTO_SMARTPORT () {
!!Provision this configuration when Link up event is triggered
!!and Cisco DMP is detected:
    if [[ $LINKUP -eq YES ]]; then
        conf t
            interface $INTERFACE
                macro description $TRIGGER
                switchport access vlan $ACCESS_VLAN
                switchport mode access
                switchport block unicast
                mls qos trust dscp
                spanning-tree portfast
                switchport port-security
                switchport port-security maximum 1
                switchport port-security violation shutdown
                spanning-tree bpduguard enable
                priority-queue out
            exit
        end
    fi
!!Remove dynamic configuration when Link Down event is triggered.
    if [[ $LINKUP -eq NO ]]; then
        conf t
            interface $INTERFACE
                no macro description
                no switchport access vlan $ACCESS_VLAN
                no switchport block unicast
                no switchport port-security
                no switchport port-security maximum 1
                no switchport port-security violation shutdown
                no mls qos trust dscp
                no spanning-tree portfast
                no spanning-tree bpduguard enable
                no priority-queue out
                if [[ $AUTH_ENABLED -eq NO ]]; then
                    no switchport mode access
                fi
            exit
        end
    fi
}
```

```
}
```

Comparing the Auto Smartport macro configuration with a recommended manual configuration, it can be seen that the majority of the recommended manual configuration is in the macro template. Some of the advanced QoS parameters, such as MQC-based DSCP marking, may have to be manually configured.

Implementing Auto SmartPort Macro

School network administrators must enable Cisco Auto SmartPort Macro function along with basic network parameters on access layer switches to dynamically detect and provision the configuration for various types of end-points. Enabling Cisco Auto Smartport macro function globally enables all the physical ports and provisions and un-provisions the network configuration for the Cisco DMP based on shell triggers and functions. It also provides the flexibility to disable the Auto Smartport function on a per-port basis where the static configuration is required. The following is the simple global configuration to enable Cisco Auto Smartport processing for all the physical ports:

```
3750
```

```
cr26-3750(config)#macro auto global processing
```

```
cr26-3750#show macro auto interface | inc Auto
```

```
Global Auto Smart Port Status
Auto Smart Ports Enabled
```

As described earlier, Cisco Auto Smartport can leverage multiple Layer 2 technologies to detect the end-points, by default Auto SmartPort use the pre-defined MAC address-group range to dynamically detect the Cisco DMP based on Ethernet OUI address. To deploy Cisco DMP based on Ethernet OUI, no additional configuration is required. To enable secure access-control solution, Cisco Secure ACS and MAB can be integrated to authenticate Cisco DMP based on registered MAC address in the ACS database.

```
cr26-3750#show macro auto address-group CISCO_DMP_EVENT
```

```
MAC Address Group Configuration:
```

```
Group Name OUI MAC ADDRESS
```

```
-----
CISCO_DMP_EVENT 0023.AC
000F.44
```

Because some of the network parameters like VLAN IDs are unique in the network, the school administrator needs to determine the common VLAN ID to deploy for a common set of end points. For example, when Cisco DMP is detected on Switch1, then it must dynamically detect the media player and assign it to appropriate VLAN and execute the network configuration template. By default, when Cisco Auto Smartport detects the Cisco DMP device on the port it configures the port in access-mode and assigned it a default VLAN ID = 1. After applying following single global configuration, the Auto Smartport automatically assigns all the Cisco DMP in to user-defined VLAN.

```
cr26-3750(config)#macro auto device media-player ACCESS_VLAN=58
```

```
cr26-3750#show macro auto device media-player | inc Device|ACCESS
```

```
Device:media-player
```

```
Configurable Parameters:ACCESS_VLAN
```

```
Defaults Parameters:ACCESS_VLAN=1
```

```
Current Parameters:ACCESS_VLAN=58
```

Tuning Auto SmartPort Macro

Cisco Auto Smartport is optimized in detecting the end points and provisioning the configuration for rapid and error-free deployments. The shell function that performs the configuration provisioning and un-provisioning task is based on physical link up and down events. In initial deployment, the end-points

can be detected using different Layer 2 techniques and all dynamically provisioned configurations can be saved in configuration files. Due to its nature the configuration is removed and then the same configuration is re-applied when the link goes down temporarily for any common reason, e.g., link flap, end-point is power cycled, etc.

To make configuration persistent during such a link flap, the following single global configuration can be applied to retain the dynamic configuration during a link flap:

```
cr26-3750(config)#macro auto sticky
```

Implementing Cisco Digital Media Player

Once the recommended network edge configuration on the access layer is implemented, the Cisco DMP is ready to be deployed. Since Cisco DMP uses an embedded Linux OS which is not accessible directly to end users, the basic network parameters must be provisioned using Web-based Cisco DMP-Device Manager (DM). The Cisco DMP-DM is divided into three major configuration modes:

- Settings (Network/Browser/Storage)
- Display
- DMP Administration

The school administrator must configure the basic network parameters to deploy Cisco DMP in production network; the DMM administrator from the district office can apply the global display and management parameters to DMP without intervening school administrator for any advanced configuration task.

This chapter provides the following deployment guidelines to successfully deploy Cisco DMP and Cisco DMM appliance server communication in the network:

- Assigning IP address to Cisco DMP
- Registering Cisco DMP to Cisco DMM database

Assigning IP Address to Cisco DMP

The default IP setting on Cisco DMP is to dynamically acquire IP address and gateway information from DHCP server. It is recommended to assign a unique static IP address to DMP as it provides flexibility to the network administrator to provide secured DMP-DM GUI access with ACLs and the ability to provide distinguished QoS treatment for control traffic between Cisco DMP and DMM appliance server. [Figure 8-15](#) is a simple IP configuration task that the school administrator must perform to change the default IP address method from DHCP to static IP address mode:

Figure 8-15 Assigning DMP Static IP Address

The figure consists of two screenshots of a 'Network Configuration' interface. The top screenshot shows the 'Dynamic IP Addressing (DHCP)' dropdown set to 'Enabled'. The bottom screenshot shows the same interface with 'Dynamic IP Addressing (DHCP)' set to 'Disabled'. In the bottom screenshot, the following fields are populated: IP Address (10 . 125 . 4 . 130), Subnet Mask (255 . 255 . 255 . 128), Default Gateway (10 . 125 . 4 . 129), and DNS Server (10 . 125 . 31 . 2). A red arrow points from the 'Enabled' dropdown in the top screenshot to the 'Disabled' dropdown in the bottom screenshot. Another red arrow points from the 'IP Address' field in the bottom screenshot to a text box on the right that says 'Statically assign IP, Mask, Gateway and DNS address information'. A vertical text '227862' is on the right side of the bottom screenshot.

Network Configuration	
DMP MAC Address	00:0f:44:00:f9:44
Dynamic IP Addressing (DHCP)	Enabled

Network Configuration	
DMP MAC Address	00:0f:44:00:f9:44
Dynamic IP Addressing (DHCP)	Disabled
IP Address	10 . 125 . 4 . 130
Subnet Mask	255 . 255 . 255 . 128
Default Gateway	10 . 125 . 4 . 129
DNS Server	10 . 125 . 31 . 2

Statically assign IP, Mask, Gateway and DNS address information

227862

Registering Cisco DMP to Cisco DMM Database

The first step to enable communication between digital signage components is to register network wide deployed Cisco DMP into the centralized Cisco DMM appliance database. Cisco DMM appliance requires basic information from Cisco DMP to register—MAC and IP address, firmware version and storage information. Centralized DMM appliance can register large numbers of DMPs across the school network and it may become an operational challenge to manage each DMP player. DMM administrator can create a logical DMP group along with the range of IP subnet; DMM-DSM automatically groups the registered DMPs based on assigned IP address. The following are some of the advantages in deploying DMP group in school architecture:

- Organize registered DMPs into a single logical group.
- Instead of managing each individual DMP, the DMP group allows the DMM administrator to manage a group of DMPs collectively.
- Accelerate digital signage content deployment and instruction to the DMP group instead of individual players.
- Like content management, common display attributes to all DMPs in the DMP group.

The Cisco DMS solution provides flexibility to the DMM administrator for manual or automatic Cisco DMP registration into the database. Depending on the number of Cisco DMP deployed across the network, either of the registration process can be selected.

- **Manual DMP Registration**—The DMM administrator must manually enter Cisco DMP MAC and IP address information into the DMM database. For better operational management and troubleshooting, the DMP must be assigned to an logical DMP groups.
- **Auto DMP Registration**—Is a highly scalable, simplified, and error-free DMP registration solution for large deployments. To auto-register and auto-group the DMP in user-defined groups, the range of IP subnets or CIDR ranges must be specified to scan the Cisco DMP players in the network. Multiple IP subnets can be configured for single DMP group. The DMM appliance transmits TCP based unicast packet with pre-defined port number 7777 to scan Cisco DMP, which cannot be modified by the user. Hence for successful auto-registration process, it is recommended to make sure TCP port 7777 is not filtered anywhere in the network. The DMM admin can control the DMM appliance to trigger on-demand or schedule scan to locate DMP in the network for auto registration.

The DMM admin must complete these three steps sequentially to successfully deploy DMM groups and auto DMP registration in the DMM-DSM:

Step 1 Configure DMM Group and assign an IP subnet.

Figure 8-16 Configuring DMP Group Using DMM-DSM

Step 2 Configure DMP Discovery Application and assign an IP subnet.

Figure 8-17 Configuring DMP Discovery Application

Step 3 Trigger the DMP discovery with manual action or schedule to discover in future.
Manual DMP Discovery Trigger

Figure 8-18 Triggering DMP Discovery Manually

Refreshing the window in few seconds will reflect the dynamically discovered Cisco DMP that gets automatically registered and grouped as depicted in [Figure 8-19](#). The default name of the auto-registered DMP is the same as their MAC address; the DMM admin must change to reflect with proper name or location name.

Figure 8-19 Dynamically Discovered DMP Discovery Triggered Manually

Scheduling DMP Discovery

Depending on the number of DMP groups, network ranges, and DMP players in the network, the DMP discovery may take some time. In large deployments, it is recommended to schedule Cisco DMP discovery during non-business hours. Scheduling DMP discovery in the network is identical to scheduling the digital signage publishing time. To schedule DMP discovery using Cisco DMM-DSM:

1. Click on Schedules -> Play in Future -> Select discovery month and date
2. Select the DMP group to be discovered -> Click on Add an Event Button.
3. Select DMP group from Select Group Tab and click OK.
4. Select Advanced Task from Task Type Tab and click on Select Advanced Tasks Tab.
5. Select DMP Discovery from Types and the Action Name and click OK.
6. Configure Start and Stop Action run time and optionally configure repeat value to dynamically discover Cisco DMP based on schedule.

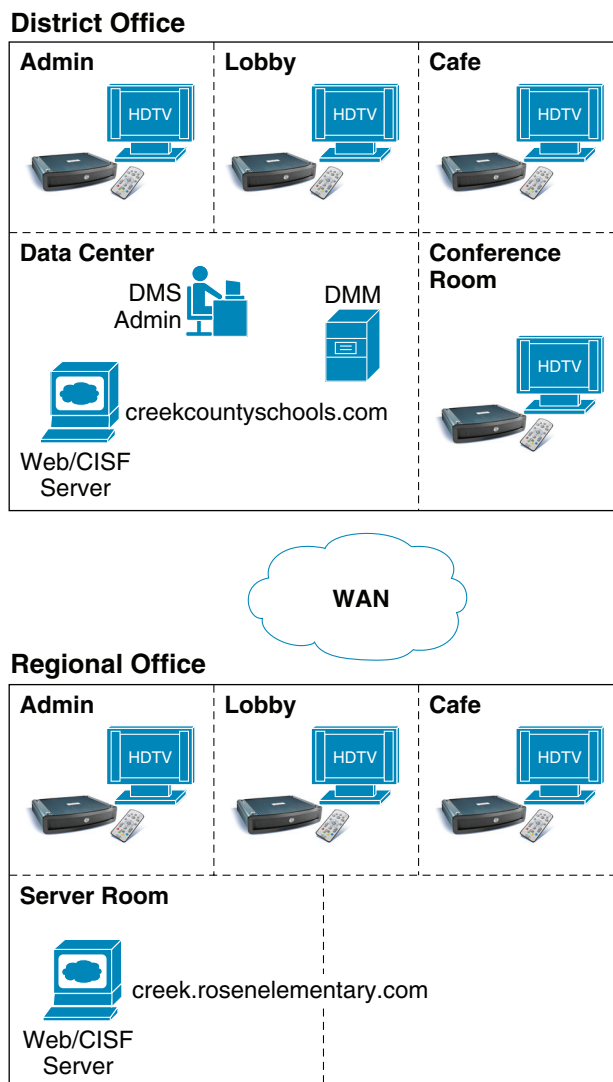

Implementing Digital Signage

Upon successfully discovering and registering the Cisco DMP in the DMM appliance database, the DMM administrator can start preparing to implement digital signage in the network. The provision checklist must include exact content path and schedule to display the content on individual or group DMP in the network. As described earlier, the content must be stored on a Web or CISF server that is physically located on the same campus network as a Cisco DMP. Hence when creating the playlists, it is recommended to specify the URL path where the content is stored.

Publishing digital signage requires three simple configuration step on DMM-DSM as depicted in [Figure 8-20](#):

Figure 8-20 Digital Signage Deployment Steps

Executing each step populates content information in DMM in the common repository, provides flexibility to compile playlist with distributed content, and schedules the digital signage publishing time by mapping the playlist to individual or group DMPs. The network topology in [Figure 8-21](#) is used as a reference point to configure each deployment step.

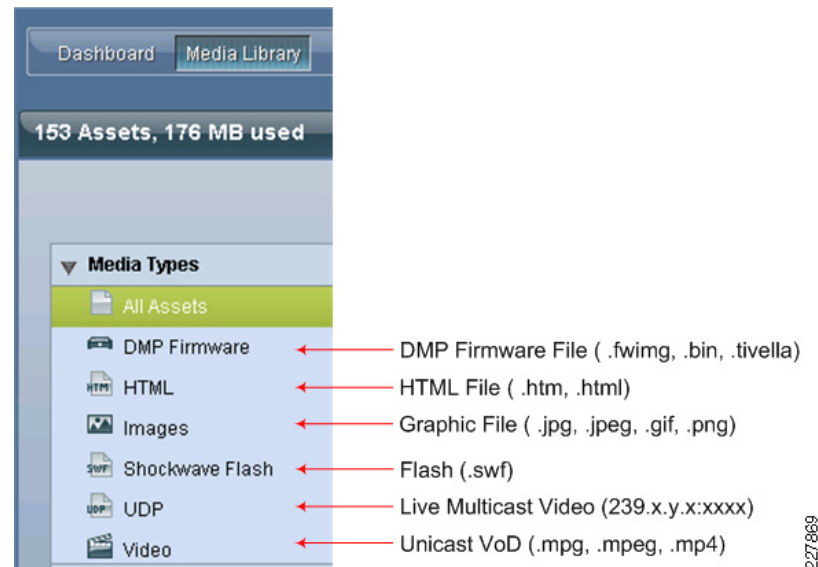

Figure 8-21 Digital Signage Network Topology

Step 1 Adding Asset in Media Library.

Cisco DMM-DSM builds an asset of digital media content in a common Media Library database.

Figure 8-22 provides information about the variety of digital media content types supported and can be stored in two major locations—remote Web/CISF content server or it must be uploaded to local DMM appliance server. As described earlier, the recommended content distribution model is to keep content distributed on remote servers that reside on the same LAN as Cisco DMPs. Cisco DMM appliance must not be used as a content server. Each asset type must be entered one at a time in the media library. Each asset is executed serially within the playlist; the Cisco DMM-DSM also provides flexibility to publish digital signage content in random order.

Figure 8-22 Supported Asset Types

Execute the following steps to add distributed digital signage (non-video) content asset into Media Library:

1. Click on Add Media Asset Button.
2. Click on Single Tab.
3. Click URL in radio button as a Source and type the exact URL to access content (e.g., <http://creek.rosenelementary.com/default.html>). Prior to deploying, the content must be tested and verified by applying same URL from local internet browser.
4. Do not click on download check box. This will prevent downloading provided HTTP URL content to the local DMM hard-drive.
5. Select File Type from drop down window based on URL extension.
6. Enter estimated or planned playback time for this asset.
7. Select the media category from Category window in which this URL fits in.
8. Optionally, provide description and content owner/developer information.
9. Click on Save button to review the entered information.
10. Click the Close button to exit the window.

Step 2 Creating Playlist.

Playlist is a user-defined logical group that is packaged with the compiled list of distributed digital signage assets which are being added in the shared Media Library database. For example, a playlist can include the intranet home page of the district office and regional school and library books catalog developed in Adobe Flash.

Cisco DMM-DSM provides the flexibility to develop playlists in two different modes—Standalone and Cisco Digital Media Designer (DMD). When the digital signage content is designed and developed outside the DMM-DMD, then DMM administrator must create a standalone playlist.

Cisco Digital Media Designer (DMD) is a Java-based, powerful, drag and drop design tool to create customized digital signage content. Cisco DMM offers pre-designed assets that can be leverage to create personalized design. DMD also offers flexibility to customized horizontal and vertical screen display orientation.

Figure 8-23 Digital Signage Playlist Options

This section provides guideline to implement a standalone playlist. Multiple playlists can be created and associated to an individual or group of DMPs. When designing the asset in the playlist, it is important to remember that the content publishing time and mappings to DMP groups are applied based on per-playlist and not on per-asset basis. The order of playlist execution is done serially based on specified time. [Figure 8-24](#) depicts the playlist order and duration time on per-cycle basis.

Figure 8-24 Digital Signage Display Order and Duration

In a best practice, the playlist can be created based on individual district office or school departments that can provide flexibility to announce the news or any other department specific content at specific time without impacting the playlist for other DMP groups deployed in different departments. Execute the following steps to compile the distributed digital signage asset and estimated or planned run time for each individual asset.

Click on Create Playlist button and follow step-by-step instruction provided in [Figure 8-25](#) to create a compiled and distributed digital signage content in playlist.

Figure 8-25 *Compiling Assets with Standalone Playlist*

Click Save → Save Cancel

227872

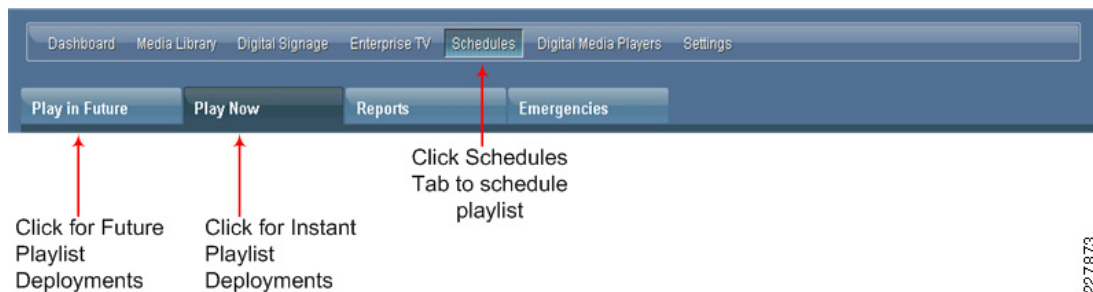

Step 3 Scheduling Playlist.

After successfully completing the above two steps the URL of distributed digital signage content is added in media library database and the playlist is compiled with the list of signage content that needs to be played for DMP group. The DMM administrator can send the playback command in two different modes—Instant Play and Future Play.

Instant Play or “Play Now” sends the playback command to selected DMP groups and all the DMPs can start displaying digital signage content immediately. Instant Play option provides an option for immediate signage content deployment; it can also be used to publish the newly added or updated signage asset in an already playing playlist. When Cisco DMP receives the new and updated playlist command from centralized DMM appliance, it aborts playing the previous playlist commands and immediately starts the display based on new information.

Future Play or “Play in Future” gives flexibility to the DMM administrator to pre-deploy digital signage in the DMM appliance database and schedule to play the playlist on a pre-determined month, date, or specific time. For example, you could have next month’s café lunch menu automatically published in the last week of the current month.

Figure 8-26 depicts tab selection to schedule the playlist in both deployments modes.

Figure 8-26 *Playlist Scheduling Modes*

Implementing Instant Play mode

Execute the step-by-step procedure as depicted in [Figure 8-27](#) to deploy digital signage instantly in the network. Cisco DMM-DSM provides the flexibility to select single, multiple, or all the DMPs using shift-key to instantaneously publish digital signage in large deployments.

Figure 8-27 Publishing Instant Digital Signage

DMP Groups	Status	Name	Description	IP Address	MAC Address	Version

CHAPTER 9

Access Layer Security Design

One of the most vulnerable points of the network is the access edge. The access layer is where end users connect to the network. In the past, network administrators have largely relied on physical security to protect this part of the network. Unauthorized users were not allowed to enter a secure building where they could plug into the network, and students didn't carry computers with them. Today, contractors and consultants regularly have access to secure areas, and a student carrying a laptop is unsurprising. Once inside, there is nothing to prevent a contractor or student from plugging into a wall jack and gaining access to the corporate network. There is no need to enter an employee office to do this. Conference rooms frequently offer network access through wall jacks or even desktop switches. Once connected to the network, everyone (employees, contractors, consultants, guests, students, and malicious users) has access to all the resources on the network.

What is commonly called the *access layer* in network design is the *business end* of the network, the part of the network that your users see and interact with. The end users do not see or appreciate the power of your collapsed core distribution layer, the elegance of your addressing plans, or the genius of your end to end network design. Your more technical users may be able to identify an RJ-45 port or WLAN access point if asked, but most users simply expect the network to be there. Training users on using the access is focused upon small—the smaller the better—number of steps users must go through to gain access to their network applications.

At the same time as providing simple uncomplicated network access for users, the access layer provides the first line of security defense for the network, provide service differentiation based upon management policies and, providing power to support the deployment of specialized devices.

The roles can be broken broadly into the following areas:

- Access layer security
- Access layer QoS
- Access layer Power-over-Ethernet (PoE)

Access Layer Security

The access layer is where your client's network devices directly connect to your network. You want their connection to be as efficient, simple, and secure as possible. This involves controlling who accesses the network and for what services. Controlling access may be as simple as blocking access, or it may involve a redirection or quarantining action.

To continue the general security metaphor part of controlling the boundary is also observing inappropriate behavior at the boundary can also result in blocked access.

The Schools SRA uses the native Cisco switch features and Cisco security products to provide boundary control services. The primary tools for access layer security in the schools are as follows:

- Catalyst Integrated Security Features (CISF)
- Cisco Clean Access (NAC)
- Cisco Identity-Based Network Networking Services (IBNS)

When implementing the security features, consideration needs to be made upon the client requirements using the access layer. In the Schools SRA, the following client connections are considered:

- Ethernet PC client ports
- Printer ports
- IP phone ports
- Wireless clients
- AP ports
- Access layer PoE
- Access layer QoS

Catalyst Integrated Security Features (CISF) Protected Ports

Catalyst Integrated Security Features (CISF) includes private VLANs, port security, DHCP snooping, IPSource Guard, secure Address Resolution Protocol (ARP) detection, and dynamic ARP inspection. These features protect the network against attacks such as man-in-the-middle, spoofing, and infrastructure denial-of-service (DoS) attacks.

- *Port Security*—Where the number of MAC addresses allowed on a switch port is monitored, and the switch can respond to violations with management messages and changes in the port state.
- *DHCP snooping*—Where DHCP messages are inspected, and filtered to ensure that DHCP server messages only come from a trusted interface.
- *IPSource Guard*—Where the IP traffic is restricted based upon DHCP or static IP address MAC bindings to ensure a host doesn't attempt to use the IP address of a neighboring host
- *Dynamic ARP inspection*—Where the all ARP packets from untrusted interfaces are inspected to ensure that they contain valid MAC address and IP address pairings, preventing ARP spoofing attacks
- *ARP rate limiting*—Where an excessive rate of ARP request (which must be processed by network hosts CPUs), and the switch responds with access restriction if this rate is exceeded.
- *Storm Control*—Prevents traffic on a LAN from being disrupted by a broadcast, multicast, or unicast storm

CISF Port Configuration

```
switchport port-security maximum 2
switchport port-security
switchport port-security aging time 2
switchport port-security violation restrict
switchport port-security aging type inactivity
ip arp inspection limit rate 100
ip dhcp snooping limit rate 100
storm-control broadcast level 20.00 10.00
storm-control multicast level 50.00 30.00
```

NAC Protected Ports

This section discusses the Cisco NAC Appliance (also known as Cisco Clean Access) in the Schools SRA. It is not intended to be a comprehensive guide on the Cisco NAC Appliance solution itself. This chapter focuses on general NAC Appliance design principles and how they apply to components of the Schools SRA.

Cisco NAC Appliance is an easily deployed NAC product that uses the network infrastructure to enforce security policy compliance on all devices seeking to access network computing resources. With Cisco NAC Appliance, network administrators can authenticate, authorize, evaluate, and remediate wired, wireless, and remote users and their machines prior to network access. The Cisco NAC Appliance identifies whether networked devices such as laptops, or IP phones are compliant with network security policies, and repairs any vulnerabilities before permitting access to the network.

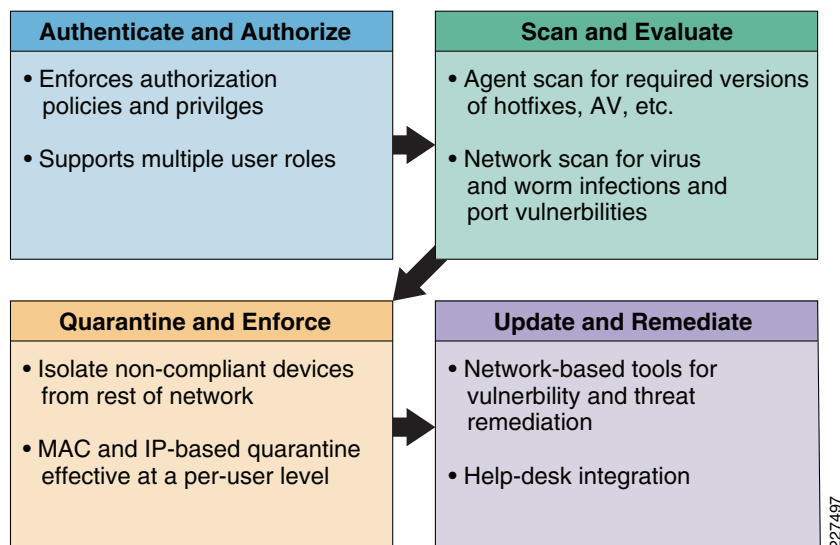

When deployed, the Cisco NAC Appliance provides the following benefits:

- Recognizes users, their devices, and their roles in the network. This first step occurs at the point of authentication, before malicious code can cause damage.
- Evaluates whether machines are compliant with security policies. Security policies can include specific anti-virus or anti-spyware software, OS updates, or patches. Cisco NAC Appliance supports policies that vary by user type, device type, or operating system.
- Enforces security policies by blocking, isolating, and repairing non-compliant machines.
- Non-compliant machines are redirected to a quarantine network, where remediation occurs at the discretion of the administrator.

Figure 9-1 shows the following four key functions of the NAC:

- Authenticate and authorize
- Scan and evaluate
- Quarantine and enforce
- Update and remediate

Figure 9-1 The Four Functions of the NAC Framework

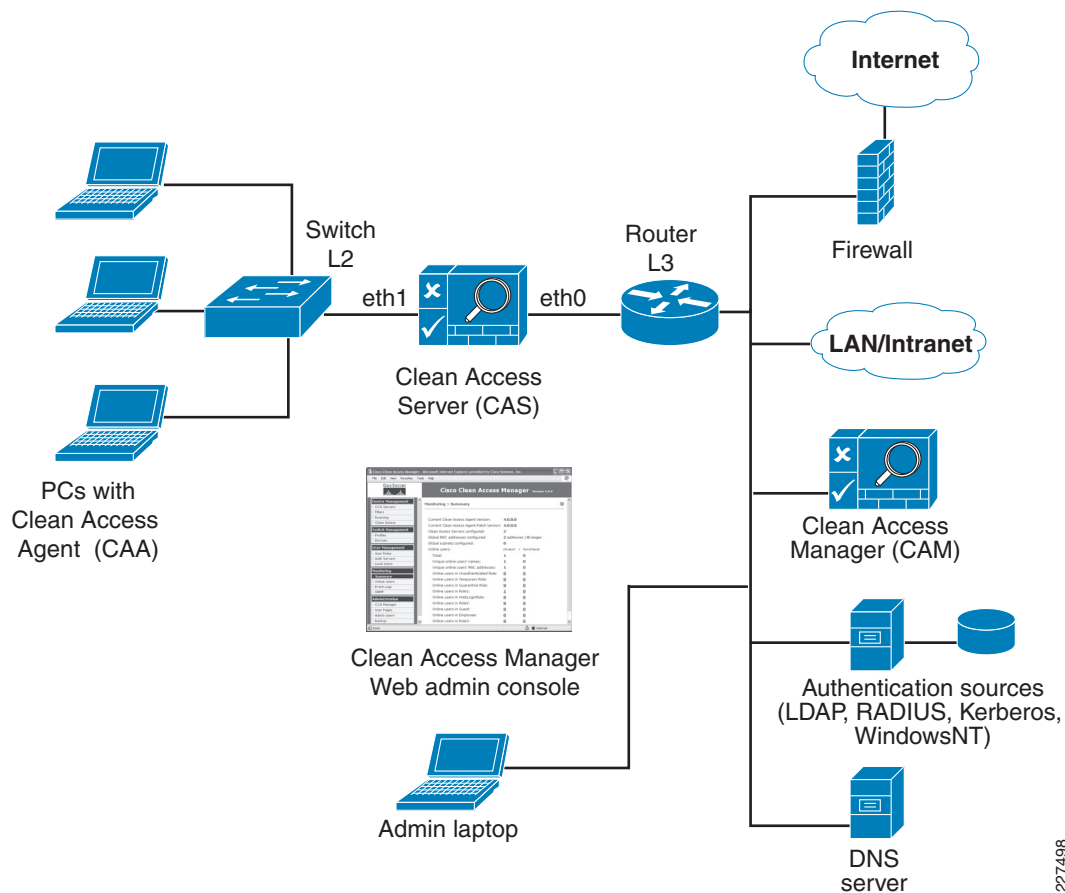

For a more in-depth overview of the Clean Access Server and Clean Access Manager, see the following URLs:

- Cisco NAC Appliance-Clean Access Server Installation and Administration Guide
http://www.cisco.com/application/pdf/en/us/guest/products/ps7122/c1626/ccmigration_09186a00807a4090.pdf
- Cisco NAC Appliance-Clean Access Manager Installation and Administration Guide
http://www.cisco.com/en/US/docs/security/nac/appliance/configuration_guide/45/cam/45cam-book.html

Cisco Clean Access Components

Cisco NAC Appliance is a network-centric integrated solution administered from the Cisco Clean Access Manager web console and enforced through the Clean Access Server and (optionally) the Clean Access Agent or Cisco NAC Web Agent. Cisco NAC Appliance checks client systems, enforces network requirements, distributes patches and antivirus software, and quarantines vulnerable or infected clients for remediation before clients access the network. Cisco NAC Appliance consists of the components shown in Figure 9-2.

Figure 9-2 NAC Components (Source Document NAC CAM Configuration Guide)

Clean Access Manager (CAM)

CAM is the administration server for Clean Access deployment. The secure web console of the Clean Access Manager is the single point of management for up to 20 Clean Access Servers in a deployment (or 40 CASs if installing a SuperCAM). For Out-of-Band (OOB) deployment, the web admin console allows you to control switches and VLAN assignment of user ports through the use of SNMP. In the Schools SRA, the CAM would be located at the district office.

Clean Access Server (CAS)

CAS is the enforcement server between the untrusted (managed) network and the trusted network. The CAS enforces the policies you have defined in the CAM web admin console, including network access privileges, authentication requirements, bandwidth restrictions, and Clean Access system requirements. You can install a CAS as either a standalone appliance (like the Cisco NAC-3300 Series) or as a network module (Cisco NME-NAC-K9) in a Cisco ISR chassis and deploy it in-band (always inline with user traffic) or OOB (inline with user traffic only during authentication/posture assessment).

The CAS can also be deployed in Layer 2 mode (users are Layer-2-adjacent to CAS) or Layer 3 mode (users are multiple Layer-3 hops away from the CAS). You can also deploy several CASs of varying size/capacity to fit the needs of varying network segments. You can install Cisco NAC-3300 Series appliances in your company headquarters core, for example to handle thousands of users and simultaneously install one or more Cisco NAC network modules in ISR platforms to accommodate smaller groups of users at a satellite office, for example.

In the Schools SRA, the CAS would be located at the schools sites and the district office, and it would be used to provide Layer-2 or Layer-3 OOB authentication/posture assessment.

Clean Access Agent (CAA)

CAA is optional read-only agent that resides on Windows clients. It checks applications, files, services, or registry keys to ensure that clients meets your specified network and software requirements prior to gaining access to the network.

Note

There is no client firewall restriction with CAA posture assessment. The agent can check the client registry, services, and applications even if a personal firewall is installed and running.

If NAC is implemented as part of the Schools SRA it is recommended that the CAA be used.

Cisco NAC Web Agent

The Cisco NAC Web Agent provides temporal posture assessment for client machines. Users launch the Cisco NAC Web Agent executable, which installs the Web Agent files in a temporary directory on the client machine via ActiveX control or Java applet. When the user terminates the Web Agent session, the Web Agent logs the user off of the network and their user ID disappears from the Online Users list.

Clean Access Policy Updates

Regular updates of prepackaged policies/rules that can be used to check the up-to-date status of operating systems, antivirus (AV), antispyware (AS), and other client software. Provides built-in support for 24 AV vendors and 17 AS vendors.

NAC Appliance Modes and Positioning

NAC Appliance allows multiple deployment options and may be placed at different points in the network. The modes of operation can be generally defined as follows:

- Out-of-band (OOB) virtual gateway
- OOB IP gateway
- In-band (IB) virtual gateway
- IB real IP gateway

OOB Modes

OOB deployments require user traffic to traverse through the NAC Appliance only during authentication, posture assessment, and remediation. When a user is authenticated and passes all policy checks, their traffic is switched normally through the network and bypasses the appliance. See [Figure 9-3](#).

Figure 9-3 Layer-2 OOB Topology

To deploy the NAC Appliance in this manner, the client device must be directly connected to the network via a Catalyst switch port. After the user is authenticated and passes posture assessment, the Clean Access Manager (CAM) instructs the switch to map the user port from an unauthenticated VLAN (which switches or routes user traffic to the NAC) to an authenticated (authorized) VLAN that offers full access privileges. For example, as shown in [Figure 9-3](#), the client PC is connected through VLAN 110 to the NAC Clean Access Server for the authentication and posture assessment, and is moved to VLAN 10 once it successfully completes the authentication and authorize, and scan and evaluation phases of the NAC framework.

In-Band Modes

When the NAC Appliance is deployed in-band, all user traffic, both unauthenticated and authenticated, passes through the NAC Appliance, which may be positioned logically or physically between end users and the network(s) being protected. See [Figure 9-4](#) for a logical in-band topology example and [Figure 9-5](#) for a physical in-band topology example.

Figure 9-4 In-Band Virtual Gateway Topology**Figure 9-5 Physical In-Band Topology**

In-Band Virtual Gateway

When the NAC Appliance is configured as a virtual gateway, it acts as a bridge between end users and the default gateway (router) for the client subnet being managed. The following two bridging options are supported by the NAC Appliance:

- *Transparent*—For a given client VLAN, the NAC Appliance bridges traffic from its untrusted interface to its trusted interface. Because the appliance is aware of “upper layer protocols”, by default it blocks all traffic except for Bridge Protocol Data Unit (BPDU) frames (spanning tree) and

those protocols explicitly permitted in the “unauthorized” role; for example, DNS and DHCP. In other words, it permits those protocols that are necessary for a client to connect to the network, authenticate, undergo posture assessment, and remediation. This option is viable when the NAC Appliance is positioned physically in-band between end users and the upstream network(s) being protected, as shown in Figure 5.

- *VLAN mapping*—This is similar in behavior to the transparent method except that rather than bridging the same VLAN from the untrusted side to the trusted side of the appliance, two VLANs are used. For example, Client VLAN 131 is defined for the untrusted interface of the NAC Appliance. There is no routed interface or switched virtual interface (SVI) associated with VLAN 131. VLAN 31 is configured between the trusted interface of the NAC Appliance and the next-hop router interface/SVI for the client subnet. A mapping rule is made in the NAC Appliance that forwards packets arriving on VLAN 131 and forwards them out VLAN 31 by swapping VLAN tag information. The process is reversed for packets returning to the client. Note that in this mode, BPDUs are not passed from the untrusted-side VLANs to their trusted-side counterparts.

The VLAN mapping option is usually selected when the NAC Appliance is positioned logically in-band between clients and the networks being protected. This is the bridging option that should be used if the NAC Appliance is going to be deployed in the virtual gateway mode.

In-Band Real IP Gateway

When the NAC Appliance is configured as a “real” IP gateway, it behaves like a router and forwards packets between its interfaces. In this scenario, one or more client VLAN/subnets reside behind the untrusted interface. The NAC Appliance acts as a default gateway for all clients residing on those networks. Conversely, a single VLAN/subnet is defined on the trusted interface, which represents the path to the protected upstream network(s).

After successful client authentication and posture assessment, the NAC Appliance by default routes traffic from the untrusted networks to the trusted interface, where it is then forwarded based on the routing topology of the network.

The NAC Appliance is not currently able to support dynamic routing protocols. As such, static routes must be configured within the trusted side of the Layer 3 network for each client subnet terminating on or residing behind the untrusted interface. These static routes should reference, as a next hop, the IP address of the trusted interface of the NAC.

If one or more Layer-3 hops exist between the untrusted NAC interface and the end-client subnets, static routes to the client networks must be configured in the NAC Appliance. Likewise, a static default route (0/0) is required within the downstream Layer 3 network (referencing the IP address of the untrusted NAC interface) to facilitate default routing behavior from the client networks to the NAC Appliance.

Depending on the topology, multiple options exist to facilitate routing to and from the NAC Appliance, including static routes, VRF-Lite, MPLS VPN, and other segmentation techniques. It is beyond the scope of this design guide to examine all possible methods.

In-Band Versus Out-of-Band

Table 9-1 summarizes different characteristics of each type of deployment.

Table 9-1 In-Band Versus Out-of-Band Deployment Characteristics

In-Band Deployment Characteristics	Out-of-Band Deployment Characteristics
The Clean Access Server (CAS) is always inline with user traffic (both before and following authentication, posture assessment and remediation). Enforcement is achieved through being inline with traffic.	The Clean Access Server (CAS) is inline with user traffic only during the process of authentication, assessment and remediation. Following that, user traffic does not come to the CAS. Enforcement is achieved through the use of SNMP to control switches and VLAN assignments to ports.
The CAS can be used to securely control authenticated and unauthenticated user traffic by using traffic policies (based on port, protocol, subnet), bandwidth policies, and so on.	The CAS can control user traffic during the authentication, assessment and remediation phase, but cannot do so post-remediation since the traffic is out-of-band.
Does not provide switch port level control	Provides port-level control by assigning ports to specific VLANs as necessary
In-Band deployment is supported when deploying for wireless networks	Wireless OOB requires a specific network topology and configuration.
Cisco NAC Appliance In-Band deployment with supported Cisco switches is compatible with 802.1x	Cisco does not recommend using 802.1x in an OOB deployment, as conflicts will likely exist between Cisco NAC Appliance OOB and 802.1x to set the VLAN on the switch interfaces/ports.

Out-of-Band Requirements

OOB implementation of Cisco NAC Appliance requires the switches and Wireless LAN Controllers be supported by the Cisco NAC Appliance software. All the switches tested as part of the development of the Schools SRA, apart from the Cisco Catalyst 2975, are supported by the Cisco NAC OOB, and the Wireless LAN Controllers are also supported by the NAC Appliance software used in this design guide. If the Catalyst 2975 is to be used as an access switch with the Cisco NAC Appliance, the NAC solution must be an in-band solution.

Note

To obtain the latest list of supported devices, check the latest version of the *Cisco NAC Appliance-Clean Access Manager Installation and Administration Guide* at the following URL:
http://www.cisco.com/en/US/docs/security/nac/appliance/configuration_guide/45/cam/45cam-book.html

Out-Of-Band, Layer 2 and Layer 3

The proposed design for the Schools SRA is an OOB design, in order the highest possible performance and scalability for traffic that has passed through the authentication, posture assessment, and remediation stages of NAC. The Schools SRA offers two different access layer options, a Layer-2 access layer for smaller schools and a hybrid Layer-2/Layer-3 access layer for larger schools. This means that either a Layer-2 OOB solution or a Layer-3 OOB NAC solution may be deployed.

NAC Deployment in the Schools SRA

The Schools SRA provides for a Cisco NAC Appliance solution at each site type, District Office, School Site 1, and School Site 2, with a CAM at the District Office, and a CAS at the District Office and Schools Sites. In each of the different site types the CAS is directly connected to the core/distribution.

The simple topology used in the Schools SRA sites means that a VLAN from an access layer to the untrusted interface of the NAC Appliance is always available as a standard component of the design, and untrusted traffic should never need to be tunneled to the CAS. This allows a common the network configuration, to support NAC at any of the School sites, regardless of whether the client devices are using a Layer-2 or Layer-3 access model. As the client can use a Layer-2 connection to the untrusted interface of the NAS in either Layer 2 or Layer 3 access mode (this requires a trunk between the Layer-3 access switch and the core/distribution. One VLAN of the trunk would carry the untrusted VLAN, and the other VLAN the IP routing for all other traffic), and the VLAN used once the client is trusted will be either be a Layer-2 access VLAN from the core/distribution switch or a Layer-3 access switch VLAN depending upon the site requirements.

This is illustrated in [Figure 9-6](#) and [Figure 9-7](#). In [Figure 9-6](#), there is a simple Layer-2 NAC OOB connection where a client device upon initial connection to the network is given VLAN 264, which connects them directly to the untrusted interface of the NAS. The mapping of this interface through the NAC VLAN 64 trusted interface allows the client to obtain an IP address that belongs on VLAN 64. To perform any action permitted by an untrusted client, upon success completion of the NAC function, the access switch is instructed, via SNMP, to change the client VLAN to VLAN 64. Even though the client has changed Layer-2 VLANs its Layer-3 network connections are unchanged.

In [Figure 9-7](#), the same processes are followed when the client is untrusted, but once the client has successfully completed its NAC functions the access switch is instructed via SNMP to change the client VLAN to VLAN 67—a subnet local to the access switch. As the Layer-3 information for the client has changed the switch is also instructed to “bounce” the client switch port to initiate a new DHCP request for an IP address appropriate to VLAN 67.

Figure 9-6 Layer 2 OOB topology

Figure 9-7 Layer 3 OOB Topology

Configuring the CAS and CAM

The initial CAS and CAM configuration are done via directly on the server interface, and this is described in the installation guide, *Cisco NAC Appliance Hardware Installation, Release 4.1*. During the configuration stage the multiple steps must be followed in configuring the NAC Appliance with IP addresses, VLANs, passwords, etc. The installation guide contains worksheets assist in the gathering and preparation of this information for both the CAM and CAS.

Once the CAM(s) and CAS(s) are configured they can be configured by their web interfaces. Almost all of the NAC Appliance solution can be configured through the CAM, and it have be access via HTTPS to the IP address assigned during the appliance configuration stages.

The first task on the CAM before beginning configuration is the installation the licenses for the solution. A license must be installed for the CAM, and the CAS servers that the CAM control. The *Cisco NAC Appliance Ordering Guide*, provides information on the ordering options.

Licenses can be entered via the CAM web interface, as show in [Figure 9-8](#).

Adding a CAS to the CAM

For a CAS server to be managed by the CAM, it must be added to the list of managed servers on the CAM. To do this the CAM needs to know the IP address of the CAS, and the Server Type (its role in the network) of the CAS. In addition to this the CAS and the CAM must have the same shared secret. The shared secret is configured during the server installation. An example of adding a CAS to the CAM, is shown in [Figure 9-9](#).

Figure 9-9 Adding a new CAS to the CAM

The screenshot shows the Cisco Clean Access Standard Manager interface. On the left is a navigation menu with sections: Device Management (containing CCA Servers, Filters, and Clean Access), OOB Management (containing Profiles and Devices), and User Management (containing User Roles, Auth Servers, and Local Users). The main content area is titled 'Cisco Clean Access Standard Manager Version 4.5.1' and 'Device Management > Clean Access Servers'. Below this are three tabs: 'List of Servers', 'New Server', and 'Authorization'. The 'New Server' tab is active, displaying a form with the following fields: 'Server IP Address' (10.40.62.11), 'Server Location' (School1), and 'Server Type' (a dropdown menu with 'Virtual Gateway' selected and a list of other options including Real-IP Gateway, NAT Gateway, Out-of-Band Virtual Gateway, Out-of-Band Real-IP Gateway, and Out-of-Band NAT Gateway).

Once the CAS has been added to the CAM, it appears in the list of servers on the CAM. From this point, it can be managed directly from the CAM for almost all tasks. An example of a list of servers is shown in [Figure 9-10](#).

Figure 9-10 List of CAS Servers

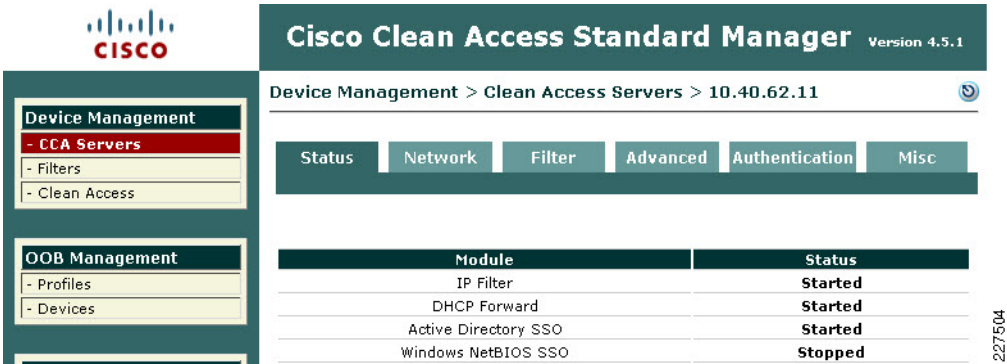

The screenshot shows the 'List of Servers' tab in the Cisco Clean Access Standard Manager. It displays a table with the following data:

IP Address	Type	Location	Status	Manage	Disconnect	Reboot	Delete
10.40.78.11	Out-of-Band Virtual Gateway		Connected				
10.40.62.11	Out-of-Band Virtual Gateway		Connected				

Managing the CAS

Once the CAS is in the list of servers managed by the CAM, it can be configured further for its role in the network. To manage the server click the icon under the Manage heading in the server list, this will connect you to the CAS server and present you with the summary menu shown in [Figure 9-11](#).

Figure 9-11 CAS Management Menu

Under the CAS Network setting tab, shown in Figure 9-12, the basic network settings for the CAS can be seen and altered, if needed. In this example, we are keeping the network configuration performed during the server installation. The primary dialog under the Network Tab is the IP dialog, shown in Figure 9-12, the other dialogs allow the DHCP options to be configured—our example uses the default of DHCP passthrough—and the DNS options where host name, domain name, and DNS server information is added, as shown in Figure 9-13.

Figure 9-12 CAS Network Settings

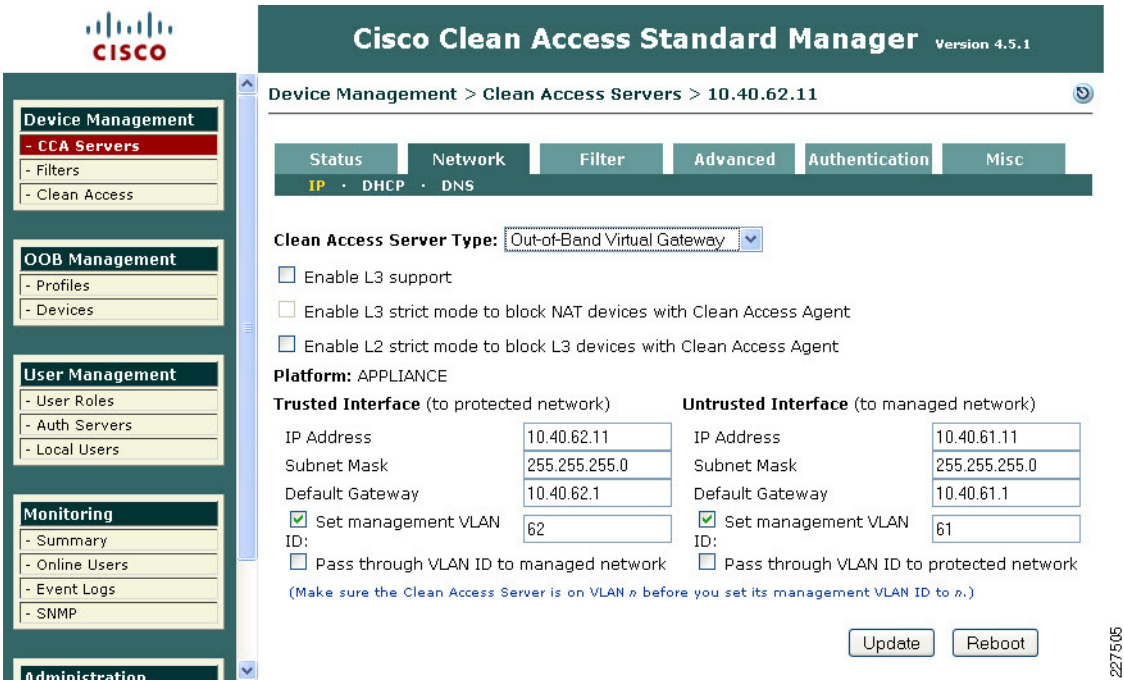

Figure 9-13 CAS DNS Settings

The screenshot shows the Cisco Clean Access Standard Manager interface. The left sidebar contains navigation menus for Device Management (CCA Servers, Filters, Clean Access), OOB Management (Profiles, Devices), and User Management (User Roles, Auth Servers, Local Users). The main content area is titled 'Cisco Clean Access Standard Manager Version 4.5.1' and shows the path 'Device Management > Clean Access Servers > 10.40.62.11'. Below this, there are tabs for Status, Network, Filter, Advanced, Authentication, and Misc. The 'DNS' sub-tab is selected under the 'Network' tab. The form contains the following fields:

- Host Name: s1casuser
- Host Domain: ese.local
- DNS Servers: 10.33.32.5 (separate multiple addresses with a comma)
- An 'Update' button is located below the DNS Servers field.

The next tab in the CAS configuration is the Filter tab (see Figure 9-14), for the purposes of our example the important dialog is the Roles where network traffic filters may be applied to different user Roles. The Role of interest at this moment is the default Unauthenticated Role. By default the Unauthenticated Role blocks all traffic. In this example we are allowing the Unauthenticated Role to pass Active Directory client authentication traffic to pass to the Active Directory Sever. This will allow a windows client to join the active Directory Domain, and windows users to authenticate to the domain although they have not been through the NAC process. This is often important to allow printer and drive mapping information to be sent to the winders users. As the user has already authenticated to the Active Directory Domain the user authentication information maybe learned from Active Directory, and the user does not have to reauthenticate for the NAC server.

**Note**

The creation of Roles and their associated filters is performed in the CAM User Management -> User Roles menu.

Figure 9-14 CAS Filter Settings

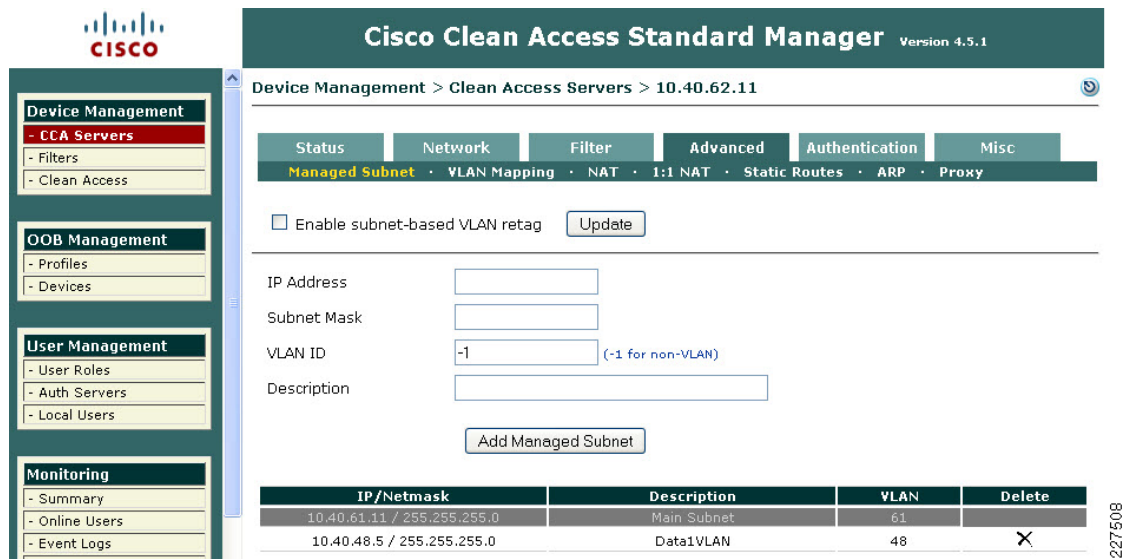

The screenshot shows the Cisco Clean Access Standard Manager interface with the 'Filter' tab selected. The path is 'Device Management > Clean Access Servers > 10.40.62.11'. The 'Filter' tab is active, showing sub-tabs for Devices, Subnets, Roles, Clean Access, and Fallback. The 'Roles' sub-tab is selected, showing a table of roles and their associated filters. The 'Unauthenticated Role' is highlighted. The table shows the following filters:

Action	Protocol	Untrusted	Trusted	Enable	Edit	Del	Move
Allow	UDP	*:*	10.33.32.5 /255.255.255.255 :88,389,636	<input checked="" type="checkbox"/>			
Allow	TCP	*:*	10.33.32.5 /255.255.255.255 :88,135,335,389,636,1025,1026	<input checked="" type="checkbox"/>			
Allow	UDP	DNS [†]					
Block	ALL						

Below the table, there is a 'Select' button and a link 'Add Policy to All Roles'. The 'Add Policy' link is also visible in the top right corner of the table area.

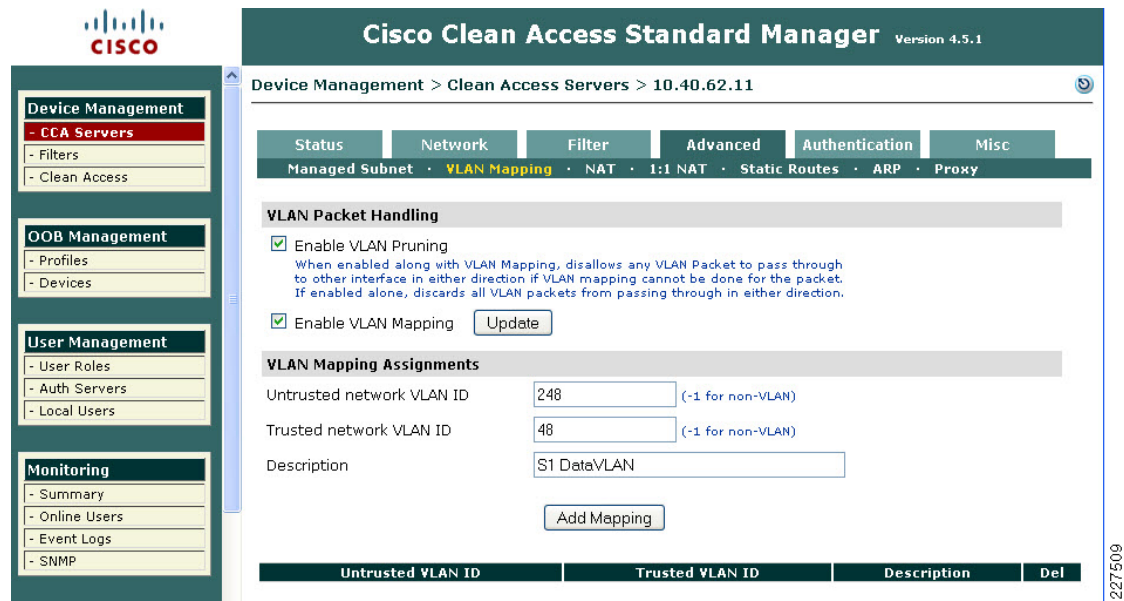

The next tab that requires configuration is the Advanced tab. This has multiple dialogs that require configuration. The first of these is the Managed Subnet dialog, where each of the trusted VLAN subnets is added to the CAS for management. An example of this shown in Figure 9-15.

Figure 9-15 CAS Managed Subnet

The next dialog of the Advanced Tab is the VLAN Mapping dialog, which tells the CAS which trusted VLAN to be mapped to an untrusted VLAN, an example of this is shown in Figure 9-16. In our example VLAN Pruning and VLAN Mapping is also enabled.

Figure 9-16 VLAN Mapping

The next tab of interest is the Authentication Tab (see [Figure 9-17](#)), this tab has multiple dialogs for configuring different authentication options. The first dialog is the Login Page Dialog. This allows the configuration of different web login pages depending upon the untrusted subnet being used for authenticating client.

Figure 9-17 Authentication Login Page

The screenshot displays the Cisco Clean Access Standard Manager web interface, Version 4.5.1. The left sidebar contains a navigation menu with sections: Device Management (CCA Servers, Filters, Clean Access), OOB Management (Profiles, Devices), User Management (User Roles, Auth Servers, Local Users), Monitoring (Summary, Online Users, Event Logs, SNMP), and Administration (CCA Manager, User Pages, Admin Users). The main content area shows the configuration for the Login Page under the Authentication tab. The breadcrumb path is Device Management > Clean Access Servers > 10.40.62.11. The configuration includes fields for VLAN ID (248), Subnet (IP/Mask) (10.40.48.0 / 255.255.255.0), Operating System (ALL), Page Type (Frameless), and Page Description. There are checkboxes for enabling the login page, using a web client to detect MAC address and OS, and installing the DHCP Refresh tool. Buttons for Update, Cancel, and View are at the bottom right.

Web Client (ActiveX/Applet): ActiveX on IE, Java Applet on non-IE Browser

☒ Use web client to detect client MAC address and Operating System.

☐ Use web client to release and renew IP address when necessary (OOB).
(Helps OOB client acquire new IP address after authentication without bouncing the switch port)

☐ Install DHCP Refresh tool into Linux/MacOS system directory.
(Avoids root/admin password prompt to refresh the IP address for Linux/MacOS clients when the web client is used to perform DHCP release and renew)

Update Cancel View

227510

The other Authentication dialog of interest in this example is the Windows Auth dialog, as Windows Single Sign On (SSO) is used in this example. To perform Windows SSO the CAS needs to be able to communicate with Active Directory to determine the authentication state of the windows user. If Active Directory confirms that the user has authenticated to Active Directory the user doesn't need to perform additional authentication to the CAS. An example of this configuration is shown in [Figure 9-18](#). There are a number of steps required configure Active Directory SSO, as these are described in the *Cisco NAC Appliance —Clean Access Server Installation and Configuration Guide*. The key components in this configuration are:

- The creation of a Active Directory client account for the CAS
- Using the KTPass Application on Active Directory to convert the account encryption to DES encryption

Figure 9-18 CAS Windows Authentication

Clean Access Roles

The unauthenticated role is common to all clients, but once the client has been authenticated a different role may be applied based upon the identity of the client, different roles may be assigned for admin staff, teachers, or students.

User roles allow you to aggregate various policies into a user role. These policies include:

- Traffic policies
- Bandwidth policies

Note If bandwidth policies are to be enforced by the Clean Access Server it must be operating in band.

- VLAN ID retagging
- Clean Access network port scanning plugins
- Clean Access Agent/Cisco NAC Web Agent client system requirements

For example, an Admin, Teacher and Student roles could each have different traffic policies and VLANs, in addition the Student Role may enforce bandwidth policies by keeping the Student Traffic In band.

For more information on roles, refer to the *Cisco NAC Appliance - Clean Access Manager Installation and Configuration Guide* at the following URL:

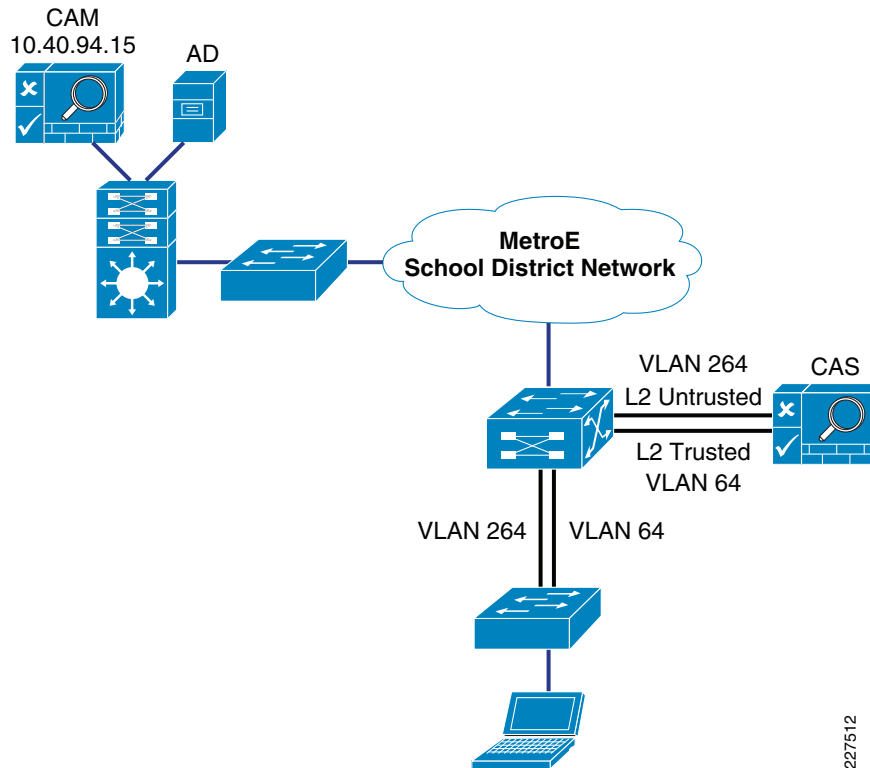

http://www.cisco.com/en/US/docs/security/nac/appliance/configuration_guide/45/cam/45cam-book.html

Layer 2 OOB Example

Figure 9-19 shows an example of a Layer-2 OOB deployment. Where a wired client connected to an access switch is originally on the untrusted VLAN 264 and is switched to a trusted VLAN 64 once it has completed the NAC functions. The first NAC function is the authentication and authorization function, and this is the first design decision in implementing the NAC solution. That is, how will authentication and authorization be achieved, and what will the user experience be.

This example is focused upon the virtual gateway example, as virtual gateway provides the simplest deployment. In the virtual gateway example the original IP addressing, interfaces, and VLANs are maintained, and normal traffic flows are maintained. The only changes are the addition of the untrusted VLANs that carry client traffic during the NAC Authentication and Authorization, Scanning and evaluation, remediation, and quarantine modes.

Figure 9-19 Layer 2 OOB Example

227512

NAC Authentication Options

The authentication option in the NAC solution can be broadly categorized as NAC Authentication or NAC Single Sign On

- *NAC Authentication*—NAC authentication gives the NAC system the role of authenticating users, a user database, either local to the NAC system or a separate system such as RADIUS, or LDAP
- *NAC Single Sign On*—NAC SSO, addresses systems that already perform authentication as part of their normal operation. For example 802.1X, VPN access, or Active Directory. NAC SSO learns the authentication state of clients through RADIUS accounting, or Active Director and therefore doesn't require the user to reenter authentication.

Topology Considerations

The Layer-2 OOB solution relies upon their being a Layer-2 network connection available between the the client devices and the Cisco CAS, in figure 5 a trunk connects the access switch to the core/distribution switch. The Cisco CAS is connected to the core/distribution switch through two

interfaces—trusted and untrusted. In such a simple network it is relatively easy to provide a Layer-2 connection between the client and the Cisco CAS, for larger networks Layer-3 OOB, which is discussed later in this section, may be a better choice.

The roles of the untrusted and trusted interfaces:

- *Untrusted Interface*—The untrusted interface connects the client to the Cisco CAS during the NAC Authentication and Authorization, Scanning and Evaluation, Remediation, and Quarantine modes
- *Trusted Interface*—The trusted interface connects the NAC CAS to the “normal” network interface. This makes a network connection available to the CAS while it is sitting between the client and the network, thus allowing client access to services such as DHCP and DNS -and user defined services. Once a client has successfully completed its authentication and scanning phases, the CAM uses SNMP to change the client VLAN, on the access switch, from the untrusted VLAN to the trusted VLAN. Thus providing a direct connection to the network that was on the other side of the CAS (the trusted network).

Availability Considerations

Both the CAS and CAM are both highly involved in client network access, and consideration must be given to the impact on clients if either a CAS or CAM should fail or need to be taken out of service for a period of time.

The CAS is inline with client devices during the authentication, authorization, and posture assessment phases of NAC, and if “In Band NAC” is being used it may be inline at all times. A CAS outage in an OOB deployment would not impact already connected clients but would prevent network access for new clients. A CAS outage for “In Line” clients prevents access for all clients.

In situations where availability of a CAS is critical an HA CAS solution may be implemented where a pair of CAS servers are installed using a primary CAS, and a secondary in hot standby. For more information refer to the *Cisco NAC Appliance - Clean Access Server Installation and Configuration Guide*.

The CAM is also a critical part of the authentication, authorization, and posture assessment phases of NAC, although it doesn't pass client traffic, the impact of its availability needs to be considered in the network design as well. Like the CAS the CAM has a HA solution that provides for a primary server and a hot standby secondary server. In addition, each CAS may be configured with a “fallback” option (as shown in [Figure 9-20](#)) that defines how it will manage client traffic in a situation where the CAM is unavailable.

In both HA CAM, and HA CAS, HA licenses are used that address the HA role of the server.

The use of the HA features will be dependent upon a School's requirements, but CAS fallback should always be configured to ensure that critical network services are available in even of a network outage.

Figure 9-20 CAS Fallback

Cisco Clean Access Lite Manager Version 4.5.1

Device Management > Clean Access Servers > 10.40.62.11

Status | Network | Filter | Advanced | Authentication | Misc
 Devices | Subnets | Roles | Clean Access | **Fallback**

The Clean Access Server periodically verifies connectivity with the Clean Access Manager (according to the Detect Interval) over the course of the specified Detect Timeout.

If the Clean Access Manager fails to respond to the Clean Access Server a minimum percentage of time (specified by the Fail Percentage), the Clean Access Server sets the traffic policy of every user role to "Allow All" or "Block All," depending on the Fallback Policy.

Following Clean Access Server Fallback, once the Clean Access Manager successfully responds to the Clean Access Server a minimum percentage of time (according to the Resume Percentage) over a subsequent Detect Timeout period, the Clean Access Server resumes normal operation.

Fallback Policy:

Detect Interval: in seconds (Minimum = 20)

Detect Timeout: in seconds (Minimum 15x Detect Interval)

Fail Percentage: % (Minimum = 25, Maximum = 50)

Resume Percentage: % (100 - Fail Percentage/2)

227513

Basic Clean Access switch Configuration

For OOB-based Clean Access some simple configuration must be performed on the switches implementing NAC. This configuration is primarily to enable SNMP communication between the switches and the CAM. Table 9-2 shows a simple SNMP v1 configuration (SNMPv2c and SNMPv3 are supported).

In addition to the switch SNMP configuration, the required trusted and untrusted VLANs must exist and be operational on the switch. If a switch has more than one IP address the **snmp-server** source interface must be specified, as the CAM must be configured with the source IP address that OOB SNMP messages will originate from, alternatively all IP addresses of interfaces on the switch can be added to the CAM. If SNMP access filtering is applied on the switch (as recommended as a best practice) the CAM must be added as a trusted address.

Basic Clean Access Out of Band Switch configuration

802.1X Protected Ports

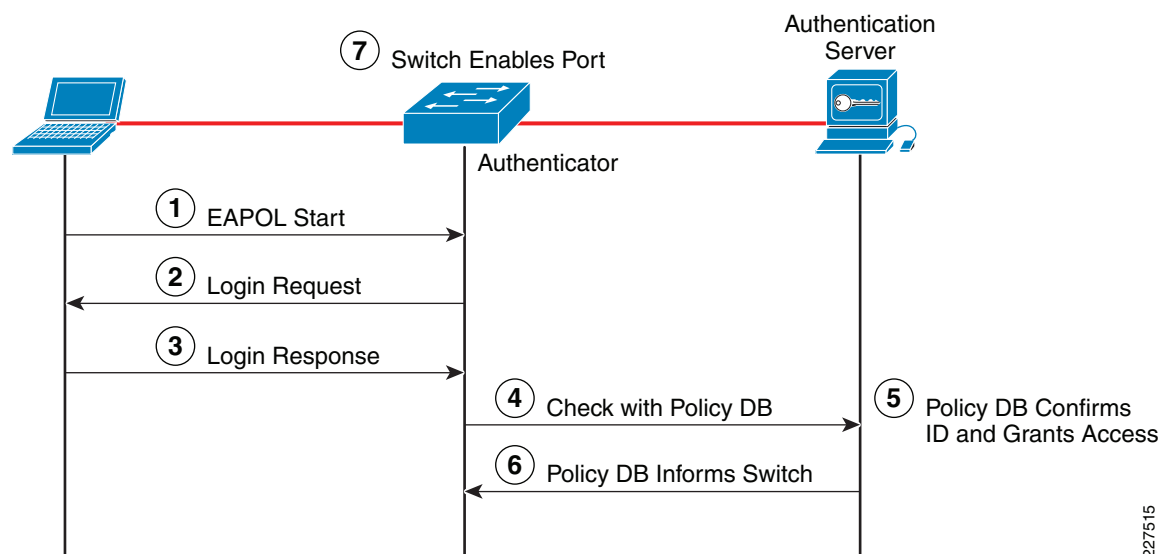

The best and most secure solution to vulnerability at the access edge is to leverage the intelligence of the network. The Cisco IBNS solution is a set of Cisco IOS software services designed to enable secure user and host access to enterprise networks powered by Cisco Catalyst switches and wireless LANs. It provides standards-based network access control at the access layer by using the 802.1X protocol to secure the physical ports where end users connect. 802.1X is an IEEE standard for media-level (Layer 2) access control, offering the capability to permit or deny network connectivity based on the identity of the end user or device. 802.1X is well-known as a way to secure wireless network access. It is equally essential in securing wired network access.

What is 802.1X?

The IEEE 802.1X protocol allows Cisco Catalyst switches to offer network access control at the port level. Every port on the switch is individually enabled or disabled based on the identity of the user or device connecting to it. When 802.1X is first enabled on a port, the switch automatically drops all traffic received on that port. There is one exception to this rule. The only traffic a switch will accept is a request to start 802.1X authentication. Only after the 802.1X authentication has successfully completed will the switch accept any other kind of traffic on the port.

The high-level message exchange in [Figure 9-21](#) illustrates how port-based access control works within an identity-based system. First, a client, such as a laptop equipped with an 802.1X supplicant, connects to an IEEE 802.1X-enabled network and sends a start message to the LAN switch the *authenticator*. Once the start message is received, the LAN switch sends a login request to the client and the client replies with a login response. The switch forwards the response to the policy database *authentication server* which authenticates the user. After the user identity is confirmed, the policy database authorizes network access for the user and informs the LAN switch. The LAN switch then enables the port connected to the client.

Figure 9-21 Port-Based Access Control

User or device credentials are processed by a AAA server. The AAA server is able to reference user or device policy profile information either internally, using the integrated user database, or externally, using database sources such as Microsoft Active Directory, LDAP, Novell NDS or Oracle databases. This enables the integration of the system into existing user management structures and schemes, thereby simplifying overall deployment.

802.1X and EAP

When authenticating users for the purposes of network access control, the system must provide user and/or device identification using strong authentication technologies known to be secure and reliable. IEEE 802.1X does not by itself dictate how this is achieved. Rather, the 802.1X protocol defines an encapsulation for the transport of the Extensible Authentication Protocol (EAP) from the client to the switch. The 802.1X encapsulation is sometimes referred to as EAP over LAN (EAPoL). The switch in turn relays the EAP information to the authentication server using the RADIUS protocol (EAP over RADIUS).

EAP, which is defined by RFC 3748, is itself a framework---not a specific authentication method. EAP provides a way for the client and the authentication server to negotiate an authentication method that they both support. There are many EAP methods but the ones used more frequently for 802.1X wired authentication include EAP-TLS, EAP-PEAP, and EAP-FAST.

How 802.1X Impacts the Network

Before enabling 802.1X in the network, it is essential to review the default security posture of a port enabled for 802.1X authentication: all traffic is dropped except 802.1X EAPoL packets. This is a fundamental change from the traditional model in which the port is enabled and all traffic is allowed from the moment that a device plugs into the port. Ports that were traditionally open will now be closed by default. This is one of the cornerstones of the strong security and network access control provided by 802.1X. However, this change in the default network access model can have a profound impact on network devices and applications. Understanding and providing for the impacts of this change will make for a smooth deployment of 802.1X network access control.

Non-802.1X-Enabled Devices

802.1X must be enabled on both the host device and on the switch to which the device connects. If a device without an 802.1X supplicant attempts to connect to a port that is enabled for 802.1X, it will be subjected to the default security policy. The default security policy says that 802.1X authentication must succeed before access to the network is granted. Therefore, by default, non-802.1X-capable devices cannot get access to an 802.1X-protected network.

Although many devices increasingly support 802.1X, there will always be devices that require network connectivity but do not and/or cannot support 802.1X. Examples of such devices include network printers, badge readers, legacy servers, and PXE boot machines. Some provision must be made for these devices.

Cisco provides two features to accommodate non-802.1X devices. These are MAC Authentication Bypass (MAB) and the Guest VLAN. These features provide fallback mechanisms when there is no 802.1X supplicant. After 802.1X times out on a port, the port can move to an open state if MAB succeeds or if the Guest VLAN is configured. Judicious application of either or both of these features will be required for a successful 802.1X deployment.

**Note**

Network-specific testing will be required to determine the optimal values for 802.1X timers to accommodate the various non-802.1X-capable devices on your network.

802.1X in Schools

As mentioned above on the requirement for 802.1X authentication is the requirement for a supplicant. This has typically been a challenge in the schools environment with a wide range of the devices and limited or no management of many of these devices. In many schools this is still the case, and this makes a district wide 802.1X very challenging. At the same time there are pockets of a school network where 802.1X may be a good choice.

For example 802.1X protected ports may be a good choice for the network ports in the District Office, and the school administrator office, as these locations are more likely to have managed PCs.

Other locations in the schools network still need protection, but student network access may be better served by a NAC Appliance solution. Network access ports in open areas such as classrooms may use 802.1X or Cisco Clean Access NAC to protect these ports.

When considering the 802.1X deployment, there are four main 802.1X authentication options to consider.

- *Basic 802.1X Authentication*—An 802.1X controlled port with an 802.1X client directly connected
- *IP Phone Ports*—An IP Phone and an 802.1X controlled port with an 802.1X client connected to the phone
- *MAC Auth By-Pass*—Using the MAC address of the client to provide authentication and bypass the 802.1X authentication process. Printer and legacy device support are typical applications
- *Web Auth*—Allowing a user to authenticate by entering username and passwords in a web page. Legacy device support and guest access are typical deployment applications

Basic 802.1X Switch Configuration

The basic 802.1X configuration controls access to an access VLAN depending upon the success or failure of the an 802.1X authentication. If the 802.1X authentication is successful, there are three basic options:

- Access to the VLAN configured on the switch port
- Access to the VLAN configured on the switch port an controlled by a access list downloaded from the AAA server
- Access to a VLAN passed to the switch by the AAA server

Table 9-3 shows example 802.1X configurations.

Table 9-3 802.1X Switch Configuration

Example 3750 802.1X PC Port Configuration	Example 3750 Global Configuration
<pre>authentication port-control auto authentication periodic dot1x pae authenticator</pre>	<pre>aaa new-model aaa authentication dot1x default group radius dot1x system-auth-control ip radius source-interface Vlan300 radius-server host 10.40.62.9 auth-port 1812 acct-port 1813 key cisco radius-server host 10.40.94.9 auth-port 1812 acct-port 1813 key cisco</pre>

For more information upon the 3750 802.1X configuration refer to the following documents:

NAC 802.1X and CISF in Combination

The three key access security features discussed above have been discussed in isolation, but can be combined. In particular, the CISF features should be considered “baseline” features that are applied on all access ports, and either NAC or 802.1X maybe overlaid on top of the CISF configuration.

The Cisco Clean Access and 802.1X configuration are also compatible (although they are not often combined in wired networks), the key consideration in combining the two is how to give the appearance of a SSO for the end user. Both 802.1X and NAC require authentication, as 802.1X authenticates the client initially, a mechanism of communicating the 802.1X authentication result to the Cisco Clean Access system is required.

If the authenticating clients join an Windows Active Directory network, the Cisco Clean Access Active Directory SSO feature allows the clients to authenticate to active directory once they have performed there 802.1X authentication. The CAM, when a client is detected, checks Active Directory to see if the client has authenticated; this allows a SSO experience for client devices that are using 802.1X and NAC.

DMP Ports

A DMP connection to the network is like that of a typical IP client. There should only be one MAC address and one IP address on that port. This means that typical PC client port security settings will work.

An DMP is primarily are receiver for packets, but if traffic classification from the DMP is important the DSCP from the DMP should be trusted

Surveillance Camera Port

An the Surveillance Camera connection to the network is like that of a typical IP client. There should only be one MAC address and one IP address on that port. This means that typical PC client port security settings will work.

An the camera marks packets with DSCP marking based upon its configured QoS policies. Therefore, to ensure that the QoS policy is effective the network must trust the DSCP Markings from the camera.

Power-over-Ethernet

The APs in the Schools SRA are 802.11n APs, and can provide greater than 100Mbps throughput, and therefore they should use 1-Gigabit Ethernet.

An LWAPP AP connection to the network is like that of a typical IP client. There should only be one MAC address and one IP address on that port. This means that typical PC client port security settings will work. If 802.1X is used on the network the APs are able to act as 802.1X supplicants and authenticate to the network. An LWAPP AP marks the LWAPP packets with DSCP marking based upon the CUWN QoS policies. Therefore to ensure that the QoS policy is effective the network must trust the DSCP Markings from the AP.

If the switch or module supports PoE, it may be able to power the APs connected to its ports.

Although the LWAPP APs can connect to the network in the same manner as a trusted PC client, it is recommend that the LWAPP APs have their own dedicated subnet and VLAN. This makes AP specific policies easier to implement within the network, and generally make network management tasks easier.

1250 Power-over-Ethernet

Today's PoE standard, 802.3af, peaks at getting 15.4 watts to the devices it powers. Unfortunately, 11n requires a bit more power in order to realize the new standard's full potential. As a result, the Aironet 1250 Series access point requires 18.5 watts in full operational mode.*Note:*There is no getting around the higher power requirements of 11n unless you either remove a radio (the Aironet 1250 Series access point can run with a single radio on 802.3af) or remove valuable 11n functionality. Though others may opt to do so, Cisco has chosen not to remove 11n's key features (such as spatial division multiplexing support or multiple transmitters/receivers) in order to allow it to be powered with legacy PoE infrastructure. How can you still use PoE functionality for a device that requires more wattage than the current standard delivers? Midspan PoE, in which an injector powers the AP, is the simple answer. Just make sure you purchase an injector that can support the additional power requirements. These can be ordered along with the Aironet 1250 or separately; the midspan PoE injector part number is AIR-PWRINJ4= and the AC adapter is AIR-PWR-SPLY1=. End-span PoE, in which the AP pulls power from the switch to which it is connected, requires a bit more planning. In 2005, the IEEE came together to address the issue of increasing power requirements and formed the 802.3at Working Group to push through a higher power PoE standard. This new standard has yet to be ratified, which would make it a full, industry-accepted protocol, but it does provide an archetype by which up to 30 watts may be delivered to a device across existing Cat5 cabling. While 802.3at makes its way through the approval process, Cisco provides an enhanced PoE (often called PoE Plus) option available in some of its flagship switching products. Using Cisco Discover Protocol (CDP) and robust power subsystem engineering, Cisco offers the Cisco Catalyst 3560E and 3750E with additional support (beyond the 802.3af specification) for customers who wish to fully power a dual-radio Aironet 1250 Series access point. If you decide that powering an Aironet 1250 Series access point via 802.2af is so important that you are willing to forgo supporting either 2.4 GHz (11b/g/n) or 5 GHz (11a/n), you can use just one RF band. In

such cases, plan to support a 2.4-GHz environment (due to the overwhelming majority of clients that support this spectrum) and upgrade to support 5 GHz when budgetary, infrastructure, and user needs align.

1140 Power-over-Ethernet (PoE)

The Cisco 1140 access point is 802.3af (15.4 W)-compliant and can be powered by any of the following 802.3af compliant devices: 2106 controller-WS-C3550, WS-C3560, and WS-C3750 switches-C1880 switch-2600, 2610, 2611, 2621, 2650, and 2651 multiservice platforms-2610XM, 2611XM, 2621XM, 2650XM, 2651XM, and 2691 multiservice platforms-2811, 2821, and 2851 integrated services routers-3620, 3631-telco, 3640, and 3660 multiservice platforms-3725 and 3745 multiservice access routers-3825 and 3845 integrated services routers-Any 802.3af compliant power injector.

**Note**

The Cisco 1140 Series access point requires a Gigabit Ethernet link to prevent the Ethernet port from becoming a bottleneck for traffic because wireless traffic speeds exceed transmit speeds of a 10/100 Ethernet port.

**Note**

The Cisco 1250 Series access point can also be powered by a power injector (AIR-PWRINJ4) or local power (AIR-PWR-SPLY).

IP Phones

The IP phones used in the Schools SRA are all able to use Power-over-Ethernet (PoE) and are able to be powered by any of the PoE access switches discussed in this guide.

CHAPTER 10

School Site Design

The core/distribution component of the schools SRA is a key element in delivering a resilient network, while providing a network configuration that is easy to manage and to deploy. This chapter discusses both core/distribution models, the Cisco 3750 Stack model and the Cisco 4500 Modular switch model. This chapter summarizes different connection types to the core/distribution models, and the key features of those connections.

Large School—Modular Switch Design

The basic modular switch School topology is shown in [Figure 10-1](#). This design is based upon a collapsed core/distribution mode, and a Layer-2 access distribution model. In this type of design all of the IP subnets are defined on the 4500 modular switch, and access to these subnets is controlled by the VLANs that are trunked to the switches.

If desired a Layer-3 access switch model may be implemented, the physical topology does not change, and centrality of EtherChannel to the design does not change. The simplicity of the network design not only allows Layer-2 or Layer-3 access layers, it also allows a hybrid deployment. This allows the majority of clients on the switch use Layer-3 access features, but a group of legacy client are able to continue to use a Layer-2 network. This can be useful when migrating from clients that do not use IP, or rely heavily upon locally broadcast information to learn about services or devices on the network.

The 4500 modular core provides resilient connections to the access LAN switches, local server switch, WLC, and SRST Router through EtherChannel. The NAC Appliance does not support EtherChannel, and the two connections are used to connect to the trusted and untrusted interfaces of the CAS.

The WAN connection to the 4500 modular is a single connection

Figure 10-1 Stacked Switch School Schematic

Core/Distribution Virtual Interfaces

The following is an example configuration of the switch virtual interfaces (SVIs) configured on the core/distribution 4500 modular switch. This SVIs are trunked to the access switches as required, and access to the VLANs are controlled by the **switchport trunk allowed vlan** command applied on the port channels. The same basic configuration is used for the server switch.

```
interface Vlan101
description Connected to cr35_2960_Dept_1_VLAN
dampening
ip address 10.127.0.1 255.255.255.192
ip helper-address 10.125.31.2
no ip redirects
no ip unreachablees
ip pim sparse-mode
load-interval 30
!
interface Vlan102
description Connected to cr35_2960_Dept_2_VLAN
dampening
ip address 10.127.0.65 255.255.255.192
ip helper-address 10.125.31.2
no ip redirects
no ip unreachablees
ip pim sparse-mode
load-interval 30
!
...
!
interface Vlan110
description Connected to cr35_2960_Dept_10_VLAN
dampening
ip address 10.127.2.65 255.255.255.192
ip helper-address 10.125.31.2
no ip redirects
no ip unreachablees
ip pim sparse-mode
load-interval 30
```

Example Port Channel Configuration

The following are examples of the port channel configuration on core/distribution 4500 modular switch and an example access switch. A similar configuration would be applied to each access switch connection with the same or different VLANs as required. From an IP routing or services level there is no requirement to span the same VLAN to multiple switches, but if there is a requirement to support legacy protocols such as AppleTalk at the school these AppleTalk VLANs can be easily spanned to different access switches as required

Example 4500 Modular Switch Port Channel Configuration

```
interface Port-channel11
description Connected to cr35-2960-SS1
switchport
switchport trunk encapsulation dot1q
switchport trunk native vlan 802
switchport trunk allowed vlan 101-110
switchport mode trunk
logging event link-status
load-interval 30
carrier-delay msec 0
qos trust dscp
```

Example 2960 Port Channel Configuration

```
interface Port-channel1
description Connected to cr35-4507-SS1
switchport trunk native vlan 802
switchport trunk allowed vlan 101-110,201
switchport mode trunk
ip arp inspection trust
load-interval 30
carrier-delay msec 0
hold-queue 2000 in
hold-queue 2000 out
ip dhcp snooping trust
```

WLC Connection

The WLC Connection to the core/distribution stack is fundamentally the same as an access switch connection, with different VLANs, and the exception of using a different QoS trust mode, where the CoS values from the WLC, are trusted. The following is an example 4500 modular switch Port Channel configuration:

```
Interface Port-channel12
description Connected to WLC-SS2
switchport trunk encapsulation dot1q
switchport trunk native vlan 802
switchport trunk allowed vlan 111-120
switchport mode trunk
load-interval 30
carrier-delay msec 0
ip dhcp snooping trust
```

NAC CAS Connection

The NAC CAS connection to the core/distribution switch. This is not an EtherChannel connection, but two switch ports are consumed. The two ports consist of a untrusted port for connecting client VLANs to the CAS prior to them completing the NAC process, and a trusted port that connects the NAS to the client VLANs used once clients have successfully completed the NAC process. The two, trusted and untrusted, ports are required even if OOB NAC is used, as the CAS requires access to the trusted VLANs during the NAC process. The following is an example of the configuration.

Core/Distribution NAC CAS Configuration

```
interface GigabitEthernet1/0/4
  description NAC Trusted Eth0
  switchport trunk encapsulation dot1q
  switchport trunk allowed vlan 48,57,62
  switchport mode trunk
  spanning-tree portfast trunk
!
interface GigabitEthernet1/0/5
!
interface GigabitEthernet1/0/6
!
interface GigabitEthernet1/0/7
!
interface GigabitEthernet1/0/8
  description NAC Untrusted Eth1
  switchport trunk encapsulation dot1q
  switchport trunk allowed vlan 61,248,257
  switchport mode trunk
  spanning-tree portfast trunk
```

SRST Connection Sample Configuration

The SRST connection to the core/distribution is another EtherChannel connection. The differences between the SRST connection and the access switch connections are that a trunk connection is not required, and that the SRST interfaces are router interfaces, requiring a slightly different connection. The following is an example of the configuration.

<pre> interface Port-channel3 description to isr for simulated PSTN GW for school2 switchport access vlan 303 switchport mode access interface GigabitEthernet2/0/20 switchport access vlan 303 switchport mode access mls qos trust dscp channel-group 3 mode on end interface GigabitEthernet3/0/20 switchport access vlan 303 switchport mode access mls qos trust dscp channel-group 3 mode on end </pre>	<pre> interface Port-channel3 description port-channel to 4500 ip address 10.40.63.9 255.255.255.252 hold-queue 150 in ! interface GigabitEthernet0/0 description \$ETH-LAN\$\$ETH-SW-LAUNCH\$\$INTF-INFO-GE 0/0\$ no ip address duplex auto speed auto media-type rj45 no keepalive channel-group 3 ! interface GigabitEthernet0/1 no ip address duplex auto speed auto media-type rj45 no keepalive channel-group 3 </pre>
--	--

WAN Connection

The WAN connection is a single port connection from the core/distribution switch, and therefore there is no EtherChannel. The key component in the WAN connection configuration is the QoS implementation, that provides traffic shaping and limiting on this interface to ensure that the voice and video are given appropriate priority, but do not starve other applications of the throughput. An example of the WAN connection configuration is shown below.

WAN Port Sample Configuration—Core/Distribution

```

interface GigabitEthernet3/0/52
  description Connected to MetroE-Core
  switchport trunk encapsulation dot1q
  switchport trunk native vlan 801
  switchport trunk allowed vlan 650
  switchport mode trunk

load-interval 30
hold-queue 2000 in
hold-queue 2000 out

```

Small School—Stacked Switch Design

The basic stacked switch school topology is shown in [Figure 10-2](#). This design is based upon a collapsed core/distribution mode, and a Layer-2 access distribution model. In this type of design, all of the IP subnets are defined on the 3750 stacked switch, and access to these subnets is controlled by the VLANs that are trunked to the switches.

The 3750 stackwise core provides resilient connections to the access LAN switches, local server switch, WLC, and SRST router through EtherChannel. The NAC Appliance does not support EtherChannel, and the two connections are used to connect to the trusted and untrusted interfaces of the CAS. The WAN connection to the 3750 stack is a single Ethernet connection.

Figure 10-2 *Stacked Switch School Schematic*

Below is an example configuration of the SVIs configured on the core/distribution 3750 stack. These SVIs are trunked to the access switches as required, and access to the VLANs are controlled by the **switchport trunk allowed vlan** command applied on the port channels. The same basic configuration is used for the server switch.

Core/Distribution Virtual Interfaces

Example Port Channel Configuration

The following example shows an example of the port channel configuration on core/distribution 3750 stack and an example access switch. A similar configuration would be applied to each access switch connection with the same or different VLANs as required. From an IP routing or services level there is no requirement to span the same VLAN to multiple switches, but if there is a requirement to support legacy protocols such as AppleTalk at the school these AppleTalk VLANs can be easily spanned to different access switches as required.

Example 3750 Stack Port Channel Configuration	Example 2960 Port Channel Configuration
<pre> Interface Port-channel11 description Connected to 2960-SS2 switchport trunk encapsulation dot1q switchport trunk native vlan 802 switchport trunk allowed vlan 101-110,900 switchport mode trunk load-interval 30 carrier-delay msec 0 ip dhcp snooping trust </pre>	<pre> Interface Port-channel1 description Connected to 3750-Core-SS2 switchport trunk native vlan 802 switchport trunk allowed vlan 101-110 switchport mode trunk ip arp inspection trust load-interval 30 ip dhcp snooping trust </pre>
<pre> interface GigabitEthernet1/0/49 description Connected to 2960-SS2 switchport trunk encapsulation dot1q switchport trunk native vlan 802 switchport trunk allowed vlan 101-110,900 switchport mode trunk load-interval 30 carrier-delay msec 0 srr-queue bandwidth share 1 30 35 5 priority-queue out udld port channel-group 11 mode active spanning-tree guard root ip dhcp snooping trust ! interface GigabitEthernet3/0/49 description Connected to 2960-SS2 switchport trunk encapsulation dot1q switchport trunk native vlan 802 switchport trunk allowed vlan 101-110,900 switchport mode trunk load-interval 30 carrier-delay msec 0 srr-queue bandwidth share 1 30 35 5 priority-queue out udld port channel-group 11 mode active spanning-tree guard root ip dhcp snooping trust </pre>	<pre> interface GigabitEthernet0/1 description Connected to 3750-Core-SS2 switchport trunk native vlan 802 switchport trunk allowed vlan 101-110 switchport mode trunk ip arp inspection trust load-interval 30 srr-queue bandwidth share 1 30 35 5 priority-queue out udld port mls qos trust dscp channel-protocol lacp channel-group 1 mode active ip dhcp snooping trust ! interface GigabitEthernet0/2 description Connected to 3750-Core-SS2 switchport trunk native vlan 802 switchport trunk allowed vlan 101-110 switchport mode trunk ip arp inspection trust load-interval 30 srr-queue bandwidth share 1 30 35 5 priority-queue out udld port mls qos trust dscp channel-protocol lacp channel-group 1 mode active ip dhcp snooping trust </pre>

WLC Connection

The WLC connection to the core/distribution stack is fundamentally the same as an access switch connection, with different VLANs, and the exception of using a different QoS trust mode, where the CoS values from the WLC, are trusted. The following is an example of the configuration.

Example 3750 Stack Port Channel Configuration

```
Interface Port-channel12
description Connected to 2960-SS2
switchport trunk encapsulation dot1q
switchport trunk native vlan 802
switchport trunk allowed vlan 111-120
switchport mode trunk
load-interval 30
carrier-delay msec 0
ip dhcp snooping trust

interface GigabitEthernet1/0/48
description Connected to WLC-SS2
switchport trunk encapsulation dot1q
switchport trunk native vlan 802
switchport trunk allowed vlan 110-120
switchport mode trunk
load-interval 30
carrier-delay msec 0
srr-queue bandwidth share 1 30 35 5
priority-queue out
udld port

mls qos trust coschannel-group 11 mode active
spanning-tree guard root
!
interface GigabitEthernet3/0/48
description Connected to WLC-SS2

```

NAC CAS Connection

The NAC CAS connection to the core/distribution switch. This is not an EtherChannel connection, but two switch ports are consumed. The two ports consist of a untrusted port for connecting client VLANs to the CAS prior to them completing the NAC process, and a trusted port that connects the NAS to the client VLANs used once clients have successfully completed the NAC process. The two, trusted and untrusted, ports are required even if OOB NAC is used, as the CAS requires access to the trusted VLANs during the NAC process. The following is an example of the configuration.

Core/Distribution NAC CAS Configuration

```

interface GigabitEthernet1/0/4
  description NAC Trusted Eth0
  switchport trunk encapsulation dot1q
  switchport trunk allowed vlan 48,57,62
  switchport mode trunk
  spanning-tree portfast trunk
!
interface GigabitEthernet1/0/5
!
interface GigabitEthernet1/0/8
  description NAC Untrusted Eth1
  switchport trunk encapsulation dot1q
  switchport trunk allowed vlan 61,248,257
  switchport mode trunk
  spanning-tree portfast trunk

```

SRST Connection

The SRST connection to the core/distribution is another EtherChannel connection. The differences between the SRST connection and the access switch connections are that a trunk connection is not required, and that the SRST interfaces are router interfaces, requiring a slightly different connection. The following is an example of the configuration.

```

interface Port-channel3
  description to isr for simulated PSTN GW for
  school1
  switchport access vlan 303
  switchport mode access
  interface GigabitEthernet2/0/20
  switchport access vlan 303

  channel-group 3
!
interface GigabitEthernet0/1
  no ip address
  duplex auto
  speed auto
  media-type rj45
  no keepalive
  channel-group 3

```

WAN Connection

The WAN connection is a single port connection from the core/distribution switch, and therefore there is no EtherChannel. The key component in the WAN connection configuration is the QoS implementation, that provides traffic shaping and limiting on this interface to ensure that the Voice and Video are given appropriate priority, but do not starve other applications of the throughput. An example of the WAN connection configuration is shown below.

```
interface GigabitEthernet3/0/52
description Connected to MetroE-Core
switchport trunk encapsulation dot1q
switchport trunk native vlan 801
switchport trunk allowed vlan 650
switchport mode trunk

```

CHAPTER 11

District Office Design

There are four main differences in the district office design:

- The use of the Supervisor 6—The Supervisor 6 supports hierarchical QoS.
- The Metro Ethernet Switch Connection—The aggregation and QoS policy enforcement point for the Metro Ethernet WAN connection to the schools
- The Services Block Switch Connection—The district office “mini-Data Center” for the management and services servers for the district and the schools
- The ASA Firewall Connection—The firewall connection to the Internet

Figure 11-1 shows a schematic of the district office network. Aside from providing core/distribution services to the access switches, the Cisco 4500 Modular switch in the district office connects the school WAN to the district office, the services such as Internet access and the Services Block of the SRA.

Figure 11-1 District Office Partial Schematic

Metro Ethernet Connection Configuration

Table 11-1 shows an example of the port-channel configuration on the core/distribution 4500 Modular switch and the 3750 Metro Ethernet switch. This is a Layer-3 connection where both the core/distribution switch and the Metro Ethernet switch are part of the same EIGRP AS. The most significant difference in this configuration from the School design using the 4500 Modular switch is the difference in the QoS configuration on the 4500 interface; this is primarily due to the district office using hierarchical QoS features of a Supervisor 6 module, rather than the Supervisor 5 used in the School SRA.

Table 11-1 *Port-Channel Configuration on the Core/Distribution 4500 Modular Switch and the 3750 Metro Ethernet Switch*

ASA Connection

The ASA firewall connection to the 4500 Modular switch is fundamentally different from the other network device connections to this switch—it uses the redundant interface features of the ASA. The ASA redundant interface is a logical interface that pairs two physical interfaces, called active and

standby interfaces. Under normal operation, the active interface is the only one passing traffic. The active interface uses the IP address defined at the redundant interface, and the MAC address of the first physical interface associated with the redundant interface. When the active interface fails, the standby interface becomes active and starts passing traffic. The same IP address and MAC address are maintained so that traffic is not disrupted. See [Table 11-2](#).

Services Block Connection

The Services Block supports the centralized servers and services for the district. The Cisco 4500 Modular switch connection to the Services Block switch uses EtherChannel, but in this case the connection between the switches is a Layer-3 connection, allowing the services block switch to keep its VLANs from stack is fundamentally the same as an access switch connection, with different VLANs. [Table 11-3](#) provides sample configurations for the Cisco 4500 Modular switch and the Services Block switch.

Table 11-3 Service Block Configuration

Core/Distribution Virtual Interfaces

The following is an example configuration of the Switch Virtual Interfaces configured on the core/distribution 4500 modular switch. This SVIs are trunked to the access switches as required, and access to the VLANs are controlled by the **switchport trunk allowed vlan** command applied on the port channels. The same basic configuration is used for the Server Switch.

```

interface Vlan101
description Connected to cr24_2960_Dept_1_VLAN

no ip unreachablees
ip pim sparse-mode
load-interval 30
```

Table 11-4 provides examples of the port-channel configuration on core/distribution 4500 modular switch and an access switch. A similar configuration would be applied to each access switch connection with the same or different VLANs as required. From an IP routing or services level there is no requirement to span the same VLAN to multiple switches, but if there is a requirement to support legacy protocols such as AppleTalk at the school these AppleTalk VLANs can be easily spanned to different access switches as required.

Table 11-4 Core/Distribution Virtual Interfaces

Example 4500 Modular switch Port Channel Configuration	Example 2960 Port Channel Configuration
--	---

Table 11-4 **Core/Distribution Virtual Interfaces (continued)**

<pre> interface Port-channel11 description Connected to cr24-2960-DO switchport switchport trunk native vlan 802 switchport trunk allowed vlan 101-110,900 switchport mode trunk logging event link-status load-interval 30 carrier-delay msec 0 service-policy output PQ-POLICER </pre>	<pre> interface Port-channel1 description Connected to cr24-4507-DO switchport trunk native vlan 802 switchport trunk allowed vlan 101-110,201,900 switchport mode trunk ip arp inspection trust load-interval 30 carrier-delay msec 0 hold-queue 2000 in hold-queue 2000 out ip dhcp snooping trust </pre>

```

NAC CAS Connection

The NAC CAS connection to the core/distribution switch. This is not an EtherChannel connection, but two switch ports are consumed. The two ports consist of a untrusted port for connecting client VLANs to the CAS prior to them completing the NAC process, and a trusted port that connects the NAS to the client VLANs used once clients have successfully completed the NAC process. The two, trusted and untrusted, ports are required even if OOB NAC is used, as the CAS requires access to the trusted VLANs during the NAC process. The following is an example of the configuration.

```

interface GigabitEthernet 3/9
description NAC Trusted Eth0
switchport trunk encapsulation dot1q
switchport trunk allowed vlan 48,57,62
switchport mode trunk
spanning-tree portfast trunk
!
interface GigabitEthernet 4/9
description NAC Untrusted Eth1
switchport trunk encapsulation dot1q
switchport trunk allowed vlan 61,248,257
switchport mode trunk
spanning-tree portfast trunk

```

SRST Connection

The SRST connection to the core/distribution is another EtherChannel connection. The differences between the SRST connection and the access switch connections are that a trunk connection is not required, and that the SRST interfaces are router interfaces, requiring a slightly different connection.

Table 11-5 provides an example of the configuration.

Table 11-5 SRST Connection

NTP

The use of Network Time Protocol (NTP) to synchronize the clocks of network devices is a well established best practice, is fundamental for the analysis of logs/events and security, but might not warrant a mention in a design guide that is focused upon introducing new designs and practices to support new services in the network.

Given that a number of key components (for example, CUWN and Cisco NAC) of the Schools SRA rely upon or benefit from time synchronization, it was decided to include a short discussion on Time Synchronization as part of the Schools SRA.

The preferred mechanism for time synchronization in the network is NTP (other systems may use their own time synchronization mechanism) and this network NTP discussion is not proposed as a the design to synchronize all devices (hosts) in the network, its goal is synchronization of the network components

of the Schools SRA. At the same time, whatever alternative times synchronization systems used in other parts of the network need to have agreement on the time, and should have a common time source at the beginning of their timing hierarchy. This will allow sufficient synchronization between hosts and network devices for the solutions deployed in the SRA.

The Schools SRA network has a hierarchy based upon the district office, as hub, and the schools as spokes. The NTP hierarchy should be the same, with the highest stratum NTP server located at the district office serving as the time reference for the district network. In order to spread the load, a hierarchy of NTP servers is used. The district office NTP server acting as the server for the district office network devices, and for the NTP server at each school, and the NTP Server for each school will act as the NTP server for network devices in that school.

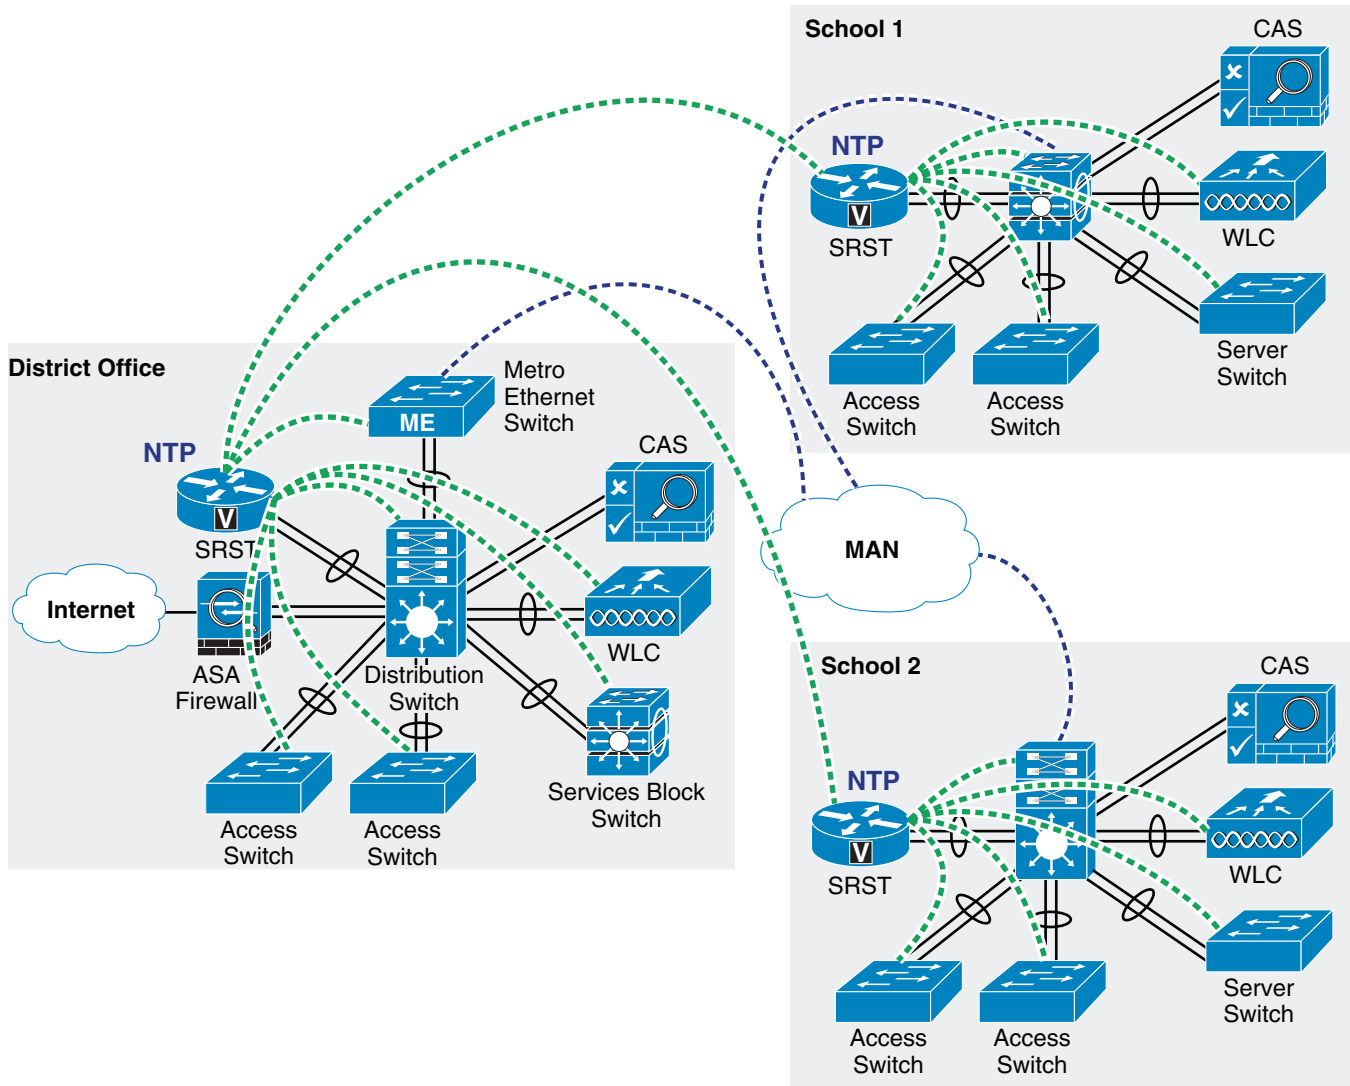

The preferred network device to act as the NTP server in the schools SRA is the ISR router at each site. The ISR is the preferred device as routers have a greater CPU capacity than switches used in the Schools SRA due to many of the general purpose task that a router may be required it perform in CPU, compared to switches that have been more optimized to perform their more limited number of tasks in ASIC.

Figure 11-2 shows a schematic of the NTP hierarchy in the school district.

For more information upon NTP refer to the *Network Time Protocol: Best Practices White Paper* at the following URL:

http://www.cisco.com/en/US/tech/tk869/tk769/technologies_white_paper09186a0080117070.shtml

Figure 11-2 NTP School District Hierarchy

When creating the NTP configuration care should be taken to protect the NTP system.

The NTP associations should be limited, and controlled by an access list, to protect against DoS attacks. The NTP system should also use NTP authentication, where possible, to protect against spoofing attacks.

DO-ISR NTP

```
access-list 99 permit x.x.x.x 0.0.0.255
access-list 99 permit y.y.y.y 0.0.0.255
ntp authentication-key 2 md5 Riewoldt

ntp clock-period 17179685
ntp max-associations 150
ntp server <DO-ISR> key 2
ntp access-group serve-only 98
```

Cisco's Service Ready Architecture for Schools is a well designed and validated network architecture that is flexible, adaptive and cost effective to support a wide range of education services. This architecture provides the ability to deliver all of the services required of an enhanced learning environment as well as the ability to collaborate with the other schools, district offices and entities beyond the district. This *Service Ready Architecture for Schools Design Guide* is broken down into modular, interdepen-

dent chapters as shown in [Table 1-1 on page 2](#).
