### **Finding Feature Information**

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <a href="https://cfnng.cisco.com/">https://cfnng.cisco.com/</a>. An account on Cisco.com is not required.

### Information About Configuring IP Unicast Routing

This module describes how to configure IP Version 4 (IPv4) unicast routing on the switch.

A switch stack operates and appears as a single router to the rest of the routers in the network.

Note

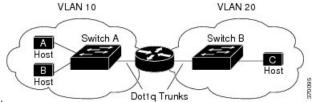

In addition to IPv4 traffic, you can also enable IP Version 6 (IPv6) unicast routing and configure interfaces to forward IPv6 traffic .

### **Information About IP Routing**

In some network environments, VLANs are associated with individual networks or subnetworks. In an IP network, each subnetwork is mapped to an individual VLAN. Configuring VLANs helps control the size of the broadcast domain and keeps local traffic local. However, network devices in different VLANs cannot communicate with one another without a Layer 3 device (router) to route traffic between the VLAN, referred to as inter-VLAN routing. You configure one or more routers to route traffic to the appropriate destination VLAN.

#### Figure 1: Routing Topology Example

This figure shows a basic routing topology. Switch A is in VLAN 10, and Switch B is in VLAN 20. The router

has an interface in each VLAN.

When Host A in VLAN 10 needs to communicate with Host B in VLAN 10, it sends a packet addressed to that host. Switch A forwards the packet directly to Host B, without sending it to the router.

When Host A sends a packet to Host C in VLAN 20, Switch A forwards the packet to the router, which receives the traffic on the VLAN 10 interface. The router checks the routing table, finds the correct outgoing interface, and forwards the packet on the VLAN 20 interface to Switch B. Switch B receives the packet and forwards it to Host C.

### **Types of Routing**

Routers and Layer 3 switches can route packets in these ways:

- · By using default routing
- By using preprogrammed static routes for the traffic
- By dynamically calculating routes by using a routing protocol

The switch supports static routes and default routes. It does not support routing protocols.

### **IP Routing and Switch Stacks**

A switch stack appears to the network as a single switch, regardless of which switch in the stack is connected to a routing peer.

The active switch performs these functions:

- It generates, maintains, and distributes the distributed Cisco Express Forwarding (dCEF) database to all stack members. The routes are programmed on all switches in the stack bases on this database.
- The MAC address of the active switch is used as the router MAC address for the whole stack, and all outside devices use this address to send IP packets to the stack.
- All IP packets that require software forwarding or processing go through the CPU of the active switch.

Stack members perform these functions:

- They act as routing standby switches, ready to take over in case they are elected as the new active switch
  if the active switch fails.
- They program the routes into hardware.

If a active switch fails, the stack detects that the active switch is down and elects one of the stack members to be the new active switch. During this period, except for a momentary interruption, the hardware continues to forward packets with no active protocols.

Upon election, the new active switch performs these functions:

- It starts generating, receiving, and processing routing updates.
- It builds routing tables, generates the CEF database, and distributes it to stack members.
- It uses its MAC address as the router MAC address. To notify its network peers of the new MAC address, it periodically (every few seconds for 5 minutes) sends a gratuitous ARP reply with the new router MAC address.

Note

If you configure the persistent MAC address feature on the stack and the active switch changes, the stack MAC address does not change for the configured time period. If the previous active switch rejoins the stack as a member switch during that time period, the stack MAC address remains the MAC address of the previous active switch.

• It attempts to determine the reachability of every proxy ARP entry by sending an ARP request to the proxy ARP IP address and receiving an ARP reply. For each reachable proxy ARP IP address, it generates a gratuitous ARP reply with the new router MAC address. This process is repeated for 5 minutes after a new active switch election.

Caution

Partitioning of the switch stack into two or more stacks might lead to undesirable behavior in the network.

If the switch is reloaded, then all the ports on that switch go down and there is a loss of traffic for the interfaces involved in routing.

# **Configuring IP Unicast Routing**

By default, IP routing is disabled on the device. For detailed IP routing configuration information, see the *Cisco IOS IP Configuration Guide*, *Release 12.2* from the *Cisco.com* page under **Documentation** > **Cisco IOS Software Releases** > **12.2 Mainline** > **Configuration Guides**.

In these procedures, the specified interface must be a device virtual interface (SVI)-a VLAN interface created by using the **interface vlan** *vlan\_id* global configuration command and by default a Layer 3 interface. All Layer 3 interfaces on which routing will occur must have IP addresses assigned to them. See the *Assigning IP Addresses to SVIs* section.

Note

The device supports 16 static routes (including user-configured routes and the default route) and any directly connected routes and default routes for the management interface. You can use the "lanbase-default" SDM template to configure the static routes. The device can have an IP address assigned to each SVI. Before enabling routing, enter the **sdm prefer lanbase-routing** global configuration command and reload the device.

Procedures for configuring routing:

- To support VLAN interfaces, create and configure VLANs on the device or switch stack, and assign VLAN membership to Layer 2 interfaces. For more information, see chapter: *Configuring VLANs*.
- Configure Layer 3 interfaces (SVIs).
- Enable IP routing on the device.
- Assign IP addresses to the Layer 3 interfaces.
- Configure static routes.

## **Enabling IP Unicast Routing**

By default, the Device is in Layer 2 switching mode and IP routing is disabled. To use the Layer 3 capabilities of the Device, you must enable IP routing.

#### **Procedure**

Command or Action	Purpose
enable	Enables privileged EXEC mode.
Example:	• Enter your password if prompted.
Device> enable	
configure terminal	Enters global configuration mode.
Example:	
Device# configure terminal	
ip routing	Enables IP routing.
Example:	
Device(config)# ip routing	
end	Returns to privileged EXEC mode.
Example:	
Device(config)# end	
	enable  Example:  Device> enable  configure terminal  Example:  Device# configure terminal  ip routing  Example:  Device(config)# ip routing  end  Example:

	Command or Action	Purpose
Step 5	show running-config	Verifies your entries.
	Example:	
	Device# show running-config	
Step 6	copy running-config startup-config	(Optional) Saves your entries in the
	Example:	configuration file.
	Device# copy running-config startup-config	

## **Assigning IP Addresses to SVIs**

To configure IP routing, you need to assign IP addresses to Layer 3 network interfaces. This enables communication with the hosts of those interfaces that use IP. IP routing is disabled by default, and no IP addresses are assigned to SVIs.

An IP address identifies a location to which IP packets can be sent. Some IP addresses are reserved for special uses and cannot be used for host, subnet, or network addresses. RFC 1166, "Internet Numbers," contains the official description of IP addresses.

An interface can have one primary IP address. A mask identifies the bits that denote the network number in an IP address. When you use the mask to subnet a network, the mask is referred to as a subnet mask. To receive an assigned network number, contact your Internet service provider.

Follow these steps to assign an IP address and a network mask to an SVI:

#### **Procedure**

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface vlan vlan-id	Enters interface configuration mode, and specifies the Layer 3 VLAN to configure.

	Command or Action	Purpose
		Note  If the interface is still in Layer 2 mode (the default), you must enter a no switchport interface configuration command before entering the ip address interface configuration command.
Step 4	ip address ip-address subnet-mask	Configures the IP address and IP subnet mask
	Example:	
	Device(config-if)# ip address 10.1.5.1 255.255.255.0	
Step 5	end	Returns to privileged EXEC mode.
	Example:	
	Device(config)# end	
Step 6	show interfaces [interface-id]	Verifies your entries.
	Example:	
	Device# show interfaces gigabitethernet 1/0/1	
Step 7	show interfaces vlan [vlan-id]	Verifies your entries.
	Example:	
	Device# show interfaces vlan 4	
Step 8	show running-config	Verifies your entries.
	Example:	
	Device# show running-config	
Step 9	copy running-config startup-config	(Optional) Saves your entries in the
	Example:	configuration file.
	Device# copy running-config startup-config	

# **Configuring Static Unicast Routes**

Static unicast routes are user-defined routes that cause packets moving between a source and a destination to take a specified path. Static routes can be important if the router cannot build a route to a particular destination and are useful for specifying a gateway of last resort to which all unroutable packets are sent.

Follow these steps to configure a static route:

#### **Procedure**

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ip route prefix mask {address   interface} [distance] vlan vlan-id	Establish a static route.
	Example:	
	Device(config)# ip route prefix mask gigabitethernet 1/0/4vlan 4	
Step 4	end	Returns to privileged EXEC mode.
	Example:	
	Device(config)# end	
Step 5	show ip route	Displays the current state of the routing table to verify the configuration.
	Example:	
	Device# show ip route	
Step 6	copy running-config startup-config	(Optional) Saves your entries in the configuration file.
	Example:	
	Device# copy running-config startup-config	

#### What to do next

Use the **no ip route** *prefix mask* {*address*| *interface*} global configuration command to remove a static route. The device retains static routes until you remove them.

# **Monitoring and Maintaining the IP Network**

You can remove all contents of a particular cache, table, or database. You can also display specific statistics.

Table 1: Commands to Clear IP Routes or Display Route Status

Command	Purpose
show ip route [address [mask] [longer-prefixes]]	Displays the current state of the routing table.
show ip route summary	Displays the current state of the routing table in summary for
show platform ip unicast	Displays platform-dependent IP unicast information.
