

Cisco Unified Communications System Release 8.x SRND

July 31, 2012

Americas Headquarters

Cisco Systems, Inc.
170 West Tasman Drive
San Jose, CA 95134-1706
USA
<http://www.cisco.com>
Tel: 408 526-4000
800 553-NETS (6387)
Fax: 408 527-0883

Text Part Number: OL-21733-18

THE SPECIFICATIONS AND INFORMATION REGARDING THE PRODUCTS IN THIS MANUAL ARE SUBJECT TO CHANGE WITHOUT NOTICE. ALL STATEMENTS, INFORMATION, AND RECOMMENDATIONS IN THIS MANUAL ARE BELIEVED TO BE ACCURATE BUT ARE PRESENTED WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED. USERS MUST TAKE FULL RESPONSIBILITY FOR THEIR APPLICATION OF ANY PRODUCTS.

THE SOFTWARE LICENSE AND LIMITED WARRANTY FOR THE ACCOMPANYING PRODUCT ARE SET FORTH IN THE INFORMATION PACKET THAT SHIPPED WITH THE PRODUCT AND ARE INCORPORATED HEREIN BY THIS REFERENCE. IF YOU ARE UNABLE TO LOCATE THE SOFTWARE LICENSE OR LIMITED WARRANTY, CONTACT YOUR CISCO REPRESENTATIVE FOR A COPY.

The Cisco implementation of TCP header compression is an adaptation of a program developed by the University of California, Berkeley (UCB) as part of UCB's public domain version of the UNIX operating system. All rights reserved. Copyright © 1981, Regents of the University of California.

NOTWITHSTANDING ANY OTHER WARRANTY HEREIN, ALL DOCUMENT FILES AND SOFTWARE OF THESE SUPPLIERS ARE PROVIDED "AS IS" WITH ALL FAULTS. CISCO AND THE ABOVE-NAMED SUPPLIERS DISCLAIM ALL WARRANTIES, EXPRESSED OR IMPLIED, INCLUDING, WITHOUT LIMITATION, THOSE OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT OR ARISING FROM A COURSE OF DEALING, USAGE, OR TRADE PRACTICE.

IN NO EVENT SHALL CISCO OR ITS SUPPLIERS BE LIABLE FOR ANY INDIRECT, SPECIAL, CONSEQUENTIAL, OR INCIDENTAL DAMAGES, INCLUDING, WITHOUT LIMITATION, LOST PROFITS OR LOSS OR DAMAGE TO DATA ARISING OUT OF THE USE OR INABILITY TO USE THIS MANUAL, EVEN IF CISCO OR ITS SUPPLIERS HAVE BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

Cisco and the Cisco logo are trademarks or registered trademarks of Cisco and/or its affiliates in the U.S. and other countries. To view a list of Cisco trademarks, go to this URL: www.cisco.com/go/trademarks. Third-party trademarks mentioned are the property of their respective owners. The use of the word partner does not imply a partnership relationship between Cisco and any other company. (1110R)

Any Internet Protocol (IP) addresses and phone numbers used in this document are not intended to be actual addresses and phone numbers. Any examples, command display output, network topology diagrams, and other figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses or phone numbers in illustrative content is unintentional and coincidental.

CONTENTS

Preface xxxix

- New or Changed Information for This Release xxxix
- Revision History xl
- Obtaining Documentation and Submitting a Service Request xli
- Cisco Product Security Overview xli
- Conventions xlii

CHAPTER 1

Introduction 1-1

- Cisco Unified Communications System Architecture 1-3
- How to Use This Design Guide 1-6

PART 1

Unified Communications Networking

CHAPTER 2

Overview of Cisco Unified Communications Networking 2-1

- Architecture 2-3
- High Availability 2-4
- Capacity Planning 2-4

CHAPTER 3

Network Infrastructure 3-1

- What's New in This Chapter 3-4
- LAN Infrastructure 3-4
 - LAN Design for High Availability 3-4
 - Campus Access Layer 3-5
 - Routed Access Layer Designs 3-7
 - Campus Distribution Layer 3-10
 - Campus Core Layer 3-12
 - Power over Ethernet (PoE) 3-13
 - Energy Conservation for IP Phones 3-13
 - Category 3 Cabling 3-15
 - IBM Type 1A and 2A Cabling 3-15
 - LAN Quality of Service (QoS) 3-16
 - Traffic Classification 3-17
 - Interface Queuing 3-19

| | |
|--|------|
| Bandwidth Provisioning | 3-20 |
| Impairments to IP Communications if QoS is Not Employed | 3-20 |
| QoS Design Considerations for Virtual Unified Communications with Cisco UCS B-Series Blade Servers | 3-20 |
| Standard Switching Element QoS Behavior | 3-21 |
| Congestion Scenario | 3-22 |
| Design Recommendations | 3-22 |
| Network Services | 3-23 |
| Domain Name System (DNS) | 3-23 |
| Dynamic Host Configuration Protocol (DHCP) | 3-25 |
| Trivial File Transfer Protocol (TFTP) | 3-28 |
| Network Time Protocol (NTP) | 3-35 |
| WAN Infrastructure | 3-36 |
| WAN Design and Configuration | 3-37 |
| Deployment Considerations | 3-37 |
| Guaranteed Bandwidth | 3-38 |
| Dynamic Multipoint VPN (DMVPN) | 3-39 |
| Best-Effort Bandwidth | 3-39 |
| WAN Quality of Service (QoS) | 3-40 |
| Traffic Prioritization | 3-41 |
| Scavenger Class | 3-43 |
| Link Efficiency Techniques | 3-43 |
| Traffic Shaping | 3-45 |
| Bandwidth Provisioning | 3-47 |
| Provisioning for Bearer Traffic | 3-48 |
| Provisioning for Call Control Traffic | 3-52 |
| Wireless LAN Infrastructure | 3-57 |
| Architecture for Voice and Video over WLAN | 3-57 |
| Wireless Access Points | 3-58 |
| Wireless LAN Controllers | 3-59 |
| Authentication Database | 3-59 |
| Supporting Wired Network | 3-59 |
| Wireless Unified Communications Endpoints | 3-60 |
| Wired Call Elements | 3-60 |
| Call Control | 3-60 |
| Media Termination | 3-60 |
| High Availability for Voice and Video over WLAN | 3-61 |
| Supporting Wired Network High Availability | 3-61 |
| WLAN High Availability | 3-61 |
| Call Processing High Availability | 3-63 |

| | |
|---|------|
| Capacity Planning for Voice and Video over WLAN | 3-63 |
| Design Considerations for Voice and Video over WLAN | 3-63 |
| Wireless AP Configuration and Design | 3-67 |
| Wireless LAN Controller Design Considerations | 3-68 |
| WLAN Quality of Service (QoS) | 3-69 |
| Traffic Classification | 3-70 |
| User Priority Mapping | 3-70 |
| Interface Queuing | 3-70 |
| Wireless Call Admission Control | 3-71 |
| Service Advertisement Framework (SAF) | 3-72 |
| Services that SAF Can Advertise | 3-72 |
| SAF Networks | 3-73 |
| SAF Forwarders, SAF Clients, and non-SAF Networks | 3-73 |
| SAF Autonomous Systems | 3-78 |

CHAPTER 4**Unified Communications Security 4-1**

| | |
|--|------|
| What's New in This Chapter | 4-2 |
| General Security | 4-3 |
| Security Policy | 4-3 |
| Security in Layers | 4-4 |
| Secure Infrastructure | 4-5 |
| Physical Security | 4-5 |
| IP Addressing | 4-5 |
| IPv6 Addressing | 4-6 |
| Access Security | 4-6 |
| Voice and Video VLANs | 4-6 |
| Switch Port | 4-8 |
| Port Security: MAC CAM Flooding | 4-8 |
| Port Security: Gratuitous ARP | 4-9 |
| Port Security: Prevent Port Access | 4-10 |
| Port Security: Prevent Rogue Network Extensions | 4-10 |
| DHCP Snooping: Prevent Rogue DHCP Server Attacks | 4-11 |
| DHCP Snooping: Prevent DHCP Starvation Attacks | 4-13 |
| DHCP Snooping: Binding Information | 4-13 |
| Requirement for Dynamic ARP Inspection | 4-14 |
| 802.1X Port-Based Authentication | 4-15 |
| Phone Security | 4-17 |
| PC Port on the Phone | 4-17 |
| PC Voice VLAN Access | 4-18 |

| | |
|--|------|
| Web Access Through the Phone | 4-19 |
| Video Capabilities | 4-19 |
| Settings Access | 4-19 |
| Phone Authentication and Encryption | 4-20 |
| VPN Client for IP Phones | 4-21 |
| Quality of Service | 4-21 |
| Access Control Lists | 4-22 |
| VLAN Access Control Lists | 4-22 |
| Router Access Control Lists | 4-23 |
| Firewalls | 4-24 |
| Routed ASA | 4-26 |
| Transparent ASA | 4-26 |
| ASA Unified Communications Proxy Feature | 4-27 |
| ASA TLS Proxy | 4-28 |
| ASA Phone Proxy | 4-28 |
| ASA Mobility Proxy Feature | 4-29 |
| ASA for Unified Presence | 4-29 |
| ASA Intercompany Media Engine Proxy | 4-29 |
| Basic Deployment | 4-30 |
| Offpath Deployment | 4-30 |
| Mid-Call PSTN Fallback | 4-31 |
| Design Considerations | 4-32 |
| High Availability | 4-33 |
| Capacity Planning | 4-33 |
| Data Center | 4-33 |
| Gateways, Trunks, and Media Resources | 4-34 |
| Putting Firewalls Around Gateways | 4-35 |
| Firewalls and H.323 | 4-36 |
| SAF Service | 4-36 |
| Unified CM Trunk Integration with Cisco Unified Border Element | 4-36 |
| Applications Servers | 4-38 |
| Single Sign-On | 4-38 |
| Cisco Security Agent on the Unified CM and Application Servers | 4-38 |
| Cisco Security Agent | 4-38 |
| SELinux | 4-39 |
| General Server Guidelines | 4-39 |
| Deployment Examples | 4-39 |
| Lobby Phone Example | 4-39 |
| Firewall Deployment Example (Centralized Deployment) | 4-40 |

| | |
|------------------------------------|------|
| Securing Network Virtualization | 4-41 |
| Scenario 1: Single Data Center | 4-42 |
| Scenario 2: Redundant Data Centers | 4-43 |
| Conclusion | 4-45 |

CHAPTER 5**Unified Communications Deployment Models 5-1**

| | |
|--|------|
| What's New in This Chapter | 5-1 |
| Deployment Model Architecture | 5-2 |
| High Availability for Deployment Models | 5-3 |
| Capacity Planning for Deployment Models | 5-3 |
| Site-Based Design | 5-3 |
| Site-Based Design Guidance | 5-5 |
| Centralized Services | 5-5 |
| Distributed Services | 5-6 |
| Inter-Networking of Services | 5-7 |
| Geographical Diversity of Unified Communications Services | 5-7 |
| Campus | 5-8 |
| Best Practices for the Campus Model | 5-9 |
| Multisite with Centralized Call Processing | 5-10 |
| Best Practices for the Centralized Call Processing Model | 5-14 |
| Remote Site Survivability | 5-14 |
| Unified CME in SRST Mode | 5-17 |
| Best Practices for Unified CME in SRST Mode | 5-18 |
| Best Practices for SRST Router | 5-18 |
| Enhanced Survivable Remote Site Telephony | 5-19 |
| Voice Over the PSTN as a Variant of Centralized Call Processing | 5-20 |
| VoPSTN Using AAR | 5-21 |
| VoPSTN Using Dial Plan | 5-23 |
| Multisite with Distributed Call Processing | 5-24 |
| Best Practices for the Distributed Call Processing Model | 5-26 |
| Call Processing Agents for the Distributed Call Processing Model | 5-27 |
| Unified CM Session Management Edition | 5-28 |
| When to Deploy Unified CM Session Management Edition | 5-29 |
| Differences Between Unified CM Session Management Edition and Standard Unified CM Clusters | 5-30 |
| Hybrid Session Management Edition and SAF CCD Deployments | 5-31 |
| Cisco Intercompany Media Engine | 5-34 |
| IME Components | 5-34 |
| GoDaddy.com Enrollment Server | 5-35 |

| | |
|---|------|
| Intercompany Media Engine Bootstrap Servers | 5-35 |
| Intercompany Media Engine Servers | 5-35 |
| Unified Communications Manager and Session Management Edition | 5-36 |
| Adaptive Security Appliance | 5-36 |
| IME Architecture | 5-36 |
| IME Learned Routes | 5-36 |
| IME Call Processing | 5-39 |
| PSTN Failover | 5-40 |
| Capacity Planning | 5-42 |
| High Availability | 5-42 |
| Design Considerations | 5-43 |
| Clustering Over the IP WAN | 5-45 |
| WAN Considerations | 5-46 |
| Intra-Cluster Communications | 5-47 |
| Unified CM Publisher | 5-47 |
| Call Detail Records (CDR) and Call Management Records (CMR) | 5-48 |
| Delay Testing | 5-48 |
| Error Rate | 5-49 |
| Troubleshooting | 5-49 |
| Local Failover Deployment Model | 5-49 |
| Unified CM Provisioning for Local Failover | 5-54 |
| Gateways for Local Failover | 5-55 |
| Voicemail for Local Failover | 5-55 |
| Music on Hold and Media Resources for Local Failover | 5-55 |
| Remote Failover Deployment Model | 5-55 |
| Cisco Business Edition 6000 Clustering over the WAN | 5-57 |
| Deploying Unified Communications on Virtualized Servers | 5-58 |
| Cisco Unified Computing System | 5-59 |
| Cisco UCS B-Series Blade Servers | 5-59 |
| Cisco UCS 5100 Series Blade Server Chassis | 5-60 |
| Cisco UCS 2100 and 2200 Series Fabric Extenders | 5-60 |
| Cisco UCS 6100 and 6200 Series Fabric Interconnect Switch | 5-60 |
| Cisco UCS Manager | 5-61 |
| Hypervisor | 5-61 |
| Storage Area Networking | 5-61 |
| Cisco UCS C-Series Rack-Mount Servers | 5-61 |
| Design Considerations for Running Virtual Unified Communications Applications on B-Series Blade Servers | 5-61 |
| Blade Server | 5-62 |
| Hypervisor | 5-62 |

| | |
|--|------|
| SAN and Storage Arrays | 5-62 |
| Design Considerations for Running Virtual Unified Communications Applications on C-Series Rack-Mount Servers | 5-62 |
| Impact of Virtual Servers on Deployment Models | 5-63 |
| Design Considerations for Section 508 Conformance | 5-63 |
| Call Routing and Dial Plan Distribution Using Call Control Discovery for the Service Advertisement Framework | 5-64 |
| Services that SAF Can Advertise | 5-65 |
| SAF Service IDs | 5-65 |
| Deploying SAF CCD Within Your Network | 5-65 |
| Comparison of SAF CCD Operation and Standard Unified CM Call Routing | 5-69 |
| CCD and Unified CM | 5-71 |
| SAF Forwarder Configuration (External SAF Client on Unified CM) | 5-72 |
| External SAF Client Instance Creation and Activation within the Unified CM Cluster | 5-72 |
| Multiple SAF Forwarders | 5-73 |
| Advanced SAF Client Configuration | 5-73 |
| SAF CCD Deployment Considerations | 5-86 |

CHAPTER 6**IP Telephony Migration Options 6-1**

| | |
|---|-----|
| Coexistence or Migration? | 6-1 |
| Migration Prerequisites | 6-1 |
| Unified Communications Migration | 6-2 |
| The Need for QSIG in Multisite Enterprises | 6-3 |
| Summary of IP Telephony Migration | 6-4 |
| Centralized Unified Communications Deployment | 6-4 |
| Which Unified Communications Service First? | 6-5 |

PART 2**Unified Communications Call Routing****CHAPTER 7****Overview of Cisco Unified Communications Call Routing 7-1**

| | |
|-------------------|-----|
| Architecture | 7-3 |
| High Availability | 7-4 |
| Capacity Planning | 7-5 |

CHAPTER 8**Call Processing 8-1**

| | |
|------------------------------|-----|
| What's New in This Chapter | 8-2 |
| Call Processing Architecture | 8-3 |
| Call Processing Hardware | 8-4 |

- Unified CM Cluster Services **8-8**
 - Cluster Server Nodes **8-9**
 - Intracluster Communications **8-11**
 - Intracluster Security **8-13**
 - Voice Activity Detection **8-13**
 - General Clustering Guidelines **8-14**
- High Availability for Call Processing **8-15**
 - Hardware Platform High Availability **8-15**
 - Network Connectivity High Availability **8-15**
 - Unified CM High Availability **8-17**
 - Call Processing Redundancy **8-17**
 - Call Processing Subscriber Redundancy **8-19**
 - TFTP Redundancy **8-22**
 - CTI Manager Redundancy **8-23**
 - UCS Call Processing Redundancy **8-23**
 - Cisco Business Edition High Availability **8-24**
- Capacity Planning for Call Processing **8-25**
 - Unified CME Capacity Planning **8-25**
 - Unified CM Capacity Planning **8-26**
 - Unified CM Capacity Planning with UCS Platforms **8-26**
 - Unified CM Capacity Planning Guidelines and Endpoint Limits **8-27**
 - Megacluster **8-27**
 - Cisco Business Edition Capacity Planning **8-28**
- Design Considerations for Call Processing **8-29**
- Computer Telephony Integration (CTI) **8-31**
 - CTI Architecture **8-32**
 - CTI Applications and Clustering Over the WAN **8-33**
 - Capacity Planning for CTI **8-34**
 - High Availability for CTI **8-35**
 - CTI Manager **8-35**
 - Redundancy, Failover, and Load Balancing **8-35**
 - Implementation **8-37**
- Gatekeeper Design Considerations **8-37**
 - Hardware Platform Selection **8-38**
 - Gatekeeper Redundancy **8-38**
 - Gatekeeper Clustering (Alternate Gatekeeper) **8-38**
 - Directory Gatekeeper Redundancy **8-41**
- Interoperability of Unified CM and Unified CM Express **8-44**
 - Overview of Interoperability Between Unified CM and Unified CME **8-45**

| | |
|--|------|
| Call Types and Call Flows | 8-45 |
| Music on Hold | 8-45 |
| Ad Hoc and Meet Me Hardware Conferencing | 8-45 |
| Unified CM and Unified CME Interoperability via SIP in a Multisite Deployment with Distributed Call Processing | 8-46 |
| Best Practices | 8-46 |
| Design Considerations | 8-47 |
| Unified CM and Unified CME Interoperability via H.323 in a Multisite Deployment with Distributed Call Processing | 8-49 |
| Best Practices | 8-50 |
| Design Considerations | 8-51 |

CHAPTER 9**Dial Plan 9-1**

| | |
|---|------|
| What's New in This Chapter | 9-2 |
| Dial Plan Architecture | 9-3 |
| High Availability for Dial Plans | 9-4 |
| Capacity Planning for Dial Plans | 9-4 |
| Planning Considerations | 9-5 |
| Dialed Pattern Recognition | 9-5 |
| Grouping by Dialing Habits | 9-6 |
| On-Net versus Off-Net Dialing | 9-6 |
| Abbreviated Dialing | 9-7 |
| Avoiding Overlap of Extension Dialing | 9-7 |
| Dialing String Length | 9-8 |
| Uniform On-Net Dial Plan | 9-8 |
| Variable Length On-Net Dial Plan | 9-10 |
| On-Net and Off-Net Access Codes | 9-10 |
| Plan Ahead | 9-11 |
| Design Considerations | 9-11 |
| Globalized Design Approach | 9-12 |
| Local Route Group | 9-13 |
| Support for + Dialing | 9-13 |
| Calling Party Number Transformations | 9-14 |
| Called Party Number Transformations | 9-14 |
| Incoming Calling Party Settings (per Gateway) | 9-14 |
| Logical Partitioning | 9-15 |
| Localized Call Ingress | 9-16 |
| Globalized Call Routing | 9-20 |
| Localized Call Egress | 9-20 |

| | |
|--|------|
| Benefits of the New Design Approach | 9-22 |
| Call Control Discovery | 9-24 |
| SAF CCD Design Considerations | 9-25 |
| Dial Plan Considerations for the Intercompany Media Engine | 9-33 |
| Design Guidelines for Multisite Deployments | 9-35 |
| Choosing a Dial Plan Approach | 9-38 |
| Deploying Uniform On-Net Dial Plans | 9-40 |
| Inter-Site Calls Within a Cluster | 9-42 |
| Outgoing PSTN and IP WAN Calls | 9-42 |
| Emergency Calls | 9-42 |
| Incoming Calls | 9-42 |
| Voicemail Calls | 9-42 |
| Deploying Variable-Length On-Net Dial Plans with Flat Addressing | 9-43 |
| Inter-Site Calls Within a Cluster | 9-45 |
| Outgoing PSTN and IP WAN Calls | 9-46 |
| Incoming Calls | 9-49 |
| Voicemail Calls | 9-49 |
| Special Considerations for Deployments Without Site Codes | 9-50 |
| Deploying Dialed Pattern Recognition in SIP Phones | 9-52 |
| Building Classes of Service for Unified CM | 9-54 |
| Building Classes of Service for Unified CM with the Traditional Approach | 9-54 |
| Building Classes of Service for Unified CM with the Line/Device Approach | 9-58 |
| Building Classes of Service for Unified CM for +E.164 Dial Plans with the Traditional Approach and Local Route Group | 9-66 |
| Using Non +E.164 Directory Numbers | 9-68 |
| Overlaps Between Directory Numbers and International PSTN Dialing | 9-69 |
| Other Classes of Service | 9-70 |
| Emergency Calls | 9-71 |
| Building Classes of Service in Cisco IOS with H.323 | 9-71 |
| Deploying Call Coverage | 9-75 |
| Deploying Call Coverage in a Multisite Centralized Call Processing Model | 9-76 |
| Deploying Call Coverage in a Multisite Distributed Call Processing Model | 9-77 |
| Hunt Pilot Scalability | 9-78 |
| Dial Plan Elements | 9-78 |
| User Interface on IP Phones | 9-79 |
| Calling Party Transformations on IP Phones | 9-79 |
| Support for + Dialing on the Phones | 9-80 |
| User Input on SCCP Phones | 9-80 |
| User Input on Type-A SIP Phones | 9-81 |
| User Input on Type-B SIP Phones | 9-83 |

| | |
|---|-------|
| SIP Dial Rules | 9-84 |
| Call Routing in Unified CM | 9-87 |
| Support for + Sign in Patterns | 9-88 |
| External Routes in Unified CM | 9-88 |
| Route Patterns | 9-89 |
| Route Lists | 9-93 |
| Route Groups | 9-93 |
| Calling and Called Party Transformation Patterns | 9-93 |
| Incoming Calling Party Settings (per Gateway) | 9-96 |
| Route Group Devices | 9-96 |
| Local Route Group | 9-97 |
| Centralized Gateway with Local Failover to the PSTN | 9-99 |
| Routing of SIP Requests in Unified CM | 9-100 |
| Calling Privileges in Unified CM | 9-101 |
| Partitions | 9-101 |
| Calling Search Spaces | 9-102 |
| Translation Patterns | 9-107 |
| Automated Alternate Routing | 9-108 |
| Establish the PSTN Number of the Destination | 9-108 |
| Prefix the Required Access Codes | 9-109 |
| Voicemail Considerations | 9-110 |
| Select the Proper Dial Plan and Route | 9-111 |
| Special Considerations for Sites Located Within the Same Local Dialing Area | 9-111 |
| Device Mobility | 9-112 |
| Extension Mobility | 9-114 |
| Special Considerations for Cisco Unified Mobility | 9-115 |
| Immediate Divert (iDivert) | 9-120 |
| Hunt Lists and Line Groups | 9-121 |
| Hunt Pilot | 9-122 |
| Hunt List | 9-122 |
| Line Group | 9-122 |
| Hunt Group Logout | 9-123 |
| Line Group Devices | 9-124 |
| Time-of-Day Routing | 9-124 |
| Logical Partitioning | 9-125 |
| Logical Partitioning Device Types | 9-126 |
| Geolocation Creation | 9-126 |
| Geolocation Assignment | 9-127 |
| Geolocation Filter Creation | 9-127 |
| Geolocation Filter Assignment | 9-127 |

- Logical Partitioning Policy Configuration 9-127
- Logical Partitioning Policy Application 9-128
- Call Routing in Cisco IOS with H.323 Dial Peers 9-128
- Call Routing in Cisco IOS with a Gatekeeper 9-131
 - Centralized Gatekeeper Configuration 9-135
 - Distributed Gatekeeper Configuration 9-137
 - Distributed Gatekeeper Configuration with Directory Gatekeeper 9-138
- Calling Privileges in Cisco IOS with H.323 Dial Peers 9-140
- Digit Manipulation in Cisco IOS with H.323 Dial Peers 9-142
- Service Advertisement Framework (SAF) Call Control Discovery (CCD) 9-144
 - SAF Forwarders 9-144
 - Requesting Service 9-145
- Dial Plan Considerations for Business Edition 3000 9-146

CHAPTER 10

Emergency Services 10-1

- What's New in This Chapter 10-2
- 911 Emergency Services Architecture 10-2
 - Public Safety Answering Point (PSAP) 10-2
 - Selective Router 10-3
 - Automatic Location Identifier Database 10-3
 - Private Switch ALI 10-3
 - 911 Network Service Provider 10-3
 - Interface Points into the Appropriate 911 Networks 10-4
 - Interface Type 10-5
 - Dynamic ANI (Trunk Connection) 10-5
 - Static ANI (Line Connection) 10-7
- Cisco Emergency Responder 10-7
- High Availability for Emergency Services 10-9
- Capacity Planning for Cisco ER Clustering 10-9
- Design Considerations for 911 Emergency Services 10-10
 - Emergency Response Location Mapping 10-10
 - Emergency Location Identification Number Mapping 10-11
 - Dial Plan Considerations 10-12
 - Gateway Considerations 10-13
 - Gateway Placement 10-13
 - Gateway Blocking 10-14
 - Answer Supervision 10-14
 - Cisco Emergency Responder Design Considerations 10-15
 - Device Mobility Across Call Admission Control Locations 10-15

| | |
|--|-------|
| Default Emergency Response Location | 10-15 |
| Cisco Emergency Responder and Extension Mobility | 10-15 |
| Soft Clients | 10-16 |
| Test Calls | 10-16 |
| PSAP Callback to Shared Directory Numbers | 10-16 |
| Cisco Emergency Responder Deployment Models | 10-17 |
| Single Cisco ER Group | 10-17 |
| Multiple Cisco ER Groups | 10-19 |
| Emergency Call Routing within a Cisco ER Cluster | 10-21 |
| WAN Deployment of Cisco Emergency Responder | 10-22 |
| ALI Formats | 10-22 |

CHAPTER 11**Call Admission Control 11-1**

| | |
|---|-------|
| What's New in This Chapter | 11-2 |
| Call Admission Control Principles | 11-3 |
| Topology-Unaware Call Admission Control | 11-3 |
| Topology-Aware Call Admission Control | 11-7 |
| Special Considerations for MPLS Networks | 11-11 |
| Call Admission Control Architecture | 11-12 |
| Unified CM Static Locations | 11-12 |
| Locations and Regions Settings | 11-14 |
| Unified CM Support for Locations and Regions | 11-14 |
| Cisco IOS Gatekeeper Zones | 11-15 |
| Unified Communications Architectures Using Resource Reservation Protocol (RSVP) | 11-17 |
| Resource Reservation Protocol (RSVP) | 11-17 |
| RSVP Principles | 11-18 |
| RSVP in MPLS Networks | 11-21 |
| RSVP and QoS in WAN Routers | 11-24 |
| RSVP Application ID | 11-28 |
| Cisco IOS Features | 11-29 |
| RSVP Design Best Practices | 11-33 |
| Bandwidth Provisioning for RSVP | 11-34 |
| Calculating RSVP Bandwidth Values for Use with Unified CM | 11-34 |
| Configuring Cisco IOS Application ID Support | 11-36 |
| Provisioning for Call Control Traffic with RSVP and Centralized Call Processing | 11-38 |
| Unified CM RSVP-Enabled Locations | 11-38 |
| Cisco RSVP Agent Provisioning | 11-40 |
| Cisco RSVP Agent Registration | 11-41 |
| RSVP Policy | 11-43 |

| | |
|---|--------|
| Migrating from Static Locations to RSVP Call Admission Control | 11-45 |
| RSVP Application ID and Unified CM | 11-48 |
| RSVP SIP Preconditions | 11-50 |
| Overview of SIP Preconditions | 11-50 |
| Unified Communications Manager and RSVP SIP Preconditions | 11-52 |
| Unified CM Interoperability and Feature Considerations | 11-61 |
| Cisco IOS Gateway and Unified CME | 11-61 |
| Service Advertisement Framework (SAF) and Call Control Discovery (CCD) Considerations | 11-67 |
| Cisco Unified SIP Proxy Considerations | 11-69 |
| Adaptive Security Appliance (ASA) Considerations | 11-69 |
| Design Considerations for Call Admission Control | 11-70 |
| Simple Hub-and-Spoke Topologies | 11-70 |
| Centralized Unified CM Deployments | 11-71 |
| Distributed Unified CM Deployments | 11-72 |
| Two-Tier Hub-and-Spoke Topologies | 11-74 |
| Centralized Unified CM Deployments | 11-75 |
| Distributed Unified CM Deployments | 11-77 |
| Simple MPLS Topologies | 11-78 |
| Centralized Unified CM Deployments | 11-80 |
| Distributed Unified CM Deployments | 11-82 |
| Generic Topologies | 11-84 |
| Centralized Unified CM Deployments | 11-85 |
| Distributed Mixed Call Processing Deployments | 11-90 |
| Call Admission Control Design Recommendations for TelePresence Video Interoperability Architectures | 11-95 |
| Supported CAC Deployment Scenarios and Design Considerations | 11-96 |
| Locations CAC Design Considerations and Recommendations | 11-97 |
| Design Recommendations | 11-97 |
| Design Considerations | 11-98 |
| RSVP CAC Design Considerations and Recommendations | 11-105 |
| Design Recommendations | 11-106 |
| Design Considerations | 11-107 |
| Call Admission Control Design Recommendations for Unified CM Session Management Edition Deployments | 11-110 |
| Session Management Edition Managing the CAC Domain with Locations CAC | 11-110 |
| Leaf Clusters Managing the CAC Domain with Locations CAC | 11-111 |
| Location-Based Call Admission Control Over Intercluster Trunk | 11-114 |
| QSIG Path Replacement Over Intercluster Trunks | 11-116 |
| Unified CM Session Management Edition with RSVP Deployments | 11-120 |

| | |
|--|--------|
| Session Management Edition Design with Leaf Clusters without RSVP SIP Precondition Support | 11-120 |
| Session Management Edition Design with Leaf Clusters with SIP Precondition Support | 11-123 |
| Session Management Edition Design with Mixed Leaf Clusters (with and without SIP Precondition Support) | 11-124 |
| Multiple Clusters Sharing a Single Platform for RSVP Agent | 11-124 |
| Design Recommendations for Call Admission Control | 11-126 |

CHAPTER 12**IP Video Telephony 12-1**

| | |
|--|-------|
| What's New in This Chapter | 12-2 |
| IP Video Telephony Solution Components | 12-2 |
| Administration Considerations | 12-3 |
| Protocols | 12-3 |
| Endpoints | 12-5 |
| Regions | 12-5 |
| Topology-Aware Locations | 12-8 |
| Retry Video Call as Audio | 12-10 |
| Wait for Far-End to Send TCS | 12-13 |
| Trunks | 12-15 |
| Multipoint Conferencing | 12-16 |
| MCU Resources for Ad-Hoc Conferences | 12-18 |
| Media Resource Groups and Lists | 12-19 |
| Intelligent Bridge Selection | 12-20 |
| H.323 and SIP MCU Resources | 12-21 |
| Sizing the MCU | 12-23 |
| IVR for Dial-In Conference | 12-24 |
| Gatekeepers | 12-25 |
| Endpoint Gatekeepers | 12-28 |
| Provisioning H.323 Clients | 12-28 |
| Provisioning H.323 MCUs | 12-33 |
| Provisioning H.320 Gateways | 12-34 |
| Gatekeeper Zone Configuration | 12-35 |
| Supported Gatekeeper Platforms | 12-40 |
| Summary of Endpoint Gatekeepers | 12-40 |
| Applications | 12-41 |
| CTI Applications | 12-42 |
| Cisco Emergency Responder | 12-42 |
| Cisco Unified Communications Manager Assistant | 12-42 |
| Cisco Unified IP Interactive Voice Response and Cisco Unified Contact Center | 12-43 |

- Cisco Unified Enterprise Attendant Console 12-43
- Cisco IP Communicator 12-43
- Collaboration Solutions 12-44
 - T.120 Application Sharing 12-44
 - Cisco Unified MeetingPlace 12-44
 - Video Interoperability 12-44
- Wireless Networking Solutions 12-46
 - Cisco Unified Wireless IP Phones 7925G and 7921G 12-46
- XML Services 12-47

CHAPTER 13

Gateways 13-1

- What's New in This Chapter 13-1
- Traffic Patterns and Gateway Sizing 13-2
 - Definitions and Terminology 13-2
 - PSTN Traffic Patterns 13-3
 - Normal Business Traffic Profile 13-3
 - Contact Center Traffic Profile 13-3
 - Gateway Sizing for Contact Center Traffic 13-4
 - Voice Activity Detection (VAD) 13-4
 - Codec 13-5
 - Performance Overload 13-5
 - Performance Tuning 13-5
- Additional Information 13-6
- Considerations for Gateway Redundancy 13-7
- TDM and VoIP Trunking Gateways 13-7
- Understanding Cisco Gateways 13-8
 - Cisco Access Analog Gateways 13-8
 - Cisco Access Digital Trunk Gateways 13-8
 - Tuning Gateway Gain Settings 13-8
- Gateway Selection 13-9
 - Core Feature Requirements 13-9
 - Gateway Protocols 13-10
 - Gateway Protocols and Core Feature Requirements 13-10
 - DTMF Relay 13-10
 - Supplementary Services 13-12
 - Unified CM Redundancy 13-15
 - Site-Specific Gateway Requirements 13-17
- Fax and Modem Support 13-19
 - Gateway Support for Fax Passthrough and Fax Relay 13-19

| | |
|---|-------|
| Best Practices | 13-21 |
| Super Group 3 Fax Support | 13-22 |
| Gateway Support for Modem Passthrough and Modem Relay | 13-23 |
| Best Practices | 13-24 |
| V.90 Support | 13-25 |
| Supported Platforms and Features | 13-25 |
| Platform Protocol Support | 13-25 |
| Gateway Configuration Examples | 13-26 |
| Gateways for Video Telephony | 13-27 |
| Routing Inbound Calls from the PSTN | 13-29 |
| Routing Outbound Calls to the PSTN | 13-31 |
| Automated Alternate Routing (AAR) | 13-32 |
| Least-Cost Routing | 13-33 |
| ISDN B-Channel Binding, Rollover, and Busy Out | 13-34 |
| Inbound Calls | 13-35 |
| Outbound Calls | 13-36 |
| Configuring the Gateways in Unified CM | 13-36 |
| Call Signaling Port Numbers | 13-36 |
| Call Signaling Timers | 13-37 |
| Bearer Capabilities of Voice Gateways | 13-37 |

CHAPTER 14**Cisco Unified CM Trunks 14-1**

| | |
|--|-------|
| What's New in This Chapter | 14-2 |
| Unified CM Trunks Solution Architecture | 14-2 |
| A Comparison of SIP and H.323 Trunks | 14-3 |
| SIP Trunks Overview | 14-6 |
| General Deployment Considerations | 14-7 |
| SIP Trunk Features and Operation | 14-7 |
| SIP Trunks Can Run on All Active Unified CM Nodes | 14-7 |
| Up to 16 SIP Trunk Destination IP Addresses | 14-7 |
| SIP OPTIONS Ping | 14-8 |
| SIP Early Offer Support over Unified CM SIP Trunks | 14-8 |
| QSIG over SIP Trunks | 14-11 |
| SIP Trunk Message Normalization and Transparency | 14-11 |
| Route Lists Run on All Active Unified CM Nodes | 14-15 |
| SIP Trunks Using DNS | 14-16 |
| High Availability for SIP Trunks | 14-18 |
| Multiple Source Unified CM Servers for Originating SIP Trunk Calls | 14-18 |
| Multiple Destination IP Addresses per SIP Trunk | 14-19 |

| | |
|---|-------|
| Design Considerations When Using Run on All Active Unified CM Nodes | 14-19 |
| Multiple SIP Trunks Using Route Lists and Route Groups | 14-19 |
| SIP OPTIONS Ping | 14-19 |
| Load Balancing for SIP Trunks | 14-19 |
| Outbound Calls over a Single SIP Trunk | 14-20 |
| Outbound Calls over Multiple SIP Trunks | 14-20 |
| SIP OPTIONS Ping | 14-20 |
| SIP Delayed Offer and Early Offer | 14-20 |
| Media Termination Points | 14-21 |
| DTMF Transport | 14-23 |
| SIP Trunk Transport Protocols | 14-24 |
| Secure SIP Trunks | 14-24 |
| Media Encryption | 14-24 |
| Signaling Encryption | 14-24 |
| Calling Party Number Transformation and SIP Trunks | 14-26 |
| SIP Trunk Service Types | 14-27 |
| Design Considerations for SIP Trunks | 14-27 |
| Considerations for SIP Intercluster Trunks | 14-27 |
| Using Standard Unified CM Groups with SIP Intercluster Trunks | 14-27 |
| Using Run on All Active Unified CM Nodes with SIP Intercluster Trunks | 14-28 |
| Using Standard Unified CM Groups and Run on All Active Unified CM Nodes with SIP Intercluster Trunks | 14-29 |
| Trunk Type and Feature Recommendations for Multi-Cluster Deployments | 14-31 |
| Multiple Clusters All Running Unified CM 8.5 or Later Releases | 14-31 |
| Multiple Clusters Running Unified CM 8.5 and Prior Releases | 14-32 |
| Trunk Design Considerations for Clustering over the WAN | 14-33 |
| Design Guidance for Clustering over the WAN with Leaf Cluster Trunks | 14-34 |
| Design Guidance for Clustering over the WAN with Unified CM Session Management Edition Cluster Trunks | 14-35 |
| Other SIP Trunk Deployment Considerations | 14-36 |
| H.323 Trunks Overview | 14-36 |
| General H.323 Intercluster Trunk Deployment Considerations | 14-37 |
| Basic Operation of H.323 Trunks | 14-37 |
| H.323 Trunk Types | 14-37 |
| Intercluster Trunk (Non-Gatekeeper Controlled) | 14-38 |
| Intercluster Trunk (Gatekeeper Controlled) | 14-44 |
| H.225 Trunk (Gatekeeper Controlled) | 14-45 |
| High Availability for Gatekeeper Controlled Trunks | 14-45 |
| Load Balancing Outbound Calls over H.323 Gatekeeper Controlled Trunks | 14-48 |
| H.323 Outbound Fast Start Call Connections | 14-49 |

| | |
|---|-------|
| H.323 Trunks with Media Termination Points | 14-50 |
| DTMF Transport | 14-50 |
| H.323 Trunk Transport Protocols | 14-50 |
| Secure H.323 Trunks | 14-50 |
| H.323 Operation in Unified CM | 14-51 |
| Other Design Considerations for H.323 Trunks | 14-55 |
| General SIP and H.323 Trunk Design Considerations | 14-55 |
| Deterministic Outbound Call Load Balancing over Unified CM Trunks | 14-55 |
| Codec Selection Over IP Trunks | 14-56 |
| Other MTP Uses | 14-57 |
| Cisco Unified CM Trunks and Emergency Services | 14-57 |
| Capacity Planning for Unified CM IP Trunks | 14-58 |
| IP PSTN and IP Trunks to Service Provider Networks | 14-58 |
| Cisco Unified Border Element | 14-58 |
| Trunk Aggregation Platforms | 14-59 |
| Unified CM Session Management Edition | 14-59 |
| Cisco Unified SIP Proxy | 14-61 |
| Trunk IP-PSTN Connection Models | 14-62 |

PART 3**Unified Communications Call Control****CHAPTER 15****Overview of Cisco Unified Communications Call Control 15-1**

| | |
|-------------------|------|
| Architecture | 15-2 |
| High Availability | 15-3 |
| Capacity Planning | 15-4 |

CHAPTER 16**LDAP Directory Integration 16-1**

| | |
|--|-------|
| What's New in This Chapter | 16-2 |
| What is Directory Integration? | 16-2 |
| Directory Access for Unified Communications Endpoints | 16-3 |
| Directory Integration with Unified CM | 16-5 |
| Cisco Unified Communications Directory Architecture | 16-7 |
| LDAP Synchronization | 16-10 |
| Synchronization Mechanism | 16-13 |
| Security Considerations | 16-15 |
| Design Considerations for LDAP Synchronization | 16-16 |
| Additional Considerations for Microsoft Active Directory | 16-16 |
| Unified CM Multi-Forest LDAP Synchronization | 16-18 |

- LDAP Authentication **16-19**
 - Design Considerations for LDAP Authentication **16-21**
 - Additional Considerations for Microsoft Active Directory **16-21**
- User Filtering for Directory Synchronization and Authentication **16-23**
 - Optimizing Unified CM Database Synchronization **16-24**
 - Using the LDAP Structure to Control Synchronization **16-24**
- LDAP Query **16-25**
 - LDAP Query Filter Syntax and Server-Side Filtering **16-25**
- High Availability **16-27**
 - Capacity Planning for Unified CM Database Synchronization **16-27**

CHAPTER 17

Media Resources 17-1

- What's New in This Chapter **17-2**
- Media Resources Architecture **17-2**
 - Media Resource Manager **17-2**
 - Cisco IP Voice Media Streaming Application **17-4**
- Voice Termination **17-4**
 - Medium and High Complexity Mode **17-5**
 - Flex Mode **17-5**
- Conferencing **17-6**
 - Audio Conferencing **17-6**
 - Video Conferencing **17-8**
 - Secure Conferencing **17-9**
- Transcoding **17-9**
 - Transcoding Resources **17-11**
- Media Termination Point (MTP) **17-12**
 - Re-Packetization of a Stream **17-12**
 - DTMF Conversion **17-12**
 - DTMF Relay Between Endpoints **17-13**
 - DTMF Relay over SIP Trunks **17-14**
 - SIP Trunk MTP Requirements **17-15**
 - DTMF Relay on SIP Gateways and Cisco Unified Border Element **17-16**
- H.323 Trunks and Gateways **17-16**
 - H.323 Supplementary Services **17-17**
 - H.323 Outbound Fast Connect **17-17**
 - DTMF Conversion **17-17**
 - DTMF Relay on H.323 Gateways and Cisco Unified Border Element **17-18**
- CTI Route Points **17-18**
 - MTP Usage with a Conference Bridge **17-18**

| | |
|--|-------|
| MTP Resources | 17-19 |
| Trusted Relay Point | 17-19 |
| Annunciator | 17-20 |
| Cisco RSVP Agent | 17-21 |
| Music on Hold | 17-21 |
| Unicast and Multicast MoH | 17-22 |
| MoH Selection Process | 17-23 |
| User and Network Hold | 17-24 |
| MoH Sources | 17-26 |
| Audio File | 17-26 |
| Fixed Source | 17-26 |
| MoH Selection | 17-26 |
| MoH Call Flows | 17-27 |
| SCCP Call Flows | 17-27 |
| SIP Call Flows | 17-30 |
| Capacity Planning for Media Resources | 17-34 |
| Considerations for Cisco 2900 and 3900 Series Platforms | 17-35 |
| Cisco 2800 and 3800 Series Platforms | 17-35 |
| Capacity Planning for Music On Hold | 17-36 |
| Co-resident and Standalone MoH | 17-36 |
| Server Platform Limits | 17-36 |
| Resource Provisioning | 17-38 |
| High Availability for Media Resources | 17-39 |
| Media Resource Groups and Lists | 17-39 |
| Redundancy and Failover Considerations for Cisco IOS-Based Media Resources | 17-40 |
| High Availability for Music On Hold | 17-40 |
| Design Considerations for Media Resources | 17-41 |
| Deployment Models | 17-41 |
| Single-Site Deployments | 17-41 |
| Multisite Deployments with Centralized Call Processing | 17-41 |
| Multisite Deployments with Distributed Call Processing | 17-42 |
| Media Functions and Voice Quality | 17-43 |
| Music on Hold Design Considerations | 17-44 |
| Codec Selection | 17-44 |
| Multicast Addressing | 17-44 |
| MoH Audio Sources | 17-45 |
| Using Multiple Fixed (Live) Audio Sources | 17-45 |
| Unicast and Multicast in the Same Unified CM Cluster | 17-46 |
| Quality of Service (QoS) | 17-47 |

| | |
|--|-------|
| Call Admission Control and MoH | 17-47 |
| Deployment Models for Music on Hold | 17-49 |
| Single-Site Campus (Relevant to All Deployments) | 17-49 |
| Centralized Multisite Deployments | 17-49 |
| Distributed Multisite Deployments | 17-52 |
| Clustering Over the WAN | 17-53 |

CHAPTER 18

Unified Communications Endpoints 18-1

| | |
|---|-------|
| What's New in This Chapter | 18-2 |
| Unified Communications Endpoints Architecture | 18-3 |
| Analog Gateways | 18-3 |
| Analog Interface Module | 18-4 |
| Low-Density Analog Interface Module | 18-4 |
| High-Density Analog Interface Module | 18-4 |
| Supported Platforms and Cisco IOS Requirements for Analog Interface Modules | 18-5 |
| Cisco Communication Media Module (CMM) | 18-6 |
| WS-X6624-FXS Analog Interface Module | 18-7 |
| Cisco VG202 and VG204 Gateways | 18-7 |
| Cisco VG224 Gateway | 18-7 |
| Cisco VG248 Gateway | 18-7 |
| Cisco ATA 186 and 188 | 18-8 |
| Additional Information on Analog Gateways | 18-8 |
| Cisco Unified IP Phones | 18-8 |
| Cisco Basic IP Phones | 18-8 |
| Cisco Unified SIP Phone 3900 Series | 18-9 |
| Cisco Unified IP Phone 6901 | 18-9 |
| Cisco Unified IP Phone 6911 | 18-9 |
| Cisco Unified IP Phone 7902G | 18-9 |
| Cisco Unified IP Phone 7905G | 18-9 |
| Cisco Unified IP Phone 7906G | 18-9 |
| Cisco Unified IP Phone 7910G and 7910G+SW | 18-10 |
| Cisco Unified IP Phone 7911G | 18-10 |
| Cisco Unified IP Phone 7912G | 18-10 |
| Cisco Business IP Phones | 18-10 |
| Cisco Unified IP Phone 6921 | 18-10 |
| Cisco Unified IP Phone 6961 | 18-10 |
| Cisco Unified IP Phone 7931G | 18-11 |
| Cisco Unified IP Phone 7940G | 18-11 |
| Cisco Unified IP Phone 7941G | 18-11 |

| | |
|--|-------|
| Cisco Unified IP Phone 7941G-GE | 18-11 |
| Cisco Unified IP Phone 7942G | 18-12 |
| Cisco Unified IP Phone 7945G | 18-12 |
| Cisco Manager IP Phones | 18-12 |
| Cisco Unified IP Phone 6941 and 6945 | 18-12 |
| Cisco Unified IP Phone 7960G | 18-12 |
| Cisco Unified IP Phone 7961G | 18-13 |
| Cisco Unified IP Phone 7961G-GE | 18-13 |
| Cisco Unified IP Phone 7962G | 18-13 |
| Cisco Unified IP Phone 7965G | 18-13 |
| Cisco Unified IP Phone 8900 Series | 18-13 |
| Cisco Executive IP Phones | 18-14 |
| Cisco Unified IP Phone 7970G | 18-14 |
| Cisco Unified IP Phone 7971G-GE | 18-14 |
| Cisco Unified IP Phone 7975G | 18-15 |
| Cisco Unified IP Phone 9951 | 18-15 |
| Cisco Unified IP Phone 9971 | 18-15 |
| Cisco Unified IP Phone Expansion Modules 7914, 7915, and 7916 | 18-15 |
| Deployment Considerations for Cisco Unified IP Phones 6921, 6941, 6945, and 6961 | 18-16 |
| Deployment Considerations for Cisco Unified IP Phones 8900 and 9900 Series | 18-16 |
| Firmware Upgrades | 18-16 |
| Network Connectivity Through a Wireless Interface | 18-17 |
| Power Over Ethernet | 18-18 |
| Applications | 18-18 |
| Support on SRST, Unified CME, and Unified CME as SRST | 18-19 |
| Support for Video | 18-19 |
| General QoS Deployment Considerations for Cisco Unified IP Phones | 18-20 |
| Additional Information on Cisco Unified IP Phones | 18-20 |
| Software-Based Endpoints | 18-21 |
| Cisco Unified Personal Communicator | 18-21 |
| Cisco IP Communicator | 18-21 |
| Cisco Unified Client Services Framework | 18-22 |
| Softphone Mode of Operation | 18-22 |
| Deskphone Control Mode of Operation | 18-22 |
| Video Design Considerations | 18-23 |
| Additional Information on Software-Based Endpoints | 18-23 |
| Wireless Endpoints | 18-23 |
| Site Survey | 18-24 |
| Authentication | 18-24 |
| Capacity | 18-26 |

| | |
|--|-------|
| Phone Configuration | 18-27 |
| Roaming | 18-27 |
| AP Call Admission Control | 18-28 |
| Bluetooth Support | 18-29 |
| Additional Information on Wireless Endpoints | 18-29 |
| Cisco Unified IP Conference Station | 18-29 |
| Video Endpoints | 18-30 |
| Cisco Unified Video Advantage | 18-30 |
| Cisco IP Video Phone 7985G | 18-33 |
| Cisco Unified IP Phones 8900 and 9900 Series | 18-33 |
| Cisco E20 Video Phone | 18-34 |
| Codecs Supported by Cisco Unified Video Advantage, Cisco IP Video Phone 7985G, Cisco Unified IP Phones 8900 and 9900 Series, and Cisco E20 Video Phone | 18-34 |
| Third-Party SCCP Video Endpoints | 18-35 |
| General QoS Deployment Considerations for Cisco Video Endpoints | 18-36 |
| Additional Information on Video Endpoints | 18-37 |
| Cisco Virtualization Experience Clients | 18-37 |
| Cisco Virtualization Experience Client 2111, 2112, 2211, and 2212 | 18-37 |
| Cisco Virtualization Experience Client 4000 | 18-37 |
| Cisco Virtualization Experience Client 6215 | 18-38 |
| Additional Information on Cisco Virtualization Experience Clients | 18-38 |
| Third-Party SIP IP Phones | 18-38 |
| QoS Recommendations | 18-39 |
| Cisco VG224 and VG248 | 18-39 |
| Cisco ATA 186 and IP Conference Station | 18-40 |
| Cisco ATA 188 and IP Phones | 18-40 |
| Software-Based Endpoints | 18-44 |
| Cisco Unified Wireless IP Phones | 18-46 |
| Video Telephony Endpoints | 18-48 |
| Cisco Unified Video Advantage with a Cisco Unified IP Phone | 18-48 |
| Cisco IP Video Phone 7985G | 18-50 |
| Sony and Tandberg SCCP Endpoints | 18-51 |
| H.323 and SIP Video Endpoints | 18-52 |
| High Availability for Unified Communications Endpoints | 18-54 |
| Capacity Planning for Unified Communications Endpoints | 18-54 |
| Design Considerations for Unified Communications Endpoints | 18-55 |
| Endpoint Features Summary | 18-55 |

CHAPTER 19

| | |
|---|-------------|
| Cisco Unified CM Applications | 19-1 |
| What's New in This Chapter | 19-2 |
| IP Phone Services | 19-2 |
| IP Phone Services Architecture | 19-2 |
| High Availability for IP Phone Services | 19-5 |
| Capacity Planning for IP Phone Services | 19-7 |
| Design Considerations for IP Phone Services | 19-7 |
| Extension Mobility | 19-7 |
| Unified CM Services for Extension Mobility | 19-8 |
| Extension Mobility Architecture | 19-8 |
| Extension Mobility Cross Cluster (EMCC) | 19-9 |
| Call Processing | 19-10 |
| Media Resources | 19-13 |
| Extension Mobility Security | 19-13 |
| High Availability for Extension Mobility | 19-14 |
| Capacity Planning for Extension Mobility | 19-16 |
| Design Considerations for Extension Mobility | 19-17 |
| Design Considerations for Extension Mobility Cross Cluster (EMCC) | 19-17 |
| Unified CM Assistant | 19-19 |
| Unified CM Assistant Architecture | 19-19 |
| Unified CM Assistant Proxy Line Mode | 19-19 |
| Unified CM Assistant Share Lined Mode | 19-20 |
| Unified CM Assistant Architecture | 19-21 |
| High Availability for Unified CM Assistant | 19-23 |
| Service and Component Redundancy | 19-23 |
| Device and Reachability Redundancy | 19-24 |
| Capacity Planning for Unified CM Assistant | 19-25 |
| Design Considerations for Unified CM Assistant | 19-27 |
| Unified CM Assistant Extension Mobility Considerations | 19-27 |
| Unified CM Assistant Dial Plan Considerations | 19-27 |
| Unified CM Assistant Console | 19-31 |
| Unified CM Assistant Console Installation | 19-31 |
| Unified CM Assistant Desktop Console QoS | 19-31 |
| Unified CM Assistant Console Directory Window | 19-31 |
| Unified CM Assistant Phone Console QoS | 19-32 |
| WebDialer | 19-32 |
| WebDialer Architecture | 19-33 |
| WebDialer Servlet | 19-33 |
| Redirector Servlet | 19-34 |

- WebDialer Architecture 19-37
- WebDialer URLs 19-38
- High Availability for WebDialer 19-39
 - Service and Component Redundancy 19-40
 - Device and Reachability Redundancy 19-40
- Capacity Planning for WebDialer 19-40
- Design Considerations for WebDialer 19-41
- Attendant Consoles 19-42
 - Attendant Console Architecture 19-43
 - High Availability for Attendant Consoles 19-45
 - Capacity Planning for Attendant Consoles 19-45
 - Design Considerations for Attendant Consoles 19-46

PART 4

Unified Communications Applications and Services

CHAPTER 20

Overview of Cisco Unified Communications Applications and Services 20-1

- Architecture 20-3
- High Availability 20-4
- Capacity Planning 20-5

CHAPTER 21

Cisco Voice Messaging 21-1

- What's New in This Chapter 21-2
- Voice Messaging Portfolio 21-3
- Messaging Deployment Models 21-5
 - Single-Site Messaging 21-6
 - Centralized Messaging 21-6
 - Distributed Messaging 21-6
- Messaging and Unified CM Deployment Model Combinations 21-7

GLOSSARY

INDEX

Preface

Revised: July 31, 2012; OL-21733-18

This document provides design considerations and guidelines for deploying Cisco Unified Communications System Release 8.x, including Cisco Unified Communications Manager 8.x and various other components of the Cisco Unified Communications System.

This document should be used in conjunction with other documentation available at the following locations:

- For other Solution Reference Network Design (SRND) documents:
<http://www.cisco.com/go/ucsrnd>
- For more information about the Cisco Unified Communications System:
<http://www.cisco.com/go/unified-techinfo>
<http://www.cisco.com>
- For more information about Cisco Unified Communications Manager:
http://www.cisco.com/en/US/products/sw/voicesw/ps556/tsd_products_support_series_home.html
<http://www.cisco.com>
- For other Cisco design guides:
<http://www.cisco.com/go/designzone>

New or Changed Information for This Release

Note

Unless stated otherwise, the information in this document applies to Release 8.x of the Cisco Unified Communications System and its components.

Within each chapter of this guide, new and revised information is listed in a section titled *What's New in This Chapter*.

Although much of the content in this document is similar to previous releases of the SRND, it has been reorganized extensively to reflect more accurately the architecture of the Cisco Unified Communications System. Cisco recommends that you review this entire document to become familiar with its structure and the system architecture.

Revision History

This document may be updated at any time without notice. You can obtain the latest version of this document online at:

<http://www.cisco.com/go/ucsrnd>

Visit this Cisco.com website periodically and check for documentation updates by comparing the revision date of your copy with the revision date of the online document.

The following table lists the revision history for this document.

| Revision Date | Document Part Number | Comments |
|--------------------|----------------------|--|
| July 31, 2012 | OL-21733-18 | Periodic update of various chapters. For details, in each chapter see <i>What's New in This Chapter</i> . |
| April 30, 2012 | OL-21733-17 | Periodic update of various chapters. For details, in each chapter see <i>What's New in This Chapter</i> . |
| February 29, 2012 | OL-21733-16 | Addition of a new chapter on Unified Communications Design and Deployment Sizing Considerations, page 29-1 . For information on other corrections and changes, in each chapter see <i>What's New in This Chapter</i> . |
| January 12, 2012 | OL-21733-15 | Minor corrections to a few illustrations. For details, in each chapter see <i>What's New in This Chapter</i> . |
| December 22, 2011 | OL-21733-14 | Updates to add information on Cisco Virtualization Experience Infrastructure (VXI), Cisco Virtualization Experience Client (VXC), and Cisco Unified Computing System (UCS). For details, in each chapter see <i>What's New in This Chapter</i> . |
| November 30, 2011 | OL-21733-13 | Updates to add information on Wireless LAN infrastructure and Cisco EnergyWise Technology. For details, see Network Infrastructure, page 1 . |
| October 31, 2011 | OL-21733-12 | Periodic update of various chapters. For details, in each chapter see <i>What's New in This Chapter</i> . |
| September 30, 2011 | OL-21733-11 | Periodic update of various chapters. For details, in each chapter see <i>What's New in This Chapter</i> . |
| August 31, 2011 | OL-21733-10 | Periodic update of various chapters. For details, in each chapter see <i>What's New in This Chapter</i> . |
| July 29, 2011 | OL-21733-09 | Periodic update of various chapters. For details, in each chapter see <i>What's New in This Chapter</i> . |
| June 30, 2011 | OL-21733-08 | Periodic update of various chapters. For details, in each chapter see <i>What's New in This Chapter</i> . |
| June 2, 2011 | OL-21733-07 | Updates for Cisco Unified Communications System Release 8.6. |
| March 31, 2011 | OL-21733-06 | Periodic update of various chapters. For details, in each chapter see <i>What's New in This Chapter</i> . |
| February 28, 2011 | OL-21733-05 | Periodic update of various chapters. For details, in each chapter see <i>What's New in This Chapter</i> . |
| January 31, 2011 | OL-21733-04 | Periodic update of various chapters. For details, in each chapter see <i>What's New in This Chapter</i> . |
| November 15, 2010 | OL-21733-03 | Updates for Cisco Unified Communications System Release 8.5. |

| Revision Date | Document Part Number | Comments |
|---------------|----------------------|---|
| July 23, 2010 | OL-21733-02 | Updates for Cisco Unified Communications System Release 8.0(2). |
| April 2, 2010 | OL-21733-01 | Initial version of this document for Cisco Unified Communications System 8.0. |

Obtaining Documentation and Submitting a Service Request

For information on obtaining documentation, submitting a service request, and gathering additional information, see the monthly *What's New in Cisco Product Documentation*, which also lists all new and revised Cisco technical documentation, at:

<http://www.cisco.com/en/US/docs/general/whatsnew/whatsnew.html>

Subscribe to the *What's New in Cisco Product Documentation* as a Really Simple Syndication (RSS) feed and set content to be delivered directly to your desktop using a reader application. The RSS feeds are a free service and Cisco currently supports RSS Version 2.0.

Cisco Product Security Overview

This product contains cryptographic features and is subject to United States and local country laws governing import, export, transfer and use. Delivery of Cisco cryptographic products does not imply third-party authority to import, export, distribute, or use encryption. Importers, exporters, distributors and users are responsible for compliance with U.S. and local country laws. By using this product you agree to comply with applicable laws and regulations. If you are unable to comply with U.S. and local laws, return this product immediately.

Further information regarding U.S. export regulations may be found at:

http://www.access.gpo.gov/bis/ear/ear_data.html

Conventions

This document uses the following conventions:

| Convention | Indication |
|---------------------------|---|
| bold font | Commands and keywords and user-entered text appear in bold font . |
| <i>italic font</i> | Document titles, new or emphasized terms, and arguments for which you supply values are in <i>italic font</i> . |
| [] | Elements in square brackets are optional. |
| { x y z } | Required alternative keywords are grouped in braces and separated by vertical bars. |
| [x y z] | Optional alternative keywords are grouped in brackets and separated by vertical bars. |
| string | A nonquoted set of characters. Do not use quotation marks around the string or the string will include the quotation marks. |
| <code>courier font</code> | Terminal sessions and information the system displays appear in <code>courier font</code> . |
| < > | Non-printing characters such as passwords are in angle brackets. |
| [] | Default responses to system prompts are in square brackets. |
| !, # | An exclamation point (!) or a pound sign (#) at the beginning of a line of code indicates a comment line. |

Note

Means *reader take note*.

Tip

Means *the following information will help you solve a problem*.

Caution

Means *reader be careful*. In this situation, you might perform an action that could result in equipment damage or loss of data.

Timesaver

Means *the described action saves time*. You can save time by performing the action described in the paragraph.

Warning

Means ***reader be warned***. In this situation, you might perform an action that could result in **bodily injury**.

CHAPTER 1

Introduction

Revised: November 15, 2010; OL-21733-18

The Cisco Unified Communications System delivers fully integrated communications by enabling data, voice, and video to be transmitted over a single network infrastructure using standards-based Internet Protocol (IP). Leveraging the framework provided by Cisco IP hardware and software products, the Cisco Unified Communications System delivers unparalleled performance and capabilities to address current and emerging communications needs in the enterprise environment. The Cisco Unified Communications family of products is designed to optimize feature functionality, reduce configuration and maintenance requirements, and provide interoperability with a wide variety of other applications. The Cisco Unified Communications System provides this capability while maintaining a high level of availability, quality of service (QoS), and security for your network.

The Cisco Unified Communications System incorporates and integrates the following major communications technologies:

- **IP telephony**

IP telephony refers to technology that transmits voice communications over a network using IP standards. Cisco Unified Communications includes a wide array of hardware and software products such as call processing agents, IP phones (both wired and wireless), voice messaging systems, video devices, and many special applications.
- **Customer contact center**

Cisco Unified Contact Center products are a combination of strategy and architecture that promote efficient and effective customer communications across a globally capable network by enabling organizations to draw from a broader range of resources to service customers. They include access to a large pool of agents and multiple channels of communication as well as customer self-help tools.
- **Video telephony**

The Cisco Unified Video Advantage products enable real-time video communications and collaboration using the same IP network and call processing agent as Cisco Unified Communications. With Cisco Unified Video Advantage, making a video call is as easy as dialing a phone number.
- **Rich-media conferencing**

Cisco Unified MeetingPlace, Cisco Unified Videoconferencing, and Cisco WebEx Software as a Service enhance the virtual meeting environment with a integrated set of IP-based tools for voice, video, and web conferencing.

- **Mobility**
Cisco wireless and mobility solutions enable users to increase productivity and responsiveness by enabling access to network resources and applications securely, regardless of location or client device.
- **TelePresence**
Cisco TelePresence delivers real-time, face-to-face interactions between people and places in their work and personal lives using advanced visual, audio, and collaboration technologies. These technologies transmit life-size, high-definition images and spatial discrete audio that make users feel like they are in the same room even when they are half a world away.
- **Applications**
Cisco provides numerous embedded applications and also works with leading-edge companies to provide the broadest selection of innovative third-party unified communications applications and products focused on critical business needs such messaging, customer care, and workforce optimization.

The remainder of this document focuses on system design considerations for deploying these technologies and applications in the Cisco Unified Communications System.

For information about other aspects of the Cisco Unified Communications System, refer to the documentation available at the following locations:

<http://www.cisco.com/go/ucsrnd>

<http://www.cisco.com/go/unified-techinfo>

You can also find additional documentation for the Cisco Unified Communications family of products at the following location:

<http://www.cisco.com>

**Note**

The design guidance in this document applies to Cisco customers and partners who want to deploy an Enterprise Unified Communications solution. For those interested in hosted or managed Unified Communication solutions, please refer to <http://www.cisco.com/go/hostedcollab> for more information.

Cisco Unified Communications System Architecture

Figure 1-1 illustrates the layered architecture of the Cisco Unified Communications System.

Figure 1-1 Architecture of the Cisco Unified Communications System

The various layers of the Cisco Unified Communications System perform the following major tasks and roles:

- Networking

This layer forms the foundation for the Unified Communications network. It includes components that provide the following functions and capabilities:

- Network infrastructure ensures a redundant and resilient network foundation with Quality of Service (QoS) enabled for Unified Communications applications.
- Voice security ensures a general security policy and a hardened and secure networking foundation for Unified Communications applications.

- Unified Communications deployment models provide tested models as well as best practices and design guidelines for deploying a Unified Communications System.
- IP telephony migration options provide guidelines on how to plan and approach a migration from standalone voice, video, and collaboration systems to an integrated Cisco Unified Communications System.

For more information on the Networking layer, see the [Overview of Cisco Unified Communications Networking, page 2-1](#).

- Call Routing

This layer handles the processing and routing of calls throughout the system. It includes components that provide the following functions and capabilities:

- Call processing agents provides telephony services and call routing capabilities.
- The dial plan provides endpoint numbering, dialed digits analysis, and classes of restriction to limit types of calls that a user can make.
- Call admission control provides mechanisms for preventing oversubscription of network bandwidth by limiting the number of calls that are allowed on the network at a given time, based on overall call capacity of the call processing components and network bandwidth.
- Video telephony services provide the ability to provision and register video endpoints as well as to set up, route, and maintain video calls on the network.
- PSTN gateways and provider voice and data services provide access to voice and data networks outside the enterprise, including the PSTN, Internet, and service provider IP-based trunks.
- Remote site survivability provides continuation of basic telephony services at remote sites when the central-site telephony services are unavailable due to failed or flapping network connectivity.

For more information on the Call Routing layer, see the [Overview of Cisco Unified Communications Call Routing, page 7-1](#).

- Call Control

This layer enables users to initiate and manage calls. It includes components that provide the following functions and capabilities:

- Integration with central Lightweight Directory Access Protocol (LDAP) directories enables companies to centralize all user information in a single repository available to Unified Communications applications, with a reduction in maintenance costs through the ease of adds, moves, and changes.
- Access to media resources provides media processing functions such as conferencing, media termination, transcoding, echo cancellation, signaling, packetization of a stream, streaming audio (annunciation), and so forth.
- Music on hold provides music (or advertising) to callers when their call is placed on hold, transferred, parked, or added to an ad-hoc conference.
- Unified Communications endpoints and feature sets range from gateways that support ordinary analog phones in an IP environment to an extensive set of native IP phones offering a range of capabilities for the end user.
- Device mobility features enable mobile users to roam from one site to another with their endpoint devices and to acquire the dynamically allocated settings of their roaming site for call routing, codec selection, media resource selection, and so forth.

- Applications embedded in the call control software provide features such as click-to-call dialing, manager-assistant applications, and the ability for users to log in to any phone, as well as support for web-based applications that can run directly on the user's desktop phone.

For more information on the Call Control layer, see the [Overview of Cisco Unified Communications Call Control, page 15-1](#).

- Applications and Services

This layer contains numerous applications and services that can be deployed on top of an existing Cisco Unified Communications infrastructure to add enhanced user features to the system. It includes components that provide the following functions and capabilities:

- Voice messaging provides voicemail services and message waiting indication.
- Rich media conferencing provides audio and video conferencing as well as web-based application and document sharing.
- Presence services provide user availability tracking across user devices and clients.
- Mobility services provide enterprise-level Unified Communications features and functionality to users outside the enterprise.
- Contact center applications provide call handling, queuing, and monitoring for large call volumes.
- Collaboration client services provide integration to Unified Communications services and leveraging of various applications.

For more information on the Applications and Services layer, see the [Overview of Cisco Unified Communications Applications and Services, page 20-1](#).

- Operations and Serviceability

This layer contains system-level services for monitoring and managing the Unified Communications network and applications. It includes components that provide the following functions and capabilities:

- User and device provisioning services provide centralized provisioning and configuration of users and devices for Unified Communications applications and services.
- Voice quality monitoring and alerting provide the ability to monitor various call flows within the system to determine whether voice quality is acceptable and to alert administrators when the voice quality is not acceptable.
- Operations and fault monitoring provides the ability to monitor all application and service operations and to issue alerts to administrators regarding network and application failures.
- Network and application probing provides the ability to probe and collect network and application traffic information at various locations throughout the deployment and to allow administrators to access and retrieve this information from a central location.

For more information on the Operations and Serviceability layer, see the [Overview of Cisco Unified Communications Operations and Serviceability, page 27-1](#).

**Note**

The design recommendations in this guide have been reviewed and found to be consistent with the Cisco Borderless Network Smart Business Architecture (SBA). Contact your Cisco representative for more information on SBA.

How to Use This Design Guide

This document provides design considerations, guidelines, and best practices for deploying a Cisco Unified Communications System. As discussed in the previous section, the architecture of the Cisco Unified Communications System consists of five layers. This document is divided into five parts corresponding to the five architectural layers. Each part of this document contains chapters that describe the components and design guidelines for the corresponding architectural layer.

The process for building a good Unified Communications system is similar to building a house: first you have to establish a solid infrastructure and foundation upon which to build all the other layers. And the other layers must be added in a particular sequence, usually from the bottom up. (For example, you have to build the walls of a house before you can put a roof on it.) In the case of a Unified Communications system, the networking layer provides the infrastructure, and the other layers must be added from the bottom up in the sequence shown in [Figure 1-1](#). The parts and chapters of this guide are organized in that same sequence to help you establish a logical process for designing your Unified Communications system.

The first chapter in each part of this guide presents an overview of the information contained in that part. The overview includes an illustration of the five architectural layers of the Cisco Unified Communications System, and the layer being discussed in that part of the guide is highlighted. For example, [Figure 1-2](#) is the illustration from the Call Control part of this guide. The Call Control layer is highlighted in a different color to show that it is the layer being discussed in that part of the guide. The layers below it (Networking and Call Routing) are visible because they must already be in place before the Call Control layer can be implemented. The layers above it (Applications & Services and Operations & Serviceability) are shaded to indicate that they cannot be implemented until the current layer (Call Control in this example) is in place.

Figure 1-2 Cisco Unified Communications Call Control Architecture

253669

If you are designing a new Unified Communications system, Cisco recommends that you develop your design according to the sequence and guidelines presented in this document. If you already have some layers of the system in place and you want to add other layers to it, Cisco recommends that you at least review the sections of this guide that pertain to the existing layers to ensure that your system complies with all the guidelines.

PART 1

Unified Communications Networking

CHAPTER 2

Overview of Cisco Unified Communications Networking

Revised: February 29, 2012; OL-21733-18

A solid network infrastructure is required to build a successful Unified Communications system in an enterprise environment. Other key aspects of the network architecture include voice security, unified communications deployment models, and migration strategies.

Unified Communications – including IP telephony, rich media, collaboration, and many other functions – places strict requirements on IP packet loss, packet delay, and delay variation (or jitter). Therefore, you need to enable most of the Quality of Service (QoS) mechanisms available on Cisco switches and routers throughout the network. For the same reasons, redundant devices and network links that provide quick convergence after network failures or topology changes are also important to ensure a highly available infrastructure. The following aspects are essential to the topic of Unified Communications networking and are specifically organized here in order of importance and relevance to one another:

- **Network Infrastructure** — Ensures a redundant and resilient foundation with QoS enabled for Unified Communications applications.
- **Voice Security** — Ensures a general security policy for Unified Communications applications and a hardened and secure networking foundation for them to rely upon.
- **Unified Communications Deployment Models** — Provide tested models in which to deploy Unified Communications call control and applications, as well as best practices and design guidelines to apply to Unified Communications deployments.
- **IP Telephony Migration Options** — Provide guidelines on how to plan and approach a migration from separate standalone voice, video, and collaboration systems to an integrated Cisco Unified Communications System.

The chapters in this part of the SRND cover the networking subjects mentioned above. Each chapter provides an introduction to the subject matter, followed by discussions surrounding architecture, high availability, capacity planning, and design considerations. The chapters focus on design-related aspects rather than product-specific support and configuration information, which is covered in the related product documentation.

This part of the SRND includes the following chapters:

- [Network Infrastructure, page 3-1](#)

This chapter describes the requirements of the network infrastructure needed to build a Cisco Unified Communications System in an enterprise environment. The sections in this chapter describe the network infrastructure features as they relate to LAN, WAN, and wireless LAN infrastructures. The chapters treat the areas of design, high availability, quality of service, and bandwidth provisioning as is pertinent to each infrastructure.

- [Unified Communications Security, page 4-1](#)

This chapter presents guidelines and recommendations for securing Unified Communications networks. The topics in this chapter range from general security, such as policy and securing the infrastructure, to phone security in VLANs, on switch ports, and with QoS. Other security aspects covered in this chapter include access control lists, securing gateways and media resources, firewalls, data center designs, securing application servers, and network virtualization.

- [Unified Communications Deployment Models, page 5-1](#)

This chapter describes the deployment models for Cisco Unified Communications Manager as they relate to the various network infrastructures such as a single site or campus, multi-site environments, and data center solutions. This chapter covers these deployment models and the best practices and design considerations for each model, including many other subtopics pertinent to the model discussed.

- [IP Telephony Migration Options, page 6-1](#)

This chapter describes several methods for migrating from separate standalone voice, video, and collaboration systems to an integrated Cisco Unified Communications System. It discusses the pros and cons of both phased migration and parallel cutover. It also describes the services needed to connect a private branch exchange (PBX) to a new Unified Communications system. The major topics discussed in this chapter include IP telephony migration, video migration, and migration of voice and desktop collaboration systems.

Architecture

The networking architecture lays the foundation upon which all other layers of the Unified Communications System are deployed. Figure 2-1 shows the logical location of the networking layer in the overall Cisco Unified Communications System architecture.

Figure 2-1 Cisco Unified Communications Networking Architecture

All other layers of the Unified Communications System architecture, including call routing, call control, applications and services, and operations and serviceability, rely heavily on the readiness of the network to support their services. The networking layer is the single most important aspect of a solid Unified Communications foundation in that it provides the quality of service needed to ensure applications have uncompromised access to network services. The networking layer also ensures the correct deployment of servers and the proper bandwidth for endpoints and services to communicate effectively and securely.

253667

High Availability

Proper design of the network infrastructure requires building a robust and redundant network from the bottom up. By structuring the LAN as a layered model (access, distribution, and core layers) and developing the LAN infrastructure one step of the model at a time, you can build a highly available, fault tolerant, and redundant network. Proper WAN infrastructure design is also extremely important for normal IP telephony operation on a converged network. Proper infrastructure design requires following basic configuration and design best-practices for deploying a WAN that is as highly available as possible and that provides guaranteed throughput. Furthermore, proper WAN infrastructure design requires deploying end-to-end QoS on all WAN links.

Wireless LAN infrastructure design becomes important when IP telephony is added to the wireless LAN (WLAN) portions of a converged network. With the addition of wireless Unified Communications endpoints such as the Cisco Unified Wireless IP Phones 7921G and 7925G, voice traffic has moved onto the WLAN and is now converged with the existing data traffic there. Just as with wired LAN and wired WAN infrastructures, the addition of voice in the WLAN requires following basic configuration and design best-practices for deploying a highly available network. In addition, proper WLAN infrastructure design requires understanding and deploying QoS on the wireless network to ensure end-to-end voice quality on the entire network.

After designing and implementing the network infrastructure properly, you can add network and application services successfully across the network, thus providing a highly available foundation upon which your Unified Communications services can run.

Capacity Planning

Scaling your network infrastructure to handle the Unified Communications applications and services that it must support requires providing adequate available bandwidth and the capability to handle the additional traffic load created by the applications.

For a complete discussion of system sizing, capacity planning, and deployment considerations related to sizing, refer to the chapter on [Unified Communications Design and Deployment Sizing Considerations](#), page 29-1.

CHAPTER 3

Network Infrastructure

Revised: July 31, 2012; OL-21733-18

This chapter describes the requirements of the network infrastructure needed to build a Cisco Unified Communications System in an enterprise environment. [Figure 3-1](#) illustrates the roles of the various devices that form the network infrastructure, and [Table 3-1](#) summarizes the features required to support each of these roles.

Unified Communications places strict requirements on IP packet loss, packet delay, and delay variation (or jitter). Therefore, you need to enable most of the Quality of Service (QoS) mechanisms available on Cisco switches and routers throughout the network. For the same reasons, redundant devices and network links that provide quick convergence after network failures or topology changes are also important to ensure a highly available infrastructure

The following sections describe the network infrastructure features as they relate to:

- [LAN Infrastructure, page 3-4](#)
- [WAN Infrastructure, page 3-36](#)
- [Wireless LAN Infrastructure, page 3-57](#)

Figure 3-1 Typical Campus Network Infrastructure

77290

Table 3-1 Required Features for Each Role in the Network Infrastructure

| Infrastructure Role | Required Features |
|--|--|
| Campus Access Switch | <ul style="list-style-type: none"> • In-Line Power¹ • Multiple Queue Support • 802.1p and 802.1Q • Fast Link Convergence |
| Campus Distribution or Core Switch | <ul style="list-style-type: none"> • Multiple Queue Support • 802.1p and 802.1Q • Traffic Classification • Traffic Reclassification |
| WAN Aggregation Router (Site that is at the hub of the network) | <ul style="list-style-type: none"> • Multiple Queue Support • Traffic Shaping • Link Fragmentation and Interleaving (LFI)² • Link Efficiency • Traffic Classification • Traffic Reclassification • 802.1p and 802.1Q |
| Branch Router (Spoke site) | <ul style="list-style-type: none"> • Multiple Queue Support • LFI² • Link Efficiency • Traffic Classification • Traffic Reclassification • 802.1p and 802.1Q |
| Branch or Smaller Site Switch | <ul style="list-style-type: none"> • In-Line Power¹ • Multiple Queue Support • 802.1p and 802.1Q |

1. Recommended.

2. For link speeds less than 786 kbps.

What's New in This Chapter

Table 3-2 lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Table 3-2 *New or Changed Information Since the Previous Release of This Document*

| New or Revised Topic | Described in | Revision Date |
|---|---|-------------------|
| Minor updates for wireless LAN infrastructure | Design Considerations for Voice and Video over WLAN, page 3-63 | July 31, 2012 |
| Wireless LAN infrastructure | Wireless LAN Infrastructure, page 3-57 | February 29, 2012 |

LAN Infrastructure

Campus LAN infrastructure design is extremely important for proper Unified Communications operation on a converged network. Proper LAN infrastructure design requires following basic configuration and design best practices for deploying a highly available network. Further, proper LAN infrastructure design requires deploying end-to-end QoS on the network. The following sections discuss these requirements:

- [LAN Design for High Availability, page 3-4](#)
- [LAN Quality of Service \(QoS\), page 3-16](#)

LAN Design for High Availability

Properly designing a LAN requires building a robust and redundant network from the top down. By structuring the LAN as a layered model (see [Figure 3-1](#)) and developing the LAN infrastructure one step of the model at a time, you can build a highly available, fault tolerant, and redundant network. Once these layers have been designed correctly, you can add network services such as DHCP and TFTP to provide additional network functionality. The following sections examine the infrastructure layers and network services:

- [Campus Access Layer, page 3-5](#)
- [Campus Distribution Layer, page 3-10](#)
- [Campus Core Layer, page 3-12](#)
- [Network Services, page 3-23](#)

For more information on campus design, refer to the *Design Zone for Campus* at

<http://www.cisco.com/go/designzone>

Campus Access Layer

The access layer of the Campus LAN includes the portion of the network from the desktop port(s) to the wiring closet switch. Access layer switches have traditionally been configured as Layer 2 devices with Layer 2 uplinks to the distribution layer. The Layer 2 and spanning tree recommendations for Layer 2 access designs are well documented and are discussed briefly below. For newer Cisco Catalyst switches supporting Layer 3 protocols, new routed access designs are possible and offer improvements in convergence times and design simplicity. Routed access designs are discussed in the section on [Routed Access Layer Designs, page 3-7](#).

Layer 2 Access Design Recommendations

Proper access layer design starts with assigning a single IP subnet per virtual LAN (VLAN). Typically, a VLAN should not span multiple wiring closet switches; that is, a VLAN should have presence in one and only one access layer switch (see [Figure 3-2](#)). This practice eliminates topological loops at Layer 2, thus avoiding temporary flow interruptions due to Spanning Tree convergence. However, with the introduction of standards-based IEEE 802.1w Rapid Spanning Tree Protocol (RSTP) and 802.1s Multiple Instance Spanning Tree Protocol (MISTP), Spanning Tree can converge at much higher rates. More importantly, confining a VLAN to a single access layer switch also serves to limit the size of the broadcast domain. There is the potential for large numbers of devices within a single VLAN or broadcast domain to generate large amounts of broadcast traffic periodically, which can be problematic. A good rule of thumb is to limit the number of devices per VLAN to about 512, which is equivalent to two Class C subnets (that is, a 23-bit subnet masked Class C address). For more information on the campus access layer, refer to the documentation on available at <http://www.cisco.com/en/US/products/hw/switches/index.html>.

Note

The recommendation to limit the number of devices in a single Unified Communications VLAN to approximately 512 is not solely due to the need to control the amount of VLAN broadcast traffic. For Linux-based Unified CM server platforms, the ARP cache has a hard limit of 1024 devices. Installing Unified CM in a VLAN with an IP subnet containing more than 1024 devices can cause the Unified CM server ARP cache to fill up quickly, which can seriously affect communications between the Unified CM server and other Unified Communications endpoints. Even though the ARP cache size on Windows-based Unified CM server platforms expands dynamically, Cisco strongly recommends a limit of 512 devices in any VLAN regardless of the operating system used by the Unified CM server platform.

Figure 3-2 Access Layer Switches and VLANs for Voice and Data

When you deploy voice, Cisco recommends that you enable two VLANs at the access layer: a native VLAN for data traffic (VLANs 10, 11, 30, 31, and 32 in [Figure 3-2](#)) and a voice VLAN under Cisco IOS or Auxiliary VLAN under CatOS for voice traffic (represented by VVIDs 110, 111, 310, 311, and 312 in [Figure 3-2](#)).

Separate voice and data VLANs are recommended for the following reasons:

- Address space conservation and voice device protection from external networks

Private addressing of phones on the voice or auxiliary VLAN ensures address conservation and ensures that phones are not accessible directly through public networks. PCs and servers are typically addressed with publicly routed subnet addresses; however, voice endpoints may be addressed using RFC 1918 private subnet addresses.
- QoS trust boundary extension to voice devices

QoS trust boundaries can be extended to voice devices without extending these trust boundaries and, in turn, QoS features to PCs and other data devices.
- Protection from malicious network attacks

VLAN access control, 802.1Q, and 802.1p tagging can provide protection for voice devices from malicious internal and external network attacks such as worms, denial of service (DoS) attacks, and attempts by data devices to gain access to priority queues through packet tagging.
- Ease of management and configuration

Separate VLANs for voice and data devices at the access layer provide ease of management and simplified QoS configuration.

To provide high-quality voice and to take advantage of the full voice feature set, access layer switches should provide support for:

- 802.1Q trunking and 802.1p for proper treatment of Layer 2 CoS packet marking on ports with phones connected
- Multiple egress queues to provide priority queuing of RTP voice packet streams

- The ability to classify or reclassify traffic and establish a network trust boundary
- Inline power capability (Although inline power capability is not mandatory, it is highly recommended for the access layer switches.)
- Layer 3 awareness and the ability to implement QoS access control lists (These features are recommended if you are using certain Unified Communications endpoints such as a PC running a softphone application that cannot benefit from an extended trust boundary.)

Spanning Tree Protocol (STP)

To minimize convergence times and maximize fault tolerance at Layer 2, enable the following STP features:

- PortFast

Enable PortFast on all access ports. The phones, PCs, or servers connected to these ports do not forward bridge protocol data units (BPDUs) that could affect STP operation. PortFast ensures that the phone or PC, when connected to the port, is able to begin receiving and transmitting traffic immediately without having to wait for STP to converge.

- Root guard or BPDU guard

Enable root guard or BPDU guard on all access ports to prevent the introduction of a rogue switch that might attempt to become the Spanning Tree root, thereby causing STP re-convergence events and potentially interrupting network traffic flows. Ports that are set to **errdisable** state by BPDU guard must either be re-enabled manually or the switch must be configured to re-enable ports automatically from the errdisable state after a configured period of time.

- UplinkFast and BackboneFast

Enable these features where appropriate to ensure that, when changes occur on the Layer 2 network, STP converges as rapidly as possible to provide high availability. When using Cisco stackable switches, enable Cross-Stack UplinkFast (CSUF) to provide fast failover and convergence if a switch in the stack fails.

- UniDirectional Link Detection (UDLD)

Enable this feature to reduce convergence and downtime on the network when link failures or misbehaviors occur, thus ensuring minimal interruption of network service. UDLD detects, and takes out of service, links where traffic is flowing in only one direction. This feature prevents defective links from being mistakenly considered as part of the network topology by the Spanning Tree and routing protocols.

Note

With the introduction of RSTP 802.1w, features such as PortFast and UplinkFast are not required because these mechanisms are built in to this standard. If RSTP has been enabled on the Catalyst switch, these commands are not necessary.

Routed Access Layer Designs

For campus designs requiring simplified configuration, common end-to-end troubleshooting tools, and the fastest convergence, a hierarchical design using Layer 3 switching in the access layer (routed access) in combination with Layer 3 switching at the distribution layer provides the fastest restoration of voice and data traffic flows.

Migrating the L2/L3 Boundary to the Access Layer

In the typical hierarchical campus design, the distribution layer uses a combination of Layer 2, Layer 3, and Layer 4 protocols and services to provide for optimal convergence, scalability, security, and manageability. In the most common distribution layer configurations, the access switch is configured as a Layer 2 switch that forwards traffic on high-speed trunk ports to the distribution switches. The distribution switches are configured to support both Layer 2 switching on their downstream access switch trunks and Layer 3 switching on their upstream ports toward the core of the network, as shown in [Figure 3-3](#).

Figure 3-3 Traditional Campus Design — Layer 2 Access with Layer 3 Distribution

The purpose of the distribution switch in this design is to provide boundary functions between the bridged Layer 2 portion of the campus and the routed Layer 3 portion, including support for the default gateway, Layer 3 policy control, and all the multicast services required.

An alternative configuration to the traditional distribution layer model illustrated in [Figure 3-3](#) is one in which the access switch acts as a full Layer 3 routing node (providing both Layer 2 and Layer 3 switching) and the access-to-distribution Layer 2 uplink trunks are replaced with Layer 3 point-to-point routed links. This alternative configuration, in which the Layer 2/3 demarcation is moved from the distribution switch to the access switch (as shown in [Figure 3-4](#)), appears to be a major change to the design but is actually just an extension of the current best-practice design.

Figure 3-4 Routed Access Campus Design – Layer 3 Access with Layer 3 Distribution

In both the traditional Layer 2 and the Layer 3 routed access designs, each access switch is configured with unique voice and data VLANs. In the Layer 3 design, the default gateway and root bridge for these VLANs is simply moved from the distribution switch to the access switch. Addressing for all end stations and for the default gateway remains the same. VLAN and specific port configurations remain unchanged on the access switch. Router interface configuration, access lists, "ip helper," and any other configuration for each VLAN remain identical but are configured on the VLAN Switched Virtual Interface (SVI) defined on the access switch instead of on the distribution switches.

There are several notable configuration changes associated with the move of the Layer 3 interface down to the access switch. It is no longer necessary to configure a Hot Standby Router Protocol (HSRP) or Gateway Load Balancing Protocol (GLBP) virtual gateway address as the "router" interfaces because all the VLANs are now local. Similarly, with a single multicast router, for each VLAN it is not necessary to perform any of the traditional multicast tuning such as tuning PIM query intervals or ensuring that the designated router is synchronized with the active HSRP gateway.

Routed Access Convergence

The many potential advantages of using a Layer 3 access design include the following:

- Improved convergence
- Simplified multicast configuration
- Dynamic traffic load balancing
- Single control plane
- Single set of troubleshooting tools (for example, ping and traceroute)

Of these advantages, perhaps the most significant is the improvement in network convergence times possible when using a routed access design configured with Enhanced Interior Gateway Routing Protocol (EIGRP) or Open Shortest Path First (OSPF) as the routing protocol. Comparing the convergence times for an optimal Layer 2 access design (either with a spanning tree loop or without a loop) against that of the Layer 3 access design, you can obtain a four-fold improvement in convergence times, from 800 to 900 msec for the Layer 2 design to less than 200 msec for the Layer 3 access design.

For more information on routed access designs, refer to the document on *High Availability Campus Network Design – Routed Access Layer using EIGRP or OSPF*, available at

http://www.cisco.com/application/pdf/en/us/guest/netso/ns432/c649/ccmigration_09186a0080811468.pdf

Campus Distribution Layer

The distribution layer of the Campus LAN includes the portion of the network from the wiring closet switches to the next-hop switch. For more information on the campus distribution layer switches, refer to the product documentation available at

<http://www.cisco.com/en/US/products/hw/switches/index.html>

At the distribution layer, it is important to provide redundancy to ensure high availability, including redundant links between the distribution layer switches (or routers) and the access layer switches. To avoid creating topological loops at Layer 2, use Layer 3 links for the connections between redundant Distribution switches when possible.

First-Hop Redundancy Protocols

In the campus hierarchical model, where the distribution switches are the L2/L3 boundary, they also act as the default gateway for the entire L2 domain that they support. Some form of redundancy is required because this environment can be large and a considerable outage could occur if the device acting as the default gateway fails.

Gateway Load Balancing Protocol (GLBP), Hot Standby Router Protocol (HSRP), and Virtual Router Redundancy Protocol (VRRP) are all first-hop redundancy protocols. Cisco initially developed HSRP to address the need for default gateway redundancy. The Internet Engineering Task Force (IETF) subsequently ratified Virtual Router Redundancy Protocol (VRRP) as the standards-based method of providing default gateway redundancy. More recently, Cisco developed GLBP to overcome some the limitations inherent in both HSRP and VRRP.

HSRP and VRRP with Cisco enhancements both provide a robust method of backing up the default gateway, and they can provide failover in less than one second to the redundant distribution switch when tuned properly.

Gateway Load Balancing Protocol (GLBP)

Like HSRP and VRRP, Cisco's Gateway Load Balancing Protocol (GLBP) protects data traffic from a failed router or circuit, while also allowing packet load sharing between a group of redundant routers. When HSRP or VRRP are used to provide default gateway redundancy, the backup members of the peer relationship are idle, waiting for a failure event to occur for them to take over and actively forward traffic.

Before the development of GLBP, methods to utilize uplinks more efficiently were difficult to implement and manage. In one technique, the HSRP and STP/RSTP root alternated between distribution node peers, with the even VLANs homed on one peer and the odd VLANs homed on the alternate. Another technique used multiple HSRP groups on a single interface and used DHCP to alternate between the multiple default gateways. These techniques worked but were not optimal from a configuration, maintenance, or management perspective.

GLBP is configured and functions like HSRP. For HSRP, a single virtual MAC address is given to the endpoints when they use Address Resolution Protocol (ARP) to learn the physical MAC address of their default gateways (see [Figure 3-5](#)).

Figure 3-5 HSRP Uses One Virtual MAC Address

Two virtual MAC addresses exist with GLBP, one for each GLBP peer (see Figure 3-6). When an endpoint uses ARP to determine its default gateway, the virtual MAC addresses are checked in a round-robin basis. Failover and convergence work just like with HSRP. The backup peer assumes the virtual MAC address of the device that has failed, and begins forwarding traffic for its failed peer.

Figure 3-6 GLBP Uses Two Virtual MAC Addresses, One for Each GLBP Peer

The end result is that a more equal utilization of the uplinks is achieved with minimal configuration. As a side effect, a convergence event on the uplink or on the primary distribution node affects only half as many hosts, giving a convergence event an average of 50 percent less impact.

For more information on HSRP, VRRP, and GLBP, refer to the *Campus Network for High Availability Design Guide*, available at

http://www.cisco.com/application/pdf/en/us/guest/netsol/ns431/c649/ccmigration_09186a008093b876.pdf

Routing Protocols

Configure Layer 3 routing protocols such as OSPF and EIGRP at the distribution layer to ensure fast convergence, load balancing, and fault tolerance. Use parameters such as routing protocol timers, path or link costs, and address summaries to optimize and control convergence times as well as to distribute traffic across multiple paths and devices. Cisco also recommends using the **passive-interface** command to prevent routing neighbor adjacencies via the access layer. These adjacencies are typically unnecessary, and they create extra CPU overhead and increased memory utilization because the routing protocol keeps track of them. By using the **passive-interface** command on all interfaces facing the access layer, you prevent routing updates from being sent out on these interfaces and, therefore, neighbor adjacencies are not formed.

Campus Core Layer

The core layer of the Campus LAN includes the portion of the network from the distribution routers or Layer 3 switches to one or more high-end core Layer 3 switches or routers. Layer 3-capable Catalyst switches at the core layer can provide connectivity between numerous campus distribution layers. For more details on the campus core layer switches, refer to the documentation on available at <http://www.cisco.com/en/US/products/hw/switches/index.html>.

At the core layer, it is again very important to provide the following types of redundancy to ensure high availability:

- Redundant link or cable paths

Redundancy here ensures that traffic can be rerouted around downed or malfunctioning links.

- Redundant devices

Redundancy here ensures that, in the event of a device failure, another device in the network can continue performing tasks that the failed device was doing.

- Redundant device sub-systems

This type of redundancy ensures that multiple power supplies and modules are available within a device so that the device can continue to function in the event that one of these components fails.

The Cisco Catalyst 6500 Virtual Switching System (VSS) 1440 is a method to ensure redundancy in all of these areas by pooling together two Catalyst 6500 supervisor engines to act as one. For more information regarding VSS, refer to the product documentation available at

<http://www.cisco.com/en/US/products/ps9336/index.html>

Routing protocols at the core layer should again be configured and optimized for path redundancy and fast convergence. There should be no STP in the core because network connectivity should be routed at Layer 3. Finally, each link between the core and distribution devices should belong to its own VLAN or subnet and be configured using a 30-bit subnet mask.

Data Center and Server Farm

Typically, Cisco Unified Communications Manager (Unified CM) cluster servers, including media resource servers, reside in a firewall-secured data center or server farm environment. In addition, centralized gateways and centralized hardware media resources such as conference bridges, DSP or transcoder farms, and media termination points may be located in the data center or server farm. The placement of firewalls in relation to Cisco Unified Communications Manager (Unified CM) cluster servers and media resources can affect how you design and implement security in your network. For design guidance on firewall placement in relation to Unified Communications systems and media resources, see [Firewalls, page 4-24](#).

Because these servers and resources are critical to voice networks, Cisco recommends distributing all Unified CM cluster servers, centralized voice gateways, and centralized hardware resources between multiple physical switches and, if possible, multiple physical locations within the campus. This distribution of resources ensures that, given a hardware failure (such as a switch or switch line card failure), at least some servers in the cluster will still be available to provide telephony services. In addition, some gateways and hardware resources will still be available to provide access to the PSTN and to provide auxiliary services. Besides being physically distributed, these servers, gateways, and hardware resources should be distributed among separate VLANs or subnets so that, if a broadcast storm or denial of service attack occurs on a particular VLAN, not all voice connectivity and services will be disrupted.

Power over Ethernet (PoE)

PoE (or inline power) is 48 Volt DC power provided over standard Ethernet unshielded twisted-pair (UTP) cable. Instead of using wall power, IP phones and other inline powered devices (PDs) such as the Aironet Wireless Access Points can receive power provided by inline power-capable Catalyst Ethernet switches or other inline power source equipment (PSE). Inline power is enabled by default on all inline power-capable Catalyst switches.

Deploying inline power-capable switches with uninterruptible power supplies (UPS) ensures that IP phones continue to receive power during power failure situations. Provided the rest of the telephony network is available during these periods of power failure, then IP phones should be able to continue making and receiving calls. You should deploy inline power-capable switches at the campus access layer within wiring closets to provide inline-powered Ethernet ports for IP phones, thus eliminating the need for wall power.

Caution

The use of power injectors or power patch panels to deliver PoE can damage some devices because power is always applied to the Ethernet pairs. PoE switch ports automatically detect the presence of a device that requires PoE before enabling it on a port-by-port basis.

In addition to Cisco PoE inline power, Cisco now supports the IEEE 802.3af PoE standard. The majority of Cisco switches and Cisco Unified IP Phones comply with the 802.3af standard. For information about which Cisco Unified IP Phones support the 802.3af PoE standard, see the [Endpoint Features Summary, page 18-55](#).

Energy Conservation for IP Phones

Cisco EnergyWise Technology provides intelligent management of energy usage for devices on the IP network, including Unified Communications endpoints that use Power over Ethernet (PoE). Cisco EnergyWise architecture can turn power on and off to devices connected with PoE on EnergyWise enabled switches, based on a configurable schedule. For more information on EnergyWise, refer to the documentation at

<http://www.cisco.com/en/US/products/ps10195/index.html>

When the PoE switch powers off IP phones for EnergyWise conservation, the phones are completely powered down. EnergyWise shuts down inline power on the ports that connect to IP phones and does so by a schedule or by commands from network management tools. When power is disabled, no verification occurs to determine whether a phone has an active call. The power is turned off and any active call is torn down. The IP phone loses registration from Cisco Unified Communications Manager and no calls can be made to or from the phone. There is no mechanism on the phone to power it on, therefore emergency calling will not be available on that phone.

The IP phone can be restarted only when the switch powers it on again. After power is restored, the IP phones will reboot and undergo a recovery process that includes requesting a new IP address, downloading a configuration file, applying any new configuration parameters, downloading new firmware or locales, and registering with Cisco Unified CM.

The EnergyWise schedule is configured and managed on the Cisco Network Infrastructure. It does not require any configuration on the IP phone or on Cisco Unified CM. However, power consumption on the phone can also be managed by a device profile configured on Unified CM. The energy saving options provided by Unified CM include the following:

- [Power Save Plus Mode, page 3-14](#)
- [Power Save Mode, page 3-14](#)

Power Save Plus Mode

In Power Save Plus mode, the phone on and off times and the idle timeout periods can be configured on the IP phones. The Cisco IP Phones' EnergyWise Power Save Plus configuration options specify the schedule for the IP phones to sleep (power down) and wake (power up). This mode requires an EnergyWise enabled network. If EnergyWise is enabled, then the sleep and wake times, as well as other parameters, can be used to control power to the phones. The Power Save Plus parameters are configured in the product-specific device profile in Cisco Unified CM Administration and sent to the IP phones as part of the phone configuration XML file.

During the configured power off period in this power saving mode, the IP phone sends a request to the switch asking for a wake-up at a specified time. If the switch is EnergyWise enabled, it accepts the request and reduces the power to the phone port, putting the phone to sleep. The sleep mode reduces the power consumption of the phone to 1 watt or less. The phone is not completely powered off in this case. When the phone is sleeping, the PoE switch provides minimal power that illuminates the Select key on the phone. A user can wake up the IP phone by using the Select button. The IP phone does not go into sleep mode if a call is active on the phone. Audio and visual alerts can optionally be configured to warn users before a phone enters the Power Save Plus mode. While the phone is in sleep mode, it is not registered to Cisco Unified CM and cannot receive any inbound calls. Use the Forward Unregistered setting in the phone's device configuration profile to specify how to treat any inbound calls to the phone's number.

Note

The Cisco EnergyWise Power Save Plus mode is supported in Unified CM 8.6 and later releases, and it requires phone firmware version 9.(2)1 or later. It is available on the Cisco Unified IP Phone 6900, 8900, and 9900 Series.

Power Save Mode

In Power Save mode, the backlight on the screen is not lit when the phone is not in use. The phone stays registered to Cisco Unified CM in this mode and can receive inbound calls and make outbound calls. Cisco Unified CM Administration has product-specific configuration options to turn off the display at a designated time on some days and all day on other days. The phone remains in Power Save mode for the scheduled duration or until the user lifts the handset or presses any button. An EnergyWise enabled network is not required for the Power Save mode. Idle times can be scheduled so that the display remains on until the timeout and then turns off automatically. The phone is still powered on in this mode and can receive inbound calls.

The Power Save mode can be used together with the Power Save Plus mode. Using both significantly reduces the total power consumption by Cisco Unified IP Phones.

For information on configuring these modes, refer to the administration guides for the Cisco Unified IP Phones, available at the following locations:

- Cisco Unified IP Phones 9900 Series
http://www.cisco.com/en/US/products/ps10453/prod_maintenance_guides_list.html
- Cisco Unified IP Phones 8900 Series
http://www.cisco.com/en/US/products/ps10451/prod_maintenance_guides_list.html
- Cisco Unified IP Phones 6900 Series
http://www.cisco.com/en/US/products/ps10326/prod_maintenance_guides_list.html

Category 3 Cabling

The use of Category 3 cabling is supported for IP Communications under the following conditions:

- Phones with a PC port and a PC attached to it should be set to 10 Mb, full-duplex.
This setting requires hard-coding the upstream switch port, the phone switch and PC ports, and the PC NIC port to 10 Mb, full-duplex. No ports should be set to AUTO negotiate. If desired, you can hard-code the phone's PC port to 10 Mb half-duplex, thereby forcing the PC's NIC to negotiate to 10 Mb half-duplex (assuming the PC's NIC is configured to AUTO negotiate). This configuration is acceptable as long as the uplink between the phone and the upstream switch port is set to 10 Mb full-duplex.
- Phones with no PC ports and with 10 Mb switch ports should be allowed to auto-negotiate to 10 Mb, half-duplex.
Because these phones support only 10 Mb Ethernet and their ports cannot be manually configured, the upstream switch port should be set to either AUTO negotiate or 10 Mb, half-duplex. In both cases, these phones will negotiate to 10 Mb, half-duplex.
- Phones with a PC port but no PC attached to it can be allowed to negotiate to 10 Mb, half-duplex.
If you leave these phones with the default switch port configuration of AUTO negotiate and configure the upstream switch port to 10 Mb, half-duplex, these phones will revert to 10Mb, half-duplex.

**Note**

The Cisco Unified IP Phone 7912 should not be used with Category 3 cable when a PC is attached because the switch and PC ports on this phone cannot be forced to 10 Mb, full duplex.

IBM Type 1A and 2A Cabling

The use of IBM Cabling System (ICS) or Token Ring shielded twisted-pair type 1A or 2A cabling is supported for IP Communications under the following conditions:

- Cable lengths should be 100 meters or less.
- Adapters without impedance matching should be used for converting from universal data connector (UDC) to RJ-45 Ethernet standard.

**Note**

There are only two twisted pairs in the Token Ring cables. Therefore, inline power for IP phones can be supported, but mid-span power insertion cannot (with Cisco Inline Power and 802.3af) because it requires more than two pairs.

**Note**

Gigabit Ethernet is not supported over IBM Cabling Systems because 1000 BASE-T requires four twisted pairs. Where an IBM Cabling System is used in conjunction with the 10/100/1000 BASE-T Ethernet interfaces on Cisco IP Phones, only speeds of 10 Mbps and 100 Mbps are supported.

Running data over the network is not always a sufficient test of the quality of the cable plant because some non-compliance issues might not be apparent. Therefore, customers might want to perform a cable plant survey to verify that their type 1A and 2A cabling installation is compliant with Ethernet standards.

LAN Quality of Service (QoS)

Until recently, quality of service was not an issue in the enterprise campus due to the asynchronous nature of data traffic and the ability of network devices to tolerate buffer overflow and packet loss. However, with new applications such as voice and video, which are sensitive to packet loss and delay, buffers and not bandwidth are the key QoS issue in the enterprise campus.

Figure 3-7 illustrates the typical oversubscription that occurs in LAN infrastructures.

Figure 3-7 Data Traffic Oversubscription in the LAN

This oversubscription, coupled with individual traffic volumes and the cumulative effects of multiple independent traffic sources, can result in the egress interface buffers becoming full instantaneously, thus causing additional packets to drop when they attempt to enter the egress buffer. The fact that campus switches use hardware-based buffers, which compared to the interface speed are much smaller than those found on WAN interfaces in routers, merely increases the potential for even short-lived traffic bursts to cause buffer overflow and dropped packets.

Applications such as file sharing (both peer-to-peer and server-based), remote networked storage, network-based backup software, and emails with large attachments, can create conditions where network congestion occurs more frequently and/or for longer durations. Some of the negative effects of recent worm attacks have been an overwhelming volume of network traffic (both unicast and broadcast-storm based), increasing network congestion. If no buffer management policy is in place, loss, delay, and jitter performance of the LAN may be affected for all traffic.

Another situation to consider is the effect of failures of redundant network elements, which cause topology changes. For example, if a distribution switch fails, all traffic flows will be reestablished through the remaining distribution switch. Prior to the failure, the load balancing design shared the load between two switches, but after the failure all flows are concentrated in a single switch, potentially causing egress buffer conditions that normally would not be present.

For applications such as voice, this packet loss and delay results in severe voice quality degradation. Therefore, QoS tools are required to manage these buffers and to minimize packet loss, delay, and delay variation (jitter).

The following types of QoS tools are needed from end to end on the network to manage traffic and ensure voice quality:

- Traffic classification

Classification involves the marking of packets with a specific priority denoting a requirement for class of service (CoS) from the network. The point at which these packet markings are trusted or not trusted is considered the trust boundary. Trust is typically extended to voice devices (phones) and not to data devices (PCs).

- Queuing or scheduling

Interface queuing or scheduling involves assigning packets to one of several queues based on classification for expedited treatment throughout the network.

- Bandwidth provisioning

Provisioning involves accurately calculating the required bandwidth for all applications plus element overhead.

The following sections discuss the use of these QoS mechanisms in a campus environment:

- [Traffic Classification, page 3-17](#)
- [Interface Queuing, page 3-19](#)
- [Bandwidth Provisioning, page 3-20](#)
- [Impairments to IP Communications if QoS is Not Employed, page 3-20](#)

Traffic Classification

It has always been an integral part of the Cisco network design architecture to classify or mark traffic as close to the edge of the network as possible. Traffic classification is an entrance criterion for access into the various queuing schemes used within the campus switches and WAN interfaces. Cisco IP Phones mark voice control signaling and voice RTP streams at the source, and they adhere to the values presented in [Table 3-3](#). As such, the IP phone can and should classify traffic flows.

[Table 3-3](#) lists the traffic classification requirements for the LAN infrastructure.

Table 3-3 Traffic Classification Guidelines for Various Types of Network Traffic

| Application | Layer-3 Classification | | | Layer-2 Classification |
|--|--|--------------------------------------|--|------------------------|
| | Type of Service (ToS) IP Precedence (IPP) | Per-Hop Behavior (PHB) | Differentiated Services Code Point (DSCP) | Class of Service (CoS) |
| Routing | 6 | CS6 | 48 | 6 |
| Voice Real-Time Transport Protocol (RTP) | 5 | EF | 46 | 5 |
| Videoconferencing | 4 | AF41 | 34 | 4 |
| Streaming video | 4 | CS4 | 32 | 4 |
| Call signaling ¹ | 3 | CS3 (currently) AF31 (previously) | 24 (currently) 26 (previously) | 3 |
| Transactional data | 2 | AF21 | 18 | 2 |
| Network management | 2 | CS2 | 16 | 2 |
| Scavenger | 1 | CS1 | 8 | 1 |
| Best effort | 0 | 0 | 0 | 0 |

1. The recommended DSCP/PHB marking for call control signaling traffic has been changed from 26/AF31 to 24/CS3. A marking migration has occurred within Cisco to reflect this change, however some products still mark signaling traffic as 26/AF31. Therefore, in the interim, Cisco recommends that both AF31 and CS3 be reserved for call signaling.

For more information about traffic classification, refer to the *Enterprise QoS Solution Reference Network Design (SRND)*, available at

<http://www.cisco.com/go/designzone>

Traffic Classification for Video Telephony

The main classes of interest for IP Video Telephony are:

- Voice
Voice is classified as CoS 5 (IP Precedence 5, PHB EF, or DSCP 46).
- Videoconferencing
Videoconferencing is classified as CoS 4 (IP Precedence 4, PHB AF41, or DSCP 34).
- Call signaling
Call signaling for voice and videoconferencing is now classified as CoS 3 (IP Precedence 3, PHB CS3, or DSCP 24) but was previously classified as PHB AF31 or DSCP 26.

Cisco highly recommends these classifications as *best practices* in a Cisco Unified Communications network.

QoS Marking Differences Between Video Calls and Voice-Only Calls

The voice component of a call can be classified in one of two ways, depending on the type of call in progress. A voice-only telephone call would have its media classified as CoS 5 (IP Precedence 5 or PHB EF), while the voice channel of a video conference would have its media classified as CoS 4 (IP Precedence 4 or PHB AF41). All the Cisco IP Video Telephony products adhere to the Cisco

Corporate QoS Baseline standard, which requires that the audio and video channels of a video call both be marked as CoS 4 (IP Precedence 4 or PHB AF41). The reasons for this recommendation include, but are not limited to, the following:

- To preserve lip-sync between the audio and video channels
- To provide separate classes for audio-only calls and video calls

The signaling class is applicable to all voice signaling protocols (such as SCCP, MGCP, and so on) as well as video signaling protocols (such as SCCP, H.225, RAS, CAST, and so on). These protocols are discussed in more detail in the section on [Software-Based Endpoints](#), page 18-44.

Given the recommended classes, the first step is to decide where the packets will be classified (that is, which device will be the first to mark the traffic with its QoS classification). There are essentially two places to mark or classify traffic:

- On the originating endpoint — the classification is then trusted by the upstream switches and routers
- On the switches and/or routers — because the endpoint is either not capable of classifying its own packets or is not trustworthy to classify them correctly

QoS Enforcement Using a Trusted Relay Point (TRP)

A Trusted Relay Point (TRP) can be used to enforce and/or re-mark the DSCP values of media flows from endpoints. This feature allows QoS to be enforced for media from endpoints such as softphones, where the media QoS values might have been modified locally.

A TRP is a media resource based upon the existing Cisco IOS media termination point (MTP) function.

Endpoints can be configured to "Use Trusted Relay Point," which will invoke a TRP for all calls.

For QoS enforcement, the TRP uses the configured QoS values for media in Unified CM's Service Parameters to re-mark and enforce the QoS values in media streams from the endpoint.

TRP functionality is supported by Cisco IOS MTPs and transcoding resources. (Use Unified CM to check "Enable TRP" on the MTP or transcoding resource to activate TRP functionality.)

Interface Queuing

After packets have been marked with the appropriate tag at Layer 2 (CoS) and Layer 3 (DSCP or PHB), it is important to configure the network to schedule or queue traffic based on this classification, so as to provide each class of traffic with the service it needs from the network. By enabling QoS on campus switches, you can configure all voice traffic to use separate queues, thus virtually eliminating the possibility of dropped voice packets when an interface buffer fills instantaneously.

Although network management tools may show that the campus network is not congested, QoS tools are still required to guarantee voice quality. Network management tools show only the average congestion over a sample time span. While useful, this average does not show the congestion peaks on a campus interface.

Transmit interface buffers within a campus tend to congest in small, finite intervals as a result of the bursty nature of network traffic. When this congestion occurs, any packets destined for that transmit interface are dropped. The only way to prevent dropped voice traffic is to configure multiple queues on campus switches. For this reason, Cisco recommends always using a switch that has at least two output queues on each port and the ability to send packets to these queues based on QoS Layer 2 and/or Layer 3 classification. The majority of Cisco Catalyst Switches support two or more output queues per port. For more information on Cisco Catalyst Switch interface queuing capabilities, refer to the documentation at <http://www.cisco.com/en/US/products/hw/switches/index.html>

Bandwidth Provisioning

In the campus LAN, bandwidth provisioning recommendations can be summarized by the motto, *Over provision and under subscribe*. This motto implies careful planning of the LAN infrastructure so that the available bandwidth is always considerably higher than the load and there is no steady-state congestion over the LAN links.

The addition of voice traffic onto a converged network does not represent a significant increase in overall network traffic load; the bandwidth provisioning is still driven by the demands of the data traffic requirements. The design goal is to avoid extensive data traffic congestion on any link that will be traversed by telephony signaling or media flows. Contrasting the bandwidth requirements of a single G.711 voice call (approximately 86 kbps) to the raw bandwidth of a FastEthernet link (100 Mbps) indicates that voice is not a source of traffic that causes network congestion in the LAN, but rather it is a traffic flow to be protected from LAN network congestion.

Impairments to IP Communications if QoS is Not Employed

If QoS is not deployed, packet drops and excessive delay and jitter can occur, leading to impairments of the telephony services. When media packets are subjected to drops, delay, and jitter, the user-perceivable effects include clicking sound, harsh-sounding voice, extended periods of silence, and echo.

When signaling packets are subjected to the same conditions, user-perceivable impairments include unresponsiveness to user input (such as delay to dial tone), continued ringing upon answer, and double dialing of digits due to the user's belief that the first attempt was not effective (thus requiring hang-up and redial). More extreme cases can include endpoint re-initialization, call termination, and the spurious activation of SRST functionality at branch offices (leading to interruption of gateway calls).

These effects apply to all deployment models. However, single-site (campus) deployments tend to be less likely to experience the conditions caused by sustained link interruptions because the larger quantity of bandwidth typically deployed in LAN environments (minimum links of 100 Mbps) allows for some residual bandwidth to be available for the IP Communications system.

In any WAN-based deployment model, traffic congestion is more likely to produce sustained and/or more frequent link interruptions because the available bandwidth is much less than in a LAN (typically less than 2 Mbps), so the link is more easily saturated. The effects of link interruptions can impact the user experience, whether or not the voice media traverses the packet network, because signaling traffic between endpoints and the Unified CM servers can also be delayed or dropped.

QoS Design Considerations for Virtual Unified Communications with Cisco UCS B-Series Blade Servers

With a virtualized Unified Communications solution, Cisco Unified Communications products can run as virtual machines on a select set of supported hypervisor, server, and storage products. The most important component in virtual Unified Communications solution is the Cisco Unified Computing System (UCS) Platform along with hypervisor virtualization technology. Virtualized Unified Communications designs have specific considerations with respect to QoS, as discussed below. For more information on the Cisco Unified Computing System (UCS) architecture, hypervisor technology for application virtualization, and Storage Area Networking (SAN) concepts, see [Deploying Unified Communications on Virtualized Servers](#), page 5-58.

In a virtualized environment, Unified Communications applications such as Cisco Unified Communications Manager (Unified CM) run as virtual machines on top of VMware. These Unified Communications virtual machines are connected to a virtual software switch rather than a hardware-based Ethernet switch for Media Convergence Server (MCS) deployments. The following types of virtual software switches are available:

- Local VMware vSwitch

Available with all editions of the VMware ESXi hypervisor and independent of the type of VMware licensing scheme. Virtual software switching is limited to the local physical blade server on which the virtual machine is running.

- Distributed VMware vSwitch

Available only with the Enterprise Plus Edition of the VMware ESXi hypervisor. Distributed virtual software switching can span multiple physical blade servers and helps simplify manageability of the software switch.

- Cisco Nexus 1000V Switch

Cisco has a software switch called the Nexus 1000 Virtual (1000V) Switch. The Cisco Nexus 1000V requires the Enterprise Plus Edition of VMware ESXi. It is a distributed virtual switch visible to multiple VMware hosts and virtual machines. The Cisco Nexus 1000V Series provides policy-based virtual machine connectivity, mobile virtual machine security, enhanced QoS, and network policy.

From the virtual connectivity point of view, each virtual machine can connect to any one of the above virtual switches residing on a blade server. The blade servers physically connect to the rest of the network via a Fabric Extender in the UCS chassis to a UCS Fabric Interconnect Switch (for example, Cisco UCS 6100 Series). The UCS Fabric Interconnect Switch is where the physical wiring connects to a customer's 1 Gb or 10 Gb Ethernet LAN and FC SAN.

From the traffic flow point of view, traffic from the virtual machines first goes to the software virtual switch (for example, VMware vSwitch, VMware Distributed vSwitch, or Cisco Nexus 1000V Switch). The virtual switch then sends the traffic to the physical UCS Fabric Interconnect Switch (UCS 6100 Series) through its blade server's Network Adapter and Fabric Extender. The UCS Fabric Interconnect Switch carries both the IP and fibre channel SAN traffic via Fibre Channel over Ethernet (FCoE) on a single wire. The UCS Fabric Interconnect Switch sends IP traffic to an IP switch (for example, Cisco Catalyst or Nexus Series Switch), and it sends SAN traffic to a Fibre Channel SAN Switch (for example, Cisco MDS Series Switch).

Standard Switching Element QoS Behavior

By default within the UCS 6100 Series Fabric Interconnect Switch, a priority QoS class is automatically created for all fibre channel (FC) traffic destined to the SAN switch. This FC QoS class has no drop policy, and all the FC traffic is marked with Layer 2 CoS value of 3. By default all other traffic (Ethernet and IP), including voice signaling and media traffic, falls into Best Effort QoS class.

The VMware local vSwitch, VMware distributed vSwitch, and UCS 6100 Series switches cannot map L3 DSCP values to L2 CoS values. Traffic can be prioritized or de-prioritized inside the UCS 6100 Switch based on L2 CoS only.

**Note**

Unified Communications applications mark the L3 DSCP values only (for instance, CS3 for voice signaling). However, it is possible to mark all traffic originating from a blade server Network Adapter with a single L2 CoS value.

The Nexus 1000V software switch has the ability to map L3 DSCP values to L2 CoS values, and vice versa, like traditional Cisco physical switches such as the Catalyst Series Switches. Therefore, when Unified Communications traffic leaves a virtual machine and enters the Nexus 1000V switch, its L3 DSCP values can be mapped to corresponding L2 CoS values. This traffic can then be prioritized or de-prioritized based on the L2 CoS value inside the UCS 6100 Switch.

For instance, voice signaling traffic with L3 DSCP value of CS3 is mapped to L2 CoS value of 3 by Nexus 1000V. All Fibre Channel over Ethernet (FCoE) traffic is marked with L2 CoS value of 3 by Cisco UCS. When voice signaling and FCoE traffic enter the Cisco UCS 6100 Fabric Interconnect Switch, both will carry a CoS value of 3. In this situation voice signaling traffic will share queues and scheduling with the Fibre Channel priority class and will be given lossless behavior. (Fibre Channel priority class for CoS 3 in the UCS 6100 Fabric Interconnect Switch does not imply that the class cannot be shared with other types of traffic.)

On the other hand, the L2 CoS value for FCoE traffic can be changed from its default value of 3 to another value, and CoS 3 can be reserved exclusively for the voice signaling traffic. However, Cisco does not suggest or recommend this approach because some Converged Network Adapters (CNAs) cause problems when the FCoE CoS value is not set to a value of 3.

Congestion Scenario

In the physical server design, the hard drives are locally attached to the MCS server, and the SCSI traffic never competes with the Ethernet IP traffic.

Virtual Unified Communications designs with UCS B-Series Systems are different than traditional MCS-based designs. In a virtual Unified Communications design, because the hard drive is remote and accessed via the FC SAN, there is a potential for FC SAN traffic to compete for bandwidth with the Ethernet IP traffic inside the UCS 6100 Series Switch. This could result in voice-related IP traffic (signaling and media) being dropped because FC traffic has a no-drop policy inside the UCS 6100 Switch. This congestion or oversubscription scenario is highly unlikely, however, because the UCS 6100 switch provides a high-capacity switching fabric, and the usable bandwidth per server blade far exceeds the maximum traffic requirements of a typical Unified Communications application.

Design Recommendations

The Nexus 1000V provides enhanced QoS and other features (for example, ACLs, DHCP snooping, IP Source Guard, SPAN, and so forth) that are essential for virtualized data centers and are not available in the other virtual switch implementations. With its capability to map L3 DSCP values to L2 CoS values, the Nexus 1000V switch is recommended for large data center implementations where Cisco Unified Communications Applications are deployed with many other virtual machines running on UCS B-Series system. For other Unified Communications deployments, the decision to use the Nexus 1000V will vary on a case-by-case basis, depending on the available bandwidth for Unified Communications Applications within the UCS architecture. If there is a possibility that a congestion scenario will arise, then the Nexus 1000V switch should be deployed.

An alternative solution that can also be deployed on all virtual switches is to configure all physical Network Adapters on the Unified Communications server blades to set a QoS policy of **Platinum** (CoS=5; No Drop Policy) for all traffic. Any other application running on the same UCS system or chassis should set the QoS policy to **best effort**. The downside to this approach is that all traffic types from virtual Unified Communications applications will have their CoS value set to Platinum, including all non-voice traffic (for example, backups, CDRs, logs, Web traffic, and so forth). Although this solution is not optimal, it does raise the priority of Unified Communications application traffic to that of FC SAN-destined traffic, thus reducing the possibility of traffic drops.

Network Services

The deployment of an IP Communications system requires the coordinated design of a well structured, highly available, and resilient network infrastructure as well as an integrated set of network services including Domain Name System (DNS), Dynamic Host Configuration Protocol (DHCP), Trivial File Transfer Protocol (TFTP), and Network Time Protocol (NTP).

Domain Name System (DNS)

DNS enables the mapping of host names and network services to IP addresses within a network or networks. DNS server(s) deployed within a network provide a database that maps network services to hostnames and, in turn, hostnames to IP addresses. Devices on the network can query the DNS server and receive IP addresses for other devices in the network, thereby facilitating communication between network devices.

Complete reliance on a single network service such as DNS can introduce an element of risk when a critical Unified Communications system is deployed. If the DNS server becomes unavailable and a network device is relying on that server to provide a hostname-to-IP-address mapping, communication can and will fail. For this reason, in networks requiring high availability, Cisco recommends that you do not rely on DNS name resolution for any communications between Unified CM and the Unified Communications endpoints.

For standard deployments, Cisco recommends that you configure Unified CM(s), gateways, and endpoint devices to use IP addresses rather than hostnames. For endpoint devices, Cisco does not recommend configuration of DNS parameters such as DNS server addresses, hostnames, and domain names. During the initial installation of the publisher node in a Unified CM cluster, the publisher will be referenced in the server table by the hostname you provided for the system. Before installation and configuration of any subsequent subscribers or the definition of any endpoints, you should change this server entry to the IP address of the publisher rather than the hostname. Each subscriber added to the cluster should be defined in this same server table via IP address and not by hostname. Each subscriber should be added to this server table one device at a time, and there should be no definitions for non-existent subscribers at any time other than for the new subscriber being installed.

During installation of the publisher and subscriber, Cisco recommend that you do not select the option to enable DNS unless DNS is specifically required for system management purposes. If DNS is enabled, Cisco still highly recommend that you do not use DNS names in the configuration of the IP Communications endpoints, gateways, and Unified CM servers. Even if DNS is enabled on the servers in the cluster, it is never used for any intra-cluster server-to-server communications and is used only for communications to devices external to the cluster itself.

Cisco Unified CM 5.0 and later releases do not permit the manual configuration of HOSTS or LHOSTS files. A local version of the HOSTS table is automatically built by the publisher in each cluster and distributed to all subscriber nodes via a secure communications channel. This local table is used for managing secure intra-cluster communications and does not contain addresses or names of any endpoints other than the Unified CM servers themselves. LMHOSTS files do not exist and are not used by Cisco Unified CM 5.0 and later releases.

Deploying Unified CM with DNS

There are some situations in which configuring and using DNS might be unavoidable. For example, if Network Address Translation (NAT) is required for communications between the IP phones and Unified CM in the IP Communications network, DNS is required to ensure proper mapping of NAT

translated addresses to network host devices. Likewise, some IP telephony disaster recovery network configurations rely on DNS to ensure proper failover of the network during failure scenarios by mapping hostnames to secondary backup site IP addresses.

If either of these two situations exists and DNS must be configured, you must deploy DNS servers in a geographically redundant fashion so that a single DNS server failure will not prevent network communications between IP telephony devices. By providing DNS server redundancy in the event of a single DNS server failure, you ensure that devices relying on DNS to communicate on the network can still receive hostname-to-IP-address mappings from a backup or secondary DNS server.

**Note**

Hostname resolution within the cluster via either the local HOSTS file or DNS queries is performed only at subsystem initialization (that is, when a server is booted up). As a result, in order for a server within the cluster to resolve a DNS name that has been changed in either the HOSTS file or the DNS server, the Cisco CallManager Service must be restarted on all servers within the cluster.

Unified CM can use DNS to:

- Provide simplified system management
- Resolve fully qualified domain names to IP addresses for trunk destinations
- Resolve fully qualified domain names to IP addresses for SIP route patterns based on domain name
- Resolve service (SRV) records to host names and then to IP addresses for SIP trunk destinations

When DNS is used, Cisco recommends defining each Unified CM cluster as a member of a valid sub-domain within the larger organizational DNS domain, defining the DNS domain on each Cisco MCS server, and defining the primary and secondary DNS server addresses on each MCS server.

Table 3-4 shows an example of how DNS server could use A records (Hostname-to-IP-address resolution), Cname records (aliases), and SRV records (service records for redundancy and load balancing) in a Unified CM environment.

Table 3-4 Example Use of DNS with Unified CM

| Host Name | Type | TTL | Data |
|---------------------------------|---------------|----------|-------------------------------|
| CUCM-Admin.cluster1.cisco.com | Host (A) | 12 Hours | 182.10.10.1 |
| CUCM1.cluster1.cisco.com | Host (A) | Default | 182.10.10.1 |
| CUCM2.cluster1.cisco.com | Host (A) | Default | 182.10.10.2 |
| CUCM3.cluster1.cisco.com | Host (A) | Default | 182.10.10.3 |
| CUCM4.cluster1.cisco.com | Host (A) | Default | 182.10.10.4 |
| TFTP-server1.cluster1.cisco.com | Host (A) | 12 Hours | 182.10.10.11 |
| TFTP-server2.cluster1.cisco.com | Host (A) | 12 Hours | 182.10.10.12 |
| www.CUCM-Admin.cisco.com | Alias (CNAME) | Default | CUCM-Admin.cluster1.cisco.com |
| _sip._tcp.cluster1.cisco.com. | Service (SRV) | Default | CUCM1.cluster1.cisco.com |
| _sip._tcp.cluster1.cisco.com. | Service (SRV) | Default | CUCM2.cluster1.cisco.com |
| _sip._tcp.cluster1.cisco.com. | Service (SRV) | Default | CUCM3.cluster1.cisco.com |
| _sip._tcp.cluster1.cisco.com. | Service (SRV) | Default | CUCM4.cluster1.cisco.com |

Dynamic Host Configuration Protocol (DHCP)

DHCP is used by hosts on the network to obtain initial configuration information, including IP address, subnet mask, default gateway, and TFTP server address. DHCP eases the administrative burden of manually configuring each host with an IP address and other configuration information. DHCP also provides automatic reconfiguration of network configuration when devices are moved between subnets. The configuration information is provided by a DHCP server located in the network, which responds to DHCP requests from DHCP-capable clients.

You should configure IP Communications endpoints to use DHCP to simplify deployment of these devices. Any RFC 2131 compliant DHCP server can be used to provide configuration information to IP Communications network devices. When deploying IP telephony devices in an existing data-only network, all you have to do is add DHCP voice scopes to an existing DHCP server for these new voice devices. Because IP telephony devices are configured to use and rely on a DHCP server for IP configuration information, you must deploy DHCP servers in a redundant fashion. At least two DHCP servers should be deployed within the telephony network such that, if one of the servers fails, the other can continue to answer DHCP client requests. You should also ensure that DHCP server(s) are configured with enough IP subnet addresses to handle all DHCP-reliant clients within the network.

DHCP Option 150

IP telephony endpoints can be configured to rely on DHCP Option 150 to identify the source of telephony configuration information, available from a server running the Trivial File Transfer Protocol (TFTP).

In the simplest configuration, where a single TFTP server is offering service to all deployed endpoints, Option 150 is delivered as a single IP address pointing to the system's designated TFTP server. The DHCP scope can also deliver two IP addresses under Option 150, for deployments where there are two TFTP servers within the same cluster. The phone would use the second address if it fails to contact the primary TFTP server, thus providing redundancy. To achieve both redundancy and load sharing between the TFTP servers, you can configure Option 150 to provide the two TFTP server addresses in reverse order for half of the DHCP scopes.

**Note**

If the primary TFTP server is available but is not able to grant the requested file to the phone (for example, because the requesting phone is not configured on that cluster), the phone will not attempt to contact the secondary TFTP server.

Cisco highly recommends using a direct IP address (that is, not relying on a DNS service) for Option 150 because doing so eliminates dependencies on DNS service availability during the phone boot-up and registration process.

**Note**

Even though IP phones support a maximum of two TFTP servers under Option 150, you could configure a Unified CM cluster with more than two TFTP servers. For instance, if a Unified CM system is clustered over a WAN at three separate sites, three TFTP servers could be deployed (one at each site). Phones within each site could then be granted a DHCP scope containing that site's TFTP server within Option 150. This configuration would bring the TFTP service closer to the endpoints, thus reducing latency and ensuring failure isolation between the sites (one site's failure would not affect TFTP service at another site).

Phone DHCP Operation Following a Power Recycle

If a phone is powered down and comes back up while the DHCP server is still offline, it will attempt to use DHCP to obtain IP addressing information (as normal). In the absence of a response from a DHCP server, the phone will re-use the previously received DHCP information to register with Unified CM.

DHCP Lease Times

Configure DHCP lease times as appropriate for the network environment. Given a fairly static network in which PCs and telephony devices remain in the same place for long periods of time, Cisco recommends longer DHCP lease times (for example, one week). Shorter lease times require more frequent renewal of the DHCP configuration and increase the amount of DHCP traffic on the network. Conversely, networks that incorporate large numbers of mobile devices, such as laptops and wireless telephony devices, should be configured with shorter DHCP lease times (for example, one day) to prevent depletion of DHCP-managed subnet addresses. Mobile devices typically use IP addresses for short increments of time and then might not request a DHCP renewal or new address for a long period of time. Longer lease times will tie up these IP addresses and prevent them from being reassigned even when they are no longer being used.

Cisco Unified IP Phones adhere to the conditions of the DHCP lease duration as specified in the DHCP server's scope configuration. Once half the lease time has expired since the last successful DHCP server acknowledgment, the IP phone will request a lease renewal. This DHCP client Request, once acknowledged by the DHCP server, will allow the IP phone to retain use of the IP scope (that is, the IP address, default gateway, subnet mask, DNS server (optional), and TFTP server (optional)) for another lease period. If the DHCP server becomes unavailable, an IP phone will not be able to renew its DHCP lease, and as soon as the lease expires, it will relinquish its IP configuration and will thus become unregistered from Unified CM until a DHCP server can grant it another valid scope.

In centralized call processing deployments, if a remote site is configured to use a centralized DHCP server (through the use of a DHCP relay agent such as the IP Helper Address in Cisco IOS) and if connectivity to the central site is severed, IP phones within the branch will not be able to renew their DHCP scope leases. In this situation, branch IP phones are at risk of seeing their DHCP lease expire, thus losing the use of their IP address, which would lead to service interruption. Given the fact that phones attempt to renew their leases at half the lease time, DHCP lease expiration can occur as soon as half the lease time since the DHCP server became unreachable. For example, if the lease time of a DHCP scope is set to 4 days and a WAN failure causes the DHCP server to be unavailable to the phones in a branch, those phones will be unable to renew their leases at half the lease time (in this case, 2 days). The IP phones could stop functioning as early as 2 days after the WAN failure, unless the WAN comes back up and the DHCP server is available before that time. If the WAN connectivity failure persists, all phones see their DHCP scope expire after a maximum of 4 days from the WAN failure.

This situation can be mitigated by one of the following methods:

- Set the DHCP scope lease to a long duration (for example, 8 days or more).
This method would give the system administrator a minimum of half the lease time to remedy any DHCP reachability problem. Long lease durations also have the effect of reducing the frequency of network traffic associated with lease renewals.
- Configure co-located DHCP server functionality (for example, run a DHCP server function on the branch's Cisco IOS router).

This approach is immune to WAN connectivity interruption. One effect of such an approach is to decentralize the management of IP addresses, requiring incremental configuration efforts in each branch. (See [DHCP Network Deployments](#), page 3-27, for more information.)

Note The term *co-located* refers to two or more devices in the same physical location, with no WAN or MAN connection between them.

DHCP Network Deployments

There are two options for deploying DHCP functionality within an IP telephony network:

- Centralized DHCP Server

Typically, for a single-site campus IP telephony deployment, the DHCP server should be installed at a central location within the campus. As mentioned previously, redundant DHCP servers should be deployed. If the IP telephony deployment also incorporates remote branch telephony sites, as in a centralized multisite Unified CM deployment, a centralized server can be used to provide DHCP service to devices in the remote sites. This type of deployment requires that you configure the **ip helper-address** on the branch router interface. Keep in mind that, if redundant DHCP servers are deployed at the central site, both servers' IP addresses must be configured as **ip helper-address**. Also note that, if branch-side telephony devices rely on a centralized DHCP server and the WAN link between the two sites fails, devices at the branch site will be unable to send DHCP requests or receive DHCP responses.

Note By default, **service dhcp** is enabled on the Cisco IOS device and does not appear in the configuration. Do not disable this service on the branch router because doing so will disable the DHCP relay agent on the device, and the **ip helper-address** configuration command will not work.

- Centralized DHCP Server and Remote Site Cisco IOS DHCP Server

When configuring DHCP for use in a centralized multisite Unified CM deployment, you can use a centralized DHCP server to provide DHCP service to centrally located devices. Remote devices could receive DHCP service from a locally installed server or from the Cisco IOS router at the remote site. This type of deployment ensures that DHCP services are available to remote telephony devices even during WAN failures. [Example 3-1](#) lists the basic Cisco IOS DHCP server configuration commands.

Example 3-1 Cisco IOS DHCP Server Configuration Commands

```
! Activate DHCP Service on the IOS Device

service dhcp

! Specify any IP Address or IP Address Range to be excluded from the DHCP pool

ip dhcp excluded-address <ip-address>|<ip-address-low> <ip-address-high>

! Specify the name of this specific DHCP pool, the subnet and mask for this
! pool, the default gateway and up to four TFTP

ip dhcp pool <dhcp-pool name>
  network <ip-subnet> <mask>
  default-router <default-gateway-ip>
  option 150 ip <tftp-server-ip-1> ...

! Note: IP phones use only the first two addresses supplied in the option 150
! field even if more than two are configured.
```

Unified CM DHCP Sever (Standalone versus Co-Resident DHCP)

Typically DHCP servers are dedicated machine(s) in most network infrastructures, and they run in conjunction with the DNS and/or the Windows Internet Naming Service (WINS) services used by that network. In some instances, given a small Unified CM deployment with no more than 1000 devices registering to the cluster, you may run the DHCP server on a Unified CM server to support those devices. However, to avoid possible resource contention such as CPU contention with other critical services running on Unified CM, Cisco recommends moving the DHCP Server functionality to a dedicated server. If more than 1000 devices are registered to the cluster, DHCP must *not* be run on a Unified CM server but instead must be run on a dedicated or standalone server(s).

**Note**

The term *co-resident* refers to two or more services or applications running on the same server.

Trivial File Transfer Protocol (TFTP)

Within a Cisco Unified CM system, endpoints such as IP phones rely on a TFTP-based process to acquire configuration files, software images, and other endpoint-specific information. The Cisco TFTP service is a file serving system that can run on one or more Unified CM servers. It builds configuration files and serves firmware files, ringer files, device configuration files, and so forth, to endpoints.

The TFTP file systems can hold several file types, such as the following:

- Phone configuration files
- Phone firmware files
- Certificate Trust List (CTL) files
- Identity Trust List (ITL) files
- Tone localization files
- User interface (UI) localization and dictionary files
- Ringer files
- Softkey files
- Dial plan files for SIP phones

The TFTP server manages and serves two types of files, those that are not modifiable (for example, firmware files for phones) and those that can be modified (for example, configuration files).

A typical configuration file contains a prioritized list of Unified CMs for a device (for example, an SCCP or SIP phone), the TCP ports on which the device connects to those Unified CMs, and an executable load identifier. Configuration files for selected devices contain locale information and URLs for the messages, directories, services, and information buttons on the phone...

When a device's configuration changes, the TFTP server rebuilds the configuration files by pulling the relevant information from the Unified CM database. The new file(s) is then downloaded to the phone once the phone has been reset. As an example, if a single phone's configuration file is modified (for example, during Extension Mobility login or logout), only that file is rebuilt and downloaded to the phone. However, if the configuration details of a device pool are changed (for example, if the primary Unified CM server is changed), then all devices in that device pool need to have their configuration files rebuilt and downloaded. For device pools that contain large numbers of devices, this file rebuilding process can impact server performance.

**Note**

Prior to Cisco Unified CM 6.1, to rebuild modified files, the TFTP server pulled information from the publisher's database. With Unified CM 6.1 and later releases, the TFTP server can perform a local database read from the database on its co-resident subscriber server. Local database read not only provides benefits such as the preservation of user-facing features when the publisher is unavailable, but also allows multiple TFTP servers to be distributed by means of clustering over the WAN. (The same latency rules for clustering over the WAN apply to TFTP servers as to servers with registered phones.) This configuration brings the TFTP service closer to the endpoints, thus reducing latency and ensuring failure isolation between the sites.

When a device requests a configuration file from the TFTP server, the TFTP server searches for the configuration file in its internal caches, the disk, and then alternate Cisco file servers (if specified). If the TFTP server finds the configuration file, it sends it to the device. If the configuration file provides Unified CM names, the device resolves the name by using DNS and opens a connection to the Unified CM. If the device does not receive an IP address or name, it uses the TFTP server name or IP address to attempt a registration connection. If the TFTP server cannot find the configuration file, it sends a "file not found" message to the device.

A device that requests a configuration file while the TFTP server is rebuilding configuration files or while it is processing the maximum number of requests, will receive a message from the TFTP server that causes the device to request the configuration file later. The Maximum Serving Count service parameter, which can be configured, specifies the maximum number of requests that can be concurrently handled by the TFTP server. (Default value = 500 requests.) Use the default value if the TFTP service is run along with other Cisco CallManager services on the same server. For a dedicated TFTP server, use the following suggested values for the Maximum Serving Count: 1500 for a single-processor system or 3000 for a dual-processor system.

The Cisco Unified IP Phones 8900 Series and 9900 Series request their TFTP configuration files over the HTTP protocol (port 6970), which is much faster than TFTP.

An Example of TFTP in Operation

Every time an endpoint reboots, the endpoint will request a configuration file (via TFTP) whose name is based on the requesting endpoint's MAC address. (For a Cisco Unified IP Phone 7961 with MAC address ABCDEF123456, the file name would be SEPABCDEF123456.cnf.xml.) The received configuration file includes the version of software that the phone must run and a list of Cisco Unified CM servers with which the phone should register. The endpoint might also download, via TFTP, ringer files, softkey templates, and other miscellaneous files to acquire the necessary configuration information before becoming operational.

If the configuration file includes software file(s) version numbers that are different than those the phone is currently using, the phone will also download the new software file(s) from the TFTP server to upgrade itself. The number of files an endpoint must download to upgrade its software varies based on the type of endpoint and the differences between the phone's current software and the new software. For example, Cisco Unified IP Phones 7961, 7970, and 7971 download five software files under the worst-case software upgrade.

TFTP File Transfer Times

Each time an endpoint requests a file, there is a new TFTP transfer session. For centralized call processing deployments, the time to complete each of these transfers will affect the time it takes for an endpoint to start and become operational as well as the time it takes for an endpoint to upgrade during a scheduled maintenance. While TFTP transfer times are not the only factor that can affect these end states, they are a significant component.

The time to complete each file transfer via TFTP is predictable as a function of the file size, the percentage of TFTP packets that must be retransmitted, and the network latency or round-trip time.

At first glance, network bandwidth might seem to be missing from the previous statement, but it is actually included via the percentage of TFTP packets that must be retransmitted. This is because, if there is not enough network bandwidth to support the file transfer(s), then packets will be dropped by the network interface queuing algorithms and will have to be retransmitted.

TFTP operates on top of the User Datagram Protocol (UDP). Unlike Transmission Control Protocol (TCP), UDP is not a reliable protocol, which means that UDP does not inherently have the ability to detect packet loss. Obviously, detecting packet loss in a file transfer is important, so RFC 1350 defines TFTP as a lock-step protocol. In other words, a TFTP sender will send one packet and wait for a response before sending the next packet (see [Figure 3-8](#)).

Figure 3-8 Example of TFTP Packet Transmission Sequence

Round Trip Time = 10ms

If a response is not received in the timeout period (4 seconds by default), the sender will resend the data packet or acknowledgement. When a packet has been sent five times without a response, the TFTP session fails. Because the timeout period is always the same and not adaptive like a TCP timeout, packet loss can significantly increase the amount of time a transfer session takes to complete.

Because the delay between each data packet is, at a minimum, equal to the network round-trip time, network latency also is a factor in the maximum throughput that a TFTP session can achieve.

In [Figure 3-9](#), the round-trip time has been increased to 40 ms and one packet has been lost in transit. While the error rate is high at 12%, it is easy to see the effect of latency and packet loss on TFTP because the time to complete the session increased from 30 ms (in [Figure 3-8](#)) to 4160 ms (in [Figure 3-9](#)).

Figure 3-9 Effect of Packet Loss on TFTP Session Completion Time

Use the following formula to calculate how long a TFTP file transfer will take to complete:

$$\text{FileTransferTime} = \text{FileSize} * [(\text{RTT} + \text{ERR} * \text{Timeout}) / 512000]$$

Where:

FileTransferTime is in seconds.

FileSize is in bytes.

RTT is the round-trip time in milliseconds.

ERR is the error rate, or percentage of packets that are lost.

Timeout is in milliseconds.

$$512000 = (\text{TFTP packet size}) * (1000 \text{ millisecond per seconds}) = (512 \text{ bytes}) * (1000 \text{ millisecond per seconds})$$

Table 3-5 and Table 3-6 illustrate the use of this equation to calculate transfer times for the software files for various endpoint device types, protocols, and network latencies.

Table 3-5 TFTP File Transfer Times for SCCP Devices

| Device Type (Cisco Unified IP Phone) | Firmware Size (bytes, rounded up to next 100k) | Time to Complete Transfer (1% error rate) | | | | |
|--------------------------------------|--|---|---------------|---------------|---------------|----------------|
| | | 40 ms RTT | 80 ms RTT | 120 ms RTT | 160 ms RTT | 200 ms RTT |
| 7985 | 15,000,000 | 39 min 3 sec | 58 min 35 sec | 78 min 7 sec | 97 min 39 sec | 117 min 11 sec |
| 7921 | 9,700,000 | 25 min 15 sec | 37 min 53 sec | 50 min 31 sec | 63 min 9 sec | 75 min 46 sec |
| 7975 | 6,300,000 | 16 min 24 sec | 24 min 36 sec | 32 min 48 sec | 41 min 0 sec | 49 min 13 sec |
| 7970 or 7971 | 6,300,000 | 16 min 24 sec | 24 min 36 sec | 32 min 48 sec | 41 min 0 sec | 49 min 13 sec |
| 7965 or 7945 | 6,300,000 | 16 min 24 sec | 24 min 36 sec | 32 min 48 sec | 41 min 0 sec | 49 min 13 sec |
| 7962 or 7942 | 6,200,000 | 16 min 8 sec | 24 min 13 sec | 32 min 17 sec | 40 min 21 sec | 48 min 26 sec |
| 7941 or 7961 | 6,100,000 | 15 min 53 sec | 23 min 49 sec | 31 min 46 sec | 39 min 42 sec | 47 min 39 sec |
| 7931 | 6,100,000 | 15 min 53 sec | 23 min 49 sec | 31 min 46 sec | 39 min 42 sec | 47 min 39 sec |
| 7911 or 7906 | 6,100,000 | 15 min 53 sec | 23 min 49 sec | 31 min 46 sec | 39 min 42 sec | 47 min 39 sec |
| 7935 | 2,100,000 | 5 min 28 sec | 8 min 12 sec | 10 min 56 sec | 13 min 40 sec | 16 min 24 sec |

Table 3-5 TFTP File Transfer Times for SCCP Devices (continued)

| Device Type (Cisco Unified IP Phone) | Firmware Size (bytes, rounded up to next 100k) | Time to Complete Transfer (1% error rate) | | | | |
|--------------------------------------|--|---|--------------|--------------|---------------|--------------|
| | | 40 ms RTT | 80 ms RTT | 120 ms RTT | 160 ms RTT | 200 ms RTT |
| 7920 | 1,200,000 | 3 min 7 sec | 4 min 41 sec | 6 min 15 sec | 7 min 48 sec | 9 min 22 sec |
| 7936 | 1,800,000 | 4 min 41 sec | 7 min 1 sec | 9 min 22 sec | 11 min 43 sec | 14 min 3 sec |
| 7940 or 7960 | 900,000 | 2 min 20 sec | 3 min 30 sec | 4 min 41 sec | 5 min 51 sec | 7 min 1 sec |
| 7910 | 400,000 | 1 min 2 sec | 1 min 33 sec | 2 min 5 sec | 2 min 36 sec | 3 min 7 sec |
| 7912 | 400,000 | 1 min 2 sec | 1 min 33 sec | 2 min 5 sec | 2 min 36 sec | 3 min 7 sec |
| 7905 | 400,000 | 1 min 2 sec | 1 min 33 sec | 2 min 5 sec | 2 min 36 sec | 3 min 7 sec |
| 7902 | 400,000 | 1 min 2 sec | 1 min 33 sec | 2 min 5 sec | 2 min 36 sec | 3 min 7 sec |

Table 3-6 TFTP File Transfer Times for SIP Devices

| Device Type (Cisco Unified IP Phone) | Firmware Size (bytes, rounded up to next 100k) | Time to Complete Transfer (1% error rate) | | | | |
|--------------------------------------|--|---|---------------|---------------|---------------|---------------|
| | | 40 ms RTT | 80 ms RTT | 120 ms RTT | 160 ms RTT | 200 ms RTT |
| 7975 | 6,600,000 | 17 min 11 sec | 25 min 46 sec | 34 min 22 sec | 42 min 58 sec | 51 min 33 sec |
| 7970 or 7971 | 6,700,000 | 17 min 26 sec | 26 min 10 sec | 34 min 53 sec | 43 min 37 sec | 52 min 20 sec |
| 7965 or 7945 | 6,600,000 | 17 min 11 sec | 25 min 46 sec | 34 min 22 sec | 42 min 58 sec | 51 min 33 sec |
| 7962 or 7942 | 6,500,000 | 16 min 55 sec | 25 min 23 sec | 33 min 51 sec | 42 min 19 sec | 50 min 46 sec |
| 7941 or 7961 | 6,500,000 | 16 min 55 sec | 25 min 23 sec | 33 min 51 sec | 42 min 19 sec | 50 min 46 sec |
| 7911 or 7906 | 6,400,000 | 16 min 40 sec | 25 min 0 sec | 33 min 20 sec | 41 min 40 sec | 50 min 0 sec |
| 7940 or 7960 | 900,000 | 2 min 20 sec | 3 min 30 sec | 4 min 41 sec | 5 min 51 sec | 7 min 1 sec |
| 7912 | 400,000 | 1 min 2 sec | 1 min 33 sec | 2 min 5 sec | 2 min 36 sec | 3 min 7 sec |
| 7905 | 400,000 | 1 min 2 sec | 1 min 33 sec | 2 min 5 sec | 2 min 36 sec | 3 min 7 sec |

The values in [Table 3-5](#) and [Table 3-6](#) are the approximate times to download the necessary firmware files to the phone. This is *not* an estimate of the time that it will take for a phone to upgrade to the new firmware and become operational.

Cisco Unified IP Phone Firmware Releases 7.x have a 10-minute timeout when downloading new files. If the transfer is not completed within this time, the phone will discard the download even if the transfer completes successfully later. If you experience this problem, Cisco recommends that you use a local TFTP server to upgrade phones to the 8.x firmware releases, which have a timeout value of 61 minutes.

Because network latency and packet loss have such an effect on TFTP transfer times, a local TFTP Server can be advantageous. This local TFTP server may be a Unified CM subscriber in a deployment with cluster over the WAN or an alternative local TFTP "Load Server" running on a Cisco Integrated Services Router (ISR), for example. Newer endpoints (which have larger firmware files) can be configured with a Load Server address, which allows the endpoint to download the relatively small configuration files from the central TFTP server but use a local TFTP Server (which is not part of the Unified CM cluster) to download the larger software files. For details on which Cisco IP Phones support an alternative local TFTP Load Server, see [Endpoint Features Summary, page 18-55](#).

**Note**

The exact process each phone goes through on startup and the size of the files downloaded will depend on the phone model, the signaling type configured for the phone (SCCP, MGCP, or SIP) and the previous state of the phone. While there are differences in which files are requested, the general process each phone follows is the same, and in all cases TFTP is used to request and deliver the appropriate files. The general recommendations for TFTP server deployment do not change based on the protocol and/or phone models deployed.

TFTP Server Redundancy

Option 150 allows up to two IP addresses to be returned to phones as part of the DHCP scope. The phone tries the first address in the list, and it tries the subsequent address only if it cannot establish communications with the first TFTP server. This address list provides a redundancy mechanism that enables phones to obtain TFTP services from another server even if their primary TFTP server has failed.

TFTP Load Sharing

Cisco recommends that you grant different ordered lists of TFTP servers to different subnets to allow for load balancing. For example:

- In subnet 10.1.1.0/24: Option 150: TFTP1_Primary, TFTP1_Secondary
- In subnet 10.1.2.0/24: Option 150: TFTP1_Secondary, TFTP1_Primary

Under normal operations, a phone in subnet 10.1.1.0/24 will request TFTP services from TFTP1_Primary, while a phone in subnet 10.1.2.0/24 will request TFTP services from TFTP1_Secondary. If TFTP1_Primary fails, then phones from both subnets will request TFTP services from TFTP1_Secondary.

Load balancing avoids having a single TFTP server hot-spot, where all phones from multiple clusters rely on the same server for service. TFTP load balancing is especially important when phone software loads are transferred, such as during a Unified CM upgrade, because more files of larger size are being transferred, thus imposing a bigger load on the TFTP server.

Centralized TFTP Services

In multi-cluster systems, it is possible to have a single subnet or VLAN containing phones from multiple clusters. In this situation, the TFTP servers whose addresses are provided to all phones in the subnet or VLAN must answer the file transfer requests made by each phone, regardless of which cluster contains the phone. In a centralized TFTP deployment, a set of TFTP servers associated with one of the clusters must provide TFTP services to all the phones in the multi-cluster system.

In order to provide this single point of file access, each cluster's TFTP server must be able to serve files via the central proxy TFTP server. With Cisco Unified CM 5.0 and later releases, this proxy arrangement is accomplished by configuring a set of possible redirect locations in the central TFTP server, pointing to each of the other clusters' TFTP servers. This configuration uses a HOST redirect statement in the Alternate File Locations on the centralized TFTP server, one for each of the other clusters. Each of the redundant TFTP servers in the centralized cluster should point to one of the redundant servers in each of the child clusters. It is not necessary to point the centralized server to both redundant servers in the child clusters because the redistribution of files within each individual cluster and the failover mechanisms of the phones between the redundant servers in the central cluster provide for a very high degree of fault tolerance.

[Figure 3-10](#) shows an example of the operation of this process. A request from a phone registered to Cluster 3 is directed to the centralized TFTP server configured in Cluster 1 (C1_TFTP_Primary). This server will in turn query each of the configured alternate TFTP servers until one responds with a copy

of the file initially requested by the phone. Requests to the centralized secondary TFTP server (C1_TFTP_Secondary) will be sent by proxy to the other clusters' secondary TFTP servers until either the requested file is found or all servers report that the requested file does not exist.

Figure 3-10 Centralized TFTP Servers

Centralized TFTP in a Mixed Environment, with Servers Running Different Releases of Cisco Unified CM

During migration from an older Unified CM release to Unified CM 5.0 and later releases, it is likely that a large centralized TFTP environment will have to operate in a mixed mode. Prior to Unified CM 5.0, the centralized TFTP servers did not request files from the child servers but rather had the TFTP directories of each of those clusters remotely mounted to the central server, which in turn was able to search all of the local and remote directories for the requested file. During a period of migration, it is necessary to provide a centralized TFTP server that can operate in both modes (mixed mode): *remote mount* for releases prior to Unified CM 5.0 and *proxy request* for Unified CM 5.0 and later releases. Because the servers for Unified CM 5.0 and later releases do not support remotely mounted file systems in a mixed environment, it is necessary to position Cisco Unified CM 4.1(3)SR3a or a later Windows OS-based release of Unified CM as the centralized mixed-mode TFTP cluster.

Note

Cisco Unified CM Release 4.1(3)SR3a (and subsequent Unified CM releases for the Windows OS platform) contain an upgrade to the cTFTP server daemon that allows it to support mixed-mode centralized TFTP designs. With these releases, the centralized TFTP server supports both remote mount and proxy request as methods for reaching Alternate TFTP Files servers in other clusters.

When configuring the mixed-mode TFTP server, it is necessary to specify the servers for Unified CM 5.0 and later releases via the HOST proxy request and to specify any servers prior to Unified CM 4.1(3)SR3a by using the remote mount configuration process, as shown in [Example 3-2](#). (See below for details on the remote mount configuration.) Any child cluster supporting mixed mode can be configured as either a remote mount or as a proxy cluster.

For centralized TFTP configurations, ensure that the main TFTP server exists in the cluster that runs the highest version of Cisco Unified Communications Manager. For example, if you are using a centralized TFTP server between a compatible Cisco Unified CM 4.x (mixed mode) cluster and a Unified CM 7.0 cluster, ensure that the central TFTP server exists in the Cisco Unified CM 7.0 cluster.

If the centralized TFTP server exists in the cluster that runs the lower version of Cisco Unified Communications Manager, all phones use the locale files from this centralized TFTP server. These older locale files can create display issues for phones registered to clusters running a higher version of Cisco Unified CM because the newer localized phrases are not included in the locale files that are served from the main cluster's TFTP server.

Example 3-2 Mixed-Mode TFTP Configuration

On the Unified CM TFTP server, configure **Service Parameters > TFTP Server > Cisco TFTP (Active) Parameters** as follows:

- Parameter Name = Parameter Value
- Alternate Cisco File Server = HOST://10.10.10.1
- Alternate Cisco File Server = C:\Program Files\Cisco\TFTPpath\TFTP2

For more information on remote mount alternate Cisco File server configuration, see the *Cisco Unified Communications SRND Based on Cisco Unified CallManager 4.x*, available at

<http://www.cisco.com/go/ucsrnd>

Network Time Protocol (NTP)

NTP allows network devices to synchronize their clocks to a network time server or network-capable clock. NTP is critical for ensuring that all devices in a network have the same time. When troubleshooting or managing a telephony network, it is crucial to synchronize the time stamps within all error and security logs, traces, and system reports on devices throughout the network. This synchronization enables administrators to recreate network activities and behaviors based on a common timeline. Billing records and call detail records (CDRs) also require accurate synchronized time.

Unified CM NTP Time Synchronization

Time synchronization is especially critical on Unified CM servers. In addition to ensuring that CDR records are accurate and that log files are synchronized, having an accurate time source is necessary for any future IPsec features to be enabled within the cluster and for communications with any external entity.

Unified CM automatically synchronizes the NTP time of all subscribers in the cluster to the publisher. During installation, each subscriber is automatically configured to point to an NTP server running on the publisher. The publisher considers itself to be a master server and provides time for the cluster based on its internal hardware clock unless it is configured to synchronize from an external server. Cisco highly recommends configuring the publisher to point to a Stratum-1, Stratum-2, or Stratum-3 NTP server to ensure that the cluster time is synchronized with an external time source.

Cisco recommends synchronizing Unified CM with a Cisco IOS or Linux-based NTP server. Using Windows Time Services as an NTP server is not recommended or supported because Windows Time Services often use Simple Network Time Protocol (SNTP), and Linux-based Unified CM cannot successfully synchronize with SNTP.

The external NTP server specified for the primary node should be NTP v4 (version 4) to avoid potential compatibility, accuracy, and network jitter problems. External NTP servers *must* be NTP v4 if IPv6 addressing is used.

**Note**

Manual configuration of the NTP.conf file is no longer possible, and any changes made to the file will be replaced automatically by the system configuration.

For additional information about NTP time synchronization in a Cisco Unified Communications environment, refer to the *Cisco IP Telephony Clock Synchronization: Best Practices* white paper, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/products_white_paper0900aecd8037fdb5.shtml

Cisco IOS and CatOS NTP Time Synchronization

Time synchronization is also important for other devices within the network. Cisco IOS routers and Catalyst switches should be configured to synchronize their time with the rest of the network devices via NTP. This is critical for ensuring that debug, syslog, and console log messages are time-stamped appropriately. Troubleshooting telephony network issues is simplified when a clear timeline can be drawn for events that occur on devices throughout the network.

[Example 3-3](#) illustrates the configuration of NTP time synchronization on Cisco IOS and CatOS devices.

Example 3-3 Cisco IOS and CatOS NTP Configuration

Cisco IOS configuration:

```
ntp server 64.100.21.254
```

CatOS configuration:

```
set ntp server 64.100.21.254
set ntp client enable
```

To ensure proper NTP time synchronization on routers and switches, it might be necessary to configure time zones using the **clock timezone** command (in Cisco IOS) and/or the **set timezone** command (in CatOS).

WAN Infrastructure

Proper WAN infrastructure design is also extremely important for normal Unified Communications operation on a converged network. Proper infrastructure design requires following basic configuration and design best practices for deploying a WAN that is as highly available as possible and that provides guaranteed throughput. Furthermore, proper WAN infrastructure design requires deploying end-to-end QoS on all WAN links. The following sections discuss these requirements:

- [WAN Design and Configuration, page 3-37](#)

- [WAN Quality of Service \(QoS\)](#), page 3-40
- [Resource Reservation Protocol \(RSVP\)](#), page 11-17
- [Bandwidth Provisioning](#), page 3-47

WAN Design and Configuration

Properly designing a WAN requires building fault-tolerant network links and planning for the possibility that these links might become unavailable. By carefully choosing WAN topologies, provisioning the required bandwidth, and approaching the WAN infrastructure as another layer in the network topology, you can build a fault-tolerant and redundant network. The following sections examine the required infrastructure layers and network services:

- [Deployment Considerations](#), page 3-37
- [Guaranteed Bandwidth](#), page 3-38
- [Best-Effort Bandwidth](#), page 3-39

Deployment Considerations

WAN deployments for voice networks may use a hub-and-spoke, fully meshed, or partially meshed topology. A hub-and-spoke topology consists of a central hub site and multiple remote spoke sites connected into the central hub site. In this scenario, each remote or spoke site is one WAN-link hop away from the central or hub site and two WAN-link hops away from all other spoke sites. A meshed topology may contain multiple WAN links and any number of hops between the sites. In this scenario there may be many different paths to the same site or there may be different links used for communication with some sites compared to other sites. The simplest example is three sites, each with a WAN link to the other two sites, forming a triangle. In that case there are two potential paths between each site to each other site.

Topology-unaware call admission control requires the WAN to be hub-and-spoke, or a spoke-less hub in the case of MPLS VPN. This topology ensures that call admission control, provided by Unified CM's locations or a gatekeeper, works properly in keeping track of the bandwidth available between any two sites in the WAN. In addition, multiple hub-and-spoke deployments can be interconnected via WAN links.

Topology-aware call admission control may be used with either hub-and-spoke or an arbitrary WAN topology. This form of call admission control requires parts of the WAN infrastructure to support Resource Reservation Protocol (RSVP). For details, see [Resource Reservation Protocol \(RSVP\)](#), page 11-17, and [Call Admission Control](#), page 11-1.

For more information about centralized and distributed multisite deployment models as well as Multiprotocol Label Switching (MPLS) implications for these deployment models, see the chapter on [Unified Communications Deployment Models](#), page 5-1.

WAN links should, when possible, be made redundant to provide higher levels of fault tolerance. Redundant WAN links provided by different service providers or located in different physical ingress/egress points within the network can ensure backup bandwidth and connectivity in the event that a single link fails. In non-failure scenarios, these redundant links may be used to provide additional bandwidth and offer load balancing of traffic on a per-flow basis over multiple paths and equipment within the WAN. Topology-unaware call admission control normally requires redundant paths to be over-provisioned and under-subscribed to allow for failures that reduce the available bandwidth between

sites without the call admission control mechanism being aware of those failures or the reduction in bandwidth. Topology-aware call admission control is able to adjust dynamically to many of the topology changes and allows for efficient use of the total available bandwidth.

Voice and data should remain converged at the WAN, just as they are converged at the LAN. QoS provisioning and queuing mechanisms are typically available in a WAN environment to ensure that voice and data can interoperate on the same WAN links. Attempts to separate and forward voice and data over different links can be problematic in many instances because the failure of one link typically forces all traffic over a single link, thus diminishing throughput for each type of traffic and in most cases reducing the quality of voice. Furthermore, maintaining separate network links or devices makes troubleshooting and management difficult at best.

Because of the potential for WAN links to fail or to become oversubscribed, Cisco recommends deploying non-centralized resources as appropriate at sites on the other side of the WAN. Specifically, media resources, DHCP servers, voice gateways, and call processing applications such as Survivable Remote Site Telephony (SRST) and Cisco Unified Communications Manager Express (Unified CME) should be deployed at non-central sites when and if appropriate, depending on the site size and how critical these functions are to that site. Keep in mind that de-centralizing voice applications and devices can increase the complexity of network deployments, the complexity of managing these resources throughout the enterprise, and the overall cost of a the network solution; however, these factors can be mitigated by the fact that the resources will be available during a WAN link failure.

When deploying voice in a WAN environment, Cisco recommends that you use the lower-bandwidth G.729 codec for any voice calls that will traverse WAN links because this practice will provide bandwidth savings on these lower-speed links. Furthermore, media resources such as MoH should be configured to use multicast transport mechanism when possible because this practice will provide additional bandwidth savings.

Where calls are made over best-effort networks with no QoS guarantees for voice, consider using Internet Low Bit Rate Codec (iLBC), which enables graceful speech quality degradation and good error resilience characteristics in networks where frames can get lost. See [Table 3-9](#) for details of bandwidth consumption based on codec type and sample size.

Delay in IP Voice Networks

Recommendation G.114 of the International Telecommunication Union (ITU) states that the one-way delay in a voice network should be less than or equal to 150 milliseconds. It is important to keep this in mind when implementing low-speed WAN links within a network. Topologies, technologies, and physical distance should be considered for WAN links so that one-way delay is kept at or below this 150-millisecond recommendation. Implementing a VoIP network where the one-way delay exceeds 150 milliseconds introduces issues not only with the quality of the voice call but also with call setup and media cut-through times because several call signaling messages need to be exchanged between each device and the call processing application in order to establish the call.

Guaranteed Bandwidth

Because voice is typically deemed a critical network application, it is imperative that bearer and signaling voice traffic always reaches its destination. For this reason, it is important to choose a WAN topology and link type that can provide guaranteed dedicated bandwidth. The following WAN link technologies can provide guaranteed dedicated bandwidth:

- Leased Lines
- Frame Relay
- Asynchronous Transfer Mode (ATM)
- ATM/Frame-Relay Service Interworking

- Multiprotocol Label Switching (MPLS)
- Cisco Voice and Video Enabled IP Security VPN (IPSec V3PN)

These link technologies, when deployed in a dedicated fashion or when deployed in a private network, can provide guaranteed traffic throughput. All of these WAN link technologies can be provisioned at specific speeds or bandwidth sizes. In addition, these link technologies have built-in mechanisms that help guarantee throughput of network traffic even at low link speeds. Features such as traffic shaping, fragmentation and packet interleaving, and committed information rates (CIR) can help ensure that packets are not dropped in the WAN, that all packets are given access at regular intervals to the WAN link, and that enough bandwidth is available for all network traffic attempting to traverse these links.

Dynamic Multipoint VPN (DMVPN)

Spoke-to-spoke DMVPN networks can provide benefits for Cisco Unified Communications compared with hub-and-spoke topologies. Spoke-to-spoke tunnels can provide a reduction in end-to-end latency by reducing the number of WAN hops and decryption/encryption stages. In addition, DMVPN offers a simplified means of configuring the equivalent of a full mesh of point-to-point tunnels without the associated administrative and operational overhead. The use of spoke-to-spoke tunnels also reduces traffic at the hub, thus providing bandwidth and router processing capacity savings. Spoke-to-spoke DMVPN networks, however, are sensitive to the delay variation (jitter) caused during the transition of RTP packets routing from the spoke-hub-spoke path to the spoke-to-spoke path. This variation in delay during the DMVPN path transition occurs very early in the call and is generally unnoticeable, although a single momentary audio distortion might be heard if the latency difference is above 100 ms.

For information on the deployment of multisite DMVPN WANs with centralized call processing, refer to the *Cisco Unified Communications Voice over Spoke-to-Spoke DMVPN Test Results and Recommendations*, available at <http://www.cisco.com/go/designzone>.

Best-Effort Bandwidth

There are some WAN topologies that are unable to provide guaranteed dedicated bandwidth to ensure that network traffic will reach its destination, even when that traffic is critical. These topologies are extremely problematic for voice traffic, not only because they provide no mechanisms to provision guaranteed network throughput, but also because they provide no traffic shaping, packet fragmentation and interleaving, queuing mechanisms, or end-to-end QoS to ensure that critical traffic such as voice will be given preferential treatment.

The following WAN network topologies and link types are examples of this kind of best-effort bandwidth technology:

- The Internet
- DSL
- Cable
- Satellite
- Wireless

In most cases, none of these link types can provide the guaranteed network connectivity and bandwidth required for critical voice and voice applications. However, these technologies might be suitable for personal or telecommuter-type network deployments. At times, these topologies can provide highly available network connectivity and adequate network throughput; but at other times, these topologies can become unavailable for extended periods of time, can be throttled to speeds that render network throughput unacceptable for real-time applications such as voice, or can cause extensive packet losses and require repeated retransmissions. In other words, these links and topologies are unable to provide

guaranteed bandwidth, and when traffic is sent on these links, it is sent best-effort with no guarantee that it will reach its destination. For this reason, Cisco recommends that you do *not* use best-effort WAN topologies for voice-enabled networks that require enterprise-class voice services and quality.

**Note**

There are some new QoS mechanisms for DSL and cable technologies that can provide guaranteed bandwidth; however, these mechanisms are not typically deployed by many service providers. For any service that offers QoS guarantees over networks that are typically based on best-effort, it is important to review and understand the bandwidth and QoS guarantees offered in the service provider's service level agreement (SLA).

**Note**

Upstream and downstream QoS mechanisms are now supported for wireless networks. For more information on QoS for Voice over Wireless LANs, refer to the *Voice over Wireless LAN Design Guide*, available at http://www.cisco.com/en/US/solutions/ns340/ns414/ns742/ns820/landing_voice_wireless.html.

WAN Quality of Service (QoS)

Before placing voice and video traffic on a network, it is important to ensure that there is adequate bandwidth for all required applications. Once this bandwidth has been provisioned, voice priority queuing must be performed on all interfaces. This queuing is required to reduce jitter and possible packet loss if a burst of traffic oversubscribes a buffer. This queuing requirement is similar to the one for the LAN infrastructure.

Next, the WAN typically requires additional mechanisms such as traffic shaping to ensure that WAN links are not sent more traffic than they can handle, which could cause dropped packets.

Finally, link efficiency techniques can be applied to WAN paths. For example, link fragmentation and interleaving (LFI) can be used to prevent small voice packets from being queued behind large data packets, which could lead to unacceptable delays on low-speed links.

The goal of these QoS mechanisms is to ensure reliable, high-quality voice by reducing delay, packet loss, and jitter for the voice traffic. [Table 3-7](#) lists the QoS features and tools required for the WAN infrastructure to achieve this goal.

Table 3-7 QoS Features and Tools Required to Support Unified Communications for Each WAN Technology and Link Speed

| WAN Technology | Link Speed: 56 kbps to 768 kbps | Link Speed: Greater than 768 kbps |
|----------------|---|---|

The following sections highlight some of the most important features and techniques to consider when designing a WAN to support both voice and data traffic:

- [Traffic Prioritization, page 3-41](#)
- [Link Efficiency Techniques, page 3-43](#)
- [Traffic Shaping, page 3-45](#)

Traffic Prioritization

In choosing from among the many available prioritization schemes, the major factors to consider include the type of traffic involved and the type of media on the WAN. For multi-service traffic over an IP WAN, Cisco recommends low-latency queuing (LLQ) for all links. This method supports up to 64 traffic classes, with the ability to specify, for example, priority queuing behavior for voice and interactive video, minimum bandwidth class-based weighted fair queuing for voice control traffic, additional minimum bandwidth weighted fair queues for mission critical data, and a default best-effort queue for all other traffic types.

[Figure 3-11](#) shows an example prioritization scheme.

Figure 3-11 Optimized Queuing for VoIP over the WAN

Cisco recommends the following prioritization criteria for LLQ:

- The criterion for *voice* to be placed into a priority queue is the differentiated services code point (DSCP) value of 46, or a per-hop behavior (PHB) value of EF.
- The criterion for *video conferencing* traffic to be placed into a priority queue is a DSCP value of 34, or a PHB value of AF41. However, due to the larger packet sizes of video traffic, these packets should be placed in the priority queue only on WAN links that are faster than 768 Kbps. Link speeds below this value require packet fragmentation, but packets placed in the priority queue are not fragmented, thus smaller voice packets could be queued behind larger video packets. For links speeds of 768 Kbps or lower, video conferencing traffic should be placed in a separate class-based weighted fair queue (CBWFQ).

Note One-way video traffic, such as the traffic generated by streaming video applications for services such as video-on-demand or live video feeds, should always use a CBWFQ scheme because that type of traffic has a much higher delay tolerance than two-way video conferencing traffic

- As the WAN links become congested, it is possible to starve the *voice control* signaling protocols, thereby eliminating the ability of the IP phones to complete calls across the IP WAN. Therefore, voice control protocols, such as H.323, MGCP, and Skinny Client Control Protocol (SCCP), require their own class-based weighted fair queue. The entrance criterion for this queue is a DSCP value of 24 or a PHB value of CS3.

Note Cisco has transitioned the marking of voice control protocols from DSCP 26 (PHB AF31) to DSCP 24 (PHB CS3). However, some products still mark signaling traffic as DSCP 26 (PHB AF31); therefore, Cisco recommends that you reserve both AF31 and CS3 for call signaling.

- In some cases, certain data traffic might require better than best-effort treatment. This traffic is referred to as *mission-critical data*, and it is placed into one or more queues that have the required amount of bandwidth. The queuing scheme within this class is first-in-first-out (FIFO) with a minimum allocated bandwidth. Traffic in this class that exceeds the configured bandwidth limit is placed in the default queue. The entrance criterion for this queue could be a Transmission Control Protocol (TCP) port number, a Layer 3 address, or a DSCP/PHB value.
- All remaining enterprise traffic can be placed in a default queue for best-effort treatment. If you specify the keyword **fair**, the queuing algorithm will be weighted fair queuing (WFQ).

Scavenger Class

The Scavenger class is intended to provide less than best-effort services to certain applications. Applications assigned to this class have little or no contribution to the organizational objectives of the enterprise and are typically entertainment oriented in nature. Assigning Scavenger traffic to a minimal bandwidth queue forces it to be squelched to virtually nothing during periods of congestion, but it allows it to be available if bandwidth is not being used for business purposes, such as might occur during off-peak hours.

- Scavenger traffic should be marked as DSCP CS1.
- Scavenger traffic should be assigned the lowest configurable queuing service. For instance, in Cisco IOS, this means assigning a CBWFQ of 1% to Scavenger class.

Link Efficiency Techniques

The following link efficiency techniques improve the quality and efficiency of low-speed WAN links.

Compressed Real-Time Transport Protocol (cRTP)

You can increase link efficiency by using Compressed Real-Time Transport Protocol (cRTP). This protocol compresses a 40-byte IP, User Datagram Protocol (UDP), and RTP header into approximately two to four bytes. cRTP operates on a per-hop basis. Use cRTP on a particular link only if that link meets *all* of the following conditions:

- Voice traffic represents more than 33% of the load on the specific link.
- The link uses a low bit-rate codec (such as G.729).
- No other real-time application (such as video conferencing) is using the same link.

If the link fails to meet any one of the preceding conditions, then cRTP is not effective and you should not use it on that link. Another important parameter to consider before using cRTP is router CPU utilization, which is adversely affected by compression and decompression operations.

cRTP on ATM and Frame Relay Service Inter-Working (SIW) links requires the use of Multilink Point-to-Point Protocol (MLP).

Note that cRTP compression occurs as the final step before a packet leaves the egress interface; that is, after LLQ class-based queueing has occurred. Beginning in Cisco IOS Release 12.(2)2T and later, cRTP provides a feedback mechanism to the LLQ class-based queueing mechanism that allows the bandwidth in the *voice* class to be configured based on the compressed packet value. With Cisco IOS releases prior to 12.(2)2T, this mechanism is not in place, so the LLQ is unaware of the compressed bandwidth and, therefore, the *voice* class bandwidth has to be provisioned as if no compression is taking place. [Table 3-8](#) shows an example of the difference in *voice* class bandwidth configuration given a 512-kbps link with G.729 codec and a requirement for 10 calls.

Note that [Table 3-8](#) assumes 24 kbps for non-cRTP G.729 calls and 10 kbps for cRTP G.729 calls. These bandwidth numbers are based on voice payload and IP/UDP/RTP headers only. They do not take into consideration Layer 2 header bandwidth. However, actual bandwidth provisioning should also include Layer 2 header bandwidth based on the type WAN link used.

Table 3-8 LLQ Voice Class Bandwidth Requirements for 10 Calls with 512 kbps Link Bandwidth and G.729 Codec

| Cisco IOS Release | With cRTP Not Configured | With cRTP Configured |
|-------------------|--------------------------|-----------------------|
| Prior to 12.2(2)T | 240 kbps | 240 kbps ¹ |
| 12.2(2)T or later | 240 kbps | 100 kbps |

1. 140 kbps of unnecessary bandwidth must be configured in the LLQ *voice* class.

It should also be noted that, beginning in Cisco IOS Release 12.2(13)T, cRTP can be configured as part of the voice class with the Class-Based cRTP feature. This option allows cRTP to be specified within a class, attached to an interface via a service policy. This new feature provides compression statistics and bandwidth status via the **show policy interface** command, which can be very helpful in determining the offered rate on an interface service policy class given the fact that cRTP is compressing the IP/RTP headers.

For additional recommendations about using cRTP with a Voice and Video Enabled IPsec VPN (V3PN), refer to the V3PN documentation available at

http://www.cisco.com/en/US/solutions/ns340/ns414/ns742/ns817/landing_voice_video.html

Link Fragmentation and Interleaving (LFI)

For low-speed links (less than 768 kbps), use of link fragmentation and interleaving (LFI) mechanisms is required for acceptable voice quality. This technique limits jitter by preventing voice traffic from being delayed behind large data frames, as illustrated in Figure 3-12. The two techniques that exist for this purpose are Multilink Point-to-Point Protocol (MLP) LFI (for Leased Lines, ATM, and SIW) and FRF.12 for Frame Relay.

Figure 3-12 Link Fragmentation and Interleaving (LFI)

Voice-Adaptive Fragmentation (VAF)

In addition to the LFI mechanisms mentioned above, voice-adaptive fragmentation (VAF) is another LFI mechanism for Frame Relay links. VAF uses FRF.12 Frame Relay LFI; however, once configured, fragmentation occurs only when traffic is present in the LLQ priority queue or when H.323 signaling packets are detected on the interface. This method ensures that, when voice traffic is being sent on the WAN interface, large packets are fragmented and interleaved. However, when voice traffic is not present on the WAN link, traffic is forwarded across the link unfragmented, thus reducing the overhead required for fragmentation.

VAF is typically used in combination with voice-adaptive traffic shaping (see [Voice-Adaptive Traffic Shaping \(VATS\)](#), page 3-46). VAF is an optional LFI tool, and you should exercise care when enabling it because there is a slight delay between the time when voice activity is detected and the time when the

LFI mechanism engages. In addition, a configurable deactivation timer (default of 30 seconds) must expire after the last voice packet is detected and before VAF is deactivated, so during that time LFI will occur unnecessarily. VAF is available in Cisco IOS Release 12.2(15)T and later.

Traffic Shaping

Traffic shaping is required for multiple-access, non-broadcast media such as ATM and Frame Relay, where the physical access speed varies between two endpoints and several branch sites are typically aggregated to a single router interface at the central site.

Figure 3-13 illustrates the main reasons why traffic shaping is needed when transporting voice and data on the same IP WAN.

Figure 3-13 Traffic Shaping with Frame Relay and ATM

Figure 3-13 shows three different scenarios:

1. Line speed mismatch

While the central-site interface is typically a high-speed one (such as T1 or higher), smaller remote branch interfaces may have significantly lower line speeds, such as 64 kbps. If data is sent at full rate from the central site to a slow-speed remote site, the interface at the remote site might become congested, resulting in dropped packets which causes a degradation in voice quality.

2. Oversubscription of the link between the central site and the remote sites

It is common practice in Frame Relay or ATM networks to oversubscribe bandwidth when aggregating many remote sites to a single central site. For example, there may be multiple remote sites that connect to the WAN with a T1 interface, yet the central site has only a single T1 interface. While this configuration allows the deployment to benefit from statistical multiplexing, the router interface at the central site can become congested during traffic bursts, thus degrading voice quality.

3. Bursting above Committed Information Rate (CIR)

Another common configuration is to allow traffic bursts above the CIR, which represents the rate that the service provider has guaranteed to transport across its network with no loss and low delay. For example, a remote site with a T1 interface might have a CIR of only 64 kbps. When more than 64 kbps worth of traffic is sent across the WAN, the provider marks the additional traffic as "discard eligible." If congestion occurs in the provider network, this traffic will be dropped with no regard to traffic classification, possibly having a negative effect on voice quality.

Traffic shaping provides a solution to these issues by limiting the traffic sent out an interface to a rate lower than the line rate, thus ensuring that no congestion occurs on either end of the WAN. [Figure 3-14](#) illustrates this mechanism with a generic example, where R is the rate with traffic shaping applied.

Figure 3-14 Traffic Shaping Mechanism

Voice-Adaptive Traffic Shaping (VATS)

VATS is an optional dynamic mechanism that shapes traffic on Frame Relay permanent virtual circuits (PVCs) at different rates based on whether voice is being sent across the WAN. The presence of traffic in the LLQ voice priority queue or the detection of H.323 signaling on the link causes VATS to engage. Typically, Frame Relay shapes traffic to the guaranteed bandwidth or CIR of the PVC at all times. However, because these PVCs are typically allowed to burst above the CIR (up to line speed), traffic shaping keeps traffic from using the additional bandwidth that might be present in the WAN. With VATS enabled on Frame Relay PVCs, WAN interfaces are able to send at CIR when voice traffic is present on the link. However, when voice is not present, non-voice traffic is able to burst up to line speed and take advantage of the additional bandwidth that might be present in the WAN.

When VATS is used in combination with voice-adaptive fragmentation (VAF) (see [Link Fragmentation and Interleaving \(LFI\)](#), page 3-44), all non-voice traffic is fragmented and all traffic is shaped to the CIR of the WAN link when voice activity is detected on the interface.

As with VAF, exercise care when enabling VATS because activation can have an adverse effect on non-voice traffic. When voice is present on the link, data applications will experience decreased throughput because they are throttled back to well below CIR. This behavior will likely result in packet drops and delays for non-voice traffic. Furthermore, after voice traffic is no longer detected, the deactivation timer (default of 30 seconds) must expire before traffic can burst back to line speed. It is

important, when using VATS, to set end-user expectations and make them aware that data applications will experience slowdowns on a regular basis due to the presence of voice calls across the WAN. VATS is available in Cisco IOS Release 12.2(15)T and later.

For more information on the Voice-Adaptive Traffic Shaping and Fragmentation features and how to configure them, refer to the documentation at

http://www.cisco.com/en/US/docs/ios/12_2t/12_2t15/feature/guide/ft_vats.html

Bandwidth Provisioning

Properly provisioning the network bandwidth is a major component of designing a successful IP network. You can calculate the required bandwidth by adding the bandwidth requirements for each major application (for example, voice, video, and data). This sum then represents the minimum bandwidth requirement for any given link, and it should not exceed approximately 75% of the total available bandwidth for the link. This 75% rule assumes that some bandwidth is required for overhead traffic, such as routing and Layer 2 keep-alives. Figure 3-15 illustrates this bandwidth provisioning process.

Figure 3-15 Link Bandwidth Provisioning

In addition to using no more than 75% of the total available bandwidth for data, voice, and video, the total bandwidth configured for all LLQ priority queues should typically not exceed 33% of the total link bandwidth. Provisioning more than 33% of the available bandwidth for the priority queue can be problematic for a number of reasons. First, provisioning more than 33% of the bandwidth for voice can result in increased CPU usage. Because each voice call will send 50 packets per second (with 20 ms samples), provisioning for large numbers of calls in the priority queue can lead to high CPU levels due to high packet rates. In addition, if more than one type of traffic is provisioned in the priority queue (for example, voice and video), this configuration defeats the purpose of enabling QoS because the priority queue essentially becomes a first-in, first-out (FIFO) queue. A larger percentage of reserved priority bandwidth effectively dampens the QoS effects by making more of the link bandwidth FIFO. Finally, allocating more than 33% of the available bandwidth can effectively starve any data queues that are provisioned. Obviously, for very slow links (less than 192 kbps), the recommendation to provision no more than 33% of the link bandwidth for the priority queue(s) might be unrealistic because a single call could require more than 33% of the link bandwidth. In these situations, and in situations where specific business needs cannot be met while holding to this recommendation, it may be necessary to exceed the 33% rule.

From a traffic standpoint, an IP telephony call consists of two parts:

- The voice and video bearer streams, which consists of Real-Time Transport Protocol (RTP) packets that contain the actual voice samples.
- The call control signaling, which consists of packets belonging to one of several protocols, according to the endpoints involved in the call (for example, H.323, MGCP, SCCP, or (J)TAPI). Call control functions are, for instance, those used to set up, maintain, tear down, or redirect a call.

Bandwidth provisioning should include not only the bearer traffic but also the call control traffic. In fact, in multisite WAN deployments, the call control traffic (as well as the bearer traffic) must traverse the WAN, and failure to allocate sufficient bandwidth for it can adversely affect the user experience.

The next three sub-sections describe the bandwidth provisioning recommendations for the following types of traffic:

- Voice and video bearer traffic in all multisite WAN deployments (see [Provisioning for Bearer Traffic, page 3-48](#))
- Call control traffic in multisite WAN deployments with centralized call processing (see [.Provisioning for Call Control Traffic with Centralized Call Processing, page 3-52](#))
- Call control traffic in multisite WAN deployments with distributed call processing (see [Provisioning for Call Control Traffic with Distributed Call Processing, page 3-56](#))

Provisioning for Bearer Traffic

The section describes bandwidth provisioning for the following types of traffic:

- [Voice Bearer Traffic, page 3-48](#)
- [Video Bearer Traffic, page 3-51](#)

Voice Bearer Traffic

As illustrated in [Figure 3-16](#), a voice-over-IP (VoIP) packet consists of the voice payload, IP header, User Datagram Protocol (UDP) header, Real-Time Transport Protocol (RTP) header, and Layer 2 Link header. When Secure Real-Time Transport Protocol (SRTP) encryption is used, the voice payload for each packet is increased by 4 bytes. The link header varies in size according to the Layer 2 media used.

Figure 3-16 Typical VoIP Packet

The bandwidth consumed by VoIP streams is calculated by adding the packet payload and all headers (in bits), then multiplying by the packet rate per second, as follows:

$$\text{Layer 2 bandwidth in kbps} = [(\text{Packets per second}) * (X \text{ bytes for voice payload} + 40 \text{ bytes for RTP/UDP/IP headers} + Y \text{ bytes for Layer 2 overhead}) * 8 \text{ bits}] / 1000$$

$$\text{Layer 3 bandwidth in kbps} = [(\text{Packets per second}) * (X \text{ bytes for voice payload} + 40 \text{ bytes for RTP/UDP/IP headers}) * 8 \text{ bits}] / 1000$$

$$\text{Packets per second} = [1/(\text{sampling rate in msec})] * 1000$$

Voice payload in bytes = [(codec bit rate in kbps) * (sampling rate in msec)] / 8

Table 3-9 details the Layer 3 bandwidth per VoIP flow. Table 3-9 lists the bandwidth consumed by the voice payload and IP header only, at a default packet rate of 50 packets per second (pps) and at a rate of 33.3 pps for both non-encrypted and encrypted payloads. Table 3-9 does not include Layer 2 header overhead and does not take into account any possible compression schemes, such as compressed Real-Time Transport Protocol (cRTP). You can use the Service Parameters menu in Unified CM Administration to adjust the codec sampling rate.

Table 3-9 Bandwidth Consumption for Voice Payload and IP Header Only

| CODEC | Sampling Rate | Voice Payload in Bytes | Packets per Second | Bandwidth per Conversation |
|----------------------------|---------------|------------------------|--------------------|----------------------------|
| G.711 and G.722-64k | 20 ms | 160 | 50.0 | 80.0 kbps |
| G.711 and G.722-64k (SRTP) | 20 ms | 164 | 50.0 | 81.6 kbps |
| G.711 and G.722-64k | 30 ms | 240 | 33.3 | 74.7 kbps |
| G.711 and G.722-64k (SRTP) | 30 ms | 244 | 33.3 | 75.8 kbps |
| iLBC | 20 ms | 38 | 50.0 | 31.2 kbps |
| iLBC (SRTP) | 20 ms | 42 | 50.0 | 32.8 kbps |
| iLBC | 30 ms | 50 | 33.3 | 24.0 kbps |
| iLBC (SRTP) | 30 ms | 54 | 33.3 | 25.1 kbps |
| G.729A | 20 ms | 20 | 50.0 | 24.0 kbps |
| G.729A (SRTP) | 20 ms | 24 | 50.0 | 25.6 kbps |
| G.729A | 30 ms | 30 | 33.3 | 18.7 kbps |
| G.729A (SRTP) | 30 ms | 34 | 33.3 | 19.8 kbps |

A more accurate method for provisioning is to include the Layer 2 headers in the bandwidth calculations. Table 3-10 lists the amount of bandwidth consumed by voice traffic when the Layer 2 headers are included in the calculations.

Table 3-10 Bandwidth Consumption with Layer 2 Headers Included

| CODEC | Header Type and Size | | | | | | |
|---|----------------------|----------------|---|------------------------|-------------------|-----------------|------------------|
| | Ethernet 14 Bytes | PPP 6 Bytes | ATM 53-Byte Cells with a 48-Byte Payload | Frame Relay 4 Bytes | MLPPP 10 Bytes | MPLS 4 Bytes | WLAN 24 Bytes |
| G.711 and G.722-64k at 50.0 pps | 85.6 kbps | 82.4 kbps | 106.0 kbps | 81.6 kbps | 84.0 kbps | 81.6 kbps | 89.6 kbps |
| G.711 and G.722-64k (SRTP) at 50.0 pps | 87.2 kbps | 84.0 kbps | 106.0 kbps | 83.2 kbps | 85.6 kbps | 83.2 kbps | N/A |
| G.711 and G.722-64k at 33.3 pps | 78.4 kbps | 76.3 kbps | 84.8 kbps | 75.7 kbps | 77.3 kbps | 75.7 kbps | 81.1 kbps |
| G.711 and G.722-64k (SRTP) at 33.3 pps | 79.5 kbps | 77.4 kbps | 84.8 kbps | 76.8 kbps | 78.4 kbps | 76.8 kbps | N/A |
| iLBC at 50.0 pps | 36.8 kbps | 33.6 kbps | 42.4 kbps | 32.8 kbps | 35.2 kbps | 32.8 kbps | 40.8 kbps |

Table 3-10 Bandwidth Consumption with Layer 2 Headers Included (continued)

| CODEC | Header Type and Size | | | | | | |
|------------------------------|----------------------|----------------|---|------------------------|-------------------|-----------------|------------------|
| | Ethernet 14 Bytes | PPP 6 Bytes | ATM 53-Byte Cells with a 48-Byte Payload | Frame Relay 4 Bytes | MLPPP 10 Bytes | MPLS 4 Bytes | WLAN 24 Bytes |
| iLBC (SRTP) at 50.0 pps | 38.4 kbps | 35.2 kbps | 42.4 kbps | 34.4 kbps | 36.8 kbps | 34.4 kbps | 42.4 kbps |
| iLBC at 33.3 pps | 27.7 kbps | 25.6 kbps | 28.3 kbps | 25.0 kbps | 26.6 kbps | 25.0 kbps | 30.4 kbps |
| iLBC (SRTP) at 33.3 pps | 28.8 kbps | 26.6 kbps | 42.4 kbps | 26.1 kbps | 27.7 kbps | 26.1 kbps | 31.5 kbps |

| G729A (SRTP) at 33.3 pps | 23.5 kbps | 21.4 kbps | 28.3 kbps | 20.8 kbps | 22.4 kbps | 20.8 kbps | 26.2 kbps |

While it is possible to configure the sampling rate above 30 ms, doing so usually results in very poor voice quality. As illustrated in [Figure 3-17](#), as sampling size increases, the number of packets per second decreases, resulting in a smaller impact to the CPU of the device. Likewise, as the sample size increases, IP header overhead is lower because the payload per packet is larger. However, as sample size increases, so does packetization delay, resulting in higher end-to-end delay for voice traffic. The trade-off between packetization delay and packets per second must be considered when configuring sample size. While this trade-off is optimized at 20 ms, 30 ms sample sizes still provide a reasonable ratio of delay to packets per second; however, with 40 ms sample sizes, the packetization delay becomes too high.

Figure 3-17 Voice Sample Size: Packets per Second vs. Packetization Delay

114470

Video Bearer Traffic

For audio, it is relatively easy to calculate a percentage of overhead per packet given the sample size of each packet. For video, however, it is nearly impossible to calculate an exact percentage of overhead because the payload varies depending upon how much motion is present in the video (that is, how many pixels changed since the last frame).

To resolve this inability to calculate the exact overhead ratio for video, Cisco recommends that you add 20% to the call speed regardless of which type of Layer-2 medium the packets are traversing. The additional 20% gives plenty of headroom to allow for the differences between Ethernet, ATM, Frame Relay, PPP, HDLC, and other transport protocols, as well as some cushion for the bursty nature of video traffic.

Note that the call speed requested by the endpoint (for example, 128 kbps, 256 kbps, and so forth) represents the maximum burst speed of the call, with some additional amount for a cushion. The average speed of the call is typically much less than these values.

Provisioning for Call Control Traffic

When Unified Communications endpoints are separated from their call control application by a WAN, or when two interconnected Unified Communications systems are separated by a WAN, consideration must be given to the amount of bandwidth that must be provisioned for call control and signaling traffic between these endpoints and systems. This section discusses WAN bandwidth provisioning for call signaling traffic where centralized or distributed call processing models are deployed. For more information on Unified Communications centralized and distributed call processing deployment models, see [Unified Communications Deployment Models, page 5-1](#).

Provisioning for Call Control Traffic with Centralized Call Processing

In a centralized call processing deployment, the Unified CM cluster and the applications (such as voicemail) are located at the central site, while several remote sites are connected through an IP WAN. The remote sites rely on the centralized Unified CMs to handle their call processing.

The following considerations apply to this deployment model:

- Each time a remote branch phone places a call, the control traffic traverses the IP WAN to reach the Unified CM at the central site, even if the call is local to the branch.
- The signaling protocols that may traverse the IP WAN in this deployment model are SCCP (encrypted and non-encrypted), SIP (encrypted and non-encrypted), H.323, MGCP, and CTI-QBE. All the control traffic is exchanged between a Unified CM at the central site and endpoints or gateways at the remote branches.
- If RSVP is deployed within the cluster, the control traffic between the Unified CM cluster at the central site and the Cisco RSVP Agents at the remote sites uses the SCCP protocol.

As a consequence, you must provision bandwidth for control traffic that traverses the WAN between the branch routers and the WAN aggregation router at the central site.

The control traffic that traverses the WAN in this scenario can be split into two categories:

- Quiescent traffic, which consists of keep-alive messages periodically exchanged between the branch endpoints (phones, gateways, and Cisco RSVP Agents) and Unified CM, regardless of call activity. This traffic is a function of the quantity of endpoints.
- Call-related traffic, which consists of signaling messages exchanged between the branch endpoints and the Unified CM at the central site when a call needs to be set up, torn down, forwarded, and so forth. This traffic is a function of the quantity of endpoints and their associated call volume.

To obtain an estimate of the generated call control traffic, it is necessary to make some assumptions regarding the average number of calls per hour made by each branch IP phone. In the interest of simplicity, the calculations in this section assume an average of 10 calls per hour per phone.

Note

If this average number does not satisfy the needs of your specific deployment, you can calculate the recommended bandwidth by using the advanced formulas provided in [Advanced Formulas, page 3-54](#).

Given the assumptions made, and initially considering the case of a remote branch with no signaling encryption configured, the recommended bandwidth needed for call control traffic can be obtained from the following formula:

Equation 1A: Recommended Bandwidth Needed for SCCP Control Traffic without Signaling Encryption.

$$\text{Bandwidth (bps)} = 265 * (\text{Number of IP phones and gateways in the branch})$$

Equation 1B: Recommended Bandwidth Needed for SIP Control Traffic without Signaling Encryption.

$$\text{Bandwidth (bps)} = 538 * (\text{Number of IP phones and gateways in the branch})$$

If a site features a mix of SCCP and SIP endpoints, the two equations above should be employed separately for the quantity of each type of phone used, and the results added.

Equation 1 and all other formulas within this section include a 25% over-provisioning factor. Control traffic has a bursty nature, with peaks of high activity followed by periods of low activity. For this reason, assigning just the minimum bandwidth required to a control traffic queue can result in undesired effects such as buffering delays and, potentially, packet drops during periods of high activity. The default queue depth for a Class-Based Weighted Fair Queuing (CBWFQ) queue in Cisco IOS equals 64 packets. The bandwidth assigned to this queue determines its servicing rate. Assuming that the bandwidth configured is the average bandwidth consumed by this type of traffic, it is clear that, during the periods of high activity, the servicing rate will not be sufficient to "drain" all the incoming packets out of the queue, thus causing them to be buffered. Note that, if the 64-packet limit is reached, any subsequent packets are either assigned to the best-effort queue or are dropped. It is therefore advisable to introduce this 25% over-provisioning factor to absorb and smooth the variations in the traffic pattern and to minimize the risk of a temporary buffer overrun. This is equivalent to increasing the servicing rate of the queue.

If encryption is configured, the recommended bandwidth is affected because encryption increases the size of signaling packets exchanged between Unified CM and the endpoints. The following formula takes into account the impact of signaling encryption:

Equation 2A: Recommended Bandwidth Needed for SCCP Control Traffic with Signaling Encryption.

$$\text{Bandwidth with signaling encryption (bps)} = 415 * (\text{Number of IP phones and gateways in the branch})$$

Equation 2B: Recommended Bandwidth Needed for SIP Control Traffic with Signaling Encryption.

$$\text{Bandwidth with signaling encryption (bps)} = 619 * (\text{Number of IP phones and gateways in the branch})$$

If we now take into account the fact that the smallest bandwidth that can be assigned to a queue on a Cisco IOS router is 8 kbps, we can summarize the values of minimum and recommended bandwidth for various branch office sizes, as shown in [Table 3-11](#).

Table 3-11 Recommended Layer 3 Bandwidth for Call Control Traffic With and Without Signaling Encryption

| Branch Office Size (Number of IP Phones and Gateways) | Recommended Bandwidth for SCCP Control Traffic (no encryption) | Recommended Bandwidth for SCCP Control Traffic (with encryption) | Recommended Bandwidth for SIP Control Traffic (no encryption) | Recommended Bandwidth for SIP Control Traffic (with encryption) |
|--|---|---|--|--|
| 1 to 10 | 8 kbps | 8 kbps | 8 kbps | 8 kbps |
| 20 | 8 kbps | 9 kbps | 11 kbps | 12 kbps |
| 30 | 8 kbps | 13 kbps | 16 kbps | 19 kbps |
| 40 | 11 kbps | 17 kbps | 22 kbps | 25 kbps |
| 50 | 14 kbps | 21 kbps | 27 kbps | 31 kbps |
| 100 | 27 kbps | 42 kbps | 54 kbps | 62 kbps |
| 150 | 40 kbps | 62 kbps | 81 kbps | 93 kbps |

**Note**

[Table 3-11](#) assumes 10 calls per hour per phone, and it does not include RSVP control traffic. To determine the RSVP-related bandwidth to add to the values in this table, see [Considerations for Calls Using RSVP, page 11-38](#).

**Note**

If an RSVP-based locations policy is used for inter-site calls, the values of [Table 3-11](#) must be increased to compensate for the control traffic of the Cisco RSVP Agent. For example, if 10% of the calls go over the WAN, multiply the value from [Table 3-11](#) by 1.1.

Advanced Formulas

The previous formulas presented in this section assume an average call rate per phone of 10 calls per hour. However, this rate might not correspond to your deployment if the call patterns are significantly different (for example, with call center agents at the branches). To calculate call control bandwidth requirements in these cases, use the following formulas, which contain an additional variable (CH) that represents the average calls per hour per phone:

Equation 3A: Recommended Bandwidth Needed for SCCP Control Traffic for a Branch with No Signaling Encryption.

$$\text{Bandwidth (bps)} = (53 + 21 * \text{CH}) * (\text{Number of IP phones and gateways in the branch})$$

Equation 3B: Recommended Bandwidth Needed for SIP Control Traffic for a Branch with No Signaling Encryption.

$$\text{Bandwidth (bps)} = (138 + 40 * \text{CH}) * (\text{Number of IP phones and gateways in the branch})$$

Equation 4A: Recommended Bandwidth Needed for SCCP Control Traffic for a Remote Branch with Signaling Encryption.

$$\text{Bandwidth with signaling encryption (bps)} = (73.5 + 33.9 * \text{CH}) * (\text{Number of IP phones and gateways in the branch})$$

Equation 4B: Recommended Bandwidth Needed for SIP Control Traffic for a Remote Branch with Signaling Encryption.

$$\text{Bandwidth with signaling encryption (bps)} = (159 + 46 * \text{CH}) * (\text{Number of IP phones and gateways in the branch})$$

**Note**

Equations 3A and 4A are based on the default SCCP keep-alive period of 30 seconds, while equations 3B and 4B are based on the default SIP keep-alive period of 120 seconds.

Considerations for Shared Line Appearances

Calls placed to shared line appearances, or calls sent to line groups using the Broadcast distribution algorithm, have two net effects on the bandwidth consumed by the system:

- Because all the phones on which the line is configured ring simultaneously, they represent a load on the system corresponding to a much higher calls-per-hour (CH) value than the CH of the line. The corresponding bandwidth consumption is therefore increased. The network infrastructure's bandwidth provisioning requires adjustments when WAN-connected shared line functionality is deployed. The CH value employed for Equations 3 and 4 must be increased according to the following formula:

$$\text{CHS} = \text{CHL} * (\text{Number line appearances}) / (\text{Number of lines})$$

Where CHS is the shared-line calls per hour to be used in Equations 3 and 4, and CHL is the calls-per-hour rating of the line. For example, if a site is configured with 5 lines making an average of 6 calls per hour but 2 of those lines are shared across 4 different phones, then:

Number of lines = 5

Number of line appearances = (2 lines appear on 4 phones, and 3 lines appear on only one phone) = $(2*4) + 3 = 11$ line appearances

CHL = 6

CHS = $6 * (11 / 5) = 13.2$

- Because each of the ringing phones requires a separate signaling control stream, the quantity of packets sent from Unified CM to the same branch is increased in linear proportion to the quantity of phones ringing. Because Unified CM is attached to the network through a 100 Mbps interface, it can instantaneously generate a very large quantity of packets that must be buffered while the queuing mechanism is servicing the signaling traffic. The servicing speed is limited by the WAN interface's effective information transfer speed, which is typically two orders of magnitude smaller than 100 Mbps.

This traffic may overwhelm the queue depth of the central site's WAN router. By default, the queue depth available for each of the classes of traffic in Cisco IOS is 64. In order to prevent any packets from being dropped before they are queued for the WAN interface, you must ensure that the signaling queue's depth is sized to hold all the packets from at least one full shared-line event for each shared-line phone. Avoiding drops is paramount in ensuring that the call does not create a race condition where dropped packets are retransmitted, causing system response times to suffer.

Therefore, the quantity of packets required to operate shared-line phones is as follows:

- SCCP protocol: 13 packets per shared-line phone
- SIP protocol: 11 packets per shared-line phone

For example, with SCCP and with 6 phones sharing the same line, the queue depth for the signaling class of traffic must be adjusted to a minimum of 78. [Table 3-12](#) provides recommended queue depths based on the quantity of shared line appearances within a branch site.

Table 3-12 Recommended Queue Depth per Branch Site

| Number of Shared Line Appearances | Queue Depth (Packets) | |
|-----------------------------------|-----------------------|-----|
| | SCCP | SIP |
| 5 | 65 | 55 |
| 10 | 130 | 110 |
| 15 | 195 | 165 |
| 20 | 260 | 220 |
| 25 | 325 | 275 |

When using a Layer 2 WAN technology such as Frame Relay, this adjustment must be made on the circuit corresponding to the branch where the shared-line phones are located.

When using a Layer 3 WAN technology such as MPLS, there may be a single signaling queue servicing multiple branches. In this case, adjustment must be made for the total of all branches serviced.

Provisioning for Call Control Traffic with Distributed Call Processing

In distributed call processing deployments, several sites are connected through an IP WAN. Each site contains a Unified CM cluster and can follow either the single-site model or the centralized call processing model. A gatekeeper may be used for call admission control between sites.

The following considerations apply to this deployment model:

- The signaling protocol used to place a call across the WAN is H.323 or SIP.
- Control traffic is exchanged between the Cisco IOS gatekeeper and the Unified CM clusters at each site, as well as between the Unified CM clusters themselves.

Therefore, bandwidth for control traffic must be provisioned on the WAN links between Unified CMs as well as between each Unified CM and the gatekeeper. Because the topology is limited to hub-and-spoke, with the gatekeeper typically located at the hub, the WAN link that connects each site to the other sites usually coincides with the link that connects the site to the gatekeeper.

The control traffic that traverses the WAN belongs to one of the following categories:

- Quiescent traffic, which consists of registration messages periodically exchanged between each Unified CM and the gatekeeper
- Call-related traffic, which in turn consists of two types of traffic:
 - Call admission control traffic, exchanged between the Unified CMs and the call admission control device (such as a gatekeeper or Cisco RSVP Agent) before a call can be set up and after it has been torn down.
 - Signaling traffic associated with a media stream, exchanged over an intercluster trunk when a call needs to be set up, torn down, forwarded, and so on.

Because the total amount of control traffic depends on the number of calls that are set up and torn down at any given time, it is necessary to make some assumptions about the call patterns and the link utilization. The WAN links that connect each of the spoke sites to the hub site are normally provisioned to accommodate different types of traffic (for example, data, voice, and video). Using a traditional telephony analogy, we can view the portion of the WAN link that has been provisioned for voice as a number of *virtual tie lines*.

Assuming an average call duration of 2 minutes and 100 percent utilization of each virtual tie line, we can derive that each tie line carries a volume of 30 calls per hour. This assumption allows us to obtain the following formula that expresses the recommended bandwidth for call control traffic as a function of the number of virtual tie lines.

Equation 6: Recommended Bandwidth Based on Number of Virtual Tie Lines.

$$\text{Recommended Bandwidth (bps)} = 116 * (\text{Number of virtual tie lines})$$

If we take into account the fact that 8 kbps is the smallest bandwidth that can be assigned to a queue on a Cisco IOS router, we can deduce that a minimum queue size of 8 kbps can accommodate the call control traffic generated by *up to 70 virtual tie lines*. This amount should be sufficient for most large enterprise deployments.

Wireless LAN Infrastructure

Wireless LAN infrastructure design becomes important when Unified Communications is added to the wireless LAN (WLAN) portions of a converged network. With the introduction of Cisco Unified Wireless endpoints, voice and video traffic has moved onto the WLAN and is now converged with the existing data traffic there. Just as with wired LAN and wired WAN infrastructure, the addition of voice and video in the WLAN requires following basic configuration and design best-practices for deploying a highly available network. In addition, proper WLAN infrastructure design requires understanding and deploying QoS on the wireless network to ensure end-to-end voice and video quality on the entire network. The following sections discuss these requirements:

- [Architecture for Voice and Video over WLAN, page 3-57](#)
- [High Availability for Voice and Video over WLAN, page 3-61](#)
- [Capacity Planning for Voice and Video over WLAN, page 3-63](#)
- [Design Considerations for Voice and Video over WLAN, page 3-63](#)

For more information about Voice over Wireless LANs, refer to the latest version of the *Voice over Wireless LAN Design Guide*, available at

http://www.cisco.com/en/US/solutions/ns340/ns414/ns742/ns820/landing_voice_wireless.html

Architecture for Voice and Video over WLAN

IP telephony architecture has used wired devices since its inception, but enterprise users have long sought the ability to communicate while moving through the company premises. Wireless IP networks have enabled IP telephony to deliver enterprise mobility by providing on-premises roaming communications to the users with wireless IP telephony devices.

Wireless IP telephony and wireless IP video telephony are extensions of their wired counterparts, which leverage the same call elements. Additionally, wireless IP telephony and IP video telephony take advantage of wireless 802.11-enabled media, thus providing a cordless IP voice and video experience. The cordless experience is achieved by leveraging the wireless network infrastructure elements for the transmission and reception of the control and media packets.

The architecture for voice and video over wireless LAN includes the following basic elements, illustrated in [Figure 3-18](#):

- [Wireless Access Points, page 3-58](#)
- [Wireless LAN Controllers, page 3-59](#)
- [Authentication Database, page 3-59](#)
- [Supporting Wired Network, page 3-59](#)
- [Wireless Unified Communications Endpoints, page 3-60](#)
- [Wired Call Elements, page 3-60](#)

Figure 3-18 Basic Layout for a Voice and Video Wireless Network

Wireless Access Points

The wireless access points enable wireless devices (Unified Communications endpoints in the case of voice and video over WLAN) to communicate with wired network elements. Access points function as adapters between the wired and wireless world, creating an entry-way between these two media. Cisco access points can be managed by a wireless LAN controller (WLC) or they can function in autonomous mode. When the access points are managed by a WLC they are referred as Lightweight Access Points, and in this mode they use the Lightweight Access Point Protocol (LWAPP) or Control and Provisioning of Wireless Access Points (CAPWAP) protocol, depending on the controller version, when communicating with the WLC.

Figure 3-19 illustrates the basic relationship between lightweight access points and WLCs. Although the example depicted in Figure 3-19 is for a CAPWAP WLC, from the traffic flow and relationship perspective there are no discernible differences between CAPWAP and LWAPP, so the example also applies to wireless LWAPP networks. Some advantages of leveraging WLCs and lightweight access points for the wireless infrastructure include ease of management, dynamic network tuning, and high availability. However, if you are using the managed mode instead of the autonomous mode in the access points, you need to consider the network tunneling effect of the LWAPP-WLC communication architecture when designing your solution. This network tunneling effect is discussed in more depth in the section on [Wireless LAN Controller Design Considerations](#), page 3-68.

Figure 3-19 Lightweight Access Point

Wireless LAN Controllers

Many corporate environments require deployment of wireless networks on a large scale. The wireless LAN controller (WLC) is a device that assumes a central role in the wireless network and helps to make it easier to manage such large-scale deployments. Traditional roles of access points, such as association or authentication of wireless clients, are done by the WLC. Access points, called Lightweight Access Points (LWAPs) in the Unified Communications environment, register themselves with a WLC and tunnel all the management and data packets to the WLCs, which then switch the packets between wireless clients and the wired portion of the network. All the configurations are done on the WLC. LWAPs download the entire configuration from WLCs and act as a wireless interface to the clients.

Authentication Database

The authentication database is a core component of the wireless networks, and it holds the credentials of the users to be authenticated while the wireless association is in progress. The authentication database provides the network administrators with a centralized repository to validate the credentials. Network administrators simply add the wireless network users to the authentication database instead of having to add the users to all the wireless access points with which the wireless devices might associate.

In a typical wireless authentication scenario, the WLC couples with the authentication database to allow the wireless association to proceed or fail. Authentication databases commonly used are LDAP and RADIUS, although under some scenarios the WLC can also store a small user database locally that can be used for authentication purposes.

Supporting Wired Network

The supporting wired network is the portion of the system that serves as a path between WLCs, APs, and wired call elements. Because the APs need or might need to communicate to the wired world, part of the wired network has to enable those communications. The supporting wired network consists of the switches, routers, and wired medium (WAN links and optical links) that work together to communicate with the various components that form the architecture for voice and video over WLAN.

Wireless Unified Communications Endpoints

The wireless Unified Communications endpoints are the components of the architecture for voice and video over WLAN that users employ to communicate with each other. These endpoints can be voice-only or enabled for both voice and video. When end users employ the wireless communications endpoints to call a desired destination, the endpoints in turn forward the request to their associated call processing server. If the call is allowed, the endpoints process the voice or video, encode it, and send it to the receiving device or the next hop of processing. Typical Cisco wireless Unified Communications endpoints are wireless IP phones, voice and video software clients running on desktop computers, mobile smart phones connected through wireless media, and mobile collaboration enterprise tablets.

Wired Call Elements

Whether the wireless Unified Communications endpoints initiate a session between each other or with wired endpoints, wired call elements are involved in some way. Wired call elements are the supporting Unified Communications infrastructure (gateways and call processing entities), with voice and video endpoints coupled to that infrastructure.

Wired call elements are needed typically to address two requirements:

- [Call Control, page 3-60](#)
- [Media Termination, page 3-60](#)

Call Control

Cisco wireless Unified Communications endpoints require a call control or call processing server to route calls efficiently and to provide a feature-rich experience for the end users. The call processing entity resides somewhere in the wired network, either in the LAN or across a WAN.

Call control for the Cisco wireless Unified Communications endpoints is achieved through a call control protocol, either SIP or SCCP.

Media Termination

Media termination on wired Unified Communications endpoints occurs when the end users of the wireless Unified Communications endpoints communicate with IP phones, PSTN users, or video endpoints. Voice gateways, IP phones, video terminals, PBX trunks, and transcoders all serve as termination points for media when a user communicates through them. This media termination occurs by means of coding and decoding of the voice or video session for the user communication.

High Availability for Voice and Video over WLAN

Providing high availability in Unified Communications solutions is a critical requirement for meeting the modern demands of continuous connectivity. Unified Communications deployments designed for high availability increase reliability and up time. Using real-time applications such as voice or video over WLAN without high availability could have very adverse effects on the end user experience, including an inability to make voice or video calls.

Designing a solution for voice and video over WLAN with high availability requires focusing of the following main areas:

- [Supporting Wired Network High Availability, page 3-61](#)
- [WLAN High Availability, page 3-61](#)
- [Call Processing High Availability, page 3-63](#)

Supporting Wired Network High Availability

When deploying voice and video over WLAN, the same high-availability strategies used in wired networks can be applied to the wired components of the solution for voice and video over WLAN. For example, you can optimize layer convergence in the network to minimize disruption and take advantage of equal-cost redundant paths.

See [LAN Design for High Availability, page 3-4](#), for further information about how to design highly available wired networks.

WLAN High Availability

A unique aspect of high availability for voice and video over WLAN is high availability of radio frequency (RF) coverage to provide Wi-Fi channel coverage that is not dependent upon a single WLAN radio. The Wi-Fi channel coverage is provided by the AP radios in the 2.4 GHz and 5 GHz frequency bands. The primary mechanism for providing RF high availability is cell boundary overlap. In general, a cell boundary overlap of 20% to 30% on non-adjacent channels is recommended to provide high availability in the wireless network. For mission-critical environments there should be at least two APs visible at the required signal level (-67 dBm or better). An overlap of 20% means that the RF cells of APs using non-adjacent channels overlap each other on 20% of their coverage area, while the remaining 80% of the coverage area is handled by a single AP. [Figure 3-20](#) depicts a 20% overlap of AP non-adjacent channel cells to provide high availability. Furthermore, when determining the locations for installing the APs, avoid mounting them on reflective surfaces (such as metal, glass, and so forth), which could cause multi-path effects that result in signal distortion.

Figure 3-20 Non-Adjacent Channel Access Point Overlap

Careful deployment of APs and channel configuration within the wireless infrastructure are imperative for proper wireless network operation. For this reason, Cisco requires customers to conduct a complete and thorough site survey before deploying wireless networks in a production environment. The survey should include verifying non-overlapping channel configurations, Wi-Fi channel coverage, and required data and traffic rates; eliminating rogue APs; and identifying and mitigating the impact of potential interference sources.

Additionally, evaluate utilizing a 5 GHz frequency band, which is generally less crowded and thus usually less prone to interference. If Bluetooth is used then 5 GHz 802.11a is highly recommended. Similarly, the usage of Cisco CleanAir technology will increase the WLAN reliability by detecting radio frequency interference in real time and providing a self-healing and self-optimizing wireless network. For further information about Cisco CleanAir technology, refer to the product documentation available at

<http://www.cisco.com/en/US/netsol/ns1070/index.html>

For further information on how to provide high availability in a WLAN that supports rich media, refer to the *Voice over Wireless LAN Design Guide*, available at

http://www.cisco.com/en/US/solutions/ns340/ns414/ns742/ns820/landing_voice_wireless.html

Call Processing High Availability

For information regarding call processing resiliency, see [High Availability for Call Processing, page 8-15](#).

Capacity Planning for Voice and Video over WLAN

A crucial piece in planning for voice and video over WLAN is adequately sizing the solution for the desired call capacity. Capacity is defined as the number of simultaneous voice and video sessions over WLAN that can be supported in a given area. Capacity can vary depending upon the RF environment, the Unified Communications endpoint features, and the WLAN system features. For instance, a solution using Cisco Unified Wireless IP Phones 7925G on a WLAN that provides optimized WLAN services (such as the Cisco Unified Wireless Network) would have a maximum call capacity of 27 simultaneous sessions per channel at a data rate of 24 Mbps or higher for both 802.11a and 802.11g. On the other hand, a similar solution using only Cisco Cius making video calls at 720p and a video rate of 2,500 kbps on a WLAN, where access points are configured as 802.11a/n with a data rate index of Modulation and Coding Scheme 7 in 40 MHz channels, would have a maximum capacity of 7 video calls (two bidirectional voice and video streams) per channel.

To achieve these capacities, there must be minimal wireless LAN background traffic and radio frequency (RF) utilization, and Bluetooth must be disabled in the devices. It is also important to understand that call capacities are established per non-overlapping channel because the limiting factor is the channel capacity and not the number of access points (APs).

The call capacity specified by the actual wireless Unified Communications endpoint should be used for deployment purposes because it is the supported capacity of that endpoint. For capacity information about the wireless endpoints, refer to the following documentation:

- Cisco Unified IP Phones 7900 Series Design Guides
http://www.cisco.com/en/US/products/hw/phones/ps379/products_implementation_design_guides_list.html
- Cisco Unified IP Phones 9900 Series Deployment Guide
http://www.cisco.com/en/US/products/ps10453/products_implementation_design_guides_list.html
- Cisco Cius Deployment Guide
http://www.cisco.com/en/US/products/ps11156/products_implementation_design_guides_list.html

For further information about calculating call capacity in a WLAN, refer to the *Voice over Wireless LAN Design Guide*, available at

http://www.cisco.com/en/US/solutions/ns340/ns414/ns742/ns820/landing_voice_wireless.html

Design Considerations for Voice and Video over WLAN

This section provides additional design considerations for deploying Unified Communications endpoints over WLAN solutions. WLAN configuration specifics can vary depending on the voice or video WLAN devices being used and the WLAN design. The following sections provide general guidelines and best practices for designing the WLAN infrastructure:

- [VLANs, page 3-64](#)
- [Roaming, page 3-64](#)
- [Wireless Channels, page 3-65](#)

- [Wireless Interference and Multipath Distortion, page 3-66](#)
- [Multicast on the WLAN, page 3-66](#)
- [Wireless AP Configuration and Design, page 3-67](#)
- [Wireless LAN Controller Design Considerations, page 3-68](#)
- [WAN Quality of Service \(QoS\), page 3-40](#)

VLANs

Just as with a wired LAN infrastructure, when deploying voice or video in a wireless LAN, you should enable at least two virtual LANs (VLANs) at the Access Layer. The Access Layer in a wireless LAN environment includes the access point (AP) and the first-hop access switch. On the AP and access switch, you should configure both a native VLAN for data traffic and a voice VLAN (under Cisco IOS) or Auxiliary VLAN (under CatOS) for voice traffic. This auxiliary voice VLAN should be separate from all the other wired voice VLANs in the network. However, when the wireless clients (for example, smart phones or software rich-media clients) do not support the concept of an auxiliary VLAN, alternative packet marking strategies (for example, packet classification per port) must be applied to segregate the important traffic such as voice and video and treat it with priority. When deploying a wireless infrastructure, Cisco also recommends configuring a separate management VLAN for the management of WLAN APs. This management VLAN should not have a WLAN appearance; that is, it should not have an associated service set identifier (SSID) and it should not be directly accessible from the WLAN.

Roaming

To improve the user experience, Cisco recommends designing the cell boundary distribution with a 20% to 30% overlap of non-adjacent channels to facilitate seamless roaming of the wireless client between access points. Furthermore, when devices roam at Layer 3, they move from one AP to another AP across native VLAN boundaries. When the WLAN infrastructure consists of autonomous APs, a Cisco Wireless LAN Controller allows the Cisco Unified Wireless endpoints to keep their IP addresses and roam at Layer 3 while still maintaining an active call. Seamless Layer 3 roaming occurs only when the client is roaming within the same mobility group. For details about the Cisco Wireless LAN Controller and Layer 3 roaming, refer to the product documentation available at

<http://www.cisco.com/en/US/products/hw/wireless/index.html>

Seamless Layer 3 roaming for clients across a lightweight access point infrastructure is accomplished by WLAN controllers that use dynamic interface tunneling. Cisco Wireless Unified Communications endpoints that roam across WLAN controllers and VLANs can keep their IP address when using the same SSID and therefore can maintain an active call.

Note

In dual-band WLANs (those with 2.4 GHz and 5 GHz bands), it is possible to roam between 802.11b/g and 802.11a with the same SSID, provided the client is capable of supporting both bands. However, this can cause gaps in the voice path. If Cisco Unified Wireless IP Phones 7921 or 7925 are used, make sure that firmware version 1.3(4) or higher is installed on the phones to avoid these gaps; otherwise use only one band for voice. (The Cisco Unified Wireless IP Phone 7926 provides seamless inter-band roaming from its first firmware version.)

Wireless Channels

Wireless endpoints and APs communicate by means of radios on particular channels. When communicating on one channel, wireless endpoints typically are unaware of traffic and communication occurring on other non-overlapping channels.

Optimal channel configuration for 2.4 GHz 802.11b/g/n requires a minimum of five-channel separation between configured channels to prevent interference or overlap between channels. Non-overlapping channels have 22 MHz of separation. Channel 1 is 2.412 GHz, channel 6 is 2.437 GHz, and channel 11 is 2.462 GHz. In North America, with allowable channels of 1 to 11, channels 1, 6, and 11 are the three usable non-overlapping channels for APs and wireless endpoint devices. However, in Europe where the allowable channels are 1 to 13, multiple combinations of five-channel separation are possible. Multiple combinations of five-channel separation are also possible in Japan, where the allowable channels are 1 to 14.

Optimal channel configuration for 5 GHz 802.11a and 802.11n requires a minimum of one-channel separation to prevent interference or overlap between channels. In North America, there are 20 possible non-overlapping channels: 36, 40, 44, 48, 52, 56, 60, 64, 100, 104, 108, 112, 116, 132, 136, 140, 149, 153, 157, and 161. Europe and Japan allow 16 possible non-overlapping channels: 36, 40, 44, 48, 52, 56, 60, 64, 100, 104, 108, 112, 116, 132, 136, and 140. Because of the larger set of non-overlapping channels, 802.11a and 5 GHz 802.11n allow for more densely deployed WLANs; however, Cisco recommends not enabling all channels but using a 12-channel design instead.

Note that the 802.11a and 802.11n bands (when using channels operating at 5.25 to 5.725 GHz, which are 15 of the 24 possible channels) do require support for Dynamic Frequency Selection (DFS) and Transmit Power Control (TPC) on some channels in order to avoid interference with radar (military, satellite, and weather). Regulations require that channels 52 to 64, 100 to 116, and 132 to 140 support DFS and TPC. TPC ensures that transmissions on these channels are not powerful enough to cause interference. DFS monitors channels for radar pulses and, when it detects a radar pulse, DFS stops transmission on the channel and switches to a new channel.

AP coverage should be deployed so that no (or minimal) overlap occurs between APs configured with the same channel. Same-channel overlap should typically occur at 19 dBm of separation. However, proper AP deployment and coverage on non-overlapping channels requires a minimum overlap of 20%. This amount of overlap ensures smooth roaming for wireless endpoints as they move between AP coverage cells. Overlap of less than 20% can result in slower roaming times and poor voice quality.

Deploying wireless devices in a multi-story building such as an office high-rise or hospital introduces a third dimension to wireless AP and channel coverage planning. Both the 2.4 GHz and 5.0 GHz wave forms of 802.11 can pass through floors and ceilings as well as walls. For this reason, not only is it important to consider overlapping cells or channels on the same floor, but it is also necessary to consider channel overlap between adjacent floors. With the 2.4 GHz wireless spectrum limited to only three usable non-overlapping channels, proper overlap design can be achieved only through careful three-dimensional planning.

**Note**

Careful deployment of APs and channel configuration within the wireless infrastructure are imperative for proper wireless network operation. For this reason, Cisco requires that a complete and thorough site survey be conducted before deploying wireless networks in a production environment. The survey should include verifying non-overlapping channel configurations, AP coverage, and required data and traffic rates; eliminating rogue APs; and identifying and mitigating the impact of potential interference sources.

Wireless Interference and Multipath Distortion

Interference sources within a wireless environment can severely limit endpoint connectivity and channel coverage. In addition, objects and obstructions can cause signal reflection and multipath distortion. Multipath distortion occurs when traffic or signaling travels in more than one direction from the source to the destination. Typically, some of the traffic arrives at the destination before the rest of the traffic, which can result in delay and bit errors in some cases. You can reduce the effects of multipath distortion by eliminating or reducing interference sources and obstructions, and by using diversity antennas so that only a single antenna is receiving traffic at any one time. Interference sources should be identified during the site survey and, if possible, eliminated. At the very least, interference impact should be alleviated by proper AP placement and the use of location-appropriate directional or omni-directional diversity radio antennas.

Possible interference and multipath distortion sources include:

- Other APs on overlapping channels
- Other 2.4 GHz and 5 GHz devices, such as 2.4 GHz cordless phones, personal wireless network devices, sulphur plasma lighting systems, microwave ovens, rogue APs, and other WLAN equipment that takes advantage of the license-free operation of the 2.4 GHz and 5 GHz bands
- Metal equipment, structures, and other metal or reflective surfaces such as metal I-beams, filing cabinets, equipment racks, wire mesh or metallic walls, fire doors and fire walls, concrete, and heating and air conditioning ducts
- High-power electrical devices such as transformers, heavy-duty electric motors, refrigerators, elevators, and elevator equipment
- High-power electrical devices such as transformers, heavy-duty electric motors, refrigerators, elevators and elevator equipment, and any other power devices that could cause electromagnetic interference (EMI)

Because Bluetooth-enabled devices use the same 2.4 GHz radio band as 802.11b/g/n devices, it is possible that Bluetooth and 802.11b/g/n devices can interfere with each other, thus resulting in connectivity issues. Due to the potential for Bluetooth devices to interfere with and disrupt 802.11b/g/n WLAN voice and video devices (resulting in poor voice quality, de-registration, call setup delays, and/or reduce per-channel-cell call capacity), Cisco recommends, when possible, that you deploy all WLAN voice and video devices on the 5 GHz Wi-Fi band using 802.11a and/or 802.11n protocols. By deploying wireless clients on the 5 GHz radio band, you can avoid interference caused by Bluetooth devices. Additionally, Cisco CleanAir technology is recommended within the wireless infrastructure because it enables real-time interference detection. For more information about Cisco CleanAir technology, refer to the product documentation available at

<http://www.cisco.com/en/US/netsol/ns1070/index.html>

Note

802.11n can operate on both the 2.4 GHz and 5 GHz bands; however, Cisco recommends using 5 GHz for Unified Communications.

Multicast on the WLAN

By design, multicast does not have the acknowledgement level of unicast. According to 802.11 specifications, the access point must buffer all multicast packets until the next Delivery Traffic Indicator Message (DTIM) period is met. The DTIM period is a multiple of the beacon period. If the beacon period is 100 ms (typical default) and the DTIM value is 2, then the access point must wait up to 200 ms before transmitting a single buffered multicast packet. The time period between beacons (as a product of the DTIM setting) is used by battery-powered devices to go into power save mode temporarily. This power save mode helps the device conserve battery power.

Multicast on WLAN presents a twofold problem in which administrators must weigh multicast traffic quality requirements against battery life requirements. First, delaying multicast packets will negatively affect multicast traffic quality, especially for applications that multicast real-time traffic such as voice and video. In order to limit the delay of multicast traffic, DTIM periods should typically be set to a value of 1 so that the amount of time multicast packets are buffered is low enough to eliminate any perceptible delay in multicast traffic delivery. However, when the DTIM period is set to a value of 1, the amount of time that battery-powered WLAN devices are able to go into power save mode is shortened, and therefore battery life is shortened. In order to conserve battery power and lengthen battery life, DTIM periods should typically be set to a value of 2 or more.

For WLAN networks with no multicast applications or traffic, the DTIM period should be set to a value of 2 or higher. For WLAN networks where multicast applications are present, the DTIM period should be set to a value of 2 with a 100 ms beacon period whenever possible; however, if multicast traffic quality suffers or if unacceptable delay occurs, then the DTIM value should be lowered to 1. If the DTIM value is set to 1, administrators must keep in mind that battery life of battery-operated devices will be shortened significantly.

Before enabling multicast applications on the wireless network, Cisco recommends testing these applications to ensure that performance and behavior are acceptable.

For additional considerations with multicast traffic, see the chapter on [Media Resources, page 17-1](#).

Wireless AP Configuration and Design

Proper AP selection, deployment, and configuration are essential to ensure that the wireless network handles voice traffic in a way that provides high-quality voice to the end users.

AP Selection

For recommends on deploying access points for wireless voice, refer to the documentation at http://www.cisco.com/en/US/products/ps5678/Products_Sub_Category_Home.html.

AP Deployment

The number of devices active with an AP affects the amount of time each device has access to the transport medium, the Wi-Fi channel. As the number of devices increases, the traffic contention increases. Associating more devices to the AP and the bandwidth of the medium can result in poor performance and slower response times for all the endpoint devices associated to the AP.

While there is no specific mechanism prior to Cisco Wireless LAN Controller release 7.2 to ensure that only a limited number of devices are associated to a single AP, system administrators can manage device-to-AP ratios by conducting periodic site surveys and analyzing user and device traffic patterns. If additional devices and users are added to the network in a particular area, additional site surveys should be conducted to determine whether additional APs are required to handle the number of endpoints that need to access the network.

Additionally, APs that support Cisco CleanAir technology should be considered because they provide the additional function of remote monitoring of the Wi-Fi channel.

AP Configuration

When deploying wireless voice, observe the following specific AP configuration requirements:

- Enable Address Resolution Protocol (ARP) caching.

ARP caching is required on the AP because it enables the AP to answer ARP requests for the wireless endpoint devices without requiring the endpoint to leave power-save or idle mode. This feature results in extended battery life for the wireless endpoint devices.

- Enable Dynamic Transmit Power Control (DTPC) on the AP.
This ensures that the transmit power of the AP matches the transmit power of the voice endpoints. Matching transmit power helps eliminate the possibility of one-way audio traffic. Voice endpoints adjust their transmit power based on the Limit Client Power (mW) setting of the AP to which they are associated.
- Assign a Service Set Identifier (SSID) to each VLAN configured on the AP.
SSIDs enable endpoints to select the wireless VLAN they will use for sending and receiving traffic. These wireless VLANs and SSIDs map to wired VLANs. For voice endpoints, this mapping ensures priority queuing treatment and access to the voice VLAN on the wired network.
- Enable **QoS Element for Wireless Phones** on the AP.
This feature ensures that the AP will provide QoS Basic Service Set (QBSS) information elements in beacons. The QBSS element provides an estimate of the channel utilization on the AP, and Cisco wireless voice devices use it to help make roaming decisions and to reject call attempts when loads are too high. The APs also provide 802.11e clear channel assessment (CCA) QBSS in beacons. The CCA-based QBSS values reflect true channel utilization.
- Configure two QoS policies on the AP, and apply them to the VLANs and interfaces.
To ensure that voice traffic is given priority queuing treatment, configure a voice policy and a data policy with default classifications for the respective VLANs. (See [Interface Queuing](#), page 3-70, for more information).

Wireless LAN Controller Design Considerations

When designing a wireless network that will service voice or video, it is important to consider the role that the wireless LAN controller plays with regard to the voice and video media path if the access points used are not autonomous or stand alone. Because all wireless traffic is tunneled to its correspondent wireless LAN controller regardless of its point of origin and destination, it is critical to adequately size the network connectivity entry points of the wireless controllers. [Figure 3-21](#) is a representation of this problem. If any Cisco Cius tries to call another Cius, the traffic has to be hairpinned in the wireless LAN controller and sent to the receiving device. This includes the scenario where both devices are associated to the same AP.

The switch ports where the wireless LAN controllers are connected should provide enough bandwidth coverage for the traffic generated by the Unified Communications devices, whether they are video or voice endpoints and whether their traffic is control or media traffic.

Figure 3-21 Traffic Concentrated at the Wireless LAN Controller Network Entry Point

284268

Additionally, the switch interface and switch platform egress buffer levels should match the maximum combined burst you plan to support in your wireless network.

Failure to select adequate buffer levels could lead to packet drops and severely affect the user experience of video over a wireless LAN, while lack of bandwidth coverage would cause packets to be queued and in extreme cases cause delayed packets

WLAN Quality of Service (QoS)

Just as QoS is necessary for the LAN and WAN wired network infrastructure in order to ensure high voice quality, QoS is also required for the wireless LAN infrastructure. Because of the bursty nature of data traffic and the fact that real-time traffic such as voice and video are sensitive to packet loss and delay, QoS tools are required to manage wireless LAN buffers, limit radio contention, and minimize packet loss, delay, and delay variation.

However, unlike most wired networks, wireless networks are a shared medium, and wireless endpoints do not have dedicated bandwidth for sending and receiving traffic. While wireless endpoints can mark traffic with 802.1p CoS, ToS, DSCP, and PHB, the shared nature of the wireless network means limited admission control and access to the network for these endpoints.

Wireless QoS involves the following main areas of configuration:

- [Traffic Classification, page 3-70](#)
- [User Priority Mapping, page 3-70](#)
- [Interface Queuing, page 3-70](#)
- [Wireless Call Admission Control, page 3-71](#)

Traffic Classification

As with the wired network infrastructure, it is important to classify or mark pertinent wireless traffic as close to the edge of the network as possible. Because traffic marking is an entrance criterion for queuing schemes throughout the wired and wireless network, marking should be done at the wireless endpoint device whenever possible. Marking or classification by wireless network devices should be identical to that for wired network devices, as indicated in [Table 3-13](#).

In accordance with traffic classification guidelines for wired networks, the Cisco wireless Unified Communications endpoints mark voice media traffic or voice RTP traffic with DSCP 46 (or PHB EF), video media traffic or video RTP traffic with DSCP 34 (or PHB AF41), and call control signaling traffic (SCCP or SIP) with DSCP 24 (or PHB CS3). Once this traffic is marked, it can be given priority or better than best-effort treatment and queuing throughout the network. All wireless voice and video devices that are capable of marking traffic should do it in this manner. All other traffic on the wireless network should be marked as best-effort or with some intermediary classification as outlined in wired network marking guidelines. If the wireless voice or video devices are unable to do packet marking, alternate methods such as port-based marking should be implemented to provide priority to video and voice traffic.

User Priority Mapping

While 802.1p and DSCP (Differentiated Service Code Point) are the standards to set priorities on wired networks, 802.11e is the standard used for wireless networks. This is commonly referred as User Priority (UP), and it is important to map the UP to its appropriate DSCP value. [Table 3-13](#) lists the values for Unified Communications traffic.

Table 3-13 QoS Traffic Classification

| Traffic Type | DSCP (PHB) | 802.1p UP | IEEE 802.11e UP |
|-------------------------|------------|-----------|-----------------|
| Voice | 46 (EF) | 5 | 6 |
| Video | 34 (AF41) | 4 | 5 |
| Voice and video control | 24 (CS3) | 3 | 4 |

For further information about 802.11e and its configuration, refer to your corresponding product documentation available at

http://www.cisco.com/en/US/products/ps6302/Products_Sub_Category_Home.html

Interface Queuing

Once traffic marking has occurred, it is necessary to enable the wired network APs and devices to provide QoS queuing so that voice and video traffic types are given separate queues to reduce the chances of this traffic being dropped or delayed as it traverses the wireless LAN. Queuing on the

wireless network occurs in two directions, upstream and downstream. Upstream queuing concerns traffic traveling from the wireless endpoint up to the AP, and from the AP up to the wired network. Downstream queuing concerns traffic traveling from the wired network to the AP and down to the wireless endpoint.

For upstream queuing, devices that support Wi-Fi Multimedia (WMM) are able to take advantage of queuing mechanisms, including priority queuing.

As for downstream QoS, Cisco APs currently provide up to eight queues for downstream traffic being sent to wireless clients. The entrance criterion for these queues can be based on a number of factors, including DSCP, access control lists (ACLs), and VLAN. Although eight queues are available, Cisco recommends using only two queues when deploying wireless voice. All voice media and signaling traffic should be placed in the highest-priority queue, and all other traffic should be placed in the best-effort queue. This ensures the best possible queuing treatment for voice traffic.

In order to set up this two-queue configuration for autonomous APs, create two QoS policies on the AP. Name one policy **Voice**, and configure it with the class of service **Voice < 10 ms Latency (6)** as the Default Classification for all packets on the VLAN. Name the other policy **Data**, and configure it with the class of service **Best Effort (0)** as the Default Classification for all packets on the VLAN. Then assign the Data policy to the incoming and outgoing radio interface for the data VLAN(s), and assign the Voice policy to the incoming and outgoing radio interfaces for the voice VLAN(s). With the QoS policies applied at the VLAN level, the AP is not forced to examine every packet coming in or going out to determine the type of queuing the packet should receive.

For lightweight APs, the WLAN controller has built-in QoS profiles that can provide the same queuing policy. Voice VLAN or voice traffic is configured to use the **Platinum** policy, which sets priority queuing for the voice queue. Data VLAN or data traffic is configured to use the **Silver** policy, which sets best-effort queuing for the Data queue. These policies are then assigned to the incoming and outgoing radio interfaces based on the VLAN.

The above configurations ensure that all voice and video media and signaling are given priority queuing treatment in a downstream direction.

**Note**

Because Wi-Fi Multimedia (WMM) access is based on Enhanced Distributed Channel Access (EDCA), it is important to assign the right priorities to the traffic to avoid Arbitration Inter-Frame Space (AIFS) alteration and delivery delay. For further information on Cisco Unified Wireless QoS, refer to the *Enterprise Mobility Design Guide*, available at http://www.cisco.com/en/US/solutions/ns340/ns414/ns742/ns820/landing_ent_mob_design.html.

Wireless Call Admission Control

To avoid exceeding the capacity limit of a given AP channel, some form of call admission control is required. Cisco APs and wireless Unified Communications clients now use Traffic Specification (TSPEC) instead of QoS Basic Service Set (QBSS) for call admission control.

Wi-Fi Multimedia Traffic Specification (WMM TSPEC) is the QoS mechanism that enables WLAN clients to provide an indication of their bandwidth and QoS requirements so that APs can react to those requirements. When a client is preparing to make a call, it sends an Add Traffic Stream (ADDTS) message to the AP with which it is associated, indicating the TSPEC. The AP can then accept or reject the ADDTS request based on whether bandwidth and priority treatment are available. If the call is rejected, the client receives a Network Busy message. If the client is roaming, the TSPEC request is embedded in the re-association request message to the new AP as part of the association process, and the TSPEC response is embedded in the re-association response.

Alternatively, endpoints without WMM TSPEC support, but using SIP as call signaling, can be managed by the AP. Media snooping must be enabled for the service set identifier (SSID). The client's implementation of SIP must match that of the Wireless LAN Controller, including encryption and port numbers. For details about media snooping, refer to the *Cisco Wireless LAN Controller Configuration Guide*, available at

<http://www.cisco.com/en/US/docs/wireless/controller/7.0/configuration/guide/c70wlan.html>

**Note**

Currently there is no call admission control support for video. The QoS Basic Service Set (QBSS) information element is sent by the AP only if **QoS Element for Wireless Phones** has been enable on the AP. (Refer to [Wireless AP Configuration and Design, page 3-67.](#))

Service Advertisement Framework (SAF)

The Cisco Service Advertisement Framework (SAF) enables networking applications to advertise and discover information about networked services within an IP network. SAF consists of the following functional components and protocols:

- SAF Clients advertise and consume information about services.
- SAF Forwarders distribute and maintain SAF service availability information.
- SAF Client Protocol is used between SAF Clients and SAF Forwarders.
- SAF Forwarder Protocol is used between SAF Forwarders.

The nature of the advertised service is unimportant to the network of SAF Forwarders. The SAF Forwarder protocol is designed to dynamically distribute information about the availability of services to SAF client applications that have registered to the SAF network.

Services that SAF Can Advertise

In theory, any service can be advertised through SAF. The first service to use SAF is Cisco Unified Communications Call Control Discovery (CCD). CCD uses SAF to distribute and maintain information about the availability of internal directory numbers (DNs) hosted by call control agents such as Cisco Unified CM and Unified CME. CCD also distributes the corresponding number prefixes that allow these internal directory numbers to be reached from the PSTN ("To PSTN" prefixes).

The dynamic nature of SAF and the ability for call agents to advertise the availability of their hosted DN ranges and To PSTN prefixes to other call agents in a SAF network, provides distinct advantages over other static and more labor-intensive methods of dial plan distribution. For more information on SAF CCD, see [Call Routing and Dial Plan Distribution Using Call Control Discovery for the Service Advertisement Framework, page 5-64.](#)

SAF Networks

SAF networks contain a number of functional components, as described in the following sections.

SAF Forwarders, SAF Clients, and non-SAF Networks

In a Cisco SAF network, service information is distributed through a network of SAF-capable nodes that assume specific functions to efficiently distribute knowledge of services and facilitate their discovery. Cisco SAF network nodes are classified by two functional responsibilities:

- SAF Forwarder
- SAF Client

To configure a Cisco SAF network, you must configure both SAF Forwarders and SAF Clients. The flexibility of Cisco SAF allows you to configure a single edge router to act as a Cisco SAF Forwarder and a Cisco SAF Client, if necessary.

The following platforms support the SAF Forwarder:

- Cisco Integrated Services Routers (ISR), ISR Generation 2 (ISR G2), and 7200 Series Routers with Cisco IOS Release 15.0(1)M (See <http://www.cisco.com/ios/release/15mt>)
- Cisco 7600 Series Routers with Cisco IOS Release 12.2(33)SRE
- Cisco ASR 1000 Series Aggregation Services Routers with Cisco IOS Release 12.2XE 2.5.0 (RLS5)

The following platforms support the SAF Client:

- Cisco Integrated Services Routers (ISR) and ISR Generation 2 (ISR G2) with Cisco IOS Release 15.0(1)M (See <http://www.cisco.com/ios/release/15mt>)
- Cisco Unified Communications Manager 8.0(1) and higher versions

Cisco SAF Forwarder

The SAF Forwarder runs on a Cisco IOS router. A Cisco SAF Forwarder receives services advertised by Cisco SAF Clients, distributes the services reliably throughout the network of SAF Forwarders, and makes services available for Cisco SAF Clients to use.

Cisco SAF Forwarders use IP multicast to automatically discover and communicate as peers with other Cisco SAF Forwarders on a LAN. On networks that do not support IP multicast, SAF Forwarders can connect statically as peers by creating unicast point-to-point adjacencies with SAF neighbors.

To enable SAF within a network, you need to configure only a subset of the routers as SAF Forwarders. Once peer relationships have been created between the SAF Forwarders, the TCP/IP-based SAF messages exchanged between SAF Forwarders can traverse any IP network. Networks of non-SAF routers and SAF routers can run any IP routing protocol.

The SAF Forwarder Protocol (SAF-FP) is a "service" routing protocol, not an IP routing protocol. The SAF Forwarder Protocol routes information about services over IP networks. SAF-FP is based on EIGRP technology and takes advantage of many of the features historically developed for EIGRP-based IP routing, applying this functionality to the distribution of service information.

The SAF-Forwarder Protocol has the following characteristics:

- Uses the DUAL algorithm and split horizon rule to prevent routing loops
- Does not send periodic broadcasts, but sends updates only when changes occur
- Uses a keep-alive mechanism to track the availability of peer SAF Forwarders

- Is scalable and provides fast convergence when a SAF Forwarder fails
- Provides methods for SAF peer (neighbor) authentication

A Cisco SAF Forwarder provides the basis of the relationship between a Cisco SAF Client and the SAF network. Cisco SAF Forwarders may be located anywhere within the network but are normally located at the edges, or boundaries, of a network. (See Figure 3-22.) The Client/Forwarder relationship is used to maintain the state of each advertised service. If a Client removes a service or disconnects from the Forwarder node, the node informs the SAF network about the services that are no longer available. When a SAF Forwarder node receives advertisements from other Forwarder nodes, it keeps a copy of the entire advertisement and then forwards it to other SAF peers.

Figure 3-22 SAF Clients, SAF Forwarders, and Adjacencies Across Non-SAF Networks

Cisco SAF Client Overview

A Cisco SAF Client can be a producer of services (advertises services to the SAF network), a consumer of services (requests one or more services from the SAF network), or both. SAF clients perform three basic functions:

- Registering with the SAF network
- Publishing services
- Subscribing to services

SAF Clients take two forms (see [Figure 3-23](#)):

- Internal SAF clients

An internal SAF client resides on the same Cisco IOS platform as the SAF Forwarder. The Client/Forwarder connection is established through an internal application programming interface (API). Call control applications that reside in Cisco IOS, such as Cisco Unified Communications Manager Express (Unified CME), can use the internal SAF client to connect to a co-resident internal SAF Forwarder.

- External SAF clients

External SAF clients do not reside within Cisco IOS, and they use the SAF Client Protocol (SAF-CP) to communicate to a Cisco IOS-based SAF Forwarder. An external Cisco SAF client, such as the SAF client used by Cisco Unified CM, initiates a TCP/IP connection to a Cisco SAF Forwarder through a configured IP address and port number.

Figure 3-23 External and Internal SAF Clients and SAF Forwarders

Once the connection between the Client and Forwarder is established, the Cisco SAF Client sends a Register message to the Cisco SAF Forwarder. This register message uses a handle (called a "client label") to uniquely identify the Cisco SAF Client from all other Cisco SAF Clients connected to the Cisco SAF Forwarder. Once the Cisco SAF Client has completed its registration with the SAF Forwarder, it can then advertise (publish) services to, or request (subscribe) services from, the SAF network.

When advertising a service, a Cisco SAF Client publishes (sends) advertisements that contain details of the offered service to the Cisco SAF Forwarder. The Cisco SAF Client can send multiple publish requests, each advertising a distinct service. The Cisco SAF Forwarder advertises all services published by the Cisco SAF Client.

When requesting a service, the Cisco SAF Client sends the Forwarder a subscribe request. The subscribe request contains a filter that describes the set of services in which the Cisco SAF Client is interested. In response to this request, the Cisco SAF Forwarder sends the current set of services that match the filter to the Cisco SAF Client in a series of notify requests. Multiple notify requests are sent in order to provide flow control, and the Cisco SAF Client must respond to each notify request before the Cisco SAF Forwarder sends the next request. As with a publish request, the Cisco SAF Client can generate multiple subscribe requests, each with a different filter. The Cisco SAF Client can also generate an unsubscribe request, which removes one of its existing subscriptions.

Cisco External SAF Client and SAF Forwarder Interaction

Client/Forwarder Authentication

During the establishment of the TCP/IP connection between an external SAF Client and SAF Forwarder, a shared secret consisting of a username and a password is used for authentication. The username is used as an index to determine which password to use as the shared secret. When a Cisco SAF Client sends a request, it sends attributes that include its username, the actual message contents, and the MD5 hash of the password. When a Cisco SAF Forwarder receives a request, it locates the username attribute and uses it to access its local copy of the password. It then computes the MD5 hash of its locally stored password. If the passwords match, the Cisco SAF Client is authenticated and the connection proceeds. A Cisco SAF Forwarder can also elect to reject the request.

Client /Forwarder Keepalive

Once a SAF client has published its services to the SAF network, the Cisco SAF Forwarder uses a keepalive mechanism to track the status of the Cisco SAF Client. A Cisco SAF Forwarder and a Cisco SAF Client exchange a keepalive timer value at the time of registration. A Cisco SAF Forwarder considers a Cisco SAF Client to have failed if it has not seen a request from the Cisco SAF Client in a time period equal to the keepalive timer value. A Cisco SAF Client ensures that the interval between requests never exceeds this value. If a Cisco SAF Client has no data to send, it generates a register message to refresh the timer.

When a Cisco SAF Forwarder detects that the Cisco SAF Client has failed, it withdraws the services advertised on behalf of that Cisco SAF Client from the network and removes any subscriptions that the Cisco SAF Client had established. A Cisco SAF Client can be unregistered manually to cause a Cisco SAF Forwarder to withdraw all services and subscriptions gracefully.

SAF Forwarder Deployment Options

To enable SAF in a Unified Communications network, you must add one or more SAF Forwarders to the Unified Communications network. For Cisco IOS call control applications such as Unified CME, the SAF Client and Forwarder are co-resident on the router and can be used to interconnect to other SAF Forwarders in the SAF network. Non-IOS call control applications that use an External SAF Client, such as Unified CM, must connect to a Cisco IOS SAF Forwarder configured in the Unified Communications network. SAF Forwarders that are not co-resident with call control applications can be placed anywhere in the network. The number and location of these Forwarders largely depend on the degree of resilience and redundancy required within the SAF network. To provide redundancy, a minimum of two SAF Forwarders are required (see [Figure 3-24](#).) Additional SAF Forwarders can be added to the SAF network to provide additional redundancy and local SAF Forwarder resources for each grouping of Unified CM clusters (see [Figure 3-25](#)). With the initial version of SAF for Cisco IOS Release 15.0(1) on Cisco ISR and 7200 Series Routers, up to 50 clients can connect to a single SAF Forwarder.

Figure 3-24 SAF Network with Two Dedicated SAF Forwarders and Two Unified CME SAF Forwarders

253799

Figure 3-25 SAF Network with Multiple Redundant Dedicated SAF Forwarders and Two Unified CME SAF Forwarders

SAF Autonomous Systems

Similar to IP routing protocols, SAF uses the concept of an autonomous system (AS) to define the boundaries of a SAF network and the common SAF Forwarders within that SAF network. (See [Figure 3-26](#).) The majority of SAF deployments require only a single SAF AS; however, in some cases (for example, where segregation of SAF services is required) multiple SAF ASs may be deployed. Each external SAF client can connect and publish to a single SAF AS. If you deploy multiple External SAF clients in a Unified CM cluster, the cluster can publish services into multiple SAF ASs and receive advertisements from each AS. Internal SAF clients can publish and subscribe to any number of Cisco IOS co-resident SAF ASs. Redistribution of SAF Services between SAF ASs is not available today.

Figure 3-26 SAF Autonomous Systems

SAF Forwarder Loopback Addresses and Split Horizon

In Figure 3-27, if loopback addresses are used in the configuration of the SAF Forwarders, the split horizon rule comes into effect and the central SAF Forwarder does not forward advertisements between spoke Forwarders. To allow the central SAF Forwarder to forward advertisements between spoke Forwarders (and hence avoid the need to configure a full mesh of SAF peers), use the **no split horizon** command under the loopback interface of the central SAF Forwarder.

Figure 3-27 SAF and Split Horizon

For more information on Cisco IOS SAF configuration, refer to the *Cisco IOS Service Advertisement Framework Configuration Guide*, available at

http://www.cisco.com/en/US/docs/ios/saf/configuration/guide/15_0/saf_15_0_book.html

CHAPTER 4

Unified Communications Security

Revised: February 29, 2012; OL-21733-18

Securing the various components in a Cisco Unified Communications System is necessary for protecting the integrity and confidentiality of voice calls.

This chapter presents security guidelines pertaining specifically to Unified Communications technology and the voice network. For more information on data network security, refer to the Cisco SAFE Blueprint documentation available at

http://www.cisco.com/en/US/netsol/ns744/networking_solutions_program_home.html

Following the guidelines in this chapter does not guarantee a secure environment, nor will it prevent all penetration attacks on a network. You can achieve reasonable security by establishing a good security policy, following that security policy, staying up-to-date on the latest developments in the hacker and security communities, and maintaining and monitoring all systems with sound system administration practices.

This chapter addresses centralized and distributed call processing, including clustering over the WAN but not local failover mechanisms such as Survivable Remote Site Telephony (SRST). This chapter assumes that all remote sites have a redundant link to the head-end or local call-processing backup in case of head-end failure. The interaction between Network Address Translation (NAT) and IP Telephony, for the most part, is not addressed here. This chapter also assumes that all networks are privately addressed and do not contain overlapping IP addresses.

What's New in This Chapter

Table 4-1 lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Table 4-1 *New or Changed Information Since the Previous Release of This Document*

| New or Revised Topic | Described in: | Revision Date |
|---|---|----------------------|
| Security Enhanced Linux (SELinux) | SELinux, page 4-39 | February 29, 2012 |
| Minor corrections and changes | Various sections throughout this chapter | October 31, 2011 |
| Authentication certificates | Phone Authentication and Encryption, page 4-20 | June 2, 2011 |
| Single sign-on | Single Sign-On, page 4-38 | June 2, 2011 |
| Adaptive Security Appliance (ASA) support for IPv6 | Firewalls, page 4-24 | January 31, 2011 |
| Application inspection | Firewalls, page 4-24 | January 31, 2011 |
| 802.1X authentication | 802.1X Port-Based Authentication, page 4-15 | July 23, 2010 |
| Adaptive Security Appliance (ASA) Unified Communications Proxy features | ASA Unified Communications Proxy Feature, page 4-27 | April 2, 2010 |

General Security

This section covers general security features and practices that can be used to protect the voice data within a network.

Security Policy

Cisco Systems recommends creating a security policy associated with every network technology deployed within your enterprise. The security policy defines which data in your network is sensitive so that it can be protected properly when transported throughout the network. Having this security policy helps you define the security levels required for the types of data traffic that are on your network. Each type of data may or may not require its own security policy.

If no security policy exists for data on the company network, you should create one before enabling any of the security recommendations in this chapter. Without a security policy, it is difficult to ascertain whether the security that is enabled in a network is doing what it is designed to accomplish. Without a security policy, there is also no systematic way of enabling security for all the applications and types of data that run in a network.

**Note**

While it is important to adhere to the security guidelines and recommendations presented in this chapter, they alone are not sufficient to constitute a security policy for your company. You must define a corporate security policy before implementing any security technology.

This chapter details the features and functionality of a Cisco Systems network that are available to protect the Unified Communications data on a network. It is up to the security policy to define which data to protect, how much protection is needed for that type of data, and which security techniques to use to provide that protection.

One of the more difficult issues with a security policy that includes IP Telephony is combining the security policies that usually exist for both the data network and the traditional voice network. Ensure that all aspects of the integration of the voice data onto the network are secured at the correct level for your security policy or corporate environment.

The basis of a good security policy is defining how important your data is within the network. Once you have ranked the data according to its importance, you can decide how the security levels should be established for each type of data. You can then achieve the correct level of security by using both the network and application features.

In summary, you can use the following process to define a security policy:

- Define the data that is on the network.
- Define the importance of that data.
- Apply security based on the importance of the data.

Security in Layers

This chapter starts with hardening the IP phone endpoints in a Cisco Unified Communications Solution and works its way through the network from the phone to the access switch, to the distribution layer, into the core, and then into the data center. (See Figure 4-1.) Cisco recommends building layer upon layer of security, starting at the access port into the network itself. This design approach gives a network architect the ability to place the devices where it is both physically and logically easy to deploy Cisco Unified Communications applications. But with this ease of deployment, the security complexity increases because the devices can be placed anywhere in a network as long as they have connectivity.

Figure 4-1 Layers of Security

148489

Secure Infrastructure

As the IP Telephony data crosses a network, that data is only as safe and secure as the devices that are transporting the data. Depending on the security level that is defined in your security policy, the security of the network devices might have to be improved or they might already be secure enough for the transportation of IP Telephony traffic.

There are many best practices within a data network that, if used, will increase the entire security of your network. For example, instead of using Telnet (which sends passwords in clear text) to connect to any of the network devices, use Secure Shell (SSH, the secure form of Telnet) so that an attacker would not be able to see a password in clear text.

Gateways and gatekeepers can be configured with Cisco IOS feature sets that provide the required voice functionality but support only Telnet and not Secure Shell (SSH). Cisco recommends that you use access control lists (ACLs) to control who is permitted to connect to the routers using Telnet. It is more secure to connect to the gatekeeper from a host that is in a secure segment of the network, because user names and passwords are sent over Telnet in clear text.

You should also use firewalls, access control lists, authentication services, and other Cisco security tools to help protect these devices from unauthorized access.

Physical Security

Just as a traditional PBX is usually locked in a secure environment, the IP network should be treated in a similar way. Each of the devices that carries IP Telephony traffic is really part of an IP PBX, and normal general security practices should be used to control access to those devices. Once a user or attacker has physical access to one of the devices in a network, all kinds of problems could occur. Even if you have excellent password security and the user or attacker cannot get into the network device, that does not mean that they cannot cause havoc in a network by simply unplugging the device and stopping all traffic.

For more information on general security practices, refer to the documentation at the following locations:

- http://www.cisco.com/en/US/netsol/ns744/networking_solutions_program_home.html
- http://www.cisco.com/en/US/products/svcs/ps2961/ps2952/serv_group_home.html

IP Addressing

IP addressing can be critical for controlling the data that flows in and out of the logically separated IP Telephony network. The more defined the IP addressing is within a network, the easier it becomes to control the devices on the network.

As stated in other sections of this document (see [Campus Access Layer, page 3-5](#)), you should use IP addressing based on RFC 1918. This method of addressing allows deployment of an IP Telephony system into a network without redoing the IP addressing of the network. Using RFC 1918 also allows for better control in the network because the IP addresses of the voice endpoints are well defined and easy to understand. If the voice endpoints are all addressed within a 10.x.x.x. network, access control lists (ACLs) and tracking of data to and from those devices are simplified.

If you have a well defined IP addressing plan for your voice deployments, it becomes easier to write ACLs for controlling the IP Telephony traffic and it also helps with firewall deployments.

Using RFC 1918 enables you easily to deploy one VLAN per switch, which is a best practice for campus design, and also enables you to keep the Voice VLAN free of any Spanning Tree Protocol (STP) loops.

If deployed correctly, route summarization could help to keep the routing table about the same as before the voice deployment, or just slightly larger.

IPv6 Addressing

The introduction of IPv6 addressing has extended the network address space and increased the options for privacy and security of endpoints. Though both IPv4 and IPv6 have similar security concerns, IPv6 provides some advantages. For example, one of the major benefits with IPv6 is the enormous size of the subnets, which discourages automated scanning and reconnaissance attacks.

For a comparison of IPv6 and IPv4 in terms of security, refer to the *IPv6 and IPv4 Threat Comparison and Best-Practice Evaluation*, available at:

http://www.cisco.com/web/about/security/security_services/ciag/documents/v6-v4-threats.pdf

When considering IPv6 as your IP addressing method, adhere to the best practices documented in the following campus and branch office design guides:

- *Deploying IPv6 in Campus Networks*

<http://www.cisco.com/en/US/docs/solutions/Enterprise/Campus/CampIPv6.html>

- *Deploying IPv6 in Branch Networks*

<http://www.cisco.com/en/US/docs/solutions/Enterprise/Branch/BrchIPv6.html>

Access Security

This section covers security features at the Access level that can be used to protect the voice data within a network.

Voice and Video VLANs

Before the phone has its IP address, the phone determines which VLAN it should be in by means of the Cisco Discovery Protocol (CDP) negotiation that takes place between the phone and the switch. This negotiation allows the phone to send packets with 802.1q tags to the switch in a "voice VLAN" so that the voice data and all other data coming from the PC behind the phone are separated from each other at Layer 2. Voice VLANs are not required for the phones to operate, but they provide additional separation from other data on the network.

Voice VLANs can be assigned automatically from the switch to the phone, thus allowing for Layer 2 and Layer 3 separations between voice data and all other data on a network. A voice VLAN also allows for a different IP addressing scheme because the separate VLAN can have a separate IP scope at the Dynamic Host Configuration Protocol (DHCP) server.

Applications use CDP messaging from the phones to assist in locating phones during an emergency call. The location of the phone will be much more difficult to determine if CDP is not enabled on the access port to which that phone is attached.

There is a possibility that information could be gathered from the CDP messaging that would normally go to the phone, and that information could be used to discover some of the network. Not all devices that can be used for voice or video with Unified CM are able to use CDP to assist in discovering the voice VLAN.

Sony and Tandberg SCCP endpoints do not support Cisco Discovery Protocol (CDP) or 802.1Q VLAN ID tagging. To allow device discovery when third-party devices are involved, use the Link Layer Discovery Protocol (LLDP). LLDP for Media Endpoint Devices (LLDP-MED) is an extension to LLDP that enhances support for voice endpoints. LLDP-MED defines how a switch port transitions from LLDP to LLDP-MED if it detects an LLDP-MED-capable endpoint. Support for both LLDP and LLDP-MED on IP phones and LAN switches depends on the firmware and device models. To determine if LLDP-MED is supported on particular phone or switch models, check the specific product release notes or bulletins available at:

- http://www.cisco.com/en/US/products/hw/phones/ps379/prod_release_notes_list.html
- http://www.cisco.com/en/US/products/sw/iosswrel/ps5012/prod_bulletins_list.html

**Note**

If an IP phone with LLDP-MED capability is connected to a Cisco Catalyst switch running an earlier Cisco IOS release that does not support LLDP, the switch might indicate that an extra device has been connected to the switch port. This can happen if the Cisco Catalyst switch is using Port Security to count the number of devices connected. The appearance of an LLDP packet might cause the port count to increase and cause the switch to disable the port. Verify that your Cisco Catalyst switch supports LLDP, or increase the port count to a minimum of three, before deploying Cisco IP Phones with firmware that supports LLDP-MED Link Layer protocol.

Cisco Unified Video Advantage is a client application running on a PC, but it is also associated with an IP Phone. The PC will likely reside in the data VLAN while the phone will likely reside in the voice VLAN. To associate with the IP Phone, Cisco Unified Video Advantage uses the Cisco Audio Session Tunnel (CAST) protocol, which operates over TCP/IP. Therefore, Cisco Unified Video Advantage will have to communicate through whatever Layer 3 router is configured to route IP packets between the voice and data VLANs. If there are any access control lists or firewalls configured between those VLANs, they will have to be modified to permit the CAST protocol to operate. Fortunately, CAST uses TCP port 4224 in both directions, making this task easier. Cisco Unified Video Advantage communicates with the IP Phone but not with Unified CM, except when Cisco Unified Video Advantage periodically checks with the TFTP server (which could be co-resident on one or more of the Unified CM servers) to download any software updates. Therefore, you must also permit the TFTP protocol between the data VLAN and the TFTP server(s).

H.323 clients, Multipoint Control Units (MCUs), and gateways communicate with Unified CM using the H.323 protocol. Unified CM H.323 trunks (such as H.225 and intercluster trunk variants as well as the RASAggregator trunk type) use a random port range rather than the well-known TCP port 1720. Therefore, you must permit a wide range of TCP ports between these devices and the Unified CM servers. For port usage details, refer to the latest version of the *Cisco Unified Communications Manager TCP and UDP Port Usage* guide, available at:

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

MCUs and gateways are considered infrastructure devices, and they typically reside within the datacenter adjacent to the Unified CM servers. H.323 clients, on the other hand, typically reside in the data VLAN.

Cisco Unified Videoconferencing 3500 Series MCUs configured to run in SCCP mode communicate with the TFTP server(s) to download their configuration, with the Unified CM servers for signaling, and with other endpoints for RTP media traffic. Therefore, TFTP must be permitted between the MCU and

the TFTP server(s), TCP port 2000 must be permitted between the MCUs and the Unified CM server(s), and UDP ports for RTP media must be permitted between the MCUs and the voice, data, and gateway VLANs

Switch Port

There are many security features within a Cisco switch infrastructure that can be used to secure a data network. This section describes some of the features that can be used in Cisco Access Switches to protect the IP Telephony data within a network. (See Figure 4-2.) This section does not cover all of the security features available for all of the current Cisco switches, but it does list the most common security features used across many of the switches that Cisco manufactures. For additional information on the security features available on the particular Cisco gear deployed within your network, refer to the appropriate product documentation available at

<http://www.cisco.com>

Figure 4-2 A Typical Access Layer Design to Which the Phones Attach

Port Security: MAC CAM Flooding

A classic attack on a switched network is a MAC content-addressable memory (CAM) flooding attack. This type of attack floods the switch with so many MAC addresses that the switch does not know which port an end station or device is attached to. When the switch does not know which port a device is attached to, it broadcasts the traffic destined for that device to the entire VLAN. In this way, the attacker is able to see all traffic that is coming to all the users in a VLAN.

To disallow malicious MAC flooding attacks from hacker tools such as macof, limit the number of MAC addresses allowed to access individual ports based on the connectivity requirements for those ports. Malicious end-user stations can use macof to originate MAC flooding from random-source to random-destination MAC addresses, both directly connected to the switch port or through the IP phone. The macof tool is very aggressive and typically can fill a Cisco Catalyst switch content-addressable memory (CAM) table in less than ten seconds. The flooding of subsequent packets that remain unlearned because the CAM table is filled, is as disruptive and insecure as packets on a shared Ethernet hub for the VLAN that is being attacked.

Either port security or dynamic port security can be used to inhibit a MAC flooding attack. A customer with no requirement to use port security as an authorization mechanism would want to use dynamic port security with the number of MAC addresses appropriate to the function attached to a particular port. For example, a port with only a workstation attached to it would want to limit the number of learned MAC addresses to one. A port with a Cisco Unified IP Phone and a workstation behind it would want to set

the number of learned MAC addresses to two (one for the IP phone itself and one for the workstation behind the phone) if a workstation is going to plug into the PC port on the phone. This setting in the past has been three MAC addresses, used with the older way of configuring the port in trunk mode. If you use the multi-VLAN access mode of configuration for the phone port, this setting will be two MAC addresses, one for the phone and one for the PC plugged into the phone. If there will be no workstation on the PC port, then the number of MAC addresses on that port should be set to one. These configurations are for a multi-VLAN access port on a switch. The configuration could be different if the port is set to trunk mode (not the recommended deployment of an access port with a phone and PC).

Port Security: Gratuitous ARP

Just like any other data device on the network, the phones are vulnerable to traditional data attacks. The phones have features to prevent some of the common data attacks that can occur on a corporate network. One such feature is Gratuitous ARP (Gratuitous Address Resolution Protocol, or GARP). This feature helps to prevent man-in-the-middle (MITM) attacks to the phone. A MITM attack involves an attacker who tricks an end station into believing that he is the router and tricks the router into believing that he is the end station. This scheme makes all the traffic between the router and the end station travel through the attacker, thus enabling the attacker to log all of the traffic or inject new traffic into the data conversation.

The Gratuitous ARP feature configured on an IP phone protects the phone from a traditional MITM attack on the signaling and RTP voice streams that are sourced from the phone to the network. It helps protect the phones from having an attacker capture the signaling and RTP voice streams from the phone if the attacker was able to get onto the voice segment of the network. This feature protects only the phones; it does not protect the rest of the infrastructure from a Gratuitous ARP attack. This feature is of less importance if you are running a Cisco infrastructure because the switch port provides features that protect both the phones and the network gear. For a description of these switch port features see the section on [Switch Port](#), page 4-8.

Note

The Gratuitous ARP feature does not apply to devices configured using IPv6 addressing. IPv6 uses neighbor discovery (ND) and not ARP.

The downstream signaling and RTP voice streams coming from another phone or coming across the network are not protected by this feature in the phone. Only the data coming from the phone that has this feature enabled is protected. (See [Figure 4-3](#).)

If the default gateway is running Hot Standby Router Protocol (HSRP), if the HSRP configuration uses the burned-in MAC address rather than the virtual MAC address for the default gateway, and if the primary router fails-over to a secondary router that has a new MAC address, the phones could maintain the old MAC address of the default gateway. This scenario could cause an outage for up to 40 minutes. Always use the virtual MAC address in an HSRP environment to avoid this potential problem.

Figure 4-3 Gratuitous ARP Protects the Phone that Has It but Not Other Traffic

As shown in [Figure 4-3](#), the traffic from the phone that has Gratuitous ARP is protected, but the attacker could still see the traffic coming from another endpoint because that endpoint might not have the ability to protect the data flow.

Port Security: Prevent Port Access

Prevent all port access except from those devices designated by their MAC addresses to be on the port. This is a form of device-level security authorization. This requirement is used to authorize access to the network by using the single credential of the device's MAC address. By using port security (in its non-dynamic form), a network administrator would be required to associate MAC addresses statically for every port. However, with dynamic port security, network administrators can merely specify the number of MAC addresses they would like the switch to learn and, assuming the correct devices are the first devices to connect to the port, allow only those devices access to that port for some period of time.

The period of time can be determined by either a fixed timer or an inactivity timer (non-persistent access), or it can be permanently assigned. In the latter case, the MAC address learned will remain on the port even in the event of a reload or reboot of the switch.

No provision is made for device mobility by static port security or persistent dynamic port security. Although it is not the primary requirement, MAC flooding attacks are implicitly prevented by port security configurations that aim to limit access to certain MAC addresses.

From a security perspective, there are better mechanisms for both authenticating and authorizing port access based on userid and/or password credentials rather than using MAC address authorization. MAC addresses alone can easily be spoofed or falsified by most operating systems.

Port Security: Prevent Rogue Network Extensions

Port security prevents an attacker from flooding the CAM table of a switch and from turning any VLAN into a hub that transmits all received traffic to all ports. It also prevents unapproved extensions of the network by adding hubs or switches into the network. Because it limits the number of MAC addresses to a port, port security can also be used as a mechanism to inhibit user extension to the IT-created network. For example, if a user plugs a wireless access point (AP) into a user-facing port or data port on a phone with port security defined for a single MAC address, the wireless AP itself would occupy that MAC address and not allow any devices behind it to access the network. (See [Figure 4-4](#).) Generally, a configuration appropriate to stop MAC flooding is also appropriate to inhibit rogue access.

Figure 4-4 Limited Number of MAC Addresses Prevents Rogue Network Extensions

If the number of MAC addresses is not defined correctly, there is a possibility of denying access to the network or error-disabling the port and removing all devices from the network.

DHCP Snooping: Prevent Rogue DHCP Server Attacks

Dynamic Host Configuration Protocol (DHCP) Snooping prevents a non-approved DHCP or rogue DHCP server from handing out IP addresses on a network by blocking all replies to a DHCP request unless that port is allowed to reply. Because most phone deployments use DHCP to provide IP addresses to the phones, you should use the DHCP Snooping feature in the switches to secure DHCP messaging. Rogue DHCP servers can attempt to respond to the broadcast messages from a client to give out incorrect IP addresses, or they can attempt to confuse the client that is requesting an address.

When enabled, DHCP Snooping treats all ports in a VLAN as untrusted by default. An untrusted port is a user-facing port that should never make any reserved DHCP responses. If an untrusted DHCP-snooping port makes a DHCP server response, it will be blocked from responding. Therefore, rogue DHCP servers will be prevented from responding. However, legitimately attached DHCP servers or uplinks to legitimate servers must be trusted.

[Figure 4-5](#) illustrates the normal operation of a network-attached device that requests an IP address from the DHCP server.

Figure 4-5 Normal Operation of a DHCP Request

However, an attacker can request not just a single IP address but all of the IP addresses that are available within a VLAN. (See Figure 4-6.) This means that there would be no addresses for a legitimate device trying to get on the network, and without an IP address the phone cannot connect to Unified CM.

Figure 4-6 An Attacker Can Take All Available IP Addresses on the VLAN

DHCP Snooping: Prevent DHCP Starvation Attacks

DHCP address scope starvation attacks from tools such as Gobbler are used to create a DHCP denial-of-service (DoS) attack. Because the Gobbler tool makes DHCP requests from different random source MAC addresses, you can prevent it from starving a DHCP address space by using port security to limit the number of MAC addresses. (See [Figure 4-7](#).) However, a more sophisticated DHCP starvation tool can make the DHCP requests from a single source MAC address and vary the DHCP payload information. With DHCP Snooping enabled, untrusted ports will make a comparison of the source MAC address to the DHCP payload information and fail the request if they do not match.

Figure 4-7 Using DHCP Snooping to Prevent DHCP Starvation Attacks

DHCP Snooping prevents any single device from capturing all the IP addresses in any given scope, but incorrect configurations of this feature can deny IP addresses to approved users.

DHCP Snooping: Binding Information

Another function of DHCP Snooping is to record the DHCP binding information for untrusted ports that successfully get IP addresses from the DHCP servers. The binding information is recorded in a table on the Cisco Catalyst switch. The DHCP binding table contains the IP address, MAC address, lease length, port, and VLAN information for each binding entry. The binding information from DHCP Snooping remains in effect for the length of the DHCP binding period set by the DHCP server (that is, the DHCP lease time). The DHCP binding information is used to create dynamic entries for Dynamic ARP Inspection (DAI) to limit ARP responses for only those addresses that are DHCP-bound. The DHCP binding information is also used by the IP source guard to limit sourcing of IP packets to only those addresses that are DHCP-bound.

There is a maximum limit to the number of binding table entries that each type of switch can store for DHCP Snooping. (Refer to the product documentation for your switch to determine this limit.) If you are concerned about the number of entries in your switch's binding table, you can reduce the lease time on the DHCP scope so that the entries in the binding table time-out sooner. The entries remain in the DHCP binding table until the lease runs out. In other words, the entries remain in the DHCP Snooping binding table as long as the DHCP server thinks the end station has that address. They are not removed from the port when the workstation or phone is unplugged.

If you have a Cisco Unified IP Phone plugged into a port and then move it to a different port, you might have two entries in the DHCP binding table with the same MAC and IP address on different ports. This behavior is considered normal operation.

Requirement for Dynamic ARP Inspection

Dynamic Address Resolution Protocol (ARP) Inspection (DAI) is a feature used on the switch to prevent Gratuitous ARP attacks on the devices plugged into the switch and on the router. Although it is similar to the Gratuitous ARP feature mentioned previously for the phones, Dynamic ARP protects all the devices on the LAN, and it is not just a phone feature.

In its most basic function, Address Resolution Protocol (ARP) enables a station to bind a MAC address to an IP address in an ARP cache, so that the two stations can communicate on a LAN segment. A station sends out an ARP request as a MAC broadcast. The station that owns the IP address in that request will give an ARP response (with its IP and MAC address) to the requesting station. The requesting station will cache the response in its ARP cache, which has a limited lifetime. The default ARP cache lifetime for Microsoft Windows is 2 minutes; for Linux, the default lifetime is 30 seconds; and for Cisco IP phones, the default lifetime is 40 minutes.

ARP also makes the provision for a function called Gratuitous ARP. Gratuitous ARP (GARP) is an unsolicited ARP reply. In its normal usage, it is sent as a MAC broadcast. All stations on a LAN segment that receive a GARP message will cache this unsolicited ARP reply, which acknowledges the sender as the owner of the IP address contained in the GARP message. Gratuitous ARP has a legitimate use for a station that needs to take over an address for another station on failure.

However, Gratuitous ARP can also be exploited by malicious programs that want to illegitimately take on the identity of another station. When a malicious station redirects traffic to itself from two other stations that were talking to each other, the hacker who sent the GARP messages becomes the man-in-the-middle. Hacker programs such as ettercap do this with precision by issuing "private" GARP messages to specific MAC addresses rather than broadcasting them. In this way, the victim of the attack does not see the GARP packet for its own address. Ettercap also keeps its ARP poisoning in effect by repeatedly sending the private GARP messages every 30 seconds.

Dynamic ARP Inspection (DAI) is used to inspect all ARP requests and replies (gratuitous or non-gratuitous) coming from untrusted (or user-facing) ports to ensure that they belong to the ARP owner. The ARP owner is the port that has a DHCP binding which matches the IP address contained in the ARP reply. ARP packets from a DAI trusted port are not inspected and are bridged to their respective VLANs.

Using DAI

Dynamic ARP Inspection (DAI) requires that a DHCP binding be present to legitimize ARP responses or Gratuitous ARP messages. If a host does not use DHCP to obtain its address, it must either be trusted or an ARP inspection access control list (ACL) must be created to map the host's IP and MAC address. (See [Figure 4-8.](#)) Like DHCP Snooping, DAI is enabled per VLAN, with all ports defined as untrusted by default. To leverage the binding information from DHCP Snooping, DAI requires that DHCP Snooping be enabled on the VLAN prior to enabling DAI. If DHCP Snooping is not enabled before you enable DAI, none of the devices in that VLAN will be able to use ARP to connect to any other device in their VLAN, including the default gateway. The result will be a self-imposed denial of service to any device in that VLAN.

Figure 4-8 Using DHCP Snooping and DAI to Block ARP Attacks

Because of the importance of the DHCP Snooping binding table to the use of DAI, it is important to back up the binding table. The DHCP Snooping binding table can be backed up to bootflash, File Transfer Protocol (FTP), Remote Copy Protocol (RCP), slot0, and Trivial File Transfer Protocol (TFTP). If the DHCP Snooping binding table is not backed up, the Cisco Unified IP Phones could lose contact with the default gateway during a switch reboot. For example, assume that the DHCP Snooping binding table is not backed up and that you are using Cisco Unified IP Phones with a power adapter instead of line power. When the switch comes back up after a reboot, there will be no DHCP Snooping binding table entry for the phone, and the phone will not be able to communicate with the default gateway unless the DHCP Snooping binding table is backed up and loads the old information before traffic starts to flow from the phone.

Incorrect configurations of this feature can deny network access to approved users. If a device has no entry in the DHCP Snooping binding table, then that device will not be able to use ARP to connect to the default gateway and therefore will not be able to send traffic. If you use static IP addresses, those addresses will have to be entered manually into the DHCP Snooping binding table. If you have devices that do not use DHCP again to obtain their IP addresses when a link goes down (some UNIX or Linux machines behave this way), then you must back up the DHCP Snooping binding table.

802.1X Port-Based Authentication

The 802.1X authentication feature can be used to identify and validate the device credentials of a Cisco Unified IP Phone before granting it access to the network. 802.1X is a MAC-layer protocol that interacts between an end device and a RADIUS server. It encapsulates the Extensible Authentication Protocol (EAP) over LAN, or EAPOL, to transport the authentication messages between the end devices and the switch. In the 802.1X authentication process, the Cisco Unified IP Phone acts as an 802.1X supplicant and initiates the request to access the network. The Cisco Catalyst Switch, acting as the authenticator, passes the request to the authentication server and then either allows or restricts the phone from accessing the network.

802.1X can also be used to authenticate the data devices attached to the Cisco Unified IP Phones. An EAPOL pass-through mechanism is used by the Cisco Unified IP Phones, allowing the locally attached PC to pass EAPOL messages to the 802.1X authenticator. The Cisco Catalyst Switch port needs to be configured in multiple-authentication mode to permit one device on the voice VLAN and multiple authenticated devices on the data VLAN.

**Note**

Cisco recommends authenticating the IP phone before the attached data device is authenticated.

The multiple-authentication mode assigns authenticated devices to either a data or voice VLAN, depending on the attributes received from the authentication server when access is approved. The 802.1X port is divided into a data domain and a voice domain.

In multiple-authentication mode, a guest VLAN can be enabled on the 802.1x port. The switch assigns end clients to a guest VLAN when the authentication server does not receive a response to its EAPOL identity frame or when EAPOL packets are not sent by the client. This allows data devices attached to a Cisco IP Phone, that do not support 802.1X, to be connected to the network.

A voice VLAN must be configured for the IP phone when the switch port is in a multiple-host mode. The RADIUS server must be configured to send a Cisco Attribute-Value (AV) pair attribute with a value of **device-traffic-class=voice**. Without this value, the switch treats the IP phone as a data device.

Dynamic VLAN assignment from a RADIUS server is supported only for data devices.

When a data or a voice device is detected on a port, its MAC address is blocked until authorization succeeds. If the authorization fails, the MAC address remains blocked for 5 minutes.

When the 802.1x authentication is enabled on an access port on which a voice VLAN is configured and to which a Cisco IP Phone is already connected, the phone loses connectivity to the switch for up to 30 seconds.

Most Cisco IP Phones support authentication by means of X.509 certificates using the EAP-Transport Layer Security (EAP-TLS) or EAP-Flexible Authentication with Secure Tunneling (EAP-FAST) methods of authentication. Some of the older models that do not support either method can be authenticated using MAC Authentication Bypass (MAB), which enables a Cisco Catalyst Switch to check the MAC address of the connecting device as the method of authentication.

To determine support for the 802.1X feature configuration, refer to the product guides for the Cisco Unified IP Phones and the Cisco Catalyst Switches, available at <http://www.cisco.com>.

**Note**

Cisco Secure Access Control System (ACS) 4.2 supports certificate-only authorization for enabling EAP-FAST. For enabling EAP-TLS, use ACS 5.x or later versions.

For configuration information, refer to the *IP Telephony for 802.1x Design Guide*, available at

http://www.cisco.com/en/US/docs/solutions/Enterprise/Security/TrustSec_1.99/IP_Tele/IP_Telephony_DIG.html

Phone Security

Cisco Unified IP Phones contain built-in features to increase security on an IP Telephony network. These features can be enabled or disabled on a phone-by-phone basis to increase the security of an IP Telephony deployment. Depending on the placement of the phones, a security policy will help determine if these features need to be enabled and where they should be enabled. (See [Figure 4-9](#).)

Figure 4-9 Security at the Phone Level

The following security considerations apply to IP phones:

- [PC Port on the Phone](#), page 4-17
- [PC Voice VLAN Access](#), page 4-18
- [Web Access Through the Phone](#), page 4-19
- [Video Capabilities](#), page 4-19
- [Settings Access](#), page 4-19
- [Phone Authentication and Encryption](#), page 4-20
- [VPN Client for IP Phones](#), page 4-21

Before attempting to configure the security features on a phone, check the documentation at the following link to make sure the features are available on that particular phone model:

<http://www.cisco.com/en/US/products/sw/voicesw/index.html>

PC Port on the Phone

The phone has the ability to turn on or turn off the port on the back of the phone, to which a PC would normally be connected. This feature can be used as a control point to access the network if that type of control is necessary.

Depending on the security policy and placement of the phones, the PC port on the back of any given phone might have to be disabled. Disabling this port would prevent a device from plugging into the back of the phone and getting network access through the phone itself. A phone in a common area such as a lobby would typically have its port disabled. Most companies would not want someone to get into the network on a non-controlled port because physical security is very weak in a lobby. Phones in a normal work area might also have their ports disabled if the security policy requires that no device should ever get access to the network through a phone PC port. Depending on the model of phone deployed, Cisco

Web Access Through the Phone

Each Cisco Unified IP Phone has a web server built into it to help with debugging and remote status of the phone for management purposes. The web server also enables the phones to receive applications pushed from Cisco Unified Communications Manager (Unified CM) to the phones. Access to this web server can be enabled or disabled on a phone by means of the Web Access feature in the Unified CM configuration. This setting can be global, or it could be enabled or disabled on a phone-by-phone basis.

If the web server is globally disabled but it is needed to help with debugging, then the administrator for Unified CM will have to enable this feature on the phones. The ability to get to this web page can be controlled by an ACL in the network, leaving network operators with the capability to get to the web page when needed.

With the Web Access feature disabled, the phones will be unable to receive applications pushed to them from Unified CM.

Video Capabilities

For Cisco Unified Video Advantage to operate properly, the PC port and Video Capabilities must both be enabled. The other settings can safely be disabled. The Device Security Mode operates as specified even when Cisco Unified Video Advantage is in use, but Cisco Unified Video Advantage itself does not support authentication or encryption of the Cisco Audio Session Tunnel (CAST) protocol or its RTP media traffic. When an IP Phone is in Authenticated mode, the Skinny Client Control Protocol (SCCP) signaling between the phone and Unified CM will be authenticated, but the CAST signaling between the phone and Cisco Unified Video Advantage will not be authenticated. Likewise, when a phone is in Encrypted mode, the audio stream between the phones will be encrypted, but the video streams between the Cisco Unified Video Advantage clients will not be encrypted. Users should be notified that the video channel is not encrypted even though an icon on the phone appears to indicate that they are in an encrypted call.

Settings Access

Each Cisco Unified IP Phone has a network settings page that lists many of the network elements and detailed information that is needed for the phone to operate. This information could be used by an attacker to start a reconnaissance on the network with some of the information that is displayed on the phone's web page. For example, an attacker could look at the settings page to determine the default gateway, the TFTP server, and the Unified CM IP address. Each of these pieces of information could be used to gain access to the voice network or to attack a device in the voice network.

This access can be disabled on a phone-by-phone basis to prevent end users or attackers from obtaining the additional information such as Unified CM IP address and TFTP server information. With access to the phone settings page disabled, end users lose the ability to change many of the settings on the phone that they would normally be able to control, such as speaker volume, contrast, and ring type. It might not be practical to use this security feature because of the limitations it places on end users with respect to the phone interface.

For more information on the phone settings page, refer to the latest version of the *Cisco Unified Communications Manager Administration Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

Phone Authentication and Encryption

Unified CM can be configured to provide multiple levels of security to the phones within a voice system, if those phones support those features. This includes device authentication and media and signaling encryption using X.509 certificates. Depending on your security policy, phone placement, and phone support, the security can be configured to fit the needs of your company.

For information on which Cisco Unified IP Phone models support specific security features, refer to the documentation available at

http://www.cisco.com/en/US/products/hw/phones/ps379/tsd_products_support_series_home.html

To enable security on the phones and in the Unified CM cluster, refer to the *Cisco Unified Communications Manager Security Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

When the Public Key Infrastructure (PKI) security features are properly configured in Unified CM, all supported phones will have the following capabilities:

- Integrity — Does not allow TFTP file manipulation but does allow Transport Layer Security (TLS) signaling to the phones when enabled.
- Authentication — The image for the phone is authenticated from Unified CM to the phone, and the device (phone) is authenticated to Unified CM. All signaling messages between the phone and Unified CM are verified as being sent from the authorized device.
- Encryption — For supported devices, signaling and media can be encrypted to prevent eavesdropping.
- Secure Real-time Transport Protocol (SRTP) — Is supported to Cisco IOS gateways and on phone-to-phone communications. Cisco Unity also supports SRTP for voicemail.

Unified CM supports authentication, integrity, and encryption for calls between two Cisco Unified IP Phones but not for all devices or phones. To determine if your device supports these features, refer to the documentation available at

http://www.cisco.com/en/US/products/hw/phones/ps379/tsd_products_support_series_home.html

Unified CM uses certificates for securing identities and enabling encryption. The certificates can be either Manufacturing Installed Certificates (MIC) or Locally Significant Certificates (LSC). MICs are already pre-installed and LSCs are installed by Unified CM's Cisco Certificate Authority Proxy Function (CAPF). Unified CM creates self-signed certificates, but signing of certificates by a third-party certificate authority (CA) using PKCS #10 Certificate Signing Request (CSR) is also supported. When using third-party CAs, the CAPF can be signed by the CA, but the phone LSCs are still generated by the CAPF. When MICs are used, the Cisco CA and the Cisco Manufacturing CA certificates act as the root certificates. When self-signed LSCs are used, the CAPF certificate is the root certificate. When an external CA is used, the CAPF acts as the subordinate CA and the external CA is the root CA.

Auto-registration does not work if you configure the cluster for mixed mode, which is required for device authentication. You cannot implement signaling or media encryption if device authentication does not exist in the cluster – that is, if you do not install and configure the Cisco Certificate Trust List (CTL) client. Application layer protocol inspection and Application Layer Gateways (ALGs) that allow IP Telephony traffic to traverse firewalls and Network Address Translation (NAT) also do not work with signaling encryption. Not all gateways, phones, or conference are supported with encrypted media.

Encrypting media makes recording and monitoring of calls more difficult and expensive. It also makes troubleshooting VoIP problems more challenging.

VPN Client for IP Phones

Cisco Unified IP Phones with an embedded VPN client provide a secure option for connecting phones outside the network to the Unified Communications solution in the enterprise. This functionality does not require an external VPN router and provides a secure communications tunnel for Layer 3 and higher traffic over an untrusted network between the phone at the deployed location and the corporate network.

The VPN client in Cisco Unified IP Phones uses Cisco SSL VPN technology and can connect to both the Cisco ASA 5500 Series VPN head-end and the Cisco Integrated Services Routers with the Cisco IOS SSL VPN software feature. The voice traffic is carried in UDP and protected by Datagram Transport Layer Security (DTLS) protocol. The integrated VPN tunnel applies only to voice and IP phone services. A PC connected to the PC port cannot use this tunnel and needs to establish its own VPN tunnel for any traffic from the PC.

For a phone with the embedded VPN client, you must first configure the phone with the VPN configuration parameters, including the VPN concentrator addresses, VPN concentrator credentials, user or phone ID, and credential policy. Because of the sensitivity of this information, the phone must be provisioned within the corporate network before the phone can attempt connecting over an untrusted network. Deploying the phone without first staging the phone in the corporate network is not supported.

The settings menu on the phone's user interface allows the user to enable or disable VPN tunnel establishment. When the VPN tunnel establishment is enabled, the phone starts to establish a VPN tunnel. The phone can be configured with up to three VPN concentrators to provide redundancy. The VPN client supports redirection from a VPN concentrator to other VPN concentrators as a load balancing mechanism.

For instructions on configuring the phones for the VPN client, refer to the latest version of the *Cisco Unified Communications Manager Administration Guide*, available at:

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

**Note**

The phones must be running firmware release 9.0(2) or higher to support VPN clients. This feature is available only on Cisco Unified IP Phones 79x2 and 79x5 with 9.0(2) firmware, registered to Cisco Unified CM 8.x. Only phones provisioned with IPv4 addresses are supported with the VPN client feature.

Quality of Service

Quality of Service (QoS) is a vital part of any security policy for an enterprise network. Even though most people think of QoS as setting the priority of traffic in a network, it also controls the amount of data that is allowed into the network. In the case of Cisco switches, that control point is at the port level when the data comes from the phone to the Ethernet switch. The more control applied at the edge of the network at the access port, the fewer problems will be encountered as the data aggregates in the network.

QoS can be used to control not only the priority of the traffic in the network but also the amount of traffic that can travel through any specific interface. Cisco Smartports templates have been created to assist in deploying voice QoS in a network at the access port level.

A rigorous QoS policy can control and prevent denial-of-service attacks in the network by throttling traffic rates.

As mentioned previously in the lobby phone example, you can provide enough flow control of the traffic at the access port level to prevent any attacker from launching a denial-of-service (DoS) attack from that port in the lobby. The configuration for that example was not as aggressive as it could be because the QoS configuration allowed traffic sent to the port to exceed the maximum rate, but the traffic was

remarked to the level of scavenger class. Given a more aggressive QoS policy, any amount of traffic that exceeded that maximum limit of the policy could just be dropped at the port, and that "unknown" traffic would never make it into the network. QoS should be enabled across the entire network to give the IP Telephony data high priority from end to end.

For more information on QoS, refer to the chapter on [Network Infrastructure, page 3-1](#), and the *Enterprise QoS Solution Reference Network Design (SRND) Guide* available at

<http://www.cisco.com/go/designzone>

Access Control Lists

This section covers access control lists (ACLs) and their uses in protecting voice data.

VLAN Access Control Lists

You can use VLAN access control lists (ACLs) to control data that flows on a network. Cisco switches have the capability of controlling Layers 2 to 4 within a VLAN ACL. Depending on the types of switches in a network, VLAN ACLs can be used to block traffic into and out of a particular VLAN. They can also be used to block intra-VLAN traffic to control what happens inside the VLAN between devices.

If you plan to deploy a VLAN ACL, you should verify which ports are needed to allow the phones to function with each application used in your IP Telephony network. Normally any VLAN ACL would be applied to the VLAN that the phones use. This would allow control at the access port, as close as possible to the devices that are plugged into that access port.

Refer to the following product documentation for information on configuring VLAN ACLs:

- Cisco Catalyst 3750 Switches
http://www.cisco.com/en/US/products/hw/switches/ps5023/products_installation_and_configuration_guides_list.html
- Cisco Catalyst 4500 Series Switches
http://www.cisco.com/en/US/products/hw/switches/ps4324/products_installation_and_configuration_guides_list.html
- Cisco Catalyst 6500 Series Switches
http://www.cisco.com/en/US/products/hw/switches/ps708/products_installation_and_configuration_guides_list.html

For more details on how to apply VLAN ACLs, refer to the following documentation:

- Cisco Catalyst 3750 Switches
http://www.cisco.com/en/US/products/hw/switches/ps5023/products_installation_and_configuration_guides_list.html
- Cisco Catalyst 4500 Series Switches
http://www.cisco.com/en/US/products/hw/switches/ps4324/products_installation_and_configuration_guides_list.html
- Cisco Catalyst 6500 Series Switches
http://www.cisco.com/en/US/products/hw/switches/ps708/products_installation_and_configuration_guides_list.html

ACLs provide the ability to control the network traffic in and out of a VLAN as well as the ability to control the traffic within the VLAN.

VLAN ACLs are very difficult to deploy and manage at an access-port level that is highly mobile. Because of these management issues, care should be taken when deploying VLAN ACLs at the access port in the network.

Router Access Control Lists

As with VLAN ACLs, routers have the ability to process both inbound and outbound ACLs by port. The first Layer 3 device is the demarcation point between voice data and other types of data when using voice and data VLANs, where the two types of data are allowed to send traffic to each other. Unlike the VLAN ACLs, router ACLs are not deployed in every access device in your network. Rather, they are applied at the edge router, where all data is prepared for routing across the network. This is the perfect location to apply a Layer 3 ACL to control which areas the devices in each of the VLANs have the ability to access within a network. Layer 3 ACLs can be deployed across your entire network to protect devices from each other at points where the traffic converges. (See Figure 4-11.)

Figure 4-11 Router ACLs at Layer 3

There are many types of ACLs that can be deployed at Layer 3. For descriptions and examples of the most common types, refer to *Configuring Commonly Used IP ACLs*, available (with Cisco partner login required) at

http://cisco.com/en/US/partner/tech/tk648/tk361/technologies_configuration_example09186a0080100548.shtml

Depending on your security policy, the Layer 3 ACLs can be as simple as not allowing IP traffic from the non-voice VLANs to access the voice gateway in the network, or the ACLs can be detailed enough to control the individual ports and the time of the day that are used by other devices to communicate to IP Telephony devices. As the ACLs become more granular and detailed, any changes in port usage in a network could break not only voice but also other applications in the network.

If there are software phones in the network, if web access to the phone is allowed, or if you use the Attendant Console or other applications that need access to the voice VLAN subnets, the ACLs are much more difficult to deploy and control.

For IP phones restricted to specific subnets and limited to a voice VLAN, ACLs can be written to block all traffic (by IP address or IP range) to Unified CMs, voice gateways, phones, and any other voice application that is being used for voice-only services. This method simplifies the ACLs at Layer 3 compared to the ACLs at Layer 2 or VLAN ACLs.

Firewalls

Firewalls can be used in conjunction with ACLs to protect the voice servers and the voice gateways from devices that are not allowed to communicate with IP Telephony devices. Because of the dynamic nature of the ports used by IP Telephony, having a firewall does help to control opening up a large range of ports needed for IP Telephony communications. Given the complexities that firewalls introduce into a network design, you must take care in placing and configuring the firewalls and the devices around the firewalls to allow the traffic that is considered correct to pass while blocking the traffic that needs to be blocked.

IP Telephony networks have unique data flows. The phones use a client/server model for signaling for call setup, and Unified CM controls the phones through that signaling. The data flows for the IP Telephony RTP streams are more like a peer-to-peer network, and the phones or gateways talk directly to each other via the RTP streams. If the signaling flows do not go through the firewall so that the firewall can inspect the signaling traffic, the RTP streams could be blocked because the firewall will not know which ports need to be opened to allow the RTP streams for a conversation.

A firewall placed in a correctly designed network can force all the data through that device, so capacities and performance need to be taken into account. Performance includes the amount of latency, which can be increased by a firewall if the firewall is under high load or even under attack. The general rule in an IP Telephony deployment is to keep the CPU usage of the firewalls to less than 60% for normal usage. If the CPU runs over 60%, it increases the chance of impacting IP phones, call setup, and registration. If the CPU usage stays at a sustained level above 60%, the registered IP phones will be affected, quality of calls in progress will degrade, and call setup for new calls will suffer. In the worst case, if the sustained CPU usage stays above 60%, phones will start to unregister. When this happens, they will attempt to re-register with Unified CM, thus increasing the load on the firewalls even more. If this were to happen, the effect would be a rolling blackout of phones unregistering and attempting to re-register with Unified CM. Until the CPU usage of the firewall decreases to under 60% sustained load, this rolling blackout would continue and most (if not all) of the phones would be affected. If you are currently using a Cisco firewall in your network, you should monitor the CPU usage carefully when adding IP Telephony traffic to your network so that you do not adversely affect that traffic.

There are many ways to deploy firewalls. This section concentrates on the Cisco Adaptive Security Appliance (ASA) in the active/standby mode in both routed and transparent scenarios. Each of the configurations in this section is in single-context mode within the voice sections of the firewall configurations.

Note

The Cisco Firewall Services Module (FWSM) is not supported with Cisco Unified Communications 8.x applications. If you are using FWSM in your network, you will have to specify ACLs to allow traffic for these applications.

All of the Cisco firewalls can run in either multiple-context or single-context mode. In single-context mode, the firewall is a single firewall that controls all traffic flowing through it. In multiple-context mode, the firewalls can be turned into many virtual firewalls. Each of these contexts or virtual firewalls have their own configurations and can be controlled by different groups or administrators. Each time a

new context is added to a firewall, it will increase the load and memory requirements on that firewall. When you deploy a new context, make sure that the CPU requirements are met so that voice RTP streams are not adversely affected.

Adaptive Security Appliances have limited support for application inspection of IPv6 traffic for Unified Communications application servers and endpoints. Cisco recommends not using IPv6 for Unified Communications if ASAs are deployed in your network.

**Note**

An ASA with No Payload Encryption model disables Unified Communications features.

A firewall provides a security control point in the network for applications that run over the network. A firewall also provides dynamic opening of ports for IP Telephony conversations if that traffic is running through the firewall.

Using its application inspection capability, the firewall can inspect the traffic that runs through it to determine if that traffic is really the type of traffic that the firewall is expecting. For example, does the HTTP traffic really look like HTTP traffic, or is it an attack? If it is an attack, then the firewall drops that packet and does not allow it to get to the HTTP server behind the firewall.

Not all IP Telephony application servers or applications are supported with firewall application layer protocol inspection. Some of these applications include Cisco Unity voicemail servers, Cisco Unified Attendant Console, Cisco Unified Contact Center Enterprise, and Cisco Unified Contact Center Express. ACLs can be written for these applications to allow traffic to flow through a firewall.

**Note**

The timers for failover on the firewalls are set quite high by default. To keep from affecting voice RTP streams as they go through the firewall if there is a failover, Cisco recommends reducing those timer settings to less than one second. If this is done, and if there is a failover, the amount of time that the RTP streams could be affected will be less because the firewalls will fail-over quicker and there will be less impact on the RTP streams during the failover time.

When firewalls are placed between different Unified Communications components, the application inspection must be enabled for all protocols used for communications between the components. Application inspection can fail in call flow scenarios used by features such as Silent Monitoring by Unified Communications Manager, when the firewall is between the remote agent phones and the supervisor phones.

Unified Communications devices using TCP, such as Cisco Unified Communications Manager, support the TCP SACK option to speed up data transfer in case of packet loss. But not all firewalls support the TCP SACK option. In that case, TCP sessions established between Unified Communications devices through such a firewall will encounter problems if they attempt to use the TCP SACK option, and the TCP session might fail. Therefore, the firewalls should provide full support for the TCP SACK option. If support is not available, then the firewalls should be able to modify the TCP packets during the three-way handshake and to disable TCP SACK option support so that the endpoints will not attempt to use this option.

To determine if the applications running on your network are supported with the version of firewall in the network or if ACLs have to be written, refer to the appropriate application documentation available at

<http://www.cisco.com>

Routed ASA

The ASA firewall in routed mode acts as a router between connected networks, and each interface requires an IP address on a different subnet. In single-context mode, the routed firewall supports Open Shortest Path First (OSPF) and Routing Information Protocol (RIP) in passive mode. Multiple-context mode supports static routes only. ASA version 8.x also supports Enhanced Interior Gateway Routing Protocol (EIGRP). Cisco recommends using the advanced routing capabilities of the upstream and downstream routers instead of relying on the security appliance for extensive routing needs. For more information on the routed mode, refer to the *Cisco Security Appliance Command Line Configuration Guide*, available at

http://www.cisco.com/en/US/products/ps6120/products_installation_and_configuration_guides_list.html

The routed ASA firewall supports QoS, NAT, and VPN termination to the box, which are not supported in the transparent mode (see [Transparent ASA, page 4-26](#)). With the routed configuration, each interface on the ASA would have an IP address. In the transparent mode, there would be no IP address on the interfaces other than the IP address to manage the ASA remotely.

The limitations of this mode, when compared to the transparent mode, are that the device can be seen in the network and, because of that, it can be a point of attack. In addition, placing a routed ASA firewall in a network changes the network routing because some of the routing can be done by the firewall. IP addresses must also be available for all the interfaces on the firewall that are going to be used, so changing the IP addresses of the routers in the network might also be required. If a routing protocol or RSVP is to be allowed through the ASA firewall, then an ACL will have to be put on the inside (or most trusted) interface to allow that traffic to pass to the outside (or lesser trusted) interfaces. That ACL must also define all other traffic that will be allowed out of the most trusted interface.

Transparent ASA

The ASA firewall can be configured to be a Layer 2 firewall (also known as "bump in the wire" or "stealth firewall"). In this configuration, the firewall does not have an IP address (other than for management purposes), and all of the transactions are done at Layer 2 of the network. Even though the firewall acts as a bridge, Layer 3 traffic cannot pass through the security appliance unless you explicitly permit it with an extended access list. The only traffic allowed without an access list is Address Resolution Protocol (ARP) traffic.

This configuration has the advantage that an attacker cannot see the firewall because it is not doing any dynamic routing. Static routing is required to make the firewall work even in transparent mode.

This configuration also makes it easier to place the firewall into an existing network because routing does not have to change for the firewall. It also makes the firewall easier to manage and debug because it is not doing any routing within the firewall. Because the firewall is not processing routing requests, the performance of the firewall is usually somewhat higher with **inspect** commands and overall traffic than the same firewall model and software that is doing routing.

With transparent mode, if you are going to pass data for routing, you will also have to define the ACLs both inside and outside the firewall to allow traffic, unlike with the same firewall in routed mode. Cisco Discovery Protocol (CDP) traffic will not pass through the device even if it is defined. Each directly connected network must be on the same subnet. You cannot share interfaces between contexts; if you plan on running multiple-context mode, you will have to use additional interfaces. You must define all non-IP traffic, such as routing protocols, with an ACL to allow that traffic through the firewall. QoS is not supported in transparent mode. Multicast traffic can be allowed to go through the firewall with an extended ACL, but it is not a multicast device. In transparent mode, the firewall does not support VPN termination other than for the management interface.

If a routing protocol or RSVP is to be allowed through the ASA firewall, then an ACL will have to be put on the inside (or most trusted) interface to allow that traffic to pass to the outside (or lesser trusted) interfaces. That ACL must also define all other traffic that will be allowed out of the most trusted interface.

For more information on the transparent mode, refer to the *Cisco Security Appliance Command Line Configuration Guide*, available at

http://www.cisco.com/en/US/products/ps6120/products_installation_and_configuration_guides_list.html

**Note**

Using NAT in transparent mode requires ASA version 8.0(2) or later. For more information, refer to the *Cisco ASA 5500 Series Release Notes* at

<http://www.cisco.com/en/US/docs/security/asa/asa80/release/notes/asarn80.html>.

ASA Unified Communications Proxy Feature

The Cisco Unified Communications Proxy feature on the Cisco ASA 5500 Series appliances includes multiple solutions for encryption and perimeter security services. These features enable secure communications between Unified Communications systems and endpoints connected over untrusted networks. The TLS proxy feature terminates and applies security policies to internally encrypted Cisco IP endpoints. The phone proxy, mobility proxy, and presence federation security services allow secure communication services between the enterprise network and remote users, mobile solutions, and other external networks.

All these features are licensed under the Cisco Unified Communications Proxy umbrella. For details about the licensing and deployment requirements for this feature, refer to the following documentation:

- *Cisco ASA Unified Communications Proxy Licensing Guide*

http://www.cisco.com/en/US/prod/collateral/vpndevc/ps6032/ps6094/ps6120/at_a_glance_c45-509624.pdf

- *Cisco ASA 5500 Series Unified Communications Deployments* data sheet

http://www.cisco.com/en/US/prod/collateral/vpndevc/ps6032/ps6094/ps6120/product_data_sheet0900aecd8073cbbf.html

The Cisco Unified Communications Proxy features are licensed by TLS session. For the phone proxy or TLS proxy, each IP phone may have more than one connection to the Unified CM server, one connection to the primary Unified CM and one connection to the backup Unified CM. In this case, the phone proxy uses two Unified Communications Proxy sessions because two TLS sessions are set up. For the mobility proxy and presence federation proxy, each endpoint utilizes one Unified Communications Proxy session.

Enabling the Cisco Unified Communications Proxy features requires careful capacity considerations. It is necessary to ensure that the CPU utilization on the ASA stays around or below 60% when proxy sessions are in use in order to prevent phones from losing their registration and affecting other traffic when trying to reregister.

ASA TLS Proxy

This feature adds the capability for an ASA firewall to perform inspection of encrypted voice signaling. When an endpoint device is configured for encrypted signaling, an Application Layer gateway is unable to perform functions such as NAT fixup because it is unable to inspect the signaling. The TLS proxy feature allows the ASA to participate in the TLS session over which the signaling is sent, and the ASA is then able to decode the signaling stream, perform any necessary fixup, and then re-encrypt the signaling.

When the ASA firewall is placed between an IP phone and the Unified CM to which it is registered, the TLS proxy is inserted into the TLS session. A phone with encrypted signaling uses TLS as a transport between itself and Unified CM. When the TLS proxy is involved, there are two TLS sessions for each phone registration, one between the phone and the ASA and the second between the ASA and Unified CM.

The ASA is the only firewall with application inspection capability that has a controlled method to allow a call with encrypted signaling to work, because it is able to inspect that signaling.

The TLS proxy is added as a trusted entity to the Certificate Trust List (CTL) that is used by the phones. The CTL file is allowed to contain 16 entries which include all servers that need to have a trust relationship with the phones. Therefore, the number of TLS proxies configured to work with a given cluster is limited by the number of free entries in the Certificate Trust List.

ASA Phone Proxy

The Cisco ASA Phone Proxy feature enables termination of Cisco SRTP/TLS-encrypted endpoints for secure remote access. The phone proxy allows large-scale deployments of secure phones without a large-scale deployment of VPN remote access hardware. End-user infrastructure is limited to just the IP endpoint, without VPN tunnels or hardware. The Cisco ASA Phone Proxy is the replacement product for the Cisco Unified Phone Proxy.

The ASA Phone Proxy supports Unified CM clusters in both mixed mode and nonsecure mode. But in either scenario, the remote phones capable of encryption are always forced to be in encrypted mode, and the signaling and media are terminated on the ASA Phone Proxy.

In a nonsecure cluster mode or a mixed mode where the phones are configured as nonsecure, the ASA Phone Proxy terminates the TLS connections from the phones and initiates a TCP connection to Unified CM. The proxy also converts the media from the remote IP phones, converting SRTP to RTP before forwarding it to the internal network IP phone.

In a mixed-mode cluster where the internal IP phones are authenticated but not configured for encryption, the ASA Phone Proxy does not convert the TLS connection for Unified CM to TCP, but the SRTP is converted to RTP. If the internal IP phones are configured as encrypted, then neither the TLS connection nor the SRTP is converted.

Note

The ASA Phone Proxy does not support inspection of packets from phones connecting to it over a VPN tunnel. Therefore, sending phone proxy traffic through a VPN tunnel is not supported.

Note

The ASA 5500 appliances running version 8.4 can support the Phone Proxy feature when integrated with Unified CM 8.0(x) but do not support Phone Proxy with Unified CM versions 8.5(x) and 8.6(x).

The ASA Phone Proxy does not support encrypted TFTP configuration files and HTTPS traffic to the phones. The configuration file encryption option needs to be disabled for the phone connected to an ASA Phone Proxy. The ASA Phone Proxy is not supported when the ASA is running in transparent mode or multimode. In addition, Cisco Unified Personal Communicator is not supported with ASA Phone Proxy.

For a list of differences between TLS Proxy and ASA Phone Proxy capabilities, refer to the document *TLS Proxy vs. Phone Proxy*, available at:

http://www.cisco.com/en/US/solutions/collateral/ns340/ns394/ns165/ns391/white_paper_c11-493584.html

ASA Mobility Proxy Feature

The Cisco ASA Mobility Proxy facilitates secure connectivity between the Cisco Unified Mobile Communicator software and the Cisco Unified Mobility Advantage server. The Mobility Proxy can intercept the TLS connection between the Cisco Unified Mobile Communicator software and server. The Mobility Proxy inspects and applies policies to the mobility traffic using the Mobile Multiplexing Protocol (MMP) inspection engine to enforce protocol conformance for Cisco Unified Mobile Communicator running on Blackberry, Symbian, and Windows mobile devices.

For deployments with Cisco Mobility Advantage, Cisco recommends using the ASA as both the firewall and the Mobility Proxy. However, this feature can also be implemented as just the Mobility Proxy, utilizing an existing firewall.

Note

Starting with Cisco ASA version 8.2(x), the Mobility Proxy application no longer requires a Cisco Unified Communications Proxy license.

ASA for Unified Presence

This proxy feature facilitates secure presence federation between Cisco Unified Presence and the Microsoft Office Communications Server (OCS) Presence solutions, thus allowing networks with Cisco Unified Presence solutions to federate and share presence information with other businesses. The Presence Federation Proxy is implemented as a TLS proxy for the TLS connection between the Cisco Unified Presence servers in one network and the Microsoft Access Proxy servers in another network.

ASA Intercompany Media Engine Proxy

The ASA Cisco Intercompany Media Engine (IME) proxy is a required component of the Cisco IME solution for IME call processing. The IME enables secure business-to-business communication systems that support enhanced Unified Communications features and that do not have to go through the PSTN network. For more information about the IME call processing phase of the solution, see [Cisco Intercompany Media Engine, page 5-34](#). The IME-enabled ASA provides perimeter security functions such as anti-spam blocking of non-IME calls and audio quality monitoring for the Fallback feature, inspects SIP messages, and acts as a proxy for SIP to SIP/TLS and RTP/SRTP conversions. The IME-enabled ASA terminates and re-initiates connections, which allows it to inspect the SIP messaging

and apply SIP ALG processing. The ASA will convert the SIP/TLS traffic to TCP going toward Unified CM if Unified CM is not secure, or it will connect through TLS if Unified CM is secure. The following deployment models apply to the IME-enabled ASA:

- Basic (Inline)
- Offpath

Basic Deployment

In a basic (inline) deployment, the Internet ASA is configured with the IME feature, and all Internet-bound traffic from the Unified CM cluster will naturally traverse this IME-enabled ASA. As shown in Figure 4-12, the IME-enabled ASA resides on the edge of the enterprise and proxies all IME-related SIP trunk signaling and audio/video RTP media to remote enterprises.

Figure 4-12 Intercompany Media Engine ASA Basic (Inline) Deployment Model

Offpath Deployment

In deployments where there are existing firewalls in the enterprise network, it might not be possible to replace or upgrade the existing firewall to support the IME feature or to change the existing security architecture by adding an IME-enabled ASA inline with the Internet firewall. In this scenario, the ASA can be implemented in an offpath model for IME. Offpath is the recommended deployment method.

In an offpath deployment, inbound and outbound IME calls pass through an IME-enabled ASA that is located in the DMZ, as illustrated in figure 4-20. Unified CM is configured to direct all SIP signaling to the IME-enabled ASA. All other Internet-bound traffic does not flow through the IME-enabled ASA.

Figure 4-13 Intercompany Media Engine ASA Offpath Deployment Model

Inbound IME calls from remote enterprises are addressed to the outside interface of the IME-enabled ASA, which utilizes static NAT or PAT to create a mapping to each Unified CM node on the inside. This behavior is the same for both deployment options. For outbound IME calls, offpath deployment requires that Unified CM send calls directly to the offpath IME-enabled ASA. This is accomplished via a mapping service protocol. Unified CM sends a mapping service request for the IME-enabled ASA to provide an internal IP address and port number to be used as the destination IP address and port number of the remote destination in the IME learned route. Unified CM then addresses the SIP Invite for this IME call to this internal IP address, which will guarantee the packet is forwarded to the IME-enabled ASA. Once the packet is received by the IME-enabled ASA, it then forwards the calls to the external IP address of the called party.

Mid-Call PSTN Fallback

The IME solution also provides a mechanism to allow calls to fall back to the PSTN if the quality of service (QoS) degrades below an acceptable level. The IME-enabled ASAs on the originating and terminating sides monitor all audio streams (not video) incoming from the internet and analyze the media against an algorithm with configurable sensitivity settings. Based on the observed loss and jitter measurements of an RTP stream, if the IME-enabled ASA determines call quality has deteriorated past its sensitivity threshold, it sends a SIP Refer message to its Unified CM to trigger the fallback. While the IME call remains active, the Unified CM on the originating side sets up a PSTN call in the background to the specific IME fallback DID (obtained during SIP call setup) of the remote enterprise. Once the terminating side Unified CM identifies the PSTN call as the fallback call for the IME call and a connection is established, both Unified CMs instruct the endpoints to switch media to the respective PSTN gateways. This change is seamless to the user. Any advanced features such as video are lost, but the audio portion of the call remains intact.

Cisco recommends starting with the default fallback sensitivity level and making revisions after determining how many calls are in fact falling back to PSTN connectivity. For more details regarding the IME solution and ASA configuration, refer to the Cisco Intercompany Media Engine Proxy information in the *Cisco ASA 5500 Series Configuration Guide using the CLI*, available at

<http://www.cisco.com/en/US/docs/security/asa/asa83/configuration/guide/config.html>

Design Considerations

The IME-enabled ASA requires at least two external (global) IP addresses, one for SIP signaling and one for media termination if PAT is used for incoming calls from remote enterprises. If NAT is implemented, more may be required. The external IP address on the IME-enabled ASA for SIP signaling is what is advertised in IME learned routes.

The IME-enabled ASA also requires at least two internal IP addresses, one for SIP signaling and one for media termination. PAT is used for incoming IME calls from Unified CM.

Note

Although the IME-enabled ASA interfaces are referred to as external and internal, if the ASA is deployed in a DMZ, both interfaces may be on subnets that exist within the DMZ. At a minimum, the external interface subnet needs to be accessible from the Internet, and the internal interface subnet must be accessible from the intranet.

For any non-IME firewalls in the network that separate two components of the solution, it is imperative to open the proper pinholes to allow IME communications between the following components:

- IME server and Unified CM
- IME server and GoDaddy Enrollment Server
- IME server and the peer-to-peer IME server network (Distributed Cache Ring)
- IME-enabled ASA (internal) and Unified CM
- IME-enabled ASA (internal) and IME internal endpoints (media)
- IME-enabled ASA (external) and remote enterprise IME-enabled ASA

For a complete list of ports for the IME solution components, refer to the *Cisco Intercompany Media Engine Installation and Configuration Guide*, available at

http://cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

If there is an intranet firewall between the IME-enabled ASA and the Unified CM that is performing NAT, the following conditions must be met:

- This intranet firewall must be a Cisco ASA capable of SIP ALG functionality to allow the proper fixup of incoming and outgoing SIP messaging.
- There must be a static NAT entry to translate Unified CM's real IP address to an address reachable by the IME-enabled ASA.

The Cisco IME-enabled ASA typically has a default route for reaching Internet subnets. It also requires IP routes to all potential subnets containing internal endpoints. This includes data subnets that may include Cisco Unified Video Advantage cameras.

The IME solution requires its own Certificate Authority for validating ASA certificates used for establishing SIP/TLS connections. The IME-enabled ASA must verify SIP SSL certificates against this Certificate Authority (CA).

**Note**

GoDaddy.com is the only authorized certificate provider for establishing secure SIP TLS connections with remote enterprises.

High Availability

IME-enabled ASAs can be deployed in an active/standby failover mode to provide stateless failover of IME communications. If an outage occurs, all calls being established, as well as existing calls, will be lost. Stateful failover is not supported.

With the offpath deployment method, Unified CM is capable of configuring multiple IME Services (sets of enrolled and excluded DIDs), each with its own IME firewall. This can add further resiliency to the solution.

Capacity Planning

Each model of ASA is rated for handling a certain number of audio and video calls. For current IME call capacities for the ASA, see [Capacity Planning, page 5-42](#).

With the offpath model, each IME Service (set of enrolled and excluded DIDs) configured in Unified CM is associated with an IME-enabled ASA. Multiple IME Services can exist in Unified CM, allowing an administrator to spread the load across multiple IME-enabled ASAs, thus increasing overall capacity.

Data Center

Within the data center, the security policy should define what security is needed for the IP Telephony applications servers. Because the Cisco Unified Communications servers are based on IP, the security that you would put on any other time-sensitive data within a data center could be applied to those servers as well.

If clustering over the WAN is being used between data centers, any additional security that is applied both within and between those data centers has to fit within the maximum round-trip time that is allowed between nodes in a cluster. In a multisite or redundant data center implementation that uses clustering over the WAN, if your current security policy for application servers requires securing the traffic between servers across data center firewalls, then Cisco recommends using IPSec tunnels for this traffic between the infrastructure security systems already deployed.

To design appropriate data center security for your data applications, Cisco recommends following the guidelines presented in the *Data Center Networking: Server Farm Security SRND (Server Farm Security in the Business Ready Data Center Architecture)*, available at

<http://www.cisco.com/go/designzone>

Gateways, Trunks, and Media Resources

Gateways and media resources are devices that convert an IP Telephony call into a PSTN call. When an outside call is placed, the gateway or media resource is one of the few places within an IP Telephony network to which all the voice RTP streams flow.

Because IP Telephony gateways and media resources can be placed almost anywhere in a network, securing an IP Telephony gateway or media resource might be considered more difficult than securing other devices, depending on your security policy. However, depending on which point trust is established in the network, the gateways and media resources can be quite easy to secure. Because of the way the gateways and media resources are controlled by Unified CM, if the path that the signaling takes to the gateway or media resource is in what is considered a secure section of the network, a simple ACL can be used to control signaling to and from the gateway or media resource. If the network is not considered secure between the gateways (or media resources) and where the Unified CMs are located (such as when a gateway is located at a remote branch), the infrastructure can be used to build IPsec tunnels to the gateways and media resources to protect the signaling. Most networks would most likely use a combination of the two approaches (ACL and IPsec) to secure those devices.

For H.323 videoconferencing devices, an ACL can be written to block port 1720 for H.225 trunks from any H.323 client in the network. This method would block users from initiating an H.225 session with each other directly. Cisco devices might use different ports for H.225, so refer to the product documentation for your equipment to see which port is used. If possible, change the port to 1720 so that only one ACL is needed to control signaling.

Because we use QoS at the edge of the network, if an attacker can get into the voice VLAN and determine where the gateways and media resources are, QoS at the port would limit how much data the attacker would be able to send to the gateway or media resource. (See [Figure 4-14](#).)

Figure 4-14 Securing Gateways and Media Resources with IPsec, ACLs, and QoS

Some gateways and media resources support Secure RTP (SRTP) to the gateways and media resources from the phones, if the phone is enabled for SRTP. To determine if a gateway or media resource supports SRTP, refer to the appropriate product documentation at:

<http://www.cisco.com>

For more information on IPSec tunnels, refer to the *Site-to-Site IPSec VPN Solution Reference Network Design (SRND)*, available at:

<http://www.cisco.com/go/designzone>

Putting Firewalls Around Gateways

Some very interesting issues arise from placing firewalls between a phone making a call and the gateway to the PSTN network. Stateful firewalls look into the signaling messages between Unified CM, the gateway, and the phone, and they open a pinhole for the RTP streams to allow the call to take place. To do the same thing with a normal ACL, the entire port ranges used by the RTP streams would have to be open to the gateway.

There are two ways to deploy gateways within a network: behind a firewall and in front of a firewall. If you place the gateway behind a firewall, all the media from the phones that are using that gateway have to flow through the firewall, and additional CPU resources are required to run those streams through the firewall. In turn, the firewall adds control of those streams and protects the gateway from denial-of-service attacks. (See [Figure 4-15](#).)

Figure 4-15 Gateway Placed Behind a Firewall

The second way to deploy the gateway is outside the firewall. Because the only type of data that is ever sent to the gateway from the phones is RTP streams, the access switch's QoS features control the amount of RTP traffic that can be sent to that gateway. The only thing that Unified CM sends to the gateway is the signaling to set up the call. If the gateway is put in an area of the network that is trusted, the only communication that has to be allowed between Unified CM and the gateway is that signaling. (See [Figure 4-15](#).) This method of deployment decreases the load on the firewall because the RTP streams are not going through the firewall.

Unlike an ACL, most firewall configurations will open only the RTP stream port that Unified CM has told the phone and the gateway to use between those two devices as long as the signaling goes through the firewall. The firewall also has additional features for DoS attacks and Cisco Intrusion Prevention System (IPS) signatures to look at interesting traffic and determine if any attackers are doing something they should not be doing.

As stated in the section on [Firewalls, page 4-24](#), when a firewall is looking at all the signaling and RTP streams from phones to a gateway, capacity could be an issue. Also, if data other than voice data is running through the firewall, CPU usage must be monitored to make sure that the firewall does not affect the calls that are running through the firewall.

Firewalls and H.323

H.323 utilizes H.245 for setting up the media streams between endpoints, and for the duration of that call the H.245 session remains active between Unified CM and the H.323 gateway. Subsequent changes to the call flow are done through H.245.

By default, a Cisco firewall tracks the H.245 session and the associated RTP streams of calls, and it will time-out the H.245 session if no RTP traffic crosses the firewall for longer than 5 minutes. For topologies where at least one H.323 gateway and the other endpoints are all on one side of the firewall, the firewall will not see the RTP traffic. After 5 minutes, the H.245 session will be blocked by the firewall, which stops control of that stream but does not affect the stream itself. For example, no supplementary services will be available. This default behavior can be changed in firewall configuration so that the maximum anticipated call duration is specified.

The advantage of the configuration change from default is that it prevents H.323 from losing any call functionality when all endpoints are on the same side of the firewall.

SAF Service

Unified CM employs the Cisco Service Advertisement Framework (SAF) network service for its Call Control Discovery (CCD) feature (see [Service Advertisement Framework \(SAF\), page 3-72](#)). This capability uses a SIP trunk or a non-gatekeeper controlled H.323 trunk associated with the Call Control Discovery advertising service. The service advertises the call negotiation information for these trunks, including the dynamic port number for the H.323 trunk, the standard port 5060 for the SIP trunk, and the SIP route header information.

The Adaptive Security Appliances do not have application inspection for the SAF network service. When Unified CM uses a SAF-enabled H.323 trunk to place a call, the ASA cannot inspect the SAF packet to learn the ephemeral port number used in the H.225 signalling. Therefore, in scenarios where call traffic from SAF-enabled H.323 trunks traverses the ASAs, ACLs must be configured on the ASAs to allow this signaling traffic. The ACL configuration must account for all the ports used by the H.225 and H.245 signaling. ACL configuration is not required when SAF-enabled SIP trunks with the standard 5060 port are used.

Unified CM Trunk Integration with Cisco Unified Border Element

Unified CM trunks provide an additional point of IP connectivity between the enterprise network and external networks. Additional security measures must be applied to these interconnects to mitigate threats inherent in data and IP telephony applications. Implementing a Cisco Unified Border Element between the Unified CM trunks and the external network provides for more flexible and secure interoperability options.

The Cisco Unified Border Element is a Cisco IOS software feature that provides voice application demarcation and security threat mitigation techniques applicable to both voice and data traffic. Cisco Unified Border Element can be configured in conjunction with Cisco IOS Firewall, Authentication, and VPN features on the same device to increase security for the Unified CM trunks integrated with service provider networks or other external networks. These Cisco IOS security features can serve as a defense against outside attacks and as a checkpoint for the internal traffic exiting to the service provider's network through the router. Infrastructure access control lists (ACLs) can also be used to prevent unauthorized access, DoS attacks, or distributed DoS (DDoS) attacks that originate from the service provider or a network connected to the service provider's network, as well as to prevent intrusions and data theft.

Cisco Unified Border Element is a back-to-back user agent (B2BUA) that provides the capability to hide network topology on signaling and media. It enables security and operational independence of the network and provides NAT service by substituting the Cisco Unified Border Element IP address on all traffic.

Cisco Unified Border Element can be used to re-mark DSCP QoS parameters on media and signaling packets between networks. This ensures that traffic adheres to QoS policies within the network.

Cisco IOS Firewall features, used in combination with Cisco Unified Border Element, provide Application Inspection and Control (AIC) to match signaling messages and manage traffic. This helps prevent SIP trunk DoS attacks and allows message filtering based on content and rate limiting.

Cisco Unified Border Element allows for SIP trunk registration. This capability is not available in Unified CM SIP trunks.

Cisco Unified Border Element can register the enterprise network's E.164 DID numbers to the service provider's SIP trunk on behalf of the endpoints behind it. If Cisco Unified Border Element is used to proxy the network's E.164 DID numbers, the status of the actual endpoint is not monitored. Therefore unregistered endpoints might still be seen as available.

Cisco Unified Border Element can connect RTP enterprise networks with SRTP over an external network. This allows secure communications without the need to deploy SRTP within the enterprise. It also supports RTP-SRTP interworking, but this is limited to a small number of codecs, including G.711 mulaw, G.711 alaw, G.729abr8, G.729ar8, G.729br8, and G.729r8.

Certain SIP service providers require SIP trunks to be registered before they allow call service. This ensures that calls originate only from well-known endpoints, thus making the service negotiation between the enterprise and the service provider more secure. Unified CM does not support registration on SIP trunks natively, but this support can be accomplished by using a Cisco Unified Border Element. The Cisco Unified Border Element registers to the service provider with the phone numbers of the enterprise on behalf of Cisco Unified Communications Manager.

For configuration and product details about Cisco Unified Border Element, refer to the documentation at:

- <http://www.cisco.com/en/US/products/sw/voicesw/ps5640/index.html>
- http://www.cisco.com/en/US/products/sw/voicesw/ps5640/products_installation_and_configuration_guides_list.html

Applications Servers

For a list of the Unified CM security features and how to enable them, refer to the *Cisco Unified Communications Manager Security Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

Before enabling any of the Unified CM security features, verify that they will satisfy the security requirements specified in your enterprise security policy for these types of devices in a network. For more information, refer to the *Cisco ASA 5500 Series Release Notes* at

<http://www.cisco.com/en/US/docs/security/asa/asa80/release/notes/asarn80.html>

Single Sign-On

The Single Sign-On (SSO) feature was introduced in Cisco Unified CM 8.5(1), and it allows end users to log into a Windows domain and have secure access to the Unified Communication Manager's User Options page and the Cisco Unified Communications Integration for Microsoft Office Communicator (CUCIMOC) application.

Configuring Single Sign-On requires integration of Cisco Unified CM with third-party applications, including Microsoft Windows Servers, Microsoft Active Directory, and the ForgeRock Open Access Manager (OpenAM). For configuration details, refer to the latest version of the *Cisco Unified Communications Manager Features and Services Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

Cisco Security Agent on the Unified CM and Application Servers

The Cisco Security Agent is used on most of the application servers that Cisco uses to provide IP Telephony and IP Telephony services. The Cisco Security Agent software is Host Intrusion Prevention software that looks at the behavior of the traffic to and from the server, and the way the applications are running on that server, to determine if everything is working correctly. If something is considered abnormal, then the Cisco Security Agent software prevents that activity from happening.

Cisco Security Agent

Cisco developed a default Cisco Security Agent policy for its servers that allows all the correct things needed for that IP Telephony server to function, while also preventing known and unknown attacks from affecting the IP Telephony servers. This software protects the application and the operating system from both viruses and worm attacks. To get the maximum protection from these types of intrusions, ensure that the newest version of the Cisco Security Agent software is always installed on your servers. With the unmanaged agent installed on your servers, you will be able to see the logs of attacks on only the system where the agent is installed. You will have to log into each system to check the log files that might be there because of some type of alarm that has occurred. The unmanaged Cisco Security Agent is installed by default when you install Unified CM.

The unmanaged Cisco Security Agent protects each system from both known and unknown attacks, worms, and viruses. When run in unmanaged mode, Cisco Security Agent does not correlate alarms, and you have to access each system individually to see the log files on that system.

**Note**

Cisco Unified CM 8.x currently does *not* support managed Cisco Security Agent capability.

SELinux

Security Enhanced Linux (SELinux) is an integrated Linux OS feature for implementing security policies. It has replaced Cisco Security Agent in Cisco Unified CM 8.6(1) and later releases.

General Server Guidelines

Your Unified CM and other IP Telephony application servers should not be treated as normal servers. Anything you do while configuring the system could affect calls that are trying to be places or that are in progress. As with any other business-class application, major configuration changes should be done within maintenance windows to keep from disrupting phone conversations.

Standard security policies for application servers might not be adequate for IP Telephony servers. Unlike email servers or web servers, voice servers will not allow you to refresh a screen or re-send a message. The voice communications are real-time events. Any security policy for IP Telephony servers should ensure that work that is not related to configuring or managing the voice systems is not done on the IP Telephony servers at any time. Activities that might be considered normal on application servers within a network (for example, surfing the internet) should not take place on the IP Telephony servers.

In addition, Cisco provides a well defined patch system for the IP Telephony servers, and it should be applied based on the patch policy within your IT organization. You should not patch the system normally using the OS vendor's patch system unless it is approved by Cisco Systems. All patches should be downloaded from Cisco or from the OS vendor as directed by Cisco Systems, and applied according to the patch installation process.

You should use the OS hardening techniques if your security policy requires you to lock down the OS even more than what is provided in the default installation.

To receive security alerts, you can subscribe to the Cisco Notification service at:

<http://www.cisco.com/cisco/support/notifications.html>

Deployment Examples

This section presents examples of what could be done from a security perspective for a lobby phone and a firewall deployment. A good security policy should be in place to cover deployments similar to these types.

Lobby Phone Example

The example in this section illustrates one possible way to configure a phone and a network for use in an area with low physical security, such as a lobby area. None of the features in this example are required for a lobby phone, but if your security policy states more security is needed, then you could use the features listed in this example.

Because you would not want anyone to gain access to the network from the PC port on the phone, you should disable the PC port on the back of the phone to limit network access (see [PC Port on the Phone, page 4-17](#)). You should also disable the settings page on the phone so that potential attackers cannot see the IP addresses of the network to which the lobby phone is connected (see [Settings Access, page 4-19](#)). The disadvantage of not being able to change the settings on the phone usually will not matter for a lobby phone.

Because there is very little chance that a lobby phone will be moved, you could use a static IP address for that phone. A static IP address would prevent an attacker from unplugging the phone and then plugging into that phone port to get a new IP address (see [IP Addressing, page 4-5](#)). Also, if the phone is unplugged, the port state will change and the phone will no longer be registered with Unified CM. You can track this event in just the lobby phone ports to see if someone is trying to attach to the network.

Using static port security for the phone and not allowing the MAC address to be learned would mean that an attacker would have to change his MAC address to that of the phone, if he were able to discover that address. Dynamic port security could be used with an unlimited timer to learn the MAC address (but never unlearn it), so that it would not have to be added. Then the switch port would not have to be changed to clear that MAC address unless the phone is changed. The MAC address is listed in a label on the bottom of the phone. If listing the MAC address is considered a security issue, the label can be removed and replaced with a "Lobby Phone" label to identify the device. (See [Switch Port, page 4-8](#).)

A single VLAN could be used and Cisco Discovery Protocol (CDP) could be disabled on the port so that attackers would not be able to see any information from the Ethernet port about that port or switch to which it is attached. In this case, the phone would not have a CDP entry in the switch for E911 emergency calls, and each lobby phone would need either a label or an information message to local security when an emergency number is dialed.

A static entry in the DHCP Snooping binding table could be made because there would be no DHCP on the port (see [DHCP Snooping: Prevent Rogue DHCP Server Attacks, page 4-11](#)). Once the static entry is in the DHCP Snooping binding table, Dynamic ARP Inspection could be enabled on the VLAN to keep the attacker from getting other information about one of the Layer 2 neighbors on the network (see [Requirement for Dynamic ARP Inspection, page 4-14](#)).

With a static entry in the DHCP Snooping binding table, IP Source Guard could be used. If an attacker got the MAC address and the IP address and then started sending packets, only packets with the correct IP address could be sent.

A VLAN ACL could be written to allow only the ports and IP addresses that are needed for the phones to operate (see [VLAN Access Control Lists, page 4-22](#)). The following example contains a very small ACL that can be applied to a port at Layer 2 or at the first Layer 3 device to help control access into the network (see [Router Access Control Lists, page 4-23](#)). This example is based on a Cisco 7960 IP Phone being used in a lobby area, without music on hold to the phone or HTTP access from the phone.

Firewall Deployment Example (Centralized Deployment)

The example in this section is one way that firewalls could be deployed within the data center, with Unified CMs behind them (see [Figure 4-16](#)). In this example, the Unified CMs are in a centralized deployment, single cluster with all the phones outside the firewalls. Because the network in this deployment already contained firewalls that are configured in routed mode within the corporate data center, the load was reviewed before the placement of gateways was determined. After reviewing the average load of the firewall, it was decided that all the RTP streams would not transverse the firewall in order to keep the firewalls under the 60% CPU load (see [Putting Firewalls Around Gateways, page 4-35](#)). The gateways are placed outside the firewalls, and ACLs within the network are used to control the TCP data flow to and from the gateways from the Unified CMs. An ACL is also written in the network to control the RTP streams from the phones because the IP addresses of the phones are well defined (see [IP Addressing, page 4-5](#)). The voice applications servers are placed within the demilitarized zone (DMZ), and ACLs are used at the firewalls to control access to and from the Unified CMs and to the users in the network. This configuration will limit the amount of RTP streams through the firewall using inspects, which will minimize the impact to the firewalls when the new voice applications are added to the existing network.

Figure 4-16 Firewall Deployment Example

Securing Network Virtualization

This section describes the challenges with providing homogenous connectivity for communications between virtual networks and a technique for overcoming these challenges. It assumes familiarity with Virtual Route Forwarding and Network Virtualization. Network design principles for these technologies are described in the Network Virtualization documentation available at <http://www.cisco.com/go/designzone>.

This discussion is not meant as an endorsement to use virtualization as a method to increase the security of a Unified Communications solution. Its purpose is to explain how such deployments can layer Unified Communications onto the existing infrastructure. Refer to the Network Virtualization documentation for evaluating the advantages and disadvantages of virtualization technology.

When a network is based on virtualization technology, there is a logical separation of traffic at Layer 3, and separate routing tables exist for each virtual network. Due to the lack of routing information, devices in different virtual networks cannot communicate with one another. This environment works well for client-server deployments where all user endpoints communicate with devices in the data center only, but it has issues for providing peer-to-peer communication. Regardless of how the virtual networks are arranged – whether by department, location, type of traffic (data or voice), or some other basis – the core issue is the same: endpoints in different Virtual Private Network Routing and Forwarding tables (VRFs) do not have the capability to communicate to one another. Figure 4-17 shows a solution that uses a shared VRF located in the data center to provide connectivity between a software-based phone located in one VRF and a hardware phone located in another VRF. This solution may also apply to other variants of this situation. Network Virtualization requires that fire-walling of the data center be implemented for the demarcation between the data center and the campus networks, and the following discussion shows how this can be implemented.

Scenario 1: Single Data Center

Figure 4-17 Single Data Center

This scenario is the simplest to implement and is an incremental configuration change beyond the usual network virtualization implementation. This design incorporates a data center router with the capability to route packets to any VRF, and it is called the fusion router. (Refer to the Network Virtualization documentation for details on the configuration of the fusion router.) The deployment scenario for enabling peer-to-peer communications traffic utilizes the fusion router for routing between VRFs and the firewall capabilities for securing access to the data center.

The following base requirements apply to this scenario:

- Campus routers send packets for other campus VRFs toward the fusion router via default routing, so all router hops must route by default to the fusion router. The data center shared VRF has route information about each campus VRF. All VRFs other than the shared VRF have no direct connectivity.
- A Unified CM cluster is located in a shared VRF in the data center, and communication within that shared VRF is totally unhindered.

- The shared VRF is located in the data center. If multiple data centers exist, the shared VRF spans all the data centers.

The application layer gateway at the data center edge specifies access lists to open ports for TFTP and SCCP or SIP sessions originated on the outside toward the Unified CM cluster in the data center. TFTP is required to allow phones to download their configuration and software images from their TFTP server, and SCCP or SIP is required to allow them to register with the Unified CM cluster. Refer to Unified CM product documentation for a list of appropriate port numbers for the particular version of software used.

In this scenario, all call signaling from communication devices in each VRF passes through the application layer gateway, and inspection of that signaling allows the application layer gateway to dynamically open the necessary UDP pinholes for each VRF for the RTP traffic to pass from the outside of the firewall toward the fusion router. Without the inspection occurring on the firewalls, each RTP stream that originates from an endpoint on the outside is not allowed to pass through the firewall. It is the inspection of the call control signaling that allows the UDP traffic to be forwarded through the firewall.

This deployment model provides a method to allow communication devices on a VRF-enabled network to have peer-to-peer connectivity. The application layer gateway provides secure access to the shared VLAN and the fusion router. All media streams between different VRFs do not take the most direct path between endpoints. The media is backhauled to the data center to be routed via the fusion router.

Scenario 2: Redundant Data Centers

When redundant data centers are involved, the scenario becomes more complicated. It is necessary to ensure that the call setup signaling passes through the same application layer gateway that the corresponding RTP stream is going to use. If the signaling and media take different paths, a UDP pinhole is not opened. [Figure 4-18](#) illustrates an example of a problematic scenario. The hardware phone on the left is controlled by the subscribers in the data center on the left, and the corresponding call control signaling passes through the left firewall. Pinholes are opened in that firewall for the RTP stream. However, the routing might not guarantee that the RTP media stream follows the same path, and the firewall on the right blocks that stream.

Figure 4-18 Call Signaling and Media Take Different Paths

271408

The solution is to utilize Trusted Relay Point (TRP) functionality. (See [Figure 4-19](#).) Subscribers in each data center can invoke TRPs that provide anchoring of the media and ensure that the media streams flow through the appropriate firewall. A phone controlled by a subscriber in the left data center must invoke a TRP in that data center, and a phone controlled by a subscriber in the right data center must invoke a TRP located in the right data center. The TRP provides an IP address that enables a specific host route for media that can ensure the exact same routing path as the call signaling. This is used to ensure that signaling and media pass via the same firewall, thus solving the issue.

Figure 4-19 Redundant Data Centers with TRPs

TRPs are media termination point resources that are invoked at the device level for any call involving that device. Each device has a configuration checkbox that specifies whether a TRP should be invoked.

Conclusion

This chapter did not cover all of the security that could be enabled to protect the voice data within your network. The techniques presented here are just a subset of all the tools that are available to network administrators to protect all the data within a network. On the other hand, even these tools do not have to be enabled within a network, depending on what level of security is required for the data within the network overall. Choose your security methods wisely. As the security within a network increases, so do the complexity and troubleshooting problems. It is up to each enterprise to define both the risks and the requirements of its organization and then to apply the appropriate security within the network and on the devices attached to that network.

■ Conclusion

CHAPTER 5

Unified Communications Deployment Models

Revised: July 31, 2012; OL-21733-18

This chapter describes the deployment models for Cisco Unified Communications Systems.

Earlier versions of this chapter based the deployment models discussion on the call processing deployment models for Cisco Unified Communications Manager (Unified CM) exclusively. The current version of this chapter, by contrast, introduces a site-based approach to the design guidance for the constituent technologies of the Cisco Unified Communications System. The intent is to offer design guidance for the entire Cisco Unified Communications System, which includes much more than just the call processing service.

For design guidance with earlier releases of Cisco Unified Communications, refer to the Cisco Unified Communications Solution Reference Network Design (SRND) documentation available at

<http://www.cisco.com/go/ucsrnd>

What's New in This Chapter

Table 5-1 lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Table 5-1 New or Changed Information Since the Previous Release of This Document

| New or Revised Topic | Described in | Revision Date |
|--|---|-------------------|
| Cisco Unified Border Element on a Cisco SPA8800 or SPA8900 IP Telephony Gateway | Multisite with Centralized Call Processing, page 5-10 | July 31, 2012 |
| Clustering over the WAN support for Unified Communications applications in Cisco Business Edition 6000 deployments | Clustering over the WAN for Business Edition 6000 Co-Resident Applications, page 5-58 | February 29, 2012 |
| Megaclusters | Deployment Model Architecture, page 5-2 | February 29, 2012 |
| Cisco Cius and Cisco Virtualization Experience Client (VXC) deployment models | Various sections throughout this chapter | December 22, 2011 |
| Minor updates to information on Cisco Unified Communications Manager Session Management Edition | Various sections throughout this chapter | December 22, 2011 |
| Minor updates to information on Cisco Unified Computing System | Deploying Unified Communications on Virtualized Servers, page 5-58 | December 22, 2011 |

Deployment Model Architecture

In general terms, the deployment model architecture follows that of the enterprise it is deployed to serve. Deployment models describe the reference architecture required to satisfy the Unified Communications needs of well-defined, typical topologies of enterprises. For example, a centralized call processing deployment model caters to enterprises whose operational footprint is based on multiple sites linked to one or few centralized headquarters offices.

In some cases, the deployment model of a technology will depart from that of the enterprise, due to technological constraints. For example, if an enterprise has a single campus whose scale exceeds that of a single service instance (such as a call processing service provided by Cisco Unified Communications Manager), then a single campus might require more than a single instance of a call processing cluster or a single messaging product.

Another option for customers who exceed the sizing limits of a standard cluster is to consider deploying a megacluster, which can provide increased scalability. For more information about megaclusters, see [Megacluster, page 8-27](#).

**Note**

Unless otherwise specified, all information contained within this SRND that relates to call processing deployments (including capacity, high availability, and general design considerations) applies only to a standard cluster.

High Availability for Deployment Models

Unified Communications services offer many capabilities aimed at achieving high availability. They may be implemented in various ways, such as:

- Failover redundancy

For services that are considered essential, redundant elements should be deployed so that no single point of failure is present in the design. The redundancy between the two (or more) elements is automated. For example, the clustering technology used in Cisco Unified Communications Manager (Unified CM) allows for up to three servers to provide backup for each other. This type of redundancy may cross technological boundaries. For example, a phone may have as its first three preferred call control agents, three separate Unified CM servers belonging to the same call processing cluster. As a fourth choice, the phone can also be configured to rely on a Cisco IOS router for call processing services.

- Redundant links

In some instances, it is advantageous to deploy redundant IP links, such as IP WAN links, to guard against the failure of a single WAN link.

- Geographical diversity

Some products support the distribution of redundant service nodes across WAN links so that, if an entire site is off-line (such as would be the case during an extended power outage exceeding the capabilities of provisioned UPS and generator backup systems), another site in a different location can ensure business continuance.

Capacity Planning for Deployment Models

The capacities of various deployment models are typically integrally linked to the capacities of the products upon which they are based. Where appropriate in this chapter, capacities are called out. For some of the products supporting services covered in more detail in other sections of this document, the capacities of those products are discussed in their respective sections.

Site-Based Design

Across all technologies that make up the Cisco Unified Communications System, the following common set of criteria emerges as the main drivers of design:

Size

In this context, size generally refers to the number of users, which translates into a quantity of IP telephones, voice mail boxes, presence watchers, and so forth. Size also can be considered in terms of processing capacity for sites where few (or no) users are present, such as data centers.

Network Connectivity

The site's connectivity into the rest of the system has three main components driving the design:

- Bandwidth enabled for Quality of Service (QoS)
- Latency
- Reliability

These components are often considered adequate in the Local Area Network (LAN): QoS is achievable with all LAN equipment, bandwidth is typically in the Gigabit range, latency is minimal (in the order of a few milliseconds), and excellent reliability is the norm.

The Metropolitan Area Network (MAN) often approaches the LAN in all three dimensions: bandwidth is still typically in the multiple Megabit range, latency is typically in the low tens of milliseconds, and excellent reliability is common. Packet treatment policies are generally available from MAN providers, so that end-to-end QoS is achievable.

The Wide Area Network (WAN) generally requires extra attention to these components: the bandwidth is at a cost premium, the latencies may depend not only on effective serialization speeds but also on actual transmission delays related to physical distance, and the reliability can be impacted by a multitude of factors. The QoS performance can also require extra operational costs and configuration effort.

Bandwidth has great influence on the types of Unified Communications services available at a site, and on the way these services are provided. For example, if a site serving 20 users is connected with 1.5 Mbps of bandwidth to the rest of the system, the site's voice, presence, instant messaging, email, and video services can readily be hosted at a remote datacenter site. If that same site is hosting 1000 users, some of the services would best be hosted locally to avoid saturating the comparatively limited bandwidth with signaling and media flows. Another alternative is to consider increasing the bandwidth to allow services to be delivered across the WAN from a remote datacenter site.

The influence of latency on design varies, based on the type of Unified Communications service considered for remote deployment. If a voice service is hosted across a WAN where the one-way latency is 200 ms, for example, users might experience issues such as delay-to-dialtone or increased media cut-through delays. For other services such as presence, there might be no problem with a 200 ms latency.

Reliability of the site's connectivity into the rest of the network is a fundamental consideration in determining the appropriate deployment model for any technology. When reliability is high, most Unified Communications components allow for the deployment of services hosted from a remote site; when reliability is inconsistent, some Unified Communications components might not perform reliably when hosted remotely; if the reliability is poor, co-location of the Unified Communications services at the site might be required.

High Availability Requirements

The high availability of services is always a design goal. Pragmatic design decisions are required when balancing the need for reliability and the cost of achieving it. The following elements all affect a design's ability to deliver high availability:

- Bandwidth reliability, directly affecting the deployment model for any Unified Communications service
- Power availability

Power loss is a very disruptive event in any system, not only because it prevents the consumption of services while the power is out, but also because of the ripple effects caused by power restoration. A site with highly available power (for example, a site whose power grid connection is stable, backed-up by uninterruptible power supplies (UPSs) and by generator power) can typically be chosen to host any Unified Communications service. If a site has inconsistent power availability, it would not be judicious to use it as a hosting site.

- Environmental factors such as heat, humidity, vibration, and so forth
- Availability of qualified personnel

Some Unified Communications services are delivered through the use of equipment such as servers that require periodical maintenance. Some Unified Communications functions such as the hosting of Unified Communications call agent servers are best deployed at sites staffed with qualified personnel.

Site-Based Design Guidance

Throughout this document, design guidance is organized along the lines of the various Unified Communications services and technologies. For instance, the call processing chapter contains not only the actual description of the call processing services, but also design guidance pertaining to deploying IP phones and Cisco Unified Communications servers based on a site's size, network connectivity, and high availability requirements. Likewise, the call admission control chapter focuses on the technical explanation of that technology while also incorporating site-based design considerations.

Generally speaking, most aspects of any given Unified Communications service or technology are applicable to all deployments, no matter the site's size or network connectivity. When applicable, site-based design considerations are called out. Services can be centralized, distributed, inter-networked, and geographically diversified.

Centralized Services

For applications where enterprise branch sites are geographically dispersed and interconnected over a Wide Area Network, the Cisco Unified Communications services can be deployed at a central location while serving endpoints over the WAN connections. For example, the call processing service can be deployed in a centralized manner, requiring only IP connectivity with the remote sites to deliver telephony services. Likewise, voice messaging services, such as those provided by the Cisco Unity Connection platform, can also be provisioned centrally to deliver services to endpoints remotely connected across an IP WAN.

Centrally provisioned Unified Communications services can be impacted by WAN connectivity interruptions; for each service, the available local survivability options should be planned. As an example, the call processing service as offered by Cisco Unified CM can be configured with local survivability functionality such as SRST or Cisco Unified Communications Manager Express

(Unified CME). Likewise, a centralized voice messaging service such as that of Cisco Unity Connection can be provisioned to allow remote sites operating under SRST or Unified CME to access voice messaging services at the central site, through the PSTN.

The centralization of services need not be uniform across all Unified Communications services. For example, a system can be deployed where multiple sites rely on a centralized call processing service, but can also be provisioned with a de-centralized (distributed) voice messaging service such as Cisco Unity Express. Likewise, a Unified Communications system could be deployed where call processing is provisioned locally at each site through Cisco Unified Communications Manager Express, with a centralized voice messaging service such as Cisco Unity Connection.

In many cases, the main criteria driving the design for each service are the availability and quality of the IP network between sites. The centralization of Unified Communications services offers advantages of economy of scale in both capital and operational expenses associated with the hosting and operation of equipment in situations where the IP connectivity between sites offers the following characteristics:

- Enough bandwidth for the anticipated traffic load, including peak hour access loads such as those generated by access to voicemail, access to centralized PSTN connectivity, and inter-site on-net communications including voice and video
- High availability, where the WAN service provider adheres to a Service Level Agreement to maintain and restore connectivity promptly
- Low latency, where local events at the remote site will not suffer if the round-trip time to the main central site imparts some delays to the system's response times

Also, when a given service is deployed centrally to serve endpoints at multiple sites, there are often advantages of feature transparency afforded by the use of the same processing resources for users at multiple sites. For example, when two sites are served by the same centralized Cisco Unified Communications Manager cluster, the users can share line appearances between the two sites. This benefit would not be available if each site were served by different (distributed) call processing systems.

These advantages of feature transparency and economies of scale should be evaluated against the relative cost of establishing and operating a WAN network configured to accommodate the demands of Unified Communications traffic.

Distributed Services

Unified Communications services can also be deployed independently over multiple sites, in a distributed fashion. For example, two sites (or more) can be provisioned with independent call processing Cisco Unified CME nodes, with no reliance on the WAN for availability of service to their co-located endpoints. Likewise, sites can be provisioned with independent voice messaging systems such as Cisco Unity Express.

The main advantage of distributing Unified Communications services lies in the independence of the deployment approach from the relative availability and cost of WAN connectivity. For example, if a company operates a site in a remote location where WAN connectivity is not available, is very expensive, or is not reliable, then provisioning an independent call processing node such as Cisco Unified Communications Manager Express within the remote site will avoid any call processing interruptions if the WAN goes down.

Inter-Networking of Services

If two sites are provisioned with independent services, they can still be interconnected to achieve some degree of inter-site feature transparency. For example, a distributed call processing service provisioned through Cisco Unified Communications Manager Express can be inter-networked through H.323 or SIP trunks to permit IP calls between the sites. Likewise, separate instances of Cisco Unity Connection or Cisco Unity Express can partake in the same messaging network to achieve the routing of messages and the exchange of subscriber and directory information within a unified messaging network.

Geographical Diversity of Unified Communications Services

Some services can be provisioned in multiple redundant nodes across the IP WAN, allowing for continued service through site disruptions such as loss of power, network outages, or even compromises in the physical integrity of a site by events such as fire or earthquake.

To achieve such geographical diversity, the individual service must support redundant nodes as well as the deployment of these nodes across the latency and bandwidth constraints of the IP WAN. For example, the call processing service of Unified CM does support the deployment of a single cluster's call processing nodes across an IP WAN as long as the total end-to-end round-trip time between the nodes does not exceed 80 ms and an appropriate quantity of QoS-enabled bandwidth is provisioned. By contrast, Unified CME does not offer redundancy, and thus cannot be deployed in a geographically diverse configuration.

Table 5-2 summarizes the ability of each Cisco Unified Communications service to be deployed in the manners outlined above.

Table 5-2 Available Deployment Options for Cisco Unified Communications Services

| Service | Centralized | Distributed | Inter-Networked | Geographical Diversity |
|-----------------------------|-------------|--|---|------------------------|
| Cisco Unified CM | Yes | Yes | Yes | Yes |
| Cisco Unified CME | No | Yes | Yes | No |
| Cisco Business Edition 6000 | Yes | Yes | Yes | Yes |
| Cisco Business Edition 5000 | Yes | Yes | Yes | No |
| Cisco Business Edition 3000 | Yes | No | No | No |
| Cisco Unity Express | No | Yes | Yes, with Cisco Unified Messaging Gateway | No |
| Cisco Unity | Yes | Yes (One Cisco Unity per site) | Yes, with Cisco Unified Messaging Gateway | Yes |
| Cisco Unity Connection | Yes | Yes (One Cisco Unity Connection per site) | Yes, with Cisco Unified Messaging Gateway | Yes |
| Cisco Emergency Responder | Yes | Yes (One Emergency Responder group per site) | Yes, through Emergency Responder clustering | Yes |
| Cisco Unified Presence | Yes | Yes (one Cisco Unified Presence per site) | Yes, through inter-domain federation | No |
| Cisco Unified Mobility | Yes | Yes, as Unified CM Single Number Reach | No | Yes |

Because call processing is a fundamental service, the basic call processing deployment models are introduced in this chapter. For a detailed technical discussion on Cisco Unified Communications Manager call processing, refer to the chapter on [Call Processing](#), page 8-1.

Campus

In this call processing deployment model, the Unified Communications services and the endpoints are co-located in the campus, and the QoS-enabled network between the service nodes, the endpoints, and applications is considered highly available, offering virtually unlimited bandwidth with less than 15 ms of latency end-to-end. Likewise, the quality and availability of power are very high, and services are hosted in an appropriate data center environment. Communications between the endpoints traverses a LAN or a MAN, and communications outside the enterprise goes over an external network such as the PSTN. An enterprise would typically deploy the campus model over a single building or over a group of buildings connected by a LAN or MAN.

Figure 5-1 Example of a Campus Deployment

The campus model typically has the following design characteristics:

- Single Cisco Unified CM cluster. Some campus call processing deployments may require more than one Unified CM cluster, for instance, if scale calls for more endpoints than can be serviced by a single cluster or if a cluster needs to be dedicated to an application such as a call center.
- Alternatively for smaller deployments, Cisco Business Edition 3000, 5000, or 6000 may be deployed in the campus.
- Maximum of 40,000 configured and registered Skinny Client Control Protocol (SCCP) or Session Initiation Protocol (SIP) IP phones, Cisco Cius, video endpoints, mobile clients, and Cisco Virtualization Experience Clients (VXC) per Unified CM cluster.
- Maximum of 2,100 gateways and trunks (that is, the total number of H.323 gateways, H.323 trunks, digital MGCP devices, and SIP trunks) per Unified CM cluster.
- Trunks and/or gateways (IP or PSTN) for all calls to destinations outside the campus.
- Co-located digital signal processor (DSP) resources for conferencing, transcoding, and media termination point (MTP).
- Other Unified Communications services, such as messaging (voicemail), presence, and mobility are typically co-located.
- Interfaces to legacy voice services such as PBXs and voicemail systems are connected within the campus, with no operational costs associated with bandwidth or connectivity.
- Multipoint Control Unit (MCU) resources are required for multipoint video conferencing. Depending on conferencing requirements, these resources may be either SCCP or H.323, or both.
- H.323 and H.320 video gateways are needed to communicate with H.320 videoconferencing devices on the public ISDN network.
- High-bandwidth audio is available (for example, G.722 or Cisco Wideband Audio) between devices within the site.
- High-bandwidth video (for example, 384 kbps or greater) is available between devices within the site. The Cisco Unified Video Advantage Wideband Codec, operating at 7 Mbps, is also supported.

Best Practices for the Campus Model

Follow these guidelines and best practices when implementing the single-site model:

- Ensure that the infrastructure is highly available, enabled for QoS, and configured to offer resiliency, fast convergence, and inline power.
- Know the calling patterns for your enterprise. Use the campus model if most of the calls from your enterprise are within the same site or to PSTN users outside your enterprise.
- Use G.711 codecs for all endpoints. This practice eliminates the consumption of digital signal processor (DSP) resources for transcoding, and those resources can be allocated to other functions such as conferencing and media termination points (MTPs).
- Implement the recommended network infrastructure for high availability, connectivity options for phones (in-line power), Quality of Service (QoS) mechanisms, and security. (See [Network Infrastructure](#), page 3-1.)
- Follow the provisioning recommendations listed in the chapter on [Call Processing](#), page 8-1.

Multisite with Centralized Call Processing

In this call processing deployment model, endpoints are remotely located from the call processing service, across a QoS-enabled Wide Area Network. Due to the limited quantity of bandwidth available across the WAN, a call admission control mechanism is required to manage the number of calls admitted on any given WAN link, to keep the load within the limits of the available bandwidth. On-net communication between the endpoints traverses either a LAN/MAN (when endpoints are located in the same site) or a WAN (when endpoints are located in different sites). Communication outside the enterprise goes over an external network such as the PSTN, through a gateway that can be co-located with the endpoint or at a different location (for example, when using a centralized gateway at the main site or when doing Tail End Hop Off (TEHO) across the enterprise network).

The IP WAN also carries call control signaling between the central site and the remote sites. [Figure 5-2](#) illustrates a typical centralized call processing deployment, with a Unified CM cluster as the call processing agent at the central site and a QoS-enabled IP WAN to connect all the sites. In this deployment model, other Unified Communications services such as voice messaging, presence and mobility are often hosted at the central site as well to reduce the overall costs of administration and maintenance. In situations where the availability of the WAN is unreliable or when WAN bandwidth costs are high, it is possible to consider decentralizing some Unified Communications services such as voice messaging (voicemail) so that the service's availability is not impacted by WAN outages.

**Note**

In each solution for the centralized call processing model presented in this document, the various sites connect to an IP WAN with QoS enabled.

Figure 5-2 Multisite Deployment with Centralized Call Processing

The multisite model with centralized call processing has the following design characteristics:

- Single Unified CM cluster. Some centralized call processing deployments may require more than one Unified CM cluster, for instance, if scale calls for more endpoints than can be serviced by a single cluster or if a cluster needs to be dedicated to an application such as a call center.
- For smaller deployments, Cisco Business Edition 3000 may be deployed in centralized call processing configurations for up to 9 remote sites.
- Cisco Business Edition 5000 may be deployed in centralized call processing configurations for up to 19 remote sites.
- Cisco Business Edition 6000 may be deployed in centralized call processing configurations for up to 49 remote sites.
- Maximum of 40,000 configured and registered Skinny Client Control Protocol (SCCP) or Session Initiation Protocol (SIP) IP phones, Cisco Cius, video endpoints, mobile clients, and Cisco Virtualization Experience Clients (VXC) per Unified CM cluster.
- Maximum of 2,000 locations or branch sites per Unified CM cluster.
- Maximum of 2,100 gateways and trunks (that is, the total number of H.323 gateways, H.323 trunks, digital MGCP devices, and SIP trunks) per Unified CM cluster.
- PSTN connectivity for all off-net calls.

- Digital signal processor (DSP) resources for conferencing, transcoding, and media termination point (MTP) are distributed locally to each site to reduce WAN bandwidth consumption on calls requiring DSPs.
- Capability to integrate with legacy private branch exchange (PBX) and voicemail systems. Interfaces to legacy voice services such as PBXs and voicemail systems can be connected within the central site, with no operational costs associated with bandwidth or connectivity. Connectivity to legacy systems located at remote sites may require the operational expenses associated with the provisioning of extra WAN bandwidth.
- H.323 clients, MCUs, and H.323/H.320 gateways that require a gatekeeper to place calls must register with a Cisco IOS Gatekeeper. Unified CM then uses an H.323 trunk to integrate with the gatekeeper and provide call routing and bandwidth management services for the H.323 devices registered to it. Multiple Cisco IOS Gatekeepers may be used to provide redundancy.
- MCU resources are required for multipoint video conferencing. Depending on conferencing requirements, these resources may be either SCCP or H.323, or both, and may all be located at the central site or may be distributed to the remote sites if local conferencing resources are required.
- H.323/H.320 video gateways are needed to communicate with H.320 videoconferencing devices on the public ISDN network. These gateways may all be located at the central site or may be distributed to the remote sites if local ISDN access is required.
- The system allows for the automated selection of high-bandwidth audio (for example, G.711, G.722, or Cisco Wideband Audio) between devices within the site, while selecting low-bandwidth audio (for example, G.729 or G.728) between devices in different sites.
- The system allows for the automated selection of high-bandwidth video (for example, 384 kbps or greater) between devices in the same site, and low-bandwidth video (for example, 128 kbps) between devices at different sites. The Cisco Unified Video Advantage Wideband Codec, operating at 7 Mbps, is recommended only for calls between devices at the same site.
- A minimum of 768 kbps or greater WAN link speed should be used when video is to be placed on the WAN.
- Unified CM locations (static or RSVP-enabled) provide call admission control.
- For voice and video calls, automated alternate routing (AAR) provides the automated rerouting of calls through the PSTN when call admission control denies a call due to lack of bandwidth. AAR relies on a gateway being available to route the call from the calling phone toward the PSTN, and another gateway to accept the call from the PSTN at the remote site, to be connected to the called phone.
- Call Forward Unregistered (CFUR) functionality provides the automated rerouting of calls through the PSTN when an endpoint is considered unregistered due to a remote WAN link failure. CFUR relies on a gateway being available to route the call from the calling phone toward the PSTN, and another gateway to accept the call from the PSTN at the remote site, to be connected to the called phone.
- Survivable Remote Site Telephony (SRST) for video. SCCP video endpoints located at remote sites become audio-only devices if the WAN connection fails.
- Cisco Unified Communications Manager Express (Unified CME) may be used for remote site survivability instead of an SRST router.
- Cisco Unified Communications Manager Express (Unified CME) can be integrated with the Cisco Unity server in the branch office or remote site. The Cisco Unity server is registered to the Unified CM at the central site in normal mode and can fall back to Unified CME in SRST mode when Unified CM is not reachable, or during a WAN outage, to provide the users at the branch offices with access to their voicemail with MWI.

- As with other call processing types that support multisite centralized call processing, Cisco Business Edition 3000 allows PSTN routing through both central and remote site gateways. Providing a local gateway at remote sites for local PSTN breakout is a necessary requirement for countries providing emergency services for users located at remote sites. The local gateway at the remote site provides call routing to the local PSAP of the remote site location. Local PSTN breakout at remote sites might also be needed or required for countries having strict regulations requiring separation of IP telephony networks from the PSTN. Where regulations allow, local PSTN breakout through the remote site gateway can be used to enable toll bypass or tail-end hop off (TEHO). Business Edition 3000 provides country-based dial plan configuration to enable routing to configured PSTN gateways as well as policy mechanisms to control PSTN access restrictions (as applicable based on local country regulations). Business Edition 3000 supports local PSTN breakout only through the MGCP-controlled Cisco 2901 Integrated Services Router (ISR). Local breakout at a remote site can also be provided through analog trunks using a Cisco SPA8800 IP Telephony Gateway or through SIP trunks using Cisco Unified Border Element on a Cisco SPA8800 or SPA8900 IP Telephony Gateway (sometimes referred to as “CUBE Lite”).
- Business Edition 3000 does not support SRST or remote site survivability.

Connectivity options for the IP WAN include:

- Leased lines
- Frame Relay
- Asynchronous Transfer Mode (ATM)
- ATM and Frame Relay Service Inter-Working (SIW)
- Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN)
- Voice and Video Enabled IP Security Protocol (IPSec) VPN (V3PN)

Routers that reside at the WAN edges require quality of service (QoS) mechanisms, such as priority queuing and traffic shaping, to protect the voice traffic from the data traffic across the WAN, where bandwidth is typically scarce. In addition, a call admission control scheme is needed to avoid oversubscribing the WAN links with voice traffic and deteriorating the quality of established calls. For centralized call processing deployments, *locations* (static or RSVP-enabled) configured within Unified CM provide call admission control. (Refer to the chapter on [Call Admission Control](#), page 11-1, for more information on locations.)

A variety of Cisco gateways can provide the remote sites with PSTN access. When the IP WAN is down, or if all the available bandwidth on the IP WAN has been consumed, calls from users at remote sites can be rerouted through the PSTN. The Cisco Unified Survivable Remote Site Telephony (SRST) feature, available for both SCCP and SIP phones, provides call processing at the branch offices for Cisco Unified IP Phones if they lose their connection to the remote primary, secondary, or tertiary Unified CM or if the WAN connection is down. Cisco Unified SRST functionality is available on Cisco IOS gateways running the SRST feature or on Cisco Unified CME running in SRST mode. Unified CME running in SRST mode provides more features for the phones than SRST on a Cisco IOS gateway.

Best Practices for the Centralized Call Processing Model

Follow these guidelines and best practices when implementing multisite centralized call processing deployments:

- Minimize delay between Unified CM and remote locations to reduce voice cut-through delays (also known as clipping).
- Configure locations (static or RSVP-enabled) in Unified CM to provide call admission control into and out of remote branches. See the chapter on [Call Admission Control, page 11-1](#), for details on how to apply this mechanism to the various WAN topologies.
- The number of IP phones and line appearances supported in Survivable Remote Site Telephony (SRST) mode at each remote site depends on the branch router platform, the amount of memory installed, and the Cisco IOS release. SRST on a Cisco IOS gateway supports up to 1,500 phones, while Unified CME running in SRST mode supports 350 phones. (For the latest SRST or Unified CME platform and code specifications, refer to the SRST and Unified CME documentation available at <http://www.cisco.com>.) Generally speaking, however, the choice of whether to adopt a centralized call processing or distributed call processing approach for a given site depends on a number of factors such as:
 - IP WAN bandwidth or delay limitations
 - Criticality of the voice network
 - Feature set needs
 - Scalability
 - Ease of management
 - Cost

If a distributed call processing model is deemed more suitable for the customer's business needs, the choices include installing a Unified CM cluster at each site or running Unified CME at the remote sites.

- At the remote sites, use the following features to ensure call processing survivability in the event of a WAN failure:
 - For SCCP phones, use SRST on a Cisco IOS gateway or Unified CME running in SRST mode.
 - For SIP phones, use SIP SRST.
 - For MGCP phones, use MGCP Gateway Fallback.

SRST or Unified CME in SRST mode, SIP SRST, and MGCP Gateway Fallback can reside with each other on the same Cisco IOS gateway.

Remote Site Survivability

When deploying Cisco Unified Communications across a WAN with the centralized call processing model, you should take additional steps to ensure that data and voice services at the remote sites are highly available. [Table 5-3](#) summarizes the different strategies for providing high availability at the

remote sites. The choice of one of these strategies may depend on several factors, such as specific business or application requirements, the priorities associated with highly available data and voice services, and cost considerations.

Table 5-3 Strategies for High Availability at the Remote Sites

| Strategy | High Availability for Data Services? | High Availability for Voice Services? |
|---|--------------------------------------|---------------------------------------|
| Redundant IP WAN links in branch router | Yes | Yes |
| Redundant branch router platforms + Redundant IP WAN links | Yes | Yes |
| Data-only ISDN backup + SRST or Unified CME | Yes | Yes |
| Data and voice ISDN backup | Yes | Yes (see rules below) |
| Cisco Unified Survivable Remote Site Telephony (SRST) or Unified CME in SRST mode | No | Yes |

The first two solutions listed in [Table 5-3](#) provide high availability at the network infrastructure layer by adding redundancy to the IP WAN access points, thus maintaining IP connectivity between the remote IP phones and the centralized Unified CM at all times. These solutions apply to both data and voice services, and are entirely transparent to the call processing layer. The options range from adding a redundant IP WAN link at the branch router to adding a second branch router platform with a redundant IP WAN link.

The third and fourth solutions in [Table 5-3](#) use an ISDN backup link to provide survivability during WAN failures. The two deployment options for ISDN backup are:

- Data-only ISDN backup

With this option, ISDN is used for data survivability only, while SRST or Unified CME in SRST mode is used for voice survivability. Note that you should configure an access control list on the branch router to prevent traffic from telephony signaling protocols such as Skinny Client Control Protocol (SCCP), H.323, Media Gateway Control Protocol (MGCP), or Session Initiation Protocol (SIP) from entering the ISDN interface, so that signaling from the IP phones does not reach the Unified CM at the central site. This is to ensure that the telephony endpoints located at the branch detect the WAN's failure and rely on local SRST resources.

- Data and voice ISDN backup

With this option, ISDN is used for both data and voice survivability. In this case, SRST or Unified CME in SRST mode is not used because the IP phones maintain IP connectivity to the Unified CM cluster at all times. However, Cisco recommends that you use ISDN to transport data and voice traffic only if all of the following conditions are true:

- The bandwidth allocated to voice traffic on the ISDN link is the same as the bandwidth allocated to voice traffic on the IP WAN link.
- The ISDN link bandwidth is fixed.
- All the required QoS features have been deployed on the router's ISDN interfaces. Refer to the chapter on [Network Infrastructure, page 3-1](#), for more details on QoS.

The fifth solution listed in [Table 5-3](#), Survivable Remote Site Telephony (SRST) or Unified CME in SRST mode, provides high availability for voice services only, by providing a subset of the call processing capabilities within the remote office router and enhancing the IP phones with the ability to “re-home” to the call processing functions in the local router if a WAN failure is detected. [Figure 5-3](#) illustrates a typical call scenario with SRST or Unified CME in SRST mode.

Figure 5-3 Survivable Remote Site Telephony (SRST) or Unified CME in SRST Mode

Under normal operations shown in the left part of [Figure 5-3](#), the branch office connects to the central site via an IP WAN, which carries data traffic, voice traffic, and call signaling. The IP phones at the branch office exchange call signaling information with the Unified CM cluster at the central site and place their calls across the IP WAN. The branch router or gateway forwards both types of traffic (call signaling and voice) transparently and has no knowledge of the IP phones.

If the WAN link to the branch office fails, or if some other event causes loss of connectivity to the Unified CM cluster, the branch IP phones re-register with the branch router in SRST mode. The branch router, SRST, or Unified CME running in SRST mode, queries the IP phones for their configuration and

uses this information to build its own configuration automatically. The branch IP phones can then make and receive calls either within the branch's network or through the PSTN. The phone displays the message "Unified CM fallback mode," and some advanced Unified CM features are unavailable and are grayed out on the phone display.

When WAN connectivity to the central site is reestablished, the branch IP phones automatically re-register with the Unified CM cluster and resume normal operation. The branch SRST router deletes its information about the IP phones and reverts to its standard routing or gateway configuration. Unified CME running in SRST mode at the branch can choose to save the learned phone and line configuration to the running configuration on the Unified CME router by using the auto-provision option. If **auto-provision none** is configured, none of the auto-provisioned phone or line configuration information is written to the running configuration of the Unified CME router. Hence, no configuration change is required on Unified CME if the IP phone is replaced and the MAC address changes.

**Note**

When WAN connectivity to the central site is reestablished, or when Unified CM is reachable again, phones in SRST mode with active calls will not immediately re-register to Unified CM until those active calls are terminated.

**Note**

The remote site survivability features explained above are not supported with Business Edition 3000.

Unified CME in SRST Mode

When Unified CME is used in SRST mode, it provides more call processing features for the IP phones than are available with the SRST feature on a router. In addition to the SRST features such as call preservation, auto-provisioning, and failover, Unified CME in SRST mode also provides most of the Unified CME telephony features for the SCCP phones, including:

- Paging
- Conferencing
- Hunt groups
- Basic automatic call distribution (B-ACD)
- Call park, call pickup, call pickup groups
- Overlay-DN, softkey templates
- Cisco IP Communicator
- Cisco Unified Video Advantage
- Integration with Cisco Unity with MWI support at remote sites, with distributed Microsoft Exchange or IBM Lotus Domino server

Unified CME in SRST mode provides call processing support for SCCP phones in case of a WAN failure. However, Unified CME in SRST mode does not provide fallback support for MGCP phones or endpoints. To enable SIP and MGCP phones to fall back if they lose their connection to the SIP proxy server or Unified CM, or if the WAN connection fails, you can additionally configure both the SIP SRST feature and the MGCP Gateway Fallback feature on the same Unified CME server running as the SRST fallback server.

Best Practices for Unified CME in SRST Mode

- Use the Unified CME IP address as the IP address for SRST reference in the Unified CM configuration.
- The Connection Monitor Duration is a timer that specifies how long phones monitor the WAN link before initiating a fallback from SRST to Unified CM. The default setting of 120 seconds should be used in most cases. However, to prevent phones in SRST mode from falling back and re-homing to Unified CM with flapping links, you can set the Connection Monitor Duration parameter on Unified CM to a longer period so that phones do not keep registering back and forth between the SRST router and Unified CM. Do not set the value to an extensively longer period because this will prevent the phones from falling back from SRST to Unified CM for a long amount of time.
- Phones in SRST fallback mode will not re-home to Unified CM when they are in active state.
- Phones in SRST fallback mode revert to non-secure mode from secure conferencing.
- Configure **auto-provision none** to prevent writing any learned ephone-dn or ephone configuration to the running configuration of the Unified CME router. This eliminates the need to change the configuration if the IP phone is replaced or the MAC address changes.

For more information on using Unified CME in SRST mode, refer to the *Cisco Unified Communications Manager Express System Administrator Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps4625/products_installation_and_configuration_guides_list.html

For more information on SIP SRST, refer to the *Cisco Unified SIP SRST System Administrator Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps2169/products_installation_and_configuration_guides_list.html

For more information on MGCP Gateway fallback, refer to the information on MGCP gateway fallback in the *Cisco CallManager and Cisco IOS Interoperability Guide*, available at

http://www.cisco.com/en/US/docs/ios/12_3/vvf_c/interop/ccm_c.html

Best Practices for SRST Router

Use a Cisco Unified SRST router, rather than Unified CME in SRST mode, for the following deployment scenarios:

- For supporting a maximum of 1,500 phones on a single SRST router.
- For up to 3,000 phones, use two SRST routers. Dial plans must be properly configured to route the calls back and forth between the SRST routers.
- For simple, one-time configuration of basic SRST functions.
- For SRTP media encryption, which is available only in Cisco Unified SRST (Secure SRST).
- For support of the Cisco VG248 Voice Gateway.

For routing calls to and from phones that are unreachable or not registered to the SRST router, use the **alias** command.

Enhanced Survivable Remote Site Telephony

Enhanced Survivable Remote Site Telephony (E-SRST) simplifies the deployment of Cisco Unified CME running SRST in the branch. E-SRST architecture is built on top of Survivable Remote Site Voicemail (SRSV). (See [Figure 5-4](#).) During normal operation, E-SRST utilizes Cisco Unified Messaging Gateway E-SRST located at headquarters site to regularly retrieve configurations (for example, calling search space, partition, hunt group, call park, call pickup, and so forth, if configured) from Cisco Unified CM and upload them to provision the branch router with similar functionality for use in SRST mode. Thus, E-SRST reduces manual configuration required in Unified CME running SRST and enables users to have a similar calling experience in both SRST and normal modes.

Figure 5-4 Enhanced Survivable Remote Site Telephony Deployment

E-SRST consumes bandwidth from the WAN link when uploading the Unified CM configurations to provision the branch router. The E-SRST software does not perform packet marking, therefore the E-SRST traffic will travel as best-effort on the network. Cisco recommends maintaining this best-effort marking, which is IP Precedence 0 (DSCP 0 or PHB BE), to ensure that it does not interfere with real-time high priority voice traffic. To ensure E-SRST traffic does not cause congestion and to reduce the chances of packet drop, Cisco recommends scheduling the configuration upload to take place during non-peak hours (for example, in the evening hours or during the weekend). The configuration upload schedule can be set from the Unified Messaging Gateway E-SRST web interface.

Consider the following guidelines when you deploy E-SRST:

- Unified Messaging Gateway E-SRST supports up to 1000 SRST nodes.
- E-SRST is supported only in the branch routers with Unified CME running SRST.
- E-SRST is not supported on the Cisco Unified Communications 500 Series platform or Cisco Unified CM Business Edition.
- The branch voice gateway and SRST must be located in the same router.
- There is no high availability support for configuration upload with Unified Messaging Gateway E-SRST. If the Unified Messaging Gateway is unavailable, configuration upload is not possible.

- E-SRST and SRSV can be deployed using the same Unified Messaging Gateway and Unified CME running SRST. In this case, SRST together with SRSV support up to a total of 1000 nodes.
- E-SRST is not supported in deployments where NAT is used between the headquarters and branch locations.
- Secure Unified CME connection is not supported with E-SRST.

**Note**

The enhanced remote site survivability feature explained above is not supported with Cisco Business Edition 3000.

Voice Over the PSTN as a Variant of Centralized Call Processing

Centralized call processing deployments can be adapted so that inter-site voice media is sent over the PSTN instead of the WAN. With this configuration, the signaling (call control) of all telephony endpoints is still controlled by the central Unified CM cluster, therefore this Voice over the PSTN (VoPSTN) model variation still requires a QoS-enabled WAN with appropriate bandwidth configured for the signaling traffic.

You can implement VoPSTN in one of the following ways:

- Using the automated alternate routing (AAR) feature. (For more information on AAR, see the section on [Automated Alternate Routing, page 9-108.](#))
- Using a combination of dial plan constructs in both Unified CM and the PSTN gateways.

VoPSTN can be an attractive option in deployments where IP WAN bandwidth is either scarce or expensive with respect to PSTN charges, or where IP WAN bandwidth upgrades are planned for a later date but the Cisco Unified Communications system is already being deployed.

**Note**

VoPSTN deployments offer basic voice functionality that is a reduced subset of the Unified CM feature set.

In particular, regardless of the implementation choice, the system designer should address the following issues, among others:

- Centralized voicemail requires:
 - A telephony network provider that supports redirected dialed number identification service (RDNIS) end-to-end for all locations that are part of the deployment. RDNIS is required so that calls redirected to voicemail carry the redirecting DN, to ensure proper voicemail box selection.
 - If the voicemail system is accessed through an MGCP gateway, the voicemail pilot number must be a fully qualified E.164 number.
- The Extension Mobility feature is limited to IP phones contained within a single branch site.
- All on-net (intra-cluster) calls will be delivered to the destination phone with the same call treatment as an off-net (PSTN) call. This includes the quantity of digits delivered in the call directories such as Missed Calls and Received Calls.
- Each inter-branch call generates two independent call detail records (CDRs): one for the call leg from the calling phone to the PSTN, and the other for the call leg from the PSTN to the called phone.
- There is no way to distinguish the ring type for on-net and off-net calls.
- All destination phones require a fully qualified Direct Inward Dial (DID) PSTN number that can be called directly. Non-DID DNs cannot be reached directly from a different branch site.

- With VoPSTN, music on hold (MoH) is limited to cases where the holding party is co-located with the MoH resource. If MoH servers are deployed at the central site, then only calls placed on hold by devices at the central site will receive the hold music.
- Transfers to a destination outside the branch site will result in the hairpinning of the call through the branch's gateway. Traffic engineering of the branch's gateway resources must be adjusted accordingly.
- Call forwarding of any call coming into the branch's gateway to a destination outside the branch site will result in hairpinning of the call through the gateway, thus using two trunk ports. This behavior applies to:
 - Calls forwarded to a voicemail system located outside the branch
 - Calls forwarded to an on-net abbreviated dialing destination located in a different branch

The gateway port utilization resulting from these call forwarding flows should be taken into account when sizing the trunks connecting the branch to the PSTN.

- Conferencing resources must be co-located with the phone initiating the conference.
- VoPSTN does not support applications that require streaming of IP audio from the central site (that is, not traversing a gateway). These applications include, but are not limited to:
 - Centralized music on hold (MoH) servers
 - Interactive Voice Response (IVR)
 - CTI-based applications
- Use of the Attendant Console outside of the central site can require a considerable amount of bandwidth if the remote sites must access large user account directories without caching them.
- Because all inter-branch media (including transfers) are sent through the PSTN, the gateway trunk group must be sized to accommodate all inter-branch traffic, transfers, and centralized voicemail access.
- Cisco recommends that you do not deploy shared lines across branches, such that the devices sharing the line are in different branches.

In addition to these general considerations, the following sections present recommendations and issues specific to each of the following implementation methods:

- [VoPSTN Using AAR, page 5-21](#)
- [VoPSTN Using Dial Plan, page 5-23](#)

VoPSTN Using AAR

This method consists of configuring the Unified CM dial plan as in a traditional centralized call processing deployment, with the automated alternate routing (AAR) feature also properly configured. AAR provides transparent re-routing over the PSTN of inter-site calls when the locations mechanism for call admission control determines that there is not enough available WAN bandwidth to accept an additional call.

To use the PSTN as the primary (and only) voice path, you can configure the call admission control bandwidth of each location (branch site) to be 1 kbps, thus preventing *all* calls from traversing the WAN. With this configuration, all inter-site calls trigger the AAR functionality, which automatically re-routes the calls over the PSTN.

The AAR implementation method for VoPSTN offers the following benefits:

- An easy migration path to a complete Cisco Unified Communications deployment. When bandwidth becomes available to support voice media over the WAN, the dial plan can be maintained intact, and the only change needed is to update the location bandwidth value for each site.
- Support for some supplementary features, such as callback on busy.

In addition to the general considerations listed for VoPSTN, the following design guidelines apply to the AAR implementation method:

- AAR functionality must be configured properly.
- As a general rule, supported call initiation devices include IP phones, gateways, and line-side gateway-driven analog phones.
- Inter-branch calls can use AAR only if the destination devices are IP phones or Cisco Unity ports.
- Inter-branch calls to other endpoints must use a fully qualified E.164 number.
- All on-net, inter-branch calls will display the message, "Network congestion, rerouting."
- If destination phones become unregistered (for example, due to WAN connectivity interruption), AAR functionality will not be invoked and abbreviated dialing will be possible only if Call Forward Unregistered (CFUR) is configured. If the destination phone has registered with an SRST router, then it can also be reached by directly dialing its PSTN DID number.
- If originating phones become unregistered (for example, due to WAN connectivity interruption), they will go into SRST (or Unified CME as SRST) mode. To preserve abbreviated dialing functionality under these conditions, configure the SRST (or Unified CME as SRST) router with an appropriate set of translation rules to match the abbreviated dialing form of the destination and translate it into the form required by the PSTN to route calls to the destination.
- Shared lines within the same branch should be configured in a partition included only in that branch's calling search spaces. Inter-site access to the shared line requires one of the following:
 - The originating site dials the DID number of the shared line.
 - If inter-site abbreviated dialing to the shared line is desired, use a translation pattern that expands the user-dialed abbreviated string to the DID number of the shared line.

Note In this case, direct dialing of the shared line's DN from another branch would trigger multiple AAR-based PSTN calls.

VoPSTN Using Dial Plan

This method relies on a specific dial plan configuration within Unified CM and the PSTN gateways to route all inter-site calls over the PSTN. The dial plan must place IP phone DN's at each site into a different partition, and their calling search space must provide access only to the site's internal partition and a set of route patterns that point to the local PSTN gateway.

Abbreviated inter-site dialing can still be provided via a set of translations at each branch site, one for each of the other branch sites. These translations are best accomplished with H.323 gateways and translation rules within Cisco IOS.

The dial plan method for implementing VoPSTN offers the following benefits:

- Easier configuration because AAR is not needed.
- Abbreviated dialing automatically works even under WAN failure conditions on either the originating or destination side, because the Cisco IOS translation rules within the H.323 gateway are effective in SRST mode.

In addition to the general considerations listed for VoPSTN, the following design guidelines apply to the dial plan implementation method:

- There is no support for supplementary features such as callback on busy.
- Some CTI-based applications do not support overlapping extensions (that is, two or more phones configured with the same DN, although in different partitions).
- There is no easy migration to a complete Cisco Unified Communications deployment because the dial plan needs to be redesigned.

Multisite with Distributed Call Processing

The model for a multisite deployment with distributed call processing consists of multiple independent sites, each with its own call processing agent cluster connected to an IP WAN that carries voice traffic between the distributed sites. [Figure 5-5](#) illustrates a typical distributed call processing deployment.

Figure 5-5 Multisite Deployment with Distributed Call Processing

Each site in the distributed call processing model can be one of the following:

- A single site with its own call processing agent, which can be either:
 - Cisco Unified Communications Manager (Unified CM)
 - Cisco Business Edition 5000 and Business Edition 6000
 - Cisco Unified Communications Manager Express (Unified CME)

- Other IP PBX
- A centralized call processing site and all of its associated remote sites
- A legacy PBX with Voice over IP (VoIP) gateway

The multisite model with distributed call processing has the following design characteristics:

- Maximum of 40,000 configured and registered Skinny Client Control Protocol (SCCP) or Session Initiation Protocol (SIP) IP phones, Cisco Cius, video endpoints, mobile clients, and Cisco Virtualization Experience Clients (VXC) per Unified CM cluster.
- Maximum of 2,100 gateways and trunks (that is, the total number of H.323 gateways, H.323 trunks, digital MGCP devices, and SIP trunks) per Unified CM cluster.
- PSTN for all external calls.
- Digital signal processor (DSP) resources for conferencing, transcoding, and media termination point (MTP) are distributed locally to each site to reduce WAN bandwidth consumption on calls requiring DSPs.
- Voicemail, unified messaging, and Cisco Unified Presence components.
- Capability to integrate with legacy private branch exchange (PBX) and voicemail systems.
- H.323 clients, MCUs, and H.323/H.320 gateways that require a gatekeeper to place calls must register with a Cisco IOS Gatekeeper. Unified CM then uses an H.323 trunk to integrate with the gatekeeper and provide call routing and bandwidth management services for the H.323 devices registered to it. Multiple Cisco IOS Gatekeepers may be used to provide redundancy. Cisco IOS Gatekeepers may also be used to provide call routing and bandwidth management between the distributed Unified CM clusters. In most situations, Cisco recommends that each Unified CM cluster have its own set of endpoint gatekeepers and that a separate set of gatekeepers be used to manage the intercluster calls. It is possible in some circumstances to use the same set of gatekeepers for both functions, depending on the size of the network, complexity of the dial plan, and so forth. (For details, see [Gatekeepers, page 12-25](#).)
- MCU resources are required in each cluster for multipoint video conferencing. Depending on conferencing requirements, these resources may be either SCCP or H.323, or both, and may all be located at the regional sites or may be distributed to the remote sites of each cluster if local conferencing resources are required.
- H.323/H.320 video gateways are needed to communicate with H.320 videoconferencing devices on the public ISDN network. These gateways may all be located at the regional sites or may be distributed to the remote sites of each cluster if local ISDN access is required.
- High-bandwidth audio (for example, G.711, G.722, or Cisco Wideband Audio) between devices in the same site, but low-bandwidth audio (for example, G.729 or G.728) between devices in different sites.
- High-bandwidth video (for example, 384 kbps or greater) between devices in the same site, but low-bandwidth video (for example, 128 kbps) between devices at different sites. The Cisco Unified Video Advantage Wideband Codec, operating at 7 Mbps, is recommended only for calls between devices at the same site. Note that the Cisco VT Camera Wideband Video Codec is not supported over intercluster trunks.
- Minimum of 768 kbps or greater WAN link speeds. Video is *not* recommended on WAN connections that operate at speeds lower than 768 kbps.
- Call admission control is provided by Unified CM locations for calls between sites controlled by the same Unified CM cluster, and by the Cisco IOS Gatekeeper for calls between Unified CM clusters (that is, intercluster trunks).

An IP WAN interconnects all the distributed call processing sites. Typically, the PSTN serves as a backup connection between the sites in case the IP WAN connection fails or does not have any more available bandwidth. A site connected only through the PSTN is a standalone site and is not covered by the distributed call processing model. (See [Campus](#), page 5-8.)

Connectivity options for the IP WAN include:

- Leased lines
- Frame Relay
- Asynchronous Transfer Mode (ATM)
- ATM and Frame Relay Service Inter-Working (SIW)
- Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN)
- Voice and Video Enabled IP Security Protocol (IPSec) VPN (V3PN)

Best Practices for the Distributed Call Processing Model

A multisite deployment with distributed call processing has many of the same requirements as a single site or a multisite deployment with centralized call processing. Follow the best practices from these other models in addition to the ones listed here for the distributed call processing model. (See [Campus](#), page 5-8, and [Multisite with Centralized Call Processing](#), page 5-10.)

Cisco Unified Communications Manager Session Management Edition clusters, H.323 gatekeepers, or Session Initiation Protocol (SIP) proxy servers can be used to provide dial plan aggregation and resolution in multisite distributed call processing deployments. The following best practices apply to the use of these dial plan aggregation devices:

Unified CM Session Management Edition Clusters

Cisco Unified Communications Manager Session Management Edition is commonly used as a dial plan aggregation device in distributed call processing deployments. Unified CM Session Management Edition supports multiple protocols (SIP, H.323, MGCP, and SCCP), has sophisticated trunk and digit manipulation features, and uses the same code and user interface as Unified CM. Unified CM Session Management Edition cluster deployments typically consist of many trunks and no (or very few) Unified Communications endpoints. When sizing the Unified CM Session Management Edition cluster, give consideration to the traffic distribution within the Unified Communications system. Unified CM Session Management Edition clusters can use all of the high availability features (such as clustering over the WAN, CallManager Groups, and Run on all Unified CM Nodes) that are available to Unified CM clusters.

For detailed information on Unified CM Session Management Edition cluster deployments, refer to the *Cisco Unified Communications Manager Session Management Edition Deployment Guide*, available at

http://www.cisco.com/en/US/products/ps10661/products_implementation_design_guides_list.html

Gatekeeper Deployments

- Use a Cisco IOS gatekeeper to provide call admission control into and out of each site.
- To provide high availability of the gatekeeper, use Hot Standby Router Protocol (HSRP) gatekeeper pairs, gatekeeper clustering, and alternate gatekeeper support. In addition, use multiple gatekeepers to provide redundancy within the network. (See [Gatekeeper Design Considerations](#), page 8-37.)
- Size the platforms appropriately to ensure that performance and capacity requirements can be met.

- Use only one type of codec on the WAN because the H.323 specification does not allow for Layer 2, IP, User Data Protocol (UDP), or Real-time Transport Protocol (RTP) header overhead in the bandwidth request. (Header overhead is allowed only in the payload or encoded voice part of the packet.) Using one type of codec on the WAN simplifies capacity planning by eliminating the need to over-provision the IP WAN to allow for the worst-case scenario.
- Gatekeeper networks can scale to hundreds of sites, and the design is limited only by the WAN topology.

For more information on the various functions performed by gatekeepers, refer to the following sections:

- For gatekeeper call admission control, see [Call Admission Control, page 11-1](#).
- For gatekeeper scalability and redundancy, see [Call Processing, page 8-1](#).
- For gatekeeper dial plan resolution, see [Dial Plan, page 9-1](#).

SIP Proxy Deployments

SIP devices provide resolution of E.164 numbers as well as SIP uniform resource identifiers (URIs) to enable endpoints to place calls to each other. Unified CM supports the use of E.164 numbers only.

The following best practices apply to the use of SIP proxies:

- Provide adequate redundancy for the SIP proxies.
- Ensure that the SIP proxies have the capacity for the call rate and number of calls required in the network.
- Planning for call admission control is outside the scope of this document.

Call Processing Agents for the Distributed Call Processing Model

Your choice of call processing agent will vary, based on many factors. The main factors, for the purpose of design, are the size of the site and the functionality required.

For a distributed call processing deployment, each site has its own call processing agent. The design of each site varies with the call processing agent, the functionality required, and the fault tolerance required. For example, in a site with 500 phones, a Unified CM cluster containing two servers can provide one-to-one redundancy, with the backup server being used as a publisher and Trivial File Transfer Protocol (TFTP) server.

The requirement for IP-based applications also greatly affects the choice of call processing agent because only Unified CM provides the required support for many Cisco IP applications.

[Table 5-4](#) lists recommended call processing agents.

Table 5-4 Recommended Call Processing Agents

| Call Processing Agent | Recommended Size | Comments |
|--|--------------------|--|
| Cisco Unified Communications Manager Express (Unified CME) | Up to 450 phones | <ul style="list-style-type: none"> • For small remote sites • Capacity depends on Cisco IOS platform |
| Cisco Business Edition 5000 | Up to 575 phones | <ul style="list-style-type: none"> • For small sites • Supports centralized or distributed call processing |
| Cisco Business Edition 6000 | Up to 1,200 phones | <ul style="list-style-type: none"> • For small to medium sites • Supports centralized or distributed call processing |

Table 5-4 Recommended Call Processing Agents (continued)

| Call Processing Agent | Recommended Size | Comments |
|---|---------------------|--|
| Cisco Unified Communications Manager (Unified CM) | 50 to 40,000 phones | <ul style="list-style-type: none"> • Small to large sites, depending on the size of the Unified CM cluster • Supports centralized or distributed call processing |
| Legacy PBX with VoIP gateway | Depends on PBX | <ul style="list-style-type: none"> • Number of IP WAN calls and functionality depend on the PBX-to-VoIP gateway protocol and the gateway platform |

When multiple call processing agents are present in the same system, you can configure each one manually to be aware of the others, or you can use the Cisco Service Advertisement Framework (SAF) to share call routing and dial plan information automatically between call agents. For details about SAF, see [Call Routing and Dial Plan Distribution Using Call Control Discovery for the Service Advertisement Framework, page 5-64](#).

Unified CM Session Management Edition

Unified Communications deployments using Cisco Unified Communications Manager Session Management Edition are a variation of the multisite distributed call processing deployment model and are typically employed to interconnect large numbers of unified communications systems through a single front-end system, in this case the Unified CM Session Management Edition. This section discusses the relevant design considerations for deploying Unified CM Session Management Edition.

Cisco Unified CM Session Management Edition is essentially a Unified CM cluster with trunk interfaces only and no IP endpoints. It enables aggregation of multiple unified communications systems, referred to as leaf systems.

Session Management Edition deployments can be used to migrate a deployment of multiple PBXs and associated phones to a Unified CM cluster with IP phones and relatively few trunks. The Session Management Edition cluster may start with a large number of trunks interconnecting third-party PBXs; and migrate over time to a Unified CM cluster deployment with thousands of IP phones.

With Cisco Unified CM 8.0 and later releases, Unified CM Session Management Edition supports the following features:

- H.323 Annex M1 intercluster trunks
- SIP intercluster trunks
- SIP trunks
- H.323 trunks
- MGCP trunks
- Voice calls
- Video calls
- Encrypted calls
- Fax calls

Unified CM Session Management Edition may also be used to connect to third-party unified communications systems such as PSTN connections, PBXs, and centralized unified communications applications. (See Figure 5-6.) However, as with any standard Unified CM cluster, third-party connections to Unified CM Session Management Edition should be system tested for interoperability prior to use in a production environment.

Figure 5-6 Multisite Deployment with Unified CM Session Management Edition

When to Deploy Unified CM Session Management Edition

Cisco recommends deploying Unified CM Session Management Edition if you want to do any of the following:

- Create and manage a centralized dial plan

Rather than configuring each unified communications system with a separate dial plan and trunks to connect to all the other unified communications systems, Unified CM Session Management Edition allows you to configure the leaf unified communications systems with a simplified dial plan and trunk(s) pointing to the Session Management cluster. Unified CM Session Management Edition holds the centralized dial plan and corresponding reachability information about all the other unified communications systems.

- Provide centralized PSTN access

Unified CM Session Management Edition can be used to aggregate PSTN access to one (or more) centralized PSTN trunks. Centralized PSTN access is commonly combined with the reduction, or elimination, of branch-based PSTN circuits.

- Centralize applications
The deployment of a Unified CM Session Management Edition enables commonly used applications such as conferencing or videoconferencing to connect directly to the Session Management cluster, thus reducing the overhead of managing multiple trunks to leaf systems.
- Aggregate PBXs for migration to a Unified Communications system
Unified CM Session Management Edition can provide an aggregation point for multiple PBXs as part of the migration from legacy PBXs to a Cisco Unified Communications System.

Differences Between Unified CM Session Management Edition and Standard Unified CM Clusters

The Unified CM Session Management Edition software is exactly the same as Unified CM. However, the software has been enhanced significantly to satisfy the requirements and the constraints of this new deployment model. Unified CM Session Management Edition is designed to support a large number of trunk-to-trunk connections, and as such it is subject to the following design considerations:

- Capacity
It is important to correctly size the Unified CM Session Management cluster based on the expected BHCA traffic load between leaf Unified Communications systems (for example, Unified CM clusters and PBXs), to and from any centralized PSTN connections, and to any centralized applications. Determine the average BHCA and Call Holding Time for users of your Unified Communications system and share this information with your Cisco account Systems Engineer (SE) or Cisco Partner to size your Unified CM Session Management Edition cluster correctly.
- Trunks
Where possible, avoid the use of static MTPs on Unified CM trunks (you must not enable **MTP required** on the SIP or H.323 trunks of leaf Unified CM or Unified CM Session Management Edition clusters). Trunks that do not use “MTP required” offer more codec choices; support voice, video, and encryption; and do not anchor trunk calls to MTP resources. Dynamically inserted MTPs can be used on trunks (for example, for DTMF translation from in-band to out-of-band). If SIP Early Offer is required by a third-party unified communications system, use either the “Early Offer support for voice and video calls (insert MTP if needed)” on Unified CM SIP trunks or the Delayed Offer to Early Offer feature with Cisco Unified Border Element.
- Unified CM versions
Both the Unified CM Session Management Edition and Unified CM leaf clusters should be deployed with Cisco Unified CM 7.1(2) or later release. Earlier versions of Unified CM can be deployed but might experience problems that can be resolved only by upgrading your cluster to Unified CM 7.1(2) or later release.
- Interoperability
Even though most vendors do conform to standards, differences can and do exist between protocol implementations from various vendors. As with any standard Unified CM cluster, Cisco strongly recommends that you conduct end-to-end system interoperability testing with any unverified third-party unified communications system before deploying the system in a production environment. The interoperability testing should verify call flows and features from Cisco and third-party leaf systems through the Unified CM Session Management cluster. To learn which third-party unified communications systems have been tested by the Cisco Interoperability team, refer to the information available on the Cisco Interoperability Portal at

http://www.cisco.com/en/US/solutions/ns340/ns414/ns728/interOp_ucSessionMgr.html

- Load balancing for inbound and outbound calls

Configure trunks on the Unified CM Session Management Edition and leaf unified communications systems so that inbound and outbound calls are evenly distributed across the Unified CM servers within the Session Management cluster. For more information on load balancing for trunk calls, refer to the chapter on [Cisco Unified CM Trunks](#), page 14-1.

- Design guidance and assistance

For detailed information on Unified CM Session Management Edition designs and deployments, refer to the *Cisco Unified Communications Manager Session Management Edition Deployment Guide*, available at

http://www.cisco.com/en/US/products/ps10661/products_implementation_design_guides_list.html

Unified CM Session Management Edition designs should be reviewed by your Cisco SE in conjunction with the Cisco Unified CM Session Management Team.

Hybrid Session Management Edition and SAF CCD Deployments

Session Management Edition deployments provide internal dial plan aggregation. Cisco Service Advertisement Framework (SAF) Call Control Discovery (CCD) deployments distribute both the internal dial plan and the corresponding external "To PSTN" dial plan to participating SAF CCD Unified Communications systems. Combining Session Management Edition and SAF CCD enables Session Management Edition to act as the central Session Manager for all leaf Unified Communications systems, while also using SAF CCD to distribute both the internal and external "To PSTN" dial plans to all SAF CCD participating Unified CM leaf clusters.

A Session Management Edition and SAF hybrid deployment uses a specific configuration of SAF CCD to allow all calls between leaf clusters to be routed only through the Session Management Edition cluster. The SAF configuration consists of two parts:

- Advertising SAF CCD routes to leaf clusters from/through Session Management Edition
- Advertising SAF CCD routes from leaf clusters to Session Management Edition

Note

This discussion assumes that you have already configured your Cisco IOS SAF Forwarders and basic SAF CCD configuration on Unified CM (that is, Advertising Service, Requesting Service, SAF enabled Trunks, and so forth). This design uses a single SAF Autonomous System (AS).

Advertising SAF CCD Routes to Leaf Clusters from/through Session Management Edition

On the Session Management Edition cluster, create the DN patterns, DN Groups, and corresponding "to DID" rules for the internal number ranges and external "To PSTN" numbers hosted by each SAF-enabled leaf cluster. Publish these DN patterns to the SAF AS by associating them with one or more SAF-enabled trunks and advertising services. These DN patterns and corresponding routes to Session Management Edition are learned by all SAF-enabled leaf clusters. While Session Management Edition is reachable through the IP WAN, all intercluster calls are routed through Session Management Edition. When Session Management Edition is unreachable, intercluster calls are routed through the leaf cluster's local PSTN gateway after the called number has been modified using the learned DN pattern's "to DID" rule.

Advertising SAF CCD Routes from Leaf Clusters to Session Management Edition

The purpose of advertising each leaf cluster's hosted DN ranges to the SAF AS is to allow the Session Management Edition cluster to learn about these DN ranges and leaf cluster reachability. These number ranges are also learned by all other leaf clusters. (See Figure 5-7.) To prevent direct leaf-to-leaf routes from being used, in each leaf cluster, block learned routes from all other leaf clusters. Routes can be blocked based on whether they match either the IP address the SAF nodes in each of the leaf clusters or (preferably) the Remote Call Control Entity Name for each leaf cluster. (This is the Unified CM Cluster ID in the Unified CM Enterprise Parameters menu.)

Figure 5-7 Advertising SAF CCD Routes in a Session Management Edition Deployment

Session Management Edition SAF CCD Routing Table

| DN Pattern | "to DID"rule | IP address | Protocol |
|------------|--------------|------------|----------|
| 1XXX | 0:+1212444 | 10.1.1.1 | SIP |
| 8XXX | 0:+1408902 | 10.8.8.8 | SIP |

Leaf 1 SAF CCD Routing Table

| DN Pattern | "to DID"rule | IP address | Protocol |
|-----------------|-----------------------|---------------------|----------------|
| 1XXX | 0:+1212444 | 10.2.2.2 | SIP |
| 8XXX | 0:+1408902 | 10.2.2.2 | SIP |
| 8XXX | 0:+1408902 | 10.8.8.8 | SIP |

Leaf 8 SAF CCD Routing Table

| DN Pattern | "to DID"rule | IP address | Protocol |
|-----------------|-----------------------|---------------------|----------------|
| 1XXX | 0:+1212444 | 10.2.2.2 | SIP |
| 1XXX | 0:+1212444 | 10.1.1.1 | SIP |
| 8XXX | 0:+1408902 | 10.2.2.2 | SIP |

254275

Operational Considerations for Session Management Edition and SAF CCD Deployments

The following operational considerations apply to deployments of Cisco Unified CM Session Management Edition with Service Advertisement Framework (SAF) Call Control Discovery (CCD).

Leaf Clusters Learning Their Own DN Ranges from Session Management Edition

As can be seen in the SAF CCD routing tables in [Figure 5-7](#), leaf clusters learn about the reachability of their own DN ranges from Session Management Edition. These DN ranges can be blocked in the same way that intercluster DN ranges and routes are blocked. If these Session Management Edition SAF CCD routes are not blocked, they are selected only for intra-cluster calls if the calling search space of the calling device has the SAF CCD learned routes partition ordered above the internal DN's partition. In most cases, the internal DN partition will be ordered above the SAF CCD partition, so that intra-cluster calls are not routed through Session Management Edition.

Routing Calls to the PSTN When IP Routes from Session Management Edition to Leaf Clusters Are Not Available

Two configuration options are available when re-routing calls to the PSTN:

- Re-route calls to the PSTN through a PSTN gateway associated with Session Management Edition
If the Session Management Edition cluster has PSTN access and you wish to re-route calls that are unreachable through an IP path from Session Management Edition to the destination leaf cluster, make sure each leaf cluster advertises a "to DID" rule for each advertised DN range or group to Session Management Edition. This "to DID" rule is used by Session Management Edition to modify the called number and to route the call through the inbound trunk's Automated Alternate Routing (AAR) calling search space (CSS).
- Re-route calls to the PSTN from the originating leaf cluster
If the Session Management Edition cluster does not have PSTN access and you wish to re-route calls that are unreachable from Session Management Edition to the destination leaf cluster through the PSTN at the originating leaf cluster, make sure each leaf cluster does not advertise a "to DID" rule for each advertised DN range or group to Session Management Edition. In this case, if a signaling path cannot be established from Session Management Edition to the destination leaf cluster, Session Management Edition signals the call failure to the originating leaf cluster, which in turn uses its "to DID" rule (learned from Session Management Edition) to modify the called number and route the call through the calling device's Automated Alternate Routing (AAR) calling search space (CSS).

Calls to Non-SAF Unified Communications Systems over Static Session Management Edition Trunks

Session Management Edition can use SAF CCD to advertise the DN ranges of non-SAF Unified Communications systems to all SAF-enabled leaf clusters. Calls from leaf clusters to non-SAF Unified Communications systems through the Session Management Edition cluster use SAF trunks to reach Session Management Edition. Session Management Edition then uses a configured route pattern and corresponding static (standard) trunk to reach the non-SAF Unified Communications system.

PSTN Fallback for Calls to Non-SAF Unified Communications Systems

There are two options for PSTN fallback if the non-SAF Unified Communications system is not reachable through a static trunk from Session Management Edition:

- Re-route calls to the PSTN from the originating leaf cluster.
With this option, a single trunk is configured from Session Management Edition to the destination Unified Communications system. If a signaling path cannot be established from Session Management Edition to the destination Unified Communications system, Session Management

Edition signals the call failure to the originating leaf cluster, which in turn uses its "to DID" rule (learned from Session Management Edition) to modify the called number and route the call through the calling device's Automated Alternate Routing (AAR) calling search space (CSS).

- Re-route calls to the PSTN from Session Management Edition.

With this option, create two trunks as part of a route list and route group. The first-choice trunk is configured from Session Management Edition to the destination Unified Communications system, while the second-choice trunk is configured from Session Management Edition to its local PSTN gateway. If a signaling path cannot be established from Session Management Edition to the destination Unified Communications system, Session Management Edition chooses the second trunk to the PSTN. The route group that contains the PSTN trunk can be used to modify the internal called number to its PSTN equivalent.

Cisco Intercompany Media Engine

Cisco Intercompany Media Engine (IME) is another variation of a multisite deployment with distributed call processing; however, with IME the sites are separate enterprise organizations. The term *boundary-less* Unified Communications is used to describe this technology because it allows for the business-to-business extension of Unified Communications capabilities such as high-fidelity codecs, enhanced caller ID, and video telephony outside the corporate networks. The solution learns routes in a dynamic, secure manner and provides for secure communications between organizations across the internet. Organizations that work closely together and have high levels of intercompany communications will benefit most from the enhanced communications offered by IME. This section discusses the components of the solution and the high-level architecture, with relevant design considerations for deploying IME.

IME Components

The IME solution consists of several components to allow for the dynamic learning of IME routes and the secure encryption of call signaling and media between organizations. Two elements of the solution are hosted on the internet: the GoDaddy.com Enrollment Servers and the Intercompany Media Engine Bootstrap Servers, hosted by GoDaddy.com and Cisco, respectively. The following additional integral components are deployed on-premises:

- Cisco Intercompany Media Engine Server
- Cisco Unified Communications Manager (Unified CM)
- Cisco Adaptive Security Appliance (ASA)

Figure 5-8 illustrates a high-level view of the deployed components.

Figure 5-8 Cisco Intercompany Media Engine Components

GoDaddy.com Enrollment Server

The GoDaddy.com Enrollment Server validates all IME servers before they enter the ring of IME Servers formed over the Internet. Only IME servers installed and enrolled with the proper GoDaddy.com certificates are allowed to participate in the ring. This enrollment server is accessed only prior to entry into the ring or when certificates expire and an IME server must re-enroll.

Intercompany Media Engine Bootstrap Servers

The IME bootstrap servers are a collection of globally accessible IME servers owned and operated by Cisco. Each IME server participating in the ring (also known as the distributed cache ring) joins the network by first connecting to an IME bootstrap server. The peer-to-peer certificate obtained in the enrollment process is used for all peer-to-peer TLS connections, including the initial connection to the bootstrap server.

Intercompany Media Engine Servers

Each organization owns and operates one or more IME servers on their network. The IME server is responsible for publishing directory numbers owned by the organization to the distributed cache ring, validating call records, learning routes to remote enterprises, and pushing IME learned routes to Unified CM. It is involved only with the IME learning cycle of the solution and does not play a role in the real-time signaling or media communications.

Unified Communications Manager and Session Management Edition

Cisco Unified CM 8.x or Unified CM Session Management Edition 8.x is required for any organization to participate in IME. Unified CM communicates with IME servers to upload the IME designated directory numbers to the distributed cache ring and sends call records to IME for PSTN calls made by these directory numbers. Unified CM also receives IME learned routes that are validated by IME servers and initiates dynamic SIP trunk calls to the remote directory numbers in these IME learned routes. SIP trunk signaling always flows through an IME-enabled Adaptive Security Appliance (ASA).

Adaptive Security Appliance

All IME calls must flow through an IME-enabled Adaptive Security Appliance (ASA), which provides perimeter security for the solution. The IME-enabled ASA is responsible for receiving SIP signaling communications (outbound from Unified CM or inbound from remote enterprises), validating IME tickets, performing address translation, and providing SIP to SIP+TLS conversion for secure signaling across the Internet. Audio and video media between organizations also flow through the IME-enabled ASA, where it provides RTP-to-Secure RTP (sRTP) conversion and voice quality monitoring of the audio stream incoming from the Internet. There are off path and basic (inline) deployment options. For more information on these deployment options, see [ASA Intercompany Media Engine Proxy, page 4-29](#).

IME Architecture

The architecture of IME is reflected in the way IME operates. The operation of IME involves the following high-level phases:

- [IME Learned Routes, page 5-36](#)
- [IME Call Processing, page 5-39](#)

IME Learned Routes

After enrolling with the GoDaddy.com Enrollment Server and being validated by the IME Bootstrap Server, an IME server becomes an active server on the peer-to-peer ring. IME servers from all organizations participating in IME join the ring on the Internet and communicate using a secure peer-to-peer technology based on the Resource Location And Discovery (RELOAD) protocol. The IME servers create a distributed hash table that stores one IME-specific piece of information: a one-way hash of all published +E.164 directory numbers and the IME server peer ID that owns them. This information is distributed across all IME servers, and the architecture of the peer-to-peer technology is such that IME servers can dynamically join or leave the ring without degradation of the ring's functionality. Establishing the IME server on the ring and publishing the enterprise's IME-enrolled directory numbers is the first step toward learning IME routes. [Figure 5-9](#) shows a logical view of the distributed cache ring (DCR).

Figure 5-9 Intercompany Media Engine Distributed Cache Ring

253842

**Note**

A draft has been submitted to the IETF governing body to standardize the IME server peer-to-peer protocol. More information is available at <http://datatracker.ietf.org/doc/draft-rosenberg-dispatch-vipr-reload-usage/>.

**Note**

IME requires all directory numbers associated with the Intercompany Media Network to be in E.164 format, including the international + prefix (such as +14085551212). This is referred to as +E.164 format throughout this document.

Figure 5-10 illustrates the IME Learned Route process.

Figure 5-10 Intercompany Media Engine Learned Route Process

After the IME solution is deployed in an organization, select directory numbers can be enrolled administratively for IME, and these +E.164 numbers will be published to the distributed cache ring. The first call from an IME directory number uses the PSTN as it did before (Step 1 in Figure 5-10). Because it is an IME directory number, after the call is completed, information about that call in the form of a Voice Call Record (VCR), a CDR-like record specific to IME, is uploaded to the IME server by means of Validation Access Protocol (VAP) (Step 2 in Figure 5-10).

Voice call records contain information such as the called and calling numbers in +E.164 format and the start and stop time of the call. At some point later (it is not real time), the IME server of the enterprise that originated the call will query its peers on the DCR in an attempt to find the enterprise that owns this +E.164 called number (Step 3 in Figure 5-10). When the owner of this called number is discovered (which implies that this directory number has been enrolled in IME by another enterprise), the validation process begins. All communication between IME servers occurs over 128-bit AES TLS. The terminating-side IME server verifies that the called/calling number and start/stop times of the originating IME server's VCR match a corresponding VCR on the terminating side. If verified, the terminating IME server sends a successful reply to the originating IME server that includes a "ticket" (a security hash that only the terminating-side ASA can decipher, as described in [IME Call Processing, page 5-39](#)) and the external IP address to which IME SIP trunk calls should be directed for this +E.164 number (Step 4 in Figure 5-10). This constitutes an IME learned route. The originating IME server receives this learned route and at some point later publishes it to Unified CM by means of VAP (Step 5 in Figure 5-10). When Unified CM receives this IME learned route, it inserts the route into the Unified CM database. At this point, when any IME-enabled directory number in the originating enterprise makes a call to a number in the IME learned routes list, it will be an IME call. Note there are no real-time communications involved in learning IME routes. For a detailed example of learned routes, refer to the *Cisco Intercompany Media Engine Installation and Configuration Guide*, available at

http://www.cisco.com/en/US/products/ps10669/prod_maintenance_guides_list.html

Note

Unified CM provides a facility for blocking IME learned routes insertion into the Unified CM database for defined prefixes or domains.

**Note**

Unified CM has a method of transforming called and calling numbers to a globalized +E.164 format specifically for IME VCRs, even if a globalized dial plan is not implemented. For more information on +E.164 transformations for VCRs, see [Dial Plan Considerations for the Intercompany Media Engine](#), page 9-33.

IME Call Processing

Once an IME learned route exists in the Unified CM database, the information in the route is used to set up an IME call. However, the IME server itself is no longer involved in the call processing phase. [Figure 5-11](#) illustrates a high-level view of IME call processing.

Figure 5-11 Intercompany Media Engine Call Processing

253844

**Note**

IME also supports the use of secure SIP signaling via TLS between IME-enabled ASA and Unified CM.

To initiate an IME call, the called number must match an IME learned route pattern in the database and the directory number of the calling endpoint must be enrolled in IME. If these criteria are met, Unified CM dynamically invokes an IME SIP trunk addressed to the external IP address or fully qualified domain name (FQDN) of the terminating enterprise that was included in the IME learned route. IME learned route patterns are in +E.164 format; however, even if a globalized Unified CM dial plan is not deployed, the same process available for converting called numbers to +E.164 format for IME-specific VCRs is used to analyze outgoing called numbers on gateways and to convert them to +E.164 format for IME-specific analysis only. For more information on E.164 transformation profiles, see [Dial Plan Considerations for the Intercompany Media Engine](#), page 9-33.

An IME-enabled ASA serves as a proxy for all IME communications with remote organizations. The ASA provides network address translation (NAT) and SIP application layer gateway (ALG) functionality to translate addressing inside the SIP messaging itself. There are two deployment options for the IME-enabled ASA: basic (inline) or offpath. Offpath is the recommended method because it provides the capability for Unified CM to direct IME traffic to an IME-enabled ASA in a DMZ. This allows use of an existing ASA already deployed in the network that all Unified CM internet-bound traffic would otherwise travel through. For more information about basic and offpath ASA deployments, see [ASA Intercompany Media Engine Proxy](#), page 4-29.

The originating Unified CM initiates a SIP Invite that reaches the IME-enabled ASA (Step 1 in [Figure 5-11](#)) and that includes the security hash ticket from the learned route as an attribute in the SIP header. The ASA will fix-up the packets at the SIP level so that its externally facing IP address appears as the source of the Invite and extends it to the external IP address of the remote enterprise over a secure (256 bit AES) TLS connection (Step 2 in [Figure 5-11](#)). The external IP address listed in an IME learned route correlates with the outside address of the IME-enabled ASA that receives inbound SIP signaling on behalf of a Unified CM cluster. The terminating ASA receives the SIP Invite, decrypts it, and validates the ticket. Any request without a valid ticket is blocked. After the ticket has been verified, the ASA performs NAT and ALG functions before forwarding the ticket on to the terminating Unified CM (Step 3 in [Figure 5-11](#)).

**Note**

The IME Server and IME-enabled ASA do not have direct communications; however, they are both configured with an identical **epoch ticketpassword**, which allows for successful ticket validations.

Once successful SIP signaling has been negotiated, each IME-enabled ASA instructs its respective Unified CMs to have the endpoints stream RTP media directly to its internal media termination address (Step 4 in [Figure 5-11](#)). The ASAs take in this RTP stream, encrypt it, perform NAT, and send it across to the remote ASA as sRTP sourced from its external media termination address, including audio and video media (Step 5 in [Figure 5-11](#)). At this point, the two endpoints have an active IME call.

The IME solution also provides a mechanism to allow calls to fall-back to the PSTN if the voice quality of the audio stream degrades below an acceptable level. Advanced features such as video are lost, but the audio portion of the call remains intact and the change is otherwise unapparent to the user.

For more details regarding the IME fallback feature and IME-enabled ASA configuration, refer to the information on configuring Cisco Intercompany Media Engine Proxy in the *Cisco ASA 5500 Series Configuration Guide using the CLI*, 8.3, available at

<http://www.cisco.com/en/US/docs/security/asa/asa83/configuration/guide/config.html>

PSTN Failover

Cisco IME uses the public internet to carry business-to-business traffic. To avoid negative user experience caused by possible packet loss in the public network, the IME-enabled ASA involved in the call continuously monitors the inbound SRTP stream and calculates RTP statistics in real-time. The IME-enabled ASA looks for random packet loss, small bursts of lost packets, and bursts of large packet loss. All three packet impairment conditions are used to decide whether the call meets the defined minimum quality limits. If the measured quality as defined by the calculated real-time RTP statistics falls below certain pre-defined quality limits, the IME-enabled ASA initiates PSTN fallback for the affected call as shown in [Figure 5-12](#). The QoS management algorithm maintains five sensitivity levels with varying packet impairment thresholds to allow granular control of the PSTN fallback sensitivity. The Fallback QoS Sensitivity Level can be set on a global basis or per IME Enrolled Group.

Figure 5-12 IME PSTN Failover

After an IME call is established, the ASA inspects RTP packets as they flow through it from outside to inside. The ASA inspects the sequence numbers and timestamps, and based on the observed packet loss, an algorithm decides whether a fallback is required. The algorithm uses the fallback QoS sensitivity levels to create a set of packet loss thresholds for each QoS sensitivity level. If the algorithm indicates a fallback is needed (step 1 in Figure 5-12), the ASA sends an out-of-dialog REFER to Cisco Unified Communications Manager, asking for it to fallback to the PSTN (step 2 in Figure 5-12).

As the terminating Unified CM receives the REFER, it issues a mid-dialog REFER to the originating Unified CM over the existing dialog. This REFER is required to inform the originating Unified CM of the required fallback. The PSTN call required for the PSTN fallback is always initiated by the Unified CM originating the IME call, regardless of whether the IME-enabled ASA on the originating or terminating side triggers the fallback.

The originating Unified CM then places a PSTN call to the Fallback Directory E.164 Number advertised by the terminating Unified CM as part of the SIP call setup (step 3 in Figure 5-12). The Fallback Directory E.164 Number can be configured both in the global Fallback Feature Configuration Settings and in the Fallback Profile Configuration Settings, thus allowing different Fallback E.164 Numbers per IME Enrolled Group.

The call to the Fallback Directory E.164 Number by default is routed using the calling device's AAR calling search space. The global Fallback Feature Configuration Settings and the Fallback Profile Configuration Settings also allow you to use the calling device's Reroute Calling Search Space.

When a PSTN call is routed to a configured Fallback Directory E.164 Number, Unified CM has to associate the incoming call with the correct IME call. The first step is to match the caller ID of this PSTN call against the caller ID signalling from the originating Unified CM in the SIP INVITE of the initial VoIP call (step 4 in Figure 5-12). If sufficient digits (as defined by the Number of Digits for Caller ID Partial Match in the global Fallback Feature Configuration Settings or in the Fallback Profile Configuration Settings) are matched, the Unified CM terminating the PSTN fallback call informs the Unified CM originating the PSTN call by sending a single DTMF digit 1. The originating Unified CM immediately splits the VoIP call, connects the PSTN leg with the phone, and terminates the VoIP leg. If the caller IDs do not match, the terminating Unified CM sends a single DTMF digit 2 (step 5 in Figure 5-12).

The originating Unified CM waits for DTMF digits. If a 1 is received, the originating Unified CM immediately splits the VoIP call, connects the PSTN leg with the phone, and terminates the VoIP leg (step 6 in Figure 5-12).

If a 2 is received, indicating that the terminating Unified CM was not able to associate the PSTN fallback call with a unique existing IME VoIP call, the originating Unified CM out-pulses a DTMF sequence uniquely identifying the call. This DTMF sequence is learned from the terminating Unified CM as part of the SIP exchange during the initial IME VoIP call establishment. After sending the DTMF sequence, the originating Unified CM splits the VoIP call, connects the PSTN leg with the phone, and terminates the VoIP leg (step 6, in [Figure 5-12](#)).

Unified CM expects to receive the DTMF digits received as part of the PSTN fallback procedure to be delivered out-of-band.

Capacity Planning

IME servers are sized according to how many enrolled DIDs will be published on them. [Table 5-5](#) provides the current supported capacity limits per platform.

Table 5-5 *IME Server Supported Capacities*

| Platform | Maximum Number of Enrolled DIDs |
|-------------------------------------|---------------------------------|
| Cisco MCS 7825-H2/I2 and 7825-H4/I4 | 20,000 |
| Cisco MCS 7845-H2/I2 and 7845-I3 | 40,000 |

Because all IME call media (audio and video) flow through the IME-enabled ASA, capacity depends on the type and number of calls flowing through it. The IME-enabled ASA monitors only the audio stream incoming from the internet for voice quality. The video media is not monitored for voice quality, but it does flow through the IME-enabled ASA for RTP-to-sRTP conversion, and the bandwidth of the video directly affects the number of sessions each can handle. [Table 5-6](#) provides capacity limits for the ASA-5550 and ASA-5580. Performance limits of other ASA models have not been validated yet.

Table 5-6 *Maximum Number of Calls per Type and ASA Model*

| ASA Model | Voice G.711 | Video 300 kbps | Video 800 kbps | Video 1 Mbps |
|------------------|-------------|----------------|----------------|--------------|
| ASA-5550 4 GB | 480 calls | 240 calls | 120 calls | 80 calls |
| ASA-5580-20 4 GB | 900 calls | 600 calls | 300 calls | 200 calls |

Unified CM does not have a limit on the number of IME calls it can handle, but IME calls should be factored into the overall call capacity provided by the cluster. Your Cisco Partner or Cisco Systems Engineer should use the Cisco Unified Communications Sizing Tool (<http://tools.cisco.com/cucst>) to validate all designs that handle large call traffic volumes. The Sizing Tool can accurately determine the number of servers or clusters required to meet your design criteria.

High Availability

The IME route learning phase involves several aspects of high availability. The distributed cache ring (DCR) itself has a high degree of redundancy built into the peer-to-peer technology, where the information stored on the DCR peers is adjusted as IME servers join or leave the ring. Multiple IME bootstrap servers are also hosted by Cisco to guarantee that valid IME servers can join the ring at any time. These aspects are inherent to the solution.

In Unified CM, each IME Service (which defines a set of enrolled DID ranges, excluded DID ranges, and IME servers, among other parameters) can consist of a primary and secondary IME Server. Both servers are up and active, and Unified CM uploads the enrolled DID ranges and any terminating call VCRs to both servers. However, originating call VCRs are uploaded to the primary IME server only; therefore, only the primary will initiate validation requests, while either can process validation requests received from other enterprises because both have terminating call VCRs. There is no direct communication between primary and secondary IME servers regarding VCRs, so originating call VCRs stored for validation on the primary would be lost in the event of an outage. A recommended option is to split the enrolled DID ranges into two ranges and to create two IME Services whereby the primary IME server for service A is the secondary IME server for service B, and vice versa. This balances the originating call validation load across the IME Servers and further minimizes the number of originating VCRs that are lost in the event of an outage.

On the Unified CM side, once an IME Service is configured, the Unified CM responsible for initiating VAP communications with the primary IME server is determined by the device pool of the IME SIP trunk associated with the IME Service. The Unified CM Group attribute associated with the device pool determines the primary, secondary, and tertiary Unified CM responsible for the service. In the event that the primary is down, the secondary Unified CM picks up VAP communications with the active IME server.

With respect to call processing, the Unified CM Group associated with the IME SIP trunk in the IME Service also determines which Unified CM subscribers initiate IME calls. This allows for IME calls to continue in the event that the primary Unified CM for the IME SIP trunk is offline. For receiving calls, each IME Service can configure external IP address and port pairs for Unified CM call processing subscribers in the cluster. Each external IP address and port pair is actually an IP address and port that is configured on the IME-enabled ASA and that has a 1:1 correlation to a Unified CM call processing node. When there are multiple external IP addresses and ports in an IME route, Unified CM sends calls for this IME route in a circular fashion so that calls are load-balanced across Unified CM servers at the remote enterprise. If a remote Unified CM is offline, the originating Unified CM tries the next external IP address and port in the list. If no response is received and this list is exhausted, the call is sent to the PSTN as it would have been without IME.

Dual IME-enabled ASAs may also be deployed in active-standby mode; however, this does not provide stateful failover. In the event of a failover, active calls are disconnected, but subsequent IME calls connect through the standby (now active) ASA. For deployments with an offpath IME-enabled ASA, the IME Service configuration in Unified CM allows for a single IME firewall to be associated. Multiple IME-enabled ASAs can be deployed to handle IME calls for different enrolled DID ranges, thus offering a mechanism of load balancing IME calls in addition to increasing capacity.

**Note**

Active-active failover mode is not supported for the IME-enabled ASA.

While an IME call is connected, the IME-enabled ASA is capable of monitoring the quality of the call. If the quality falls below a certain sensitivity level, the call is moved back to the PSTN. For more information, see [ASA Intercompany Media Engine Proxy, page 4-29](#).

Design Considerations

The IME solution requires that IME servers and the IME-enabled ASA have publicly reachable IP addressing; therefore, they are most commonly placed in an organization's DMZ. This may require close coordination between groups responsible for security and Unified Communications within the

organization. It is important for both the security and Unified Communications teams to be involved from the early design stages of an IME project. In addition, observe the following guidelines and considerations when designing an IME solution for your enterprise:

- Cisco requires the use of Network Time Protocol for all Unified CM servers, IME servers, and IME-enabled ASAs. They must be synchronized to a dependable, high-stratum clock source. It is vital to Voice Call Record start and stop times during the IME route learning phase.
- A hosted IME solution deployment model is also supported. In a hosted IME deployment, an IME server publishes enrolled directory numbers and validates VCRs on behalf of multiple Unified CM or Unified CM Session Management Edition clusters. For more information, refer to the information on hosted IME solutions in the *Cisco Intercompany Media Engine Installation and Configuration Guide*, available at

http://www.cisco.com/en/US/products/ps10669/prod_maintenance_guides_list.html

IME Servers

- By default, VAP communications between Unified CM and the IME server are authenticated only. When an IME server is located in the DMZ, Cisco recommends configuring VAP communications as authenticated and encrypted, which will force the communications to occur over TLS. This requires additional configuration to share security certificates.

Unified CM and Unified CM Session Management Edition

- The Intercompany Media Network requires all published numbers to be in +E.164 format to ensure their global uniqueness. Calling and called numbers must be converted to +E.164 format so that, when IME-specific Voice Call Records (VCRs) are uploaded to IME servers, they are in the proper format. Unified CM provides a facility to transform calling and called numbers to +E.164 format solely for IME purposes, which will not affect normal dial plan digit analysis. For more information, refer to the E.164 transformation profile information in the *Cisco Intercompany Media Engine Installation and Configuration Guide*, available at

http://www.cisco.com/en/US/products/ps10669/prod_maintenance_guides_list.html

- Gateways or trunks used for PSTN connectivity must have the PSTN Access checkbox checked in order for calling and called numbers to be analyzed for IME participation. Upon upgrade to Unified CM 8.x, this parameter is enabled by default for all gateways and trunks. You can uncheck it if it is not required.
- Configuration settings in Unified CM for the regions between internal endpoints and the IME SIP trunk determine the audio and video capabilities allowed for IME calls.
- To limit capacity through the IME-enabled ASAs, Cisco recommends applying Unified CM locations-based call admission control to the IME SIP trunk to control the number of audio and video calls sent through the ASA. When the bandwidth limits are reached, subsequent calls will be routed through the PSTN as they were prior to IME deployment.
- Cisco recommends explicitly trusting the domains of remote enterprises with which your organization intends to communicate through IME. Once a trust group is configured, there is a default deny on all other domains that try to validate VCRs.
- Unicast music on hold (MoH) is supported during user-initiated hold and transfer scenarios. To work properly through the firewalls, the MoH full-duplex streaming service parameter must be enabled.
- Cisco recommends excluding analog and fax station directory numbers from the enrolled group of DIDs for an IME server because they will not benefit from enhanced Unified Communications and because fax calls are not supported over IME.

IME-Enabled ASA

- For more information on basic and offpath ASA deployments as well as security considerations for other firewalls in the network, see [ASA Intercompany Media Engine Proxy, page 4-29](#).
- High-bandwidth video (greater than 384 kbps) is supported; however, it directly affects the capacity of calls flowing through the IME-enabled ASA.
- Fallback sensitivity levels should be left at the default settings for the initial IME deployment. Fallback should be monitored during the first few months of use and then adjusted accordingly. Cisco recommends viewing call detail records to find calls generated on behalf of IME or fallback. Appropriate fallback sensitivity levels will vary from enterprise to enterprise.
- When endpoints with IME-enrolled DIDs are remotely located with VPN connectivity into the enterprise, latency and jitter characteristics for calls with these endpoints will be amplified and could result in the IME-enabled ASAs triggering more frequent fallbacks to the PSTN. If fallbacks occur too frequently for a specific endpoint, it might be necessary either to configure these devices with a device pool that has a fallback profile with no fallback enabled, to lower the fallback sensitivity levels, or to remove the enrolled DID from IME.

Clustering Over the IP WAN

You may deploy a single Unified CM cluster across multiple sites that are connected by an IP WAN with QoS features enabled. This section provides a brief overview of clustering over the WAN. For further information, refer to the chapter on [Call Processing, page 8-1](#).

Clustering over the WAN can support two types of deployments:

- [Local Failover Deployment Model, page 5-49](#)

Local failover requires that you place the Unified CM subscriber and backup servers at the same site, with no WAN between them. This type of deployment is ideal for two to four sites with Unified CM.

- [Remote Failover Deployment Model, page 5-55](#)

Remote failover allows you to deploy primary and backup call processing servers split across the WAN. Using this type of deployment, you may have multiple sites with Unified CM subscribers being backed up by Unified CM subscribers at another site.

Note

Remote failover deployments might require higher bandwidth because a large amount of intra-cluster traffic flows between the subscriber servers.

You can also use a combination of the two deployment models to satisfy specific site requirements. For example, two main sites may each have primary and backup subscribers, with another two sites containing only a primary server each and utilizing either shared backups or dedicated backups at the two main sites.

Some of the key advantages of clustering over the WAN are:

- Single point of administration for users for all sites within the cluster
- Feature transparency
- Shared line appearances
- Extension mobility within the cluster
- Unified dial plan

These features make this solution ideal as a disaster recovery plan for business continuance sites or as a single solution for multiple small or medium sites.

WAN Considerations

For clustering over the WAN to be successful, you must carefully plan, design, and implement various characteristics of the WAN itself. The Intra-Cluster Communication Signaling (ICCS) between Unified CM servers consists of many traffic types. The ICCS traffic types are classified as either priority or best-effort. Priority ICCS traffic is marked with IP Precedence 3 (DSCP 24 or PHB CS3). Best-effort ICCS traffic is marked with IP Precedence 0 (DSCP 0 or PHB BE). The various types of ICCS traffic are described in [Intra-Cluster Communications, page 5-47](#), which also provides further guidelines for provisioning. The following design guidelines apply to the indicated WAN characteristics:

- Delay

The maximum one-way delay between any two Unified CM servers should not exceed 40 msec, or 80 msec round-trip time. Measuring the delay is covered in [Delay Testing, page 5-48](#). Propagation delay between two sites introduces 6 microseconds per kilometer without any other network delays being considered. This equates to a theoretical maximum distance of approximately 3000 km for 20 ms delay or approximately 1860 miles. These distances are provided only as relative guidelines and in reality will be shorter due to other delay incurred within the network.

- Jitter

Jitter is the varying delay that packets incur through the network due to processing, queue, buffer, congestion, or path variation delay. Jitter for the IP Precedence 3 ICCS traffic must be minimized using Quality of Service (QoS) features.

- Packet loss and errors

The network should be engineered to provide sufficient prioritized bandwidth for all ICCS traffic, especially the priority ICCS traffic. Standard QoS mechanisms must be implemented to avoid congestion and packet loss. If packets are lost due to line errors or other “real world” conditions, the ICCS packet will be retransmitted because it uses the TCP protocol for reliable transmission. The retransmission might result in a call being delayed during setup, disconnect (teardown), or other supplementary services during the call. Some packet loss conditions could result in a lost call, but this scenario should be no more likely than errors occurring on a T1 or E1, which affect calls via a trunk to the PSTN/ISDN.

- Bandwidth

Provision the correct amount of bandwidth between each server for the expected call volume, type of devices, and number of devices. This bandwidth is in addition to any other bandwidth for other applications sharing the network, including voice and video traffic between the sites. The bandwidth provisioned must have QoS enabled to provide the prioritization and scheduling for the different classes of traffic. The general rule of thumb for bandwidth is to over-provision and under-subscribe.

- Quality of Service

The network infrastructure relies on QoS engineering to provide consistent and predictable end-to-end levels of service for traffic. Neither QoS nor bandwidth alone is the solution; rather, QoS-enabled bandwidth must be engineered into the network infrastructure.

Intra-Cluster Communications

In general, intra-cluster communications means all traffic between servers. There is also a real-time protocol called Intra-Cluster Communication Signaling (ICCS), which provides the communications with the Cisco CallManager Service process that is at the heart of the call processing in each server or node within the cluster.

The intra-cluster traffic between the servers consists of the following:

- Database traffic from the IBM Informix Dynamic Server (IDS) database that provides the main configuration information. The IDS traffic may be re-prioritized in line with Cisco QoS recommendations to a higher priority data service (for example, IP Precedence 1 if required by the particular business needs). An example of this is extensive use of Extension Mobility, which relies on IDS database configuration.
- Firewall management traffic, which is used to authenticate the subscribers to the publisher to access the publisher's database. The management traffic flows between all servers in a cluster. The management traffic may be prioritized in line with Cisco QoS recommendations to a higher priority data service (for example, IP Precedence 1 if required by the particular business needs).
- ICCS real-time traffic, which consists of signaling, call admission control, and other information regarding calls as they are initiated and completed. ICCS uses a Transmission Control Protocol (TCP) connection between all servers that have the Cisco CallManager Service enabled. The connections are a full mesh between these servers. This traffic is priority ICCS traffic and is marked dependant on release and service parameter configuration.
- CTI Manager real-time traffic is used for CTI devices involved in calls or for controlling or monitoring other third-party devices on the Unified CM servers. This traffic is marked as priority ICCS traffic and exists between the Unified CM server with the CTI Manager and the Unified CM server with the CTI device.

**Note**

For detailed information on various types of traffic between Unified CM servers, refer to the TCP and UDP port usage documents at http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html.

Unified CM Publisher

The publisher server replicates a partial read-only copy of the master database to all other servers in the cluster. Most of the database modifications are done on the publisher. If changes such as administration updates are made in the publisher's master database during a period when another server in the cluster is unreachable, the publisher will replicate the updated database when communications are re-established. Database modifications for user-facing call processing features are made on the subscriber servers to which the IP phones are registered. These features include:

- Call Forward All (CFA)
- Message Waiting Indication (MWI)
- Privacy Enable/Disable
- Do Not Disturb (DND) Enable/Disable
- Extension Mobility Login (EM)
- Monitor (for future use; currently no updates at the user level)
- Hunt Group Logout

- Device Mobility
- CTI Certificate Authority Proxy Function (CAPF) status for end users and application users
- Credential hacking and authentication

Each subscriber replicates these changes to every other server in the cluster. Any other configuration changes cannot be made on the database during the period when the publisher is unreachable or offline. Most normal operations of the cluster, including the following, will *not* be affected during the period of publisher failure:

- Call processing
- Failover
- Registration of previously configured devices

Other services or applications might also be affected, and their ability to function without the publisher should be verified when deployed.

Call Detail Records (CDR) and Call Management Records (CMR)

Call detail records and call management records, when enabled, are collected by each subscriber and uploaded to the publisher periodically. During a period that the publisher is unreachable, the CDRs and CMRs are stored on the subscriber's local hard disk. When connectivity is re-established to the publisher, all outstanding CDRs are uploaded to the publisher, which stores the records in the CDR Analysis and Reporting (CAR) database.

Delay Testing

The maximum round-trip time (RTT) between any two servers must not exceed 80 msec. This time limit must include all delays in the transmission path between the two servers. Verifying the round trip delay using the **ping** utility on the Unified CM server will not provide an accurate result. The ping is sent as a best-effort tagged packet and is not transported using the same QoS-enabled path as the ICCS traffic. Therefore, Cisco recommends that you verify the delay by using the closest network device to the Unified CM servers, ideally the access switch to which the server is attached. Cisco IOS provides an extended ping capable to set the Layer 3 type of service (ToS) bits to make sure the ping packet is sent on the same QoS-enabled path that the ICCS traffic will traverse. The time recorded by the extended ping is the round-trip time (RTT), or the time it takes to traverse the communications path and return.

The following example shows a Cisco IOS extended ping with the ToS bit (IP Precedence) set to 3:

```
Access_SW#ping
Protocol [ip]:
Target IP address: 10.10.10.10
Repeat count [5]:
Datagram size [100]:
Timeout in seconds [2]:
Extended commands [n]: y
Source address or interface:
Type of service [0]: 3
Set DF bit in IP header? [no]:
Validate reply data? [no]:
Data pattern [0xABCD]:
Loose, Strict, Record, Timestamp, Verbose[none]:
Sweep range of sizes [n]:
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.10.10.10, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/4 ms
```

Error Rate

The expected error rate should be zero. Any errors, dropped packets, or other impairments to the IP network can have an impact to the call processing performance of the cluster. This may be noticeable by delay in dial tone, slow key or display response on the IP phone, or delay from off-hook to connection of the voice path. Although Unified CM will tolerate random errors, they should be avoided to avoid impairing the performance of the cluster.

Troubleshooting

If the Unified CM subscribers in a cluster are experiencing impairment of the ICCS communication due to higher than expected delay, errors, or dropped packets, some of the following symptoms might occur:

- IP phones, gateways, or other devices on a remote Unified CM server within the cluster might temporarily be unreachable.
- Calls might be disconnected or might fail during call setup.
- Users might experience longer than expected delays before hearing dial tone.
- Busy hour call completions (BHCC) might be low.
- The ICCS (SDL session) might be reset or disconnected.

In summary, perform the following tasks to troubleshoot ICCS communication problems:

- Verify the delay between the servers.
- Check all links for errors or dropped packets.
- Verify that QoS is correctly configured.
- Verify that sufficient bandwidth is provisioned for the queues and across the WAN to support all the traffic.

Local Failover Deployment Model

The local failover deployment model provides the most resilience for clustering over the WAN. Each of the sites in this model contains at least one primary Unified CM subscriber and one backup subscriber. This configuration can support up to four sites. The maximum number of phones and other devices will be dependant on the quantity and type of servers deployed. The maximum total number of IP phones for all sites is 30,000. (See [Figure 5-13](#).)

Figure 5-13 Example of Local Failover Model

Observe the following guidelines when implementing the local failover model:

- Configure each site to contain at least one primary Unified CM subscriber and one backup subscriber.
- Configure Unified CM *groups* and *device pools* to allow devices within the site to register with only the servers at that site under all conditions.
- Cisco highly recommends that you replicate key services (TFTP, DNS, DHCP, LDAP, and IP Phone Services), all media resources (conference bridges and music on hold), and gateways at each site to provide the highest level of resiliency. You could also extend this practice to include a voicemail system at each site.
- Under a WAN failure condition, sites without access to the publisher database will lose some functionality. For example, system administration at the remote site will not be able to add, modify, or delete any part of the configuration. However, users can continue to access the user-facing features listed in the section on [Unified CM Publisher](#), page 5-47.
- Under WAN failure conditions, calls made to phone numbers that are not currently communicating with the subscriber placing the call, will result in either a fast-busy tone or a call forward (possibly to voicemail or to a destination configured under Call Forward Unregistered).

- The maximum allowed round-trip time (RTT) between any two servers in the Unified CM cluster is 80 msec.

Note At a higher round-trip delay time and higher busy hour call attempts (BHCA), voice cut-through delay might be higher, causing initial voice clipping when a voice call is established.

- A minimum of 1.544 Mbps (T1) bandwidth is required for Intra-Cluster Communication Signaling (ICCS) for 10,000 busy hour call attempts (BHCA) between sites that are clustered over the WAN. This is a minimum bandwidth requirement for call control traffic, and it applies to deployments where directory numbers are not shared between sites that are clustered over the WAN. The following equation may be used as a guideline to calculate the bandwidth for more than 10,000 BHCA between non-shared directory numbers at a specific delay:

$$\text{Total Bandwidth (Mbps)} = (\text{Total BHCA}/10,000) * (1 + 0.006 * \text{Delay}), \text{ where} \\ \text{Delay} = \text{RTT delay in msec}$$

This call control traffic is classified as priority traffic. Priority ICCS traffic is marked with IP Precedence 3 (DSCP 24 or PHB CS3).

- In addition to the bandwidth required for Intra-Cluster Communication Signaling (ICCS) traffic, a minimum of 1.544 Mbps (T1) bandwidth is required for database and other inter-server traffic for every subscriber server remote to the publisher.
- For customers who also want to deploy CTI Manager over the WAN (see [Figure 5-14](#)), the following formula can be used to calculate the bandwidth (Mbps) for the CTI Intra-Cluster Communication Signaling (ICCS) traffic between the Unified CM subscriber running the CTI Manager service and the Unified CM subscriber to which the CTI endpoint is registered:

$$\text{With Unified CM 8.6(1) and earlier releases, CTI ICCS bandwidth (Mbps)} \\ = (\text{Total BHCA}/10,000) * 1.25$$

$$\text{With Unified CM 8.6(2) and later releases, CTI ICCS bandwidth (Mbps)} \\ = (\text{Total BHCA}/10,000) * 0.53$$

Figure 5-14 CTI Over the WAN

- For deployments where the J/TAPI application is remote from the Unified CM subscriber (see [Figure 5-15](#)), the following formula can be used to calculate the Quick Buffer Encoding (QBE) J/TAPI bandwidth for a typical J/TAPI application with Unified CM 8.6(2) and later releases:

$$\text{J/TAPI bandwidth (Mbps)} = (\text{Total BHCA}/10,000) * 0.28$$

The bandwidth may vary depending on the J/TAPI application. Check with the application developer or provider to validate the bandwidth requirement.

Figure 5-15 J/TAPI Over the WAN

**Example 5-1 Bandwidth Calculation for Two Sites**

Consider two sites, Site 1 and Site 2, with Unified CM clustered over the WAN across these two sites that are 80 msec round-trip time apart. Site 1 has one publisher, one combined TFTP and music on hold (MoH) server, and two Unified CM subscriber servers. Site 2 has one TFTP/MoH server and two Unified CM subscriber servers. Site 1 has 5000 phones, each having one DN; and Site 2 has 5000 phones, each having one DN. During the busy hour, 2500 phones in Site 1 call 2500 phones in Site 2, each at 3 BHCA. During that same busy hour, 2500 phones in Site 2 also call 2500 phones in Site 1, each at 3 BHCA. In this case:

Total BHCA during the busy hour = $2500 * 3 + 2500 * 3 = 15,000$

Total bandwidth required between the sites = Total ICCS bandwidth + Total database bandwidth

Because total BHCA is 15,000 (greater than 10,000), we can use the formula to calculate:

Total ICCS bandwidth = $(15,000/10,000) * (1 + 0.006 * 80) = 2.22$ Mbps

Total database bandwidth = (Number of servers remote to the publisher) * 1.544 = $3 * 1.544 = 4.632$ Mbps

Total bandwidth required between the sites = 2.22 Mbps + 4.632 Mbps = 6.852 Mbps (Approximately 7 Mbps)

- When directory numbers are shared between sites that are clustered over the WAN, additional bandwidth must be reserved. This overhead or additional bandwidth (in addition to the minimum 1.544 Mbps bandwidth) for 10,000 BHCA between shared DNs can be calculated using the following equation:

Overhead = $(0.012 * \text{Delay} * \text{Shared-line}) + (0.65 * \text{Shared-line})$, where:

Delay = RTT delay over the IP WAN, in msec

Shared-line = Average number of additional phones on which a directory number is shared across the WAN.

The following equation may be used as a guideline to calculate the bandwidth for more than 10,000 BHCA between shared directory numbers at a specific delay:

Total bandwidth (Mbps) = $(\text{Total BHCA}/10,000) * (1 + 0.006 * \text{Delay} + 0.012 * \text{Delay} * \text{Shared-line} + 0.65 * \text{Shared-line})$, where:

Delay = RTT delay in msec

Shared-line = Average number of additional phones on which a directory number is shared across the WAN.

Example 5-2 Bandwidth Calculation for Two Sites with Shared Directory Numbers

Consider two sites, Site 1 and Site 2, with Unified CM clustered over the WAN across these two sites that are 80 msec round-trip time apart. Site 1 has one publisher, one combined TFTP and music on hold (MoH) server, and two Unified CM subscriber servers. Site 2 has one TFTP/MoH server and two Unified CM subscriber servers. Site 1 has 5000 phones, each having one DN; and Site 2 has 5000 phones, each sharing a DN with the 5000 phones in Site 1. Thus, each DN is shared across the WAN with an average of one additional phone. During the busy hour, 2500 phones in Site 1 call 2500 phones in Site 2, each at 3 BHCA. This also causes the phones in Site 1 to ring. During that same busy hour, 2500 phones in Site 2 call 2500 phones in Site 1, each at 3 BHCA. This also causes the phones in Site 2 to ring. In this case:

Total BHCA during the busy hour = $2500 * 3 + 2500 * 3 = 15,000$

Total bandwidth required between the sites = Total ICCS bandwidth + Total database bandwidth

Because total BHCA is 15,000 (greater than 10,000), we can use the formula to calculate:

Total ICCS bandwidth = $(15,000/10,000) * (1 + 0.006*80 + 0.012*80*1 + 0.65*1) = 4.635$ Mbps

Total database bandwidth = (Number of servers remote to the publisher) * 1.544 = $3 * 1.544 = 4.632$ Mbps

Total bandwidth required between the sites = 4.635 Mbps + 4.632 Mbps = 9.267 Mbps (Approximately 10 Mbps)

**Note**

The bandwidth requirements stated above are strictly for ICCS, database, and other inter-server traffic. If calls are going over the IP WAN, additional bandwidth must be provisioned for voice or media traffic, depending on the voice codec used for the calls.

- Subscriber servers in the cluster read their local database. Database modifications can occur in both the local database as well as the publisher database, depending on the type of changes. Informix Dynamic Server (IDS) database replication is used to synchronize the databases on the various servers in the cluster. Therefore, when recovering from failure conditions such as the loss of WAN connectivity for an extended period of time, the Unified CM databases must be synchronized with any changes that might have been made during the outage. This process happens automatically when database connectivity is restored to the publisher and other servers in the cluster. This process can take longer over low bandwidth and/or higher delay links. In rare scenarios, manual reset or repair of the database replication between servers in the cluster might be required. This is performed by using the commands such as **utils dbreplication repair all** and/or **utils dbreplication reset all** at the command line interface (CLI). Repair or reset of database replication using the CLI on remote subscribers over the WAN causes all Unified CM databases in the cluster to be re-synchronized, in which case additional bandwidth above 1.544 Mbps might be required. Lower bandwidths can take longer for database replication repair or reset to complete.

**Note**

Repairing or resetting of database replication on multiple subscribers at the same remote location can result in increased time for database replication to complete. Cisco recommends repairing or resetting of database replication on these remote subscribers one at a time. Repairing or resetting of database replication on subscribers at different remote locations may be performed simultaneously.

- If remote branches using centralized call processing are connected to the main sites via clustering over the WAN, pay careful attention to the configuration of call admission control to avoid oversubscribing the links used for clustering over the WAN.
 - If the bandwidth is not limited on the links used for clustering over the WAN (that is, if the interfaces to the links are OC-3s or STM-1s and there is no requirement for call admission control), then the remote sites may be connected to any of the main sites because all the main sites should be configured as location `Hub_None`. This configuration still maintains hub-and-spoke topology for purposes of call admission control.
 - If you are using the Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) feature, all sites in Unified CM locations and the remote sites may register with any of the main sites.
 - If bandwidth is limited between the main sites, call admission control must be used between sites, and all remote sites must register with the main site that is configured as location `Hub_None`. This main site is considered the hub site, and all other remote sites and clustering-over-the-WAN sites are spokes sites.
- During a software upgrade, all servers in the cluster should be upgraded during the same maintenance period, using the standard upgrade procedures outlined in the software release notes. The software upgrade time might increase for higher round-trip delay time over the IP WAN. Lower bandwidths such as 1.544 Mbps (T1 link) can cause the software upgrade process to take longer to complete, in which case additional bandwidth above 1.544 Mbps might be required if a faster upgrade process is desired.

Unified CM Provisioning for Local Failover

Provisioning of the Unified CM cluster for the local failover model should follow the design guidelines for capacities outlined in the chapter on [Call Processing, page 8-1](#). If voice or video calls are allowed across the WAN between the sites, then you must configure Unified CM *locations* in addition to the default location for the other sites, to provide call admission control between the sites. If the bandwidth is over-provisioned for the number of devices, it is still best practice to configure call admission control based on locations. If the locations-based call admission control rejects a call, automatic failover to the PSTN can be provided by the automated alternate routing (AAR) feature.

To improve redundancy and upgrade times, Cisco recommends that you enable the Cisco Trivial File Transfer Protocol (TFTP) service on two Unified CM servers. More than two TFTP servers can be deployed in a cluster, however this configuration can result in an extended period for rebuilding all the TFTP files on all TFTP servers.

You can run the TFTP service on either a publisher or a subscriber server, depending on the site and the available capacity of the server. The TFTP server option must be correctly set in the DHCP servers at each site. If DHCP is not in use or if the TFTP server is manually configured, you should configure the correct address for the site.

Other services, which may affect normal operation of Unified CM during WAN outages, should also be replicated at all sites to ensure uninterrupted service. These services include DHCP servers, DNS servers, corporate directories, and IP phone services. On each DHCP server, set the DNS server address correctly for each location.

IP phones may have shared line appearances between the sites. During a WAN outage, call control for each line appearance is segmented, but call control returns to a single Unified CM server once the WAN is restored. During the WAN restoration period, there is additional traffic between the two sites. If this situation occurs during a period of high call volume, the shared lines might not operate as expected during that period. This situation should not last more than a few minutes, but if it is a concern, you can provision additional prioritized bandwidth to minimize the effects.

Gateways for Local Failover

Normally, gateways should be provided at all sites for access to the PSTN. The device pools should be configured to register the gateways with the Unified CM servers at the same site. Call routing (route patterns, route lists, and route groups) should also be configured to select the local gateways at the site as the first choice for PSTN access and the other site gateways as a second choice for overflow. Take special care to ensure emergency service access at each site.

You can centralize access to the PSTN gateways if access is not required during a WAN failure and if sufficient additional bandwidth is configured for the number of calls across the WAN. For E911 requirements, additional gateways might be needed at each site.

Voicemail for Local Failover

Cisco Unity or other voicemail systems can be deployed at all sites and integrated into the Unified CM cluster. This configuration provides voicemail access even during a WAN failure and without using the PSTN. Using Voice Mail Profiles, you can allocate the correct voicemail system for the site to the IP phones in the same location. You can configure a maximum of four voicemail systems per cluster that use the SMDI protocol, that are attached directly to the COM port on a subscriber, and that use the Cisco Messaging Interface (CMI).

Music on Hold and Media Resources for Local Failover

Music on hold (MoH) servers and other media resources such as conference bridges should be provisioned at each site, with sufficient capacity for the type and number of users. Through the use of media resource groups (MRGs) and media resource group lists (MRGLs), media resources are provided by the on-site resource and are available during a WAN failure.

Remote Failover Deployment Model

The remote failover deployment model provides flexibility for the placement of backup servers. Each of the sites contains at least one primary Unified CM subscriber and may or may not have a backup subscriber. This model allows for multiple sites, with IP phones and other devices normally registered to a local subscriber when using 1:1 redundancy and the 50/50 load balancing option described in the chapter on [Call Processing, page 8-1](#). Backup subscribers are located across the WAN at one or more of the other sites. (See [Figure 5-16](#).)

Figure 5-16 Remote Failover Model with Four Sites

When implementing the remote failover model, observe all guidelines for the local failover model (see [Local Failover Deployment Model, page 5-49](#)), with the following modifications:

- Configure each site to contain at least one primary Unified CM subscriber and an optional backup subscriber as desired. If a backup subscriber over the IP WAN is not desired, a Survivable Remote Site Telephony (SRST) router may be used as a backup call processing agent.
- You may configure Unified CM *groups* and *device pools* to allow devices to register with servers over the WAN as a second or third choice.
- Signaling or call control traffic requires bandwidth when devices are registered across the WAN with a remote Unified CM server in the same cluster. This bandwidth might be more than the ICCS traffic and should be calculated using the bandwidth provisioning calculations for signaling, as described in [Bandwidth Provisioning, page 3-47](#).

Note

You can also combine the features of these two types of deployments for disaster recovery purposes. For example, Unified CM groups permit configuring up to three servers (primary, secondary and tertiary). Therefore, you can configure the Unified CM groups to have primary and secondary servers that are located at the same site and the tertiary server at a remote site over the WAN.

Cisco Business Edition 6000 Clustering over the WAN

Cisco Business Edition 6000 may be deployed using the clustering-over-the-WAN call processing local failover model. In this type of deployment, two Business Edition 6000 server nodes are deployed at each of two sites to provide geographic redundancy for the Unified CM call processing application. The two Business Edition 6000 server nodes may both be UCS C200 Rack-Mount Servers, or alternatively one of the servers may be a regular Cisco Media Convergence Server (MCS).

Business Edition 6000 call processing clustering over the WAN deployments must observe the same guidelines and requirements as with regular Unified CM clustering over the WAN and as described earlier. Observe the following guidelines when clustering Business Edition 6000 over the WAN with the local failover model:

- Configure Unified CM groups and device pools to allow devices within each site to register with only the servers at that site under all conditions.
- Cisco highly recommends that you replicate key services (TFTP, DNS, DHCP, LDAP, and IP Phone Services), all media resources (conference bridges and music on hold), and gateways at each site to provide the highest level of resiliency.
- Under a WAN failure condition, the site without access to the publisher database will lose some functionality. For example, system administration at the secondary site will not be able to add, modify, or delete any part of the configuration. However, users can continue to access the user-facing features listed in the section on [Unified CM Publisher, page 5-47](#).
- Under WAN failure conditions, calls made to phone numbers that are not currently communicating with the subscriber placing the call, will result in either a fast-busy tone or a call forward (possibly to voicemail or to a destination configured under Call Forward Unregistered).
- The maximum allowed round-trip time (RTT) between the two Business Edition 6000 server nodes at the two sites is 80 msec.
- 1.544 Mbps (T1) bandwidth is required for Intra-Cluster Communication Signaling (ICCS) busy hour call attempts (BHCA) between the two sites that are clustered over the WAN. This is a bandwidth requirement for call control traffic, and it applies to deployments where directory numbers are not shared between sites that are clustered over the WAN. This call control traffic is classified as priority traffic. Priority ICCS traffic is marked with IP Precedence 3 (DSCP 24 or PHB CS3).
- In addition to the bandwidth required for Intra-Cluster Communication Signaling (ICCS) traffic, an additional 1.544 Mbps (T1) of bandwidth is required for database and other traffic between the two Business Edition 6000 server nodes.

More than two UCS C200 Rack-Mount Servers may be clustered for a Business Edition 6000 deployment to provide additional geographic redundancy beyond two sites with the remote failover model for clustering over the WAN (see [Remote Failover Deployment Model, page 5-55](#)). However, the total number of users across the Business Edition 6000 cluster may not exceed 1,000 and the total number of configured devices across the cluster may not exceed 1,200. A deployment of UCS C200 Rack-Mount Servers in a cluster exceeding 1,000 users and 1,200 configured devices is considered a regular Unified CM cluster, and as such it is bound by all requirements and design guidance for regular Unified CM clusters.

In deployments of Business Edition 6000 with more than two UCS C200 Rack-Mount Servers in the remote failover model for clustering over the WAN, the following additional guidelines must be observed:

- 1.544 Mbps (T1) bandwidth is required for Intra-Cluster Communication Signaling (ICCS) busy hour call attempts (BHCA) between each site that is clustered over the WAN. This is a bandwidth requirement for call control traffic.
- In addition to the bandwidth required for Intra-Cluster Communication Signaling (ICCS) traffic, an additional 1.544 Mbps (T1) of bandwidth is required for database and other inter-server traffic between any server nodes remote from the Business Edition 6000 publisher node.

Clustering over the WAN for Business Edition 6000 Co-Resident Applications

In addition to clustering call processing services over the WAN, Cisco Business Edition 6000 co-resident applications (Cisco Unity Connection, Cisco Unified Presence, and Cisco Unified Contact Center Express) may also be clustered over the WAN provided that these deployments adhere to the same guidelines and restrictions as apply to these applications running on separate systems.

Each co-resident application must adhere strictly to maximum delay and bandwidth requirements. Furthermore, it is important to understand that, while maximum delay budget will apply to all applications, the WAN bandwidth required for each clustered application (including call processing) must be added together to derive the appropriate WAN bandwidth requirement.

Observe the following general guidelines when clustering co-resident Cisco Business Edition 6000 applications and services:

- Round-trip delay across the WAN must not exceed 80 milliseconds because this is the maximum round-trip delay supported across all applications, including call processing.
- The bandwidth requirement on the WAN is based on the total of each application's bandwidth requirement for clustering over the WAN. For example, if all applications (Cisco Unified CM, Unified Presence, Unity Connection, and Unified Contact Center Express) are clustered over the WAN, the total bandwidth required on the WAN would be calculated as follows:

(Total required WAN bandwidth) = (Unified CM required bandwidth) + (Unified Presence required bandwidth) + (Unity Connection required bandwidth) + (Unified Contact Center Express required bandwidth)

For information on clustering delay and bandwidth requirement for each co-resident application, refer to the following information:

- For Cisco Unified Presence, see [Clustering Over the WAN, page 23-22](#).
- For Cisco Unity Connection, see [Cisco Unity Connection Redundancy and Clustering Over the WAN, page 21-22](#).
- For Cisco Unified Contact Center Express, see [Clustering Over the IP WAN, page 26-10](#).

Deploying Unified Communications on Virtualized Servers

Cisco Unified Communications applications can run in a virtualized environment as virtual machines using the VMware ESXi hypervisor. Two hardware options are available:

- Tested Reference Configurations (TRC), which are selected hardware configurations based on Cisco Unified Computing System (UCS) platforms
- Specification-based hardware that provides more hardware flexibility and that, for example, adds support for other Cisco UCS, Hewlett-Packard, and IBM platforms listed in the VMware Hardware Compatibility List (available at <http://www.vmware.com/resources/compatibility/search.php>)

This section presents a short introduction of the Cisco Unified Computing System (UCS) architecture, Hypervisor Technology for Application Virtualization, and Storage Area Networking (SAN) concepts, with a simple overview of where each product fits in a Cisco Virtualized Unified Communications solution for enterprises. It also includes design considerations for deploying Unified Communications applications over virtualized servers.

This description is not meant to replace or supersede product-specific detailed design guidelines available at the following locations:

- <http://www.cisco.com/en/US/products/ps10265/index.html>
- <http://www.cisco.com/go/uc-virtualized>

For sizing aspects of Unified Communications systems on virtualized servers, use the Cisco Unified Communications Sizing Tool, available to Cisco partners and employees (with valid login authentication) at

<http://tools.cisco.com/cucst>

Cisco Unified Computing System

Unified Computing is an architecture that integrates computing resources (CPU, memory, and I/O), IP networking, network-based storage, and virtualization, into a single highly available system. This level of integration provides economies of power and cooling, simplified server connectivity into the network, dynamic application instance repositioning between physical hosts, and pooled disk storage capacity.

The Cisco Unified Computing System is built from many components. But from a server standpoint, the UCS architecture is divided into the following two categories:

- [Cisco UCS B-Series Blade Servers, page 5-59](#)
- [Cisco UCS C-Series Rack-Mount Servers, page 5-61](#)

For more details on the Cisco Unified Computing System architecture, refer to the documentation available at

<http://www.cisco.com/en/US/netsol/ns944/index.html>

Cisco UCS B-Series Blade Servers

The Cisco Unified Computing System (UCS) features blade servers based on x86 architecture. Blade servers provide computing resources (memory, CPU, and I/O) to operating systems and applications. Blade servers have access to the unified fabric through mezzanine form factor Converged Network Adapters (CNA).

The architecture uses a unified fabric that provides transport for LAN, storage, and high-performance computing traffic over a single infrastructure with the help of technologies such as Fibre Channel over Ethernet (FCoE). (See [Figure 5-17](#).) Cisco's unified fabric technology is built on a 10-Gbps Ethernet foundation that eliminates the need for multiple sets of adapters, cables, and switches for LANs, SANs, and high-performance computing networks.

Figure 5-17 Basic Architecture of Unified Communications on Cisco UCS B-Series Blade Servers

This section briefly describes the primary UCS components and how they function in a Unified Communications solution. For details about the Cisco UCS B-Series Blade Servers, refer to the model comparison at

http://www.cisco.com/en/US/products/ps10280/prod_models_comparison.html

Cisco UCS 5100 Series Blade Server Chassis

The Cisco UCS 5100 Series Blade Server chassis not only hosts the B-Series blade servers but also provides connectivity to the uplink Fabric Interconnect Switch by means of Cisco UCS Fabric Extenders.

Cisco UCS 2100 and 2200 Series Fabric Extenders

Cisco UCS 2100 and 2200 Series Fabric Extenders are inserted into the B-Series chassis, and they connect the Cisco UCS 5100 Series Blade Server Chassis to the Cisco UCS Fabric Interconnect Switch. The fabric extender can pass traffic between the blade server's FCoE-capable CNA to the fabric interconnect switch using Fibre Channel over Ethernet (FCoE) protocol.

Cisco UCS 6100 and 6200 Series Fabric Interconnect Switch

A Cisco UCS 6100 and 6200 Series Fabric Interconnect Switch is 10 Gigabit FCoE-capable switch. The B-Series Chassis (and the blade servers) connect to the fabric interconnect, and it connects to the LAN or SAN switching elements in the data center.

Cisco UCS Manager

Management is integrated into all the components of the system, enabling the entire UCS system to be managed as a single entity through the Cisco UCS Manager. Cisco UCS Manager provides an intuitive user interface to manage all system configuration operations.

Hypervisor

A hypervisor is a thin software system that runs directly on the server hardware to control the hardware, and it allows multiple operating systems (guests) to run on a server (host computer) concurrently. A guest operating system (such as that of Cisco Unified CM) thus runs on another level above the hypervisor. Hypervisors are one of the foundation elements in the cloud computing and virtualization technologies, and they consolidate applications onto fewer servers.

Storage Area Networking

Storage area networking (SAN) enables attachment of remote storage devices or storage arrays to the servers so that storage appears to the operating system to be attached locally to the server. SAN storage can be shared between multiple servers.

Cisco UCS C-Series Rack-Mount Servers

Beside the B-Series Blade Servers, the Cisco Unified Computing System (UCS) also features general purpose rack-mount servers based on x86 architecture. The C-Series Rack-Mount Servers provide computing resources (memory, CPU, and I/O) and optional local storage to operating systems and applications. For more information on C-Series servers, refer to the documentation at

<http://www.cisco.com/en/US/products/ps10493/index.html>

Design Considerations for Running Virtual Unified Communications Applications on B-Series Blade Servers

This section highlights some design rules and considerations that must be followed for running Unified Communications services on virtualized servers. Many Cisco Unified Communications applications support virtualization on a B-Series Blade server, such as:

- Cisco Unified Communications Manager (Unified CM)
- Cisco Unified CM Session Manager Edition
- Cisco Unity Connection
- Cisco Unified Presence
- Cisco Unified Contact Center Express
- Cisco Unified Contact Center Enterprise

For a full list of supported Cisco Unified Communications applications, refer to the documentation available at

<http://www.cisco.com/go/uc-virtualized>

Blade Server

The Cisco B-Series Blade Servers support multiple CPU sockets, and each CPU socket can host multiple multi-core processors. For example, one B200 blade has two CPU sockets that can host up to two multi-core processors. This provides the ability to run multiple Unified Communications applications on a single blade server.

Cisco Unified Communications applications should be run on dedicated blades that are not running any non-Unified Communications applications. Each Unified Communications application should be allotted dedicated processing and memory resources, so that the resources are not oversubscribed.

Hypervisor

The VMware ESXi Hypervisor is required to run virtual Unified Communications applications. The local hard drives attached to the Blade Server cannot be used to store virtual machines; they can be used only to install the ESXi hypervisor software. Unified Communications applications must follow the respective guidelines for their virtual machine template and configuration.

VMware vCenter is not mandatory when using a Tested Reference Configuration, but it is strongly recommended to manage multiple ESXi hosts for a large deployment.

For specific configuration and sizing requirements for virtual machines, refer to the respective product documentation available at

<http://www.cisco.com/go/uc-virtualized>

SAN and Storage Arrays

Tested Reference Configurations based on the Cisco UCS B-Series platform require the virtual machines to run from a Fibre Channel SAN storage array. The SAN storage array must satisfy the requirements of the VMware hardware compatibility list. Other storage options such as iSCSI, FCoE SAN, and NFS NAS are supported with the specification-based hardware support. For more details, refer to the documentation available at

<http://www.cisco.com/go/uc-virtualized>

Design Considerations for Running Virtual Unified Communications Applications on C-Series Rack-Mount Servers

Tested Reference Configurations are also available with Cisco UCS C-Series Rack Mount Servers such as the Cisco UCS C200, C210 and C260.

Many Cisco Unified Communications applications support virtualization on a C-Series Rack Mount Server, such as:

- Cisco Unified Communications Manager (Unified CM)
- Cisco Unified CM Session Manager Edition
- Cisco Unity Connection
- Cisco Unified Presence
- Cisco Unified Contact Center Express
- Cisco Unified Contact Center Enterprise

For a full list of supported Cisco Unified Communications applications, refer to the documentation available at

<http://www.cisco.com/go/uc-virtualized>

Unlike with the UCS B-Series, the Tested Reference Configurations based on the high-end UCS C-Series Rack Mount Servers (for example, C210 and C260) support storing virtual machines either locally on the directly attached storage drives or on an FC SAN storage array. Multiple Unified Communications applications can reside on the same C-Series server. Low-end UCS C-Series Rack Mount Servers (for example, C200) allow only local storage of Cisco Unified Communications virtual machines.

UCS C210 servers support more user capacity than UCS C200 servers.

There are specific requirements that must be met in order to run Cisco Unified Communications applications as virtual servers on the UCS C-Series Rack-Mount Servers. These requirements are mentioned in the following document:

http://www.cisco.com/en/US/prod/collateral/voicesw/ps6790/ps5748/ps378/solution_overview_c22-597556.html

Impact of Virtual Servers on Deployment Models

Deploying Cisco Unified Communications applications on virtualized servers supports the same deployment models as when physical servers are used. The chapter on [Network Infrastructure, page 3-1](#), offers some design guidance on how to integrate the QoS capabilities of Cisco UCS B-Series virtualized servers into the network. Also, the integration of physical servers (such as Cisco MCS servers) and Cisco UCS virtual servers is supported in many cases. As an example, music on hold (MoH) servers can run on Cisco MCS server platforms, while also being part of a cluster whose other member servers are run on Cisco UCS virtual servers.

All the call processing deployment models described in this chapter are supported over Cisco UCS virtual server platforms.

Design Considerations for Section 508 Conformance

Regardless of which deployment model you choose, you should consider designing your Cisco Unified Communications network to make the telephony features more accessible to users with disabilities, in conformance with Section 255 of the Telecommunications Act and U.S. Section 508.

Observe the following basic design guidelines when configuring your Cisco Unified Communications network to conform to Section 508:

- Enable Quality of Service (QoS) on the network.
- Configure only the G.711 codec for phones that will be connected to a terminal teletype (TTY) device or a Telephone Device for the Deaf (TDD). Although low bit-rate codecs such as G.729 are acceptable for audio transmissions, they do not work well for TTY/TDD devices if they have an error rate higher than 1% Total Character Error Rate (TCER).
- Configure TTY/TDD devices for G.711 across the WAN, if necessary.
- Enable (turn ON) Echo Cancellation for optimal performance.
- Voice Activity Detection (VAD) does not appear to have an effect on the quality of the TTY/TDD connection, so it may be disabled or enabled.

- Configure the appropriate *regions* and *device pools* in Unified CM to ensure that the TTY/TDD devices always use G.711 codecs.
- Connect the TTY/TDD to the Cisco Unified Communications network in either of the following ways:
 - Direct connection (Recommended method)
Plug a TTY/TDD with an RJ-11 analog line option directly into a Cisco FXS port. Any Cisco voice gateway with an FXS port will work. Cisco recommends this method of connection.
 - Acoustic coupling
Place the IP phone handset into a coupling device on the TTY/TDD. Acoustic coupling is less reliable than an RJ-11 connection because the coupling device is generally more susceptible to transmission errors caused by ambient room noise and other factors.
- If stutter dial tone is required, use an analog phone in conjunction with an FXS port on the Cisco VG224 or ATA 187. In addition, most Cisco IP Phones support stutter dial tone, which is sometimes referred to as audible message waiting indication (AMWI). For a list of the specific Cisco IP Phone models that support this functionality, see the [Endpoint Features Summary, page 18-55](#).

Call Routing and Dial Plan Distribution Using Call Control Discovery for the Service Advertisement Framework

When multiple call processing agents are present in the same system, each can be configured manually to be aware of the others. This configuration can be time consuming and error prone. Call routing between the various call processing agents requires the configuration of static routes on the call agents and updating them when changes occur.

Instead, the Cisco Service Advertisement Framework (SAF) can be used to share call routing and dial plan information automatically between call agents. SAF allows non-Cisco call agents (such as TDM PBXs) to partake in the Service Advertisement Framework when they are interconnected through a Cisco IOS gateway.

The Service Advertisement Framework (SAF) enables networking applications to advertise and discover information about networked services within an IP network. SAF consists of the following functional components and protocols:

- SAF Clients — Advertise and consume information about services.
- SAF Forwarders — Distribute and maintain SAF service availability information.
- The SAF Client Protocol — Used between SAF Clients and SAF Forwarders.
- The SAF Forwarder Protocol — Used between SAF Forwarders.

The nature of the advertised service is unimportant to the network of SAF Forwarders. The SAF Forwarder protocol is designed to dynamically distribute information about the availability of services to SAF client applications that have registered to the SAF network.

Services that SAF Can Advertise

In theory, any service can be advertised through SAF. The first service to use SAF is Cisco Unified Communications Call Control Discovery (CCD). CCD uses SAF to distribute and maintain information about the availability of internal directory numbers (DNs) hosted by call control agents such as Cisco Unified CM and Unified CME. CCD also distributes the corresponding number prefixes that allow these internal directory numbers to be reached from the PSTN ("To PSTN" prefixes).

The dynamic nature of SAF and the ability for call agents to advertise the availability of their hosted DN ranges and To PSTN prefixes to other call agents in a SAF network, provides distinct advantages over other static and more labor-intensive methods of dial plan distribution.

This chapter discusses the deployment of Call Control Discovery (CCD) in SAF-enabled Unified Communications networks. For more information on SAF itself, see [Service Advertisement Framework \(SAF\)](#), page 3-72.

The following Cisco products support the Call Control Discovery (CCD) service for SAF:

- Cisco Unified Communications Manager (Unified CM) Release 8.0(1) or higher
- Cisco Unified Communications Manager Express (Unified CME) on a Cisco Integrated Services Router (ISR)
- Survivable Remote Site Telephony (SRST) on a Cisco ISR platform
- Cisco Unified Border Element on a Cisco ISR platform
- Cisco IOS Gateways on a Cisco ISR platform

CCD is supported on Cisco ISR platforms running Cisco IOS Release 15.0(1)M or higher. For more information on Cisco IOS Release 15.0(1)M, refer to the following websites:

- <http://www.cisco.com/ios/release/15mt>
- <http://www.cisco.com/en/US/products/ps10621/index.html>

For information on the use of CCD with Unified CM, refer to the *Cisco Unified Communications Manager Features and Services Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

SAF Service IDs

CCD is the first SAF service. SAF services are identified to a network of SAF Forwarders and Clients by their SAF Service ID. CCD for Unified Communications uses a SAF Service ID of 101:2:x.x.x.x, where:

- Service ID 101 = Unified Communications
- Sub-Service ID 2 = CCD
- Instance ID x.x.x.x = ID of Unified CM cluster (PKID) or Cisco IOS device

Deploying SAF CCD Within Your Network

The SAF CCD service allows information about the location and availability of directory number ranges hosted by call control agents, such as Unified CM and Unified CME, to be propagated dynamically within a SAF-enabled Unified Communications network.

Figure 5-20 Advertising Unified CM Internal DN Ranges and Corresponding "To PSTN" Prefixes to the SAF Network

Figure 5-22 Dynamic Call Routing with SAF CCD

Any call made using SAF learned routes has automatic PSTN failover if the IP path to the called number is not available (see Figure 5-23). The call is routed according to the following order:

- Take the selected IP path to reach the called number.
- If the IP path is not available, use the PSTN prefix to modify the called number and route the call through the PSTN.

SAF Forwarder Configuration (External SAF Client on Unified CM)

The SAF Forwarder Configuration on Unified CM represents the configuration of the External SAF Client to a SAF Forwarder in a Unified Communications network. The Unified CM SAF Forwarder configuration defines the following items:

- The destination IP address and port number of the remote SAF Forwarder
- The Security Profile (username and password) used to authenticate with the SAF Forwarder
- The Client Label

This is a string that the SAF Forwarder uses to map the Unified CM external client into a specific SAF Autonomous System. Cisco IOS supports bulk provisioning of the Client Label, whereby a client-label string that ends with an @ is considered as a base name or label. A base label configured on a router will accept any character following the @ in the base name as a valid client-label to identify a client in the REGISTER message sent by an external client.

For example, Unified CM cluster A can use CUCM-A as the base name for the cluster and can append a number after the @ following the base name for each configured SAF Forwarder (external SAF Client in Unified CM). By defining the external client CUCM-A as a base name in Cisco IOS, the Cisco IOS forwarder will accept any client label beginning with CUCM-A@, such as any of the following labels:

- CUCM-A@Client-1
- CUCM-A@Client-2
- CUCM-A@Client-3
- CUCM-A@Client-4

This allows SAF Clients 1 through 4 to register with the same SAF Forwarder and SAF autonomous system (AS).

External SAF Client Instance Creation and Activation within the Unified CM Cluster

By default, an instance of the external SAF client configured through the SAF Forwarder Configuration page in Unified CM is created on every call processing node within the cluster (see [Figure 5-24](#)). The external SAF client is activated only if an instance of a CCD Advertising Service or the CCD Requesting Service is also active on the call processing node. The activation of Advertising and Requesting Services on call processing nodes is determined by the SAF trunks associated with each service. (For details, see [CCD Advertising and Requesting Services, page 5-75](#).)

Figure 5-24 Single SAF Forwarder Defined in Unified CM

Figure 5-24 shows four active External SAF Clients connecting to a single SAF Forwarder. (The greyed-out SAF client is not activated because there is no active Advertising or Requesting Service associated with that Unified CM node). Each active External SAF client establishes a connection to the SAF Forwarder, registers with the SAF network, publishes its associated Services, and subscribes to the SAF CCD service active in the SAF AS. Such duplication can be useful for resilience and redundancy, but it can also create overhead within the cluster and the SAF Forwarder. By carefully selecting where the Advertising and Requesting Services run within the cluster, you can fine-tune this duplication and redundancy. For more information, see the [CCD Advertising and Requesting Services](#), page 5-75.

Multiple SAF Forwarders

You can configure multiple SAF Forwarders within a cluster for redundancy. The SAF Client establishes a secure connection to the primary and the backup SAF Forwarders, registers with the SAF Forwarders, and sends a publish request for the HostedDN service to the primary SAF Forwarder. The SAF Client makes an arbitrary decision on selecting one SAF Forwarder as primary and another as backup at system startup time, based on the first SAF Forwarder to respond to a registration request from the client. The SAF Client publishes and subscribes services to the primary SAF Forwarder only. The SAF Client maintains the connection to the SAF Forwarder by sending keepalives to the SAF Forwarder at regular intervals. If the connection to the primary SAF Forwarder fails, the SAF Client switches to the backup SAF Forwarder, sending all the publish and subscription requests to the backup SAF Forwarder that it had sent to the primary SAF Forwarder.

Figure 5-25 Two SAF Forwarders Defined in Unified CM

Advanced SAF Client Configuration

By default, for each configured SAF Forwarder a corresponding instance of the SAF client is created on every call processing node within the Unified CM cluster. Using the advanced SAF Forwarder configuration option, the administrator can create the SAF client on selected call processing nodes within the cluster. This configuration option enables the administrator to create the SAF client on specific nodes within the cluster and to configure SAF CCD with spatial distribution of CCD services for systems that employ clustering over the WAN.

SAF CCD and Clustering over the WAN

By creating multiple SAF client instances and multiple Advertising Services and associating them with specific Unified CM nodes within a cluster that uses clustering over the WAN, you can advertise CCD Hosted Directory Number ranges into the SAF network, with a geographical association to their local Unified CM trunks and nodes within the cluster.

Figure 5-26 SAF CCD-Selected SAF Client Configuration for Clustering over the WAN

SAF-Enabled Trunks

SAF-enabled trunks are used solely to route calls between SAF-enabled call control applications. They cannot be used with standard route patterns, route lists, and route groups. You cannot configure the destination address of a SAF-enabled trunk because this destination address is learned through SAF; however, you can configure all other trunk parameters.

You can enable SAF on the following trunk types:

- SIP trunks — Enabled by selecting **Call Control Discovery** as the Trunk Service Type when creating a new SIP trunk.
- H.323 Non-Gatekeeper controlled intercluster trunks — Enabled by checking the **Enable SAF** check box on the Trunk configuration page.

Both of these trunk types may be used between Unified CM clusters and between Unified CM and Cisco IOS gateways.

CCD uses SAF-enabled trunks for two purposes:

- To originate calls — These SAF-enabled trunks are associated with the CCD Requesting Service.
- To accept incoming calls — These SAF-enabled trunks are associated with the CCD Advertising Service. The IP addresses and port numbers of these SAF-enabled trunks are published with the DN ranges associated with the Advertising Service.

A SAF-enabled trunk can be used by both the Advertising and Requesting Service.

When the CCD Advertising Service publishes the trunk details for a hosted DN range, it sends the IP address and port number of each Unified CM node in the SAF trunk's Cisco Unified Communications Manager Group in separate SAF advertisements. For example, to advertise hosted DN range 5XXX from SIP trunk A, which has CUCM1 and CUCM2 in its Cisco Unified Communications Manager Group, the CCD Advertising Service would publish two advertisements:

- 5XXX via SIP trunk IP address (CUCM1) port number 5060
- 5XXX via SIP trunk IP address (CUCM2) port number 5060

The Requesting Service of the cluster receiving this advertisement would place two routes to 5XXX in its SAF learned routes partition:

- 5XXX via SIP trunk IP address (CUCM1) port number 5060
- 5XXX via SIP trunk IP address (CUCM2) port number 5060

Calls to 5XXX from this cluster would select the two available SIP trunk destinations in round-robin order.

SAF trunks support TCP or UDP transport protocols. Because a SAF trunk can accept incoming calls from multiple call control applications, TLS-based Signalling Authentication and Encryption is not supported over SAF-enabled trunks.

Hosted DN Patterns and Hosted DN Groups

Hosted DN groups represent groups of hosted DN patterns. The hosted DN patterns in a hosted DN group typically represent the range of directory numbers associated with a physical site. Digit strip and prepend information for "To PSTN" failover routing can be configured for each hosted DN group. The same DN pattern cannot be associated with multiple hosted DN groups.

A hosted DN pattern can define a single directory number (for example, 5000), or a range of directory numbers (for example, 5XXX). Every DN pattern must be unique. Each hosted DN pattern can be configured with digit strip and prepend information for PSTN failover routing. The PSTN failover configuration on the hosted DN pattern takes precedence over the PSTN failover configuration at the hosted DN group level.

CCD Advertising and Requesting Services

CCD uses two Unified CM services to communicate with the SAF network: the Advertising Service, which is used to publish DN ranges and their associated trunks to the SAF network, and the Requesting Service, which is used to learn about the reachability of DN ranges from other call agents in the SAF network. The following sections describe these two services.

CCD Advertising Service

The CCD Advertising Service associates one hosted DN group with a SAF-enabled SIP and/or H.323 trunk. The Advertising Service is created and activated on each server in the Cisco Unified Communications Manager Group (Unified CM Group) of its associated SAF-enabled trunk(s). The

Advertising Service uses the SAF Client on each of the servers in the Unified CM Group of each trunk to publish information about the group of hosted DNs and associated trunk nodes to the client's SAF Forwarder. (See [Figure 5-27](#).)

Because SIP and H.323 trunks support different feature sets (for example, H.323 trunks support QSIG over Annex M1), it is typical to select only one trunk type per Advertising Service. If both an H.323 and a SIP trunk are selected, calls to the hosted DN ranges associated with this Advertising Service will be distributed in a round-robin fashion across both the SIP and H.323 trunks.

Figure 5-27 CCD Advertising Service 1 Active on CM1 and CM2

You can create multiple advertising services within a Unified CM cluster. An Advertising Service can use the same (or different) SAF-enabled trunks as other Advertising Services. However, each Advertising Service must be associated with a unique hosted DN group, and the same hosted DN pattern cannot be advertised by multiple Advertising Services within a cluster. Creating multiple Advertising Services allows inbound calls to be distributed by DN range across multiple trunk servers within a cluster. (See [Figure 5-28](#).)

Figure 5-28 CCD Advertising Service 2 Active on CM5 and CM6

CCD Requesting Service

The CCD Requesting Service collects information about hosted DN routes advertised in the SAF AS and places them into a partition for SAF learned routes. (See Figure 5-29.) The Requesting Service is also used to select which SAF trunks will be used to initiate outbound SAF calls. More than one SAF-enabled trunk can be selected. If multiple trunks are selected, these SAF trunks and their corresponding Unified CM Group server nodes are selected on a round-robin basis for outbound calls. Similar to the Advertising Service, trunks of the same protocol type are usually associated to the Requesting Service. The Requesting service also allows digits to be prefixed to learned DN patterns and learned "To PSTN" patterns.

Only a single Requesting Service can be configured in the Unified CM cluster, and the Requesting Service is activated on all of the nodes in the Unified CM Groups of its associated SAF trunks.

Figure 5-29 Unified CM CCD Requesting Service

Blocking CCD Learned Patterns

Unified CM enables the SAF CCD administrator to purge and block learned route information from the SAF CCD learned routes partition. Routes can be blocked based on whether they match one or more of the following entries:

- Learned Pattern (for example, 500X)
- Learned Pattern Prefix (for example, +1408)
- Remote Call Control Entity Name (This is the Unified CM Cluster ID in Enterprise Parameters.)
- Remote Call Control IP Address (This could be the address of a Cisco IOS SAF CCD router or one or more Unified CM servers in a Unified CM cluster.)

If required, these entries can be used in a logical AND combination such as the following:

Pattern = "5XXX" AND Prefix = "+1408" AND Remote Call Control Address = "10.10.1.1"

Blocking CCD learned patterns can be particularly useful in SAF CCD deployments where a Unified CM cluster connects to multiple SAF ASs and wishes to advertise DN route information to an AS but does not wish to receive some or all of the DN route information being sent by the AS.

Displaying SAF Learned Routes in Unified CM

Because SAF learned routes are dynamic in nature, they are not held in the Unified CM database but are stored in memory. Use the Cisco Unified Communications Manager Real-Time Monitoring Tool (RTMT) to display SAF learned routes and to monitor SAF Forwarders (see [Figure 5-30](#)).

Figure 5-30 Real-Time Monitoring Tool (RTMT) for SAF CCD

| Pattern | TimeSta... | Status | Protocol | AgentId | IP Address | ToDID | CUC... |
|---------|-------------|-----------|-----------|------------|--------------------|-------|--------|
| 141XXX | 2009/10/... | Reachable | SIP | C10.194... | 10.194.121.14(5... | | 1 |
| 141XXX | 2009/10/... | Reachable | H323(Q... | C10.194... | 10.194.121.14(4... | | 1 |

Cisco IOS-Based SAF CCD

Cisco IOS-based SAF CCD is supported by Unified CME, SRST, Cisco Unified Border Element, and Cisco IOS Gateways on the Integrated Services Router (ISR) platform with Cisco IOS Release 15.0(1)M. (See [Figure 5-31](#).) The configuration of Cisco IOS SAF CCD is the same across all of these products. SRST, however, is a special case of CCD and is discussed in the section on [SAF CCD and SRST](#), page 5-83.

Figure 5-31 Cisco IOS-Based SAF CCD Call Agents

For Unified CME, Cisco IOS TDM gateways, and Cisco Unified Border Element, SAF CCD can be used to advertise the internal directory number ranges and "To PSTN" prefixes of the endpoints associated with each of these products and also to subscribe to SAF advertisements from other SAF CCD-enabled call control applications.

For both Cisco IOS and Unified CM, Cisco does *not* recommend using SAF CCD to advertise external PSTN number ranges (for example, for tail-end hop off) for the following key reasons:

- SAF CCD provides no information about the capacity of IP, PSTN, or TDM trunks. (For example, an ISDN BRI with two DS0s and a T1 TDM interface with 24 DS0s would be weighted equally by SAF CCD.)
- All SAF CCD routes are placed into a single partition. This means that any SAF CCD user has access to all learned SAF CCD routes and that no SAF CCD classes of service can be created.

Although the principles of Cisco IOS SAF CCD configuration are the same as those for Unified CM, the naming conventions and commands are different.

Internal SAF Clients

For Cisco IOS-based SAF CCD applications, the SAF Client and Forwarder are co-resident within Cisco IOS. Configuration and authentication is not required between the internal SAF Client and internal SAF Forwarder.

External SAF Clients

To enable the authentication of an external SAF Client to a Cisco IOS SAF Forwarder, use the **external-client** Cisco IOS command to define the external client's label or base name, username, password, and keepalive timer.

SAF-Enabled Trunks

SAF trunks are defined under the **profile trunk-route** Cisco IOS command. The trunk-route profile defines the IP address, port number, protocol (SIP or H.323), and transport protocol (UDP or TCP) for the SAF trunk.

DN Patterns, DN Blocks, and DN Service

The definition and configuration of directory numbers, DN ranges and "To PSTN" prefixes is slightly different in Cisco IOS when compared with Unified CM configuration. Cisco IOS uses the concept of DN blocks to group DN numbers and DN ranges. A DN block can contain more than one DN pattern. The "To PSTN" failover rules for stripping and prefixing digits are also defined at the DN block command line. The PSTN failover rule is known as an **alias** in Cisco IOS. (The PSTN failover rule is applied to the concatenated Site Code and Extension DN Pattern.) The following example shows the Cisco IOS configuration for a DN block:

```
profile dn-block 1 alias 1408902 strip 3
  pattern 1 extension 5xxx
  pattern 2 extension 6xxx
```

Call Control Profile, DN Service, and Site Code

The CCD call control profile is associated with a DN service. A DN service in Cisco IOS can be considered to be equivalent to an Advertising Service in Unified CM. The DN service is used to group one or more DN blocks, one trunk route, and one site code. If present, the site code consists of one or more digits that are prepended to the advertised extension DN patterns.

Multiple call control profiles can be created. The same DN blocks, trunk routes, and site codes can be reused in multiple call control profiles, but only one profile can be associated with a SAF AS.

Publishing and Subscribing to SAF Services within a SAF AS

Call control profiles advertise their associated DN ranges, "To PSTN" failover rules, and trunk route to one SAF AS by means of a configured SAF "channel." A SAF channel can publish the CCD service information contained in only one call control profile to a single SAF AS. (See [Figure 5-32](#).)

Figure 5-32 Cisco IOS CCD Service Call Control 1 Advertising Through Channel 1 to SAF AS 100

A SAF Channel can subscribe to all CCD services within a SAF AS using a wildcard service ID, or up to two selected SAF CCD services that are identified by the instance values in the SAF service ID. (The instance value for Unified CM is the cluster PKID.) For example:

Wildcard SAF Service ID =

| Service: | Sub-service: | Instance. | Instance. | Instance. | Instance. |
|----------|--------------|-----------|-----------|-----------|-----------|
| 101: | 2: | FFFFFFFF. | FFFFFFFF. | FFFFFFFF. | FFFFFFFF. |

Tip

Use the Cisco IOS command **show eigrp service-family ipv4 [AS number] events** to display the Service ID for the Cisco IOS SAF CCD service on the router. The Service ID will be displayed as "connected" (for example, 101:2:59F8412.0.0.6F0100).

Outbound SAF CCD Calls in Cisco IOS

Cisco IOS adds SAF as a configurable session target to standard Cisco IOS voice dial peers. Dial peers can also be assigned a preference setting to control the order in which standard and SAF dial peers are selected.

SAF CCD and SRST

SRST CCD is a special type of SAF deployment. SRST CCD does not advertise any number ranges into SAF; it only listens to the advertisements from other SAF CCD services such as Unified CM, Unified CME, and so forth. SRST CCD does not use SAF learned IP routes at any time; only PSTN routes are used and only when the router and associated phones are in SRST mode.

You can use SAF for SRST CCD to avoid the labour-intensive task of updating every SRST router with a new number expansion rule every time a new SRST router is added to the Unified Communications network.

With standard (non-SAF) SRST operation, if Unified CM becomes unavailable, phones register their extension numbers to their SRST reference router. (See Figure 5-33.) In SRST mode, calls can be made to other phones registered to the SRST router by dialing their extension number as normal. When a phone in SRST mode is used to call a phone in another site, the PSTN number of the called phone must be dialed. (See Figure 5-34.) The number expansion command in Cisco IOS, much like the PSTN failover rule in SAF CCD, allows the dialed extension number to be expanded to the full PSTN number in SRST mode.

In a Unified Communications deployment with many SRST routers, when a new SRST router is added to the Unified Communications network, every SRST router must add a number expansion rule that corresponds to the PSTN access prefix for this new SRST site.

SAF for SRST CCD allows the PSTN failover rules for every SRST site to be distributed to every SRST router within the SAF AS.

Figure 5-35 A Global SAF Network with Regional Call Agents and SAF Clients and Forwarders

Figure 5-36 shows a logical diagram of the same global SAF network with regional call agents and SAF Clients and Forwarders

Figure 5-36 Logical Representation of Global SAF Network with Regional Call Agents and SAF Clients and Forwarders

SAF CCD Deployment Considerations

Migration to SAF CCD is relatively risk free. The SAF CCD network can be built and tested for basic operation and scalability before any devices that use SAF are enabled in the network. Unified CM users can be given the capability to use the SAF CCD network by adding the SAF Learned Routes Partition to their device or profile. In Cisco IOS the preference for SAF dial peers can be prioritized above standard dial peers. This allows SAF to be enabled incrementally throughout the network.

The following scalability limits apply to Unified CM and Cisco IOS SAF CCD products:

- Up to 2,000 advertised DN patterns per Unified CM cluster
- Up to 20,000 learned DN patterns per Unified CM cluster
- Up to 125 advertised DN patterns per Unified CME, Cisco Unified Border Element, or Cisco IOS Gateway
- Up to 6,000 learned DN patterns per Unified CME, Cisco Unified Border Element, Cisco IOS Gateway, or SRST (platform-dependant)

In very large SAF CCD networks, multiple SAF ASs can be used to limit the distribution of SAF advertised DN patterns. Unified CM and/or Cisco Unified Border Element may also be used to manually summarize SAF advertisements from one SAF AS and statically advertise them into another SAF AS.

SAF CCD Port Numbers

SAF CCD uses the following port numbers:

- SAF EIGRP — IP Protocol 88
- Unified CM SAF Client to Cisco IOS SAF Forwarder — TCP port 5050 (configurable)
- Advertised SIP trunks — port 5060
- Advertised H.323 — ephemeral port number

**Note**

The Cisco Adaptive Security Appliance (ASA) firewall uses standard SIP inspection and fix-up to open pinholes in the firewall for the RTP media streams of SAF enabled SIP trunk calls. H.323 inspection and fix-up of SAF-enabled H.323 trunk calls are not supported.

CHAPTER 6

IP Telephony Migration Options

Revised: April 2, 2010; OL-21733-18

This chapter describes several methods for migrating from separate standalone communication components to an integrated Cisco Unified Communications System. The topics discussed in this chapter are viewed from a customer or business viewpoint rather than a technical viewpoint that is more of a decision based around which protocol to use or which features are required.

Coexistence or Migration?

This is an important question that needs to be answered.

Coexistence typically means two or more systems coexisting for an extended period of time (for example, anything greater than six months). Under this scenario feature transparency, whether for PBX, voicemail, or other features, becomes a more significant consideration. Investment and/or upgrades to existing systems might be necessary in order to deliver the level of feature transparency required.

Migration typically occurs over a shorter period of time (for example, less than six months). Under this scenario users are more likely to tolerate a subset of existing features, knowing that the migration will be complete in a "short" period of time. Often existing system capabilities may be sufficient for this "short" period of time, therefore migration is often less costly when compared to coexistence.

Migration Prerequisites

Before implementing any Unified Communications service, customers should ensure that the underlying IP infrastructure is "UC ready," including redundancy, high availability, Quality of Service (QoS), in-line powered Ethernet ports, and so forth. For further details, refer to the chapter on [Network Infrastructure](#), page 3-1.

Typically some kind of site or user-survey should be performed to ensure that all requirements (for example, fax/modems, environmental control systems, and so forth) are appropriately identified and accounted for.

Unified Communications Migration

There are two main methods for migrating to a Unified Communications system (or any individual Unified Communications service, for that matter):

Phased Migration

This method typically starts with a small trial focused around the Unified Communications service to be deployed. Once the customer is familiar with the Unified Communications service trial, then the migration starts by moving groups of users, one group at a time, to the production version of that Unified Communications service.

Parallel Cutover

This method begins similar to the phased approach; however, once the customer is satisfied with the progress of the trial, then a time and date are chosen for cutting-over all the users at once to the new Unified Communications service.

A parallel cutover has the following advantages over a phased migration:

- If something unexpected occurs, the parallel cutover provides a back-out plan that allows you to revert, with minimal effort, to the previous system, which is essentially still intact. For example, with phased migration from a PBX, service can be restored to the users simply by transferring the inbound PSTN trunks from the IP telephony gateway(s) back to the PBX.
- The parallel cutover allows for verification of the configuration of the Unified Communications service before the system carries live traffic. This scenario can be run for any length of time prior to the cutover of the Unified Communications service, thereby ensuring correct configuration of all user information such as phones, gateways, the dial plan, mailboxes, and so forth.
- Training can be carried out at a more relaxed pace by allowing subscribers to explore and use the Unified Communications service at their own leisure prior to the cutover.
- The system administrator does not have to make special provisions for "communities of interest." With a phased approach, you have to consider maintaining the integrity of features such as call pick-up groups, hunt groups, shared lines, and so forth. These associations can be easily accounted for when moving the complete Unified Communications service in a parallel cutover.

One disadvantage of the parallel cutover is that it requires the Unified Communications service, including the supporting infrastructure, to be fully funded from the beginning because the entire service must be deployed prior to bringing it into service. With a phased migration, on the other hand, you can purchase individual components of the system as and when they are needed, and this approach does not prevent you from starting with a small trial system prior to moving to full deployment.

Neither method is right or wrong, and both depend upon individual customer circumstances and preferences to determine which option is most suitable.

Example 6-1 *Phased Migration for IP Telephony*

This approach typically entails a small IP telephony trial that is connected to the main corporate PBX. The choice of which signaling protocol to use is determined by the required features and functionality as well as by the cost of implementation. Cisco Unified Communications Manager (Unified CM) can support either regular PSTN-type PRI or QSIG PRI as well as H.323 and SIP. Of these options, QSIG PRI typically provides the highest level of feature transparency between any two systems.

PSTN-type PRI provides for basic call connectivity as well as Automatic Number Identification (ANI). In some instances, the protocol also supports calling name information. This level of connectivity is available to all PBXs and therefore is considered to be the least costly option; that is, if the PBX can connect to the public network through PRI, then it can connect to Unified CM because Unified CM can be configured as the "network" side of the connection.

With either PSTN-type PRI or QSIG, the process for a phased migration is similar: move users from the PBX to Unified CM in groups, one group at a time, until the migration is complete.

The Cisco San Jose campus, consisting of some 23,000 users housed in approximately 60 buildings, was migrated to IP telephony in this manner and took just over one year from start to finish at the rate of one building per weekend. All users in the selected building were identified, and their extensions were deleted from the PBX on a Friday evening. At the same time, additions were made to the PBX routing tables so that anyone dialing those extension numbers would then be routed over the correct PRI trunk for delivery to Unified CM. During the weekend, new extensions were created in Unified CM for the users, and new IP phones were delivered to their appropriate office locations, ready for use by Monday morning. This process was repeated for each building until all users had been migrated.

Example 6-2 *Parallel Cutover for IP Telephony*

All IP phones and gateways are fully configured and deployed so that users have two phones on their desk simultaneously, an IP phone as well as a PBX phone. This approach provides the opportunity not only to test the system but also to familiarize users with their new IP phones. Outbound-only trunks can also be connected to the IP telephony system, giving users the opportunity to use their new IP phones to place external as well as internal calls.

Once the IP telephony system is fully deployed, you can select a time and date for bringing the new system into full service by transferring the inbound PSTN trunks from the PBX to the IP telephony gateways. You can also leave the PBX in place until such time as you are confident in the operation of the IP telephony system, at which point the PBX can then be decommissioned.

The Cisco San Jose campus voicemail service was provided by four Octel 350 systems serving some 23,000 users. Cisco Unity servers were installed and users' mailboxes were configured. Users had access to their Unity mailbox by dialing the new access number, in order to allow them to record their name and greeting(s) as well as to allow them to familiarize themselves with the new Telephony User Interface (TUI). Approximately two weeks later, a Unified CM Bulk Administration Tool (BAT) update was carried out on a Friday evening to change the Call-Forward Busy and No-Answer (CFB/CFNA) numbers as well as the Messages button destination number for all users to the Unity system. Upon returning to work on Monday morning, users were serviced by Unity. The Octel 350 systems were left in place for one month to allow users to respond to any messages residing on those systems before they were decommissioned.

The Need for QSIG in Multisite Enterprises

While some enterprises consist of only one location, others consist of many sites, some of which may potentially be spread over large distances. PBX networks for multisite enterprises are usually connected using T1 or E1 PRI trunks (depending on location) running a proprietary protocol such as Avaya DCS, Nortel MCDN, Siemens CorNet, NEC CCIS, Fujitsu FIPN, or Alcatel ABC, among others. These proprietary networking protocols enable the PBXs to deliver a high level of feature transparency between end users.

QSIG was developed to enable the interconnection of PBXs from different vendors, thereby allowing similar levels of feature transparency.

By supporting QSIG, Unified CM can be introduced into a large enterprise network while also maintaining feature transparency between users. PBX locations can then be converted to IP telephony whenever convenient.

However, unless you already have QSIG enabled on your PBX or have a specific need for its additional features and functionality, the cost of upgrading the PBX might be hard to justify if it will be retired within a short period of time. For example, why spend \$30,000 on enabling the PBX for QSIG if you plan to retire the PBX in two or three months?

Summary of IP Telephony Migration

Although both methods of IP telephony migration work well and neither method is right or wrong, the parallel cutover method usually works best in most cases. In addition, large enterprises can improve upon either migration method by using QSIG to enable Unified CM to become part of the enterprise network.

Cisco has a lab facility dedicated to testing interoperability between Unified CM and PBX systems. The results of that testing are made available as application notes, which are posted at

<http://www.cisco.com/go/interoperability>

The application notes are updated frequently, and new documents are continuously added to this website. Check the website often to obtain the latest information.

Centralized Unified Communications Deployment

In the case of an enterprise that has chosen to deploy Unified Communications in a centralized manner, two options exist:

- Start from the outside and work inward toward the central site (that is, smallest to largest).
- Start from the central site and work outward toward the edges.

The majority of customers choose the first option because it has the following advantages:

- It gives them the opportunity to fully deploy all the Unified Communications services and then conduct a small trial prior to rolling Unified Communications out to the remote locations.
- The rollout of Unified Communications can be done one location at a time, and subsequent locations can be migrated when convenient.
- This option is the lowest cost to implement once the core Unified Communications services are deployed at the central site.
- IT staff will gain valuable experience during migration of the smaller sites prior to migrating the central site.

The remote sites should be migrated by the parallel approach, whereas the central site can be migrated using either the parallel or phased approach.

Which Unified Communications Service First?

This choice is very much dependent on the customer's individual business needs, and the Cisco Unified Communications solution allows for most of its individual services to be deployed independently of the others; for example, IP telephony, voice messaging, contact center, and collaboration can all be deployed independently from each others.

This capability provides the customer with great flexibility. Consider a customer who is faced with a voicemail system that has since gone end-of-support and is suffering various issues leading to customer dissatisfaction. Cisco Unity can often be deployed and integrated with the current PBX, thereby solving this issue. Once the new voicemail system is operating appropriately, then attention can turn to the next Unified Communications service, namely IP telephony.

■ Which Unified Communications Service First?

PART 2

Unified Communications Call Routing

CHAPTER 7

Overview of Cisco Unified Communications Call Routing

Revised: February 29, 2012; OL-21733-18

Once the network infrastructure has been put in place for your Cisco Unified Communications System, call routing applications, components, and services can be layered on top of this infrastructure. There are numerous applications and features that can, and in some cases must, be deployed on the network infrastructure. In general, you should deploy the following call routing components, features, and services:

- Call processing agent — Provides telephony services and call routing capabilities.
- Dial plan — Provides endpoint numbering, dialed digits analysis, and classes of restriction to limit types of calls that a user can make.
- Call admission control — Provides mechanisms for preventing oversubscription of network bandwidth by limiting the number of calls that are allowed on the network at a given time based on overall call capacity of the call processing components and network bandwidth.
- Video telephony services — Provide the ability to provision and register video endpoints as well as to set up, route, and maintain video calls on the network.
- PSTN gateways and provider voice and data services — Provide access to voice and data networks outside the enterprise, including the PSTN, Internet, and service provider IP-based trunks.
- Remote site survivability — Provides continuation of basic telephony services at remote sites when the central-site telephony services are unavailable due to failed or flapping network connectivity.

The chapters in this part of the SRND cover the features, components, and services mentioned above. Each chapter provides an introduction to the component or service, followed by discussions surrounding architecture, high availability, capacity planning, and design considerations. The chapters focus on design-related aspects of the applications and services rather than product-specific support and configuration information, which is covered in the related product documentation.

This part of the SRND includes the following chapters:

- [Call Processing, page 8-1](#)

This chapter examines the various types of call processing applications and platforms that facilitates IP telephony call routing. The chapter examines the call processing architecture, including hardware options, Unified CM clustering capabilities, high availability considerations for call processing, and capacity planning.

- [Dial Plan, page 9-1](#)

This chapter explores dial plan features and functions that enable the call processing application to route calls to appropriate numbers. The chapter considers various aspects of dial plan services, including dial plan constructs, dial plan numbering options and design considerations, classes of restriction, inbound and outbound calling features, and dial plan and call routing redundancy mechanisms.

- [Emergency Services, page 10-1](#)

This chapter discusses accessing emergency services through Public Safety Answering Points (PSAPs) on the PSTN from within the enterprise IP telephony environments, an important aspect of most deployments due to possible critical needs for medical, fire, and other emergency response services. The chapter provides an overview of the various emergency service components both inside and outside the enterprise. It also discusses planning, 911 network service providers, gateway interfaces, and number-to-location mapping.

- [Call Admission Control, page 11-1](#)

This chapter examines the potential for oversubscribing IP links, which causes the voice quality for phone calls to become unacceptable. It also examines the use of call admission control to allow only a certain number of simultaneous calls on the network at a given time to prevent oversubscription. This chapter covers call admission control types, including location-based call admission control and RSVP, as well as design and deployment guidelines for successfully deploying admission control services.

- [IP Video Telephony, page 12-1](#)

This chapter covers video telephony, an important and integral part of collaborative communication. The chapter discusses video telephony components, protocols and codecs, multipoint conferencing, and gatekeeper aspects for video call routing.

- [Gateways, page 13-1](#)

This chapter explores voice and IP gateways, which are critical components of Unified Communications deployments because they provide the path for connecting to phones on the public telephone network. This chapter looks at gateway traffic types and patterns, protocols, capacity planning, and platform selection, as well as fax and modem support.

- [Cisco Unified CM Trunks, page 14-1](#)

This chapter covers both intercluster and provider trunks, which provide the ability to route voice calls over IP and leverage various Unified Communications features and functions. This chapter discusses H.323 and SIP trunks, codecs, and supplementary services over these trunks, as well as sizing of trunks to accommodate network call load.

Architecture

Just as with other network and application technology systems, Unified Communications call routing components and services must be layered on top of the underlying network infrastructures. Figure 7-1 shows the logical location of call routing applications and services in the overall Cisco Unified Communications System architecture.

Figure 7-1 Cisco Unified Communications Call Routing Architecture

Unified Communications call routing components and services such as call processing agents and IP and PSTN gateways rely on the underlying network infrastructure for network connectivity and access. By connecting to the underlying network infrastructure, call routing components and features are able to leverage end-to-end network connectivity and quality of service to access both the enterprise and public telephone networks. In turn, call routing applications and services provide basic Unified Communications functions such as call control, dial plan, call admission control, and gateway services to other applications and services in the deployment. For example, a Unified CM cluster connects to the IP network through a switch in order to communicate with other devices and applications within the

network as well as to access other devices and services in other locations. At the same time, the Unified CM cluster provides services such as phone registration and media resource provisioning and allocation to call control components and services such as IP phones.

Further, just as call routing components rely on the network infrastructure for network connectivity, call routing components and services are also often dependent upon each other for full functionality. For example, while Unified CM provides registration and call routing services to various IP endpoints within the network, it is completely dependent upon gateways and gateway services to route calls beyond the enterprise.

High Availability

As with the network infrastructure, critical Unified Communications call routing services should be made highly available to ensure that required features and functionality remain available if failures occur in the network or with individual call routing components. It is important to understand the various types of failures that can occur and the design considerations around those failures. In some cases, the failure of a single server or component (for example, a subscriber node in a Unified CM cluster) might have little or no impact due to the redundant nature of the Unified CM clustering mechanism. However, in other cases a single failure can impact multiple components or services. For example, the failure of a PSTN or IP gateway could result in loss of access to the public telephone network, and even though a call processing agent such as Unified CM is still available and able to provide most features and services, it cannot route calls to the PSTN because there is no path available if the gateway fails. To avoid these types of situations, you should deploy multiple PSTN gateways to provide redundant gateway services, and you should configure the call processing agent to handle call routing to both gateways as needed.

For features and services such as dial plan and call admission control, high availability considerations include temporary loss of functionality due to network connectivity or call processing agent application server failures, resulting in the inability of the call agent to route calls and therefore the inability for callers to make calls. Oversubscription of the network could also occur if call admission control services are not available to the endpoints initiating a call. For example, if RSVP call admission control is in use and an RSVP agent fails or loses connectivity to the network, the call may still go through but without the call admission control service being aware of the call, thus potentially resulting in poor quality. To avoid these types of scenarios, provide call admission control resiliency by deploying multiple RSVP agents so that a failed RSVP agent will not prevent another RSVP agent from providing the call admission control service.

High availability considerations are also a concern for components and services such as video endpoints and remote site survivability. For deployments with network-attached remote sites where devices are leveraging call processing services from an agent in a central site, remote site survivability using SRST, for example, can ensure that local phones within the remote site will still receive call processing services in the event of a connectivity failure to the central site. Likewise, to ensure that video endpoints are highly available, you can deploy more than one multipoint control unit (MCU) in case one fails.

Capacity Planning

The network infrastructures must be designed and deployed with consideration for the capacity and scalability of the individual components and the overall system. Similarly, deployments of call routing components and services must also be designed with attention to capacity and scalability considerations. When deploying various call routing applications and services, not only is it important to consider the scalability of the applications and services themselves, but you must also consider the scalability of the underlying network infrastructure. Certainly the network infrastructure must have available bandwidth and be capable of handling the additional traffic load that the call routing components will create. Similarly, the call routing infrastructure and its components must be capable of handling all the required device configurations and registrations as well as the call load or busy hour call attempts (BHCA),

For example, with call processing agents such as Unified CM, it is critical to assess the size of the deployment in terms of number of users, endpoints, and calls per user per hour, and to deploy sufficient resources to handle the required load. If a call processing agent is undersized and does not have sufficient resources, features and services will begin to fail as the load increases. Two of the chief considerations when attempting to size a call processing deployment are the call processing type and the call processing hardware. Both of these are critical for sizing the system appropriately given the number of users, locations, devices, and so on. As an example, Cisco Unified Communications Manager has a much higher capacity than Cisco Unified Communications Manager Express and should therefore be used for larger deployments. In addition, the server platform selected to run the call processing agent will, in many cases, determine the maximum load.

Capacity planning for remote site survivability is much the same in that it relies on backup call processing hardware. Selecting the appropriate Cisco IOS platform to provide backup or survivable call processing services typically begins with determining the number of devices or users that must be supported at that site in the event that connectivity to the central site is disrupted. Equally critical in this sizing exercise is the local PSTN gateway services. In the event of a central site connection failure, will the local PSTN gateway have sufficient circuits to be able to route all calls without blocking during the busiest hour? If the answer is no, adding additional gateways or trunks will be necessary to appropriately size the remote site for backup call processing.

PSTN and IP gateways must also be sized appropriately for a deployment, so that sufficient capacity is available to handle all calls in the busiest hour. In some cases, you might have to deploy multiple PSTN or IP gateways to provide enough resources.

When sizing call admission control, ensure that sufficient bandwidth is available over network connections to support the required number of calls. If sufficient bandwidth is not available, additional network capacity, gateways, and IP or telephony trunks may be required.

Sizing dial plan services is also important. However, in most cases dial plan capacity in terms of the number of endpoints or phone numbers, route patterns, or other dial plan constructs, is completely dependent upon the type of call processing agent and platform used.

For components and services such as video telephony, appropriate sizing is just as critical. Capacity planning considerations for video telephony center mainly on network bandwidth, available video ports, and MCU sessions. In most cases additional capacity can be added by increasing the number of application servers and MCUs or by upgrading server or MCU hardware with higher-scale models, assuming the underlying network infrastructure is capable of handling the additional load.

For a complete discussion of system sizing, capacity planning, and deployment considerations related to sizing, refer to the chapter on [Unified Communications Design and Deployment Sizing Considerations, page 29-1](#).

CHAPTER 8

Call Processing

Revised: February 29, 2012; OL-21733-18

The handling and processing of voice and video calls is a critical function provided by IP telephony systems. This functionality is handled by some type of call processing entity or agent. Given the critical nature of call processing operations, it is important to design unified communications deployments to ensure that call processing systems are scalable enough to handle the required number of users and devices and are resilient enough to handle various network and application outages or failures.

This chapter provides guidance for designing scalable and resilient call processing systems with Cisco call processing products. These products include Cisco Unified Communications Manager (Unified CM), Cisco Business Edition, and Cisco Unified Communications Manager Express (Unified CME). In addition, this chapter provides coverage for gatekeeper functionality, which is another critical function for unified communications deployments in scenarios where multiple call processing systems or agents are deployed in parallel. In all cases, the discussions focus predominately on the following factors:

- Scale — The number of users, locations, gateways, applications, and so forth
- Performance — The call rate
- Resilience — The amount of redundancy

Specifically, this chapter focuses on the following topics:

- [Call Processing Architecture, page 8-3](#)

This section discusses general call processing architecture and the various call processing hardware options. This section also provides information on Unified CM clustering.

- [High Availability for Call Processing, page 8-15](#)

This section examines high availability considerations for call processing, including network redundancy, server or platform redundancy, and load-balancing.

- [Capacity Planning for Call Processing, page 8-25](#)

This section provides an overview of sizing for call processing deployments and introduces the Unified Communications Sizing Tool. This tool provides guidance on sizing and required resources for various components of a Unified Communications deployment, and it should be used when planning an IP Telephony deployment.

- [Design Considerations for Call Processing, page 8-29](#)

This section provides a summarized list of high-level design guidelines and best practices for deploying call processing.

- [Computer Telephony Integration \(CTI\)](#), page 8-31
This section explains the Cisco Computer Telephony Integration (CTI) architecture and discusses CTI components and interfaces, CTI functionality, and CTI provisioning and capacity planning.
- [Gatekeeper Design Considerations](#), page 8-37
This section explains how gatekeepers can be used in a Cisco Unified Communications deployment. Cisco Gatekeeper may also be paired with other standby gatekeepers or may be clustered for higher performance and resilience. Gatekeepers may also be used for call routing and call admission control.
- [Interoperability of Unified CM and Unified CM Express](#), page 8-44
This section explains the H.323 and SIP integration between Cisco Unified CM and Cisco Unified Communications Manager Express (Unified CME) in a distributed call processing deployment.

What's New in This Chapter

[Table 8-1](#) lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Call Processing Architecture

In order to design and deploy a successful Unified Communications system, it is critical to understand the underlying call processing architecture that provides call routing functionality. This functionality is provided by the following Cisco call processing agents:

- Cisco Unified Communications Manager Express (Unified CME)

Cisco Unified CME provides call processing services for small single-site deployments, larger distributed multi-site deployments, and deployments in which a local call processing entity at a remote site is needed to provide backup capabilities for a centralized call processing deployment of Cisco Unified CM.

- Cisco Business Edition

Cisco Business Edition provides call processing services for small single-site deployments or small distributed multisite deployments. There are three versions of Cisco Business Edition: Business Edition 3000, Business Edition 5000 and Business Edition 6000. The main differences between the three versions are as follows:

- The hardware on which Cisco Business Edition is deployed and the number of applications and services that can be run co-resident. Business Edition 3000 and 5000 provide co-resident Cisco Unified CM call processing and Cisco Unity Connection messaging services. Business Edition 6000 includes up to four co-resident applications consisting of Unified CM and Unity Connection as well as any two of the following: Cisco Unified Presence, Cisco Contact Center Express, and Cisco Unified Attendant Console services.

Note Business Edition 3000 and Business Edition 6000 are supported beginning with Cisco Unified CM 8.5.

- The capacity of the system. Cisco Business Edition supports between 300 and 1,000 users and between 400 and 1,200 endpoints, depending on the version.
 - The install and upgrade procedure. Business Edition 3000 and 5000 use a single software image to install and/or upgrade Unified CM and Unity Connection natively on the supported Cisco MCS platforms. Business Edition 6000 uses discrete software images to install and/or upgrade up to four co-resident applications (Unified CM, Unity Connection, Unified Presences, Unified Contact Center Express, and Unified Attendant Console) in VMware on the Cisco UCS C200 Series platform. Beginning with Unified CM 8.6, Business Edition 6000 may be deployed with Cisco Unified Provisioning Manager (Cisco Unified PM) as one of the four co-resident applications. An Open Virtualization Archive (OVA) template is used for a copy-based installation of Cisco Unified PM on the Business Edition 6000 server.
- Cisco Unified Communications Manager (Unified CM)
- Cisco Unified CM provides call processing services for small to very large single-site deployments, multi-site centralized call processing deployments, and/or multi-site distributed call processing deployments.

This section examines various call processing hardware options and then provides an overview of Unified CM clustering.

Call Processing Hardware

Three enterprise call processing types are supported on various types of platforms:

- Cisco Unified CME runs on Cisco Integrated Services Routers (ISR).
- Cisco Business Edition 3000 and Business Edition 5000 run as appliances directly on Cisco Media Convergence Servers (MCS). Cisco Business Edition 6000 runs as a virtual machine with the VMware Hypervisor on a Cisco Unified Computing System (UCS) C-Series Server.
- Cisco Unified CM runs either as an appliance directly on MCS (or equivalent) servers or as a virtual machine with the VMware Hypervisor. When Unified CM is deployed as a virtual machine, two hardware options are available: Tested Reference Configurations and specification-based hardware support. Tested Reference Configurations (TRC) are selected hardware configurations based on the Cisco UCS hardware. They are tested and documented for specific guaranteed performance, capacity, and application co-residency scenarios running "full-load" Unified Communications

virtual machines. TRCs are intended for customers who want a packaged solution from Cisco that is pre-engineered for a specific deployment scenario and/or customers who are not experienced with hardware virtualization. For more information on the TRC, refer to the documentation at

[http://docwiki.cisco.com/wiki/Tested_Reference_Configurations_\(TRC\)](http://docwiki.cisco.com/wiki/Tested_Reference_Configurations_(TRC))

Alternatively, more flexible hardware configurations are possible with the specification-based hardware support which, for example, adds support for Cisco UCS, Hewlett-Packard, and IBM platforms listed in the VMware Hardware Compatibility List (<http://www.vmware.com/resources/compatibility/search.php>), and for iSCSI, FCoE, and NAS (NFS) storage systems. Specification-based hardware support is intended for customers with extensive expertise in virtualization as well as server and storage sizing, who wish to use their own hardware standards. For more information on the specification-based hardware support, refer to the documentation at

http://docwiki.cisco.com/wiki/Specification-Based_Hardware_Support

Table 8-2 provides a summary of the three enterprise call processing types, the types of servers or platforms on which these call processing applications reside, and the overall characteristics of those platforms. The table includes the Tested Reference Configurations for the Cisco UCS platforms but not the platforms that are supported with the specification-based hardware support.

Table 8-2 Types of Call Processing Platforms

| Call Processing Type | Platform Type | Cisco Platform Model | Characteristics |
|------------------------|--|--|---|
| Cisco Unified CME | Cisco IOS Router | 2800, 2900, 3700, 3800, and 3900 Series ¹ | <ul style="list-style-type: none"> • Single processor • Single or multiple power supplies, depending on model |
| Cisco Business Edition | Cisco Unified Computing System (UCS) C-Series Rack-Mount Servers (Business Edition 6000) | UCS C-Series: C200 M2 | <ul style="list-style-type: none"> • Multiple processors • Single power supply² • Multiple SAS disk drives with RAID 10 support (running ESXi and also storing Cisco Unified Communications virtual machines on local disk drives) • No bare metal support⁶ |
| | Standard Cisco Media Convergence Server (MCS) for Business Edition 5000 | MCS 7828 ³ | <ul style="list-style-type: none"> • Single processor • Single power supply • SATA controller with RAID 0/1 support • Dual IP interfaces |
| | Standard MCS for Business Edition 3000 version 8.5(1) and later | MCS 7816-I5 | <ul style="list-style-type: none"> • Single processor • Single power supply • Non-RAID SATA hard disk • Dual IP interfaces |

Table 8-2 *Types of Call Processing Platforms (continued)*

| Call Processing Type | Platform Type | Cisco Platform Model | Characteristics |
|---|--|--|---|
| Cisco Unified CM | Standard MCS | MCS 7815, MCS 7816, or equivalent | <ul style="list-style-type: none"> • Single processor • Single power supply • Non-RAID SATA hard disk • Dual IP interfaces⁴ |
| | Standard MCS with RAID | MCS 7825 or equivalent | <ul style="list-style-type: none"> • Single processor • Single power supply • SATA controller with RAID 0/1 support • Dual IP interfaces |
| | High-availability MCS | MCS 7835, MCS 7845, or equivalent | <ul style="list-style-type: none"> • One or multiple processors • Multiple power supplies • Multiple Serial Attached SCSI (SAS) drives with RAID 1 • Dual IP interfaces |
| | Unified Computing System (UCS) B-Series Blade Servers | UCS B-Series (for example, B200, B230, B440) | <ul style="list-style-type: none"> • Half-width or full-width blade • Multiple processors • Multiple power supplies • Multiple SAS disk drives (running ESXi)⁵ or diskless blades • Cisco Unified Communications virtual machines stored on FC SAN Storage • No bare metal support⁶ |
| | Unified Computing System (UCS) C-Series Rack-Mount Servers | Low-end UCS C-Series (for example, C200) | <ul style="list-style-type: none"> • Multiple processors • One or multiple power supplies • Multiple SAS local disk drives • No bare metal support⁶ |
| High-end UCS C-Series (for example, C210, C260) | | <ul style="list-style-type: none"> • Multiple processors • Multiple power supplies • Multiple SAS local disk drives running ESXi only, running ESXi and Unified Communications Virtual Machines, or diskless servers • No bare metal support⁶ | |

1. This is not an exhaustive list of supported Cisco IOS platforms.

2. Although the UCS C200 Rack-Mount Servers support multiple power supplies, the Business Edition 6000 configuration supports only a single power supply.

3. The Cisco MCS 7828 supports only Business Edition 5000.

4. The Cisco MCS 7815 platform has only a single IP interface

5. UCS B-Series blade server disks are for virtual machine software (ESXi) only. Applications such as Unified CM are not installed and do not run on the on-blade drives.

6. UCS B-Series and C-Series servers offer no bare metal support for Cisco Unified Communications applications. UCS B-Series and C-Series servers must run ESXi hypervisor software.

For a complete list of supported MCS servers or equivalents, refer to the documentation available at

<http://www.cisco.com/go/swonly>

For a complete list of Tested Reference Configurations or for details on the specification-based hardware support, refer to the documentation available at

<http://www.cisco.com/go/uc-virtualized>

Determining the appropriate call processing type and platform for a particular deployment will depend on the scale, performance, and redundancy required. In general, Unified CM and the higher-end MCS and UCS servers provide more capacity and higher availability, while Cisco Unified CME and Cisco Business Edition provide lower levels of capacity and redundancy. For specifics regarding redundancy and scalability, see the sections on [High Availability for Call Processing, page 8-15](#), and [Capacity Planning for Call Processing, page 8-25](#).

Unified CM Cluster Services

Cisco Unified CME, Business Edition 3000 and 5000, and Unified CM running on an MCS-7815 or MCS-7816 are standalone call processing applications or entities. However, Unified CM running on all other server platforms involves the concept of clustering. The Unified CM architecture enables a group of physical servers to work together as a single call processing entity or IP PBX system. This grouping of servers is known as a *cluster*. A cluster of Unified CM servers may be distributed across an IP network, within design limitations, allowing for spatial redundancy and, hence, resilience to be designed into the Unified Communications System.

Within a Unified CM cluster, there are servers that provide unique services. Each of these services can coexist with others on the same physical server. For example, in a small system it is possible to have a single server providing database services, call processing services, and media resource services. As the scale and performance requirements of the cluster increase, many of these services should be moved to dedicated physical servers.

Note

While Cisco recommends using the same server model for all servers in a cluster, mixing server models within a cluster is supported provided that all of the individual hardware versions are supported and that all servers are running the same version of Unified CM. However, differences in capacity between various server models within a cluster must be considered because the overall cluster capacity might ultimately be dictated by the capacity of the smallest server within the cluster. Mixing servers from different vendors within a cluster is also supported and does not have any adverse capacity implications, provided that all servers in the cluster are the same model type. For information on call processing capacity, see the section on [Capacity Planning for Call Processing, page 8-25](#).

The following section describes the various functions performed by the servers that form a Unified CM cluster, and it provides guidelines for deploying the servers in ways that achieve the desired scale, performance, and resilience.

Cluster Server Nodes

Figure 8-1 illustrates a typical Unified CM cluster consisting of multiple server nodes.

Figure 8-1 Typical Unified CM Cluster

Publisher

The publisher is a required server in all clusters, and as shown in Figure 8-1, there can be only one publisher per cluster. This server is the first to be installed and provides the database services to all other subscribers in the cluster. The publisher server is the only server that has full read and write access to the configuration database.

On larger systems with more than 1250 users, Cisco recommends a dedicated publisher to prevent administrative operations from affecting the telephony services. A dedicated publisher does not provide call processing or TFTP services running on the server. Instead, other subscriber servers within the cluster provide these services.

The choice of hardware platform for the publisher should be based on the desired scale and performance of the cluster. Cisco recommends that the publisher have the same server performance capability as the call processing subscribers. Ideally the publisher should also be a high-availability server to minimize the impact of a hardware failure.

Subscriber

During installation of the Unified CM software, you can define two types of servers, publisher and subscriber. These terms are used to define the database relationship during installation. When the software is installed initially, only the database and network services are enabled. All subscriber nodes subscribe to the publisher to obtain a copy of the database information. However, in order to reduce initialization time for the Unified CM cluster, all subscriber servers in the cluster attempt to use their local copy of the database when initializing. This reduces the overall initialization time for a Unified CM cluster. All subscriber nodes rely on change notification from the publisher or other subscriber nodes in order to keep their local copy of the database updated.

As shown in Figure 8-1, multiple subscriber nodes can be members of the same cluster. Subscriber nodes include Unified CM call processing subscriber nodes, TFTP subscriber nodes, and media resource subscriber nodes that provide functions such as conferencing and music on hold (MoH).

Call Processing Subscriber

A call processing subscriber is a server that has the Cisco CallManager Service enabled. Once this service is enabled, the server is able to perform call processing functions. Devices such as phones, gateways, and media resources can register and make calls only to servers with this service enabled. As shown in [Figure 8-1](#), multiple call processing subscribers can be members of the same cluster. In fact, Unified CM supports up to eight call processing subscriber nodes per cluster.

Each call processing subscriber node in a cluster requires its own server license in order to enable the Cisco CallManager Service on that subscriber node. The Cisco CallManager Service cannot be enabled on a server if the publisher is not available because the publisher acts as a licensing server and distributes the licenses needed to activate the Cisco CallManager Service.

TFTP Subscriber

A TFTP subscriber or server node performs two main functions as part of the Unified CM cluster:

- The serving of files for services, including configuration files for devices such as phones and gateways, binary files for the upgrade of phones as well as some gateways, and various security files
- Generation of configuration and security files, which are usually signed and in some cases encrypted before being available for download

The Cisco TFTP service that provides this functionality can be enabled on any server in the cluster. However, in a cluster with more than 1250 users, other services might be impacted by configuration changes that can cause the TFTP service to regenerate configuration files. Therefore, Cisco recommends that you dedicate a specific subscriber node to the TFTP service, as shown in [Figure 8-1](#), for a cluster with more than 1250 users or any features that cause frequent configuration changes.

Cisco recommends that you use the same hardware platform for the TFTP subscribers as used for the call processing subscribers.

Media Resource Subscriber

A media resource subscriber or server node provides media services such as conferencing and music on hold to endpoints and gateways. These types of media resource services are provided by the Cisco IP Voice Media Streaming Application service, which can be enabled on any server node in the cluster.

Media resources include:

- Music on Hold (MoH) — Provides multicast or unicast music to devices that are placed on hold or temporary hold, transferred, or added to a conference. (See [Music on Hold](#), page 17-21.)
- Annunciator service — Provides announcements in place of tones to indicate incorrectly dialed numbers or call routing unavailability. (See [Annunciator](#), page 17-20.)
- Conference bridges — Provide software-based conferencing for ad-hoc and meet-me conferences. (See [Conferencing](#), page 17-6.)
- Media termination point (MTP) services — Provide features for H.323 clients, H.323 trunks, and Session Initiation Protocol (SIP) endpoints and trunks. (See [Media Termination Point \(MTP\)](#), page 17-12.)

Because of the additional processing and network requirements for media resource services, it is essential to follow all guidelines for running media resources within a cluster. Generally, Cisco recommends non-dedicated media resource subscribers for multicast MoH and annunciator services, but dedicated media resource subscribers as shown in [Figure 8-1](#) are recommended for unicast MoH as well as large-scale software-based conferencing and MTPs unless those services are within the design guidelines detailed in the chapter on [Media Resources](#), page 17-1.

Additional Cluster Services

In addition to the specific types of subscriber nodes within a Unified CM cluster, there are also other services that can be run on the Unified CM call processing subscriber nodes to provide additional functionality and enable additional features.

Computer Telephony Integration (CTI) Manager

The CTI Manager service acts as a broker between the Cisco CallManager service and TAPI or JTAPI integrated applications. This service is required in a cluster for any applications that utilize CTI. The CTI Manager service provides authentication of the CTI application and enables the application to monitor and/or control endpoint lines. CTI Manager can be enabled only on call processing subscribers, thus allowing for a maximum of eight nodes running the CTI Manager service in a cluster.

For more details on CTI Manager, see [Computer Telephony Integration \(CTI\)](#), page 8-31.

Unified CM Applications

Various types of application services can be enabled on Unified CM, such as Cisco Unified CM Assistant, Extension Mobility, and Web Dialer. For detailed design guidance on these applications, see the chapter on [Cisco Unified CM Applications](#), page 19-1.

Intracluster Communications

There are two primary kinds of intracluster communications, or communications within a Unified CM cluster (see [Figure 8-2](#) and [Figure 8-3](#).) The first is a mechanism for distributing the database that contains all the device configuration information (see "Database replication" in [Figure 8-2](#)). The configuration database is stored on a publisher server, and a copy is replicated to the subscriber nodes of the cluster. Most of the database changes are made on the publisher and are then communicated to the subscriber databases, thus ensuring that the configuration is consistent across the members of the cluster and facilitating spatial redundancy of the database.

Database modifications for user-facing call processing features are made on the subscriber servers to which an end-user device is registered. The subscriber servers then replicate these database modifications to all the other servers in the cluster, thus providing redundancy for the user-facing features. (See "Call processing user-facing feature replication" in [Figure 8-2](#).) These features include:

- Call Forward All (CFA)
- Message waiting indicator (MWI)
- Privacy Enable/Disable
- Extension Mobility login/logout
- Hunt Group login/logout
- Device Mobility
- Certificate Authority Proxy Function (CAPF) status for end users and applications users
- Credential hacking and authentication

Figure 8-2 Replication of the Database and User-Facing Features

The second type of intracluster communication, called Intra-Cluster Communication Signaling (ICCS), involves the propagation and replication of run-time data such as registration of devices, locations bandwidth, and shared media resources (see Figure 8-3). This information is shared across all members of a cluster running the Cisco CallManager Service (call processing subscribers), and it ensures the optimum routing of calls between members of the cluster and associated gateways.

Figure 8-3 Intra-Cluster Communication Signaling (ICCS)

Intracuster Security

Each server in a Unified CM cluster runs an internal dynamic firewall. The application ports on Unified CM are protected by source IP filtering. The dynamic firewall opens these application ports only to authenticated or trusted servers. (See [Figure 8-4](#).)

Figure 8-4 Intracuster Security

This security mechanism is applicable only between server nodes in a single Unified CM cluster. Unified CM subscribers are authenticated in a cluster before they can access the publisher's database. The intra-cluster communication and database replication take place only between authenticated servers. During the installation process, a subscriber node is authenticated to the publisher using a pre-shared key authentication mechanism. The authentication process involves the following steps:

1. Install the publisher server using a security password.
2. Configure the subscriber server on the publisher by using Unified CM Administration.
3. Install the subscriber server using the same security password used during publisher server installation.
4. After the subscriber is installed, the server attempts to establish connection to the publisher on a management channel using UDP 8500. The subscriber sends all the credentials to the publisher, such as hostname, IP address, and so forth. The credentials are authenticated using the security password used during the installation process.
5. The publisher verifies the subscriber's credentials using its own security password.
6. The publisher adds the subscriber as a trusted source to its dynamic firewall table if the information is valid. The subscriber is allowed access to the database.
7. The subscriber gets a list of other subscriber servers from the publisher. All the subscribers establish a management channel with each other, thus creating a mesh topology.

Voice Activity Detection

Cisco recommends that you leave voice activity detection (VAD) disabled within the Unified CM cluster. VAD is disabled by default in the Unified CM service parameters, and you should disable it on H.323 and SIP dial peers configured on Cisco IOS gateways by using the **no vad** command.

General Clustering Guidelines

The following guidelines apply to all Unified CM clusters:

**Note**

A cluster may contain a mix of server platforms, but all servers in the cluster must run the same Unified CM software release.

- Under normal circumstances, place all members of the cluster within the same LAN or MAN.
- If the cluster spans an IP WAN, follow the guidelines for clustering over an IP WAN as specified in the section on Clustering Over the IP WAN, page 2-21.
- A Unified CM cluster may contain as many as 20 servers, of which a maximum of eight call processing subscribers (nodes running the Cisco CallManager Service) are allowed. The other server nodes within the cluster may be configured as a dedicated database publisher, dedicated TFTP subscriber, or media resource subscriber.
- When deploying Unified CM on Cisco MCS 7815, MCS 7816, or equivalent servers, there is a maximum limit of two servers in a deployment: one acting as the publisher, TFTP, and backup call processing subscriber node, and the other acting as the primary call processing subscriber. A maximum of 500 phones is supported in this configuration with a Cisco MCS 7816 or equivalent server.
- When deploying a two-server cluster with high-capacity servers, Cisco recommends that you do not exceed 1250 users in the cluster. Above 1250 users, a dedicated publisher and separate servers for primary and backup call processing subscribers is recommended.
- Business Edition 3000 8.5(1) runs on the MCS 7816 server platform, while Business Edition 3000 8.6(1) and later versions run on either the MCS 7816 or the MCS 7890-C1 purpose-built appliance. In either case Business Edition 3000 provides a single instance of Unified CM (a combined publisher and single subscriber instance). A secondary subscriber instance is not configurable.
- Business Edition 5000 runs on a single hardware platform (MCS 7828), and it provides a single instance of Unified CM (a combined publisher and single subscriber instance). A secondary subscriber instance is not configurable.
- Business Edition 6000 runs on a UCS C200 Rack-Mount Server and provides a single instance of Unified CM (a combined publisher and single subscriber instance). An additional UCS C200 server may be deployed to provide subscriber redundancy either in an active/standby or load balancing fashion for Cisco Business Edition call processing as well as other co-resident applications. Cisco recommends deploying redundant servers with load balancing so that the load is distributed between the two UCS C200 servers. Alternatively an MCS server can be used to provide Unified CM subscriber redundancy either in active/standby or load balancing fashion.
- When deploying Unified CM on Cisco UCS B-Series or C-Series Servers, just as with a cluster of MCS servers, each Unified CM node instance can be a publisher node, call processing subscriber node, TFTP subscriber node, or media resource subscriber node. As with any Unified CM cluster, only a single publisher node per cluster is supported.

- While the Cisco UCS B-Series Blade Servers and C-Series Rack-Mount Servers do support a local keyboard, video, and mouse (KVM) cable connection that provides a DB9 serial port, a Video Graphics Array (VGA) monitor port, and two Universal Serial Bus (USB) ports, the Unified CM VMware virtual application has no access to these USB and serial ports. Therefore, there is no ability to attach USB devices such as audio cards (MOH-USB-AUDIO=), serial-to-USB connectors (USB-SERIAL-CA=), or flash drives to these servers. The following alternate options are available:
 - For MoH live audio source feed, consider using Cisco IOS-based gateway multicast MoH for live audio source connectivity or deploying one Unified CM subscriber node on an MCS server as part of the Unified CM cluster to allow connectivity of the USB MoH audio card (MOH-USB-AUDIO=).
 - For SMDI serial connections, deploy one Unified CM subscriber node on an MCS server as part of the Unified CM cluster for USB serial connectivity.
 - For saving system install logs, use virtual floppy softmedia.

High Availability for Call Processing

You should deploy the call processing services within a Unified Communications System in a highly available manner so that a failure of a single call processing component will not render all call processing services unavailable.

Hardware Platform High Availability

You should select the call processing platform based not only on the size and scalability of a particular deployment, but also on the redundant nature of the platform hardware.

For example, for highly available deployments you should select platforms with multiple processors and multiple hard disk drives. Not only is this important for higher-scale deployments, but it is also critical for deployments that require high availability so that an individual component failure does not result in loss of features or services.

Furthermore, when possible, choose platforms with dual power supplies to ensure that a single power supply failure will not result in the loss of a platform. See [Table 8-2](#) to determine which platforms support dual power supplies. Plug platforms with dual power supplies into two different power sources to avoid the failure of one power circuit causing the entire platform to fail. The use of dual power supplies combined with the use of uninterruptible power supply (UPS) sources will ensure maximum power availability. In deployments where dual power supply platforms are not feasible, Cisco still recommends the use of a UPS in situations where building power does not have the required level of power availability.

Network Connectivity High Availability

Connectivity to the IP network is also a critical consideration for maximum performance and high availability. Connect call processing platforms to the network at the highest possible speed to ensure maximum throughput, typically 1000 Mbps or 100 Mbps full-duplex depending on the platform. If 1000 or 100 Mbps network access is not available on smaller deployments, then use 10 Mbps full-duplex. Whenever possible, ensure that platforms are connected to the network using full-duplex, which can be achieved with 10 Mbps and 100 Mbps by hard-coding the network switch port and the platform interface port. For 1000 Mbps, Cisco recommends using Auto/Auto for speed and duplex configuration on both the platform interface port and the network switch port.

**Note**

A mismatch will occur if either the platform interface port or the network switch port is left in Auto mode and the other port is configured manually. The best practice is to configure both the platform port and the network switch port manually, with the exception of Gigabit Ethernet ports which should be set to Auto/Auto.

In addition to speed and duplex of IP network connectivity, equally important is the resilience of this network connectivity. Unified communications deployments are highly dependent on the underlying network connectivity for true redundancy. For this reason it is critical to deploy and configure the underlying network infrastructure in a highly resilient manner. For details on designing highly available network infrastructures, see the chapter on [Network Infrastructure, page 3-1](#). In all cases, the network should be designed so that, given a switch or router failure within the infrastructure, a majority of users will have access to a majority of the services provided within the deployment.

To maximize call processing availability, locate and connect call processing platforms in separate buildings and/or separate network switches when possible to ensure that the impact to call processing will be minimized if there is a failure of the building or network infrastructure switch. With Unified CM call processing, this means distributing cluster server nodes among multiple buildings or locations within the LAN or MAN deployment whenever possible. And at the very least, it means physically distributing network connections between different physical network switches in the same location.

Furthermore, even though Cisco Unified CME and Cisco Business Edition are standalone call processing entities, providing physical distribution and therefore redundancy for these call processing types still makes sense when deploying multiple call processing entities. Whenever possible in those scenarios, install each instance of Unified CME or Business Edition in a different physical location within the network, or at the very least physically attach them to different network switches.

Besides deploying a highly available network infrastructure and physically distributing call processing platforms across network components and locations, it is also good practice to provide highly available physical connections to the network from each call processing entity. Whenever possible, use dual network attachments to connect the platform to two different ports on two physically separate network switches so that a single upstream hardware port or switch failure will not result in loss of network connectivity for the platform. A Unified CME router platform can have more than one physical network interface and can be dual-attached to a network. Likewise, the MCS server platform for Unified CM and Business Edition 5000 call processing types can also be dual-attached to the network using network interface card (NIC) teaming.

NIC Teaming for Network Fault Tolerance

The NIC teaming feature allows a Cisco MCS (or HP or IBM equivalent server) to be connected to the IP network through two NICs and, therefore, two physical cables. NIC teaming prevents network downtime by transferring the workload from the failed port to the working port. NIC teaming cannot be used for load balancing or increasing the interface speed. NIC teaming is supported on dual-NIC Cisco MCS platforms (or HP or IBM equivalents).

**Note**

The MCS 7815 platform (or HP or IBM equivalent) has only a single network interface port and therefore cannot perform NIC teaming.

UCS Network Fault Tolerance

Cisco UCS B-Series Blade Servers leverage the UCS network attachment infrastructure as well as the underlying network attached storage area network (SAN). This back-end UCS network infrastructure, including redundant parallel switching fabric extenders and interconnects as well as Fibre Channel or gigabit ethernet uplinks, provides highly available network attachment and storage for these servers. For

details on highly available virtual data center deployments of the UCS network and storage infrastructure, refer to the document on *Designing Secure Multi-Tenancy into Virtualized Data Centers*, available at http://www.cisco.com/en/US/docs/solutions/Enterprise/Data_Center/Virtualization/secureldg.html.

Unified CM High Availability

Because of the underlying Unified CM clustering mechanism, a Unified Communications System has additional high availability considerations above and beyond hardware platform disk and power component redundancy, physical network location, and connectivity redundancy. This section examines call processing subscriber redundancy considerations, call processing load balancing, and redundancy of additional cluster services.

Call Processing Redundancy

Unified CM provides the following call processing redundancy configuration options or schemes:

- Two to one (2:1) — For every two primary call processing subscribers, there is one shared secondary or backup call processing subscriber.
- One to one (1:1) — For every primary call processing subscriber, there is a secondary or backup call processing subscriber.

These redundancy schemes are facilitated by the built-in registration failover mechanism within the Unified CM cluster architecture, which enables endpoints to re-register to a backup call processing subscriber node when the endpoint's primary call processing subscriber node fails. The registration failover mechanism can achieve failover rates for Skinny Client Control Protocol (SCCP) IP phones of approximately 125 registrations per second. The registration failover rate for Session Initiation Protocol (SIP) phones is approximately 40 registrations per second.

The call processing redundancy scheme you select determines not only the fault tolerance of the deployment, but also the fault tolerance of any upgrade.

With 1:1 redundancy, multiple primary call processing subscriber failures can occur without impacting call processing capabilities. With 2:1 redundancy, on the other hand, only one of the primary call processing subscribers out of the two primary call processing subscribers that share a backup call processing subscriber can fail without impacting call processing.

Likewise, with the 1:1 redundancy scheme, upgrades to the cluster can be performed with only a single set of endpoint registration failover periods impacting the call processing services. Whereas with the 2:1 redundancy scheme, upgrades to the cluster require multiple registration failover periods.

A Unified CM cluster can be upgraded with minimal impact to the services. Two different versions (releases) of Unified CM may be on the same server, one in the active partition and the other in the inactive partition. All services and devices use the Unified CM version in the active partition for all Unified CM functionality. During the upgrade process, the cluster operations continue using its current release of Unified CM in the active partition, while the upgrade version gets installed in the inactive partition. Once the upgrade process is complete, the servers can be rebooted to switch the inactive partition to the active partition, thus running the new version of Unified CM.

With the 1:1 redundancy scheme, the following steps enable you to upgrade the cluster while minimizing downtime:

-
- Step 1** Install the new version of Unified CM in the inactive partition, first on the publisher and then on all subscribers (call processing, TFTP, and media resource subscribers). Do not reboot.
 - Step 2** Reboot the publisher and switch to the new version.
 - Step 3** Reboot the TFTP subscriber node(s) one at a time and switch to the new version.
 - Step 4** Reboot any dedicated media resource subscriber nodes one at a time and switch to the new version.
 - Step 5** Reboot the backup call processing subscribers one at a time and switch to the new version.
 - Step 6** Reboot the primary call processing subscribers one at a time and switch to the new version. Device registrations will fail-over to the previously upgraded and rebooted backup call processing subscribers. After each primary call processing subscriber is rebooted, devices will begin to re-register to the primary call processing subscriber.
-

With this upgrade method, there is no period (except for the registration failover period) when devices are registered to subscriber servers that are running different versions of the Unified CM software.

While the 2:1 redundancy scheme allows for fewer servers in a cluster, registration failover occurs more frequently during upgrades, increasing the overall duration of the upgrade as well as the amount of time call processing services for a particular endpoint will be unavailable. Because there is only a single backup call processing subscriber per pair of primary call processing subscribers, it might be possible to reboot to the new version on only one of the primary call processing subscribers in a pair at a time in order to prevent oversubscribing the single backup call processing subscriber. As a result, there may be a period of time after the first primary call processing subscriber in each pair is switched to the new version, in which endpoint registrations will have to be moved from the backup subscriber to the newly upgraded primary subscriber before the endpoint registrations on the second primary subscriber can be moved to the backup subscriber to allow a reboot to the new version. During this time, not only will endpoints on the second primary call processing subscriber be unavailable while they re-register to the backup subscriber, but until they re-register to a node running the new version, they will also be unable to reach endpoints on other subscriber nodes that have already been upgraded.

**Note**

Before you do an upgrade, Cisco recommends that you back up the Unified CM and Call Detail Record (CDR) database to an external network directory using the Disaster Recovery Framework. This practice will prevent any loss of data if the upgrade fails.

**Note**

Because an upgrade of a Unified CM cluster results in a period of time in which some or most devices lose registration and call processing services temporarily, you should plan upgrades in advance and implement them during a scheduled maintenance window. While downtime and loss of services to devices can be minimized by selecting the 1:1 redundancy scheme, there will still be some period of time in which call processing services are not available to some or all users.

For more information on upgrading Unified CM, refer to the install and upgrade guides available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_installation_guides_list.html

Unified CM Redundancy with Survivable Remote Site Telephony (SRST)

Cisco IOS SRST provides highly available call processing services for endpoints in locations remote from the Unified CM cluster. Unified CM clustering redundancy schemes certainly provide a high level of redundancy for call processing and other application services within a LAN or MAN environment. However, for remote locations separated from the central Unified CM cluster by a WAN or other low-speed links, SRST can be used as a redundancy method to provide basic call processing services to these remote locations in the event of loss of network connectivity between the remote and central sites. Cisco recommends deploying SRST-capable Cisco IOS routers at each remote site where call processing services are considered critical and need to be maintained in the event that connectivity to the Unified CM cluster is lost. Endpoints at these remote locations must be configured with an appropriate SRST reference within Unified CM so that the endpoint knows what address to use to connect to the SRST router for call processing services when connectivity to Unified CM subscribers is unavailable.

Unified CME on a Cisco IOS router can also be used at a remote site to provide enhanced SRST functionality in the event that connectivity to the central Unified CM cluster is lost. Unified CME provides more backup call processing features for the IP phones than are available with the regular SRST feature on a router. However, the endpoint capacities for Unified CME acting as SRST are typically less than for basic SRST.

Call Processing Subscriber Redundancy

Depending on the redundancy scheme chosen (see [Call Processing Redundancy, page 8-17](#)), the call processing subscriber will be either a primary (active) subscriber or a backup (standby) subscriber. In the load-balancing option, the subscriber can be both a primary and backup subscriber. When planning the design of a cluster, you should generally dedicate the call processing subscribers to this function. In larger-scale or higher-performance clusters, the call processing service should not be enabled on the publisher and TFTP subscriber nodes. 1:1 redundancy uses dedicated pairs of primary and backup subscribers, while 2:1 redundancy uses a pair of primary subscribers that share one backup subscriber.

The following figures illustrate typical cluster configurations to provide call processing redundancy with Unified CM.

Figure 8-5 Basic Redundancy Schemes

Figure 8-5 illustrates the two basic redundancy schemes available. In each case the backup server must be capable of handling the capacity of at least a single primary call processing server failure. In the 2:1 redundancy scheme, the backup might have to be capable of handling the failure of a single call processing server or potentially both primary call processing servers, depending on the requirements of a particular deployment. For information on sizing the capacity of the servers and choosing the hardware platforms, see the section on [Capacity Planning for Call Processing, page 8-25](#).

**Note**

2:1 redundancy is not supported on Cisco MCS 7845-I3 or equivalent Open Virtualization Archive (OVA) 10K servers. You must use 1:1 redundancy when more than 7,500 IP phones are registered on the two primary subscribers because there cannot be more than 7,500 backup registrations on a single backup subscriber.

Figure 8-6 1:1 Redundancy Configuration Options

114952

Figure 8-7 2:1 Redundancy Configuration Options

114953

In Figure 8-6, the five options shown all indicate 1:1 redundancy. In Figure 8-7, the five options shown all indicate 2:1 redundancy. In both cases, Option 1 is used for clusters supporting less than 1250 users. Options 2 through 5 illustrate increasingly scalable clusters for each redundancy scheme. The exact scale depends on the hardware platforms chosen or required.

These illustrations show only publisher and call processing subscribers. They do not account for other subscriber nodes such as TFTP and media resources.

Note

It is possible to define up to three call processing subscribers per Unified CM group. Adding a tertiary subscriber for additional backup extends the above redundancy schemes to 2:1:1 or 1:1:1 redundancy. However, with the exception of using tertiary subscriber servers in deployments with clustering over the WAN (see [Remote Failover Deployment Model, page 5-55](#)), tertiary subscriber redundancy is not recommended for endpoint devices located in remote sites because failover to SRST will be further delayed if the endpoint must check for connectivity to a tertiary subscriber.

Although not shown in the Figure 8-6 or Figure 8-7, it is also possible to deploy a single-server cluster with an MCS 7825 or larger server. With an MCS 7825 or equivalent server, the endpoint configuration and registration limit is 500 for a single-server cluster. With a higher-availability server, the single-server cluster should not exceed 1000 endpoint configuration and registrations. Note that in a single-server configuration, there is no backup call processing subscriber and therefore no cluster redundancy mechanism. Survivable Remote Site Telephony (SRST) can be used as a redundancy mechanism in these types of deployments to provide minimal call processing services during periods when Unified CM is not available. However, Cisco does not recommend a single-server deployment for production environments.

Load Balancing

In Unified CM clusters with the 1:1 redundancy scheme, device registration and call processing services can be load-balanced across the primary and backup call processing subscriber.

Normally a backup server has no devices registered to it unless its primary is unavailable. This makes it easier to troubleshoot a deployment because there is a maximum of four primary call processing subscriber nodes that will be handling the call processing load at a given time. Further, this potentially simplifies configuration by reducing the number of Unified CM redundancy groups and device pools.

In a load-balanced deployment, up to half of the device registration and call processing load can be moved from the primary to the secondary subscriber by using the Unified CM redundancy groups and device pool settings. In this way each primary and backup call processing subscriber pair provides device registration and call processing services to as many as half of the total devices serviced by this pair of call processing subscribers. This is referred to as 50/50 load balancing. The 50/50 load balancing model provides the following benefits:

- Load sharing — The registration and call processing load is distributed on multiple servers, which can provide faster response time.
- Faster failover and failback — Because all devices (such as IP phones, CTI ports, gateways, trunks, voicemail ports, and so forth) are distributed across all active subscribers, only some of the devices fail-over to the secondary subscriber if the primary subscriber fails. In this way, you can reduce by 50% the impact of any server becoming unavailable.

To plan for 50/50 load balancing, calculate the capacity of a cluster without load balancing, and then distribute the load across the primary and backup subscribers based on devices and call volume. To allow for failure of the primary or the backup server, do not let the total load on the primary and secondary subscribers exceed that of a single subscriber server.

**Note**

During upgrades of a Unified CM cluster with 50/50 load balancing, upgrades to the backup call processing subscriber will result in devices registered to that subscriber (up to half of the total devices serviced by the primary and backup subscriber pair) failing over to the primary call processing subscriber.

TFTP Redundancy

Cisco recommends deploying more than one dedicated TFTP subscriber node for a large Unified CM cluster, thus providing redundancy for TFTP services. While two TFTP subscribers are typically sufficient, more than two TFTP servers can be deployed in a cluster, but this can result in an extended period for rebuilding of all TFTP files on all TFTP subscribers.

In addition to providing one or more redundant TFTP subscribers, you must configure endpoints to take advantage of these redundant TFTP nodes. When configuring the TFTP options using DHCP or statically, define a TFTP subscriber node IP address array containing the IP addresses of both TFTP subscriber nodes within the cluster. In this way, by creating two DHCP scopes with two different IP address arrays (or by manually configuring endpoints with two different TFTP subscriber node IP addresses), you can assign half of the endpoint devices to use TFTP subscriber A as the primary and TFTP subscriber B as the backup, and the other half to use TFTP subscriber B as the primary and TFTP subscriber A as the backup. In addition to providing redundancy during a failure of one TFTP subscriber, this method of distributing endpoints across multiple TFTP subscribers provides load balancing so that one TFTP subscriber is not handling all the TFTP service load.

**Note**

When adding a specific binary or firmware load for a phone or gateway, you must add the file(s) to each TFTP subscriber node in the cluster.

CTI Manager Redundancy

All CTI integrated applications communicate with a call processing subscriber node running the CTI Manager service. Further, most CTI applications have the ability to specify redundant CTI Manager service nodes. For this reason, Cisco recommends activating the CTI Manager service on at least two call processing subscribers within the cluster. With both a primary and backup CTI Manager configured, in the event of a failure the application will switch to a backup CTI Manager to receive CTI services.

As stated previously, the CTI Manager service can be enabled only on call processing subscribers, therefore there is a maximum of eight CTI Managers per cluster. Cisco recommends that you load-balance CTI applications across the enabled CTI Managers in the cluster to provide maximum resilience, performance, and redundancy.

Generally, it is good practice to associate devices that will be controlled or monitored by a CTI application with the same server pair used for the CTI Manager service. For example, an interactive voice response (IVR) application requires four CTI ports. They would be provisioned as follows, assuming the use of 1:1 redundancy and 50/50 load balancing:

- Two CTI ports would have a Unified CM redundancy group of server A as the primary call processing subscriber and server B as the backup subscriber. The other two ports would have a Unified CM redundancy group of server B as the primary subscriber and server A as the backup subscriber.
- The IVR application would be configured to use the CTI Manager on subscriber A as the primary and subscriber B as the backup.

The above example allows for redundancy in case of failure of the CTI Manager on subscriber A and also allows for the IVR call load to be spread across two servers. This approach also minimizes the impact of a Unified CM subscriber node failure.

For more details on CTI and CTI Manager, see [Computer Telephony Integration \(CTI\)](#), page 8-31.

UCS Call Processing Redundancy

For deployments of Unified CM on Cisco UCS B-Series Blade Servers and C-Series Rack-Mount Servers, all previous call processing, TFTP, and CTI Manager redundancy schemes still apply. While the C-Series Rack-Mount Servers are deployed in the same redundant manner as the MCS servers, the UCS B-Series Blade Servers have additional redundancy considerations because of the virtual nature of server nodes: namely, the installation and residency of Unified CM server node instances across server blades.

As illustrated in [Figure 8-8](#), observe the following guidelines when deploying Unified CM on a UCS B-Series Blade Server to ensure the highest level of call processing redundancy:

- Each primary call processing subscriber node instance should reside on a different physical UCS B-Series blade than its backup call processing subscriber node instance. This ensures that the failure of a blade containing the primary call processing node instance does not impact the system's ability to provide endpoints with access to their backup call processing subscriber node.
- When deploying multiple TFTP or media resource subscriber nodes instances for redundancy of those services, always distribute redundant subscriber nodes across more than one UCS blade to ensure that a failure of a single blade does not eliminate those services. This ensures that, given

the failure of a blade containing a TFTP or media resource subscriber, endpoints will still be able to access TFTP and media resource services on a subscriber node residing on another blade. Endpoints can also be distributed among redundant TFTP and media resource subscriber node instances to balance system load in non-failure scenarios.

- When deploying CTI applications, always make sure that call processing subscriber node instances running the CTI Manager service are distributed across more than one UCS blade to ensure that a failure of a single blade does not eliminate CTI services. Further, CTI applications should be configured to use the CTI Manager service running on the subscriber node instance on one blade as the primary CTI Manager and the CTI Manager service running on the subscriber node on another blade as the backup CTI Manager.

Figure 8-8 Unified CM Server Node Distribution on UCS

In addition to distributing subscriber node instances across multiple blades, you may distribute subscriber node instances across multiple Cisco UCS 5100 Blade Chassis for additional redundancy and scalability.

For more information about redundancy and provisioning of host resources for virtual machines, refer to the documentation at <http://www.cisco.com/go/uc-virtualized>.

Cisco Business Edition High Availability

The main considerations for high availability of Cisco Business Edition are network connectivity, power, and redundancy for call processing and registration.

As shown in [Table 8-2](#), both the MCS 7816 platform used for Business Edition 3000 and the MCS 7828 platform used for Business Edition 5000 have dual IP interfaces or NICs for redundant network attachment. However, only Business Edition 5000 supports NIC Teaming for network connectivity redundancy. Business Edition 3000 installed on an MCS 7816 server does not support NIC Teaming. The MCS 7980-C1 purpose-built appliance for Business Edition 3000 has only a single IP interface and therefore does not provide support for redundant network attachment or NIC Teaming.

Business Edition 3000 and Business Edition 5000 each reside on their own single standalone platforms (a combined publisher and single subscriber instance with no ability to configure a secondary subscriber instance). They do not support node clustering and therefore cannot leverage the call processing redundancy schemes available with Unified CM. For this reason, the only way to provide call processing

and registration redundancy for endpoints in these types of deployments is by using SRST or Unified CME acting as SRST. However, only Business Edition 5000 supports SRST. There is not ability to provide highly available call processing and registration with Business Edition 3000.

On the other hand, Business Edition 6000 does support node clustering with one additional server and therefore can provide redundant call processing and registration services. Business Edition 6000 can be deployed with a second UCS C200 Rack-Mount Server (or MCS server) to provide high availability for call processing as well as other applications and services.

**Note**

More than two UCS C200 Rack-Mount Servers may be clustered for a Business Edition 6000 deployment to provide additional redundancy and/or geographic distribution as with a clustering over the WAN deployment. However, the total number of users across the cluster may not exceed 1,000 and the total number of configured devices across the cluster may not exceed 1,200. A deployment of UCS C200 Rack-Mount Servers in a cluster exceeding 1,000 users and 1,200 configured devices is considered a regular Unified CM cluster, and as such the deployment must follow high availability design guidance for regular Unified CM. (See [Unified CM High Availability, page 8-17.](#))

Capacity Planning for Call Processing

Call processing capacity planning is critical for successful unified communications deployments. Given the many features and functions provided by call processing services as well as the many types of devices for which call processing entities can provide registration and transaction services, it important to size the call processing infrastructure and its individual components to ensure they meet the capacity needs of a particular deployment.

IP phones, software clients, voicemail ports, CTI (TAPI or JTAPI) devices, gateways, and DSP resources for media services such as transcoding and conferencing, all register to a call processing entity. Each of these devices requires resources from the call processing platform with which it is registered. The required resources can include memory, processor usage, and disk I/O.

Besides adding registration load to call processing platforms, after registration each device then consumes additional platform resources during transactions, which are normally in the form of calls. For example, a device that makes only 6 calls per hour consumes fewer resources than a device making 12 calls per hour.

For more information about call processing sizing and for a complete discussion of system sizing, capacity planning, and deployment considerations, see the chapter on [Unified Communications Design and Deployment Sizing Considerations, page 29-1.](#)

Unified CME Capacity Planning

When deploying Unified CME, it is critical to select a Cisco IOS router platform that provides the desired capacity in terms of number of supported endpoints required. In addition, platform memory capacity should also be considered if the Unified CME router is providing additional services above and beyond call processing, such as IP routing, DNS lookup, dynamic host configuration protocol (DHCP) address services, or VXML scripting.

Unified CME can support a maximum of 450 endpoints on a single Cisco IOS platform; however, each router platform has a different endpoint capacity based on the size of the system. Because Unified CME is not supported within the Cisco Unified Communications Sizing Tool, it is imperative to follow capacity information provided in the product data sheets available at

http://www.cisco.com/en/US/products/sw/voicesw/ps4625/products_data_sheets_list.html

Unified CM Capacity Planning

This section examines capacity planning for Unified CM. The recommendations provided in this section are based on calculations made using the Unified Communications Sizing Tool, with default trace levels and call detail records (CDRs) enabled. In some cases higher levels of performance and capacity can be achieved by disabling, reducing, or reconfiguring other functions that are not directly related to processing calls. Enabling and increasing utilization of these functions can also have an impact on the call processing capabilities of the system and in some cases can reduce the overall capacity. These functions include tracing, call detail recording, highly complex dial plans, and other services that are co-resident on the Unified CM platform. Highly complex dial plans can include multiple line appearances as well as large numbers of partitions, calling search spaces, route patterns, translations, route groups, hunt groups, pickup groups, route lists, call forwarding, co-resident services, and other co-resident applications. All of these functions can consume additional resources within the Unified CM system.

You can use the following techniques to improve system performance:

- Install additional certified memory in the server, up to the maximum supported for the particular platform. Cisco recommends doubling the RAM in MCS 7825 and MCS 7835 or equivalent servers with large configurations for that server class. Verification using the Cisco Real Time Monitoring Tool (RTMT) will indicate if this memory upgrade is required. As the server approaches maximum utilization of physical memory, the operating system will start to swap to disk. This swapping is a sign that additional physical memory should be installed.
- A Unified CM cluster with a very large dial plan containing many gateways, route patterns, translation patterns, and partitions, can take an extended amount of time to initialize when the Cisco CallManager Service is first started. If the system does not initialize within the default time, you can modify the system initialization timer (a Unified CM service parameter) to allow additional time for the configuration to initialize. For details on the system initialization time, refer to the online help for Service Parameters in Unified CM Administration.

Unified CM Capacity Planning with UCS Platforms

In a virtualized deployment, most Unified Communications applications such as Unified CM must be installed using a predefined template that specifies the configuration of the virtual machine's virtual hardware. These templates are distributed through Open Virtualization Archives (OVA), an open standards-based method for packaging and distributing virtual machine templates.

These OVA templates define the number of virtual CPU, the amount of virtual memory, the number and size of hard drives, and so forth, and they determine the capacity of the application. For Unified CM, there are multiple OVA templates available, one for almost each server class (although there is no template corresponding to the MCS 7815 or MCS 7816). A Unified CM virtual machine instance running on a VMware or Cisco UCS server has the same capacity as a Unified CM node running directly on a Cisco MCS server when using the corresponding OVA template. For example, the OVA template for Unified CM supporting 7,500 users and/or devices has the same capacity as the MCS 7845-H2/I2 server.

Unified CM Capacity Planning Guidelines and Endpoint Limits

The following capacity guidelines apply to Cisco Unified CM:

- Within a cluster, a maximum of 8 call processing subscriber nodes can be enabled with the Cisco CallManager Service. Other servers may be used for more dedicated functions such as publisher, TFTP subscribers, and media resources subscribers.
- Each cluster can support configuration and registration for a maximum of:
 - 40,000 secured or unsecured SCCP or SIP endpoints with Unified CM 8.6(1) and later releases
 - 30,000 secured or unsecured SCCP or SIP endpoints with Unified CM 8.5 and earlier releases.
- A cluster consisting of server node instances running on VMware can support different capacities depending on the OVA template that is chosen. For most Cisco MCS server classes, there is a corresponding OVA template that provides a Unified CM instance with the same capacities (number of phones, gateways, locations, regions, CTI connections, and so forth) as the MCS server class. Because multiple virtual machine instances can run on the same blade or server, the total capacity on a blade or server can therefore be higher than on an MCS server.
- The maximum recommended trace setting for Unified CM is 2,000 files of 2 MB for both System Diagnostic Interface (SDI) and Signaling Distribution Layer (SDL) traces, for a total of 4,000 files. Each process has a setting for maximum number of files, and each process is allowed 2,000 files for SDL and 2,000 files for SDI. Trace settings for all other components must be configured within the limit of 126 MB (for example, 63 files of 2 MB each). These are suggested upper limits. Unless specific troubleshooting under high call rates requires increasing the maximum file setting, the default settings are sufficient for collecting sufficient traces in most circumstances.

For more information about Unified CM capacity planning considerations, including sizing limits as well as a complete discussion of system sizing, capacity planning, and deployment considerations, see the chapter on [Unified Communications Design and Deployment Sizing Considerations, page 29-1](#).

Megacluster

The term *megacluster* defines and identifies certain Unified CM deployments that allow for further increases in scalability. A megacluster provides more device capacity through the support of additional Unified CM subscriber nodes, with a maximum of eight Unified CM subscriber pairs per megacluster, thus allowing for a maximum of 80,000 devices with Cisco Unified CM 8.6 and later releases.

A megacluster can also be deployed where customers simply require local call-processing functionality, rather than using Survivable Remote Site Telephony (SRST), beyond the maximum eight sites allowed in a standard cluster deployment. For example, consider a large hospital that has twelve locations and each location has only 1,000 devices. This total of 12,000 devices could be accommodated within a standard cluster, which has a maximum device capacity of 40,000 devices. In this case however, it is the desire for additional Unified CM subscribers rather than additional device capacity that is requiring a megacluster deployment.

When considering a megacluster deployment, the primary areas impacting capacity are as follows:

- The megacluster may contain a total of 21 servers consisting of 16 subscribers, 2 TFTP servers, 2 music on hold (MoH) servers, and 1 publisher
- Server type must be either Cisco MCS 7845-I3/H3 class or Cisco Unified Computing System (UCS) C-Series or B-Series using the 10K Open Virtualization Archive (OVA) template.
- Redundancy model must be 1:1.

All other capacities relating to a standard cluster also apply to a megacluster. Note that support for a megacluster deployment is granted only following the successful review of a detailed design, including the submission of the results from the Cisco Unified Communications Sizing Tool. For more information about the Cisco Unified Communications Sizing Tool and the sizing of Unified CM standard clusters and megaclusters, see the chapter on [Unified Communications Design and Deployment Sizing Considerations, page 29-1](#).

Due to the many potential complexities surrounding megacluster deployments, customers who wish to pursue such a deployment must engage either their Cisco Account Team or their certified Cisco Unified Communications Partner.

**Note**

Unless otherwise specified, all information contained within this SRND that relates to call processing deployments (including capacity, high availability, and general design considerations) applies only to a standard cluster.

Cisco Business Edition Capacity Planning

Just as with Unified CM, many types of devices can register with Cisco Business Edition, and each of these devices requires registration and transaction resources from the platform with which it is registered. Likewise the users and their busy hour call attempts (BHCA) consume additional system resources. Each Cisco Business Edition system has specific user, endpoint, and BHCA capacity thresholds based on the available system resources of the platform. The maximum number of users and endpoints supported by Cisco Business Edition are 1,000 and 1,200 respectively. The maximum BHCA supported by Cisco Business Edition is 5,000.

For more information about Cisco Business Edition capacity planning considerations, including sizing examples and per-platform sizing limits as well as a complete discussion of system sizing, capacity planning, and deployment considerations, see the chapter on [Unified Communications Design and Deployment Sizing Considerations, page 29-1](#).

For additional information on Cisco Business Edition capacities as well as all other Cisco Business Edition product information, refer to the following product documentation:

- Cisco Business Edition 3000
http://www.cisco.com/en/US/products/ps11370/tsd_products_support_series_home.html
- Cisco Business Edition 5000
http://www.cisco.com/en/US/products/ps7273/tsd_products_support_series_home.html
- Cisco Business Edition 6000
http://docwiki.cisco.com/wiki/Cisco_Unified_Communications_Manager_Business_Edition_6000

Design Considerations for Call Processing

Observe the following design recommendations and guidelines when deploying Cisco call processing:

Cisco Unified CME

- Unified CME supports a maximum of 450 endpoints. However, depending on the Cisco IOS router model, endpoint capacity could be significantly lower. For additional information about Unified CME platforms and capacities, refer to the Cisco Unified Communications Manager Express compatibility information available at http://www.cisco.com/en/US/products/sw/voicesw/ps4625/products_device_support_tables_list.html.
- When possible, dual-attach the Unified CME router to the network using multiple IP interfaces to provide maximum network availability. Likewise, if multiple instances of Unified CME are required in the same deployment, distribute them across multiple physical switches or locations.
- When possible, deploy the Unified CME router with dual power supplies and/or an uninterruptible power supply (UPS) in order to provide maximum availability of the platform.

Cisco Business Edition

- Business Edition 3000 runs on either the MCS 7816 or the MCS 7890-C1 (with version 8.6(1) and later) acting as a combined publisher and single subscriber instance. A secondary subscriber instance is not configurable.
- Business Edition 5000 runs on a single hardware platform (MCS 7828) acting as a combined publisher and single subscriber instance. A secondary subscriber instance is not configurable.
- Business Edition 6000 runs on a UCS C200 Rack-Mount Server acting as a combined publisher and single subscriber instance. A second UCS C200 server can be deployed to provide call processing redundancy by means of a secondary subscriber. Alternatively an MCS server can be used to provide redundancy.

Note More than two UCS C200 Rack-Mount Servers may be clustered for a Business Edition 6000 deployment to provide additional redundancy and/or geographic distribution. However, the total number of users across the cluster may not exceed 1,000 and the total number of configured devices across the cluster may not exceed 1,200.

- Cisco Business Edition supports a maximum of 1,200 endpoints. However, actual endpoint capacity depends on total system BHCA, which cannot exceed a maximum of 5,000. For additional information about Cisco Business Edition capacity, including sizing examples and per-platform sizing limits, see the chapter on [Unified Communications Design and Deployment Sizing Considerations, page 29-1](#).
- Dual-attach the MCS 7828 server for Business Edition 5000 to the network using NIC teaming to provide maximum high availability. Business Edition 3000 does not support NIC teaming.
- If multiple instances of Business Edition 5000 or Business Edition 6000 are required in the same deployment, distribute them across multiple physical switches.

- Because the Cisco Business Edition platforms (MCS 7816, MCS 7828, MCS 7890-C1, and UCS C200) do not have or support dual power supplies, use an uninterruptible power supply (UPS) to provide maximum availability of the platform.
- When deploying Business Edition 6000 with two servers for high availability (two UCS C200 Rack-Mount Servers or one UCS C200 Rack-Mount Server and one MCS server), device registration should be load-balanced between the two servers in order to distribute system load. This is preferable to using the second server for standby redundancy.
- Business Edition 3000 provides support only for very specific types of endpoints and gateways:
 - Business Edition 3000 supports a limited set of endpoints. For a list of supported endpoints, refer to the *Administration Guide for Cisco Business Edition 3000*, available at http://www.cisco.com/en/US/products/ps11370/prod_maintenance_guides_list.html
 - Business Edition 3000 PSTN connectivity is supported only through the Cisco 2901 Integrated Services Router (ISR) and only with MGCP backhauled T1/E1 PRI trunks.
 - Business Edition 3000 does not support intercluster trunking and therefore does not support distributed call processing deployments.

Cisco Unified CM

- You can enable a maximum of 8 call processing subscriber nodes (nodes running the Cisco CallManager Service) within a Cisco Unified CM cluster. Additional servers may be dedicated and used for publisher, TFTP, and media resources services. An approved megacluster deployment supports a maximum of 16 call processing subscriber nodes.
- Each Unified CM cluster can support configuration and registration for a maximum of 40,000 secured or unsecured endpoints with Unified CM 8.6(1) and later releases. For Unified CM 8.5 and earlier releases, a maximum of 30,000 secured or unsecured endpoints is supported. For additional information about Unified CM capacity planning, including per-platform sizing limits, see the chapter on [Unified Communications Design and Deployment Sizing Considerations, page 29-1](#).
- When deploying a two-server cluster with high-capacity servers, Cisco recommends that you do not exceed 1250 users in the cluster. Above 1250 users, Cisco recommends a dedicated publisher and separate servers for primary and backup call processing subscribers.
- Cisco recommends using the same server model for all servers in a cluster. However, mixing server models and even different server vendor models within a cluster is supported, provided that all of the individual hardware versions are supported and that all servers are running the same version of Unified CM.
- 2:1 redundancy is not supported on Cisco MCS 7845-I3 or equivalent Open Virtualization Archive (OVA) 10K servers. You must use the 1:1 call processing redundancy scheme when more than 7,500 IP phones are registered on the two primary subscribers because there cannot be more than 7,500 backup registrations on a single backup subscriber.
- Dual-attach MCS servers to the network using NIC teaming to provide maximum high availability. The MCS 7815 has only a single network interface port and therefore cannot perform NIC teaming.
- Whenever possible, distribute the Unified CM servers across multiple physical switches within the network and across multiple physical locations within the same network to minimize the impact of a switch failure or the loss of a particular network location.
- Deploy SRST or Unified CME acting as SRST on Cisco IOS routers at remote locations to provide fallback call processing services in the event that these locations lose connectivity to the Unified CM cluster.
- Cisco recommends leaving voice activity detection (VAD) disabled in the Unified CM cluster. You should also disable VAD on Cisco IOS H.323 and SIP dial peers by using the **no vad** command.

- When deploying Unified CM on Cisco UCS B-Series Blade Servers, ensure that server node instances are distributed across blades servers within the UCS chassis so that backup or redundant subscriber nodes are on different physical blades than primary subscriber nodes.
- Both UCS B-Series Blade Servers and high-end Rack-Mount Servers (for example, C210 and C260) can be configured with multiple Open Virtualization Archive (OVA) templates. The largest OVA template supports 10,000 devices and provides the same capacities (number of endpoints, gateways, locations, regions, and so forth) as an MCS 7845-I3 server. For information on proper OVA sizing as well as the use of the Cisco Unified Communications Sizing Tool, see the chapter on [Unified Communications Design and Deployment Sizing Considerations, page 29-1](#).
- While the UCS B-Series Blade Servers and C-Series Rack-Mount Servers do support USB and serial ports through a KVM cable, the Unified CM VMware virtual application has no access to those ports. Therefore, if you deploy Unified CM on UCS, it will not be possible to attach fixed live audio sources for MoH, to make a serial SMDI connection to a legacy voicemail system, or to attach a USB flash drive for writing log files. The following alternate options are available:
 - For MoH live audio source feed, consider using Cisco IOS-based gateway multicast MoH for live audio source connectivity or deploying one Unified CM subscriber node on an MCS server as part of the Unified CM cluster to allow connectivity of the USB MoH audio card (MOH-USB-AUDIO=).
 - For SMDI serial connections, deploy one Unified CM subscriber node on an MCS server as part of the Unified CM cluster for USB serial connectivity.
 - For saving system installation logs, use virtual floppy softmedia.
- Cisco supports Unified CM clusters running some subscriber server node instances on UCS B-Series Blade Servers, some on C-Series Rack-Mount Servers, and other subscriber server node instances on MCS server platforms.

Computer Telephony Integration (CTI)

Cisco Computer Telephony Integration (CTI) extends the rich feature set available on Cisco Unified CM to third-party applications. These Cisco CTI-enabled applications improve user productivity, enhance the communication experience, and deliver superior customer service. At the desktop, Cisco CTI enables third-party applications to make calls from within Microsoft Outlook, open windows or start applications based on incoming caller ID, and remotely track calls and contacts for billing purposes. Cisco CTI-enabled server applications can intelligently route contacts through an enterprise network, provide automated caller services such as auto-attendant and interactive voice response (IVR), as well as capture media for contact recording and analysis.

CTI applications generally fall into one of two major categories:

- First-party applications — Monitor, control, and media termination

First-party CTI applications are designed to register devices such as CTI ports and route points for call setup, tear-down, and media termination. Because these applications are directly in the media path, they can respond to media-layer events such as in-band DTMF. Interactive voice response and Cisco Attendant Console are examples of first-party CTI applications that monitor and control calls while also interacting with call media.

- Third-party application — Monitor and control

Third-party CTI applications can also monitor and control calls, but they do not directly control media termination.

- Monitoring applications

A CTI application that monitors the state of a Cisco IP device is called a monitoring application. A busy-lamp-field application that displays on-hook/off-hook status or uses that information to indicate a user's availability in the form of Presence are both examples of third-party CTI monitoring applications.

- Call control applications

Any application that uses Cisco CTI to remotely control a Cisco IP device using out-of-band signaling is a call control application. Cisco Unified Personal Communicator, when configured to remotely control a Cisco IP device, is a good example of a call control application.

- Monitor + call control applications

These are any CTI applications that monitor and control a Cisco IP device. Cisco Unified Contact Center Enterprise is a good example of a combined monitor and control application because it monitors the status of agents and controls agent phones through the agent desktop.

**Note**

While the distinction between a monitor, call control, and monitor + control application is called out here, this granularity is not exposed to the application developer. All CTI applications using Cisco CTI are enabled for both monitoring and control.

CTI Architecture

Cisco CTI consists of the following components (see [Figure 8-9](#)), which interact to enable applications to take advantage of the telephony feature set available in Cisco Unified CM:

- CTI-enabled application — Cisco or third-party application written to provide specific telephony features and/or functionality.
- JTAPI and TAPI — Two standard interfaces supported by Cisco CTI. Developers can choose to write applications using their preferred method library.
- Unified JTAPI and Unified TSP Client — Converts external messages to internal Quick Buffer Encoding (QBE) messages used by Cisco Unified CM.
- Quick Buffer Encoding (QBE) — Unified CM internal communication messages.
- Provider — A logical representation of a connection between the application and CTI Manager, used to facilitate communication. The provider sends device and call events to the application while accepting control instructions that allow the application to control the device remotely.
- Signaling Distribution Layer (SDL) — Unified CM internal communication messages.
- Publisher and subscriber — Cisco Unified Communications Manager (Unified CM) servers.
- CCM — The Cisco CallManager Service (ccm.exe), the telephony processing engine.
- CTI Manager (CTIM) — A service that runs on one or more Unified CM subscribers operating in primary/secondary mode and that authenticates and authorizes telephony applications to control and/or monitor Cisco IP devices.

Figure 8-9 Cisco CTI Architecture

Once an application is authenticated and authorized, the CTIM acts as the broker between the telephony application and the Cisco CallManager Service. (This service is the call control agent and should not be confused with the overall product name Cisco Unified Communications Manager.) The CTIM responds to requests from telephony applications and converts them to Signaling Distribution Layer (SDL) messages used internally in the Unified CM system. Messages from the Cisco CallManager Service are also received by the CTIM and directed to the appropriate telephony application for processing.

The CTIM may be activated on any of the Unified CM subscriber servers in a cluster that have the Cisco CallManager Service active. This allows up to eight CTIMs to be active within a Unified CM cluster. Standalone CTIMs are currently not supported.

CTI Applications and Clustering Over the WAN

Deployments that employ clustering over the WAN are supported in the following two scenarios:

- CTI Manager over the WAN (see [Figure 8-10](#))

In this scenario, the CTI application and its associated CTI Manager are on one side of the WAN (Site 1), and the monitored or controlled devices are on the other side, registered to a Unified CM subscriber (Site 2). The round-trip time (RTT) must not exceed the currently supported limit of 80 ms for clustering over the WAN. To calculate the necessary bandwidth for CTI traffic, use the formula in the section on [Local Failover Deployment Model](#), page 5-49. Note that this bandwidth is in addition to the Intra-Cluster Communication Signaling (ICCS) bandwidth calculated as described in the section on [Local Failover Deployment Model](#), page 5-49, as well as any bandwidth required for audio (RTP traffic).

Figure 8-10 CTI Over the WAN

- TAPI and JTAPI applications over the WAN (CTI application over the WAN; see [Figure 8-11](#))

In this scenario, the CTI application is on one side of the WAN (Site 1), and its associated CTI Manager is on the other side (Site 2). In this scenario, it is up to the CTI application developer or provider to ascertain whether or not their application can accommodate the RTT as implemented. In some cases failover and failback times might be higher than if the application is co-located with its CTI Manager. In those cases, the application developer or provider should provide guidance as to the behavior of their application under these conditions.

Figure 8-11 JTAPI Over the WAN

Note Support for TAPI and JTAPI over the WAN is application dependent. Both customers and application developers or providers should ensure that their applications are compatible with any such deployment involving clustering over the WAN.

Capacity Planning for CTI

The maximum number of supported CTI connections and maximum number of CTI-controlled devices is 40,000 per cluster. For more information on CTI capacity planning, including per-platform node and cluster CTI capacities as well as CTI resource calculation formulas and examples, see the chapter on [Unified Communications Design and Deployment Sizing Considerations](#), page 29-1.

High Availability for CTI

This section provides some guidelines for provisioning CTI for high availability.

CTI Manager

CTI Manager must be enabled on at least one and possibly all call processing subscribers within the Unified CM cluster. The client-side interfaces (TAPI TSP or JTAPI client) allow for two IP addresses each, which then point to Unified CM servers running the CTIM service. For CTI application redundancy, Cisco recommends having the CTIM service activated on at least two Unified CM servers in a cluster, as shown in [Figure 8-12](#).

Redundancy, Failover, and Load Balancing

For CTI applications that require redundancy, the TAPI TSP or JTAPI client can be configured with two IP addresses, thereby allowing an alternate CTI Manager to be used in the event of a failure. It should be noted that this redundancy is not stateful in that no information is shared and/or made available between the two CTI Managers, and therefore the CTI application will have some degree of re-initialization to go through, depending on the exact nature of the failover.

When a CTI Manager fails-over, just the CTI application login process is repeated on the now-active CTI Manager. Whereas, if the Unified CM server itself fails, then the re-initialization process is longer due to the re-registration of all the devices from the failed Unified CM to the now-active Unified CM, followed by the CTI application login process.

For CTI applications that require load balancing or that could benefit from this configuration, the CTI application can simply connect to two CTI Managers simultaneously, as shown in [Figure 8-12](#).

Figure 8-12 Redundancy and Load Balancing

Figure 8-13 shows an example of this type of configuration for Cisco Unified Contact Center Enterprise (Unified CCE). This type of configuration has the following characteristics:

- Unified CCE uses two Peripheral Gateways (PGs) for redundancy.
- Each PG logs into a different CTI Manager.
- Only one PG is active at any one time.

Figure 8-13 CTI Redundancy with Cisco Unified Contact Center Enterprise

271551

Figure 8-14 shows an example of this type of configuration for Cisco Unified Contact Center Express (Unified CCX). This type of configuration has the following characteristics:

- Unified CCX has two IP addresses configured, one for each CTI Manager.
- If connection to the primary CTI Manager is lost, Unified CCX fails-over to its secondary CTI Manager.

Figure 8-14 CTI Redundancy with Cisco Unified Contact Center Express

Implementation

For guidance and support on writing applications, application developers should consult the Cisco Developer Connection, located at

<http://developer.cisco.com/web/cdc/community>

Gatekeeper Design Considerations

A single Cisco IOS gatekeeper can provide call routing and call admission control for up to 100 Unified CM clusters in a distributed call processing environment. Multiple gatekeepers can be configured to support thousands of Unified CM clusters. You can also implement a hybrid Unified CM and toll-bypass network by using Cisco IOS gatekeepers to provide communication and call admission control between the H.323 gateways and Unified CM.

Gatekeeper call admission control is a policy-based scheme requiring static configuration of available resources. The gatekeeper is not aware of the network topology, so it is limited to hub-and-spoke topologies.

Most Cisco IOS routers support the gatekeeper feature. For specific platform support for gatekeeper functionality, refer to the *Cisco IOS H323 Gatekeeper Data Sheet*, available at

http://www.cisco.com/en/US/prod/collateral/voicesw/ps6788/vcallcon/ps4139/data_sheet_c78_561921.html

You can configure Cisco IOS gatekeepers in a number of different ways for redundancy, load balancing, and hierarchical call routing. This section considers the design requirements for building a gatekeeper network, but it does not deal with the call admission control or dial plan resolution aspects, which are covered in the chapters on [Call Admission Control, page 11-1](#), and [Dial Plan, page 9-1](#), respectively.

For additional information regarding gatekeepers, refer to the *Cisco IOS H.323 Configuration Guide*, available at

http://www.cisco.com/en/US/products/ps10591/products_installation_and_configuration_guides_list.html

Hardware Platform Selection

The choice of gatekeeper platform is based on the number of calls per second and the number of concurrent calls. A higher number of calls per second requires a more powerful CPU. A higher number of concurrent calls requires more memory. Select Cisco IOS routers with large memory capacity and higher performance CPUs when design requirements include high call volumes and large numbers of simultaneous calls.

For more information about gatekeeper platforms, refer to the *Cisco IOS H323 Gatekeeper Data Sheet*, available at

http://www.cisco.com/en/US/prod/collateral/voicesw/ps6788/vcallcon/ps4139/data_sheet_c78_561921.html

Gatekeeper Redundancy

With gatekeepers providing all call routing and admission control for intercluster communications, redundancy is required. There are two methods for providing gatekeeper redundancy: gatekeeper clustering and directory gatekeeper.

**Note**

Cisco recommends that you use gatekeeper clustering to provide gatekeeper redundancy whenever possible. Do not use Hot Standby Router Protocol (HSRP) for gatekeeper redundancy unless gatekeeper clustering is not available in your software feature set.

Gatekeeper Clustering (Alternate Gatekeeper)

Gatekeeper clustering (alternate gatekeeper) enables the configuration of a "local" gatekeeper cluster, with each gatekeeper acting as primary for some Unified CM trunks and an alternate for others. Gatekeeper Update Protocol (GUP) is used to exchange state information between gatekeepers in a local

cluster. GUP tracks and reports CPU utilization, memory usage, active calls, and number of registered endpoints for each gatekeeper in the cluster. Load balancing is supported by setting thresholds for any of the following parameters in the GUP messaging:

- CPU utilization
- Memory utilization
- Number of active calls
- Number of registered endpoints

With the support of gatekeeper clustering (alternate gatekeeper), stateful redundancy and load balancing is available. Gatekeeper clustering provides the following features:

- Local and remote clusters
- Up to five gatekeepers in a local cluster
- Gatekeepers in local clusters can be located in different subnets or locations
- No failover delay (Because the alternate gatekeeper is already aware of the endpoint, it does not have to go through the full registration process.)
- Gatekeepers in a cluster pass state information and provide load balancing

Figure 8-15 shows three sites with Unified CM distributed call processing and three distributed gatekeepers configured in a local cluster.

Figure 8-15 Gatekeeper Clustering

In **Figure 8-15**, each site's Unified CM cluster registers to the local gatekeeper. The local gatekeeper service is made redundant using gatekeeper clustering such that each local gatekeeper is backed up by a gatekeeper at another site.

Consider the following guidelines when deploying gatekeeper clustering:

- Each Unified CM cluster should have a local zone configured to support Unified CM trunk registrations. This local zone is configured within Unified CM and on the gatekeeper located with the Unified CM cluster. In the example shown in **Figure 8-15**, the Unified CM cluster located in the San Jose site will have a gatekeeper controlled trunk with a zone name matching the local zone name configured on the San Jose gatekeeper (Gatekeeper 1). Likewise, the Chicago and New York Unified CM clusters will have zone names matching the local zone name on the gatekeepers located in their respective locations (Gatekeeper 2 in Chicago and Gatekeeper 3 in New York).

- A gatekeeper cluster is defined for each local zone, with backup zones on the other gatekeepers configured using the **element** command. In the example shown in Figure 8-15, the San Jose gatekeeper (Gatekeeper 1) has a local zone with elements for both the Chicago gatekeeper (Gatekeeper 2) and New York gatekeeper (Gatekeeper 3). Likewise, the Chicago and New York gatekeepers have local zones with elements for both the San Jose gatekeeper and each other (respectively).
- Use the **gw-type-prefix** command to allow all locally unresolved calls to be forwarded to a device registered with the configured technology prefix in the local zone. In the example shown in Figure 8-15, each Unified CM gatekeeper controlled trunk is configured with a technology prefix of 1#* and the gatekeeper at each site is configured with a default-technology gw-type-prefix of 1#*.
- Load balancing between clustered gatekeepers is configured using the **load-balance** command. Given the example shown in Figure 8-15, each site's gatekeeper can be configured to load balance or move endpoint/gateway registration from the local gatekeeper to the alternate gatekeeper within the cluster based on thresholds for CPU utilization, memory utilization, number of endpoints, and/or number of calls. For example, the San Jose gatekeeper (Gatekeeper 1) might be configured to move endpoint or gateway registrations to the Chicago gatekeeper based on a high-water CPU and memory threshold of 80%. In that case, if the San Jose gatekeeper's memory or CPU utilization reaches 80%, the gatekeeper will begin sending Chicago gatekeeper information in the H.323 Registration, Admission, and Status (RAS) messages it sends to the San Jose Unified CM cluster to maintain trunk registration state. Likewise, the other gatekeepers in Chicago and New York could be similarly configured to load-balance local Unified CM trunk registration loads at those sites to gatekeepers located in other sites.
- When routing calls between the three Unified CM clusters in Figure 8-15, the gatekeeper at each site should be configured to check that appropriate bandwidth is available on the network between that location and the location to which the call is being routed. If there is not sufficient bandwidth, the call should not be routed. The **bandwidth interzone** command is recommended for specifying interzone call bandwidth between the distributed Unified CM locations.
- Use the **arq reject-unknown-prefix** command to guard against potential call routing loops across redundant Unified CM trunks within a cluster. This command prevents the gatekeeper from forwarding call routing requests back to the local gateway or Unified CM trunk when the dialed prefix does not match a defined prefix.

For additional information regarding gatekeeper deployment and configuration, refer to the *Cisco IOS H.323 Configuration Guide*, available at

http://www.cisco.com/en/US/products/ps10591/products_installation_and_configuration_guides_list.html

Directory Gatekeeper Redundancy

You can implement directory gatekeeper redundancy by using HSRP or by configuring multiple identical directory gatekeepers. When a gatekeeper is configured with multiple remote zones using the same zone prefix, the gatekeeper can use either of the following methods:

- Sequential LRQs (default)

Redundant remote zones (matching zone prefixes) are assigned a cost, and LRQs are sent to the matching zones in order based on the cost values. Using sequential LRQs saves WAN bandwidth by not blasting LRQs to all matching gatekeepers.
- LRQ Blast

LRQs are sent to redundant zones (matching zone prefixes) simultaneously. The first gatekeeper to respond with an Location Confirm (LCF) is the one that is used.

Cisco recommends that you use multiple active directory gatekeepers with sequential LRQs, thus allowing directory gatekeepers to be placed in different locations. Using HSRP requires both directory gatekeepers to be located in the same subnet, and only one gatekeeper can be active at any time.

Figure 8-16 shows the same three-site Unified CM distributed call processing deployment with three distributed local gatekeepers as shown in Figure 8-15. However, unlike the deployment illustrated in Figure 8-15, the deployment in Figure 8-16 depicts the three distributed local gatekeepers relying on two active directory gatekeepers for redundant inter-site call routing (rather than relying on alternate or clustered gatekeepers).

Figure 8-16 Redundant Directory Gatekeepers

Consider the following guidelines when deploying redundant directory gatekeepers:

- When configuring redundancy for directory gatekeepers, configure each directory gatekeeper with a local zone. In the example shown in [Figure 8-16](#), the directory gatekeeper located in San Jose (West DGK) is configured with one local zone name and IP address, while the directory gatekeeper located in New York (East DGK) is configured with another local zone name and IP address.
- Directory gatekeepers should be configured with remote zones corresponding to each gatekeeper in the network. In the example shown in [Figure 8-16](#), both the directory gatekeeper in San Jose (West DGK) and the one in New York (East DGK) are configured with a remote zone corresponding to the gatekeeper at the San Jose site (Gatekeeper 1), a remote zone corresponding to the gatekeeper at the Chicago site (Gatekeeper 2), and a remote zone corresponding to the gatekeeper at the New York site (Gatekeeper 3). The configuration for these remote sites is the same on both directory gatekeepers.
- Each directory gatekeeper is configured with dialed number prefixes corresponding to each remote zone for inter-zone call routing. In the example shown in [Figure 8-16](#), both directory gatekeepers are configured with prefixes corresponding to the local area code serviced by each site's gatekeeper. For example, the prefix 408 is configured for the San Jose gatekeeper (Gatekeeper 1) remote zone, the prefix 720 is configured for the Chicago gatekeeper (Gatekeeper 2) remote zone, and the prefix 212 is configured for the New York gatekeeper (Gatekeeper 3) remote zone. Additional prefixes can be configured for each remote zone as needed to accommodate other dialed number prefixes. Because calls are never routed to the local directory gatekeeper zone, a prefix is not required for those zones. In addition to configuring specific prefixes, the wildcard notation * can be used to match all prefixes not explicitly defined.
- Configure the **lrq forward-queries** command on each directory gatekeeper to ensure that call setup location requests (LRQ) received from one gatekeeper are forwarded to one of the other gatekeepers as appropriate for service based on dialed prefixes. Given the example shown in [Figure 8-16](#), both the directory gatekeeper in San Jose (West DGK) and the one in New York (East DGK) should be configured to forward LRQ queries.

Note Directory gatekeepers do not contain any active endpoint registrations and do not supply any bandwidth management.

- Just as with the previous example ([Figure 8-15](#)), the local site gatekeepers shown at each site in [Figure 8-16](#) provide gatekeeper services and registration for Unified CM cluster trunks at each site.
- Each local site gatekeepers is configured with a remote zone for each directory gatekeeper. Given the example depicted in [Figure 8-16](#), the local gatekeeper in the San Jose site (Gatekeeper 1) has remote zones configured for both the directory gatekeeper in San Jose (West DGK) and the directory gatekeeper in New York (East DGK). The local gatekeepers at the Chicago (Gatekeeper 2) and New York (Gatekeeper 3) sites are configured identically.
- Each local site gatekeeper should be configured to limit bandwidth between the local gatekeeper zone and any remote zones configured. In the example shown in [Figure 8-16](#), each local gatekeeper is configured with the **bandwidth remote** command determining the amount of bandwidth available for routing calls to the remote zone directory gatekeepers. For example, the **bandwidth remote** command is configured on the San Jose gatekeeper (Gatekeeper 1) to limit the available bandwidth for routing calls to the remote zone defined for the directory gatekeeper in San Jose (West DGK) and the remote zone defined for the directory gatekeeper in New York (East DGK). This in turn limits the bandwidth available for routing calls between the San Jose site gatekeeper (Gatekeeper 1) and either of the other site gatekeepers (Gatekeeper 2 or Gatekeeper 3). This same configuration would be replicated on the other local site gatekeepers.

- Each local site gatekeeper is configured with zone prefixes for the local zone corresponding to the local gatekeeper and for both remote zones corresponding to the two directory gatekeepers. The former local zone prefix handles call routing to the local Unified CM cluster, while the latter remote zone prefixes handle inter-zone call routing to the other gatekeeper sites. Given the example depicted in [Figure 8-16](#), the local gatekeeper in the San Jose site (Gatekeeper 1) is configured with a local zone prefix of 408 and remote zone prefixes of ten dots (.) corresponding to the two directory gatekeepers (East DGK and West DGK). These ten dot (.) prefixes match all normalized ten-digit E.164 dialed numbers that do not begin with the local zone prefix of 408. Thus all calls routed by Gatekeeper 1 that do not begin with 408 will be routed to one of the other gatekeeper sites through one of the directory gatekeepers. The local gatekeepers at the Chicago (Gatekeeper 2) and New York (Gatekeeper 3) sites are configured with local zone prefixes 720 and 212 respectively, along with the same general remote zone ten-dot prefixes.
- Sequential location requests (LRQs) are used by default when matching zone prefixes are configured. In the example shown in [Figure 8-16](#), for all calls routed to dialed numbers that do not start with 408, the local gatekeeper at the San Jose site (Gatekeeper 1) will first send an LRQ to the directory gatekeeper located in San Jose (West DGK) based on the generic ten-dot (.) prefix configured for the remote zone corresponding to the West DGK. If a response is not received from the West DGK, then Gatekeeper 1 will send an LRQ to the directory gatekeeper located in New York (East DGK) based on the generic ten-dot (.) prefix configured for the remote zone corresponding to the East DGK. Similarly, local gatekeepers at the Chicago (Gatekeeper 2) and the New York (Gatekeeper 3) sites will first send an LRQ to one of the directory gatekeepers based on remote zone and ten-dot (.) prefix configuration and to the second directory gatekeeper if a response is not received from the first.
- Just as with the previous gatekeeper clustering example ([Figure 8-15](#)), the **gw-type-prefix** command is used to ensure all locally unresolved calls are forwarded to a device registered with the configured technology prefix in the local zone. Likewise, the **arq reject-unknown-prefix** command guards against potential call routing loops across redundant Unified CM trunks within a cluster.

For additional information regarding directory gatekeeper deployment and configuration, refer to the *Cisco IOS H.323 Configuration Guide*, available at

http://www.cisco.com/en/US/products/ps10591/products_installation_and_configuration_guides_list.html

Interoperability of Unified CM and Unified CM Express

This section explains the requirements for interoperability and internetworking of Cisco Unified CM with Cisco Unified Communications Manager Express (Unified CME) using H.323 or SIP trunking protocol in a multisite IP telephony deployment. This section highlights the recommended deployments between phones controlled by Unified CM and phones controlled by Unified CME.

This section covers the following topics:

- [Overview of Interoperability Between Unified CM and Unified CME, page 8-45](#)
- [Unified CM and Unified CME Interoperability via SIP in a Multisite Deployment with Distributed Call Processing, page 8-46](#)
- [Unified CM and Unified CME Interoperability via H.323 in a Multisite Deployment with Distributed Call Processing, page 8-49](#)

Overview of Interoperability Between Unified CM and Unified CME

Either H.323 or SIP can be used as a trunking protocol to interconnect Unified CM and Unified CME. When deploying Unified CM at the headquarters or central site in conjunction with one or more Unified CME systems for branch offices, network administrators must choose either the SIP or H.323 protocol after careful consideration of protocol specifics and supported features across the WAN trunk. Using H.323 trunks to connect Unified CM and Unified CME has been the predominant method in past years, until more enhanced capabilities for SIP phones and SIP trunks were added in Unified CM and Unified CME. This section first describes some of the features and capabilities that are independent of the trunking protocol for Unified CM and Unified CME interoperability, then it explains some of the most common design scenarios and best practices for using SIP trunks and H.323 trunks.

Call Types and Call Flows

In general, Unified CM and Unified CME interworking allows all combination of calls from SCCP IP phones to SIP IP phones, or vice versa, across a SIP trunk or H.323 trunk. Calls can be transferred (blind or consultative) or forwarded back and forth between the Unified CM and Unified CME SIP and/or SCCP IP phones.

When connected to Unified CM via H.323 trunks, Unified CME can auto-detect Unified CM calls. When a call terminating on Unified CME is transferred or forwarded, Unified CME regenerates the call and routes the call appropriately to another Unified CME or Unified CM by hairpinning the call. Unified CME hairpins the call legs from Unified CM for the VoIP calls across SIP or H.323 trunks when needed. For more information on allowing auto-detection on a non-H.450 supported Unified CM network and for enabling or disabling supplementary services for H450.2, H450.3, or SIP, refer to the Unified CME product documentation available at

http://www.cisco.com/en/US/products/sw/voicesw/ps4625/tsd_products_support_series_home.html

When connected to Unified CM via SIP trunks, Unified CME does not auto-detect Unified CM calls. By default, Unified CME always tries to redirect calls using either a SIP Refer message for call transfer or a SIP 302 Moved Temporarily message for call forward; if that fails, Unified CME will then try to hairpin the call.

Music on Hold

While Unified CM can be enabled to stream MoH in both G.711 and G.729 formats, Unified CME streams MoH only in G.711 format. Therefore, when Unified CME controls the MoH audio on a call placed on hold, it requires a transcoder to transcode between a G.711 MoH stream and a G.729 call leg.

Ad Hoc and Meet Me Hardware Conferencing

Hardware DSP resources are required for both Ad Hoc and Meet Me conferences. Whether connected via SIP, H.323, or PSTN, both Unified CM and Unified CME phones can be invited or added to an Ad Hoc conference to become conference participants as long as the phones are reachable from the network. When calls are put on hold during an active conference session, music will not be heard by the conference participants in the conference session.

For information on required and supported DSP resources and the maximum number of conference participants allowed for Ad Hoc or Meet Me conferences, refer to the Unified CME product documentation available at

http://www.cisco.com/en/US/products/sw/voicesw/ps4625/tsd_products_support_series_home.html

Unified CM and Unified CME Interoperability via SIP in a Multisite Deployment with Distributed Call Processing

Unified CM can communicate directly with Unified CME using a SIP interface. [Figure 8-17](#) shows a Cisco Unified Communications multisite deployment with Unified CM networked directly with Cisco Unified CME using a SIP trunk.

Figure 8-17 Multisite Deployment with Unified CM and Unified CME Using SIP Trunks

Best Practices

Follow these guidelines and best practices when using the deployment model illustrated in [Figure 8-17](#):

- Configure a SIP Trunk Security Profile with **Accept Replaces Header** selected.
- Configure a SIP trunk on Unified CM using the SIP Trunk Security Profile created, and also specify a ReRouting CSS. The ReRouting CSS is used to determine where a SIP user (transferor) can refer another user (transferee) to a third user (transfer target) and which features a SIP user can invoke using the SIP 302 Redirection Response and INVITE with Replaces.
- For SIP trunks there is no need to enable the use of media termination points (MTPs) when using SCCP endpoints on Unified CME. However, SIP endpoints on Unified CME require the use of media termination points on Unified CM to be able to handle delayed offer/answer exchanges with the SIP protocol (that is, the reception of INVITES with no Session Description Protocol).

- Route calls to Unified CME via a SIP trunk using the Unified CM dial plan configuration (route patterns, route lists, and route groups).
- Use Unified CM device pools and regions to configure a G.711 codec within the site and the G.729 codec for remote Unified CME sites.
- Configure the **allow-connections sip to sip** command under **voice services voip** on Unified CME to allow SIP-to-SIP call connections.
- For SIP endpoints, configure the **mode cme** command under **voice register global**, and configure **dtmf-relay rtp-nte** under the **voice register pool** commands for each SIP phone on Unified CME.
- For SCCP endpoints, configure the **transfer-system full-consult** command and the **transfer-pattern .T** command under **telephony-service** on Unified CME.
- Configure the SIP WAN interface voip dial-peers to forward or redirect calls, destined for Unified CM, with **session protocol sipv2** and **dtmf-relay [sip-notify | rtp-nte]** on Unified CME.

Design Considerations

This section first covers some characteristics and design considerations for Unified CM and Unified CME interoperability via SIP in some main areas such as supplementary services for call transfer and forward, presence service for busy lamp field (BLF) notification for speed-dial buttons and directory call lists, and out-of-dialog (OOD-Refer) for integration with partner applications and third-party phone control for click-to-dial between the Unified CM phones and Unified CME phones. The section also covers some general design considerations for Unified CM and Unified CME interoperability via SIP.

Supplementary Services

SIP Refer or SIP 302 Moved Temporarily messages can be used for supplementary services such as call transfer or call forward on Unified CME or Unified CM to instruct the transferee (referee) or phone being forwarded (forwardee) to initiate a new call to the transfer-to (refer-to) target or forward-to target. No hairpinning is needed for call transfer or call forward scenarios when the SIP Refer or SIP 302 Moved Temporarily message is supported.

However, **supplementary-service** must be disabled if there are certain extensions that have no DID mapping or if Unified CM or Unified CME does not have a dial plan to route the call to the DID in the SIP 302 Moved Temporarily message. When **supplementary-service** is disabled, Unified CME hairpins the calls or sends a re-invite SIP message to Unified CM to replace the media path to the new called party ID. Both signaling and media are hairpinned, even when multiple Unified CMEs are involved for further call forwards. The **supplementary-service** can also be disabled for transferred calls. In this case, the SIP Refer message will not be sent to Unified CM, but the transferee (referee) party and transfer-to party (refer-to target) are hairpinned.

Note

Supplementary services can be disabled with the command **no supplementary-service sip moved-temporarily** or **no supplementary-service sip refer** under **voice service voip** or **dial-peer voice xxxx voip**.

The following examples illustrate the call flows when supplementary services are disabled:

- Unified CM phone B calls Unified CME phone A, which is set to call-forward (all, busy, or no answer) to phone C (either a Unified CM phone, a Unified CME phone on the same or different Unified CME, or a PSTN phone).

Unified CME does not send the SIP 302 Moved Temporarily message to Unified CM, but hairpins the call between Unified CM phone B and phone C.

- Unified CM phone B calls Unified CME phone A, which transfer the call to phone C (either a Unified CM phone, a Unified CME phone, or a PSTN phone).

Unified CME does not send the SIP Refer message to Unified CM, but hairpins the call between Unified CM phone B and phone C.

General Design Considerations for Unified CM and Unified CME Interoperability via SIP

- Disable **supplementary-service** if SIP 302 Moved Temporarily or SIP Refer messages are not supported by Unified CM, otherwise Unified CM cannot route the call to the transfer-to or forward-to target.
- In a SIP-to-SIP call scenario, a Refer message is sent by default from the transferor to the transferee, the transferee sets up a new call to the transfer-to target, and the transferor hears ringback tone by default while waiting for the transfer at connect. If **supplementary-service** is disabled on Unified CME, Unified CME will provide in-band ringback tone right after the call between the transferee and transfer-to target is connected.
- Presence service is supported on Unified CM and Unified CME via SIP trunk only.
- The OOD-Refer feature allows third-party applications to connect two endpoints on Unified CM or Unified CME through the use of the SIP REFER method. Consider the following factors when using OOD-Refer:
 - Both Unified CM and Unified CME must be configured to enable the OOD-Refer feature.
 - Call Hold, Transfer, and Conference are not supported during an OOD-Refer transaction, but they are not blocked by Unified CME.
 - Call transfer is supported only after the OOD-Refer call is in the connected state and not before the call is connected; therefore, call transfer-at-alert is not supported.
- Control signaling in TLS is supported, but SRTP is not supported over the SIP trunk.
- Video is not supported on SIP phones, nor is it supported over SIP trunks.
- SRTP over a SIP trunk is a gateway feature in Cisco IOS for Unified CM. SRTP support is not available with Unified CM and Unified CME interworking via SIP trunks.

Note

When multiple PSTN connections exist (one for Unified CM and one for Unified CME), fully attended transfer between a Unified CM endpoint and a Unified CME endpoint to a PSTN endpoint will fail. The recommendation is to use blind transfer when using multiple PSTN connections, and it is configured under **telephony-service** as **transfer-system full-blind**.

**Note**

Cisco Unified CME supports video calls across SIP trunks between multiple Unified CMEs. This capability applies in distributed call processing deployments that use Unified CMEs only. Video calls between Unified CM and Unified CME over SIP trunks are not supported. For configuration details, refer to the *Cisco Unified Communications Manager Express System Administrator Guide*, available at http://www.cisco.com/en/US/products/sw/voicesw/ps4625/products_installation_and_configuration_guides_list.html.

Unified CM and Unified CME Interoperability via H.323 in a Multisite Deployment with Distributed Call Processing

There are two deployment options to achieve interoperability between Unified CM and Unified CME via H.323 connections in a multisite WAN deployment with distributed call processing. The first option is to deploy a Cisco Unified Border Element as a front-end device of Unified CM, which has a peer-to-peer H.323 connection with a remote Unified CME system. The Cisco Unified Border Element performs dial plan resolution between Unified CM and Unified CME, and it also terminates and re-originates call signaling messages between the two. The Cisco Unified Border Element acts as a proxy device for a system that does not support H.450 for its supplementary services, such as Unified CM, which uses Empty Capability Sets (ECS) to invoke supplementary services. The Cisco Unified Border Element can also act as the PSTN gateway for the Unified CM cluster so that a separate PSTN gateway is not needed.

The second option is to deploy a via-zone gatekeeper. Unified CM, Unified CME, and the Cisco Unified Border Element all register with the via-zone gatekeeper as VoIP gateway devices. The via-zone gatekeeper performs dial plan resolution and bandwidth restrictions between Unified CM and Unified CME. The via-zone gatekeeper also inserts a Cisco Unified Border Element in the call path to interwork between ECS and H.450 to invoke the supplementary services. For detailed information on the via-zone gateway and Cisco Unified Border Element, see the chapter on [Call Admission Control, page 11-1](#).

These two deployment options have the following differences:

- With the first option, the Cisco Unified Border Element registers with Unified CM as an H.323 gateway device; with the second option, it registers with via-zone gatekeeper as a VoIP gateway device.
- With the first option, the Cisco Unified Border Element performs dial plan resolution based on the VoIP dial-peer configurations on the Cisco Unified Border Element; with the second option, the via-zone gatekeeper performs dial plan resolution based on the gatekeeper dial plan configuration.
- With the first option, there is no call admission control mechanism that oversees both call legs; with the second option, the via-zone gatekeeper performs gatekeeper zone-based call admission control.
- With the second option, the via-zone gatekeeper can also act as an infrastructure gatekeeper for Unified CM, to manage all dial plan resolution and bandwidth restrictions between Unified CM clusters, between a Unified CM cluster and a network of H.323 VoIP gateways, or between a Unified CM cluster and a service provider's H.323 VoIP transport network.

[Figure 8-18](#) shows H.323 integration between Unified CM and Unified CME using a via-zone gatekeeper and Cisco Unified Border Element.

Figure 8-18 Multisite Deployment with Unified CM and Unified CME Using a Cisco Unified Border Element or Via-Zone Gatekeeper

Best Practices

This section discusses configuration guidelines and best practices when using the deployment model illustrated in [Figure 8-18](#) with the second deployment option (via-zone gatekeeper):

- Configure a gatekeeper-controlled H.225 trunk between Unified CM and the via-zone gatekeeper. Media termination point (MTP) resources are required over the trunk only when Unified CME tries to initiate an outbound H.323 fast-start call.
- The **Wait For Far End H.245 Terminal Capability Set (TCS)** option must be unchecked to prevent stalemate situations from occurring when the H.323 devices at both sides of the trunk are waiting the far end to send TCS first and the H.245 connection times out after a few seconds.
- Configure the Unified CM service parameter **Send H225 user info message to H225 info for Call Progress Tone**, which will make Unified CM send the H.225 Info message to Unified CME to play ringback tone or tone-on-hold.
- Use the Unified CM dial plan configuration (route patterns, route lists, and route groups) to send calls destined for Unified CME to the gatekeeper-controlled H.225 trunk.
- Register Unified CME and the Cisco Unified Border Element as H.323 gateways with the via-zone gatekeeper.

- Configure the **allow-connection h323 to h323** command on the Cisco Unified Border Element to allow H.323-to-H.323 call connections. This command is optional to configure on Unified CME. Configure **allow-connection h323 to sip** if Cisco Unity Connection is used on Unified CME.
- Supplementary services such as transfer and call forward will result in calls being media hairpinned when the two endpoints reside in the same Unified CME branch location.

**Note**

The only configuration difference between the two deployment options is that the first option requires configuring the Cisco Unified Border Element as an H.323 gateway device in Unified CM. The rest of the configuration guidelines listed above are the same for both options.

**Note**

When multiple PSTN connections exist (one for Unified CM and one for Unified CME), fully attended transfer between a Unified CM endpoint and a Unified CME endpoint to a PSTN endpoint will fail. The recommendation is to use blind transfer when using multiple PSTN connections, and it is configured under **telephony-service** as **transfer-system full-blind**.

Design Considerations

In an H.323 deployment, Unified CME supports call transfer, call forward with H.450.2, and H.450.3 as part of the H.450 standards. However, Unified CM does not support H.450, and supplementary services such as call transfer, call forward, call hold or resume are done using the Empty Capabilities Set (ECS). Therefore, when calls are transferred or forwarded between Unified CM and Unified CME, they are hairpinned and routed with a Cisco Unified Border Element and with or without a gatekeeper, as described as the two deployment models in the previous section. This section lists some of the design considerations and best practices for Unified CM and Unified CME interoperability via H.323.

Supplementary Services Such as Call Transfer and Call Forward

Unified CME can auto-detect Unified CM, which does not support H.450, by using H.450.12 protocol to automatically discover the H.450.x capabilities. Unified CME uses VoIP hairpin routing for calls between Unified CM and Unified CME. When the call is terminated, Unified CME hairpins the call from the Unified CM phone by re-originating and routing the call as appropriate.

**Note**

When Unified CME detects that Unified CM does not support H.450, Unified CME hairpins the calls by hairpinning both signaling and media at Unified CME. This causes double the amount of bandwidth to be consumed when calls are transferred or forwarded across the WAN. (For example, if a Unified CM phone calls a Unified CME phone and the Unified CME phone transfers the call to a second Unified CM phone, Unified CME hairpins both the signaling and media even though the call is between two Unified CM phones.) To avoid this double bandwidth consumption on the WAN, Cisco recommends using the Cisco Unified Border Element to act as an H.450 tandem gateway and to allow for H.450-to-ECS mapping for supplementary services such as call transfer or call forward.

Supported Call Flows

Unified CME is a back-to-back user agent (B2BUA), thus call flows work from SCCP phone to SCCP phone and from SCCP phone to SIP phone. SIP phone calls work over H.323 trunks, but supplementary features are not supported.

Security

Unified CME provides secure signaling with TLS and media encryption with SRTP. Unified CM also supports secure signaling via TLS and secure media via SRTP. However, interworking between secure Unified CM and secure Unified CME is not supported.

Video

Observe the following design considerations when implementing video functionality with Unified CME:

- All endpoints on Unified CM and Unified CME must be configured as video-capable endpoints. The video codec and formats for all the video-capable endpoints must match.
- Unified CM and Unified CME support basic video calls; however, supplementary services such as call transfer and call forward are not supported for video calls between Unified CM and Unified CME. To support supplementary services with Unified CME, H.450 must be enabled on all Unified CMEs and voice gateways. Because Unified CM does not support H.450, video calls will revert to audio-only calls when supplementary services are needed between Unified CM phones and Unified CME phones.
- Conference calls revert to audio only.
- WAN bandwidth must meet the minimum video bit rate of 384 kbps for video traffic to traverse the WAN.
- Video basic calls are supported on SCCP phones only and are not supported on SIP phones.

H.320 Video via ISDN

Observe the following design considerations when implementing H.320 video functionality via ISDN:

- When directly connected to an H.320 endpoint via a PRI or BRI interface, Unified CME and Cisco IOS routers currently support only 128 kbps video calls.
- When H.320 is enabled on Unified CME and PSTN gateways to interwork with Unified CM, use a separate dial-peer for video calls to differentiate them from voice-only calls. Configure **bear-cap speech** under the **voice-port** configuration on Unified CME.
- H.320 does not support supplementary services.

General Design Considerations for Unified CM and Unified CME Interoperability via H.323

- Configure Unified CME to auto-detect Unified CM by using H.450.12 to hairpin the calls between Unified CM and Unified CME phones.
- For SCCP-to-SCCP calls or SCCP-to-SIP calls, an H.323 trunk can be deployed between Unified CM and Unified CME.
- While Unified CME supports secure signaling with TLS and secure media with SRTP, conferencing call flows cannot be secured. Further, security interoperability is not supported between Unified CM and Unified CME phones.
- Deploy video only for SCCP phones (with support of basic calls), and not for SIP phones.
- MTP functionality is not compatible with video; for video calls to work, the MTP feature must be disabled (unchecked).
- Make sure that IP connectivity between Unified CM and Unified CME works properly.
- Make sure the local video setup works correctly for each Unified CME local zone and Unified CM location (local SCCP).
- Use the existing voice dial-plan infrastructure.

- Observe the following guidelines for video traffic shaping:
 - Mark the video and audio channels of a video call with CoS 4 to preserve lip-sync and to separate video from audio-only calls.
 - Place voice and video traffic in different queues.
 - Use Priority Queuing (PQ) for voice and video traffic. Two different policies are required for voice-only calls and video (voice stream + video stream) calls based on Classifications. Voice calls are protected from video calls because the voice stream in a video call is marked the same as the video stream in the video call.
- Video should not be deployed in links with less than 768 kbps of bandwidth.
- With link speeds greater than 768 kbps and with proper call admission control to avoid oversubscription, placing video traffic in a PQ does not introduce a noticeable increase in delay to the voice packets.
- There is no need to configure fragmentation for speeds greater than 768 kbps.
- cRTP is not recommended for video packets. (Because video packets are large, cRTP is of no help with video.)
- Voice and video traffic should occupy no more than 33% of the link capacity.
- When calculating video bandwidth, add 20% to the total video data rate of the call to account for overhead.

For more details on integrating Unified CME with Unified CM through H.323, refer to the *Cisco Unified CME Solution Reference Network Design Guide*, available at

CHAPTER 9

Dial Plan

Revised: July 31, 2012; OL-21733-18

The dial plan is one of the key elements of a Unified Communications system, and an integral part of all call processing agents. Generally, the dial plan is responsible for instructing the call processing agent on how to route calls. Specifically, the dial plan performs the following main functions:

- Endpoint addressing

Reachability of internal destinations is provided by assigning directory numbers (DNs) to all endpoints (such as IP phones, fax machines, and analog phones) and applications (such as voicemail systems, auto attendants, and conferencing systems)

- Path selection

Depending on the calling device, different paths can be selected to reach the same destination. Moreover, a secondary path can be used when the primary path is not available (for example, a call can be transparently rerouted over the PSTN during an IP WAN failure).

- Calling privileges

Different groups of devices can be assigned to different classes of service, by granting or denying access to certain destinations. For example, lobby phones might be allowed to reach only internal and local PSTN destinations, while executive phones could have unrestricted PSTN access.

- Digit manipulation

In some cases, it is necessary to manipulate the dialed string before routing the call; for example, when rerouting over the PSTN a call originally dialed using the on-net access code, or when expanding an abbreviated code (such as 0 for the operator) to an extension. Digit manipulation is also used to adapt the local dialing habits of a user to the global routes used to select a path for a call. For example, a French user may dial 0 00 1 212 555 1234 to call a number in New York. That same number is reachable to a caller in Chicago by dialing 9 1 212 555 1234. Both localized user inputs can be translated to a global form of +1 212 555 1234, so that a single route is used to select a path for the call.

- Call coverage

Special groups of devices can be created to handle incoming calls for a certain service according to different rules (top-down, circular hunt, longest idle, or broadcast). The dial plan information covered in this chapter applies to any Unified Communications deployment model; in particular, when deploying multi-site systems, the system designer should pay close attention to the site-specific dialing habits as well as site-specific routing of calls, such as the use of a gateway co-located with a specific group of users.

This chapter presents information intended to guide the system designer toward a dial plan that accommodates the legacy dialing habits of telephony users, while also taking advantage of new functionality afforded by the increasing integration between computing technology and telephony, such as dialing from contacts, click-to-call actions from computers and smart phones, and adoption of mobility-related features. The chapter is structured to offer information of the following main areas:

- [Planning Considerations, page 9-5](#)

This section analyzes the thought process involved in planning an IP Telephony dial plan, ranging from the number of digits used for internal extensions to the overall architecture of a company's internal dial plan. (Prerequisite: Some familiarity with dial plans in general.)

- [Design Considerations, page 9-11](#)

This section contains design and deployment guidelines related to multisite IP Telephony networks, endpoint addressing methods, approaches to building classes of service, and call coverage functionality. (Prerequisite: A working knowledge of Cisco Unified Communications Manager and Cisco IOS is recommended.)

- [Dial Plan Elements, page 9-78](#)

This section provides detailed background explanations of the elements of a Cisco Unified Communications dial plan. Covered topics include call routing logic, calling privileges, and digit manipulation techniques for various Cisco products. (Prerequisite: A working knowledge of Cisco Unified Communications Manager and Cisco IOS is recommended.) This section does not supersede product-specific documentation, nor does it present all the information available in the Cisco Unified Communications Manager help files. It does highlight some fundamental functionality elements essential to the understanding of design-related concepts presented herein.

For more details, refer to the *Cisco Unified Communications Manager System Guide*, the *Cisco IOS Voice, Video, and Fax Configuration Guide, Release 12.2*, and other product documentation available at

<http://www.cisco.com>

What's New in This Chapter

[Table 9-1](#) lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Dial Plan Architecture

Figure 9-1 illustrates the fundamental architecture of dial plans based on Cisco Unified Communications Manager (Unified CM).

Figure 9-1 Basic Dial Plan Architecture

The digit analysis function controls which calls are allowed to a user, to a gateway, or to an application. This function is where call privileges (also known as classes of service) are implemented. The following fundamental constructs are used to implement digit analysis:

- Patterns (such as directory number patterns and translation patterns)
Patterns are numerical representations of telephone numbers which, when matched, trigger call routing.
- Partitions
Partitions are used to separate patterns into logical groups. For instance, partitions allow the provisioning of two separate extensions set to 1000.
- Calling search spaces
Calling search spaces allow control over what groups of patterns a device (such as a phone) can access. For instance, devices at one site can be given access to the local partition containing extension 1000, without having access to a different site's extension 1000.

The call routing function controls the path selection for a call. This function is where IP trunks, PSTN trunks, or even connections to legacy PBXs, are chosen to carry a particular call. The call routing function also allows for the automated failover of calls from, for example, an IP connection as a first choice to a PSTN connection as a backup choice, in case the first choice is not available because no bandwidth is available or because a particular portion of the network is not available.

For both of these functions, Unified CM offers the system designer many tools with which digit manipulation can be effected and with which control over the call processing can be performed for different situations. For example, the system administrator can configure the types of calls allowed from a phone when it is roaming between different sites, how a call is processed when the phone is busy or when it rings with no answer, or which destinations a phone can use when call-forwarding all calls.

The fundamental elements of the individual features of this architecture are presented in multiple documents. The product-specific documentation, along with the help files in Unified CM, offer the most fundamental descriptions of the features. The section on [Dial Plan Elements, page 9-78](#), in this chapter offers the next level of functionality description. The section on [Design Considerations, page 9-11](#) in this document offers the system designer top-down architectural information to be considered when designing a dial plan.

High Availability for Dial Plans

In Cisco Unified CM, dial plan functionality is inherently made available by the clustering capabilities of Unified CM servers. All dial plan configuration is made redundant by the same mechanisms that allow other Unified CM services to be redundant. Specifically, Unified Communications Manager groups are used to control phones, route lists, and gateways, so that a single failure of a Unified CM server does not render any dial plan function unavailable.

For call paths relying on external trunks, an additional level of availability is afforded by the use of alternate routes. For instance, a route list can be used to establish a primary path to a given off-cluster destination, followed by a secondary or even a tertiary choice. If the higher-order choice (such as an IP trunk) is not available, the next order choice will be attempted, until either the call is established successfully or all preconfigured choices have been exhausted.

For calls between on-cluster endpoints, such as calls between two IP phones, if the IP path is not available due to a network failure, the Call Forward Unregistered feature is invoked, allowing the routing of the call through an alternate network such as the PSTN. If the IP path is not available due to lack of bandwidth on the network, the Automated Alternate Routing (AAR) feature is invoked to route the call through an alternate network.

External dial plan resolution subsystems such as H.323 gatekeepers or SIP proxies should also be provisioned with applicable redundancy capabilities, to offer yet another level of high availability.

Capacity Planning for Dial Plans

The configuration of dial plans is typically not onerous on the Unified CM configuration when compared to other capacity-affecting aspects such as the number of gateways, the number of CTI connections, or the rate of call attempts (BHCA). The Cisco Unified Communications Sizing Tool does incorporate dial plan information in its calculations for system provisioning. This tool is available to Cisco employees and partners, with proper login authentication, at <http://tools.cisco.com/cucst>.

Planning Considerations

The dial plan is the most fundamental attribute of a telephony system. It is at the very core of the user experience because it defines the rules that govern how a user reaches any destination. These rules include:

- Extension dialing — how many digits must be dialed to reach an extension on the system
- Extension addressing — how many digits are used to identify extensions
- Dialing privileges — allowing or not allowing certain types of calls
- Path selection — for example, using the IP network for on-net calls, or using one carrier for local PSTN calls and another for international calls
- Automated selection of alternate paths in case of network congestion — for example, using the local carrier for international calls if the preferred international carrier cannot handle the call
- Blocking of certain numbers— for example, pay-per-minute calls
- Transformation of the called number — for example, retaining only the last five digits of a call dialed as a ten-digit number
- Transformation of the calling number — for example, replacing a caller's extension with the office's main number when calling the PSTN

A dial plan suitable for an IP telephony system is not fundamentally different from a dial plan designed for a traditional TDM telephony system; however, an IP-based system presents the dial plan architect with some new possibilities. For example, because of the flexibility of IP-based technology, telephony users in separate sites who used to be served by different, independent TDM systems can now be included in one, unified IP-based system. These new possibilities afforded by IP-based systems require some rethinking of the way we look at dial plans. This section examines some of the elements that the system planner must consider to properly establish the requirements that drive the design of the dial plan.

Dialed Pattern Recognition

Digit strings dialed by a user on a telephone generally follow patterns. For instance, many enterprises implement a five-digit abbreviated dialing pattern for calls made within the same office location. Also, many enterprises rely on a single-digit access code to represent outside dialing, followed by some quantity of digits to reach a local PSTN number or a long-distance PSTN number (for example, 9 followed by seven digits to reach a local number, or 9 followed by 1 and ten digits to reach a long-distance destination).

The system administrator must plan the system's recognition of these patterns to ensure that the system will act promptly upon detection of a string that corresponds to a predetermined pattern so that users experience no (or minimal) post-dialing delay.

For phones using the Skinny Client Control Protocol (SCCP) and for SIP phones using the Key Press Markup Language (KPML) during dialing, you can implement pattern recognition in Cisco Unified Communications Manager (Unified CM) by configuring route patterns, translation patterns, phone DNs, and so forth. With each digit dialed by the user, the phone sends a signaling message to Unified CM, which performs the incremental work of recognizing a matching pattern. As each key press from the user input is collected, Unified CM's digit analysis provides appropriate user feedback, such as:

- Playing dial tone when the phone first goes off-hook
- Stopping dial tone once a digit has been dialed

- Providing secondary dial tone if an appropriate sequence of digits has been dialed, such as when the off-net access code 9 is dialed

Once digit dialing is completed, Unified CM provides user feedback in the form of call progress tones, such as ringback tone if the destination is in the alerting stage or reorder tone if the destination is invalid.

IP phones running the Session Initiation Protocol (SIP) can be configured with pattern recognition instructions called SIP dial rules. When used, they accomplish the bulk of the task of pattern recognition within the phone. Once a pattern is recognized, the SIP phone sends an invitation to Unified CM to place a call to the number corresponding to the user's input. That action, called a SIP INVITE, is subjected to the Unified CM dial plan in the same way a call from an IP phone running the SCCP protocol would be, except that Unified CM's digit analysis is presented with a completed dial string (that is, all of the digits entered by the user are presented as a block to Unified CM for processing). In this mode of operation, user feedback during the dialing of the digit string is limited to what the phone can provide (see [SIP Dial Rules, page 9-84](#)). Once the string has been composed, user feedback can still be provided by Unified CM in the form of call progress tones.

Grouping by Dialing Habits

Most telephony users are used to dialing telephone numbers according to local habits. These are composed of various dialing rules applicable to calls placed to destinations within an office location (intra-site calls), destinations within a company but between different sites (inter-site calls), and destinations outside the company (off-net calls). The form used in dialing these different types of calls varies according to user preferences and local PSTN dialing requirements.

On-Net versus Off-Net Dialing

Calls that originate and terminate on the same telephony network are considered to be on-network (or on-net). By contrast, if a call originates in company A and terminates at company B, it probably has to be routed through different telephony networks: first company A's network, followed by the PSTN, and finally into company B's network. From the caller's perspective, the call was routed off-network (or off-net); from the called party's perspective, the call originated off-net.

In TDM systems, the on-net boundaries of a telephony system are established by the PBX or Centrex system, and they typically do not extend outside of a single site. When they do, they typically do not include sites not immediately on the periphery of a large system hub.

One of the key attributes of IP telephony is its ability to expand the boundaries of calls that can be considered on-net. For instance, telephony users in an enterprise with six dispersed branch offices might be used to reaching one colleague with abbreviated dialing (for example, four-digit dialing) if the called party is located in the same site but dialing a full PSTN number to reach another colleague located in a different site. With an IP-based system where all users are served by the same IP network, it now becomes economically feasible to unite all six branches under a four-digit abbreviated dialing plan, with the IP network as the preferred path and automated overflow to the PSTN as a secondary path if the IP network is congested.

Abbreviated Dialing

Consider an extension with direct inward dial (DID) capability, which can be reached directly from the PSTN. An off-net PSTN caller has to dial the fully qualified PSTN number (for example, 1 415 555 1234) to reach a DID extension. An on-net caller might, however, prefer the ability to reach that same extension by simply dialing the last few digits of the DID number. In a four-digit abbreviated dial plan, the on-net caller would dial only 1234 in this example to reach the same extension.

Dialing can typically be separated into four types:

- Intra-site, on-net abbreviated dialing

Many systems accommodate four- or five-digit dialing within a site. For example, Cisco employees located in San Jose, California can call the main Cisco reception number using the five-digit string 64000.

- Inter-site, abbreviated on-net dialing

For example, Cisco employees at any Cisco office can dial the San Jose reception number as 8 526 4000. The digit 8 serves as the inter-site access code, and 52 serves as the site code for San Jose.

This form is shorter than the alternative of using an off-net form to route the calls on-net (for example, allowing Cisco employees in Canada to reach the Cisco reception in San Jose by dialing 9 1 408 526 4000 while routing the call on-net). Even though the dialing form is similar to that used to reach an off-net destination, the system is configured to keep calls to on-net destinations dialed in the off-net form within the system.

- Inter-site, off-net dialing

Routing of calls between sites can be handed off to the PSTN. For example, calls made from one site in San Francisco to another site in New York can be dialed either in the on-net or off-net form described above, but routed off-net through the PSTN.

- Off-net dialing

For calls where the destination is off-net and outside of the company's dial plan, the Unified Communications system must offer a simple, locally significant dialing form to the users.

Avoiding Overlap of Extension Dialing

A telephony system must be configured so that any extension can be reached in an unambiguous manner. To accomplish this goal, the dial plan must satisfy the following requirements:

- All on-net extension dialing must be globally unique. For instance, in a system using an abbreviated four-digit on-net dial plan, there cannot be an extension 1000 in site A and another extension 1000 in site B if the requirement is to reach either of them by dialing only four digits from site C.
- There cannot be any partial overlap between different dial strings.
 - For instance, if 9 is used as an off-net access code in a four-digit abbreviated dial plan (for example, to make PSTN calls), there cannot be any extensions in the 9XXX range. Attempting to do so would create situations where calls are not routed immediately. For example, if a user dialed 9141, the system would have to wait for either more digits (if the user were dialing 9 1 415 555 1234, for example) or the expiration of the interdigit timeout before routing the call to extension 9141. Likewise, if an operator code is used (for example, 0), the entire 0XXX extension range would have to be excluded from a four-digit uniform dial plan.
 - There cannot be overlapping strings of different length. For example, a system with extensions 1000 and 10000 would force users to wait for the interdigit timeout when they dial 1000.

Dialing String Length

The number of dialable extensions determines the quantity of digits needed to dial extensions. For example, a four-digit abbreviated dial plan cannot accommodate more than 10000 extensions (from 0000 to 9999). If 0 and 9 are reserved as operator code and off-net access code, respectively, the number range is further reduced to 8000 (1000 to 8999).

Uniform On-Net Dial Plan

A dial plan can be designed so that all extensions within the system are reached in a uniform way; that is, a fixed quantity of digits is used to reach a given extension from any on-net origination point. Uniform dialing is desirable because of the simplicity it presents to users. A user does not have to remember different ways to dial a number when calling from various on-net locations.

For example, if phone A is reached by dialing 1234 from any on-net location, whether the calling phone is in the same office or at a different site, the enterprise's dial plan is deemed uniform.

When the enterprise consists of few sites, this approach can be used with few complications. The larger the enterprise, in terms of number of extensions and sites, the more of the following challenges it faces in designing a uniform dial plan:

- The number of extensions can exceed the range afforded by the quantity of digits being considered for the dial plan. For instance, if more than 8000 extensions are required (considering the exclusions of the 0XXX and 9XXX ranges), the system may require that an abbreviated dial plan use more than four digits.
- Matching on-net abbreviated extensions to DID numbers means that, when a new DID range is obtained from a local exchange carrier, it cannot conflict with the pre-existing on-net abbreviated dial ranges. For example, if the DID range of 415 555 1XXX exists in a system using a four-digit uniform abbreviated dial plan, and DID range 650 556 1XXX is also being considered, it might be desirable to increase the quantity of digits for on-net dialing to five. In this example, the five-digit on-net ranges 51XXX and 61XXX would not overlap.
- Most systems require the exclusion of certain ranges due to off-net access codes and operator dialing. In such a system where 9 and 0 are reserved codes, no dial plan (uniform or not) could accommodate on-net extension dialing that begins with 9 or 0. This means that DID ranges could not be used if they would force the use of 9 or 0 as the first digit in the dial plan. For instance, in a five-digit abbreviated dial plan, the DID range 415 559 XXXX (or any subset thereof) could not be used. In this example, alternatives include increasing the length of the abbreviated dialing to six or more digits, or avoiding any DID range whose last five digits start with 9, or even not requiring that the DID numbers match the on-net abbreviated extensions.

Once a given quantity of digits has been selected and the requisite ranges have been excluded (for example, ranges beginning with 9 or 0), the remaining dialing space has to be divided between all sites.

Most systems require that two ranges be excluded, thus leaving eight different possibilities for the leading digit of the dial range. [Table 9-2](#) exemplifies the distribution of the dialing space for a typical four-digit uniform dial plan.

Table 9-2 *Distribution of Digits in a Typical Four-Digit Uniform Dial Plan*

| Range | Use | DID Ranges | Non-DID Ranges |
|----------|--|------------------|----------------|
| 0XXX | Excluded; 0 is used as off-net access code | | |
| 1XXX | Site A extensions | 418 555 1XXX | N/A |
| 2XXX | Site B extensions | 919 555 2XXX | N/A |
| 3XXX | Site C extensions | 415 555 30XX | 3[1-9]XX |
| 4[0-4]XX | Site D extensions | 613 555 4[0-4]XX | N/A |
| 4[5-9]XX | Site E extensions | 450 555 4[5-9]XX | N/A |
| 5XXX | Site A extensions | 418 555 5XXX | N/A |
| 6XXX | Site F extensions | 514 555 6[0-8]XX | 69XX |
| 7XXX | Future | XXX XXX 7XXX | 7XXX |
| 8XXX | Future | XXX XXX 8XXX | 8XXX |
| 9XXX | Excluded; 9 is used as off-net access code | | |

For the example in [Table 9-2](#), the various sites were assigned numbers in the following ways:

- Site A, the company headquarters, requires more than 1000 extensions, so two entire ranges of numbers have been retained (1XXX and 5XXX). Note that the corresponding DID ranges must also be retained from the site's local exchange carrier.
- Site B has been assigned an entire range (2XXX), allowing for up to 1000 extensions.
- Site C was also assigned an entire range, but it has been split between 100 DID extensions (415 555 30XX) and up to 900 non-DID extensions. If growth requires more extensions for DID, any unassigned numbers from the non-DID range could be used.
- Sites D and E were each assigned 500 numbers from the 4XXX range. Note that their corresponding DID ranges must match each of the site's respective portions of the 4XXX range. Because the DID ranges are for different sites (probably from different PSTN service providers), more coordination effort is required to split ranges between sites. As the quantity of sites assigned within a given range increases, it becomes increasingly difficult (sometimes impossible) to make full use of an entire range.
- Site F's range is split between 900 DID numbers (6[0-8]XX) and 100 non-DID numbers (69XX).
- The ranges 7XXX and 8XXX are reserved for future use.

When implementing a new dial plan, one of the main desires of any planner is to avoid having to change phone numbers. In addition, the extension ranges of any existing phone systems may have overlapped without any problems in the past, but they could be incompatible with a uniform dial plan.

Variable Length On-Net Dial Plan

Systems with many sites or overlapping site extension ranges can benefit from the use of a variable-length dial plan with the following characteristics:

- Within a site, the system retains the use of abbreviated dialing for calls to on-net extensions (for example, four-digit dialing).
- Between sites, users dial an access code followed by a site code and the destination's on-net extension.
- Off-net calls require an access code followed by a PSTN number.

The use of access and site codes (see [Table 9-3](#)) enables the on-net dial plan to differentiate between extensions that would overlap if a uniform abbreviated dial plan were implemented.

Table 9-3 *Typical Use of Site Codes*

| Site Code | Range | Use | DID Ranges | Non-DID Ranges |
|-----------|-------|-------------------|--------------|----------------|
| 1 | 1XXX | Site A extensions | 418 555 10XX | 1[1-9]XX |
| 2 | 1XXX | Site B extensions | 919 555 1XXX | N/A |
| 3 | 1XXX | Site C extensions | 907 555 1XXX | N/A |

In [Table 9-3](#), sites A, B, and C are independently assigned the four-digit range 1XXX. For calls from site A to site B under the old telephony system, the calls had to be routed as off-net calls. With the new system, these calls can be dialed as on-net calls.

From site A, users simply dial 1234 to reach extension 1234. But from site B, the dial plan must accommodate the ability to reach extension 1234 at site A without conflicting with site B's own extension 1234. Therefore, each site is assigned a site code.

From site B, merely dialing the combination of site A's code with the desired extension is not feasible: in this case because 11234 would partially overlap with site B's extension 1123, thus causing interdigit timeout issues. If, instead, we assign 8 as an inter-site on-net access code, this would allow site B to dial 81234 to reach site A's extension 1234.

The following factors determine the quantity of digits required to dial an on-net, off-site extension:

- One digit for the inter-site access code
- N digits for the site code, where N is chosen to satisfy the quantity of site codes required (For example, if a system has 13 sites, then a minimum of two digits are required for the site code.)
- The quantity of digits required by the destination site's local dial plan

For example, a system with 75 sites which each use four-digit abbreviated dialing would require a format of 8 + SS + XXXX, where 8 is the on-net access code, SS is a two-digit site code, and XXXX is a four-digit extension number, giving a total of seven digits.

On-Net and Off-Net Access Codes

It is common practice in most enterprise telephony systems to dedicate a digit (for example, 9) as an off-net access code to steer calls to an off-net destination. In the variable-length on-net dial plan, another steering digit (for example, 8) is also required as an on-net access code to dial calls to on-net extensions

at other sites. These two access codes, along with the use of an operator access code (for example, 0), implicitly exclude three of the ten possible leading digits of any dialed string. This restriction might not prove convenient for either of the following reasons:

- The users would be required to know the difference between on-net and off-net destinations, and to select the proper access code.
- The exclusion of three entire dialing ranges can become too restrictive or can conflict with some pre-assigned extension ranges. For instance, if a site already uses an abbreviated dialing range beginning with 8, the use of that same digit as an access code would require a change.

In systems where the same off-net access code (for example, 9) is already in use by all sites, it might be desirable to use the same code for both off-net and on-net off-site destinations. This approach has two main implications:

- To avoid partial overlap and interdigit timeout situations, the quantity of digits expected after the access code should be uniform.
- The telephony system must be able to recognize all on-net numbers dialed as off-net numbers and to route them over the IP network. This task can be simple for small systems with only one Unified CM cluster but complex for large systems with multiple Unified CM clusters.

Plan Ahead

Implementing an IP-based system might require changing certain existing user practices. Although it is preferable to plan a new system so that the implementation is as transparent as possible to users, dialing habits might have to be adapted to accommodate the integration of multiple sites that used to be on separate telephony systems. For instance, adapting to a new global, enterprise-wide dial plan might require changing the way a user reaches another user at a different site, the quantity of digits used to make intra-site calls and, in some cases, the extension numbers. To avoid exposing users to multiple generations of dial plan changes, try to anticipate expansion of the enterprise, which could result in the addition of sites in different dialing regions, an increase in the required number of on-net extensions, PSTN renumbering (for example, an area code split), or business expansion into different countries.

Design Considerations

This section presents the following dial plan design considerations for multisite deployments:

- [Globalized Design Approach, page 9-12](#), covers guidelines and best practices that apply to deployments using the globalization dial plan features of Cisco Unified Communications Manager.
- [Call Control Discovery, page 9-24](#), explains how the Service Advertisement Framework (SAF) Call Control Discovery (CCD) service allows clusters to advertise their own hosted DN ranges into the network as well as to subscribe to advertisements generated by other call agents in the network.
- [Dial Plan Considerations for the Intercompany Media Engine, page 9-33](#), describes the Cisco Intercompany Media Engine (IME), which allows participating enterprises to route calls over the Internet between them.
- [Design Guidelines for Multisite Deployments, page 9-35](#), covers guidelines and best practices that apply to all multisite deployment models.
- [Choosing a Dial Plan Approach, page 9-38](#), presents the various approaches to organizing a dial plan for uniform versus variable-length on-net dialing and, for this second option, partitioned versus flat addressing.

- [Deploying Dialed Pattern Recognition in SIP Phones, page 9-52](#), explains how SIP dial rules can be employed to enable SIP phones to recognize certain dialing patterns.
- The following sections analyze in detail two dial plan approaches and provide configuration guidelines for each:
 - [Deploying Uniform On-Net Dial Plans, page 9-40](#)
 - [Deploying Variable-Length On-Net Dial Plans with Flat Addressing, page 9-43](#)
- The following sections present two alternative ways of configuring classes of service within Unified CM:
 - [Building Classes of Service for Unified CM with the Traditional Approach, page 9-54](#)
 - [Building Classes of Service for Unified CM with the Line/Device Approach, page 9-58](#)
- [Building Classes of Service in Cisco IOS with H.323, page 9-71](#), explains how to implement classes of service within a Cisco IOS router running the H.323 protocol.
- [Deploying Call Coverage, page 9-75](#), provides guidelines and best practices for implementing call coverage functionality using hunt lists and line groups with Unified CM.

Globalized Design Approach

This section describes dial plan features used to implement simplified call routing based on globalized numbers. The simplification is primarily obtained through the use of a single routing structure for off-net calls, no matter the source of the call. For example, two users in separate countries could use the same route patterns to carry calls to their respective local gateways, instead of requiring site-specific route patterns, each configured to match their respective dialing habits.

The main architectural approach used to attain this globalization can be summarized as follows:

- When a call enters the system, the destination number and the calling number are accepted in their local format but are then immediately globalized by the system.
- Once globalized, the called number is used to route the call to its destination through the use of route patterns expressed in the global form. The global form may be a combination of a global internal, enterprise-specific form such as 81001234 and/or a globalized PSTN representation of a DID number, such as the +E.164 form (for example, +12125551234).
- Once a destination has been identified, the calling and called numbers are localized to the form required by the endpoint, the network, or the system to which the call is to be delivered.

Thus, the guiding principle is:

Accept localized forms upon call ingress, and globalize them; route the call based on the globalized form; and localize the call to comply to the form required by the destination.

Cisco Unified Communications Manager (Unified CM) offers the following dial plan globalization capabilities:

- [Local Route Group, page 9-13](#)
- [Support for + Dialing, page 9-13](#)
- [Calling Party Number Transformations, page 9-14](#)
- [Called Party Number Transformations, page 9-14](#)
- [Incoming Calling Party Settings \(per Gateway\), page 9-14](#)
- [Logical Partitioning, page 9-15](#)

Together, these new features enable a Unified CM system to:

- Route calls based on the physical location context of the caller.
- Represent calling and called party numbers in a global form such as that described by the International Telecommunications Union's E.164 recommendation.
- Present calls to users in a format based on local dialing habits.
- Present calls to external networks (for example, the PSTN) in a manner compatible with the local requirements for calling party number, called party number, and their respective numbering types.
- Derive the global form of the calling party number on incoming calls from gateways, based on the calling number digits and the numbering type.
- Control the establishment of calls, as well as the initiation of mid-call features, between endpoints based on policies acting on each endpoint's geolocation, to comply with regulatory requirements in certain countries.

Local Route Group

The Local Route Group offers the ability to create patterns that route off-net calls to a gateway chosen for its proximity to the originating party. For example, a single pattern can be defined to route off-net, intra-country calls for all sites within a given country. Phones at every site can be configured to match this pattern, which then would route the call based on the Local Route Group associated with the calling phone. This allows a phone in site 1 to route calls through the gateway at site 1, while a phone at site 2, still using the same pattern, would route calls through the gateway at site 2. This feature simplifies the configuration of site-specific routing of off-net calls when compared to releases prior to Unified CM 7.0.

Support for + Dialing

Telephone numbers can use the + sign to represent the international dialing access code needed to reach a destination from different countries. For example, +1 408 526 4000 is the international notation for Cisco's main corporate office in the United States. To call this number, an enterprise telephony user from France typically would have to dial 0 00 1 408 526 4000, whereas a caller from the United Kingdom would have to dial 9 00 1 408 526 4000. In each case, + must be replaced with the appropriate off-net access code (as required by the enterprise telephony system) and international access code (as required by the PSTN carrier) relevant for each caller.

The system can route calls directly to destinations defined with +. For example, a user could program a WiFi phone's speed-dial entry for Cisco's main US office as +1 408 526 4000 and dial it directly when roaming in France, the UK, or anywhere else in the enterprise. In each location, the system would translate the destination number into the locally required digit string to allow the call to be routed properly.

Likewise, phone numbers dialed from a dual-mode phone are routable directly over the mobile carrier network when the phone is in GSM mode, or over the enterprise network when the phone is in WiFi mode, if the called number is represented in the +E.164 form. This allows a user to store a single destination number for a particular contact entry, and dial it no matter to which network the phone is currently attached.

This feature allows users to rely on the system to interpret phone numbers represented in the form described by the ITU E.164 recommendation and to route them properly without requiring the user to edit the number to adapt it manually to the local dialing habits.

Calling Party Number Transformations

The calling party number associated with a call routed through Unified CM might sometimes have to be adapted before it is presented to a phone or to the PSTN. For example, a call from +1 408 526 4000 might have to be presented as coming from 408 526 4000 if the destination phone is in the US or Canada, whereas a call from the same number might have to be presented to a destination phone in France as coming from 00 1 408 526 4000. This is mainly to offer users a presentation of the calling party in the customary form offered by their local PSTN, to maintain user familiarity with identification of the origin of calls ringing in.

Calls offered to gateways might require that the calling party number be manipulated to adapt it to the requirements of the telephony carrier to which the gateway is connected. For example, a call from +1 408 526 4000 offered to a gateway located in France might have to represent the calling number as 1 408 526 4000, with a Calling Party Number Type set to International. Similarly, a call from the same number offered to a gateway located in Canada might have to be represent the calling party number as 408 526 4000, with the Calling Party Number Type set to National.

This feature allows the calling party number to be adapted from the form used to route calls within the Unified CM system, to the form required by phone users or off-cluster networks.

**Note**

Some service providers might not be able to accept calling party numbers representing foreign telephone numbers, due to either technical limitations of their equipment, company policies, or governmental regulations. If calling party numbers cannot be accepted by the provider, the provider will either screen and overwrite the calling party number or reject the call. In some networks two calling party identities can exist for a call: user provided and network provided.

Called Party Number Transformations

The called number associated with a call routed through Unified CM might sometimes have to be adapted before it is presented to the PSTN. For example, a call placed to +1 408 526 4000 requires the called party number be transformed to 1 408 562 4000 with the numbering type set to National if it egresses to the PSTN through a gateway located in Canada. If the same call were re-routed toward a French gateway, the called party number would have to be transformed to 00 1 408 526 4000 with the numbering type set to International.

By manipulating the called party number as well as setting the numbering type for the called number, this feature allows the called party number to be adapted to the form required by off-cluster networks.

Incoming Calling Party Settings (per Gateway)

The calling party number associated with a call as it enters a gateway through a digital interface (for example, ISDN PRI) is also associated with an attribute identifying the calling number's numbering type as either Unknown, Subscriber, National, or International. When combined, the incoming call's calling number and its associated numbering type allow the system to determine the identity of the caller by stripping and prefixing appropriate digits to the incoming call's calling party number. Incoming Calling Party Settings allow the system to apply separate combinations of stripped and/or prefixed digits to the calling party number for each of the four calling number types.

For example, assume two calls come into a gateway located in Hamburg, Germany. Both feature a calling party number of 691234567. The first call is associated with a numbering type of Subscriber. This means the caller is located in Hamburg, thus the city code of Hamburg (40) is implied, as is the country code

of Germany (49). Therefore, a full representation of the incoming call is +49 40 69 1234567, which can be obtained by prefixing +49 40 to the incoming call's calling party number for numbering type Subscriber.

The second call is associated with a numbering type of National. This means the caller is located in Germany, and the number already contains the applicable city code (69 is the city code of Frankfurt), but the country code of Germany (49) is implied. A full representation of the second incoming call is thus +49 69 1234567, which can be obtained by prefixing +49 to the second incoming call's calling party number for numbering type National.

This feature allows the system to globalize incoming calls' calling party numbers based on the incoming party number and numbering type. In previous versions of Unified CM, these settings were implemented through the use of cluster-wide service parameters. Unified CM 7.0 introduced per-gateway settings for this feature, which allow different prefixes for each numbering type to be applied to calls entering different gateways. The settings can be configured on the gateway itself, on the gateway's device pool, or through the cluster-wide service parameters, in order of precedence. A blank entry signifies that no digits will be prefixed; to inherit the settings from the lower-precedence setting, the entry must be set to **Default**.

For all calls within a given numbering type, the prefix and strip-digits operations are applied, with no consideration for the calling party number originally received.

**Note**

Calls coming from SIP trunks or from SIP gateways are all associated with calling party numbering type Unknown.

In particular, the SIP protocol as implemented on SIP gateways and SIP trunks effectively places the incoming calling party number of all calls in the numbering type Unknown. This prevents Unified CM from applying different calling party number modifications for different calling party number categories.

Unified CM 7.1 and later releases allow the use of Incoming Calling Party Settings Calling Search Spaces (CSSs) for each number type. These CSSs are used to apply modifications to the calling party based on Calling Party Transformation Patterns. These patterns use regular expressions to match a subset of cases, followed by separate digit manipulation operations for each subset. This new capability enables Unified CM to apply different calling party number modifications for different calling party number categories. For example, a SIP trunk used to connect to the PSTN could present calls from local, national, and international parties with the numbering type set to Unknown; then each call's calling party number would be used to match a Calling Party Transformation Pattern in the trunk's CSS associated with number type Unknown, thus allowing Unified CM to apply different calling party number modifications for different calling party number categories.

Logical Partitioning

Some countries such as India have Telecom regulations requiring an enterprise's voice infrastructure to use the local PSTN exclusively when connecting calls outside the enterprise. This requires that the voice system be partitioned logically into two systems: one for Closed User Group (CUG) communications within the enterprise, and a second one to access the local PSTN. A call from an enterprise user in location A to another enterprise user in location B could be made within the CUG system; however, a call from an enterprise user in location A to a PSTN destination, no matter the location, must be made through local access to the PSTN in location A.

While existing dial plan tools can be used to prevent a call from completing if it were placed between endpoints outside the CUG, they are not able to prevent new call legs from being established while the call is in progress. For example, assume that an enterprise user in London, England, calls a co-worker in Delhi, India, over the enterprise network. Once the call is established, the user in Delhi conferences in

a customer in India, from the same line on which the call from London was received. This mid-call addition (on the same line) of a destination outside the closed user group is not preventable solely by using the existing dial plan tools in Unified CM (such as Calling Search Spaces and Partitions). Unified CM 7.1 and later releases offer logical partitioning functionality, which allows the establishment and enforcement of policies that apply not only to the initial onset of calls, but also to mid-call features such as conference and transfer.

The combination of globalization features available in Unified CM allows the system to accept calls in the local format preferred by the originating users and carriers, to route the calls on-net using global representations of the called and calling numbers, and to deliver the calls to phones or gateways in the local format required by the destination user or network. These three aspects of the dial plan design approach can be summarized as:

- [Localized Call Ingress, page 9-16](#)
- [Globalized Call Routing, page 9-20](#)
- [Localized Call Egress, page 9-20](#)

Localized Call Ingress

Unified Communications systems with multiple sites located in different regions or countries must satisfy different dialing habits from users and different signaling requirements from the service providers to which gateways are connected. Each local case can be different; this requires that the system be able to "translate" the local dialing habits and signaling requirements into a form that allows for the calls to be routed properly. Therefore, the systems must not only provide for many localized ingress requirements but also yield a single globalized form of any destination pattern.

Localized Call Ingress on Phones

Calls originating on endpoints such as phones or video terminals are typically dialed by users accustomed to a certain set of local dialing habits. Enterprise users in the US are used to dialing 9 1 408 526 4000 to reach Cisco's world headquarters in San Jose, California, whereas users in the UK would dial 9 00 1 408 526 4000 and users in France would dial 0 00 1 408 526 4000. Each of those three dialing forms features an enterprise off-net access code (9 for the US and UK, 0 for France), an international access code (00 for the UK and France, none needed for the US because the destination is intra-country), and a representation of the destination number, including the country code (1). Each of those three groups of users are dialing the same globalized destination number (+1 408 526 4000), but each with their own local dialing habits. In each of the three cases, + can be used as a global abstraction of the local dialing habits.

An enterprise telephony system must allow for the local dialing customs of users to be interpreted correctly. In all three cases above, the users are using a local dialing form to reach a common destination. The system must be configured to recognize user input and then route and deliver the call to the proper destination. Because the call can originate in many different forms, the system must provide pattern recognition to match each of those different forms.

Unified CM's translation patterns are used to convert localized user input as dialed from phones, to the global form used to route the calls within the Unified Communications system. These patterns must allow all localized dialing habits to be recognized, including:

- Intra-site on-net dialing
- Off-net local, national, and international dialing
- Local services such as emergency calling, directory and operator services
- Carrier selection codes, and so forth

For the three example calls mentioned above, the following translation patterns would be configured in separate partitions and placed in the calling search space (CSS) of:

- US phones: 9.1!, strip pre-dot, prefix +
- UK phones: 900.!, strip pre-dot, prefix +
- French phones: 000.!, strip pre-dot, prefix +

In each case, the locally significant dialed string is translated into a globalized form of +1 408 526 4000.

For on-net destinations, such as calls between two users in the same site or calls between users at different sites, translation patterns should be used to derive the globalized on-net form of the destination number. This is applicable whether on-net dialing is achieved using site codes or the fully qualified PSTN address of the phone is used as the on-net number.

For example, assume two users in the San Jose site use five-digit abbreviated dialing to call each other. User A calls User B by dialing 51234. A translation pattern specific to this site is configured to recognize any five-digit string beginning with 5 and to translate the called number to the globalized on-net form of 800151234. The translation pattern is configured as: 5XXXX, prefix 8001.

The translation pattern must be site-specific (included in the CSS of only the phones in site San Jose) to avoid confusion with extension 51234 at other sites in the system. In the example above, the on-net global form is implemented using an inter-site access code (8) and a site code (001). If the system used the fully qualified PSTN address of the phone as the on-net number, the translation pattern would instead prefix +140855, to yield a globalized on-net number of +1 408 555 1234.

**Note**

Variable Length On-net Dialing (VLOD) with flat addressing is the recommended approach where possible, because it simplifies configuration. While VLOD with partitioned addressing is supported, it entails extra configuration complexity.

Phone Calling Party Number Globalization

The calling party number for calls originating from phones is set to the number configured as the directory number of the line from which the call originates. Following the concepts of a globalized dial plan design approach, the calling party information of all calls should be globalized. If the DN format is not identical to the format chosen for the globalized internal calling party information (typically +E.164), then the correct handling of calling party information can be achieved by either making sure that all calling party transformations implemented in the system accept both the directory number format and the globalized +E.164 format as input or by making sure that the calling party information for calls from phones is also correctly set to +E.164. This can be achieved by setting the external phone number mask on the line to +E.164 and then setting the **use external phone number mask** option in a translation pattern that is matched. Using the **use external phone number mask** option on a route pattern will not work because device-level calling party transformations using a calling party transformation calling search space on the gateway or the gateway's device pool override the calling party transformation configured on route patterns, so that the input to the calling party transformation calling search space would be the untransformed directory number.

Allowing Call Ingress Using the Global Form

Phones can also provide dialed strings in the global form of the dialed number. In the case of software endpoints such as Cisco Unified Personal Communicator, + dialing can be accommodated directly from the Telephony User Interface (TUI) of the phone or can be derived from click-to-dial actions taken by the user. On Type-B IP phones, dialing + from the keypad can be achieved by pressing and holding either

the * or 0 key, depending on the phone model. Also, the missed and received calls directories can contain entries where the number includes a +. As the user dials from those directories, the resulting call into Unified CM will have a called number beginning with +.

**Note**

For definitions of Type-A and Type-B phones, see [Dial Plan Elements](#), page 9-78.

To allow such calls to be handled properly by the phone's dial plan, you must ensure that not only the localized form of dialed numbers is allowed, but also the globalized form. [Figure 9-2](#) illustrates how to accomplish this.

Figure 9-2 Allowing Localized and Globalized TUI

In [Figure 9-2](#), a US IP phone user dials 9011496100773, connects to the destination in Germany, and then releases the call. The called party calls the US user back, connects, and then releases the call. The US user then goes into the Received calls directory, selects the entry for the last received call (+49 6100 773), and presses Dial. In this example, the US user initiates two separate calls to the same destination. For the first call, the form of the destination number localized for US dialing habits is used, and the corresponding translation pattern 9011.! is matched by the user's input. Once translated, the route pattern \+[^1]! is used to route the call. For the second call, the globalized form of the destination number is used and the route pattern \+[^1]! is used directly.

The calling search spaces configured for each site should generally allow for:

- Localized intra-site dialing habits of the site
- Localized off-net dialing habits of the users at the site
- Applicable local telephony services such as emergency calls, directory and operator services
- The globalized form of on-net and off-net numbers

Except for the first item in the list above, the localized patterns used to achieve call routing can typically be reused between sites in the same dialing domain. (All sites in France dial off-net numbers the same way, as do all sites in the UK, in the US, and so forth.) However, each site must be configured with its own intra-site abbreviated dialing translation patterns so that there will be no confusion when a user in San Jose, for example, dials 51234, compared to when a user in New York dials 51234. The translation from the abbreviated intra-site form of a number to the globalized on-net form of the same destination must be achieved with site-specific translation patterns, which requires that each site be configured with its own site-specific calling search space.

Localized Call Ingress on Gateways

The called and calling numbers delivered into the Unified Communications system by external networks (for example, the PSTN) are typically localized. The form of the numbers may vary, depending on the service provider's configuration of the trunk group. As a gateway is connected to a PSTN trunk group, the system administrator must work with the PSTN service provider to determine the applicable signaling rules to be used for this specific trunk group. As calls are delivered into the system from the trunk group, some of the information about the calling and called numbers will be provided explicitly and some of it will be implied. Using this information, the system must derive the calls' globalized calling and called party numbers.

The globalization of the called party number can be implemented through one of the following methods:

- In the gateway configuration, configure **Call Routing Information > Inbound Calls**, where the quantity of significant digits to be retained from the original called number and the prefix digits to be added to the resulting string are used to globalize the called number. The prefix digits should be used to add the applicable + sign and country, region, and city codes.
- Place translation patterns in partitions referenced by the gateway's calling search space. The translation patterns should be configured to match the called party number form used by the trunks connected to the gateway, and should translate it into the global form. The prefix digits should be used to add the applicable + sign and country, region, and city codes.
- On H.323 trunks and gateways, use the incoming call's called party transformation settings available on the gateway and on the gateway's device pool. There you can define strip and prefix digit instructions or alternatively configure a called party transformation calling search space per numbering type.

The globalization of the calling party number should be implemented by using the Incoming Calling Party Settings configured either on the gateway directly or in the device pool controlling the gateway.

Note

If the administrator sets the prefix to **Default**, this indicates call processing will use the prefix at the next level setting (device pool or service parameter). Otherwise, the value configured is used as the prefix unless the field is empty, in which case there is no prefix assigned.

For example, assume a call is placed to Cisco's US headquarters (+1 408 526 4000) from a US number, and the call is delivered to a gateway located in San Jose, California. The called number provided to the gateway is 526 4000. This information is sufficient for the Cisco Unified Communications system to derive the full destination number for the call. A call delivered by the service provider on this specific

trunk group should inherit an implied country code and area code based on the characteristics of the trunk group connected to the gateway, which presumes that all destination DID numbers handled by the trunk group are from the North American Numbering Plan country code (1) and from area code 408. Therefore, the derived global form of the number is +1 408 526 4000. The calling number provided to the gateway is 555 1234, with the numbering type set to Subscriber. The numbering type allows the system to infer the country code and area code from the configured characteristics of the trunk group. Thus, the system knows that the calling number is +1 408 555 1234.

On a different call, if the calling number is 33158405858 with numbering type International, this is an indication that the global form of the calling number should be represented as +33158405858.

Globalized Call Routing

For the destination to be represented in a global form common to all cases, we must adopt a global form of the destination number from which all local forms can be derived. The + sign is the mechanism used by the ITU's E.123 recommendation to represent any global E.164 PSTN number in a global, unique way. This form is sometimes referred to as a fully qualified PSTN number.

The system can be configured with route patterns that match globalized called numbers including the + sign. These same route patterns can point to route lists and route groups featuring the Standard Local Route Group. This allows for the creation of truly global route patterns because the egress gateway can be determined from the calling endpoint's device pool at the time of the call. All the necessary tasks of adapting the calls (both the calling and the called party numbers) to the local preferences and requirements are performed once a destination has been selected.

Localized Call Egress

When calls are routed to a destination using a global form of the called and the calling numbers, you might have to consider the following localization actions when the call is delivered to its destination.

Phone Calling Party Number Localization

As a call is delivered to a phone, the calling number will be in its global form, which might not be recognizable to the called party. Typically, users prefer to see calls from callers within their country presented with an abbreviated form of the caller's number.

For example, users in the US want to see incoming calls from US callers with a ten-digit national number, without the + sign or the country code (1). If a user whose global phone number is +1 408 555 1234 calls +1 408 526 4000, the called phone would like to receive 408 555 1234 as the calling party number while the phone is ringing. To achieve this, the system administrator should configure a Calling Party Transformation Pattern of: \+1.!, strip pre-dot. The Calling Party Transformation Pattern is placed in a partition included in the destination phone's Calling Party Transformation Pattern CSS, configured at the device-pool level. As a call from +1 408 555 1234 is offered to the phone, it matches the configured Calling Party Transformation Pattern, which removes the +1 and presents a calling party number of 408 555 1234 as the call rings in.

Note

The calling party number stored in the missed and received calls directories of Type-B phones is left in its globalized form to allow one-touch dialing from the directories without requiring manual editing of the directory's stored number string. The calling party number stored in the missed and received calls directories of Type-A phones is the transformed calling party number. For Type-A phones, the transformed calling party number needs to be in the form of a supported dialing habit to make sure the user can call back from the missed and received calls directory. This behavior permits implementation of globalized dial plans even with older Type-A phones present in the network.

**Note**

Many phone users are becoming accustomed to the globalized form of PSTN numbers, mainly due to the common use of mobile phones across international boundaries. The system administrator can forego the configuration of Calling Party Transformation Patterns for phones if displaying the global form of incoming numbers is preferred.

Gateway Calling Party Number Localization

As a call is delivered to a gateway, the calling party number must be adapted to the requirements of the PSTN service provider providing the trunk group to which the gateway is connected. Calling Party Number Transformation patterns can be used to change the calling party number digit string and numbering type. Typically, a calling party number featuring the gateway's country code should be changed to remove the + sign and the explicit country code, and they should be replaced with the national prefix. Also, the numbering type of the calling party number should be changed to National. If the gateway is connected to a trunk group featuring a specific area, region, or city code, the specific combination of + sign, country code, and local area code usually must be replaced by the applicable local prefix. Also, the numbering type must be adjusted to Subscriber.

For example, assume that a call from a San Francisco user (+1 415 555 1234) is routed through a route list featuring a San Francisco gateway as a first choice and a Chicago gateway as a second choice. The San Francisco gateway is configured with two Calling Party Transformation Patterns:

- \+1415.XXXXXXX, strip pre-dot, numbering type: subscriber
- \+1.!, strip pre-dot, numbering type: national

As the call is delivered to the San Francisco gateway, the calling party number matches both Calling Party Transformation Patterns. However, the first one is a more precise match and is selected to process the calling party number. Thus, the resulting transformed number is 5551234, with a calling party type set to Subscriber.

If the gateway had not been able to process the call (for example, if all ports were busy), the call would have been sent to the Chicago gateway to egress to the PSTN. The Chicago gateway is configured with the following two Calling Party Transformation Patterns:

- \+1708.XXXXXXX, strip pre-dot, numbering type: subscriber
- \+1.!, strip pre-dot, numbering type: national

As the call is delivered into the Chicago gateway, the calling party number matches only the second Calling Party Transformation Pattern. Therefore, the resulting calling party number offered to the gateway is 4155551234, with a calling party number type set to National.

Gateway Called Party Number Localization

As a call is delivered to a gateway, the called party number must be adapted to the requirements of the PSTN service provider providing the trunk group to which the gateway is connected. Called Party Number Transformation patterns can be used to change the called party number digit string and numbering type. Typically, a called party number featuring the gateway's country code should be changed to remove the + sign and the explicit country code, and they should be replaced with the national prefix. Also, the numbering type of the called party number should be changed to National. If the gateway is connected to a trunk group featuring a specific area, region, or city code, the specific combination of + sign, country code, and local area code usually must be replaced by the applicable local prefix. Also, the numbering type must be adjusted to Subscriber.

For example, assume that a call to a San Francisco user (+1 415 555 2222) is routed through a route list featuring a San Francisco gateway as a first choice and a Chicago gateway as a second choice. The San Francisco gateway is configured with two Called Party Transformation Patterns:

- \+1415.XXXXXXX, strip pre-dot, numbering type: subscriber
- \+1.!, strip pre-dot, numbering type: national

As the call is delivered to the San Francisco gateway, the called party number matches both of the Called Party Transformation Patterns. However, the first one is a more precise match and is selected to process the called party number. Thus, the resulting transformed number is 5552222, with a called party type set to Subscriber.

If the gateway had not been able to process the call (for example, if all ports were busy), the call would have been sent to the Chicago gateway to egress to the PSTN. The Chicago gateway is configured with the following two Called Party Transformation Patterns:

- \+1708.XXXXXXX, strip pre-dot, numbering type: subscriber
- \+1.!, strip pre-dot, numbering type: national

As the call is delivered into the Chicago gateway, the called party number matches only the second Called Party Transformation Pattern. Therefore, the resulting called party number offered to the gateway is 415552222, with a called party number type set to National.

**Note**

When a call egresses to a gateway, the calling and called party transformation patterns are applied to the calling and called numbers respectively.

**Note**

SIP does not offer an indication of the numbering type. Therefore, SIP gateways will not be able to receive an indication of the called or calling party number type set by Unified CM.

Benefits of the New Design Approach

The benefits of the dial plan design approach enabled by the new globalization features in Unified CM 7.x include:

- Simplified configuration of call routing, especially when considering local egress to the PSTN
- Simplified configuration and enhanced functionality of system functions such as:
 - Automated Alternate Routing (AAR)
 - Emergency Responder (ER) site-specific failover
 - Call Forward Unregistered (CFUR)
 - Tail End Hop Off (TEHO)
 - Click-to-dial of E.164 numbers (including the + sign) from soft clients such as Cisco Unified Personal Communicator
 - Adaptive call routing for speed dials originating from roaming extension mobility users or roaming devices
 - One-touch dialing from phone directory entries, including dual-mode phones
 - One-touch dialing from missed and received call lists in IP phone directories

Automated Alternate Routing (AAR)

If the AAR destination mask is entered in the globalized form, and if every AAR CSS is able to route calls to destinations in the globalized form, then the system administrator can forego the configuration of AAR groups because their sole function is to determine what digits to prefix based on the local requirements of the calling phone's PSTN access to reach the specific destination.

Furthermore, in most cases the sole function of the AAR CSS is to route the call to the calling phone's co-located gateway; therefore, it can be configured with only a single route pattern (\+!) pointing to a route list that contains the Standard Local Route Group. Because calls routed by this single route pattern will always be routed through the Local Route Group associated with the calling endpoint, that unique AAR CSS can be used by all phones at all sites, no matter in which region or country they are located.

Cisco Emergency Responder

Call routing to Cisco Emergency Responder (ER) is typically implemented by configuring a 911 CTI route point to connect to the primary ER server and a 912 CTI route point to connect to the backup ER server.

If both ER servers are unavailable, 911 calls can be directed to the PSTN egress gateway co-located with the calling phone by configuring:

- The 911 CTI route point to Call Forward No Answer (CFNA) and Call Forward Busy (CFB) to 912, through a calling search space that contains the partition of the 912 CTI route point
- The 912 CTI route point to CFNA and CFB to 911, through a calling search space that contains a global partition, itself containing a route pattern 911 pointing to a route list that contains the Standard Local Route Group

If both CTI route points become unregistered, calls to 911 will be forwarded through the local route group as determined by the calling phone's device pool. If Device Mobility is configured, roaming phones will be associated with the visited site's device pool, and thus associated with the visited site's Local Route Group.

Call Forward Unregistered (CFUR)

To allow calls handled by the Call Forward Unregistered function to use a gateway co-located with the calling phone, configure the CFUR destination of phones using the globalized + form of their PSTN number. The CFUR CSS can be configured with only a single route pattern (\+!) pointing to a route list that contains the Standard Local Route Group. Because calls routed by this single route pattern will always be routed through the Local Route Group associated with the calling endpoint, the same CSS can be used as the CFUR CSS by all phones at all sites, no matter in which region or country they are located.

Tail End Hop Off (TEHO)

To reduce PSTN connectivity charges, system administrators might want to route calls to off-net destinations by using the IP network to bring the egress point to the PSTN as close as possible to the called number. At the same time, if the call's preferred TEHO route is not available, it might be necessary to use the calling phone's local gateway to send the call to the PSTN. This can be achieved by allowing all phones partaking in TEHO routing for a given type of number to match the same route pattern that matches the specific destination number and that points to a route list containing the TEHO egress gateway-of-choice as the first entry and the Standard Local Route Group as the second entry.

Call Control Discovery

In environments where multiple call clusters are deployed, the dial plan must be engineered to route calls between clusters over the IP network where possible, and to use the PSTN as a backup route where required.

Configuration of a cluster to allow intercluster call routing requires the addition of sets of patterns describing the DN ranges hosted in remote clusters. For each remote DN range, the local cluster must be configured with:

- Number range pattern(s) to be recognized as hosted on a remote cluster
- The primary route to reach each remote cluster destination number range, along with associated trunks and protocols
- Secondary route(s) to the destination number ranges, with their associated digit manipulation to transform the destination number to a form acceptable by the PSTN carrier.

This configuration can be done manually, by using static dial plan entries such as route patterns. When done manually, the configuration effort increases with the quantity of remote ranges to be routed. This increase is linear when all clusters are pointed to a centralized dial plan resolution platform, such as a gatekeeper, a SIP proxy, or Cisco Unified CM Session Management Edition. However, this introduces a dependency on a central control point.

The alternative is to create a full mesh, where each cluster pair is configured with intercluster trunks referenced by route patterns defining the remote DN ranges of the cluster on the other side. In this mode, no central point controls the intercluster dial plan resolution, but the configuration effort grows exponentially with the quantity of clusters because a full mesh of trunks and associated DN ranges is required to link all cluster pairs.

Cisco Unified Communications Manager offers the ability for clusters to automatically exchange the DN ranges they host by subscribing to a network-based Service Advertisement Framework (SAF) Call Control Discovery (CCD) service. SAF CCD enables clusters to advertise their own hosted DN ranges into the network as well as to subscribe to advertisements generated by other call agents in the network. The main benefits of using SAF CCD are:

- Automated distribution of call routing information between call agents participating in the same SAF CCD network, thus avoiding incremental configuration work when new call agents are added or when new DN ranges are added to a call agent
- No reliance on a centralized dial plan resolution control point
- Automated recovery of inter-call agent call routing information when routing changes occur, including when multiple Unified CM clusters are combined

The section on [Dial Plan Elements, page 9-78](#), presents some fundamental systemic functionality aspects of SAF CCD to complement the product information available in the latest version of the *Cisco Unified Communications Manager Administration Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

For more detailed information on the Service Advertisement Framework and Call Control Discovery, see [Call Routing and Dial Plan Distribution Using Call Control Discovery for the Service Advertisement Framework, page 5-64](#).

This section of the chapter is not meant to present the exhaustive product configuration of Unified CM for participation in the SAF CCD service. Rather, it focuses on the fundamental system implications of using Unified CM as a call agent in a network offering the SAF CCD service. Design considerations for the dial plan aspects of the SAF CCD service are presented in the following section.

SAF CCD Design Considerations

SAF CCD allows for the exchange of directory number (DN) information between call agents such as Cisco IOS Gateways, Unified CME, and Unified CM. To ensure optimal performance, the system should be designed with the following criteria in mind:

- [Advertising Globalized Numbers, page 9-25](#)
- [Learning Remote DN Ranges Through the SAF CCD Requesting Service, page 9-30](#)
- [Placing Calls to SAF CCD Learned DN Ranges, page 9-31](#)

Advertising Globalized Numbers

Because the DN ranges exchanged between the call agents participating in the SAF CCD service are sent to all call agents, with no regard to site-specific dialing habits, the form of the DNs exchanged through the SAF CCD service should be a global one; that is, a form that is unique among all call agents. This form can be used from any device, on any call agent, in any location in the network. Cisco recommends that all patterns advertised into a SAF CCD service be globally unique within the enterprise.

For example, assume user Paul in Liverpool, England, can be reached by calling the following numbers:

- 1234 if called by coworker John, also located in Liverpool, England
- 85551234 if called by co-worker Wolfgang from Vienna, Austria, or by any other coworker in any on-net enterprise office location worldwide, no matter what call agent controls their phone

User Brian in Hawthorne, CA, can be reached by calling the following numbers:

- 1234 if called by coworker Carl, also located in Hawthorne, CA
- 84441234 if called by coworker Bono located in Dublin, Ireland, or by any other coworker in any on-net enterprise office location worldwide, no matter what call agent controls their phone

In this example, the localized, four-digit abbreviated intra-site form of the number associated with Paul cannot be used as a global identification to be sent to all call agents because it conflicts with that of user Brian. If Paul's call agent were to send a SAF CCD advertisement into the network for DN 1234, it would conflict with that advertised by Brian's call agent in the same SAF CCD network. If user Carl were to dial 1234, there would be some conflict as to whom (Paul or Brian) he is trying to reach.

To avoid such conflicts, call agents should always advertise numbers in a form that is global; that is, a form which does not rely on a context specific to a site or a cluster. It should be a form that can be dialed from any phone on the network, and that uniquely identifies the destination DN in the entire network. The following two main forms of global DNs can be used for this purpose:

- [Site-Code Based On-Net Form, page 9-25](#)
- [+E.164 Based On-Net Form, page 9-26](#)

Site-Code Based On-Net Form

In systems where the majority of inter-site calls are dialed by using an on-net scheme based on site codes, it is better to advertise DNs in their site-code form, along with a set of rules to allow their failover to the PSTN.

Each DN is globally reachable within the system by dialing an inter-site access code, followed by a site code, followed by a local extension. For example, user Paul in Liverpool can be reached from anywhere on the enterprise network by dialing inter-site access code 8, followed by site code 555 (Liverpool, England), followed by the local extension 1234. Combined, these parts yield a global DN of 85551234, which is globally unique within the network.

In systems using site codes implemented with Variable Length On-Net Dialing (VLOD) with flat addressing, the DN ranges advertised by the cluster to the rest of the network directly match the DN form configured on the lines. This ensures that, when calls are received from other call agents into a SAF CCD trunk, no digit manipulation is required to adapt the called number to the form used internally on the lines. For example, if the cluster advertised 855512XX and it receives a call for 85551234 on a SAF CCD trunk, a match can be made directly into the single partition containing the phones.

In systems using site codes implemented with Variable Length On-Net Dialing (VLOD) with partitioned addressing, the DN ranges advertised by the cluster to the rest of the network do not directly match the DN form configured on the lines. When calls are received from other call agents into a SAF CCD trunk, the called number must be translated from the globalized form to the site-specific abbreviated form used internally on the lines. For example, if the cluster advertised 855512XX and it receives a call for 85551234 on a SAF CCD trunk, a match must first be made into the single partition containing a series of translation patterns that can adapt the called number from the incoming global form to the localized form 1234 used in the destination phone's site-specific partition.

+E.164 Based On-Net Form

In systems where the majority of inter-site calls are dialed by using the PSTN form of DNs, it is better to advertise DNs in their associated +E.164 form. The +E.164 form carries in it all the information that allows any user in any system (on-net or off-net) to reach the destination DN across any network. Cisco recommends that the DN ranges learned from the SAF CCD service be stored as-is, in their +E.164 form, and that local user input be globalized to match it.

For example: user Paul in Liverpool uses a phone whose line DN is defined as 1234 in the Liverpool partition in the English cluster. However, any coworker in a different site calls Paul by dialing the locally significant form of Paul's +E.164 form DID (+44 15 4555 1234). For Wolfgang in Austria, it is 0 00 44 15 4555 1234, and for Elvis in Memphis, TN, it is 9 011 44 15 4555 1234. User Ringo, calling from a different site in Liverpool, dials 9 0154 555 1234 to reach Paul. For user Edge, on the road somewhere in the world, the call to Paul takes on the form of a click-to-call action from a laptop, to +44 15 4555 1234.

The literal form in which Paul's +E.164 is advertised is not necessarily used as-is by users in the other clusters on the network. All but user Edge in the example above used a localized form of Paul's number. But in every case, the local form dialed can be globalized to arrive at the global form advertised by Paul's cluster.

Each cluster must accept user input in a local, habitual form. For example, for user Elvis in the United States, the habitual manual enterprise user input to reach a user in another country involves dialing an off-net access code (9), followed by an international routing code (011), followed by the E.164 number of the destination (44 15 4555 1234). In this case, the globalization of the user input requires the matching of a pattern such as 9011.!, strip pre-dot, prefix +. This one translation pattern can be used for all calls from any USA user to any destination outside the NANP country code 1.

For all users in all clusters, the locally-significant globalization rules required to globalize habitual user input to an +E.164 form are few. They must cover the globalization of local PSTN calls, national calls, and international calls. In many countries, there is only one form for all intra-country, national calls.

Note

Advertising DN ranges in the +E.164 form does not require that the DNs themselves be defined as +E.164 numbers in their host cluster.

In systems using the +E.164 form implemented with Variable Length On-Net Dialing (VLOD) with flat addressing, the DN ranges advertised by the cluster to the rest of the network directly match the DN form configured on the lines. This ensures that, when calls are received from other call agents into a SAF CCD

trunk, no digit manipulation is required to adapt the called number to the form used internally on the lines. For example, if the cluster advertised +4415455512XX and it receives a call for +441545551234 on a SAF CCD trunk, a match can be made directly into the single partition containing the phones.

In systems using the +E.164 form implemented with Variable Length On-Net Dialing (VL0D) with partitioned addressing, the DN ranges advertised by the cluster to the rest of the network do not directly match the DN form configured on the lines. When calls are received from other call agents into a SAF CCD trunk, the called number must be translated from the globalized form to the site-specific abbreviated form used internally on the lines. For example, if the cluster advertised +4415455512XX and it receives a call for +441545551234 on a SAF CCD trunk, a match must first be made into the single partition containing a series of translation patterns that can adapt the called number from the incoming global form to the localized form 1234 used in the destination phone's site-specific partition.

When Both Forms Are Required

In some systems, users reach each other by both approaches listed above. For these situations, the host clusters should advertise both the site-code form of the DN ranges as well as the +E.164 form. Because the two forms are differentiated by the use of the + sign, no overlap situation can occur between the two DN ranges advertised for a given group of phones.

Special Considerations for Non-DID Numbers

When the system requires the inter-cluster reachability of non-DID numbers, the non-DID DN ranges can be configured to use SAF CCD. However, the PSTN failover functionality will not work in the same manner as for DNs associated with a DID. For example, if a non-DID DN range such as 800033XX is advertised and there is no associated DID range to route calls through the PSTN to the lines in the host cluster, you can do either of the following:

- Configure the PSTN failover digits to yield a call to an annunciator message in the calling cluster, indicating that the call should be re-attempted later due to network congestion, or
- Configure the PSTN failover digits to yield a call to an IVR, reception phone, or other device.

Note

The +E.164 format allows the use of the +0 range to designate non-DID numbers. The +0 range can thus be used to route the calls in the +E.164 form on-net only; the PSTN will not route calls to country code 0.

Tip

When configuring non-DID ranges, subdivide the +0 range into the actual country, area, and/or city codes where the DNs are hosted. For example, a non-DID range in Chicago, IL, could start with +01708XXXXXXXX, allowing for 10 million non-DID numbers. In Frankfurt, Germany, the range could be +04969XXXXXXXX, and so forth.

PSTN Failover Considerations for SAF CCD Outgoing Calls

When a call is placed to a SAF CCD discovered number, the call is routed through one of the SAF CCD trunks associated with the requesting service, as configured under **Call Control > Call Control Discovery > Requesting Service** in Unified CM. (See [Figure 9-3](#).) If the trunk cannot accept the call (for example, if call admission control denies the call or if the trunk is down), then the call will be sent to the PSTN through the AAR calling search space (CSS) of the calling device. Because the destination number might not be in a form directly compatible with the PSTN, the destination number must first be adapted.

Figure 9-3 SAF CCD and PSTN Failover

The DN range records injected into the SAF CCD service by each call agent must carry the rules required to adapt the on-net form of the number to a form acceptable to the PSTN. The rules include what quantity of digits to strip from the left of the range (PSTN Failover Strip Digits), what digits to prefix to the post-strip called number (PSTN Failover Prepend Digits), and whether to use the DN range as-is when rerouting calls to the PSTN (Use HostedDN as PSTN Failover checkbox).

For example, in Figure 9-3 a Unified CM cluster discovers routes to other clusters. The discovered routes are placed into the partition named SAF_CCD_part. If the Paris user dials 84081234, the best-match routing logic will route the call using the SAF CCD discovered pattern 8408XXXX. If the IP route is not available, the dialed number will be combined with the ToDID information, which instructs Unified CM to strip the left-most four digits (in this case, 8408) and to prefix +1408555. This yields +14085551234, which is used to find a match through the calling phone's AAR calling search space. The call then matches the \+! route pattern and is routed through the French Intl RL route list; the first attempt will be to route the call through the HQ_RG route group, followed by an attempt to use the calling phone's local route group (in this case, Paris_RG).

These rules are configured for each advertised DN range under **Call Routing > Call Control Discovery > Hosted DN pattern** in Unified CM. They can also be configured for groups of DN ranges under **Call Routing > Call Control Discovery > Hosted DN group** in Unified CM.

Cisco recommends configuring the PSTN failover digits at the **Hosted DN pattern** level because it provides more granular control of the failover digits for each range and avoids another configuration step at the Hosted DN group level.

When Advertising DN Ranges Using Site Codes

For instance, the users in Liverpool can be reached on-net by dialing a number in the 855512XX range. Nothing in this form inherently defines the associated DID number required to route a call to this destination across the PSTN. To transform this site-code form into the +E.164 form required by the PSTN, (+44 15 4555 12XX), the advertised DN range should be stripped of its first (left-most) digit and prefixed with +44154. This is sometimes represented as S:PP, where S represents the quantity of digits to be stripped from the left and PP represents the literal digits to be prefixed to the post-strip called number. In this example, the transformation would be 1:+44154.

Note

The cluster advertising the DN range must provide the SAF CCD records with the appropriate information to fail-over to the PSTN. If this information is not provided as the routes are injected into the SAF CCD service, each of the CCD client clusters would have to be configured to adapt the PSTN failover characteristics of the learned routes. This creates an additional configuration burden and requires multiple clusters be modified if any changes are required.

Once the called number form is changed to the +E.164 form, the call is routed through the calling device's AAR CSS. A match must be made on the +E.164 form of the number. Once a route pattern is matched, the call is routed through a route list, a route group, and eventually a trunk or gateway, where called party transformation patterns are used to adapt the number from the +E.164 to the localized form required by the PSTN carrier.

When Advertising DN Ranges Using the +E.164 Form

In this case, the DN ranges are advertised directly in the +E.164 form, therefore no PSTN failover digit configuration is required. It is best to check the **Use HostedDN as PSTN Failover** checkbox under the Hosted DN Range configuration to prevent any failover PSTN digit configuration done at the Hosted DN group level from taking precedence. This may be useful when a system requires both the site-code and the +E.164 forms of a number range to be advertised through the same Hosted DN Group, to accommodate both dialing forms between clusters. In such a case, the Hosted DN group PSTN Failover configuration would apply to the site-code DN ranges and would be ignored for the +E.164 DN ranges.

Note

In SAF CCD PSTN failover digit configuration, the + sign is used to perform two main tasks: it allows the adapted PSTN failover number to avoid overlap with any other intra-site valid range in any other cluster (for instance, a cluster where 4415 is a valid intra-site extension would not overlap with +441545551234), and it allows the use of + as a differentiator in matching called party transformation patterns in situations where local calls could overlap with some country codes (for example, India country code 91 overlapping with local ten-digit dialing in Raleigh, NC, Morocco country code 212 overlapping with local ten-digit dialing in New York, NY, and so forth).

Configuring Multiple Advertising Services

Hosted DN groups are a collection of hosted DN patterns that you group together in Cisco Unified Communications Manager Administration. You assign a hosted DN group to a CCD advertising service in Unified CM Administration, and the CCD advertising service publishes all the hosted DN patterns that are a part of the hosted DN group.

You can configure multiple advertising services in Unified CM. Each advertising service establishes a unique relationship between Hosted DN ranges and the group of call processing nodes that will advertise themselves as responsible for the reception of calls to the DNs in those ranges.

An advertising service is associated with a Hosted DN group, which itself is common to a set of Hosted DN ranges. The advertising service is also associated with one SIP SAF trunk and/or one H.323 SAF trunk. Each of those trunks is associated with a device pool, which itself is associated with a Unified CM

server group. The constituent members of the Unified CM server group will be advertised as responsible for calls to any of the DN ranges in the Hosted DN group. In systems where the call processing servers are deployed as a cluster across the WAN (clustering over the WAN), Cisco recommends that the Unified CM server groups used to serve the phones be used also to advertise the DN ranges corresponding to the lines configured on the phones. This will ensure that calls made by remote SAF CCD clients to those phones are sent to the Unified CM servers co-located with the phone's controlling servers.

Learning Remote DN Ranges Through the SAF CCD Requesting Service

The SAF CCD Requesting Service is used to learn the DN ranges hosted in other call agents participating in the SAF CCD service. The Requesting Service is associated with SAF CCD trunks, and it is used to select the trunks associated with the Requesting Service when calls are placed to SAF CCD learned DN ranges.

Each DN range is associated with multiple attributes, such as:

- DN Range — For example: 8555XXXX, +1408555XXXX
- ToDID info — Representing the PSTN failover information provided by the advertising call agent. For example: 1:+1408
- IP address — Representing the signaling destination of the call agent hosting the advertised DN range. This field carries the address of the trunk used by the advertising cluster to inject the DN range into the SAF CCD service. For example: 10.0.0.1.
- Protocol — Representing the signaling protocol required to contact the call agent responsible for the hosted DN range. For example: SIP, H.323

Note

If an advertising service is associated with a trunk whose device pool features a Cisco Unified Communications Manager Group with more than one member, one SAF CCD record is advertised per member. This means that, if a single hosted DN range is advertised through a trunk with three Unified CM group members, three SAF CCD records are advertised. Load balancing is used by the calling cluster between all the records advertising the same hosted DN range.

The SAF CCD Partition

In a cluster, a single SAF CCD partition is configured and is used to contain all learned patterns, no matter the source of the advertised DN range, the required protocol, or the DN range form (site-code or +E.164) used in the advertisement. (See [Figure 9-4](#).)

Note

The SAF CCD partition is not listed for searches under **Call Routing > Class of Control > partition**.

Figure 9-4 Integration of SAF Call Control Discovery with Static Routing

The fact that all learned patterns are placed in the single call control discovery partition means that a phone cannot be given access to only a subset of learned patterns. Access to all the patterns is effected by inclusion of the Call Control Discovery Partition in a CSS used by a phone or in the CSS of a translation pattern used to adapt the dialed, localized form of a number into the globalized form advertised into the SAF CCD service.

For example, the Paris user in Figure 9-4 dials 84081234. None of the statically configured patterns matches the dialed string. However, the SAF_CCD_Part partition has been populated with DN ranges learned from the SAF CCD requesting service. The pattern 8408XXXX matches the dialed string directly and allows the user's call to be placed through a SAF CCD-enabled IP trunk. Note that the Paris and Nice users in this example have access to all the patterns in the SAF_CCD_part partition.

Placing Calls to SAF CCD Learned DN Ranges

In general, calls placed to SAF CCD learned DN ranges should match the range either directly, if the user dialed the advertised globalized number, or through a globalization translation pattern, if the user dialed the number in a local form. SAF CCD learned patterns are always learned as non-urgent. This might cause partial overlaps when the SAF CCD learned patterns are global +E.164 patterns and there is an alternative match on a \+! PSTN route pattern. In this case dialing the global on-net destination learned through SAF CCD either directly or by dialing the habitual local form that is transformed by appropriate translations will be subject to inter-digit timeout (T302).

The calling party number should be sent as-is if the DN of the caller is already in a global form (site-code or +E.164). If the calling party number is in a local form, it should be globalized before egressing the local cluster. This is best done through the use of calling party transformation patterns on the SAF CCD trunk used to place the call.

When a user dials a number corresponding to a DN range advertised by a remote call agent, the following events occur:

1. The dialed string is processed through the calling phone's effective CSS. The best-match process is used, as usual. This means that, if a call is placed to a destination matching several SAF CCD learned routes and/or patterns locally configured in the cluster, the most precise match will be chosen to match the call. In cases where multiple equal-precision matches are found, the order in which the associated partitions are listed in the effective CSS will be used. In the special case where multiple Unified CM nodes belonging to the same cluster advertise the same route, multiple equal-precision patterns will be found in the SAF CCD partition of all clusters participating in the SAF CCD service. In this case, the calls to this pattern are load-balanced between all the equal-precision matches.
2. Either a match is found directly on the dialed pattern (for example, the user dials 84081234 and this matches a pattern found in the SAF CCD partition as included in the phone's CSS), or a match is made with a translation pattern used to adapt the local form to the global form advertised in the SAF CCD partition (for example, the user in Memphis, TN, dials 9011441545551234, matches a translation pattern that adapts the called number to +441545551234, and then matches the +441545551234 found in the SAF CCD partition located in the translation pattern's CSS).
3. The call is extended through the IP trunk used to learn the pattern in the local cluster, to the trunk used to advertise the pattern in the remote cluster.
4. Upon egressing the calling cluster, the called number is in the form advertised by the remote cluster.
5. Upon egressing the calling cluster, the calling number should be provided in a global form. If the local cluster's DNs were not provisioned in a global form, calling party transformation patterns should be used to adapt the local form to the global form to be sent to the remote cluster. This is especially important to allow remote users to use the dial function from the missed and received calls lists. Note also that globalizing the calling party number should be done by the calling cluster to simplify configuration. The alternative requires configuring all remote clusters with the rules required to recognize calls coming from other clusters and globalize the calling party numbers.
6. If the IP route between the calling and the called cluster is available, the call will be received at the remote cluster into the trunk associated with the advertising service used to inject the DN range into the SAF CCD service.
7. The remote cluster's SAF CCD trunk receiving the call will look for a match in the trunk's Inbound Calls CSS.
8. If the DNs as configured in the cluster are in the same global form as that advertised into the SAF CCD service, a match is found by including the DN partitions into the SAF CCD trunk's Inbound Calls CSS. The call is offered to the called line.
9. If the DNs as configured in the cluster are in a form different than the global form advertised into the SAF CCD service, a match is found by including, in the SAF CCD trunk's Inbound Calls CSS, a partition containing translation patterns matching the global form to the local form configured on the DNs of the lines. The call is offered to the called line.
10. In step 6., if the IP route between the two clusters is not available, the PSTN failover digit transformation rules (ToDID rules) are applied to the called number, and the resulting destination number will be used to find a match in the calling device's AAR CSS.
11. At this point, the called number should be in +E.164 form and should be used to match a route pattern pointing to a route list, route group, and gateway (or trunk) combination.

12. Once the call egresses on a gateway or trunk, transformation patterns should be used to adapt both the calling and called party numbers to the form required by the PSTN carrier. At this point, the call is launched into the PSTN.
13. Once the call reaches the remote cluster, the call is processed as usual for incoming PSTN calls.

**Note**

If the design intent were to route all calls to SAF CCD learned routes through the PSTN, such as is the case when deploying the VoPSTN approach, simply put the SAF requesting service's associated trunk(s) in a call admission control static location configured with 1 kbps of bandwidth. This will force all calls to be routed through the calling device's AAR CSS.

Dial Plan Considerations for the Intercompany Media Engine

The Cisco Intercompany Media Engine (IME) allows participating enterprises to route calls over the Internet between them. When a phone participates in the IME and places calls through trunks or gateways marked as **PSTN Access**, a record of the call is sent to the enterprise's IME server, including the calling and called numbers. This record serves to flag the pairing of numbers in two different IME-participating companies for future call routing over the Internet; if another call between these same two numbers is detected by the IME server, it instructs Cisco Unified Communications Manager (Unified CM) to route the call over the Internet.

One challenge in such pairings is ensuring the consistent normalization of numbers in all the participating IME-enabled Unified CM clusters. Because the calls are initially placed over the PSTN and because these calls can traverse the boundaries of different cities, provinces or states, or even countries, the form of the number dialed by the user will vary greatly. Similarly, different companies might have adopted different approaches when assigning DNs to lines.

Cisco recommends using the +E.164 form to identify the calling and the called numbers for calls participating in the IME service. The +E.164 form affords the normalization (for example, every number begins with + followed by the country code of the associated DID number) and the globalization required to ensure consistent results.

When calls are placed toward trunks or gateways marked as PSTN Access, the trunk or gateway's associated IME E.164 transformation profile is applied. This in turn applies a set of transformation patterns to the calling party number, as well as a set of transformation patterns to the called party number. For outgoing calls, the post-transformation numbers are used in the records sent to the IME server.

**Note**

The IME E.164 Transformation Profile is configured in Unified CM under **Advanced Features > Intercompany Media Services > E.164 Transformation**.

The Intercompany Media Services E.164 Transformation configuration allows the application of transformation patterns to outgoing calls, segregated between calling party and called party. For each, a CSS can be configured, which itself contains the partitions in which the calling/called party transformation patterns are contained. The transformations are applied to either the original number (the form the number was in as it matched the route pattern) or the routing transformed number (the form the number was in once route list transformations were applied).

For the calling party number:

The original number is the DN of the phone as it matched a route pattern, when considering the calling party settings. The routing transformed number is the DN of the phone after any calling party digit manipulations are performed through route lists.

For example, a DN configured as 85551234 is placing a call to the PSTN, to 91415551000. The call is placed through a translation pattern 91[2-9]XX[2-9]XXXXXX. The translation pattern is configured to modify the called party number to +14155551000, while changing the calling party number to +14085551234. This call then matches a route pattern \+!, configured with a route list that modifies the calling party number to 408 555 1234 and the called party number to 415 555 1000.

If the Outgoing Calling Party Settings are set to apply the transformations to the original number, then +14085551234 will be used to match a calling party transformation pattern in the Outgoing Party E.164 Transformation CSS.

If the Outgoing Calling Party Settings are set to apply the transformations to the routing transformed number, then 4085551234 will be used to match a calling party transformation pattern in the Outgoing Party E.164 Transformation CSS.

For the called party number:

The original number is the dialed number as it matches the route pattern, when considering the called party settings. In the example above, the original number is +14155551000.

The routing transformed number is the destination of the phone after any digit manipulations are performed through route lists. In the example above, it is 4155551000.

No matter to which form of the number the transformations are applied, they must yield a normalized, globalized number to be sent to the IME service.

When calls are received from trunks and gateways marked as PSTN Access, the form in which the calling and called numbers are received must be normalized and globalized before they are sent to the IME service. The Incoming Transformation Profile Settings can be used to adapt the incoming form of the calling and called numbers to the +E.164 form required by the IME service. It features an Incoming Calling Party Transformation Profile as well as an Incoming Called Party Transformation Profile. For each, a CSS can be configured, which itself contains the partitions in which the calling/called party transformation patterns are contained.

The transformations for the calling number are applied to the routing transformed number; that is, the number as processed through the Incoming Calling Party Settings at the trunk or gateway level.

The transformations for the called number are applied to the number as it is presented into the gateway or trunk's CSS for inbound calls.

Design Guidelines for Multisite Deployments

The following guidelines and best practices apply in common to all multisite IP Telephony deployments. For deployments that involve more than one Unified CM cluster, also refer to the section on [Additional Considerations for Multi-Cluster Systems, page 9-37](#).

- To prevent routing loops, make sure the calling search spaces of all PSTN gateways do not include any partitions that contain external route patterns assigned to route lists and route groups that can send calls out the same gateway.
- When choosing DID ranges with your Local Exchange Carrier (LEC), try to select them so that no overlap occurs within a site. For example, if you use four-digit dialing within a site and you need two blocks of 1000 DIDs, the blocks (408)555-1XXX and (408)444-1XXX would overlap when reduced to four-digit numbers and would introduce additional complexity due to inbound and outbound translations.
- Allow for multiple ways of dialing emergency numbers. For example, in North America, configure both 911 and 9.911 as emergency route patterns within Unified CM.
- When automated alternate routing (AAR) is deployed, ensure that the external phone number mask or AAR Destination Mask configured on the IP phones is compatible with all the prefixes added by the various AAR groups. For example, in a multi-national deployment, do not include national access codes such as 0 in the mask unless they are part of the global E.164 address. The simplest way to configure AAR relies on the configuration of the AAR destination mask as the full E.164 address of the phone, including the + sign.
- You can force calls to on-net destinations, but dialed as PSTN calls, to be routed on-net within the cluster by adding translation patterns that match the E.164 DID ranges for each site and that manipulate the digits so they match the destination's internal extension. For example, if a DN is reachable on-net by dialing 1234, but someone within the system dials this same destination as 9 1 415 555 1234, you can force the call to be kept on-net by creating a translation pattern 9 1 415 555.1XXX, which removes all digits pre-dot and routes the call on-net to the resulting number. However, remember to configure the AAR calling search space to exclude the partition containing the "force on-net" translation patterns but to include a partition containing the regular route patterns pointing to the PSTN, so that automated PSTN failover is possible when the IP WAN is out of bandwidth.
- Within a centralized call processing cluster with N sites, you can implement Tail End Hop Off (TEHO) using one of the following methods:
 - TEHO with centralized failover
This method involves configuring a set of N route patterns in a global partition, with each pattern pointing to a route list that has the appropriate remote site route group as the first choice and the central site route group as the second choice.
 - TEHO with local failover
This method involves configuring N sets of N route patterns in site-specific partitions, with each pattern pointing to a route list that has the appropriate remote site route group as the first choice and the local site route group as the second choice. For the example in [Figure 9-5](#), in order to implement local failover TEHO routes to Brazil, a site in Paris, France would require a dedicated route pattern and route list to route the calls to the TEHO gateways in Brazil as a first choice or to the Paris gateways as a second choice. Because the pattern is linked to a site-specific route list, it cannot be reused at any other site. Likewise, the site in Ottawa, Canada requires its own dedicated route pattern pointing to an Ottawa-specific route list to allow local failover to a gateway in Ottawa.

Figure 9-5 TEHO Without Local Route Group

While this second approach allows for an optimal failover scenario when the remote gateway or the IP WAN is unavailable, it also introduces a high level of complexity into the dial plan because it requires a minimum of N^2 route patterns and N^2 route lists, as opposed to the N route patterns and N route lists needed with the first approach.

- TEHO with local failover with Local Route Group

The Local Route Group allows for the local failover of TEHO routes to be implemented without having to create route patterns for each site. For the example in Figure 9-6, a single TEHO pattern and route list is used by both the Paris and Ottawa sites. Because the user input for these two sites is not the same (French users dial Brazilian destinations differently than Canadian users do), the configuration relies on translation patterns to globalize the user input. The global form is then used to match a single, cluster-wide route pattern pointing to a route list whose first entry is the Brazil route group and whose second entry is the Standard Local Route Group. The local route group is resolved to the Paris route group when the calling device is in a Paris device pool, and to an Ottawa route group when the calling device is in an Ottawa device pool.

Figure 9-6 TEHO With Local Route Group

- When appropriate for your national numbering plan, you may configure an additional translation pattern at each site to catch local PSTN calls dialed as long-distance calls and to translate them into the proper abbreviated form. This translation pattern should be accessible only from phones located within the site. Such a configuration also helps simplify the AAR configuration (see [Special Considerations for Sites Located Within the Same Local Dialing Area, page 9-111](#)).
- Do not use the multilevel precedence and preemption (MLPP) feature to assign higher priority to emergency calls. An emergency-related call might not appear as such to the IP Telephony system, and you would risk terminating an existing emergency call to place another call to the main emergency service routing number. For example, an emergency situation might prompt someone to place a call to a regular ten-digit number to reach a medical professional. Preemption of this call would abort the ongoing emergency communication and could delay handling of the emergency. Also, incoming calls from emergency service personnel would be at risk of preemption by MLPP.

**Note**

A Unified CM cluster with a very large dial plan containing many gateways, route patterns, translation patterns, and partitions can take an extended amount of time to initialize when the Cisco CallManager Service is first started. If the system does not initialize within the default time, there are service parameters that you can increase to allow additional time for the configuration to initialize. For details on the service parameters, refer to the online help for Service Parameters in Unified CM Administration.

Additional Considerations for Multi-Cluster Systems

In addition to the considerations made in the previous section, observe the following best practices when designing a dial plan for a multisite deployment involving multiple Unified CM clusters:

- Avoid splitting DID ranges across multiple Unified CM clusters. This practice would make intercluster routing very difficult because summarization would not be possible. Each DID range should belong to a single Unified CM cluster.

- Avoid splitting devices within a remote site between multiple Unified CM clusters using call admission control based on static locations. Static locations-based call admission control is significant only within a cluster, and having devices belong to different clusters at the same remote site would lead to poor utilization of the IP WAN bandwidth because you would have to split the available bandwidth between the clusters. Each remote site should belong to a single Unified CM cluster. Locations can be configured in Unified CM to use RSVP as the call admission control mechanism, which allows the efficient sharing of a single site's total WAN bandwidth between phones belonging to different clusters. To take full advantage of the efficiency of RSVP-based call admission control, all phones within the remote site must be configured to use RSVP.
- Use gatekeeper-controlled intercluster trunks to route calls between Unified CM clusters. This practice enables you to add or modify clusters easily in your network without reconfiguring all other clusters.
- Implement redundancy in the connection between Unified CM and the gatekeeper by using a gatekeeper cluster and by assigning the intercluster trunk to a device pool that uses a Unified CM group with multiple servers configured.
- When sending calls to the gatekeeper, expand the called number to the full E.164 address. This practice simplifies PSTN failover when the IP WAN is not available because no additional digit manipulation is required to reroute the call via a PSTN gateway. Also, this practice eliminates the need to configure the local (calling) Unified CM with dial length information for each remote site.
- Within the gatekeeper, configure one zone per Unified CM cluster. For each cluster/zone, add zone prefix statements to match all DN ranges owned by that cluster.
- You can implement Tail-End Hop-Off (TEHO) across multiple Unified CM clusters by following these guidelines:
 - Add specific route patterns for the relevant E.164 ranges to the source (originating) Unified CM cluster, and point them to a route list that has the IP WAN route group as the first choice and the Standard Local Route Group as the second choice
 - Within the Cisco IOS gatekeeper configuration, add zone prefix statements for all the relevant E.164 ranges and point them to the appropriate Unified CM cluster
 - Ensure that the intercluster trunk calling search space in the destination Unified CM cluster includes partitions featuring route patterns that match the local PSTN numbers, and that digit manipulation is applied as needed (for example, stripping the area code before sending the call to the PSTN) by using appropriate Called Party Number Transformation Patterns.

For details on how to configure a Cisco IOS gatekeeper for distributed call processing deployments, see [Gatekeeper Design Considerations, page 8-37](#).

Choosing a Dial Plan Approach

As introduced in [Planning Considerations, page 9-5](#), there are two main approaches to a dial plan for internal destinations within an IP Telephony system:

- Uniform on-net dial plan, where each internal destination is dialed in the same way regardless of whether the caller is located in the same site or in a different site.
- Variable-length on-net dial plan, where internal destinations are dialed differently within a site than across sites. Typically, this approach uses four or five-digit abbreviated dialing for calls within a site and either full E.164 addresses or an on-net access code followed by a site code and the extension for calls across sites.

To help you decide which approach is best suited for your needs, consider the following high-level design questions:

- How many sites will eventually be served by the IP Telephony system?
- What are the calling patterns between sites or branches?
- What do users dial within a site and to reach another site?
- Are there any calling restrictions applied to on-net inter-site calls?
- What transport network (PSTN or IP WAN) will be used for most inter-site calls?
- What (if any) CTI applications are being used?
- Is there a desire for a standardized on-net dialing structure using site codes?

Uniform on-net dial plans are the easiest to design and configure; however, they work best for small to medium deployments, and they become impractical when the number of sites and users increases. They are described and analyzed in detail in the section on [Deploying Uniform On-Net Dial Plans](#), page 9-40.

Variable-length on-net dial plans are more scalable but also more complex to design and configure. [Figure 9-7](#) shows the typical requirements for a large-scale deployment using the variable-length on-net dial plan approach.

Figure 9-7 Typical Dialing Requirements for Large Multisite Deployments

With Unified CM, the main method for implementing a variable-length on-net dial plan relies on flat addressing. In this method, all internal extensions are placed in the same partition. This method is typically based on on-net site codes for inter-site calls and is analyzed in detail in the section on [Deploying Variable-Length On-Net Dial Plans with Flat Addressing, page 9-43](#). In some cases it is possible to use this approach even when using full E.164 addresses for inter-site calls, as described in the section on [Special Considerations for Deployments Without Site Codes, page 9-50](#).

Deploying Uniform On-Net Dial Plans

You can implement a uniform on-net dial plan by following these guidelines:

- Uniquely identify all phones with an abbreviated extension.
- Place all the phone DNs in a single partition.
- At each site, place PSTN route patterns in one or more site-specific partitions, according to the chosen class-of-service approach.

[Figure 9-8](#) shows an example implementation for a single Unified CM cluster deployment.

Figure 9-8 Example of Uniform On-Net Dial Plan Deployment

Use this approach if both of the following conditions apply:

- The DID ranges available do not overlap when considering the number of digits chosen to identify internal extensions.
- The number of sites covered by the IP Telephony system is not expected to grow significantly over time.

The following sections analyze implementation details and best practices for different types of calls within the framework of uniform on-net dial plans:

- [Inter-Site Calls Within a Cluster, page 9-42](#)
- [Outgoing PSTN and IP WAN Calls, page 9-42](#)
- [Incoming Calls, page 9-42](#)
- [Voicemail Calls, page 9-42](#)

Inter-Site Calls Within a Cluster

Because all internal DNs are directly reachable from every device's calling search space, all on-net calls (intra-site and inter-site) are automatically enabled and need no additional configuration within Unified CM.

Outgoing PSTN and IP WAN Calls

PSTN calls are enabled via the site-specific partitions and route patterns, so that emergency and local calls can be routed via the local branch gateway. Long-distance and international calls may be routed via the same branch gateway (as shown in [Figure 9-8](#)) or via a centralized gateway, depending on company policy. This second option would simply require an additional route list per site, with the first-choice route group pointing to the central site gateway and, optionally, a second-choice route group pointing to the local branch gateway. To allow the reuse of route patterns between sites for PSTN calls while still allowing site-specific routing of the calls, route lists referencing the Standard Local Route Group can be used.

Abbreviated dialing to another Unified CM cluster or Cisco Unified Communications Manager Express (Unified CME) is also possible via a gatekeeper. For these IP WAN calls, Cisco recommends that you expand the abbreviated string to the full E.164 via a translation pattern before sending it to the gatekeeper.

Emergency Calls

If Cisco Emergency Responder is used for managing emergency calls, the partition containing the CTI route point used to send calls to Cisco Emergency Responder should be part of the calling search space of all phones in all branches instead of the site-specific 911 patterns as illustrated in [Figure 9-8](#). Cisco Emergency Responder will be able to identify the calling phone because there is no duplicity of DNs allowed in the internal partition. For more information on Cisco Emergency Responder considerations, refer to the chapter on [Emergency Services, page 10-1](#), and to the Cisco Emergency Responder product documentation available at

<http://www.cisco.com>

Incoming Calls

Incoming PSTN calls simply require stripping the excess digits in order to match the extension length configured in Unified CM. This can be done within the gateway configuration or, alternatively, via a translation pattern included in the gateway's calling search space.

Voicemail Calls

Because every extension is unique within the system, the extension itself can be used to configure voicemail boxes within the voicemail system. No translations are necessary to send calls to the voicemail system or to enable a Message Waiting Indicator (MWI) within Unified CM.

However, when users access the voicemail system from the PSTN, they need to be trained to enter their abbreviated extension to access their voicemail boxes.

Deploying Variable-Length On-Net Dial Plans with Flat Addressing

You can implement a variable-length on-net dial plan with flat addressing by defining phone DNs as unique strings containing an on-net access code, a site code, and the extension (for example, 8-123-1000). You can place all these DNs in the same global partition, thus enabling inter-site calls using the site code, and you can define translation patterns in site-specific partitions (one translation pattern and one partition per site) to enable abbreviated dialing within a site.

This internal structure can be hidden from the end users by configuring the Line Text Label parameter within the Directory Number configuration page with the four or five-digit number that users are accustomed to dialing within the site. The external phone number mask should also be provisioned with the corresponding PSTN number in order to enable AAR and to give users a visual indication of their own DID number on the IP phone display.

[Table 9-4](#) illustrates the basic relationship between calling search spaces and partitions at each site, without taking into account additional elements required to implement classes of service:

Table 9-4 *Calling Search Spaces and Partitions for Variable-Length Dial Plans with Flat Addressing*

| Calling Search Space | Partition | Partition Contents |
|----------------------|----------------------|--|
| Site1_css | Site1Translations_pt | Translation patterns for Site 1's abbreviated dialing |
| | Site1PSTN_pt | PSTN route patterns for Site 1 (more partitions may be needed based on classes of service) |
| | Internal_pt | All IP phone DNs (unique form) |
| ... | ... | ... |
| SiteN_css | SiteNTranslations_pt | Translation patterns for Site N's abbreviated dialing |
| | SiteNPSTN_pt | PSTN route patterns for Site N (more partitions may be needed based on classes of service) |
| | Internal_pt | All IP phone DNs (unique form) |

Use this approach if one or more of the following conditions apply:

- No dialing restrictions are needed for on-net inter-site calls.
- A global on-net numbering plan using site codes is desired.
- Inter-site calls are normally routed over the IP WAN.
- CTI-based applications, such as Cisco Emergency Responder, are used across sites.

Note

If dialing restrictions need to be applied to on-net inter-site calls, or an on-net numbering plan using site codes is not desired, refer to the section on [Special Considerations for Deployments Without Site Codes](#), page 9-50, for a variant of this approach that can accommodate these needs.

The following considerations apply to this approach:

- The destination numbers of intra-site four-digit calls get expanded to the unique internal DN on the IP phone display.
- The Placed Calls directory will display the original four-digit string as dialed by the user.

- Calling number, and numbers in the Missed Calls and Received Calls directories, appear as the unique internal DN.
- To preserve the four-digit dialing feature when the IP WAN is unavailable and the branch phones are in SRST mode, you need to apply a translation rule to the **call-manager-fallback** configuration within the SRST router.
- When the branch phones are in SRST mode, the Line Text Label that masks the unique internal DN as a four-digit number on the IP phone display is not available, so the users will see their full internal DN appear instead.

To better understand how to deploy the flat addressing approach, consider again the hypothetical customer network shown in [Figure 9-9](#). In this case, it has been decided that a variable-length on-net dial plan is required, with four-digit dialing within each site (the 1XXX extension range is chosen at each site) and inter-site dialing with an eight-digit string consisting of an on-net access code (8 in this example), a three-digit site code, and the four-digit extension. The three-digit site code is derived from the NANP area code for the sites located in the United States, and from the E.164 country code followed by a site identifier for the sites located in Europe. [Table 9-5](#) summarizes the site codes chosen.

Table 9-5 Site Codes for the Customer Network in [Figure 9-9](#)

| | San Jose | New York | Dallas | London | Paris | Milan |
|-----------|----------|----------|--------|--------|-------|-------|
| Site Code | 408 | 212 | 972 | 442 | 331 | 392 |

Using the US cluster from this example, the following sections analyze implementation details and best practices for different types of calls within the framework of the flat addressing approach:

- [Inter-Site Calls Within a Cluster, page 9-45](#)
- [Outgoing PSTN and IP WAN Calls, page 9-46](#)
- [Incoming Calls, page 9-49](#)
- [Voicemail Calls, page 9-49](#)
- [Special Considerations for Deployments Without Site Codes, page 9-50](#)

Inter-Site Calls Within a Cluster

Figure 9-9 shows an example configuration for inter-site calls within the US cluster.

Figure 9-9 Inter-Site Calls Within a Cluster for the Flat Addressing Method

To provide connectivity between sites and partitions, use the following guidelines:

- Place all unique DNs, including the on-net access code 8, in a global partition (named `Internal_pt` in this example).
- Create one partition per site, each containing a translation pattern that expands four-digit numbers into the fully qualified eight-digit number for that site, thus enabling abbreviated dialing within the site.
- For each site, include both the `Internal_pt` partition and the local translation partition in the phone's calling search space.

The inclusion of the on-net access code in the DN configured in Unified CM enables you to place all internal extensions in a partition directly accessible by all phones, and at the same time ensures that all call directories on the IP phones are populated with numbers that can be directly redialed.

Note

You must ensure that the on-net access code and site code combinations do not overlap with the local abbreviated dialing range at any site.

Outgoing PSTN and IP WAN Calls

Depending on how the various types of PSTN calls need to be routed (centralized gateways versus distributed gateways), the configuration may vary.

To provide on-net connectivity for inter-site calls to the Europe (EU) cluster, the following options are possible:

Option 1: Eight-Digit Numbers Only

This option relies on a single route pattern that matches all eight-digit ranges (8XXXXXXX) and points to a route list or route group that contains only a gatekeeper-controlled intercluster trunk. The gatekeeper is configured to use the site codes as zone prefixes.

This solution is simple and easy to maintain because no information is needed about other clusters' site codes or E.164 ranges. However, no automatic PSTN failover is provided when the IP WAN is unavailable, and users are expected to redial manually using the PSTN access code and the E.164 address of the destination.

Option 2: Eight-Digit Numbers and E.164 Addresses with Centralized PSTN Failover

This option, illustrated in [Figure 9-10](#), uses a global set of translation patterns that match the Europe eight-digit ranges and translate them into the corresponding E.164 numbers. The translation patterns use the central site's calling search space (in this case, San Jose), and the call then matches the international PSTN route pattern within the central site's PSTN partition. At each site, the international PSTN route pattern points to a route list with the IP WAN route group as a first choice and the local PSTN route group as a second choice. The gatekeeper is configured to use the E.164 ranges as zone prefixes.

Figure 9-10 *Outgoing PSTN and IP WAN Calls for the Flat Addressing Method with Centralized PSTN Failover for IP WAN Calls*

Note

The configuration example in [Figure 9-10](#) assumes that the line/device approach to building classes of service is being used, but the same considerations apply when using the traditional approach.

This solution requires a little more configuration and maintenance than that outlined in Option 1 because it requires that you configure and maintain information about other clusters' site codes and E.164 ranges. On the other hand, it provides automatic PSTN failover when the IP WAN is unavailable. PSTN failover is provided using the central site's gateway only, so the IP WAN bandwidth usage is not optimal.

Also observe that calls to the Europe sites dialed as PSTN calls will automatically be placed on-net if the IP WAN is available, with an automatic PSTN failover that in this case uses the local gateway.

Option 3: Eight-Digit Numbers and E.164 Addresses with Distributed PSTN Failover

This option, illustrated in [Figure 9-11](#), uses a global set of translation patterns matching the Europe eight-digit ranges and translating them into the corresponding E.164 numbers. The translation patterns use a global calling search space (used by all sites within the North American Numbering Plan), and the call then matches the international PSTN route pattern within the NANP's PSTN partition. The international PSTN route patterns point to a route list with the IP WAN route group as a first choice and the Standard Local Route Group as a second choice. The gatekeeper is configured to use the E.164 ranges as zone prefixes.

Figure 9-12 IP WAN Access for Inter-Cluster Calls Only

Incoming Calls

Incoming PSTN calls require that the E.164 number be manipulated to obtain the eight-digit internal number in order to reach the destination phone. You can implement this requirement in any of the following ways:

- Configure the Num Digits and Prefix Digits fields within the Gateway Configuration page in Unified CM to strip and then prefix the needed digits.
- If you have configured translation patterns to force on-net inter-site calls within the cluster, you can reuse these patterns by simply prefixing the PSTN access code to the incoming called number on the gateway.
- If you are using an H.323 gateway, you can use translation rules within the gateway to manipulate the digits before sending the call to Unified CM.

The third approach has the advantage that the translation rules you configured can be reused to provide incoming PSTN connectivity to the IP phones when the branch is in SRST mode.

Voicemail Calls

Because every eight-digit extension is unique within the system, the extension itself can be used to configure voicemail boxes within the voicemail system. No translations are necessary to send calls to the voicemail system or to enable Message Waiting Indicators (MWIs) within Unified CM. Note that users are required to use their eight-digit on-net number when prompted for the mailbox number.

Special Considerations for Deployments Without Site Codes

This scenario is a variant of the flat addressing approach that does not rely on the definition of an on-net numbering plan based on site codes. In this scenario, intra-site calls are still dialed as four-digit numbers, while inter-site calls are dialed as regular PSTN calls and are then intercepted and routed across the IP WAN by Unified CM.

To implement this mechanism, follow these guidelines, illustrated in [Figure 9-13](#):

- Define the phone DNs as the full E.164 addresses and place them all in the same partition (named `OnCluster_phones` in this example).
- Configure translation patterns to accept localized user input and globalize it so that a full E.164 number is obtained. The resulting globalized numbers are routed through the CSS `E164Routing`. In this example, only two device calling search spaces are required: one accepts localized user input from the Paris site, but could be reused across all French sites. The other accepts user input from the Ottawa site, but could be reused across all NANP sites.
- Configure an E.164 routing partition (`E164_part` in this example). Create the appropriate set of route patterns and route lists to route PSTN calls. In this example, we rely on a single, cluster-wide route pattern `\+!`, which is able to route all globalized destination PSTN calls to the local route group. In addition, create translation patterns that match the existing on-cluster E.164 prefixes and route calls back to the `OnCluster_phones` partition.

As a user in Paris dials a number, it is globalized through the translation patterns located in the `French_loc2glob_part` partition, and the resulting number is then routed through the `E164Routing` CSS. If the destination number is an on-cluster DN, it will simultaneously match the generic pattern `\+!` and the urgent translation pattern with the respective specific site prefix in the `E164_part` partition. The more specific site prefix will be selected, and the call will be extended to the on-cluster DN by means of the `OnCluster` calling search space. This two-step routing is required to avoid the T.302 interdigit timeout when dialing on-net destinations. If the dialed destination is not a phone on the cluster, the globalized number routed through the `E164Routing` CSS will match only the `\+!` pattern in the `E164_part` partition, and the resulting call will be routed to the PSTN.

Figure 9-13 Variable-Length Dial Plans with Flat Addressing Without Site Codes

This configuration variant allows you to simplify the dialing rules to be followed by the users. If the destination is located within the site, use abbreviated dialing (omitted from Figure 9-13 for clarity). If the destination is outside the site, whether it is on-net or off-net, dial it in the off-net PSTN form.

- Because you are effectively forcing on-net PSTN calls, remember to configure AAR so that calls can still be placed across the PSTN when the IP WAN bandwidth is not sufficient.
- The placed-calls directory displays digit strings as they were dialed by the user. For example, if the user dialed 1000 and a call was placed to phone +16135551000, the placed-calls directory would display 1000, thus allowing for direct redialing of the number without having to edit the dial string.
- The missed-calls and received-calls directories display phone numbers as they appeared when the call was offered to the phone. Because the DN's are configured as E.164 numbers with +, one-touch dialing is possible. In Figure 9-13, note that the device CSS of the phones can route calls directly to the DN's using the globalized E.164 form, including the + sign.

Deploying Dialed Pattern Recognition in SIP Phones

The dialed pattern recognition capabilities of SIP phones need to take into account the typical dialing habits to be expected from users within the enterprise. Typically any combination of the following patterns may be in use in most enterprises:

- An abbreviated dialing pattern for calls within the same site (In the case of uniform on-net dial plans, the abbreviated dialing pattern could be used for inter-site calls.)
- An inter-site dialing pattern, typically used in variable on-net dial plans when using site codes and an on-net access code such as 8
- An off-net dialing pattern for local calls
- An off-net dialing pattern for long-distance calls
- Emergency call patterns, with and without the off-net access code
- An off-net dialing pattern for international calls

Table 9-6 and Table 9-7 show an example of the SIP dial rules that could be employed in an enterprise with the following dial plan characteristics:

- Abbreviated dialing is four digits (irrespective of whether abbreviated dialing is used for inter-site calls or not)
- Inter-site calls use 8 as an on-net access code, followed by seven digits representing the site code and DN
- Emergency dialing is allowed as 911 and as 9911
- Local seven-digit calls use 9 as an off-net access code, followed by the seven digits
- Local ten-digit calls use 9 as an off-net access code, followed by the ten digits
- Long-distance calls are dialed as 91 and ten digits
- International calls are dialed as 9011 followed by a variable quantity of digits, and dialing can be terminated by #.

Pattern recognition is concerned only with automating the collection of user digit input, to be forwarded automatically to Unified CM without requiring inter-digit timeout or pressing the Dial key. All enforcement of class of service is handled by the various calling search spaces chosen from within Unified CM. That is why all phones are configured with SIP dial rules allowing the recognition of international dialing, for example, even if not all phones will be assigned to an unrestricted class of service.

The dial plan characteristics listed above are representative of the variable-length on-net dial plan with flat addressing (see [Deploying Variable-Length On-Net Dial Plans with Flat Addressing, page 9-43](#)). From the standpoint of pattern recognition, this dial plan is compatible with the uniform on-net dial plan and the variable-length on-net dial plan with partitioned addressing (see [Deploying Uniform On-Net Dial Plans, page 9-40](#)).

For each pattern in Table 9-6 and Table 9-7, the description provides the pattern in equivalent Unified CM notation. The tables provide the SIP dial rules for both the 7905_7912 and 7940_7960_OTHER cases.

**Note**

The 7905_7912 SIP dial rules are limited to 128 characters, and the 7940_7060_OTHER SIP dial rules are limited to 8K (8,192) characters.

Table 9-6 7940_7960_OTHER Dial Rule

| Description | Pattern | Timeout | Effect |
|--|-----------|---------|---|
| Abbreviated 2XXX | 2... | 0 | The combination of these six ranges represents the four-digit abbreviated dialing patterns that could be used at any site. As any string matching [2-7]XXX is dialed, it is sent to Unified CM immediately (timeout = 0). |
| Abbreviated 3XXX | 3... | 0 | |
| Abbreviated 4XXX | 4... | 0 | |
| Abbreviated 5XXX | 5... | 0 | |
| Abbreviated 6XXX | 6... | 0 | |
| Abbreviated 7XXX | 7... | 0 | |
| Inter-site dialing 8.XXXXXXX | 8,..... | 0 | Upon recognition of 8, secondary dial tone is played and seven more digits are collected, followed by immediate forwarding to Unified CM (timeout = 0). |
| Emergency 911 | 9,11 | 0 | Upon recognition of 9, secondary dial tone is played and the digits 11 are collected, with immediate forwarding to Unified CM (timeout = 0). |
| Emergency 9.911 | 9,911 | 0 | Upon recognition of 9, secondary dial tone is played and the digits 911 are collected, with immediate forwarding to Unified CM (timeout = 0). |
| Local PSTN 7-digits | 9,..... | 3 | Upon recognition of 9, secondary dial tone is played and seven more digits are collected. Timeout of 3 seconds allows the user to continue dialing when local PSTN ten-digits dialing is configured. |
| Local PSTN 10-digits | 9,..... | 0 | Upon recognition of 9, secondary dial tone is played and ten more digits are collected, with immediate forwarding to Unified CM (timeout = 0). |
| Long Distance | 9,1,..... | 0 | Upon recognition of 9, secondary dial tone is played and ten more digits are collected, with immediate forwarding to Unified CM (timeout = 0). |
| International with 6 seconds inter-digit timeout | 9,011* | 6 | Upon recognition of 9, secondary dial tone is played, then 011 and a variable quantity of digits are collected. Timeout of 6 seconds allows for user to pause dialing without triggering a call to an incomplete string. |
| International with # as end of dialing | 9,011*# | 0 | Upon recognition of 9, secondary dial tone is played, then 011 and a variable quantity of digits are collected, terminated by #. Immediate forwarding to Unified CM (timeout = 0). |
| Operator | 0 | 0 | As soon as 0 is detected, immediate forwarding to Unified CM (timeout = 0). |

Table 9-7 7905_7912 Dial Rule

| Description | Pattern | Effect |
|---------------------------------|------------------|--|
| Abbreviated 2XXX | 2...t0 | The combination of these six ranges represents the four-digit abbreviated dialing patterns that could be used at any site. As any string matching [2-7]XXX is dialed, it is sent to Unified CM immediately (t 0). |
| Abbreviated 3XXX | 3...t0 | |
| Abbreviated 4XXX | 4...t0 | |
| Abbreviated 5XXX | 5...t0 | |
| Abbreviated 6XXX | 6...t0 | |
| Abbreviated 7XXX | 7...t0 | |
| Inter-site dialing 8.XXXXXXX | 8.....t0 | The digit 8 and seven more digits are collected, followed by immediate forwarding to Unified CM (t0). |
| Emergency 911 | 911t0 | The digits 911 are collected, with immediate forwarding to Unified CM (t0). |
| Emergency 9.911 | 9911t0 | The digits 9911 are collected, with immediate forwarding to Unified CM (t0). |
| Local 7-digits and LD | 9.....t4>#....t1 | The digit 9 and seven more digits are collected, with 4 seconds allowed for up to four other digits to be dialed. If another four digits are entered, they are sent to Unified CM after 1 second. The # would be recognized as the terminating character after 9 and seven digits are entered. |
| International | 9011>#t6- | The digits 9 011 and a variable quantity of other digits are collected. Timeout of 6 seconds allows for user to pause dialing without triggering a call to an incomplete string. The # is allowed as terminating character. |
| Operator | 0 | As soon as 0 is detected, immediate forwarding to Unified CM (timeout = 0). |

Building Classes of Service for Unified CM

Unified CM offers two main approaches to defining and applying classes of service to users and devices: the traditional approach and the line/device approach. The fundamental elements addressed for each approach include the types of calls to be allowed (for example, local, national, or international) and the path taken by the calls (for example, IP network, local gateway, or central gateway). Both elements depend on the calling search space configuration. The following sections describe the two main approaches used in Unified CM systems to implement classes of service. Both approaches are based on the fundamental functionality of the line and device calling search space.

The device calling search space can be determined dynamically based on where in the network the phone is physically located, as determined by the phone's IP address, if Device Mobility is configured. See [Device Mobility, page 9-112](#), for more details.

Building Classes of Service for Unified CM with the Traditional Approach

With Unified CM, you can define classes of service for IP Telephony users by combining partitions and device calling search spaces with external route patterns, as follows:

- Place external route patterns in partitions associated with the destinations they can call. While you could place all route patterns in a single partition, you can achieve more refined call restriction policies by associating the route patterns with partitions according to the destinations they can call.

For example, if you place local and international route patterns in the same partition, then all users can reach both local and international destinations, which might not be desirable. Cisco recommends that you group route patterns in partitions according to the reachability policies for the various classes of service.

- Configure each calling search space to be able to reach only the partitions associated with its call restriction policy. For example, configure the local calling search space to point to the internal and local partitions, so that users assigned to this calling search space can place only internal and local calls.
- Assign these calling search spaces to the phones by configuring them on the Unified CM device pages. In this way, all lines configured on the device automatically receive the same class of service.

Figure 9-14 shows a simple example for a single-site deployment.

Figure 9-14 Basic Example of Classes of Service Using the Traditional Approach

With this approach, the device calling search space performs two distinct logical functions:

- Path selection
The calling search space contains specific partitions, which in turn contain specific route patterns that point to specific PSTN gateways through route lists and their associated route groups.
- Class of service
By selectively including certain partitions and not others in the device calling search space, you effectively apply calling restrictions to certain groups of users.

As a consequence, when you apply this approach to a multisite deployment with centralized call processing, you have to replicate partitions and calling search spaces for each site because for each site you have to create classes of service and, at the same time, route the PSTN calls out of the local branch gateways, as illustrated in Figure 9-15. Alternatively, you can configure the route patterns to point to

route lists referencing the Standard Local Route Group, thus allowing the actual egress gateway to be determined by the calling phone's device pool. This allows for the pattern to be reused between sites while retaining site specificity of call routing.

Figure 9-15 Calling Search Spaces and Partitions Needed with the Traditional Approach

To facilitate on-net dialing between sites when applying this dial plan approach to a multisite deployment with centralized call processing, place all IP phone DNs in an on-cluster or internal partition that can be reached from the calling search spaces of all sites. Note that this is not possible if the IP phone DNs overlap.

Extension Mobility Considerations with the Traditional Approach

When using the Extension Mobility feature, the dialing restrictions of a phone are a function of the logged-in (or logged-out) status of the phone. Typically, a logged-out phone should be restricted to calling other phones and services (such as 911), but access to local or toll calls through the PSTN are restricted. Conversely, a phone where a user is logged-in should allow calls according to that user's dialing privileges and should route those calls to the appropriate gateway (for example, a co-located branch gateway for local calls).

With the traditional approach for building classes of service, consider the following guidelines to apply calling restrictions when using Extension Mobility:

- At each site, configure the device calling search space for all IP phones to point to only PSTN emergency services (using the local gateway).
- Configure the line calling search spaces for IP phones used for Extension Mobility in a logged-out state to point to internal numbers only.
- For each Extension Mobility user, configure the line calling search space within the device profile to point to internal numbers and the additional PSTN route patterns allowed for their specific class of service (again, using an appropriate gateway according to company policy).

Note that, when an Extension Mobility user who is normally based in Site 1 logs into an IP phone in Site 2, the path selection for PSTN calls will change as follows:

- Emergency calls will be correctly routed using Site 2's PSTN gateway because the emergency services are provided by the device calling search space of the IP phone at Site 2.
- All other PSTN calls will be routed according to the Extension Mobility user's profile (more specifically, the line calling search space configured in the device profile). Typically, this means that these PSTN calls will traverse two WAN links and use Site 1's gateway to access the PSTN.

You can use one of the following methods to modify this behavior and ensure that PSTN calls are always routed via the local PSTN gateway even when Extension Mobility users roam across different sites:

- Include local PSTN route patterns in the device calling search space and remove them from the line calling search space within the device profile. This method ensures that local PSTN calls will be routed via the co-located branch gateway, but it also means that users will be able to dial these calls even without logging into the IP phones. Long-distance and international calls will still be routed according to the Extension Mobility user's device profile, so this solution is suitable only if these calls are usually routed via a centralized gateway.
- Define multiple device profiles for each user, one for each site to which they usually roam. Each device profile is configured so that its line calling search space points to PSTN route patterns that use the local gateway for that site. This method might prove burdensome to configure and manage if a significant number of users roam to a significant number of sites.
- Implement the line/device approach described in the next section on [Building Classes of Service for Unified CM with the Line/Device Approach, page 9-58](#).

Note

When Cisco Emergency Responder is used, the site-specific calling search space configured on the device should include the partition containing the 911 CTI route point pointing to Cisco Emergency Responder. This same partition can also contain a translation pattern 9.911 pointing to the same 911 CTI route point, to allow users to dial 9911 when trying to reach emergency services.

Building Classes of Service for Unified CM with the Line/Device Approach

The traditional approach outlined in the preceding section can result in a large number of partitions and calling search spaces when applied to large multisite deployments with centralized call processing. This configuration is required because the device calling search space is used to determine both the path selection (which PSTN gateway to use for external calls) and the class of service.

It is possible to significantly decrease the total number of partitions and calling search spaces needed by dividing these two functions between the line calling search space and the device calling search space, in what is called the *line/device approach*.

Keeping in mind how the line calling search space and the device calling search space for each given IP phone are combined within Unified CM, and how the line calling search space partitions appear first in the resulting calling search space (see [Calling Privileges in Unified CM, page 9-101](#)), you can apply the following general rules to the line/device approach:

- Use the device calling search space to provide call routing information (for example, which gateway to select for PSTN calls).
- Use the line calling search space to provide class-of-service information (for example, which calls to allow).

To better understand how to apply these rules, consider the example shown in [Figure 9-16](#), where the device calling search space contains a partition with route patterns to all PSTN numbers, including international numbers. The route patterns point to a PSTN gateway via the route list and route group construct.

Figure 9-16 Key Concepts in the Line/Device Approach

At the same time, the line calling search space contains a partition with a single translation pattern that matches international numbers and that has been configured as a blocked pattern.

The resulting calling search space therefore contains two identical patterns matching international numbers, with the blocked pattern in the line calling search space appearing first. The result is that international calls from this line will be blocked.

It is possible to use route patterns instead of translation patterns to block calls within the line calling search space. To configure a blocked route pattern, first create a "dummy" gateway with an unused IP address and place it into a "dummy" route list and route group construct. Then point the route pattern to the dummy route list. The main difference between using a route pattern and a translation pattern to block calls is the end-user experience when trying to dial a blocked number, as follows:

- When a route pattern is used, the end users will be able to dial the entire number and only then will they hear a fast-busy tone.
- When a translation pattern is used, the end users will hear a fast-busy tone as soon as the number they are dialing can no longer match any allowed pattern. This behavior assumes an IP phone running SCCP, or an Type-B IP phone running SIP with no SIP dial rules configured in the phone.

Follow these guidelines to implement the line/device approach in a multisite deployment with centralized call processing:

- Create an unrestricted calling search space for each site and assign it to the phone's device calling search space. This calling search space should contain a partition featuring route patterns that route the calls to the appropriate gateway for the phone's location (for example, a co-located branch gateway for emergency services and a centralized gateway for long-distance calls).
- Create calling search spaces containing partitions featuring blocked translation/route patterns for those types of calls not part of the user's dialing privileges, and assign them to the user's lines. For instance, if a user has access to all types of calls except international, that user's line (or lines) should be configured with a calling search space that blocks the 9.011! route pattern.

Figure 9-17 shows an example of how these guidelines can apply to a multisite deployment with N sites.

Figure 9-17 Calling Search Spaces and Partitions Needed with the Line/Device Approach

This approach has the significant advantage that only a single site-specific, unrestricted calling search space is required for each site (that is, one per branch). Because the dialing privileges are implemented through the use of blocked route patterns (which are not site-dependent), the same set of blocking calling search spaces can be used in all branches.

Consequently, you can use the following formulas to calculate the total number of calling search spaces and partitions needed:

Total Partitions = (Number of classes of service) + (Number of sites) + (1 Partition for all IP phone DNs)

Total Calling Search Spaces = (Number of classes of service) + (Number of sites)

**Note**

These values represent the minimum numbers of partitions and calling search spaces required. You may need additional partitions and calling search spaces for special devices and applications, as well as for on-net patterns for other call processing agents.

**Note**

If Cisco Emergency Responder is used, the 911 CTI route pattern and 9.911 translation pattern can be placed in the global On-Cluster partition.

When applied to centralized call processing deployments with large numbers of sites, the line/device approach drastically reduces the number of partitions and calling search spaces needed. For example, a deployment with 100 remote sites and 4 classes of service requires at least 401 partitions and 400 calling search spaces with the traditional approach but only 105 partitions and 104 calling search spaces with the line/device approach.

However, the line/device approach relies on the fact that you can globally identify the types of PSTN calls that must be restricted for certain classes of service (for example, local, long-distance, and international calls). If the national numbering plan of your country does not allow this global identification of the different types of calls, the efficiency of this approach (in terms of configuration savings) is lower than that indicated in the formulas above.

For example, in France the numbering plan is based on five area codes, from 01 to 05 (plus the 06 area code for cellular phones), followed by eight digits for the subscriber number. The key characteristic is that each PSTN destination is reached by dialing exactly the same number (for example, 01XXXXXXXX for Paris numbers, 04XXXXXXXX for Nice numbers, and so on), whether calling from the same local area or from a different area. This means that it is not possible to block access to long-distance calls with a single partition and a single route pattern because the concept of "long-distance call" changes depending on the area where the calling party is located. (For example, a call to 014455667788 is a local call if the caller is in Paris but a long-distance call if the caller is in Nice or Lyon.)

In such cases, you will have to configure additional sets of blocking calling search spaces and partitions, one for each area within which local and long distance calls are dialed the same way. In the example of France, you would have to define five additional blocking calling search spaces and partitions, one for each area code, as shown in [Table 9-8](#):

Table 9-8 *The Line/Device Approach Applied to the French National Numbering Plan*

| Calling Search Space | Partition | Blocked Route Patterns |
|----------------------|---------------------|------------------------|
| Internal_css | BlockAllNational_pt | 0.0[1-6]XXXXXXXX |
| | BlockIntl_pt | 0.00!, 0.00!# |
| Local01_css | BlockLD01_pt | 0.0[2-6]XXXXXXXX |
| | BlockIntl_pt | 0.00!, 0.00!# |
| Local02_css | BlockLD02_pt | 0.0[13-6]XXXXXXXX |
| | BlockIntl_pt | 0.00!, 0.00!# |

Table 9-8 The Line/Device Approach Applied to the French National Numbering Plan

| Calling Search Space | Partition | Blocked Route Patterns |
|----------------------|--------------|------------------------|
| Local03_css | BlockLD03_pt | 0.0[124-6]XXXXXXXX |
| | BlockIntl_pt | 0.00!, 0.00!# |
| Local04_css | BlockLD04_pt | 0.0[1-356]XXXXXXXX |
| | BlockIntl_pt | 0.00!, 0.00!# |
| Local05_css | BlockLD05_pt | 0.0[1-46]XXXXXXXX |
| | BlockIntl_pt | 0.00!, 0.00!# |
| LD_css | BlockIntl_pt | 0.00!, 0.00!# |
| Intl_css | NoBlock_pt | none |

Guidelines for the Line/Device Approach

Consider the following guidelines when using the line/device approach:

- For this approach to work, the blocked patterns configured within the line calling search space must be at least as specific as the route patterns configured within the device calling search space. Wherever possible, Cisco recommends that you configure the blocked patterns as more specific than the routed ones, to avoid any possibility of error. Use extra care when dealing with the @ wildcard because the patterns defined within it are very specific.
- AAR is triggered when on-net DNs are dialed. Access to these DNs can be controlled by the same processes described previously. AAR uses a different calling search space for rerouted calls. In most cases, the AAR calling search space can be the same as the site-specific, unrestricted device calling search space because it can never be dialed directly by end users.
- Refer to the section on [Call-Forward Calling Search Spaces, page 9-104](#), for guidance on using the line/device approach for Call Forward All actions.

Note

The priority order between line and device is reversed for CTI devices (CTI route points and CTI ports). For these devices, the partitions in the device calling search space are placed before the line calling search space in the resulting calling search space. Therefore, the line/device approach cannot be applied to CTI devices such as Cisco IP SoftPhone unless you are careful not to rely solely on the concatenation order for pattern selection but instead ensure that the desired blocked pattern's precision is greater in all cases than that of the permitted pattern(s).

Globalized Numbers and Class of Service

System administrators using the line-device approach for calling search spaces should be aware that the blocked patterns used in the line CSS of endpoints might have to block not only the localized form but also the globalized form of calls. While the localized form of a number lends itself to classification as local, regional, or national, the globalized form does not. This can lead to class-of-service disparities, where direct user dialing is subjected to a class of service while one-touch dialing from the missed and received calls lists is not.

For example, consider creating a local class of service for the city of Ottawa, Ontario, Canada. All local calls in Ottawa fall into the area codes 613 and 819, and local calling is implemented using 10-digit dialing. If only localized user input is allowed on a phone in Ottawa, the class of service "local" can be imposed on a phone by allowing only calls made in the form 9[2-9]XX[2-9]XXXXXX. Any call made

to a national (long distance) destination would start with a different dialing form (off-net access code 9 followed by the national steering code 1, followed by the number), as would international calls (9 followed by 011). The form of the call defines its class.

If one-touch redial is to be implemented, the global form of local numbers is to be allowed in the phone's dial plan. For a dial plan based on line-device approach, where class-of-service is implemented through blocked patterns addressed by line calling search spaces, this means that a series of blocked patterns has to be implemented to allow only calls to area codes 613 and 819. This could be achieved, for example, by the following blocked patterns:

```
\+1[^68]!  
\+16[^1]!  
\+161[^3]!  
\+18[^1]!  
\+181[^9]!
```

Typically we require a blocked pattern per significant digit and digit string to be allowed. The above set of blocked patterns would allow local calls to be one-touch dialed from the missed or received calls list.

The situation becomes more complicated, however, because not all 613 and 819 area code destinations are local calls. While the localized patterns will permit a user to initiate a call only to local destinations (by dialing 9 819 or 9 613 as the beginning of the dial string), the globalized patterns will allow a user to receive a call from a non-local number in area code 613 or 819, go to the received calls list, and one-touch dial the number back, matching the globalized patterns. In such instances, the global form blocked patterns should be refined to represent exactly the local calling area. For the example above, this would entail defining the exact subset of area codes 613 and 819 that are within the local calling area for Ottawa. The set of refined blocked patterns can become very complex, depending on the structure of the local calling area.

Also, these +E.164 blocked patterns, in contrast to the localized form, are site-specific and cannot be reused for other sites. The line calling search space inherits this site specificity, so that the line calling search space implementing class-of-service "local" for Ottawa in the above example is specific to the site in Ottawa. This fundamentally breaks the whole idea of the line-device approach to decrease the number of required calling search spaces by creating classes of services through site-unspecific calling search spaces that can be used universally for all sites.

Extension Mobility Considerations for the Line/Device Approach

When using the Extension Mobility feature, the line/device approach provides a natural way to implement the dialing restrictions of a phone as a function of the logged-in (or logged-out) status of the phone. Typically, a logged-out phone should be restricted to calling other phones and services (such as 911), but access to local or toll calls through the PSTN are restricted. Conversely, a phone where a user is logged-in should allow calls according to that user's dialing privileges and should route those calls to the appropriate gateway (for example, a co-located branch gateway for local calls).

With the line/device approach for building classes of service, you can simply apply the same rules described in the previous section to the Extension Mobility device profile construct. Consider the following guidelines to apply calling restrictions when using Extension Mobility:

- At each site, configure the device calling search space for all IP phones to point to a site-specific partition that contains all possible PSTN route patterns and that routes them appropriately (for example, using the local gateway for emergency and local calls and a centralized gateway for long distance calls).

- Configure the line calling search space for all IP phones (or the line calling search space for the default logout device profile) to point to a global calling search space featuring blocked translation/route patterns that block all calls except those to be allowed when no user is logged in (for example, internal extensions and emergency services).
- For each Extension Mobility user, configure the line calling search space within the device profile to point to a global calling search space featuring blocked translation/route patterns to selectively block the PSTN calls that are not to be allowed for their specific class of service (for example, block only international calls). If some users must have unrestricted calling privileges, assign them to a line calling search space featuring an empty partition.

The key advantage of using the line/device approach for extension mobility is that, in a multisite deployment with centralized call processing, appropriate call routing is ensured even when users log in to IP phones located at branch sites different from their home site, as illustrated in [Figure 9-18](#).

Figure 9-18 Extension Mobility with the Line/Device Approach

As described previously in this chapter, the line calling search space configured within the device profile replaces the line calling search space configured on the physical IP phone when a user logs in through Extension Mobility. Because the call routing is correctly determined by the device calling search space, the login operation is used merely to "unlock" the phone by removing the phone's line calling search space (which contains blocked patterns) and replacing it with the device profile's line calling search space (which does not contain blocked patterns in this simplified example).

Because all the call routing is done within the device calling search space while the line calling search space only introduces blocked patterns, whenever a user logs in at a different site from their home site, they will automatically inherit all the local dialing habits for that site. For example, assume that phone DNs are defined as eight-digit numbers, but four-digit dialing is provided within each site by local translation patterns. In this case, a user roaming to a different site will not be able to dial a colleague at the home site by using only four digits because the four-digit number will now be translated according to the rules of the host site where the user logged in.

In summary, when you use the line/device approach for Extension Mobility, end-users have to adopt the dialing behavior of the site where they logged in.

Call Forwarding Considerations

When applying the Line/Device calling search space approach to a centralized call processing environment with Extension Mobility, you should be aware of the call forwarding behavior if users need to be allowed to forward all their calls to external PSTN numbers.

In [Figure 9-19](#), an Extension Mobility user is normally based in Site 1, with a device profile allows the user to place unrestricted PSTN calls and to forward all incoming calls to any PSTN number.

Figure 9-19 Call Forwarding Considerations for Extension Mobility with the Line/Device Approach

As described in the section on [Call-Forward Calling Search Spaces, page 9-104](#), the Forward All calling search space is not concatenated with the line or the device calling search spaces and therefore needs to be set to Site1_all, which includes all PSTN routes using the Site 1 gateway.

When this user moves to Site 2 and logs into phone D, the user's device profile applies its line calling search space and Forward All calling search space(s) to the physical device. For direct PSTN calls, the calling search space used is the concatenation of the line and device calling search space, and phone D's device calling search space (Site2_all) correctly points to the Site 2 gateway.

If the user now configures the phone to forward all calls to a PSTN number, any forwarded call will use the Site1_all calling search space, which still points to the Site 1 gateway. This condition results in the following behavior:

- Incoming PSTN calls enter the IP network at the Site 1 gateway and are hairpinned back into the PSTN within the same gateway.
- Calls originating from Site 1 phones (such as phone A) are correctly forwarded to the PSTN via the Site 1 gateway.
- Calls originating from Site 2 phones (such as phone C) traverse the WAN to Site 1 and access the PSTN via the Site 1 gateway. The same behavior applies to calls originating from other sites within the same Unified CM cluster.

Keep this behavior in mind when designing the network and training the users.

Building Classes of Service for Unified CM for +E.164 Dial Plans with the Traditional Approach and Local Route Group

Trying to support globalized +E.164 dialing with the line-device approach has the problem that the required blocked patterns for some classes of service make the line calling search spaces site-specific, which negates the design goal of the line-device approach to minimize the number of required calling search spaces by using site-unspecific line calling search spaces addressing the appropriate blocked patterns. With that in mind, the advantage of the line-device approach over the traditional approach seems to be minimal, especially since the introduction of the concept of local route groups with Unified CM 7.0. The use of local route groups allows the administrator to move the site-specific egress gateway selection from the route pattern to the local group selection specific to the calling device. This selection process uses the local route group configured in the calling device's device pool.

The main difference of this approach is that the effective class of service is not the result of combining route patterns on the device blocked patterns on the line, but is the direct result of any pattern addressed by the single class-of-service specific calling search space. (See [Figure 9-20](#).)

Figure 9-20 Class of Service "International" for +E.164 Dial Plans

Figure 9-20 shows an example of how to implement class of service "international" for a single site in the US. In this concept, the local habitual dialing is normalized to +E.164 through translation patterns in partitions `SJCIntra`, `SJCE164local`, and `UStoE164International`.

The translation in partition `SJCIntra` implements 4-digit intra-site dialing, assuming that all local DID's of the site are in the range +1 408 555 1XXX. Local dialing (9+7) for the site in San Jose is implemented by the translation pattern in partition `SJCE164local` by again transforming the local habitual dialing to +E.164. The same is true for partition `UStoE164International`, which implements the globalization of US habitual PSTN dialing to international and national destinations.

The naming convention used here helps to identify which pieces of the dial plan need to be replicated to support multiple classes of service, sites, and dialing domains. If the name includes the specification of a site (for example, `SJC` in partition name `SJCE164Local`), then this element needs to be replicated for every site. If the name includes the specification of a class of service (for example, `International` in `USE164International`), then it needs to be replicated for every class of service. If the name does not include the specification of a site (for example, partition `USPSTNNational`), then it can be reused for all sites.

The single calling search space creating the requested class of service can be used as a line or device calling search space. In deployments that support mobility features such as extension mobility or device mobility, the line calling search space has to be used to enable the user to keep his class of service when roaming.

Using Non +E.164 Directory Numbers

The above example assumes that all directory numbers are configured as +E.164 so that the directory numbers can be matched directly after normalizing the local habitual dialing to +E.164. In cases where directory numbers are not configured as +E.164, an intermediate routing step is required to again map from the internal +E.164 routing to the format of the configured DNs. (See [Figure 9-21](#).)

Figure 9-21 Indirection to Support Non +E.164 Directory Numbers

The additional indirection step shown in [Figure 9-21](#) makes sure that all directory numbers not in +E.164 format can be reached by dialing either the local habitual format or +E.164. Partition DN in this case does not hold the actual directory numbers but a set of urgent translation patterns matching all on-net DID ranges. If, for example, a site uses DID range +1 408 555 1XXX and the directory numbers are configured as E.164 without the leading +, then an urgent translation pattern \+.14085551XXX needs to be created in partition DN with the digit discard instruction set to discard pre-dot. A user with extension +1 408 555 1234 can now be reached from other users using the calling search space in the example by dialing:

- 1234: Translation pattern in partition SJCIntra transforms dialed digits to +14085551234, translation pattern +14085551XXX in partition DN transforms to 14085551234, and then we get a match on the directory number in partition nonE164DN.
- 95551234: Translation pattern in partition SJCE164local globalizes the dialed digits and then the call flow is the same as for 4-digit intra-site dialing.

- 914085551234: Translation pattern in partition UStoE164International globalizes the dialed digits and then the call flow is the same as for 4-digit intra-site dialing.
- +14085551234: Translation pattern +14085551XXX in partition DN transforms to 14085551234 and then we get a match on the directory number in partition nonE164DN.

Keep in mind that, when using non +E.164 directory numbers, you will have to make sure that the calling party number for calls originating from these lines is set to +E.164 to ensure that correct calling party information can be delivered for all call flows. This can be achieved by setting the external phone number mask to +E.164 for all line appearances and configuring the calling party transformations on the translation patterns in partition DN to use the external phone number mask. Another option to globalize non +E.164 directory numbers is to use the incoming call's calling party transformation calling search space on the phone or phone's device pool. This method is supported in Cisco Unified CM 9.0 and later releases, and is the recommended way to globalize directory numbers. Using globalization based on this calling search space has the advantage of also working with URI-dialed call flows for which number transformations configured on translation patterns are not applicable.

Overlaps Between Directory Numbers and International PSTN Dialing

Directory numbers in Unified CM always are stored in digit analysis as non-urgent patterns. This can lead to the situation that dialing an international on-net destination causes a partial overlap with the international PSTN route pattern `\+[^1]!`. For example, if a user in San Jose dials +496100773 and that happens to be a directory number configured on the system, then the call using the schema without the additional indirection step (Figure 9-20) will hit the interdigit time-out limit because, although we have a match on directory number `\+496100773`, there is another potential match on the variable length pattern `\+[^1]!` in partition PSTNInternational. One way to avoid this is to add specific, urgent fixed-length route patterns to the PSTNInternational partition for all countries where we have on-net directory numbers. The urgent route pattern in the PSTNInternational partition will terminate digit collection, but Unified CM will then still route the call to the best match, which in this case is the directory number in partition DN. This approach works only for countries with a fixed-length national numbering plan. If the national numbering plan is a variable-length numbering plan (such as in Germany), the only way to solve the overlap between directory numbers and the variable-length PSTN route pattern is to implement the intermediate routing step as shown in Figure 9-21. In this case the urgent translation patterns in partition DN serve the purpose of adding urgent patterns to digit analysis that will make sure that digit collection terminates as soon as a known on-net destination is dialed.

Other Classes of Service

Based on the example in [Figure 9-20](#) and [Figure 9-21](#), other classes of service such as "national" and "local" are created by removing the unnecessary PSTN route patterns and recreating the dialing normalization of the local habitual dialing habits. (See [Figure 9-22](#).)

Figure 9-22 Class of Service "National" for +E.164 Dial Plans

[Figure 9-22](#) shows how to build class of service "national." Comparing this schema to class of service "international" in [Figure 9-20](#), we see that partitions SJCIntra, SJCE164local, USPSTNNational, and SJCPSTNLocal can be reused and so can calling search spaces DN and SJCE164Local. The dialing normalization in UStoE164National has to be recreated because using the dialing normalization as defined by the patterns in partition UStoE164International in [Figure 9-20](#) would also grant access to the international PSTN route pattern `\+[^1]` in partition PSTNInternational. This is a result of the fact that, in the definition of a translation pattern, we define a single calling search space that has to be used after applying the called and calling party transformations defined in the translation pattern. Because a calling search space is equivalent to a class of service, the translation patterns inherit the class-of-service specificity of the egress calling search space defined in the translation patterns and thus also become class-of-service specific.

Dialing normalization in partition UStoE164National does include dialing normalization patterns for the local habitual international dialing 9011 because we need to support international dialing to international on-net destinations (directory numbers in partition DN outside the US).

Classes of service "local" and "internal" can be created using the same approach. Partition SJCSTNLocal is not really required to build class of service "international", but providing this differentiated PSTN access from the beginning permits reuse of partitions SJCSTNLocal and SJCtoE164Local for class of service "local". Keep in mind that partition SJCSTNLocal cannot be reused for class of service "internal," which should not provide access to the PSTN. For this class of service the dialing normalization of the local dialing has to be replicated as shown in [Figure 9-23](#).

Figure 9-23 Class of Service "internal" for +E.164 Dial Plans

292523

Emergency Calls

Access to emergency services has to be granted to all users. This can be achieved either by adding the partition with the emergency number route patterns to each calling search space or by enabling access to the emergency number route patterns through the device-level calling search space. If access to emergency numbers is granted through the device calling search space, then in roaming scenarios (for example, extension mobility) the user has to dial emergency services using the habitual dialing of the visited site, while access to emergency numbers through the line calling search space would allow the user to dial emergency services using the habitual dialing of the home site. This differentiation obviously is important only if the habitual dialing of emergency services differs between home and visiting site as, for example, in the case of a European user (emergency number 112) logging into an US phone (emergency number 911).

Building Classes of Service in Cisco IOS with H.323

The following scenarios require you to define classes of service within Cisco IOS routers running the H.323 protocol:

- Unified CM multisite deployments with centralized call processing
- Cisco Unified Communications Manager Express (Unified CME) deployments

Under normal conditions in Unified CM multisite deployments with centralized call processing, classes of service are implemented using partitions and calling search spaces within Unified CM. However, when IP WAN connectivity is lost between a branch site and the central site, Cisco SRST takes control of the branch IP phones, and all the configuration related to partitions and calling search spaces is unavailable until IP WAN connectivity is restored. Therefore, it is desirable to implement classes of service within the branch router when running in SRST mode.

Similarly, in Unified CME deployments, the router needs a mechanism to implement classes of service for the IP phones.

For both of these applications, define classes of service in Cisco IOS routers by using the class of restriction (COR) functionality (refer to [Calling Privileges in Cisco IOS with H.323 Dial Peers](#), page 9-140, for details on COR).

You can adapt the COR functionality to replicate the Unified CM concepts of partitions and calling search spaces by following these main guidelines:

- Define tags for each type of call that you want to distinguish.
- Assign "basic" outgoing corlists (equivalent to partitions), containing a single member tag, to the respective POTS dial peers that route each type of call.
- Assign "complex" incoming corlists (equivalent to calling search spaces), containing subsets of the member tags, to the IP phones that belong to the various classes of service.

[Figure 9-24](#) illustrates an implementation example based on SRST, where the IP phone with DN 2002 is configured to have unrestricted PSTN access, the IP phone with DN 2001 is configured to have only local PSTN access, and all other IP phones are configured to have access only to internal numbers and emergency services.

Figure 9-24 Building Classes of Service for Cisco SRST using COR

The following steps provide examples and guidelines for implementing a Cisco IOS solution like the one shown in Figure 9-24.

- Step 1** Using the **dial-peer cor custom** command, define meaningful tags for the various types of calls (Emergency, VMail, Local, LD, Intl):

```
dial-peer cor custom
  name Emergency
  name VMail
  name Local
  name LD
  name Intl
```

- Step 2** Using the **dial-peer cor list** command, define basic corlists to be used as partitions, each containing a single tag as a member:

```
dial-peer cor list EmPt
  member Emergency

dial-peer cor list VMailPt
  member VMail

dial-peer cor list LocalPt
  member Local

dial-peer cor list LDpt
  member LD
```

```
dial-peer cor list IntlPt
  member Intl
```

- Step 3** Using the **dial-peer cor list** command, define more complex corlists to be used as calling search spaces, each containing a subset of the tags as members according to the classes of service needed:

```
dial-peer cor list InternalCSS
  member Emergency
  member VMail
```

```
dial-peer cor list LocalCSS
  member Emergency
  member VMail
  member Local
```

```
dial-peer cor list LDCSS
  member Emergency
  member VMail
  member Local
  member LD
```

```
dial-peer cor list IntlCSS
  member Emergency
  member VMail
  member Local
  member LD
  member Intl
```

- Step 4** Using the command **corlist outgoing** *corlist-name*, configure the basic “partition” corlists as outgoing corlists assigned to the corresponding POTS dial peers:

```
dial-peer voice 100 pots
  corlist outgoing EmPt
  destination-pattern 911
  no digit-strip
  direct-inward-dial
  port 1/0:23
```

```
dial-peer voice 101 pots
  corlist outgoing VMailPt
  destination-pattern 914085551234
  forward-digits 11
  direct-inward-dial
  port 1/0:23
```

```
dial-peer voice 102 pots
  corlist outgoing LocalPt
  destination-pattern 9[2-9].....
  forward-digits 7
  direct-inward-dial
  port 1/0:23
```

```
dial-peer voice 103 pots
  corlist outgoing LDPT
  destination-pattern 91[2-9]..[2-9].....
  forward-digits 11
  direct-inward-dial
  port 1/0:23
```

```
dial-peer voice 104 pots
  corlist outgoing IntlPt
  destination-pattern 9011T
  prefix-digits 011
```

```
direct-inward-dial
port 1/0:23
```

Step 5 Using the **cor incoming** command within the **call-manager-fallback** configuration mode, configure the complex corlists acting as "calling search spaces" to be incoming corlists assigned to the various phone DNs:

```
call-manager-fallback
cor incoming InternalCSS default
cor incoming LocalCSS 1 3001 - 3003
cor incoming LDCSS 2 3004
cor incoming IntlCSS 3 3010
```

When deploying COR for SRST, keep in mind the following limitations:

- In SRST version 2.0, available on Cisco IOS Release 12.2(8)T or later, the maximum number of **cor incoming** statements allowed under **call-manager-fallback** is 5 (plus the default statement).
- In SRST version 3.0, available on Cisco IOS Release 12.3(4)T or later, the maximum number of **cor incoming** statements allowed under **call-manager-fallback** is 20 (plus the default statement).

Therefore, if the phone DNs of users with non-default privileges are not consecutive and the SRST site is relatively large, you might have to reduce the number of classes of service in SRST mode to accommodate all the DNs without exceeding these limitations.

Although the preceding example is based on Cisco SRST, the same concepts can be applied to a Cisco Unified Communications Manager Express (Unified CME) deployment, except for the following considerations:

- With Unified CME, the corlist expressing the class of service (equivalent to a calling search space) can be assigned directly to the individual IP phones by using the **cor {incoming | outgoing} corlist-name** command under the **ephone-dn dn-tag** configuration mode.
- According to COR general rules, all IP phones for which no corlist is configured have unrestricted access to all dial peers, regardless of their outgoing corlist. Unified CME has no mechanism equivalent to the **cor incoming corlist-name default** command, which applies default restrictions to all phones.

Deploying Call Coverage

Call coverage functionality is a key feature in many IP telephony deployments. Many customer-focused service companies have to route customer calls to the appropriate service representatives expeditiously. This section focuses on design guidelines for using the hunting mechanism based on hunt pilots, hunt lists, and line groups in Cisco Unified CM Release 4.1 to manage call distribution, and it covers the following main topics:

- [Deploying Call Coverage in a Multisite Centralized Call Processing Model, page 9-76](#)
- [Deploying Call Coverage in a Multisite Distributed Call Processing Model, page 9-77](#)

Note

Call coverage functionality does not offer call queues per se, and the caller is presented with ringback tone until a destination is found for the call. To provide prompting, music on hold, and so forth, Cisco offers many contact center technologies such as the Cisco Unified Customer Voice Portal (CVP). For more information on the contact center technologies available from Cisco, refer to the documentation at <http://www.cisco.com/go/ucsrnd>.

Deploying Call Coverage in a Multisite Centralized Call Processing Model

Figure 9-25 shows an example of configuring hunt lists for a multisite centralized call processing deployment. This example assumes that the hunt pilot call will be distributed first through the remote office operators. If the call is not answered or is rejected due to call admission control, the call will then be routed to central-site operators or voicemail.

Figure 9-25 Call Coverage Between Multiple Sites in a Centralized Call Processing Deployment

In centralized IP telephony systems, features such as Automated Alternate Routing (AAR) and Survivable Remote Site Telephony (SRST) may be enabled for high availability. Consider the following guidelines when deploying call coverage functionality with AAR or SRST features enabled:

- Automated Alternate Routing (AAR)

The line group members can be assigned in different locations and regions. Call admission control implemented through locations works as expected. However, a call being distributed from a hunt pilot will not use AAR to reroute a call if Unified CM blocks the call to one of its line group members due to insufficient WAN bandwidth. Instead, Unified CM distributes the call to the next available member or next available line group.

Note Cisco strongly recommends that you use only AAR to voicemail ports within line groups.

- Survivable Remote Site Telephony (SRST)
 - When Unified CM receives a call for the hunt pilot, and if some of its line group members are at the remote sites operating in SRST mode, then Unified CM skips those members and distributes the call to the next available line group member. From the perspective of Unified CM, the members operating in SRST mode are unregistered, and hunt pilot calls are not forwarded to unregistered members.
 - When a router operating in SRST mode receives a call for the hunt pilot, call coverage functionality is unavailable. The call fails if no configuration is added to reroute the call to a registered and available extension. You can use the **alias** or the **default-destination** command under the **call-manager-fallback** mode in Cisco IOS to reroute the call destined for the hunt pilot to an operator extension or to voicemail.

Deploying Call Coverage in a Multisite Distributed Call Processing Model

Beginning with Cisco Unified CM Release 4.1, route groups can no longer be added to hunt lists. Thus, a hunt list cannot be used to send the calls to other clusters or to a remote gateway. But the hunt option settings in Hunt Pilot, introduced in Cisco Unified CM Release 4.1, can be used to match a route pattern that in turn points to gateways or trunks.

Figure 9-26 shows an example of configuring hunt lists for a distributed call processing deployment with an intercluster trunk. This example assumes that the hunt pilot call is first distributed within Cluster A. If the call is not answered, it is rerouted to Cluster B for call distribution using the Forward Hunt No Answer setting, which matches a route pattern. The route pattern, in turn, points to an intercluster trunk to Cluster B.

Figure 9-26 Call Coverage Between Clusters in a Distributed Call Processing Deployment

126915

**Tip**

In distributed call processing deployments, load sharing of incoming hunt pilot calls can be managed using Cisco VoIP gateways and gatekeepers. In the event that the call is not answered within one cluster, it can overflow to another cluster for service. Calls can also be sent through gateways or trunks to IVR treatment. Tool Command Language (TCL) IVR applications can be implemented on Cisco IOS gateways.

Guidelines

When deploying call coverage functionality in a distributed call processing model, if calls are distributed across multiple clusters, then the route patterns should be properly configured to account for any digit transformations that are done on the outbound or inbound route group devices. If digit transformations are not done, then the configured route patterns and hunt pilot should be the same on all clusters, otherwise the calls will not be distributed appropriately.

Hunt Pilot Scalability

Cisco recommends using the following guidelines when deploying call coverage using top-down, circular, and longest-idle algorithms:

- The Unified CM cluster supports a maximum of 15,000 hunt list devices.
- The hunt list devices may be a combination of 1500 hunt lists with 10 IP phones in each hunt list, or a combination of 750 hunt lists with 20 IP phones in each hunt list.

**Note**

When using the broadcast algorithm for call coverage, the number of hunt list devices is limited by the number of busy hour call attempts (BHCA). Note that a BHCA of 10 on a hunt pilot pointing to a hunt list or hunt group containing 10 phones and using the broadcast algorithm is equivalent to 10 phones with a BHCA of 10.

- Cisco recommends having a maximum of 35 directory numbers in a single line group configured to send the calls simultaneously to all DNs. Additionally, the number of broadcast line groups depends on the BHCC. If there are multiple broadcast line groups in a Unified CM system, the number of maximum directory numbers in a line group must be less than 35. The number of busy hour call attempts (BHCA) for all the broadcast line groups should not exceed 35 calls set up per second.

Dial Plan Elements

This section provides design and configuration guidelines for the following dial plan elements within a Cisco Unified Communications system:

User Interface on IP Phones

Different types of IP telephones accept keypad input and present visual information in different ways. For purposes of this chapter only, we define the following phone types:

- Type-A phones — Include the Cisco Unified IP Phone 7905, 7912, 7940, and 7960.
- Type-B phones — Include the Cisco Unified IP Phone 6901, 6911, 6921, 6941, 6945, 6961, 7906, 7911, 7921, 7925, 7931, 7941, 7942, 7945, 7961, 7962, 7965, 7970, 7971, 7975, 8961, 9951, and 9971.

Calling Party Transformations on IP Phones

Calling Party Transformation Patterns allow the system to adapt the global form of the calling party's number used to route calls to phones, into the local form preferred by users.

The transformation pattern consists of a numerical representation of the calling party number to be matched. The syntax used is the same as that of other patterns such as route patterns, transformation patterns, directory numbers, and so forth.

The transformation operators include discard digit instructions (for example, pre-dot), a calling party transformation mask, prefix digits, and control over the calling party presentation (either Default, Allowed, or Restricted). Calling party transformation patterns can be configured to use the calling party's external phone number mask as the calling party number.

Partitions and calling search spaces control which calling party transformation patterns are applied to which phones. Phones can use either the device pool's calling party transformation calling search space (CSS) or the device's own calling party transformation CSS, in reverse order of precedence. Calls sent to phones are not processed through called party transformation patterns.

For phones, calling party transformation patterns affect the number displayed while the phone is ringing. The corresponding entry in the missed and received calls directories holds both the transformed number and also the original pre-transformation number. The transformed number is displayed in the directories' list, but the number used for callback is the pre-transformation number.

Support for + Dialing on the Phones

On Type-A phones, it is not possible to dial a + sign using the keypad. On Type-B phones it is possible to dial a + sign by pressing and holding either the 0 key (Cisco Unified IP Phones 7921 and 7925) or the * key (all other phone models). On Cisco Unified Personal Communicator endpoints, the + sign may be typed in by the user using the computer's keyboard or entered as part of the input string when using a click-to-dial function of the endpoint.

On Type-A phones, there is no support to display the + sign.

On Type-B phones and on Cisco Unified Personal Communicator, incoming calls can present a calling party number including + as part of the number. When a call is offered to a phone, the number shown on the ringing phone is processed by any configured calling party number transformation patterns. The missed and received calls directories hold both the original pre-transformation number and the transformed number. The number displayed in the list will be the transformed number, and the pre-transformation number will be visible only when looking at the details of an entry. The number dialed from the directory is the original pre-transformation number, allowing the one-touch dialing of previously received calls featuring the + sign as part of the calling number.

Example 9-1 Calling Party Number with + Dialing

A Type-B phone in New York receives a call from +1 408 526 4000. Calling party transformation patterns are placed in the calling party transformation CSS in the phone's device pool. One of the patterns is configured as: \+1.!, strip pre-dot.

As the call rings in, the called phone displays an incoming calling party number of 4085264000. After the call is answered and released, the received-calls directory displays the last call as 408 526 4000, but the number called when the user initiated the callback from the directory entry is +1 408 526 4000.

User Input on SCCP Phones

IP phones using SCCP report every single user input event to Unified CM immediately. For instance, as soon as the user goes off-hook, a signaling message is sent from the phone to the Unified CM server with which it is registered. The phone can be considered to be a terminal, where all decisions resulting from the user input are made by the Unified CM server's configured dial plan.

As other user events are detected by the phone, they are relayed to Unified CM individually. A user who goes off-hook and then dials 1000 would trigger five individual signaling events from the phone to Unified CM. All the resulting feedback provided to the user, such as screen messages, playing dial tone, secondary dial tone, ring back, reorder, and so forth, are commands issued by Unified CM to the phone in response to the dial plan configuration. (See [Figure 9-27](#).)

Figure 9-27 User Input and Feedback for SCCP Phones

It is neither required nor possible to configure dial plan information on IP phones running SCCP. All dial plan functionality is contained in the Unified CM cluster, including the recognition of dialing patterns as user input is collected.

If the user dials a pattern that is denied by Unified CM, reorder tone is played to the user as soon as that pattern becomes the best match in Unified CM's digit analysis. For instance, if all calls to the pay-per-minute Numbering Plan Area (or area code) 976 are denied, reorder tone would be sent to the user's phone as soon as the user dials 91976.

User Input on Type-A SIP Phones

Type-A phones differ somewhat from Type-B phones in their behavior, and Type-A phones do not offer support for Key Press Markup Language (KPML) as do Type-B phones. (See [User Input on Type-B SIP Phones](#), page 9-83.)

Type-A IP phones using SIP offer two distinct modes of operation:

- [No SIP Dial Rules Configured on the Phone](#), page 9-81
- [SIP Dial Rules Configured on the Phone](#), page 9-82

No SIP Dial Rules Configured on the Phone

[Figure 9-28](#) illustrates the behavior of a SIP Type-A phone with no dial plan rules configured on the phone. In this mode of operation, the phone accumulates all user input events until the user presses either the # key or the Dial softkey. This function is similar to the "send" button used on many mobile phones. For example, a user making a call to extension 1000 would have to press 1, 0, 0, and 0 followed by the Dial softkey or the # key. The phone would then send a SIP INVITE message to Unified CM to indicate that a call to extension 1000 is requested. As the call reaches Unified CM, it is subjected to the dial plan configuration for this phone, including all the class-of-service and call-routing logic implemented in Unified CM's dial plan.

Figure 9-28 User Input and Feedback for Type-A SIP Phones with No Dial Rules Configured

If the user dials digits but then does not press the Dial softkey or the # key, the phone will wait for inter-digit timeout (15 seconds by default) before sending a SIP INVITE message to Unified CM. For the example in [Figure 9-28](#), dialing 1, 0, 0, 0 and waiting for inter-digit timeout would result in the phone placing a call to extension 1000 after ten seconds.

Note

If the user presses the Redial softkey, the action is immediate; the user does not have to press the Dial key or wait for inter-digit timeout.

If the user dials a pattern that is denied by Unified CM, the user must enter the entire pattern and press the Dial key, and the INVITE message must be sent to Unified CM, before any indication that the call is rejected (reorder tone) is sent to the caller. For instance, if all calls to NPA 976 are denied, the user would have to dial 919765551234 and press Dial before the reorder tone would be played.

SIP Dial Rules Configured on the Phone

SIP dial rules enable the phone to recognize patterns dialed by users. Once the recognition has occurred, the sending of the SIP INVITE message to Unified CM is automated and does not require the user to press the Dial key or wait for the inter-digit timeout. (For more details, see [SIP Dial Rules, page 9-84](#).)

For example, if a branch location of the enterprise requires that calls between phones within the same branch be dialed as four-digit extensions, the phone could be configured to recognize the four-digit patterns so that the user is not required to press the Dial key or wait for the inter-digit timeout. (See [Figure 9-29](#).)

Figure 9-29 User Input and Feedback for Type-A SIP Phones with Dial Rules Configured

In [Figure 9-29](#), the phone is configured to recognize all four-digit patterns beginning with 1 and has an associated timeout value of 0. All user input actions matching the pattern will trigger the sending of the SIP INVITE message to Unified CM immediately, without requiring the user to press the Dial key.

Type-A phones using SIP dial rules offer a way to dial patterns not explicitly configured on the phone. If a dialed pattern does not match a SIP dial rule, the user can press the Dial key or wait for inter-digit timeout.

If a particular pattern is recognized by the phone but blocked by Unified CM, the user must dial the entire dial string before receiving an indication that the call is rejected by the system. For instance, if a SIP dial rule is configured on the phone to recognize calls dialed in the form 919765551234 but such calls are blocked by the Unified CM dial plan, the user will receive reorder tone at the end of dialing (after pressing the final 4 key).

User Input on Type-B SIP Phones

Type-B phones differ somewhat from Type-A phones in their behavior, and Type-B phones offer support for Key Press Markup Language (KPML) but Type-A phones do not. (See [User Input on Type-A SIP Phones](#), page 9-81.)

Type-B IP phones running SIP offer two distinct modes of operation:

- [No SIP Dial Rules Configured on the Phone](#), page 9-83
- [SIP Dial Rules Configured on the Phone](#), page 9-84

No SIP Dial Rules Configured on the Phone

Type-B IP telephones offer functionality based on the Key Press Markup Language (KPML) to report user key presses. Each one of the user input events will generate its own KPML-based message to Unified CM. From the standpoint of relaying each user action immediately to Unified CM, this mode of operation is very similar to that of phones running SCCP. (See [Figure 9-30](#).)

Figure 9-30 User Input and Feedback for Type-B SIP Phones with No Dial Rules Configured

Every user key press triggers a SIP NOTIFY message to Unified CM to report a KPML event corresponding to the key pressed by the user. This messaging enables Unified CM's digit analysis to recognize partial patterns as they are composed by the user and to provide the appropriate feedback, such as immediate reorder tone if an invalid number is being dialed.

In contrast to Type-A IP phones running SIP without dial rules, Type-B SIP phones have no Dial key to indicate the end of user input. In [Figure 9-30](#), a user dialing 1000 would be provided call progress indication (either ringback tone or reorder tone) after dialing the last 0 and without having to press the Dial key. This behavior is consistent with the user interface on phones running the SCCP protocol.

SIP Dial Rules Configured on the Phone

Type-B IP phones can be configured with SIP dial rules so that dialed pattern recognition is accomplished by the phone. (See [Figure 9-31](#).)

Figure 9-31 User Input and Feedback for Type-B SIP Phones with Dial Rules Configured

In [Figure 9-31](#), the phone is configured to recognize all four-digit patterns beginning with 1, and it has an associated timeout value of 0. All user input actions matching these criteria will trigger the sending of a SIP INVITE message to Unified CM.

Note

As soon as SIP dial rules are implemented on Type-B IP phones, KPML-based dialing is disabled. If a user dials a string of digits that do not match a SIP dial rule, none of the individual digit events will be relayed to Unified CM. Instead, the entire dialed string will be sent en-bloc to Unified CM once the dialing is complete (that is, once inter-digit timeout has occurred).

Type-B phones using SIP dial rules offer only one way to dial patterns not explicitly configured on the phone. If a dialed pattern does not match a SIP dial rule, the user has to wait for inter-digit timeout before the SIP NOTIFY message is sent to Unified CM. Unlike Type-A IP phones, Type-B IP phones do not have a Dial key to indicate the end of dialing, except when on-hook dialing is used. In the latter case, the user can press the “dial” key at any time to trigger the sending of all dialed digits to Unified CM.

Note

When a Type-B phone registers with the SRST router, the configured SIP dial rules are disabled.

If a particular pattern is recognized by the phone but blocked by Unified CM, the user must dial the entire dial string before receiving an indication that the call is rejected by the system. For instance, if a SIP dial rule is configured on the phone to recognize calls dialed in the form 919765551234 but such calls are blocked by the Unified CM dial plan, the user will receive reorder tone at the end of dialing (after pressing the 4 key).

SIP Dial Rules

Cisco Unified CM offers SIP dial rule functionality to allow phones to perform pattern recognition as user input is collected. For example, a phone can be configured to recognize the well established pattern 911 and to send a message to Unified CM to initiate an emergency call immediately, while at the same time allowing the user to enter patterns of variable length for international numbers.

It is important to note that pattern recognition configuration on the phone through the use of SIP dial rules does not supersede the Class of Service and Route Plan configurations of Unified CM. A phone might very well be configured to recognize long-distance patterns while Unified CM is configured to block such calls because the phone is assigned a class of service allowing only local calls.

There are two types of SIP dial rules, based on the phone model on which they will be deployed:

- 7905_7912 (Used for Cisco Unified IP Phones 7905 and 7912)
- 7940_7960_OTHER (Used for all other IP phone models)

There are four basic Dial Parameters that can be used as part of a dial rule:

- Pattern

This parameter is the actual numerical representation of the pattern. It can contain digits, wildcards, or instructions to play secondary dial tone. The following table provides a list of values and their effect for the two types of dial rules.

| Pattern | Dial Rule Type | |
|--------------------|---|--|
| | 7905_7912 | 7940_7960_OTHER |
| Digits 0 through 9 | Corresponding digit | Corresponding digit |
| . | Matches any digit (0 through 9) | Matches any character (0 though 9, *, #) |
| - | Indication that more digits can be entered. Must be at the end of an individual rule. | n/a |
| # | Input termination key. Place the > character in the dial rule to indicate the character position after which the # key will be recognized as input termination. For instance, in 9>#..., the # character would be recognized any time after 9 has been pressed. | n/a |
| <i>tn</i> | Indicates a timeout value of <i>n</i> seconds. For example, 1...t3 would match 1000 and trigger the sending of an invite to Unified CM after 3 seconds. | n/a |
| <i>rn</i> | Repeats the last character <i>n</i> times. For example, 1.r3 is equivalent to 1.... | n/a |
| S | When a pattern contains the modifier S, all other dial rules after this pattern are ignored. S effectively causes rule matching to cease. | n/a |

| Pattern | Dial Rule Type | |
|---------|---|---|
| | 7905_7912 | 7940_7960_OTHER |
| * | Input termination key. Place the > character in the dial rule to indicate the character position after which the * key will be recognized as input termination. | Matches one or more characters. For instance, pattern 1* would match 10, 112, 123456, and so forth. |
| , | n/a | Cause the phone to play secondary dial tone. For instance, 8,... would cause the user to hear secondary dial tone after 8 is pressed. |

- IButton

This parameter specifies the button to which the dial pattern applies. If the user is initiating a call on line button 1, only the dial patterns specified for Button 1 apply. If this optional parameter is not configured, the dial pattern applies to all lines on the phone. This parameter applies only to the Cisco SIP IP Phones 7940, 7941, 7942, 7945, 7960, 7961, 7962, 7965, 7970, 7971, and 7975. The button number corresponds to the order of the buttons on the side of the screen, from top to bottom, with 1 being on top button.

- Timeout

This parameter specifies the time, in seconds, before the system times out and dials the number as entered by the user. To have the number dialed immediately, specify 0. This parameter is available only for 7940_7960_OTHER dial rules. If this parameter is omitted, the phone's default inter-digit timeout value is used (default of 10 seconds).

- User

This parameter represents the tag that automatically gets added to the dialed number. Valid values include **IP** (when SIP Call Agents other than Unified CM are deployed) and **Phone**. This parameter is available only for 7940_7960_OTHER dial rules. This parameter is optional, and it should be omitted in deployments where Unified CM is the only call agent.

Note

The Cisco Unified IP Phone 7905 and 7912 choose patterns in the order in which they have been created in the SIP dial rules, whereas all the other phone models choose the pattern offering the longest match. The following table shows which pattern would be chosen if a user dialed 95551212.

| SIP Dial Rules | 7905_7912 | 7940_7960_OTHER |
|----------------|---------------------------------|--------------------------|
| | Chooses first matching pattern: | Chooses longest matching |
| 9..... | | pattern: 9..... |

Call Routing in Unified CM

All numeric dialing destinations configured in Unified CM are added to its internal call routing table as patterns. These destinations include IP phone lines, voicemail ports, route patterns, translation patterns, and CTI route points.

When a number is dialed, Unified CM uses closest-match logic to select which pattern to match from among all the patterns in its numeric call routing table. In practice, when multiple potentially matching numeric patterns are present, the destination pattern is chosen based on the following criteria:

- It matches the dialed string, and
- Among all the potentially matching patterns, it matches the fewest strings other than the dialed string.

For example, consider the case shown in [Figure 9-32](#), where the call routing table includes the patterns 1XXX, 12XX, and 1234.

Figure 9-32 Unified CM Call Routing Logic Example

When user A dials the string 1200, Unified CM compares it with the patterns in its call routing table. In this case, there are two potentially matching patterns, 1XXX and 12XX. Both of them match the dialed string, but 1XXX matches a total of 1000 strings (from 1000 to 1999) while 12XX matches only 100 strings (from 1200 to 1299). Therefore, 12XX is selected as the destination of this call.

When user B dials the string 1212, there are three potentially matching patterns, 1XXX, 12XX and 121X. As mentioned above, 1XXX matches 1000 strings and 12XX matches 100 strings. However, 121X matches only 10 strings; therefore it is selected as the destination of the call.

When user C dials the string 1234, there are three potentially matching patterns, 1XXX, 12XX, and 1234. As mentioned above, 1XXX matches 1000 strings and 12XX matches 100 strings. However, 1234 matches only a single string (the dialed string); therefore it is selected as the destination of this call.

**Note**

Whenever a directory number (DN) is configured in Cisco Unified CM, it is placed in the call routing table, regardless of whether the respective device (for example, an IP phone) is registered or not. An implication of this behavior is that it is not possible to rely on secondary, identical patterns to provide failover capabilities to applications when the application (and hence the primary pattern) is unregistered. Because the primary pattern is permanently in the call routing table, the secondary pattern will never be matched.

Support for + Sign in Patterns

The + sign can be used in all patterns within Unified CM, including route patterns, translations patterns, and directory numbers. To use + in its literal sense, precede it with the escape character \ to differentiate it from the regular expression operator +, which means one or more instances of the preceding character. For example:

- \+14085264000 means +14085264000
- 2+ means 2, or 22, or 222, and so forth

External Routes in Unified CM

Unified CM automatically "knows" how to route calls to internal destinations within the same cluster. For external destinations such as PSTN gateways, H.323 gatekeepers, or other Unified CM clusters, you have to use the external route construct (described in the following sections) to configure explicit routing. This construct is based upon a three-tiered architecture that allows for multiple layers of call routing as well as digit manipulation. Unified CM searches for a configured route pattern that matches the external dialed string and uses it to select a corresponding route list, which is a prioritized list of the available paths for the call. These paths are known as route groups and are very similar to trunk groups in traditional PBX terminology. [Figure 9-33](#) depicts the three-tiered architecture of the Unified CM external route construct.

Figure 9-33 External Route Pattern Architecture

The following sections describe the individual elements of the external route construct in Unified CM:

- [Route Patterns, page 9-89](#)
- [Route Lists, page 9-93](#)
- [Route Groups, page 9-93](#)
- [Route Group Devices, page 9-96](#)

Route Patterns

Route patterns are strings of digits and wildcards, such as 9.[2-9]XXXXXX, configured in Unified CM to route calls to external entities. The route pattern can point directly to a gateway for routing calls or point to a route list, which in turn points to a route group and finally to a gateway.

Cisco strongly recommends that you use the complete route pattern, route list, and route group construct because it provides the greatest flexibility for call routing, digit manipulation, route redundancy, and future dial plan growth.

The @ Wildcard

- The @ wildcard is a special macro function that expands into a series of patterns representing the entire national numbering plan for a certain country. For example, configuring a single unfiltered route pattern such as 9.@ with the North American Numbering Plan really adds 166 individual route patterns to the Unified CM internal dial plan database.
- It is possible to configure Unified CM to accept other national numbering plans. Once this is done, the @ wildcard can be used for different numbering plans even within the same Unified CM cluster, depending on the value selected in the Numbering Plan field on the Route Pattern configuration page. For more information, please refer to the *Cisco Unified CallManager Dial Plan Deployment Guide*, available at http://www.cisco.com/en/US/products/sw/voicesw/ps5629/prod_maintenance_guides_list.html
- The @ wildcard can be practical in several small and medium deployments, but it can become harder to manage and troubleshoot in large deployments because adopting the @ wildcard forces the administrator to use route filters to block certain patterns (see [Route Filters](#), page 9-90).

Route Filters

- Use route filters only with the @ route pattern to reduce the number of route patterns created by the @ wildcard. A route filter applied to a pattern not containing the @ wildcard has no effect on the resulting dial plan.
- The logical expression you enter with the route filter can be up to 1024 characters, excluding the NOT-SELECTED fields.
- As you increase the number of logical clauses in a route filter, the refresh time of the configuration page also increases and can become unacceptably long.
- For large-scale deployments, use explicit route patterns rather than the @ wildcard and route filters. This practice also facilitates management and troubleshooting because all patterns configured in Unified CM are easily visible from the Route Pattern configuration page.

International and Variable-Length Route Patterns

- International destinations are usually configured using the ! wildcard, which represents any quantity of digits. For example, in North America the route pattern 9.011! is typically configured for international calls. In most European countries, the same result is accomplished with the 0.00! route pattern.
- The ! wildcard is also used for deployments in countries where the dialed numbers can be of varying lengths. In such cases, Unified CM does not know when the dialing is complete and will wait for 15 seconds (by default) before sending the call. You can reduce this delay in any of the following ways:
 - Reduce the T302 timer (Service Parameter TimerT302_msec) to indicate end of dialing, but do not set it lower than 4 seconds to prevent premature transmission of the call before the user is finished dialing.
 - Configure a second route pattern followed by the # wildcard (for example, 9.011!# for North America or 0.00!# for Europe), and instruct the users to dial # to indicate end of dialing. This action is analogous to hitting the "send" button on a cell phone.

Overlap Sending and Overlap Receiving

In countries whose national numbering plan is not easily defined with static route patterns, you can configure Unified CM for overlap sending and overlap receiving.

Overlap sending means that Unified CM keeps collecting digits as they are dialed by the end users, and passes them on to the PSTN as they are dialed. To enable overlap sending, check the Allow Overlap Sending box on the Route Pattern Configuration page. (In some early Unified CM releases, overlap sending is enabled by setting the SendingCompleteIndicator service parameter to False.) The route pattern needs only to include the PSTN access code (for example, "9." in North America or "0." in many European countries).

Overlap receiving means that Unified CM receives the dialed digits one-by-one from a PRI PSTN gateway, and it then waits for completion of the dialed string before attempting to route the call to an internal destination. To enable overlap receiving, set the OverlapReceivingFlagForPRI service parameter to True. (In some early Unified CM releases, the parameter name was OverlapReceivingForPriFlag.)

Digit Manipulation in Route Patterns

- Digit manipulations configured on a route pattern affect the calling and called party number, no matter what route group the call eventually takes. Digit manipulations configured in the route list's view of its member route groups have a route-specific effect: only the transformations configured on the route group used to place the call will be performed.
- Digit manipulation in the route list's view of its member route group overrides any digit manipulation done in the route pattern.
- The calling and called party numbers resulting from the digit transformations configured in the route pattern and/or route lists are then processed by any Transformation Patterns configured for the devices contained in the chosen Route Group.
- If you configure digit manipulation in the route pattern, the Call Detail Record (CDR) records the dialed number after the digit manipulation has occurred. If you configure digit manipulation only in the route group, the CDR records the actual dialed number prior to the digit manipulation.
- Similarly, if you configure digit manipulation in the route pattern, the IP phone display of the calling party will show the manipulated number. If you configure digit manipulation only in the route group, the manipulations will be transparent to the end user.

Calling Line ID

- The calling line ID presentation can be enabled or disabled on the gateway and also can be manipulated in the route pattern, based on site requirements.
- If you select the option Use Calling Party's External Phone Number Mask, then the external call uses the calling line ID specified for the IP phone placing the call. If you do not select this option, then the mask placed in the Calling Party Transform Mask field is used to generate the calling party ID.

Urgent Priority

- The Urgent Priority checkbox is often used to force immediate routing of certain calls as soon as a match is detected, without waiting for the T302 timer to expire. For example, in North America, if the patterns 9.911 and 9.[2-9]XXXXXX are configured and a user dials 9911, Unified CM has to wait for the T302 timer before routing the call because further digits may cause the 9.[2-9]XXXXXX to match. If Urgent Priority is enabled for the 9.911 route pattern, Unified CM makes its routing decision as soon as the user has finished dialing 9911, without waiting for the T302 timer.

- It is important to note that the Urgent Priority checkbox forces the T302 timer to expire as soon as the configured pattern is the best match for the dialed number. This does not mean that the urgent pattern has a higher priority than other patterns; the closest-match logic described in the section on [Call Routing in Unified CM, page 9-87](#), still applies.

For example, assume the route pattern 1XX is configured as urgent and the pattern 12! is configured as a regular route pattern. If a user dials 123, Unified CM will not make its routing decision as soon as it receives the third digit because even though 1XX is an urgent pattern, it is not the best match (10 total patterns matched by 12! versus 100 patterns matched by 1XX). Unified CM will have to wait for inter-digit timeout before routing the call because the pattern 12! allows for more digits to be input by the user.

Consider another example, where pattern 12[2-5] is marked as urgent and 12! is configured as a regular pattern. If the user dials 123, the pattern 12[2-5] is the best match (4 total patterns matched by 12[2-5] versus 10 patterns matched by 12!). Because the T302 timer is aborted and because the urgent-priority pattern is the best match, no further user input is expected. Unified CM routes the call using pattern 12[2-5].

Call Classification

- Calls using this route pattern can be classified as on-net or off-net calls. This route pattern can be used to prevent toll fraud by prohibiting off-net to off-net call transfers or by tearing down a conference bridge when no on-net parties are present. (Both of these features are controlled by Service Parameters within Unified CM Administration.)
- When the "Allow device override" box is enabled, the calls are classified based on the call classification settings on the associated gateway or trunk.

Forced Account Codes (FAC)

- The Forced Account Codes (FAC) checkbox is used to restrict the outgoing calls when using a particular route pattern. If you enable FAC through route patterns, users must enter an authorization code to reach the intended recipient of the call.
- When a user dials a number that is routed through a FAC-enabled route pattern, the system plays a tone that prompts for the authorization code. To complete the call, the user authorization code must meet or exceed the level of authorization that is specified to route the dialed number.
- Only the authorization name appears in the call detail records (CDR); the authorization code does not appear in the CDR.
- The FAC feature is not available if the "Allow overlap sending" checkbox is enabled.

Client Matter Codes (CMC)

- The Client Matter Code (CMC) checkbox is used to track calls to certain numbers when using a particular route pattern. (For example, a company can use it to track calls to certain clients.)
- If you enable CMC for a route pattern, users must enter a code to reach the intended destination.
- When a user dials a number that is routed through a CMC-enabled route pattern, the system plays a tone that prompts for the code. The user must enter the correct code in order to complete the call.
- Client Matter Codes appear in the call detail records so that they can be used by the CDR analysis and reporting tool to generate reports for client billing and accounting.
- The CMC feature is not available if the "Allow overlap sending" checkbox is enabled.
- If both CMC and FAC are enabled, the user dials a number, enters the FAC when prompted to do so, and then enters the CMC at the next prompt.

SIP Route Pattern

SIP route patterns are configured in Unified CM to route or block calls to external entities based on the host portion (right-hand side) of SIP URIs. A SIP route pattern can point directly to a SIP trunk. SIP route patterns matching on the host piece of a SIP URI can match on a domain name or an IP address, both of which are possible as the right-hand side of a SIP URI. Wildcards can be used in domain name SIP route patterns to match on multiple domains (for example, *.cisco.com and ccm[1-4].uc.cisco.com). In IP address SIP route patterns, a subnet notation can be used (for example, 192.168.10.0/24).

Route Lists

A route list is a prioritized list of eligible paths (route groups) for an outbound call. A typical use of a route list is to specify two paths for a remote destination, where the first-choice path is across the IP WAN and the second-choice path is through a PSTN gateway.

Route lists have the following characteristics:

- Multiple route patterns may point to the same route list.
- A route list is a prioritized list of route groups that function as alternate paths to a given destination. For example, you can use a route list to provide least-cost routing, where the primary route group in the list offers a lower cost per call and the secondary route group is used only if the primary is unavailable due to an "all trunks busy" condition or insufficient IP WAN resources.
- Each route group in the route list can have its own digit manipulation. For example, if the route pattern is 9.@ and a user dials 9 1 408 555 4000, the IP WAN route group can strip off the 9 1 while the PSTN route group may strip off just the 9.
- Multiple route lists can contain the same route group. The digit manipulation for the route group is associated with the specific route list that points to the route group.
- If you are performing several digit manipulations in a route pattern or a route group, the order in which the transformations are performed can impact the resulting calling and called party numbers used for the call. Unified CM performs the following major types of digit manipulations in the order indicated:
 1. Discarding digits
 2. Called/calling party transformations
 3. Prefixing digits
 4. Called/calling party transformation patterns

Route Groups

Route groups control and point to specific devices, which are typically gateways (MGCP, SIP, or H.323), H.323 or SIP trunks to a gatekeeper, remote Unified CM cluster, or Cisco Unified Border Element. Unified CM sends calls to the devices according to the distribution algorithm assigned. Unified CM supports top-down and circular algorithms.

Calling and Called Party Transformation Patterns

A calling party transformation pattern allows the system to adapt the global form of the calling party's number into the local form required by off-cluster networks connected to the route group devices, such as gateways or trunks.

A called party transformation pattern allows the system to adapt the global form of the called party's number into the local form required by off-cluster networks connected to the route group devices.

**Note**

Called party transformation patterns do not have any effect on phones. The called party transformation pattern CSS of the device pool does not impart any effects on the phones to which it is assigned.

Both pattern types consist of a numerical representation of the calling or called party number to be matched. The syntax used is the same as that of other patterns such as route patterns, transformation patterns, directory numbers, and so forth. (See [Figure 9-34](#).)

The transformation operators include discard digit instructions (for example, pre-dot), a calling party transformation mask, prefix digits, and control over the calling party presentation (either Default, Allowed, or Restricted). Calling party transformation patterns can be configured to use the calling party's external phone number mask as the calling party number.

Partitions and calling search spaces control which calling party transformation patterns are applied to which gateways or trunks. Gateways or trunks can use either their associated device pool's calling party transformation CSS or the device's own calling party transformation CSS, in reverse order of precedence. The same mechanism is used to control the applicability of called party transformation patterns.

Calling and called party transformation patterns configured on a Gateway Configuration page under **Call Routing Information - Outbound Calls** affect the calling or called party number sent to the gateway, as well as the calling or called party's numbering type and numbering plan. Calling party transformation patterns applied under **Incoming Calling Party Settings** apply to calls coming from the gateway.

Figure 9-34 Calling and Called Party Transformation Patterns

Figure 9-34 illustrates how calling and called party transformation patterns would be applied to different groups of gateways connected to the PSTN in different parts of the PSTN.

Within the North American Numbering Plan (NANP), gateways located in Ottawa, Canada (airport code YOW) are assigned to the Calling Party Transformation CSS NANP_CgPTP, which contains partition NANP_calling_xforms. Any call with a calling party number beginning with +1 (that is, originating from within the NANP) would match both patterns configured within partition NANP_calling_xforms. Following the best-match logic, the first pattern will be chosen, and the calling party number will be stripped of the + sign and NANP country code 1. The remaining part of the calling party number will be used as the calling party number sent to the PSTN, with numbering type set to National.

For example, if a call from +1 613 555 1234 were sent out the YOW gateways, the calling party number would be transformed to 613 555 1234 with a numbering type set to National.

If a call from the same caller were to be sent to a French gateway, a different set of calling party transformation patterns would apply. For example, if a call from +1 613 555 1234 were sent out a gateway located in Nice, France (airport code NCE), the calling party transformation patterns contained in partition France_calling_xforms would be applied. In this case, the calling party number would be transformed to 001 613 555 1234 with the numbering type set to International.

**Note**

Calling party number transformations may be overridden once the call is sent out the gateway. Many service providers will not permit calling party numbers outside a given range, as determined by local service agreements or regulations.

The same process applies to the called party number transformation patterns. For Ottawa gateways, the assigned called party transformation CSS is YOW_CdPTP, which contains partitions NANP_Called_xforms and YOW_Called_xforms. A call placed to a destination number within the Numbering Plan Area 613 would match all patterns contained in these two partitions. However, the best match process would select pattern \+1.613[2-9]XXXXXX.

For example, on a call placed to +1 613 555 9999 through the Ottawa gateways, the called party number would be transformed to 516 555 9999 with a numbering type set to Subscriber.

Incoming Calling Party Settings (per Gateway)

Incoming calling party settings can be configured on individual gateways, at the device pool level, or at the service parameter level, in order of precedence. For each numbering type (Subscriber, National, International, or Unknown), Unified CM allows for the appropriate prefix digits to be configured. Digits can be stripped from and prefixed to the string provided as the incoming party number. The notation takes the form PP:SS, where PP represents the digits to be prefixed and SS represents a quantity of digits to be stripped. The digit stripping operation is performed first on the incoming calling party number, and then the prefix digits are added to the resulting string. For example, if the prefix digits field is configured as +33:1 and the incoming calling party number is 01 58 40 58 58, the resulting string will be +33 1 58 40 58 58.

In Cisco Unified CM 7.1, each numbering type can be configured with a Calling Search Space used to apply Calling Party Transformation Patterns to the calls. The calling search space should contain partitions containing calling party transformation patterns exclusively. This allows the modifications applied to the calling party number to be based on the structure of the calling party number rather than strictly on its numbering type. The calling party transformation patterns use regular expressions to match the calling party number. The best-match process is used to choose between multiple matches, and the selected pattern's Calling Party Transformations are applied to the call.

Route Group Devices

The route group devices are the endpoints accessed by route groups, and they typically consist of gateways or trunks to a gatekeeper or to remote Unified CMs. You can configure the following types of devices in Unified CM:

- Media Gateway Control Protocol (MGCP) gateways
- SIP gateways
- H.323 gateways
- H.225 trunk, gatekeeper controlled — trunk to standard H.323 gateways, via a gatekeeper
- Intercluster trunk, not gatekeeper controlled — direct trunk to another Unified CM cluster
- Intercluster trunk, gatekeeper controlled — trunk to other Unified CM clusters and/or H.323 gateways, via a gatekeeper
- SIP trunk — trunk to another Unified CM cluster, a Cisco Unified Border Element, a Session Border Controller, or a SIP proxy

**Note**

Both the H.225 and intercluster trunk (gatekeeper controlled) will automatically discover if the other endpoint is a standard H.323 gateway or a Unified CM and will select H.225 or Intercluster Trunk protocol accordingly.

Local Route Group

Device pools can be associated with a local route group. Route patterns using the local route group offer a unique characteristic: they allow for dynamic selection of the egress gateway, based on the device originating the call. By contrast, calls routed by route patterns using static route groups will route the call to the same gateway, no matter what device originated the call.

Example 9-2 Comparison of Local and Non-Local Route Groups

In [Figure 9-35](#), a route pattern defined as 9.1[2-9]XX[2-9]XXXXXX points to a route list referencing a non-local route group containing San Francisco gateways. If this route pattern is placed in a partition contained in the calling search spaces of phones in Dallas, San Francisco, and New York, national calls from devices in those three cities will egress to the PSTN in San Francisco.

Figure 9-35 Non-Local Route Group Behavior

271557

By contrast, if this same route pattern is modified to point to a route list containing the Standard Local Route Group, then calls made from the Dallas site would egress to the PSTN through the Dallas gateway, calls made from the New York site would egress to the PSTN through the New York gateway, and calls made from the San Francisco site would egress to the PSTN through the San Francisco gateway.

The Device Mobility feature allows the device pool to be assigned to an endpoint based on the current subnet to which it has roamed. This permits assignment of the local route group to be based on the site where the phone is currently located.

Example 9-3 Device Mobility

A phone is moved from the San Francisco site to the New York site. Based on the phone's new IP address (part of the IP subnet associated with the New York site), a New York device pool is assigned to the phone. If the next call placed by the roaming phone matches a route pattern using a route list containing the Standard Local Route Group, it will be routed through the New York gateway.

If a local route group is used in forwarded call scenarios where, for example, phone A calls phone B and B is forwarded to a destination in the PSTN, then the route pattern in the call forward calling search space of phone B determines the class of service for calls forwarded by phone B, whereas the local route

group associated with phone A's device pool is used to determine the egress gateways when hitting Standard Local Route group in the route list selected by the route pattern found using phone B's call forward calling search space. As a result, typically a gateway local to phone A is used for the forwarded call. This makes sure that the caller ID of the initial caller (phone A) can be sent to the PSTN and that this caller ID will not be screened by the provider.

Centralized Gateway with Local Failover to the PSTN

Local route groups simplify the local failover to the PSTN for systems where a centralized gateway is configured. A single route list can be used to route PSTN calls for multiple sites while allowing local failover to the gateway at the site of origin.

Example 9-4 Centralized Gateways and Local Failover

A company negotiates a favorable PSTN interconnection rate for a group of trunks located in Chicago. If a route list includes a route group containing gateways in Chicago as its first entry and the Standard Local Route Group as the second choice, then any call it processes will first be sent to the preferred lower-cost gateways in Chicago. If a Chicago gateway is not available, if no ports are free, or if there is not enough bandwidth to allow the call between the calling phone and the Chicago gateway, then the next choice will be to attempt to route the call through the gateway co-located with the calling phone, as determined by the local route group in the calling phone's device pool configuration. (See Figure 9-36.)

Figure 9-36 Centralized Gateway with Local Failover to the PSTN

Routing of SIP Requests in Unified CM

Routing of SIP requests received from SIP trunks or SIP endpoints follows certain rules to make sure that both local and intercluster routing requirements are met. SIP requests are handled according to the flowchart shown in [Figure 9-37](#).

Figure 9-37 Call Routing Logic for numeric SIP Request

292528

The first step is to check whether the right-hand side of the SIP URI is an IP address of any server that is a member of the Unified CM cluster or matches the cluster fully qualified domain name configured in Unified CM enterprise parameters. In this case the left-hand side of the URI is considered to be a local directory number and will be routed as a number using the calling device's calling search space.

The next step is to check whether the right-hand side of the SIP URI matches the organization's top-level domain configured in Unified CM enterprise parameters. If this is the case, again Unified CM will try to route the call using the calling device's calling search space. But if no match can be found, then routing will fall back to route the call by matching the right-hand side of the SIP URI against the configured SIP route patterns.

Assuming a Unified CM cluster with cluster members having IP addresses 192.168.10.10, 192.168.10.11, 192.168.20.10, and 192.168.20.11, cluster fully qualified domain name configured as ucm1.cisco.com, and organization top-level domain configured as cisco.com, then all of the following SIP URIs would be routed to local directory number 1234:

- 1234@192.168.10.10
- 1234@192.168.10.11
- 1234@192.168.20.10
- 1234@192.168.20.11
- 1234@ucm1.cisco.com
- 1234@cisco.com

Assuming that no local directory number 1234 exists, the first five calls would fail immediately while Unified CM would try to route the sixth call by matching cisco.com against the configured SIP route patterns.

Calling Privileges in Unified CM

Dialing privileges are configured in order to control which types of calls are allowed (or prevented) for a particular endpoint (such as phones, gateways, or CTI applications). All calls handled by Unified CM are subjected to the dialing privileges implemented through the configuration of the following elements:

- [Partitions, page 9-101](#)
- [Calling Search Spaces, page 9-102](#)

A *partition* is a group of directory numbers (DNs) with similar accessibility, and a *calling search space* defines which partitions are accessible to a particular device. A device can call only those DNs located in the partitions that are part of its calling search space.

As illustrated in [Figure 9-38](#), items that can be placed in partitions all have a dialable pattern, and they include phone lines, route patterns, translation patterns, CTI route group lines, CTI port lines, voicemail ports, and Meet-Me conference numbers. Conversely, items that have a calling search space are all devices capable of dialing a call, such as phones, phone lines, gateways, and applications (via their CTI route groups or voicemail ports).

Figure 9-38 Partitions and Calling Search Spaces

Partitions

The dial plan entries that you may place in a partition include IP phone directory numbers, translation patterns, route patterns, CTI route points, and voicemail ports. As described in the section on [Call Routing in Unified CM, page 9-87](#), if two or more numeric dial plan entries (directory numbers, route patterns, or so forth) overlap, Unified CM selects the entry with the closest match (most specific match) to the dialed number. In cases where two dial plan entries match the dialed pattern equally, Unified CM selects the dial plan entry that appears first in the calling search space of the device making the call.

For example, consider [Figure 9-39](#), where route patterns 1XXX and 23XX are part of Partition_A and route patterns 12XX and 23XX are part of Partition_B. The calling search space of the calling device lists the partitions in the order Partition_A:Partition_B. If the user of this device dials 2345, Unified CM selects route pattern 23XX in Partition_A as the matching entry because it appears first in the calling device's calling search space. However, if the user dials 1234, Unified CM selects route pattern 12XX in Partition_B as the matching entry because it is a closer match than 1XXX in Partition_A. Remember that the partition order in a calling search space is used exclusively as a tie-breaker in case of equal matches based on the closest-match logic.

Figure 9-39 Impact of Partition Order on the Matching Logic

Note

When multiple equal-precision matches occur in the same partition, Unified CM selects the entry that is listed first in its local dial plan database. Since you cannot configure the order in which the dial plan database lists dial plan entries, Cisco strongly recommends that you avoid any possibility of equal-precision matches coexisting within the same partition because the resulting dial plan logic is not predictable in such cases.

Partitions can be activated or deactivated based on the time and date. You can activate or deactivate partitions by first configuring time periods and schedules within Unified CM Administration and then assigning a specific time schedule to each partition. Outside of the times and days specified by the schedule, the partition is inactive, and all patterns contained within it are ignored by the Unified CM call routing engine. For more information on this feature, see [Time-of-Day Routing, page 9-124](#).

Calling Search Spaces

A calling search space defines which partitions are accessible to a particular device. Devices that are assigned a certain calling search space can access only the partitions listed in that calling search space. Attempts to dial a DN in a partition outside that calling search space will fail, and the caller will hear a busy signal.

If you configure a calling search space both on an IP phone line and on the device (phone) itself, Unified CM concatenates the two calling search spaces and places the line's calling search space in front of the device's calling search space, as shown in [Figure 9-40](#).

Figure 9-40 Concatenation of Line and Device Calling Search Spaces for IP Phones

Note

When device mobility is not used, the device calling search space is static and remains the same even as the device is moved to different parts of the network. When device mobility is enabled, the device calling search space can be determined dynamically based on where in the network the phone is physically located, as determined by the phone's IP address. See [Device Mobility, page 9-112](#), for more details.

If the same route pattern appears in two partitions, one contained in the line's calling search space and one contained in the device's calling search space, then according to the rules described in the section on [Partitions, page 9-101](#), Unified CM selects the route pattern listed first in the concatenated list of partitions (in this case, the route pattern associated with the line's calling search space).

For recommendations on how to set the line and device calling search spaces, refer to the sections on [Building Classes of Service for Unified CM with the Traditional Approach, page 9-54](#), and [Building Classes of Service for Unified CM with the Line/Device Approach, page 9-58](#).

The maximum length of the combined calling search space (device plus line) is 1024 characters, including separator characters between each partition name. (For example, the string “partition_1:partition_2:partition_3” contains 35 characters.) Thus, the maximum number of partitions in a calling search space varies, depending on the length of the partition names. Also, because the calling search space clause combines the calling search space of the device and that of the line, the maximum character limit for an individual calling search space is 512 (half of the combined calling search space clause limit of 1024 characters).

Therefore, when you are creating partitions and calling search spaces, keep the names of partitions short relative to the number of partitions that you plan to include in a calling search space. For more details on configuring calling search spaces, refer to the *Cisco Unified Communications Manager Administration Guide*, available online at

<http://www.cisco.com>

Before you configure any partitions or calling search spaces, all DNs reside in a special partition named <None>, and all devices are assigned a calling search space also named <None>. When you create custom partitions and calling search spaces, any calling search space you create also contains the <None> partition, while the <None> calling search space contains *only* the <None> partition.

Note

Any dial plan entry left in the <None> partition is implicitly reachable by *any* device making a call. Therefore, to avoid unexpected results, Cisco strongly recommends that you do not leave dial plan entries in the <None> partition.

**Note**

Cisco strongly recommends that you do not leave any calling search space defined as <None>. Doing so can introduce dial plan behavior that is difficult to predict.

Special Considerations for Transformation Patterns

Calling and called transformation patterns are also placed in partitions, and those partitions are included in calling search spaces (CSSs) but not in order to control calling privileges. The partitioning of transformation patterns serves to choose which transformations are applied to which gateways, trunks, or phones. Partitions contained in calling party transformation pattern CSSs should contain only calling party transformation patterns. Likewise, partitions contained in called party transformation pattern CSSs should contain only called party transformation patterns.

Call-Forward Calling Search Spaces

**Note**

Call Forward All actions are different than any other call-forward action in that the destination number is entered by each individual user when the feature is activated from a phone.

The system allows you to decide how call-forward calling search spaces take effect. There are three possible options, as selected by the Calling Search Space Activation policy:

- Use System Default

If you configure the Calling Search Space Activation Policy to Use System Default, then the CFA CSS Activation Policy cluster-wide service parameter determines which Forward All Calling Search Space will be used. The CFA CSS Activation Policy service parameter can be set to With Configured CSS or to With Activating Device/Line CSS (see below). By default, the CFA CSS Activation Policy service parameter is set to With Configured CSS.

- With Configured CSS

If you select the With Configured CSS option, the Forward All Calling Search Space and Secondary Calling Search Space for Forward All explicitly configured in the Directory Number Configuration window control the forward-all activation and call forwarding. If the Forward All Calling Search Space is set to None, no CSS gets configured for Forward All. A forward-all activation attempt to any directory number with a partition will fail. No change in the Forward All Calling Search Space and Secondary Calling Search Space for Forward All occurs during the forward-all activation.

- With Activating Device/Line CSS

If you prefer to use the combination of the Directory Number Calling Search Space and Device Calling Search Space without explicitly configuring a Forward All Calling Search Space, select With Activating Device/Line CSS for the Calling Search Space Activation Policy. With this option, when Forward All is activated from the phone, the Forward All Calling Search Space and Secondary Calling Search Space for Forward All are automatically populated with the Directory Number Calling Search Space and Device Calling Search Space for the activating device. When you set the Forward All Destination from Unified CM Administration, the Forward All Calling Search Space and Secondary Calling Search Space are not automatically populated and have to be configured explicitly. The two calling search spaces are concatenated, and the resulting calling search space is used to validate the number entered as a Call Forward All destination. For further details, see [Building Classes of Service for Unified CM with the Line/Device Approach, page 9-58](#).

With this configuration (Calling Search Space Activation Policy set to With Activating Device/Line), if the Forward All Calling Search Space is set to None when forward-all is activated through the phone, the combination of Directory Number Calling Search Space and activating Device Calling Search Space is used to verify the forward-all attempt.

**Note**

Call Forward All configuration typically has to satisfy two requirements: controlling the destinations to which the device is allowed to forward calls, and ensuring that optimum call routing is achieved when calls originating from various points of origin are forwarded to the Call Forward All destination. To achieve both requirements, Cisco recommends using the With Configured CSS activation policy, which allows for controlling the destinations through the Line-Device dial plan approach; the Call Forward All CSS is used to implement a set of restrictions through the use of blocked patterns, and it can be set to the same calling search space configured on the line if the regular class of service is to be used for Call Forward All. The Secondary Calling Search Space for Call Forward All should then be configured to route calls to the Standard Local Route Group; the actual route group used to route the call will be determined at the time of the call, based on the calling (forwarded) device's local route group as configured on its device pool.

On Type-A IP phones running SIP, if Call Forward All is invoked from the phone itself, the device's Rerouting Calling Search Space is used for forwarded calls. If Forward All actions are invoked from the Unified CM User page or the Unified CM Administrative page, then any Forward All action initiated from the phone is irrelevant.

For example, assume an Type-A IP phone running SIP is configured with Forward All to extension 3000 from the Unified CM User page. At the same time, the phone itself is configured to Forward All to extension 2000. All calls made to that phone will be forwarded to extension 3000.

**Note**

On Type-A IP phones running SIP, invoking Forward All from the Unified CM User or Administrative pages will not be reflected on the phone. The phone does not display any visual confirmation that calls are forwarded.

When Forward All is initiated from an IP phone running SCCP or from an Type-B IP phone running SIP, user input is simultaneously compared to the patterns allowed in the configured Forward All calling search space(s). If an invalid destination pattern is configured, the user will be presented with reorder tone. When Forward All is invoked from an Type-A IP phone running SIP, Forward All user input is stored locally on the phone and is not verified against any calling search space in Unified CM. If user input corresponds to an invalid destination, no notification is offered to the user. Calls made to that phone will be presented with reorder tone as the phone tries to initiate a SIP re-route action to an invalid destination number.

Other Call Forward Types

The calling search spaces configured for the various other types of call forward (Forward Busy, Forward No Answer, Forward No Coverage, forward on CTI failure, and Forward Unregistered) are standalone values not concatenated with any other calling search space.

Call Forward settings (except Forward All) can be configured separately for internal or external call types. For example, a user might want to have their phone Call Forward No Answer to voicemail for external callers but forward to a cell phone number if the caller is a co-worker calling from another IP phone on the network. This is possible by using different configurations for the Internal and External Call Forward settings.

When the Forward All calling search space is left as <None>, the results are difficult to predict and depend on the Unified CM release. Therefore, Cisco recommends the following best practices when configuring call-forward calling search spaces:

- Always provision the call-forward calling search spaces with a value other than <None>. This practice avoids confusion and facilitates troubleshooting because it enables the network administrator to know exactly which calling search space is being used for forwarded calls.
- Configure the Call Forward Busy and Call Forward No Answer calling search spaces with values that allow them to reach the DNs for the voicemail pilot and voicemail ports but not external PSTN numbers.
- Configure both the Call Forward All calling search space and the Secondary Calling Search Space for Forward All, according to your company's policy. Many companies choose to restrict forwarded calls to internal numbers only, to prevent users from forwarding their IP phone lines to a long-distance number and dialing their local IP phone number from the PSTN to bypass long-distance toll charges on personal calls.

The Call Forward Unregistered (CFUR) feature is a way to reroute calls placed to a temporarily unregistered destination phone. The configuration of CFUR consists of two main elements:

- Destination selection

When the DN is unregistered, calls can be rerouted to either of the following destinations:

- Voicemail

Calls can be sent to voicemail by selecting the voicemail checkbox and configuring the CFUR calling search space to contain the partition of the voicemail pilot number.

- A directory number used to reach the phone through the PSTN

This approach is preferred when a phone is located within a site whose WAN link is down. If the site is equipped with Survivable Remote Site Telephony (SRST), the phone (and its co-located PSTN gateway) will re-register with the co-located SRST router. The phone is then able to receive calls placed to its PSTN DID number.

In this case, the appropriate CFUR destination is the corresponding PSTN DID number of the original destination DN. Configure this PSTN DID in the destination field, preferably in E.164 format, including the + sign (for example, +1 415 555 1234). This allows the CFUR destination to be processed by the calling phone's local route group, whether or not it uses the same off-net access code and PSTN prefixes as the unregistered phone.

- Calling search space

Unified CM attempts to route the call to the configured destination number by using the called DN's CFUR calling search space. The CFUR calling search space is configured on the target phone and is used by all devices calling the unregistered phone. This means that all calling devices will use the same combination of route pattern, route list, and route group to place the call. Cisco recommends that you configure the CFUR calling search space to route calls to the CFUR destination using patterns pointing to route lists referencing the Standard Local Route Group. This will ensure that the egress gateway to the PSTN is chosen based on the calling device.

The Call Forward Unregistered functionality can result in telephony routing loops if a phone is unregistered while the gateway associated with the phone's DID number is still under control of Unified CM, as is the case if a phone is simply disconnected from the network. In such a case, the initial call to the phone would prompt the system to attempt a first CFUR call to the phone's DID through the PSTN. The resulting incoming PSTN call would in turn trigger another CFUR attempt to reach the same phone's DN, triggering yet another CFUR call from the central PSTN gateway through the PSTN. This cycle could repeat itself until system resources are exhausted.

The service parameter `MaximumForwardUnRegisteredHopsToDn` controls the maximum number of CFUR calls that are allowed for a DN at the same time. The default value of 0 means the counter is disabled. If any DNs are configured to reroute CFUR calls through the PSTN, loop prevention is required. Configuring this service parameter to a value of 1 would stop CFUR attempts as soon as a single call is placed through the CFUR mechanism. This setting would also allow only one call to be forwarded to voicemail, if CFUR is so configured. Configuring this service parameter to a value of 2 would allow for up to two simultaneous callers to reach the voicemail of a DN whose CFUR setting is configured for voicemail, while also limiting potential loops to two for DNs whose CFUR configuration sends calls through the PSTN.

**Note**

Extension Mobility DNs should not be configured to send Call Forward Unregistered calls to the PSTN DID associated with the DN. The DNs of Extension Mobility profiles in the logged-out state are deemed to be unregistered, therefore any calls to the PSTN DID number of a logged-out DN would trigger a routing loop. To ensure that calls made to Extension Mobility DNs in the logged-out state are sent to voicemail, ensure that their corresponding Call Forward Unregistered parameters are configured to send calls to voicemail.

Translation Patterns

Translation patterns are one of the most powerful tools in Unified CM to manipulate digits for any type of call. They follow the same general rules and use the same wildcards as route patterns. As with route patterns, you assign a translation pattern to a partition. However, when the dialed digits match the translation pattern, Unified CM does not route the call to an outside entity such as a gateway; instead, it performs the translation first and then routes the call again, this time using the calling search space configured within the translation pattern.

Translation patterns can be used for a variety of applications, as shown by the example in [Figure 9-41](#).

Figure 9-41 Application Example for Translation Patterns

In this example, the administrator wishes to provide users with an operator service that is reached by dialing 0, while also maintaining a fixed-length internal numbering plan. The IP phones are configured with the `Phone_css` calling search space, which contains the `Translations_pt` partition (among others). A translation pattern 0 is defined in this partition, and the configured Called Party Transform Mask instructs Unified CM to replace the dialed string (0) with the new string 2001, which corresponds to the DN of the operator phone. A second lookup (of 2001 this time) is forced through the call routing engine, using the `Internal_css` calling search space, and the call can now be extended to the real operator DN of 2001, which resides in the `AllIPPhones_pt` partition.

**Note**

When a dialed number is manipulated using a translation pattern, the translated number is recorded in the call detail record (CDR). However, when the digit manipulation occurs within a route list, the CDR will show the originally dialed number, not the translated one. The Placed Calls directory on the IP phone always shows the string as it was dialed by the user.

Automated Alternate Routing

The automated alternate routing (AAR) feature enables Unified CM to establish an alternate path for the voice media when the preferred path between two endpoints within the same cluster runs out of available bandwidth, as determined by the locations mechanism for call admission control.

The AAR feature applies primarily to deployments with sites connected via a WAN. For instance, if a phone in branch A calls a phone in branch B and the available bandwidth for the WAN link between the branches is insufficient (as computed by the Locations mechanism), AAR can reroute the call through the PSTN. The audio path of the call would be IP-based from the calling phone to its local (branch A) PSTN gateway, TDM-based from that gateway through the PSTN to the branch B gateway, and IP-based from the branch B gateway to the destination IP phone.

AAR can be transparent to the users. You can configure AAR so that users dial only the on-net (for example, four-digit) directory number of the called phone and no additional user input is required to reach the destination through the alternate network (such as the PSTN).

**Note**

AAR does not support CTI route points as the origin or the destination of calls. Also, AAR is incompatible with the Extension Mobility feature when users roam across different sites. Refer to [Extension Mobility, page 9-114](#), for more details.

You must provide the following main elements for AAR to function properly:

- [Establish the PSTN Number of the Destination, page 9-108](#)
- [Prefix the Required Access Codes, page 9-109](#)
- [Select the Proper Dial Plan and Route, page 9-111](#)

Establish the PSTN Number of the Destination

The rerouting of calls requires using a destination number that can be routed through the alternate network (for example, the PSTN). AAR uses the dialed digits to establish the on-cluster destination of the call and then combines them with the called party's AAR Destination Mask; if it is not configured, the External Phone Number Mask is used instead. The combination of the dialed digits and the applicable mask must yield a fully qualified number that can be routed by the alternate network.

Alternatively, by selecting the voicemail checkbox in the AAR configuration, you can allow calls to be directed to the voicemail pilot number. This choice does not rely on the numbers originally dialed by the caller, but routes the call according to the voicemail profile configuration.

**Note**

By default, the directory number configuration retains the AAR leg of the call in the call history, which ensures that the AAR forward to the voice messaging system will select the proper voice mailbox. If you choose "Remove this destination from the call forwarding history," the AAR leg of the call is not present in the call history, which would prevent the automated voice mailbox selection and would offer the caller the generic voicemail greeting.

The AAR Destination Mask is used to allow the destination phone number to be determined independently of the External Phone Number mask. For example, if Caller ID policy for a company required a phone's external phone number mask to be the main directory number of an office (such as 415 555 1000), the AAR destination mask could be set to +1 415 555 1234, to provide AAR with the phone's specific PSTN number.

For example, assume phone A in San Francisco (DN = 2345) dials an on-net DN (1234) configured on phone B located in New York. If locations-based call admission control denies the call, AAR retrieves the AAR Destination Mask of the New York phone (+1212555XXXX) and uses it to derive a number (+12125551234) that can be used to route the call on the PSTN.

It is best to configure the AAR destination mask to yield a fully qualified E.164 number, including the + sign, because this will greatly simplify the overall configuration of AAR. For example, a phone in Paris is configured with an AAR destination mask of +33 1 58 04 58 58. Because this number is a fully qualified E.164 number, it contains all the information required for the Cisco Unified Communications system to derive a routable PSTN number as required by the calling phone's gateway to the PSTN, regardless of whether it is located in France, in Canada, or anywhere else in the world. The following sections elaborate on this approach.

Prefix the Required Access Codes

If the AAR Destination Yields a Fully Qualified E.164 Number Including the + Sign

This is the simplest case; the AAR destination contains + as a wildcard to be replaced by the appropriate access codes required at each gateway. The destination number is ready to be routed to an appropriate route pattern and then transformed at the point of egress to the PSTN by the appropriate called party transformation patterns.

Example 1: A phone in Ottawa, Canada calls a phone in Paris, which triggers AAR due to a lack of bandwidth on the WAN. The AAR destination is +33 1 58 04 58 58. The AAR calling search space of the calling phone contains a route pattern \+!, which routes the call to the Standard Local Route Group. The call is routed to the local gateway in Ottawa, where called party transformation patterns will replace the + with the applicable international access code 011. The resulting call is placed to 011 33 1 58 04 58 58.

Example 2: A phone in Nice, France calls a phone in Paris, which triggers AAR due to a lack of bandwidth on the WAN. The AAR destination is +33 1 58 04 58 58. The AAR calling search space of the calling phone contains a route pattern \+!, which routes the call to the Standard Local Route Group. The call is routed to the local gateway in Nice, where called party transformation patterns will replace the + 33 with the applicable national access code 0. The resulting call is placed to 01 58 04 58 58.

If the AAR Destination Mask Yields a Number Including the Country Code

The destination number (assumed to include the country code) might require a prefix to be routed properly by the origination branch's dial plan. Furthermore, if the point of origin is located in a different area code or even a different country, then other prefixes such as international dialing access codes (for example, 00 or 011) might be required as part of the dialed string.

When configuring AAR, you place the DNs in AAR groups. For each pair of AAR groups, you can then configure prefix digits to add to the DNs for calls between the two groups, including prefix digits for calls originating and terminating within the same AAR group.

As a general rule, place DNs in the same AAR group if they share the same inter-country dialing structure. For example, all phones in the UK dial numbers outside the UK with 9 as a PSTN access code, followed by 00 for international access; all phones in France and Belgium use 0 as a PSTN access code, followed by 00 for international access; all phones in the NANP use 9 as a PSTN access code, followed by 011 for international access.

This yields the following AAR group configuration:

| AAR Group | NANP | Cent_EU | UK |
|-----------|------|---------|------|
| NANP | 9 | 9011 | 9011 |
| Cent_EU | 000 | 000 | 000 |
| UK | 900 | 900 | 9 |

Example 3: A phone in Ottawa, Canada calls a phone in Paris, which triggers AAR due to a lack of bandwidth on the WAN. The AAR destination is 33 1 58 04 58 58. The AAR group of the calling phone is NANP and that of the destination phone is Cent-EU, thus yielding a prefix of 9011. The AAR calling search space of the calling phone contains a site-specific route pattern 9011!, which routes the call to a route list in Ottawa, stripping the 9. The call is routed to the local gateway in Ottawa. The resulting call is placed to 011 33 1 58 04 58 58.

Example 4: A phone in Brussels, Belgium calls a phone in Paris, which triggers AAR due to a lack of bandwidth on the WAN. The AAR destination is 33 1 58 04 58 58. The AAR group of the calling phone and that of the destination phone is Cent-EU, thus yielding a prefix of 000. The AAR calling search space of the calling phone contains a site-specific route pattern 000!, which routes the call to a route list in Brussels, stripping the leading 0. The call is routed to the local gateway in Brussels. The resulting call is placed to 00 33 1 58 04 58 58.

Voicemail Considerations

AAR can direct calls to voicemail. The voicemail pilot number is usually dialed without the need for an off-net access code (if the voicemail pilot number is a fully qualified on-net number, such as 8 555 1000). When AAR is configured to send calls to voicemail, the AAR group mechanism will still prefix the configured access code(s). This configuration requires the creation of an AAR group to be used by all DNs whose desired AAR destination is voicemail (for example, `vmail_aar_grp`). Ensure that the configuration for this voicemail AAR group uses no prefix numbers when receiving calls from other AAR group DNs.

For example: Assume that DNs located in sites San Francisco and New York are configured with AAR group NANP, which prefixes 9 to calls made between any two DNs in the group. If a DN in San Francisco is configured to send AAR calls to voicemail (for example, 8 555 1000), a call would be placed to 985551000, which would result in a failed call. Instead, the San Francisco DN should be configured with AAR group vmail. The prefix digits for calls from AAR group NANP to AAR group vmail are `<none>`, as shown in the following table. The call will be placed successfully to 85551000.

| AAR Group | NANP | Cent_EU | UK | vmail |
|-----------|------|---------|------|--------|
| NANP | 9 | 9011 | 9011 | <none> |
| Cent_EU | 000 | 000 | 000 | <none> |
| UK | 900 | 900 | 9 | <none> |

Note

When Device Mobility is not used, the AAR group configuration of a DN remains the same even as the device is moved to different parts of the network. With Device Mobility, the AAR group can be determined dynamically based on where in the network the phone is physically located, as determined by the phone's IP address. See [Device Mobility, page 9-112](#), for more details.

Select the Proper Dial Plan and Route

AAR calls should egress through a gateway within the same location as the calling phone, thus causing the completed dial string to be sent through the origination site's dial plan. To ensure that this is the case, select the appropriate AAR calling search space on the device configuration page in Unified CM Administration. Configure the off-net dial plan entries (for example, route patterns) in the AAR calling search space to point to co-located gateways and to remove the access code before presenting the call to the PSTN.

For example, phones at the San Francisco site can be configured with an AAR calling search space that permits long distance calls dialed as 91-NPA-NXX-XXXX but that delivers them to the San Francisco gateway with the access code (9) stripped.

The AAR calling search space configuration can be greatly simplified if the local route group is used in conjunction with using a fully qualified E.164 address (including the + sign) as the AAR destination mask. A single calling search space configured with a single partition, containing a single route pattern \+!, pointing to a single route list featuring the Standard Local Route Group, can be used to route the calls of all phones at all sites in an entire cluster. This relies on the pre-configuration of the appropriate gateway-specific called party transformation patterns to adapt the universal form of the destination number to the localized form required by the service provider networks to which the call is delivered at each site.

**Note**

If you have configured additional route patterns to force on-net internal calls dialed as PSTN calls, ensure that these patterns are not matched by the AAR feature. Refer to [Design Guidelines for Multisite Deployments, page 9-35](#), for more details.

**Note**

To avoid denial of re-routed calls due to call admission control, AAR functionality requires the use of a LAN as the IP path between each endpoint and its associated gateway to the PSTN. Therefore, AAR dial plans cannot rely on centralized gateways for PSTN access.

**Note**

When Device Mobility is configured, the AAR calling search space can be determined dynamically based on where in the network the phone is physically located, as determined by the phone's IP address. See [Device Mobility, page 9-112](#), for more details.

Special Considerations for Sites Located Within the Same Local Dialing Area

In some instances, the AAR dial string might have to be modified locally to allow for dialing between sites whose phones belong to the same AAR group. For example, assume two separate sites located in France share the same country code of 33. (See [Figure 9-42](#).) In this case, a number dialed as 0 00 33 1 58 04 58 58 would have to be transformed to 01 58 04 58 58. Note that this is required only if the AAR configuration does not rely on called party transformation patterns.

This transformation is best done with a site-specific translation pattern of 00033.[1-6]XXXXXXXXX to strip the pre-dot digits and prepend 0. This translation pattern should be placed in a member partition of the AAR calling search space for the French sites only; the Belgian site still needs to reach this same destination as 0 00 33 1 58 04 58 58.

Figure 9-42 Dialed Number Transformations for AAR Calls Between Sites

Note

The AAR functionality is not triggered upon detection that the destination phone is unreachable. Therefore, WAN failures do not trigger AAR functionality.

In order to understand this better, consider an example where a Unified CM cluster has a site in London (United Kingdom), one in Paris (France), and one in Nice (France). The E.164 address of the DID range in Paris is +33145678XXX, but these extensions are usually reached as 0145678XXX when calling from within the French PSTN. When somebody in the London office wishes to dial the Paris office via the PSTN, the dialed string is 90033145678XXX. However, when somebody in the Nice office wishes to dial the Paris office via the PSTN, the dialed string is 00145678XXX.

To allow all three cases above with a single, simple AAR configuration, it is best to configure the AAR Destination Mask with the E.164 notation (including the + sign); this creates a destination number which can be interpreted by the system differently for each calling phone.

Device Mobility

Device Mobility offers functionality designed to enhance the mobility of devices within an IP network. (For example, a phone initially configured for use in San Francisco is physically moved to New York.) Although the device still registers with the same Unified CM cluster, it now will adapt some of its behavior based on the new site where it is located. Those changes are triggered by the IP subnet in which the phone is located.

When roaming, a phone will inherit the parameters associated with the device pool associated with the device's current subnet. From a dial-plan perspective, the functionality of the following five main configuration parameters can be modified due to the physical location of the phone. For these parameters to be modified, the device must be deemed as roaming outside its home physical location but within its home device mobility group.

- Local route group

the roaming device pool's Local Route Group is used. For example, if a device is roaming from San Francisco to New York, the local route group of the New York device pool is used to route calls to the PSTN whenever a pattern points to a route list invoking the Standard Local Route Group.

- Calling party transformation CSS

The roaming device pool's calling party transformation CSS is used. This allows a phone to inherit the calling party presentation mode that is customary for the phones of the visited location.

- Device calling search space

The roaming device pool's Device Mobility calling search space is used instead of the device calling search space configured on the device's configuration page. For example, if a device is roaming from San Francisco to New York, the Device Mobility calling search space of the New York device pool is used as the roaming phone's device calling search space. If you use the line/device approach to classes of service, this approach will establish the path taken for PSTN calls, routing them to the local New York gateway.

- AAR calling search space

The roaming device pool's AAR calling search space is used instead of the AAR calling search space configured on the device's configuration page. For example, if a device is roaming from San Francisco to New York, the AAR calling search space of the New York device pool is used as the roaming phone's AAR calling search space. This calling search space will establish the path taken for outgoing AAR PSTN calls, routing them to the local New York gateway.

- DN's AAR group

For incoming AAR calls, the AAR group assigned to a DN is retained, whether or not the DN's host phone is roaming. This ensures that the reachability characteristics established for the AAR destination number are retained.

For outgoing AAR calls, the calling DN's AAR group uses the roaming device pool's AAR group instead of the AAR group selected on the DN's configuration page. Note that this AAR group will be applied to all DNs on the roaming device. For example, all DNs on a device roaming from New York to Paris (assuming both locations are in the same Device Mobility group) would inherit the AAR group configured for outgoing calls in the Paris device pool. This AAR group would be applied to all DNs on the roaming device and would allow for the appropriate prepending of prefix digits to AAR calls made from DNs on the roaming phone.

Call Forward All When Roaming

When a device is roaming in the same device mobility group, Unified CM uses the Device Mobility CSS to reach the local gateway. If a user sets Call Forward All at the phone, if the CFA CSS is set to None, and if the CFA CSS Activation Policy is set to With Activating Device/Line CSS, then:

- The Device CSS and Line CSS get used as the CFA CSS when the device is in its home location.
- If the device is roaming within the same device mobility group, the Device Mobility CSS from the Roaming Device Pool and the Line CSS get used as the CFA CSS.
- If the device is roaming within a different device mobility group, the Device CSS and Line CSS get used as the CFA CSS.

The section on [Device Mobility](#), page 25-16, explains the details of this feature.

Extension Mobility

The Extension Mobility feature enables a user to log in to an IP phone and automatically apply his or her profile to that phone, including extension number, speed dials, message waiting indicator (MWI) status, and calling privileges. This mechanism relies on the creation of a device profile associated with each Extension Mobility user. The device profile is effectively a virtual IP phone on which you can configure one or more lines and define calling privileges, speed dials, and so on.

When an IP phone is in the logged-out state, (that is, no Extension Mobility user has logged into it), the phone characteristics are determined by the device configuration page and the line configuration page(s). When a user logs in to an IP phone, the device configuration does not change, but the existing line configuration is saved in the Unified CM database and is replaced by the line configuration of the user's device profile.

One of the key benefits of Extension Mobility is that users can be reached at their own extensions regardless of where they are located, provided that they can log in to an IP phone controlled by the same Unified CM cluster. When Extension Mobility is applied to multisite deployments with centralized call processing, this capability is extended to multiple sites geographically separated from each other.

However, if you combine the Extension Mobility feature with the AAR feature described in the section on [Automated Alternate Routing](#), page 9-108, some limitations exist. Consider the example shown in [Figure 9-43](#), where Extension Mobility and AAR are deployed in a centralized call processing Unified CM cluster with one site in San Jose and one in New York.

Figure 9-43 Extension Mobility and AAR

In this example, assume that an Extension Mobility user who is normally based in San Jose has a DN of 1000 and a DID number of (408) 555-1000. That user's external phone number mask (or AAR mask, if used) is therefore configured as 4085551000. The user now moves to the New York site and logs in. Also, assume that the IP WAN bandwidth between San Jose and New York has been entirely utilized.

When the user in San Jose with extension 1001 tries to call 1000, AAR is triggered and, based on the AAR calling search space of the calling party and the AAR groups of both parties, a new call to 914085551000 is attempted by the San Jose phone. This call uses the San Jose gateway to access the

PSTN, but because the DID (408) 555-1000 is owned by that same gateway, the PSTN sends the call back to it. The San Jose gateway tries to complete the call to the phone with extension 1000, which is now in New York. Because no bandwidth is available to New York, the AAR feature is invoked again, and one of the following two scenarios will occur:

- If the gateway's AAR calling search space contains external PSTN route patterns, this is the beginning of a loop that eventually uses all the PSTN trunks at the San Jose site.
- If, on the other hand, the gateway's AAR calling search space contains only internal numbers, the call fails and the caller hears a fast-busy tone. In this case, one PSTN call is placed and one is received, so two PSTN trunks are utilized on the San Jose gateway for the duration of the call setup.

**Tip**

To prevent routing loops such as the one described here, always configure all calling search spaces on the gateway configuration pages to include only internal destinations and no route patterns pointing to route lists or route groups containing that same gateway.

This example highlights the fact that Extension Mobility leverages the dynamic aspect of Cisco IP Communications and, therefore, requires that the call routing between sites use the IP network. Because the E.164 numbers defined in the PSTN are static and the PSTN network is unaware of the movements of the Extension Mobility users, the AAR feature, which relies on the PSTN for call routing, cannot be used to reach Extension Mobility users who move to a site other than their home site.

**Note**

However, if the Extension Mobility user moves to a remote site that belongs to the same AAR group as his or her home site, he or she can use the AAR feature to place calls to other sites when the available IP WAN bandwidth is not sufficient. This is because the path of such a call is determined by the AAR calling search space of the phone from which the call originates. This AAR calling search space does not change when users log in or out of Extension Mobility, and it should be configured to use the visited remote site's gateway.

**Tip**

Configure unregistered Extension Mobility profile DN's to send calls to voicemail. See [Call-Forward Calling Search Spaces, page 9-104](#), for details.

Special Considerations for Cisco Unified Mobility

Cisco Unified Mobility (see the section on [Cisco Unified Mobility, page 25-38](#)) relies on functionality that has a direct impact on call routing. To understand the effects of the Cisco Unified Mobility parameters related to dial plans, consider the following example:

**Note**

Only those parameters required in the discussion are mentioned here.

User Paul has an IP phone configured as follows:

DN: 8 555 1234

DID number: +1 408 555 1234

External Phone Number Mask: 408 555 1234

Line Calling Search Space: P_L_CSS

Device Calling Search Space: P_D_CSS

Paul's DN is associated with a Remote Destination Profile configured as follows:

Calling Search Space: P_RDP_CSS

Rerouting Calling Search Space: P_RDP_Rerouting_CSS

Calling Party Transformation CSS: P_CPT_CSS

Paul's RDP is associated with a Remote Destination configured as follows:

Destination Number: +1 514 000 9876 (This is Paul's mobile phone number, on either a single-mode or dual-mode phone.)

Calls from the PSTN placed to Paul or Ringo's DID number are handled by a gateway configured as follows:

Calling Search Space: GW_CSS

Significant digits: 7

Prefix DN: 8

User Ringo has an IP phone configured as follows:

DN: 8 555 0001

DID number: 408 555 0001

External Phone Number Mask: 408 555 0000 (This is the enterprise's main business number.)

Line Calling Search Space: R_L_CSS

Device Calling Search Space: R_D_CSS

The following sections explain the effects of the above mobility parameters on call routing.

Remote Destination Profile

Remote destination profiles (RDPs) are associated with directory numbers (for example, the DN of a user's IP phone) and with remote destinations (for example, the mobile phone number of a user). The RDP controls the interaction between the IP phone and the external numbers (for example, a mobile phone) configured as remote destinations.

Note

Remote destinations cannot be configured with on-cluster DNs as destination numbers.

Remote Destination Profile's Rerouting Calling Search Space

When a call is placed to a DN associated with a remote destination profile, the call has the effect of ringing both the DN and the number(s) configured as remote destination(s).

The ability of the caller to reach the destination IP phone is controlled by the caller's Calling Search Space settings. However, the ability for the call to be forked toward the remote destination (for example, a mobile phone) is controlled by the called mobility user's Rerouting Calling Search Space.

For example:

Ringo calls Paul from his IP phone by dialing 8 555 1234. Paul's IP phone rings, as well as his mobile phone.

Here, the ability for Ringo to reach Paul's DN is controlled by the Line and Device calling search spaces on Ringo's IP phone. The dialed destination (8 555 1234) must be in a partition found in the concatenated calling search spaces R_L_CSS and R_D_CSS.

For this same call to be forked to ring Paul's mobile phone, the configured remote destination (+1 514 000 9876) must match a pattern found in the calling search space P_RDP_Rerouting_CSS.

**Note**

Even if the dialing privileges assigned to Ringo's phone do not allow for external calls, the call to the remote destination is handled by the rerouting calling search space associated with Paul's remote destination profile.

Remote Destination Profile's Calling Search Space

In Cisco Unified CM 6.0, the RDP's calling search space is used to route calls originating from numbers defined as remote destinations. It is concatenated with the associated DN's Line CSS. The order of concatenation is Line CSS followed by the RDP's CSS.

When the calling party number of an external call made into the cluster matches a number defined as a remote destination, the calling party number is replaced with the DN of the line associated with the matching remote destination. Also, the calling search space used to route the call is the concatenation of:

- The Line calling search space of the DN associated with the matched remote destination number
- The calling search space of the RDP associated with the matched remote destination

In Unified CM 6.1 and later releases, a new service parameter (Inbound Calling Search Space for Remote Destination) controls which calling search space is used to route calls originating from one of the cluster's remote destinations. Its default setting is Trunk or Gateway Inbound Calling Search Space, which routes all incoming calls using the trunk's or gateway's configured CSS. If the service parameter is set to Remote Destination Profile + Line Calling Search Space, then the behavior is identical for all Unified CM 6.x releases. This new service parameter has no effect on the calling party number replacement.

**Note**

The default behavior of Unified CM 6.1 and later releases is different than the behavior of Unified CM 6.0 with regard to the routing of incoming calls originating from numbers defined as remote destinations. Cisco recommends using the default setting of Unified CM 6.1 because it simplifies call routing.

All the numbers defined as remote destinations within the same cluster will be searched to find a match for any external call coming into the cluster.

The following examples assume Unified CM 6.1 and later releases with the service parameter Inbound Calling Search Space for Remote Destination set to Trunk or Gateway Inbound Calling Search Space.

For example:

Paul uses his mobile phone to call Ringo at his desk. The call comes into the gateway from the PSTN, with a calling party number of 514 000 9876 and a called party number of 408 555 0001. The call is routed to Ringo's phone. The number displayed as the calling party number on Ringo's phone is Paul's desk phone number, 8 555 1234. This allows Paul's mobile phone number to remain confidential and allows Ringo's calls placed from the missed and received calls lists to ring into Paul's IP phone, thus making the full set of enterprise mobility features available.

When the call comes into the gateway, the PSTN offers a calling party number of 514 000 9876 and a called party of 408 555 0001. The gateway's configuration will retain the last seven significant digits of the called number and prefix 8, yielding 8 555 0001 as the destination number.

The system detects that the calling party number matches Paul's remote destination number. Upon detecting this match, the system will:

1. Change the calling party number to Paul's DN, 8 555 1234.
2. Route the call to the called number using the incoming gateway's calling search space. Specifically, the routing is done through the GW_CSS calling search space.

The destination (called) number presented by the gateway should be the DN of the phone, and the calling party substitution illustrated in step 1 above renders possible the use of one-touch dialing from the missed/received calls lists.

Note

There is no way to partition remote destination numbers. This is worth noting in case multiple user groups (such as different companies, sub-contractors, and so forth) are using the same cluster. In Unified CM 6.1 and later releases, when the service parameter Inbound Calling Search Space for Remote Destination is set to Trunk or Gateway Inbound Calling Search Space, the call routing is based on the incoming trunk's or gateway's CSS, regardless of whether or not the calling number matches a remote destination. However, the calling party number substitution still occurs if the calling party matches any remote destination. This means that calls from one tenant's remote destination numbers to another tenant's DID numbers will be presented with a transformed calling party number that matches the caller's on-net extension DN.

Note

Any incoming external call where Calling Party Number is not available will be routed according to the incoming gateway's CSS. This also applies to incoming calls from IP trunks, such as SIP or H.323 trunks.

Remote Destination Profile's Calling Party Transformation CSS and Transformation Patterns

Calls originating from an enterprise IP phone to a mobility-enabled DN are forked to both the enterprise destination IP phone's DN and one (or multiple) external destinations. One challenge this creates is to deliver calling party numbers adapted to each destination phone's dial plan. This is to allow for redialing of calls from missed calls and received calls lists. For an enterprise phone, the calling party numbers should be redialable enterprise phone numbers. For a remote destination on the PSTN (such as a home phone or a mobile phone), the calling party number should be transformed from the enterprise number associated with the calling IP phone to a number redialable from the PSTN (generally, the DID number of the calling phone).

When a call is placed to a mobility-enabled enterprise DN, the associated remote destination profile's calling party transformation calling search space is used to find a match to the caller's calling party number. It contains partitions which themselves contain transformation patterns.

Transformation patterns control the adaptation of calling party numbers from enterprise format to PSTN format. They differ from all other patterns in Unified CM in that they match on the calling number, not the called number. The matching process is done through a regular expression (for example, 8 555 XXXX), and the transformation process allows for the optional use of the calling DN's external phone number mask as well as transformation patterns and digit prefixing.

Once matched, they perform all configured transformations, and the resulting calling party number is used to reach all remote destinations associated with the Remote Destination Profile for which the match occurred.

For example:

When Ringo calls Paul, we want Paul's IP phone to display the calling party number as 8 555 0001 and Paul's mobile phone to display 408 555 0001.

For this case, we create a transformation pattern with the following parameters:

Pattern: 8 555 XXXX

Partition: SJ_Calling_Transform

Use calling party's external phone number mask: un-checked

Calling Party Transformation mask: 555 XXXX

Prefix Digits (outgoing calls): 408

We also have to ensure that partition SJ_Calling_Transform is placed in calling search space P_CPT_CSS.

When the call from Ringo is anchored on Paul's phone, two separate call legs are attempted. The first rings Paul's IP phone and offers the caller's DN as Calling Party Number (that is, 8 555 0001). The second call leg is attempted through Paul's Remote Destination Profile. The RDP's calling party transformation CSS, P_CPT_CSS, is used to find a match for 8 555 0001 in all the referenced partition's transformation patterns. Pattern 8 555 XXXX is matched in partition SJ_Calling_Transform. The transformation mask is applied to the calling party number and yields 555 0001. The prefix digits are added, and the resulting calling party number 408 555 0001 is used when placing the call to the remote destinations.

Note that, in this example, we chose not to use the external phone number mask because it is set to a number different than that of Ringo's DID. This offers flexibility in situations where the calling party number offered to off-net destinations is required to be different based on the relationship of the caller to the called party. The call from Ringo to Paul is between co-workers, thus the disclosure of Ringo's DID number is deemed acceptable. Ringo's next call could be to a customer, in which case the main enterprise number 408 555 0000 is the desired Calling Party Number to be offered to the destination.

**Note**

Calling Party Transformation calling search spaces do not implicitly include the <none> partition; therefore, transformation patterns left in the <none> partition do not apply to any Calling Party Transformation calling search space. This is different from all other patterns in Unified CM, where all patterns left in the <none> partition are implicitly part of every calling search space.

Application Dial Rules

Numbers defined as remote destinations are also used to identify and anchor incoming calls as enterprise mobility calls. Often, the form in which the PSTN identifies calls differs from the form in which an enterprise dial plan requires that calls to external numbers be dialed. Application dial rules can be used to adapt the form in which remote destinations are configured to the form required when forking a call to the remote destination. They allow for the removal from, and prefixing of digits to, the numbers configured as remote destinations.

For example:

Assume the number 514 000 9876 is configured as Paul's remote destination number. This corresponds to the form used by the PSTN to identify calls coming into the enterprise. But it differs from the form used by the enterprise dial plan for outgoing calls, which requires that 91 be prefixed. In this case, we need to create an application dial rule to adapt the remote destination form to the enterprise dial plan's form:

Application Dial Rule:

Name: 514000_ten

Description: Used to prefix 91 to ten-digit numbers beginning with 514000

Number begins with: 514000

Number of Digits: 10

Total digits to be removed: 0

Prefix with Pattern: 91

In this example, calls made from Paul's mobile phone into the enterprise are identified as coming from 514 000 9876. This matches the form in which his number is configured as a remote destination, thus allowing the match to be made and triggering the anchoring of the call on Paul's desk phone as well as adapting the Calling Party Number offered to the on-net destination. (For example, when a call is placed to Ringo's DID number, he sees the call as coming from 8 555 1234.)

When a call is placed to Paul's enterprise DN number, the call leg forked to his remote destination number will be processed by the application dial rule above. The string 514 000 matches the beginning of Paul's remote destination number, and it is ten digits long, so no digits are removed and 91 is prefixed. This yields 91 514 000 9876 as a number to be routed through Paul's Remote Destination Profile calling search space (P_RDP_CSS in this case).

Note

This approach offers the ability to reuse calling search spaces already defined to route calls made from IP phones. Creating new calling search spaces not requiring prefixes for outbound calls (that is, ones able to route calls to 514 000 9876 directly) is less preferable because it can create situations where external patterns overlap with on-net patterns.

Immediate Divert (iDivert)

The Immediate Divert (iDivert) function is used to send calls directly to voicemail. It can be invoked when the call is ringing (incoming), when a call is on hold, or when a call is connected. The iDivert function allows incoming calls to be diverted to either the invoking phone's voicemail box or the voicemail box of the originally called party. The enhanced functionality is applicable only to diverted calls such as forwarded calls or calls redirected by an application.

iDivert Enhancements in Cisco Unified CM 5.1

The iDivert function has been augmented in Cisco Unified CM 5.1 to allow incoming calls to be diverted to either the invoking phone's voicemail box (legacy behavior) or the voicemail box of the originally called party (enhanced behavior). The enhanced functionality is applicable only to diverted calls such as forwarded calls or calls redirected by an application.

For example:

Assume that phone A calls phone B, whose calls are forwarded to phone C. As phone C is ringing, the user at phone C activates the iDivert softkey, which offers two choices. The first choice results in the call being sent to the original called party's voicemail (in this case, phone B's voicemail box), while the second choice results in the call being sent to the iDivert invoker's voicemail (in this case, phone C's voicemail box). The same choices are available whether phone C invokes the feature while the call is ringing, connected, or placed on hold.

If a call is handled by Auto Call Pickup, Call Transfer, Call Park, Call Park Reversion, Conference, or a MeetMe Conference prior to the invocation of the iDivert function, the call is no longer considered to be a "diverted" call, and the only iDivert functionality available in this case is the legacy iDivert behavior (that is, sending the call to the invoker's voicemail). For example, assume phone A calls phone B, whose

calls are forwarded to phone C, and then phone C transfers the call to phone D. This is *not* a diverted call because the last action applied to the call was the transfer to phone D. If phone D invokes the iDivert function, the call will be sent to phone D's voicemail box.

To enable the full iDivert functionality described above, set the Unified CM service parameter **Use Legacy Immediate Divert to False**. When enabled, enhanced iDivert automatically allows the use of the feature over QSIG trunks, thus allowing an invoker's voicemail box to be hosted in a telephony system connected via QSIG.

In cases where iDivert is used in a cluster connected to other telephone systems using QSIG, there might be situations in which only the legacy iDivert functionality (where the only available choice is to send the call to the invoker's voicemail) is offered to a phone when receiving a call. For instance, assume phones A and B are in cluster 1, and phone X is another QSIG-connected telephony system. Phone A calls phone X, which is call-forwarded to phone C. After the call is connected to phone C, iDivert will offer both the legacy (invoker's voicemail) and enhanced (original called party's voicemail) destinations only if QSIG path replacement has not occurred. If phone C invokes iDivert after QSIG path replacement, the only destination available is phone C's voicemail box.

Hunt Lists and Line Groups

The *hunt pilot* is typically used for call coverage, or distributing a call through a list of Skinny Client Control Protocol (SCCP) endpoints. For call distribution, you can use a hunt construct. This hunt construct is based upon a three-tiered architecture, similar to that used to route external calls, that allows for multiple layers of call routing as well as digit manipulation.

Unified CM searches for a configured hunt pilot that matches an incoming called number and uses it to select a corresponding hunt list, which is a prioritized list of the available paths for the call. These paths are known as *line groups*. Figure 9-44 depicts the three-tiered architecture of the hunt construct in Unified CM.

Figure 9-44 Three-Tiered Architecture for the Hunt Construct in Unified CM

Hunt Pilot

Hunt pilots are strings of digits and wildcards similar to route patterns, such as 9.[2-9]XXXXXX, configured in Unified CM to route calls to directory numbers. The hunt pilot points directly to a hunt list. Hunt lists point to line groups, which finally point to SCCP endpoints.

Calls can be redirected to a final destination when the hunting fails because of one or both of the following reasons:

- All hunting options have been exhausted and the call still is not answered.
- A time-out period has expired.

This call redirection is configured in the Hunt Forward Settings section of the Hunt Pilot configuration page, and the destination for this redirect can be either of the following options:

- A specific pattern in the internal call routing table of Unified CM
- Personal preferences, which point to the Call Forward No Coverage settings for the originally called number when hunting on behalf of that number fails

For example, you can implement the personal preferences option by configuring a user's phone so that the Forward No Answer field redirects the call to a hunt pilot, in order to search for someone else who can answer the call. If the call hunting fails, either because all the hunting options were exhausted or because a time-out period expired, the call can be sent to a destination personalized for the person who was originally called. For example, if you set the Forward No Coverage field within the person's DN configuration page to the voicemail number, the call will be sent to that person's voicemail box if hunting fails.

The following considerations apply to calls handled by hunt pilots:

- Call Pickup and Group Call Pickup are not supported on calls distributed by a hunt pilot. A member of the line group cannot pick up the hunt pilot call offered to another member in the line group, even if they belong to the same call pickup group.
- The hunt pilot can distribute calls to any of its line group members, even if the members and the hunt pilot reside in different partitions. A call distributed by the hunt pilot overrides all the partitions and calling search space restrictions.

Hunt List

A hunt list is a prioritized list of eligible paths (line groups) for call coverage. Hunt lists have the following characteristics:

- Multiple hunt pilots may point to the same hunt list.
- A hunt list is a prioritized list of line groups that function as alternate sets of phones which are offered a call placed to the hunt pilot number. For example, you can use a hunt list to attempt to find a taker for the call within a set of phones at a particular site. If the call is not taken, then the hunt list attempts to offer the call through a second line group pointing to phones at a second site.
- Hunt lists do not do any digit manipulation.
- Multiple hunt lists can contain the same line group.

Line Group

Line group members are user extension numbers that are controlled by Unified CM. Thus, when the call is being distributed through the line group members, Unified CM is in control of the call. Hunt options can be applied to the call when it is not answered or if the extension is busy or unregistered.

Line groups control the order in which the call is distributed, and they have the following characteristics:

- Line groups point to specific extensions, which are typically IP phone extensions or voicemail ports.
- A single extension may be present in multiple line groups.
- Computer Telephony Integration (CTI) ports and CTI route points cannot be added within a line group. Therefore, calls cannot be distributed to endpoints controlled through CTI applications such as Cisco Customer Response Solution (CRS), IP Interactive Voice Response (IP IVR), and so forth
- Unified CM distributes calls to the devices according to the distribution algorithm assigned. Unified CM supports the following algorithms:
 - Top-down
 - Circular
 - Longest idle time
 - Broadcast
- In the event of No-Answer, Busy, or Not-Available, line groups redirect a call distributed to an extension based on the hunt options. Unified CM supports the following hunt options:
 - Try next member, then try next group in hunt list.
 - Try next member, but do not go to next group.
 - Skip remaining members and go directly to next group.
 - Stop hunting.

Hunt Group Logout

A user can log out of a hunt group by activating the HLog softkey. Once activated, this function effectively makes all lines configured on the phone act as though they are not part of any hunt group. The phone displays "Logged out of Hunt Group." If a line group contains a shared line, all instances of the shared line that are on devices in the logged-out state will not ring; conversely, all instances of the shared line on devices in the logged-in state will ring.

Lines that are not part of any hunt groups will continue to ring normally, no matter the state of the HLog function.

The HLog function can be activated from Unified CM Administration. By default, the HLog softkey is not configured on the softkey templates. Once added to a phone's softkey template, the HLog button appears in the display when the phone is in the connected, off-hook, or on-hook state.

The Hunt Group Logoff Notification service parameter provides the option of audible ring tones when calls that come in from a line group arrive at the phone in the logged-off state. The Hunt Group Logoff Notification service parameter is in the Clusterwide Parameters (Device - Phone) section of the Service Parameters Configuration page. For enabling the function, ensure that a valid ring tone file is present on the TFTP server. If an invalid file name is provided, no tone will be played

For more information about hunt algorithms and hunt options, refer to the *Cisco Unified Communications Manager Administration Guide*, available at

<http://www.cisco.com>

Line Group Devices

The line group devices are the endpoints accessed by line groups, and they can be of any of the following types:

- Any Skinny Client Control Protocol (SCCP) endpoints, such as Cisco Unified IP Phones
- SIP endpoints
- Voicemail ports (for Cisco Unity)
- H.323 clients
- FXS extensions attached to an MGCP gateway

Time-of-Day Routing

To use this feature, configure the following elements:

- Time period
- Time schedule

The time period allows you to configure start and end times for business hours. The start and end times indicate the times during which the calls can be routed. In addition to these times, you can set the event to repeat itself on a weekly or yearly basis. Moreover, you can also configure non-business hours by selecting "No business hours" from the Start Time and End Time options. All incoming calls will be blocked when this option is selected.

A time schedule is a group of specific time periods assigned to the partition. It determines whether the partition is active or inactive during the specified time periods. A matching/dialing pattern can be reached only if the partition in which the dialing pattern resides is active.

As illustrated in [Figure 9-45](#), two hunt pilots with the same calling pattern (8000) are configured in two partitions (namely, RTP_Partition and SJC_Partition). Each of these partitions is assigned a time schedule, which contains a list of defined time periods. For example, RTP phones can be reached using Hunt Pilot 1 from 8:00 AM to 12:00 PM EST (GMT - 5.00) Monday through Friday as well as 8:00 AM to 5:00 PM on Sundays. In the same way, SJC phones can be reached using Hunt Pilot 2 from 8:00 AM to 5:00 PM PST (GMT - 8.00) Monday through Friday and 8:00 AM to 5:00 PM on Saturdays. Both of the hunt pilots in this example are inactive on July 4th.

Figure 9-45 Time-of-Day Routing

For the example in [Figure 9-45](#), an incoming call to the hunt pilot (8000) on Wednesday at 3:00 PM will be forwarded to the SJC phones, while a person calling the hunt pilot on July 4th will get a fast busy tone unless there is another pattern that matches 8000.

Logical Partitioning

The elements of logical partitioning include:

- Device types, where phones are classified as *interior*, and gateways and trunks are defined as *border*. [Table 9-9](#) lists the endpoint types for different devices.
- Geolocations, where endpoints are assigned a civic address to be used in policy decisions.
- Geolocation filters, where policy decisions can be made on a subset of the geolocation objects.
- Policies, where communications between endpoints are either allowed or denied based on their comparative (filtered) geolocations and device types.

Note

Policies are not applied if all participants in a call (or call attempt) are classified as *interior*. This means that calls between phones on the same cluster are never subjected to logical partitioning policies.

**Note**

Geolocations are not to be confused with locations configured in Unified CM, which are used for call admission control, or with physical locations used for Device Mobility.

Table 9-9 Device Types

| Logical Partitioning Device Types | Cisco Unified Communications Manager Device |
|-----------------------------------|---|
| Border | <ul style="list-style-type: none"> • Gateway (for example, H.323 gateway) • Inter-luster trunk (ICT), both gatekeeper-controlled and non-gatekeeper-controlled • H.225 trunk • SIP trunk • MGCP port (E1, T1, PRI, BRI, FXO) |
| Interior | <ul style="list-style-type: none"> • Phones (SCCP, SIP, or third-party) • CTI route points • VG224 analog phones • MGCP port (FXS) • Cisco Unity voicemail (SCCP) |

Logical Partitioning Device Types

Unified CM classifies endpoints as either *interior* or *border*. This classification is fixed and cannot be modified by the system administrator.

Geolocation Creation

The (RFC) 4119 standard provides the basis for geolocations. Geolocations use the civic location format specified by the following objects:

- Name
- Description
- Country using the two-letter abbreviation
- State, Region, or Province (A1)
- County or Parish (A2)
- City or Township (A3)
- Borough or City District (A4)
- Neighborhood (A5)
- Street (A6)
- Leading Street Direction, such as N or W (PRD)
- Trailing Street Suffix, such as SW (POD)
- Address Suffix, such as Avenue, Platz (STS)
- Numeric house number (HNO)

- House Number Suffix, such as A, 1/2 (HNS)
- Landmark (LMK)
- Additional Location Information, such as Room Number (LOC)
- Floor (FLR)
- Name of Business or Resident (NAM)
- Zip or Postal Code (PC)

**Note**

In Unified CM, you must define geolocations manually.

Geolocation Assignment

Devices are assigned a geolocation from either the device page, the device pool, or the default Geolocation as configured under Enterprise Parameters, in that order of precedence.

Geolocation Filter Creation

Geolocation filters define which of the geolocation objects should be used when comparing the geolocations of different endpoints. For example, a group of phones may be assigned identical geolocations, except for the room and floor in which they are located. Policies may want to consider endpoints located within the same building as being within the same Closed User Group, and thus allowed to communicate. Even though the actual geolocations of each phone differ, the filtered geolocation is the same. This is useful when policies need to be applied to only the top-level fields of geolocation. For instance, a policy that denies communications between phones and gateways in different cities but allows communications between phones and gateways in the same city, could be based on the comparative filtered geolocations where objects more granular than the City are ignored.

Geolocation Filter Assignment

Phones inherit the filter assignment of their device pool. Gateways and trunks can be configured with a geolocation filter at the device or device pool level, in that order of precedence.

Logical Partitioning Policy Configuration

Logical partitioning policies are configured between geolocation identifiers. A geolocation identifier is the combination of a filtered geolocation and a device type. The filtered geolocation is obtained by taking a device's geolocation and applying the device's associated geolocation filter.

A policy is created as the combination of a set of geolocation objects and a device type (a source geolocation identifier) in relationship with another such combination (the target geolocation identifier). When the relationship is matched, the configured action of "allow" or "deny" is applied to the call leg.

**Note**

Each set of geolocation objects configured in a policy is considered in association with a single device type. For example, a set of geolocation objects such as Country=India, State=Karnataka, City=Bangalore needs to be associated with device type Interior for actions pertaining to Bangalore phones, and separately associated with device type Border for actions pertaining to Bangalore gateways.

Logical Partitioning Policy Application

When user action results in the creation of a new call leg (for example, when a user conferences a third caller into a preexisting call), Unified CM will match the geolocation identifiers of each participant pairs to those of preconfigured policies.

Note

When the geolocation identifiers of two devices are being evaluated by logical partitioning, no policy is applied if both devices are of device type Interior. This means that no call, conference, transfer, or so forth, between IP phones within the same cluster will ever be denied due to logical partitioning policies.

For example, consider phones A and B located in Bangalore, India, and gateway C located in Ottawa, Canada. Phone A calls phone B. Because both devices are of type Interior, no policy is invoked. The call is established, and then the user at phone A invokes a conference, which would bring in gateway C. Before the action is allowed, Unified CM will check the geolocation identifiers of A and C, as well as those of B and C, for a match with the preconfigured policies. If any of the matching policies results in a deny action, the new call leg cannot be established.

Note

The default policy in Unified CM is deny; in other words, if no policy is configured explicitly to permit a call leg, the call leg will be denied.

In the example above, unless an explicit policy is configured to allow Bangalore Interior devices to connect to Ottawa Border devices, the call leg will be denied.

Call Routing in Cisco IOS with H.323 Dial Peers

The call routing logic on Cisco IOS routers using the H.323 protocol relies on the dial peer construct. Dial peers are similar to static routes; they define where calls originate and terminate and what path the calls take through the network. Dial peers are used to identify call source and destination endpoints and to define the characteristics applied to each call leg in the call connection. Attributes within the dial peer determine which dialed digits the router collects and forwards to telephony devices.

For a detailed description of dial peers and their configuration, refer to *Configuring Dial Plans, Dial Peers, and Digit Manipulation*, part of the *Cisco IOS Voice, Video, and Fax Configuration Guide, Release 12.2*, available at

<http://www.cisco.com>

One of the keys to understanding call routing with dial peers is the concept of incoming versus outgoing call legs and, consequently, of incoming versus outgoing dial peers. Each call passing through the Cisco IOS router is considered to have two call legs, one entering the router and one exiting the router. The call leg entering the router is the *incoming call leg*, while the call leg exiting the router is the *outgoing call leg*.

Call legs can be of two main types:

- Traditional TDM telephony call legs, connecting the router to the PSTN, analog phones, or PBXs
- IP call legs, connecting the router to other gateways, gatekeepers, or Unified CMs

For all calls going through the router, Cisco IOS associates one dial peer to each call leg. Dial peers are also of two main types, according to the type of call leg with which they are associated:

- POTS dial peers, associated with traditional TDM telephony call legs
- VoIP dial peers, associated with IP call legs

Figure 9-46 shows the following examples of different types of calls going through a Cisco IOS router:

- Call 1 is from another H.323 gateway across the IP network to a traditional PBX connected to the router (for example, via a PRI interface). For this call, an incoming VoIP dial peer and an outgoing POTS dial peer are selected.
- Call 2 is from an analog phone connected to an FXS port on the router to a Unified CM cluster across the IP network. For this call, an incoming POTS dial peer and an outgoing VoIP dial peer are selected by the router.
- Call 3 is from an IP phone controlled by Cisco Unified Communications Manager Express (Unified CME) or SRST to a PSTN interface on the router (for example, a PRI interface). For this call, an automatically generated POTS dial peer (corresponding to the **ephone** configured on the router) and an outgoing POTS dial peer are selected.

Figure 9-46 Incoming and Outgoing Dial Peers

To match incoming call legs to incoming dial peers, the router selects a dial peer by matching the information elements in the setup message (called number/DNIS and calling number/ANI) with four configurable dial peer attributes. The router attempts to match these items in the following order:

1. Called number with **incoming called-number**
2. Calling number with **answer-address**
3. Called number with **destination-pattern**
4. Incoming voice port with configured voice port

The router must match only one of these conditions. It is not necessary for all the attributes to be configured in the dial peer or that every attribute match the call setup information; only one condition must be met for the router to select a dial peer. The router stops searching as soon as one dial peer is matched, and the call is routed according to the configured dial peer attributes. Even if there are other dial peers that would match, only the first match is used.

How the router selects an outbound dial peer depends on whether **direct-inward-dial** (DID) is configured in the inbound POTS dial peer:

- If DID is not configured in the inbound POTS dial peer, the router performs two-stage dialing and collects the incoming dialed string digit-by-digit. As soon as one dial peer matches the destination pattern, the router immediately places the call using the configured attributes in the matching dial peer.
- If DID is configured in the inbound POTS dial peer, the router uses the full incoming dial string to match the destination pattern in the outbound dial peer. With DID, the setup message contains all the digits necessary to route the call, so no additional digit collection is required. If more than one dial peer matches the dial string, all of the matching dial peers are used to form a *hunt group*. The router attempts to place the outbound call leg using all of the dial peers in the hunt group until one is successful.

By default, dial peers in a hunt group are selected according to the following criteria, in the order listed:

1. Longest match in phone number

This method selects the destination pattern that matches the greatest number of dialed digits. For example, if one dial peer is configured with a dial string of 345... and a second dial peer is configured with 3456789, the router would first select 3456789 because it has the longest explicit match of the two dial peers.

2. Explicit preference

This method uses the priority configured with the **preference** dial peer command. The lower the preference number, the higher the priority. The highest priority is given to the dial peer with preference order 0. If the same preference is defined in multiple dial peers with the same destination pattern, a dial peer is selected randomly.

3. Random selection

In this method, all destination patterns are weighted equally.

You can change this default selection order or choose different methods for hunting dial peers by using the **dial-peer hunt** global configuration command. An additional selection criterion is *least recent use*, which selects the destination pattern that has waited the longest since being selected (equivalent to *longest idle* for Unified CM line groups).

Observe the following best practices when configuring H.323 dial peers on a Cisco IOS router:

- To ensure that incoming PSTN calls are directly routed to their destination based on the DNIS information, create a default POTS dial peer with the **direct-inward-dial** attribute, as follows:

```
dial-peer voice 999 pots
  incoming called-number .
  direct-inward-dial
  port 1/0:23
```

- When using the router as an H.323 gateway connected to a Unified CM cluster, provide redundancy by configuring at least two VoIP dial peers with the same destination pattern pointing to two different Unified CM servers. Use the **preference** attribute to select the priority order between primary and secondary Unified CM servers. The following example shows the use of the **preference** attribute:

```
dial-peer voice 100 voip
  preference 1

!--- Make this the first choice dial peer.

ip precedence 5
destination-pattern 1...
```

```
session target ipv4:10.10.10.2

!--- This is the address of the primary Unified CM.

dtmf-relay h245-alpha

dial-peer voice 101 voip
  preference 2

!--- This is the second choice.

ip precedence 5
destination-pattern 1...
session target ipv4:10.10.10.3

!--- This is the address of the secondary Unified CM.

dtmf-relay h245-alpha
```

Call Routing in Cisco IOS with a Gatekeeper

An H.323 gatekeeper is an optional node that manages endpoints (such as H.323 terminals, gateways, and Multipoint Control Units (MCUs), as well as Cisco Unified Communications Manager Express (Unified CME) and Unified CM clusters) in an H.323 network, providing them with call routing and call admission control functions. The endpoints communicate with the gatekeeper using the H.323 Registration Admission Status (RAS) protocol.

Endpoints attempt to register with a gatekeeper on startup. When they want to communicate with another endpoint, they request admission to initiate a call using a symbolic alias for the endpoint, such as an E.164 address or an email address. If the gatekeeper decides that the call can proceed, it returns a destination IP address to the originating endpoint. This IP address might not be the actual address of the destination endpoint, but instead it might be an intermediate address, such as the address of a Cisco Unified Border Element or a gatekeeper that routes call signaling.

For more details about the H.323 protocol and the message exchange between H.323 endpoints and gatekeepers, refer to the *Cisco IOS H.323 Configuration Guide*, available at

<http://www.cisco.com>

The Cisco 2600, 3600, 3700, 2800, 3800, and 7200 Series routers all support the gatekeeper feature. You can configure Cisco IOS gatekeepers in a number of different ways for redundancy, load balancing, and hierarchical call routing. This section focuses on the call routing capabilities of the gatekeeper feature. For redundancy and scalability considerations, refer to [Gatekeeper Redundancy, page 8-38](#); for call admission control considerations, refer to [Cisco IOS Gatekeeper Zones, page 11-15](#).

Call routing in Cisco IOS gatekeeper is based on the following types of information:

- Statically configured information, such as zone prefixes and default technology prefixes
- Dynamic information, such as E.164 addresses and technology prefixes provided by H.323 devices during the registration phase
- Per-call information, such as called number and technology prefix

A zone is a collection of H.323 devices (such as endpoints, gateways, or MCUs) that register with a gatekeeper. There can be only one active gatekeeper per zone, and you can define up to 100 local zones on a single gatekeeper.

When an H.323 endpoint registers with the gatekeeper, it is assigned to a zone and it can optionally register one or more E.164 addresses for which it is responsible, as well as a technology prefix that specifies which kinds of calls it can handle (for example, voice, video, fax, and so on).

For each zone, you can configure one or more *zone prefixes* on the gatekeeper. Zone prefixes are strings that contain digits and wildcards and are used by the gatekeeper to facilitate call routing decisions. The following characters are allowed in a zone prefix string:

- All numbers between 0 and 9, which match a single specific digit
- The dot (.) wildcard, which matches one digit between 0 and 9
- The * wildcard, which matches one or more digits between 0 and 9

To understand the gatekeeper call routing behavior, it is helpful to consider the message parsing logic. [Figure 9-47](#) illustrates the parsing logic for an Admission Request (ARQ). To initiate a call, an endpoint sends an Admission Request (ARQ) to the gatekeeper. The ARQ contains either an H.323 ID or the E.164 address of the destination, or called party, as well as the E.164 address or H.323 ID of the source, or calling party.

If the ARQ contains the E.164 address (with Unified CM, the ARQ always contains an E.164 address), the ARQ may or may not contain a technology prefix. If the ARQ contains a technology prefix, the gatekeeper strips it from the called number. If the ARQ does not contain a technology prefix, the gatekeeper uses the default technology prefix if one is configured (see the **gw-type-prefix** command in the section on [Centralized Gatekeeper Configuration, page 9-135](#)). The technology prefix thus obtained is stored in memory, and the gatekeeper continues with the call routing algorithm.

Next, the gatekeeper tries to match the called number with one of the configured zone prefixes. Longest-match is used if multiple potential matches exist. If no zone prefix can be matched, and if the gatekeeper is configured to accept calls with an unknown prefix, the gatekeeper then assumes that the destination zone is equal to the source zone.

At this point, the gatekeeper searches in the chosen destination zone for a registered E.164 address that matches the called number. If there is a match, the gatekeeper can send an Admission Confirm (ACF), provided that the requested bandwidth for the call is available and that the called endpoint is registered with the gatekeeper. The ACF will contain the IP address of the destination endpoint. If the bandwidth is unavailable or the called endpoint is not registered, the gatekeeper returns an Admission Reject (ARJ) to the calling endpoint.

If there is no matching E.164 address registered in the destination zone, the gatekeeper will use the previously stored technology prefix to choose a gateway registered in that zone as the destination for the call. The same considerations regarding bandwidth availability and endpoint registration dictate whether the gatekeeper will send an ACF or an ARJ to the calling endpoint.

Upon receipt of an ACF from the gatekeeper, the source endpoint can send a setup message directly to the destination endpoint by using the IP address returned in the ACF.

Figure 9-47 Gatekeeper Address Resolution for an ARQ

91906

Figure 9-48 illustrates the parsing logic for a Location Request (LRQ). LRQ messages are exchanged between gatekeepers and are used for inter-zone (remote zone) calls. For example, gatekeeper A receives an ARQ from a local zone gateway requesting call admission for a remote zone device. Gatekeeper A then sends an LRQ message to gatekeeper B. Gatekeeper B replies to the LRQ message with either a Location Confirm (LCF) or Location Reject (LRJ) message, depending on whether it is configured to admit or reject the inter-zone call request and whether the requested resource is registered.

Figure 9-48 Gatekeeper Address Resolution for an LRQ

90617

Traditional Cisco IOS gatekeeper functionality has been extended to accommodate for Cisco Unified Border Elements through the concept of a *via-zone gatekeeper*.

A *via-zone gatekeeper* differs from legacy gatekeepers in how it uses LRQ and ARQ messages for call routing. Using *via-zone gatekeepers* will maintain normal clusters and functionality. Legacy gatekeepers examine incoming LRQs based on the called number, and more specifically the `dialedDigits` field in the `destinationInfo` portion of the LRQ. *Via-zone gatekeepers* look at the origination point of the LRQ before looking at the called number. If an LRQ comes from a gatekeeper listed in the *via-zone gatekeeper's* remote zone configurations, the gatekeeper checks to see that the zone remote configuration contains an **invia** or **outvia** keyword. If the configuration contains either of these keywords, the gatekeeper uses the new *via-zone* behavior; if not, it uses legacy behavior.

For ARQ messages, the gatekeeper determines if an **outvia** keyword is configured on the destination zone. If the **outvia** keyword is configured and the zone named with the **outvia** keyword is local to the gatekeeper, the call is directed to a Cisco Unified Border Element in that zone by returning an ACF

pointing to the Cisco Unified Border Element. If the zone named with the **outvia** keyword is remote, the gatekeeper sends a location request to the **outvia** gatekeeper rather than the remote zone gatekeeper. The **invia** keyword is not used in processing the ARQ.

Centralized Gatekeeper Configuration

A single gatekeeper can support call routing between clusters and call admission control for up to 100 Unified CM clusters. [Figure 9-49](#) illustrates a distributed call processing environment with two Unified CM clusters and a single, centralized gatekeeper.

Figure 9-49 Centralized Gatekeeper Supporting Two Clusters

[Example 9-5](#) shows the gatekeeper configuration for the example in [Figure 9-49](#).

Example 9-5 Configuration for Centralized Gatekeeper

```
gatekeeper
zone local GK-Site1 customer.com 10.1.10.100
zone local GK-Site2 customer.com
zone prefix GK-Site1 408.....
zone prefix GK-Site2 212.....
bandwidth interzone GK-Site1 160
bandwidth interzone GK-Site2 160
gw-type-prefix 1#* default-technology
arq reject-unknown-prefix
no shutdown
```

The following notes also apply to [Figure 9-49](#):

- Each Unified CM cluster has a local zone configured to support Unified CM trunk registrations.
- A zone prefix is configured for each zone to allow inter-zone and inter-cluster call routing.

- Bandwidth statements are configured for each site. Cisco recommends that you use the **bandwidth interzone** command because using the **bandwidth total** command can cause issues in some configurations. Bandwidth is measured in kilobits per second (kbps).
- The **gw-type-prefix 1# default-technology** command allows all locally unresolved calls to be forwarded to a device registered with a technology prefix of 1# in the local zone. In this example, all Unified CM trunks have been configured to register with a 1# prefix.

Technology prefixes indicate the type of call being made. The specific values used as technology prefixes are arbitrary and are defined by the network administrator. The same values should be used consistently throughout the entire deployment.

Technology prefixes are sent as a prefix to the E.164 address (phone number) to indicate whether the call is voice, video, or some other type. The # symbol is generally used to separate the prefix from the E.164 number. If a prefix is not included, the default technology prefix is used to route the call. There can be only one default technology prefix for the entire deployment.

Cisco IOS gateways automatically add a technology prefix to outbound calls if the gateway has a prefix configured. The gateway also automatically strips the prefix from incoming H.323 calls. Unified CM can register with the gatekeeper using a technology prefix, as specified on the configuration page for gatekeeper-controlled H.323 trunks. However, this technology prefix is not automatically added to outgoing calls to the gatekeeper, and is not automatically stripped from inbound calls to Unified CM. You can use translation patterns and significant digits to manipulate the called number so as to add or strip the technology prefix as needed.

- The **arq reject-unknown-prefix** command guards against potential call routing loops across redundant Unified CM trunks.

Distributed Gatekeeper Configuration

Gatekeepers can be distributed to conserve bandwidth or to provide local call routing for H.323 gateways in case of a WAN failure. [Figure 9-50](#) illustrates a distributed call processing environment with two clusters and two gatekeepers.

Figure 9-50 Distributed Gatekeepers Supporting Two Clusters

[Example 9-6](#) shows the gatekeeper configuration for Site 1 in [Figure 9-50](#).

Example 9-6 Gatekeeper Configuration for Site 1

```
gatekeeper
zone local GK-Site1 customer.com 10.1.10.100
zone remote GK-Site2 customer.com 10.1.11.100
zone prefix GK-Site1 408.....
zone prefix GK-Site2 212.....
bandwidth remote 160
gw-type-prefix 1#* default-technology
arq reject-unknown-prefix
no shutdown
```

The following notes apply to [Example 9-6](#):

- A local zone is configured for registration of local Unified CM cluster trunks.
- A remote zone is configured for routing calls to the Site 2 gatekeeper.
- Zone prefixes are configured for both zones for inter-zone call routing.
- The **bandwidth remote** command is used to limit bandwidth between the local zone and any other remote zone.
- The **gw-type-prefix 1#* default-technology** command allows all locally unresolved calls to be forwarded to a device registered with a technology prefix of 1# in the local zone. In this example, all Unified CM trunks have been configured to register with a 1# prefix.

- The **arq reject-unknown-prefix** command guards against potential call routing loops across redundant Unified CM trunks.

[Example 9-7](#) shows the gatekeeper configuration for Site 2 in [Figure 9-50](#).

Example 9-7 Gatekeeper Configuration for Site 2

```
gatekeeper
zone local GK-Site2 customer.com 10.1.11.100
zone remote GK-Site1 customer.com 10.1.10.100
zone prefix GK-Site2 212.....
zone prefix GK-Site1 408.....
bandwidth remote 160
gw-type-prefix 1#* default-technology
arq reject-unknown-prefix
no shutdown
```

The following notes apply to [Example 9-7](#):

- A local zone is configured for registration of local Unified CM cluster trunks.
- A remote zone is configured for routing calls to the Site 1 gatekeeper.
- Zone prefixes are configured for both zones for inter-zone call routing.
- The **bandwidth remote** command is used to limit bandwidth between the local zone and any other remote zone.
- The **gw-type-prefix 1# default-technology** command allows all locally unresolved calls to be forwarded to a device registered with a technology prefix of 1# in the local zone. In this example, all Unified CM trunks have been configured to register with a 1# prefix.
- The **arq reject-unknown-prefix** command guards against potential call routing loops across redundant Unified CM trunks.

Distributed Gatekeeper Configuration with Directory Gatekeeper

Because there is no gatekeeper protocol available to update gatekeeper routing tables, use of a directory gatekeeper can help make distributed gatekeeper configurations more scalable and more manageable. Implementing a directory gatekeeper makes gatekeeper configurations at each site simpler and moves most of the configuration for inter-zone communication into the directory gatekeeper.

Without a directory gatekeeper, you would have to add an entry in every gatekeeper on the network every time you add a new zone on one of the gatekeepers. However, with a directory gatekeeper, you can add the new zone in the local gatekeeper and the directory gatekeeper only. If the local gatekeeper cannot resolve a call request locally, it forwards that request to the directory gatekeeper with a matching zone prefix.

[Figure 9-51](#) illustrates a Unified CM distributed call processing environment with distributed gatekeepers for local call routing and a directory gatekeeper to provide call routing between gatekeepers.

Figure 9-51 Distributed Gatekeepers with a Directory Gatekeeper

Example 9-8 shows the gatekeeper configuration for Site 1 in Figure 9-51. Because the Site 1 and Site 2 gatekeeper configurations are almost identical in this example, only Site 1 is covered here.

Example 9-8 Gatekeeper Configuration for Site 1, with Directory Gatekeeper

```
gatekeeper
zone local GK-Site1 customer.com 10.1.10.100
zone remote DGK customer.com 10.1.10.101
zone prefix GK-Site1 408.....
zone prefix DGK .....
bandwidth remote 160
gw-type-prefix 1#* default-technology
arq reject-unknown-prefix
no shutdown
```

The following notes also apply to Example 9-8:

- A local zone is configured for registration of local Unified CM cluster trunks.
- A remote zone is configured for the directory gatekeeper.
- Zone prefixes are configured for both zones for inter-zone call routing.
- The directory gatekeeper zone prefix is configured with 10 dots. This pattern matches any unresolved 10-digit dial strings. Multiple zone prefixes can be configured for a single zone, allowing matches on different length dial strings. A wildcard (*) can also be used for a directory gatekeeper zone prefix, but this method can cause call routing issues in some instances.
- The **bandwidth remote** command is used to limit bandwidth between the local zone and any other remote zone.
- The **gw-type-prefix 1# default-technology** command allows all locally unresolved calls to be forwarded to a device registered with a technology prefix of 1# in the local zone. In this example, all Unified CM trunks have been configured to register with a 1# prefix.

- The **arq reject-unknown-prefix** command guards against potential call routing loops across redundant Unified CM trunks.

[Example 9-9](#) shows the directory gatekeeper configuration for the example in [Figure 9-51](#).

Example 9-9 Directory Gatekeeper Configuration

```
gatekeeper
zone local DGK customer.com 10.1.10.101
zone remote GK-Site1 customer.com 10.1.10.100
zone remote GK-Site2 customer.com 10.1.11.100
zone prefix GK-Site1 408*
zone prefix GK-Site2 212*
lrq forward-queries
no shutdown
```

The following notes also apply to [Example 9-9](#):

- A local zone is configured for the directory gatekeeper.
- Remote zones are configured for each remote gatekeeper.
- Zone prefixes are configured for both remote zones for inter-zone call routing. The wildcard (*) is used in the zone prefix to simplify configuration. Calls will not be routed to the DGK zone, so no prefix is required for it.
- The **lrq forward-queries** command allows the directory gatekeeper to forward an LRQ received from another gatekeeper.

Calling Privileges in Cisco IOS with H.323 Dial Peers

Use the class of restriction (COR) functionality to implement calling privileges with Cisco IOS-based systems using H.323, including H.323 gateways, SRST, and Cisco Unified Communications Manager Express (Unified CME). This functionality provides flexibility in network design, allows administrators to block calls for all users (for example, calls to 900 numbers), and applies different calling privileges to call attempts from different originators (for example, it allows some users but not others to call international numbers).

The fundamental mechanism at the center of the COR functionality relies on the definition of incoming and outgoing *corlists* that are associated to existing dial peers, where the concepts of incoming and outgoing are relative to the Cisco IOS router (as in the case of dial peers). Each corlist is defined to include a number of members, which are simply tags previously defined within Cisco IOS.

When a call goes through the router, an incoming dial peer and an outgoing dial peer are selected based on the Cisco IOS dial peer routing logic. If corlists are associated with the selected dial peers, the following additional check is performed before extending the call:

- If the members of the outgoing corlist associated with the outgoing dial peer are a subset of the members of the incoming corlist associated with the incoming dial peer, the call is permitted.
- If the members of the outgoing corlist associated with the outgoing dial peer are *not* a subset of the members of the incoming corlist associated with the incoming dial peer, the call is rejected.

If no corlist statements are applied to some dial peers, the following properties apply:

- When no incoming corlist is configured on a dial-peer, the default incoming corlist is used. The default incoming corlist has the highest possible priority, and it therefore allows this dial-peer to access all other dial-peers, regardless of their outgoing corlist.
- When no outgoing corlist is configured on a dial-peer, the default outgoing corlist is used. The default outgoing corlist has the lowest possible priority, and it therefore allows all other dial-peers to access this dial-peer, regardless of their incoming corlist.

This behavior is best illustrated with an example as shown in [Figure 9-52](#), where one VoIP dial-peer and two POTS dial-peers are defined.

Figure 9-52 Example of COR Behavior

The VoIP dial-peer is associated with the c1 incoming corlist, with members A, B, and C. You can think of members of the incoming corlist as "keys."

The first POTS dial-peer has a destination-pattern of 1.. and is associated with the c2 outgoing corlist, with members A and B. The second POTS dial-peer has a destination-pattern of 2.. and is associated with the c3 outgoing corlist, with members A, B, and D. You can think of members of the outgoing corlists as "locks."

For the call to succeed, the incoming corlist of the incoming dial-peer must have all the "keys" needed to open all the "locks" of the outgoing corlist of the outgoing dial-peer.

In the example shown in [Figure 9-52](#), a first VoIP call with destination 100 is received by the router. The Cisco IOS call routing logic matches the incoming call leg with the VoIP dial-peer and the outgoing call leg with the first POTS dial-peer. The COR logic is then applied; because the c1 incoming corlist has all the keys needed for the c2 outgoing corlist locks (A and B), the call succeeds.

A second VoIP call with destination 200 is then received by the router. The Cisco IOS call routing logic matches the incoming call leg with the VoIP dial-peer and the outgoing call leg with the second POTS dial-peer. The COR logic is then applied; because the c1 incoming corlist is missing one "key" for the c3 outgoing corlist (D), the call is rejected.

Follow these steps when configuring the COR functionality in Cisco IOS:

-
- Step 1** Define "tags" to be used as corlist members with the command **dial-peer cor custom**.
- Step 2** Define corlists with the command **dial-peer cor list corlist-name**.
- Step 3** Associate corlists with existing VoIP or POTS dial-peers by using the command **corlist {incoming | outgoing} corlist-name** within the dial-peer configuration.
-

With Cisco IOS Release 12.2(8)T and later, you can apply the COR functionality to SRST-controlled IP phones. Because IP phones register with the SRST router dynamically, SRST has no prior knowledge of the individual phones until they lose connectivity to the Unified CM cluster. Therefore, the COR feature configuration for SRST is based on the phone DNs instead. When the IP phones register with the SRST router, they communicate their DN to it, thus allowing the SRST router to assign them to the appropriate corlist.

Configure COR for IP phones controlled by SRST by using the command **cor {incoming | outgoing} corlist-name {corlist-number starting-number – ending-number | default}** within the **call-manager-fallback** configuration mode.

The following limitations apply to this command:

- The maximum number of **cor {incoming | outgoing}** statements under **call-manager-fallback** is 5 (plus the default statement) in SRST version 2.0, available on Cisco IOS Release 12.2(8)T or later.
- The maximum number of **cor {incoming | outgoing}** statements under **call-manager-fallback** is 20 (plus the default statement) in SRST version 3.0, available on Cisco IOS Release 12.3(4)T or later.

The COR functionality can also be deployed with Cisco Unified Communications Manager Express (Unified CME), using Cisco IOS Release 12.2(8)T and later. Because the individual IP phones are specifically configured within Unified CME, you can apply corlists directly to the IP phones themselves by using the command **cor {incoming | outgoing} corlist-name** within the **ephone-dn dn-tag** configuration mode of each IP phone.

Refer to the section on [Building Classes of Service in Cisco IOS with H.323](#), page 9-71, for an example of how to apply all these concepts in practice.

For more details on configuration of Cisco SRST and Unified CME, refer to the *Cisco SRST System Administrator Guide* and the *Cisco Unified Communications Manager Express System Administrator Guide*, both available at

<http://www.cisco.com>

Digit Manipulation in Cisco IOS with H.323 Dial Peers

In Cisco IOS routers running H.323, digit manipulation is performed via voice translation profiles, which are used to manipulate the calling number (ANI) or called number (DNIS) digits for a voice call or to change the numbering type of a call.

Voice translation profiles are available starting with Cisco IOS Release 12.2(11)T, and they are used to convert a telephone number into a different number before the call is matched to an incoming dial peer or before the call is forwarded by the outgoing dial peer. For example, within your company you might dial a five-digit extension to reach an employee at another site. If the call is routed through the PSTN to reach the other site, the originating gateway must use voice translation profiles to convert the five-digit extension into the ten-digit format that is recognized by the central office switch.

You configure voice translation profiles by using the **voice translation-rule** and **voice translation-profile** Cisco IOS commands, which use regular expressions to define the digit strings to be modified. You then specify if the manipulations should be associated to calling numbers, called numbers, or redirected called numbers. After you define a voice translation profile, you can apply it to any of the following elements:

- All incoming POTS call legs that terminate on a specific voice port
- All incoming VoIP call legs into the router
- Outgoing call legs associated with a specific VoIP or POTS dial peer
- All incoming or outgoing call legs that terminate on the IP phones controlled by SRST
- Incoming call legs for calls originated by all IP phones controlled by SRST

**Note**

Voice translation profiles using the **voice translation-rule** command replace and enhance the functionality previously provided by the **translation-rule** command. The syntax of the new command differs from that used by the old command. For more details, refer to **voice translation-rule** in the *Cisco IOS Voice Command Reference*, Release 12.2(11)T or later, available at <http://www.cisco.com>.

A typical application of voice translation profiles is to enable the preservation of on-net inter-site dialing habits from a branch site even when the IP WAN is unavailable and the router is running in SRST mode. For example, consider a simple deployment with a central site in San Jose and three remote sites in San Francisco, New York, and Dallas. [Table 9-10](#) shows the DID ranges and the internal site codes for this example.

Table 9-10 Example of DID Ranges and Site Codes for Translation Rule Application

| | San Jose | San Francisco | New York | Dallas |
|-----------|----------------|----------------|----------------|----------------|
| DID Range | (408) 555-1XXX | (415) 555-1XXX | (212) 555-1XXX | (972) 555-1XXX |
| Site Code | 1 | 2 | 3 | 4 |

Inter-site calls are normally placed across the IP WAN by dialing the on-net access code 8 followed by the one-digit site code and the four-digit extension of the called party. To preserve these dialing habits even when the IP WAN is down and Cisco SRST is active, the internal numbers must be converted back into the E.164 numbers before being sent to the PSTN. A sample configuration for the San Francisco router is as follows:

```
voice translation-rule 1
  rule 1 /^81/ /91408555/
  rule 2 /^83/ /91212555/
  rule 3 /^84/ /91972555/

voice translation-profile on-net-xlate
  translate called 1

call-manager-fallback
  translation-profile outgoing on-net-xlate

dial-peer voice 2 pots
  destination-pattern 91[2-9]..[2-9].....
  port 1/0:0
  direct-inward-dial
  forward-digits 11
```

With this configuration, when the San Francisco site is in SRST mode and a user dials 831000, the router will match **rule 2** of **voice translation-rule 1** and translate the called number to 912125551000. This new number will then be used to match the outgoing dial peer (**dial-peer voice 2**).

For a detailed description of dial peers and their configuration, refer to *Configuring Dial Plans, Dial Peers, and Digit Manipulation*, part of the *Cisco IOS Voice, Video, and Fax Configuration Guide, Release 12.2*, available at

<http://www.cisco.com>

For a thorough explanation of regular expression syntax in Cisco IOS, refer to the information on *Regular Expressions* in the *Cisco IOS Terminal Services Configuration Guide*, available at

http://www.cisco.com/en/US/docs/ios/termserv/configuration/guide/tsv_reg_express_ps6441_TSD_Products_Configuration_Guide_Chapter.html

Service Advertisement Framework (SAF) Call Control Discovery (CCD)

This section highlights some aspects of the Cisco Service Advertisement Framework (SAF) Call Control Discovery (CCD) service configuration in Unified CM and related Unified Communications subsystems. For more details on this subject, refer to the section on [Call Routing and Dial Plan Distribution Using Call Control Discovery for the Service Advertisement Framework, page 5-64](#), and to the latest version of the *Cisco Unified Communications Manager Administration Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

By participating in the framework as a CCD advertiser, a Unified CM cluster injects information into the network about the DN ranges it hosts. This information is sent to a Service Advertisement Framework Forwarder (SAF Forwarder), which learns the new routes and shares them with other participating SAF Forwarders and CCD requestors in the network.

By participating in the framework as a CCD requestor, a Unified CM cluster learns the DN ranges advertised by other call agents in the network from a SAF Forwarder.

SAF Forwarders

SAF Forwarders are configured on Cisco IOS routers and require Cisco IOS Release 15.0(1) or higher. For more information on configuring SAF Forwarders, consult the *Cisco IOS Service Advertisement Framework Configuration Guide*, available at

http://www.cisco.com/en/US/docs/ios/saf/configuration/guide/15_0/saf_15_0_book.html

SAF Forwarder Configuration

Within Unified CM, you need to configure both a SAF Security Profile (**Advanced Features > SAF > SAF Security Profile**) and a SAF Forwarder (**Advanced Features > SAF > SAF Forwarder**).

The SAF Security Profile configuration page in Unified CM features User Name and User Password fields. These entries must match the SAF Forwarder configuration in the Cisco IOS command line interface (CLI).

Also, the Unified CM Client Label as configured under the SAF Forwarder configuration page must match one of the external-client statements from the SAF Forwarder's CLI configuration. For example:

```
service-family ipv4 autonomous-system 1
!
topology base
  external-client sample_client_label
exit-sf-topology
```

```

exit-service-family
!

service-family external-client listen ipv4 5050
external-client sample_client_label
username sample_user_name
password sample_user_password
keepalive 10000
!

```

For more details, refer to the *Cisco IOS Service Advertisement Framework Configuration Guide*, available at

http://www.cisco.com/en/US/docs/ios/saf/configuration/guide/15_0/saf_15_0_book.html

Requesting Service

The SAF CCD learned DN ranges are populated in a dedicated CCD call routing partition in the requesting cluster. Learned DN ranges are associated with one or more CCD trunks. Calls made to CCD learned DN ranges are placed through CCD trunks associated with the requesting service. The association of CCD trunks with the requesting service is done through the Selected SAF Trunks filed under the CCD Requesting Service Info page in Unified CM, located under **Call Routing > Call Control Discovery > Requesting Service**.

The CCD records exchanged between a cluster and a SAF Forwarder include information about the DN range, the IP address of the call agent node hosting the DN range, the digit manipulation rules to adapt a DN when rerouting the call to the PSTN, and the IP signaling protocol required to call this DN range.

For example, Cluster A hosts DN range 8555XXXX, whose corresponding DID range on the PSTN is +141555XXXX. The IP address of the Cluster A subscriber associated with the CCD trunk designated to receive IP calls for this DN range is 10.1.1.1. The protocol required to reach this DN range is SIP. The CCD record associated with this DN range can be represented as follows:

| DN Range | ToDID | IP | Protocol |
|----------|---------|----------|----------|
| 8555XXXX | 1:+1415 | 10.1.1.1 | SIP |

- DN range

If a user dials 85551234, a match would be made on 8555XXXX and a call to 85551234 would be extended to the cluster that advertised the pattern.

- ToDID

This field represents the rules allowing the DN range to be reached across the PSTN. If a user dials 85551234 and the call cannot be routed through a CCD trunk, the ToDID rules are applied and the destination number is transformed to a form compatible to the PSTN. For example, the rule 1:+1415 applied to the range 8555XXXX would require the removal of one digit and the prefixing of +1415. The resulting +1415551234 would allow routing of the call to any gateway in the cluster of origin, provided that it is provisioned to route calls in the +E.164 form and that gateways are provisioned with appropriate called party transformation patterns to adapt the globalized +E.164 form of the number to a localized form acceptable to the PSTN carrier.

- IP

The IP address of the destination DN's hosting call agent node is used when placing a call across the associated CCD trunk, in the cluster of origin.

- Protocol

In this case, SIP is the protocol advertised by the call agent hosting the DN range. The other possible choice is H.323.

To view which SAF CCD records were discovered by a particular cluster, use the Cisco Unified CM Real-Time Monitoring Tool (RTMT). It offers information about the discovered DN ranges as well as information about the SAF Forwarder associations with the cluster.

Dial Plan Considerations for Business Edition 3000

Cisco Business Edition 3000 comes with a highly simplified front end with a drawer user interface (GUI). New concepts such as Site and Usage profiles have been introduced. Although the underlying concept of dial plan still remains the same with the line/device approach and calling search spaces, Business Edition 3000 implements the dial plan by using the concepts of sites and profiles. The calling privileges at the device level are defined by the Site, and restrictions to the calling privileges at line level are defined by the Usage profile, as follows:

- Site

Sites represent the geographic grouping of endpoints, including phones, users, gateways, and so forth. Privileges are given to a Site, which define the highest level of calling privileges each user at that site can achieve. This does not mean that every user will have those privileges; instead, the privileges govern the capability of each location to make calls. For example, a location can have calling privileges to dial international numbers, but that does not necessarily mean that every user at the site can make international calls.

- Usage profile

A usage profile allows the system administrator to configure most of the user settings for a phone in one place. The administrator can edit an existing usage profile, duplicate an existing usage profile to create a new profile, or add an entirely new usage profile. Each usage profile has a unique name. After configuring usage profiles, the system administrator can assign them to users or to departments, so that the settings in the usage profile apply to the phones that belong to an individual user or to an entire department.

In the Usage profile, you can configure calling privileges for users; phone features such as barge, Cisco Extension Mobility, and so on; phone hardware functionality; phone applications that may display on the phone; and the phone button template, which controls the order of the buttons and the feature buttons that display on the phone.

Note

Cisco Business Edition 3000 supports a maximum of 10 usage profiles.

The combination of Site privileges and Usage calling privileges define the actual capability for a user to dial numbers. For example, a Site can be allocated privileges to dial international calls as the highest level of calling, which essentially means that users can dial any number including international, long distance, and local calls. But if a user is attached to a usage profile that limits the dialing privilege to local calls only, then that user will be able to dial only local calls even though the site has privileges to dial international calls.

As another example, assume that the user is associated to a Usage profile and a Site that both have calling privileges to dial international calls. If this user moves to another site where the Site level privileges are limited to dialing local calls only, then this user will not be able to dial beyond local calls because the current site level calling privileges do not allow it.

Essentially, the lower of the Site level calling privileges and the Usage profile calling privileges determines the calling privileges for a user.

Translation Rules

Translation rules allow Cisco Business Edition 3000 to manipulate an incoming phone number that is part of your system and transform it to an extension before routing the call. Any call coming into the system or generated by IP phones is matched against the configured translation rule, and if the number matches, the translation is performed.

**Note**

Support for wild cards in translation rules is not available with Business Edition 3000.

Logical Partitioning

Every phone is associated to a site based upon the IP address configured on the phone. Every site is mapped to one or more subnet(s). If the phone IP address lies within one of those subnets, then the phone belongs to the site to which that subnet is mapped. If the phone acquires an IP address that is not defined in the system, then phone is assumed to be part of the central site. However, if a teleworker site is configured, then any phone whose configured IP address does not lie within one of the configured subnets will be assumed to be a teleworker phone.

The configured sites provide support for logical partitioning. While configuring sites, the administrator is required to configure the PSTN privileges. If access to the central site PSTN is not configured, the users at a remote site will not be allowed to be part of any conversation where a PSTN call leg is involved. Also, the remote site phones will not be able to initiate PSTN calls.

CHAPTER 10

Emergency Services

Revised: March 31, 2011; OL-21733-18

Emergency services are of great importance in the proper deployment of a voice system. This chapter presents a summary of the following major design considerations essential to planning for emergency calls:

- [911 Emergency Services Architecture, page 10-2](#)
- [Cisco Emergency Responder, page 10-7](#)
- [High Availability for Emergency Services, page 10-9](#)
- [Capacity Planning for Cisco ER Clustering, page 10-9](#)
- [Design Considerations for 911 Emergency Services, page 10-10](#)
- [Cisco Emergency Responder Deployment Models, page 10-17](#)
- [ALI Formats, page 10-22](#)

This chapter presents some information specific to the 911 emergency networks as deployed in Canada and the United States. Many of the concepts discussed here are adaptable to other locales. Please consult with your local telephony network provider for appropriate implementation of emergency call functionality.

In the United States, some states have already enacted legislation covering the 911 functionality required for users in a multi-line telephone system (MLTS). The National Emergency Number Association (NENA) has also produced the *NENA Technical Requirements Document on Model Legislation E9-1-1 for Multi-Line Telephone Systems*, available online at

<http://www.nena.org/>

The Federal Communications Commission (FCC) has also drafted a proposed new section to Title 47, Part 68, Section 319, which is available at

<http://www.apcointl.org/about/pbx/worddocs/mltspart68.doc>

This chapter assumes that you are familiar with the generic 911 functionality available to residential PSTN users in North America. For more information on the subject, refer to the NENA website at

<http://www.nena.org/>

What's New in This Chapter

Table 10-1 lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Table 10-1 *New or Changed Information Since the Previous Release of This Document*

| New or Revised Topic | Described in | Revision Date |
|---|---|----------------|
| Architectural components for 911 emergency services | 911 Emergency Services Architecture, page 10-2 | March 31, 2011 |
| Capacity planning for Cisco Emergency Responder | Capacity Planning for Cisco ER Clustering, page 10-9 | March 31, 2011 |
| High availability requirements for Cisco Emergency Responder | High Availability for Emergency Services, page 10-9 | March 31, 2011 |
| Requirements for deploying Cisco Emergency Responder across the WAN | WAN Deployment of Cisco Emergency Responder, page 10-22 | March 31, 2011 |

911 Emergency Services Architecture

This section highlights some of the functionality requirements for emergency calls in multi-line telephone systems (MLTS). In the context of this section, emergency calls are 911 calls serviced by the North American public switched telephone network (PSTN).

Any emergency services architecture usually consists of the following elements:

- A distressed caller should be able to dial the emergency services from a fixed line, a mobile phone, a public phone, or any device capable of making the voice call.
- An emergency services call handler must be available to respond to the emergency request and dispatch the needed services such as police, fire, and medical.
- The call handler should be able to identify the location of the distressed caller as precisely as possible to provide help.
- An emergency services network is needed to route the call to the nearest emergency services call handler with jurisdiction for the location of the caller.

The following sections explain some of the important architectural components of 911 emergency services architecture.

Public Safety Answering Point (PSAP)

The public safety answering point (PSAP) is the party responsible for answering the 911 call and arranging the appropriate emergency response, such as sending police, fire, or ambulance teams. The physical location of the phone making the 911 call is the primary factor in determining the appropriate PSAP for answering that call. Generally, each building is serviced by one local PSAP.

To determine the responsible PSAP for a given location, contact a local public safety information service such as the local fire marshal or police department. Also, the phone directory of the local exchange carrier usually lists the agency responsible for servicing 911 calls in a given area.

Typical Situation

- For a given street address, there is only one designated PSAP.
- For a given street address, all 911 calls are routed to the same PSAP.

Exceptional Situation

- The physical size of the campus puts some of the buildings in different PSAP jurisdictions.
- Some of the 911 calls need to be routed to an on-net location (campus security, building security).

Selective Router

The selective router is a node in the emergency services network that determines the appropriate PSAP for call delivery based on caller's geographic area and the automatic number identification (ANI). The Local Exchange Carrier (LEC) usually operates the selective router. Hence it is imperative to ensure that the enterprise IP telephony network is designed in such a way that the caller is routed to the appropriate selective router based on its location.

Automatic Location Identifier Database

Location information of the caller is an important part of the 911 services infrastructure. The Automatic Location Identifier (ALI) database maintains the location information for the particular geographical location served by the LEC. For every 911 call, the PSAP searches the ALI database to retrieve the caller's location based on the ANI of the calling number. The addresses are stored in the Master Street Address Guide (MSAG) format in the ALI database. The ALI database is maintained on behalf of the local emergency services administration by a contracted third party, generally the incumbent Local Exchange Carrier (LEC).

Private Switch ALI

Private Switch ALI (PS/ALI) is an enhancement to 911 emergency response systems that enables MLTS operators to provide more specific address and location information for each telephony endpoint. The service allows a customer-generated address table to be loaded into the ALI database so that each station of an MLTS system can be uniquely identified if a call is placed to 911 from that telephone number. The station-specific or location-specific automatic number identification (ANI) generated by the switching system can be passed directly to the E911 system to pinpoint the precise location of the caller. The PSAP operator can then direct emergency response personnel to the correct address, building, floor, room, or even cubicle, thereby streamlining operations and increasing accuracy.

911 Network Service Provider

After identifying the responsible PSAPs, you must also identify the 911 network service providers to which each PSAP is connected. It is commonly assumed that PSAPs receive 911 phone calls from the PSTN, but that is not the case. Instead, 911 calls are carried over dedicated, regionally significant networks, and each PSAP is connected to one or more such regional networks. In the majority of cases, the incumbent Local Exchange Carrier (LEC) is the 911 network service provider for a PSAP. Some exceptions include military installations, university campuses, federal or state parks, or other locations where the public safety responsibility falls outside the jurisdiction of the local authorities and/or where a private network is operated by an entity other than a public local exchange carrier.

If you are in doubt about the 911 network service provider for a given PSAP, contact the PSAP directly to verify the information.

Typical Situation

- For a given street address, the 911 network service provider is the incumbent Local Exchange Carrier (LEC). For a location served by Phone Company X, the corresponding PSAP is also served by Phone Company X.
- All 911 calls are routed directly to an off-net location, or all 911 calls are routed directly to an on-net location.

Exceptional Situation

- The local exchange carrier (LEC) through which the MLTS interfaces to the PSTN is *not* the same LEC that serves as 911 network service provider to the PSAP. (For example, the phone system is served by Phone Company X, but the PSAP is connected to Phone Company Y.) This situation might require either a special arrangement between the LECs or special, dedicated trunks between the phone system and the PSAP's 911 network service provider.
- Some LECs may not accept 911 calls on their networks. If this is the case, the only two options are to change LECs or to establish trunks (dedicated to 911 call routing) connected to a LEC that can route 911 calls to the appropriate PSAPs.
- Some (or all) of the 911 calls have to be routed to an on-net location such as campus security or building security. This situation can easily be accommodated during the design and implementation phases, but only if the destination of 911 calls for each phone has been properly planned and documented.

Interface Points into the Appropriate 911 Networks

For larger telephony systems, 911 connectivity might require many interface points. Typically, more than one E911 selective router is used within a LEC's territory, and these routers usually are *not* interconnected.

For example, an enterprise with a large campus could have the following situation:

- Building A located in San Francisco
- Building B located in San Jose
- San Francisco Police Department and San Jose Police Department are the appropriate PSAPs
- San Francisco Police Department and San Jose Police Department are served by the same 911 network service provider
- However, San Francisco Police Department and San Jose Police Department are served by different E911 selective routers operated by that same 911 network service provider!

This type of situation would require two separate interface points, one per E911 selective router. The information pertaining to the E911 selective router territories is generally kept by the incumbent LEC, and the local account representative for that LEC should be able to provide an enterprise customer with the pertinent information. Many LECs also provide the services of 911 subject matter experts who can consult with their own account representatives on the proper mapping of 911 access services.

Typical Situation

- For single-site deployments or campus deployments, there is usually only one PSAP for 911 calls.

- If access to only one PSAP is required, then only one interface point is required. Even if access to more than one PSAP is required, they might be reachable from the same E911 selective router, through the same centralized interface. If the enterprise's branch sites are linked via a WAN (centralized call processing), it is desirable to give each location its own local (that is, located inside each branch office) access to 911 to prevent 911 isolation during WAN failure conditions where Survivable Remote Site Telephony (SRST) operation is activated.

Exceptional Situation

- The physical size of the campus puts some of the buildings in different PSAP jurisdictions, *and*
- Some of the 911 calls have to be routed to different E911 selective routers, through different interface points.

Note

Some of the information required to establish the geographical territories of PSAPs and E911 selective routers is available online or from various competitive local exchange carrier (CLEC) information web sites. (For example, <https://clec.att.com/clec/hb/shell.cfm?section=782> provides some valuable data about the territory covered by AT&T in California and Nevada.) However, Cisco strongly recommends that you obtain proper confirmation of the appropriate interface points from the LEC prior to the design and implementation phases of 911 call routing.

Interface Type

In addition to providing voice communications, the interfaces used to present 911 calls to the network must also provide identification data about the calling party.

Automatic Number Identification (ANI) refers to the North American Numbering Plan number of the calling party, which is used by networks to route a 911 call to the proper destination. This number is also used by the PSAP to look up the Automatic Location Identification (ALI) associated with a call.

911 calls are source-routed, which means that they are routed according to the calling number. Even though different locations are all dialing the same number (911), they will reach different PSAPs based on their location of origin, which is represented by the ANI (calling number).

You can implement 911 call functionality with either of the following interface types:

- Dynamic ANI assignment
- Static ANI assignment

While dynamic ANI assignment scales better (because it supports multiple ANIs) and lends itself to all but the smallest of applications, static ANI assignment can be used in a wider variety of environments, from the smallest to the largest systems.

Dynamic ANI (Trunk Connection)

The dynamic aspect of ANI refers to the fact that a system has many phones sharing access to the 911 network across the same interface, and the ANI transmitted to the network might need to be different for each call.

There are two main types of dynamic ANI interfaces:

- Integrated Services Digital Network Primary Rate Interface (ISDN-PRI, or simply PRI)
- Centralized Automatic Message Accounting (CAMA).

PRI

This type of interface usually connects a telephony system to a PSTN Class 5 switch. The calling party number (CPN) is used at call setup time to identify the E.164 number of the calling party.

Most LECs treat the CPN differently when a call is made to 911. Depending upon the functionality available in the Class 5 switch and/or upon LEC or government policy, the CPN may not be used as the ANI for 911 call routing. Instead, the network may be programmed to use the listed directory number (LDN) or the bill-to number (BTN) for ANI purposes.

If the CPN is not used for ANI, then 911 calls coming from a PRI interface all look the same to the 911 network because they all have the same ANI, and they are all routed to the same destination (which might not be the appropriate one).

Some LECs offer a feature to provide CPN transparency through a PRI interface for 911 calls. With this feature, the CPN presented to the Class 5 switch at call setup is used as ANI to route the call. The feature name for this functionality varies, depending on the LEC. (For example, SBC calls it Inform 911 in California.)

Note

The CPN *must* be a routable North American Numbering Plan number, which means that the CPN must be entered in the routing database of the associated E911 selective router.

Note

For Direct Inward Dial (DID) phones, the DID number could be used as the ANI for 911 purposes, but only if it is properly associated with an Emergency Service Number in the 911 service provider's network. For non-DID phones, use another number. (See [Emergency Location Identification Number Mapping, page 10-11](#), for more information.)

Many Class 5 switches are connected to E911 selective routers through trunks that do not support more than one area code. In such cases, if PRI is used to carry 911 calls, then the only 911 calls that will be routed properly are those whose CPN (or ANI) have the same Numbering Plan Area (NPA) as the Class 5 switch.

Example

An MLTS is connected to a Class 5 switch in area code 514 (NPA = 514). If the MLTS were to send a 911 call on the PRI trunk, with a CPN of **450.555.1212**, the Class 5 switch would send the call to the E911 selective router with an ANI of **514.555.1212** (instead of the correct **450.555.1212**), yielding inappropriate routing and ALI lookup.

To use PRI properly as a 911 interface, the system planner must ensure that the CPN will be used for ANI and must properly identify the range of numbers (in the format NPA NXX TNTN) acceptable on the link. For example, if a PRI link is defined to accept ANI numbers within the range 514 XXX XXXX, then only calls that have a Calling Party Number with NPA = 514 will be routed appropriately.

CAMA

Centralized Automatic Message Accounting (CAMA) trunks also allow the MLTS to send calls to the 911 network, with the following differences from the PRI approach:

- CAMA trunks are connected directly into the E911 selective router. Extra mileage charges may apply to cover the distance between the E911 selective router and the MLTS gateway point.
- CAMA trunks support 911 calls only. The capital and operational expenses associated with the installation and operation of CAMA trunks support 911 traffic only.

- CAMA trunks for the MLTS market may be limited to a fixed area code, and the area code is typically implied (that is, not explicitly sent) in the link protocol. The connection assumes that all calls share the same deterministic area code, therefore only 7 or 8 digits are sent as ANI.

Static ANI (Line Connection)

Static ANI provides a line (rather than a trunk) connection to the PSTN, and the ANI of the line is associated with all 911 calls made on that line, regardless to the CPN of the calling phone. A plain old telephone service (POTS) line is used for this purpose.

POTS lines are one of the simplest and most widely supported PSTN interfaces. A POTS line usually comes fully configured to accept 911 calls. In addition, the existing E911 infrastructure supports 911 calls from POTS lines very well.

The POTS approach has the following attributes:

- The operational costs associated with a POTS line are low.
- The POTS line can even serve as a backup line in case of power failure.
- The POTS line number can be used as the callback number entered into the ALI database.
- POTS lines represent the lowest cost 911 support for locations where user density does not justify local PRI or CAMA access into the PSTN.
- POTS lines are ubiquitous in PSTN installations.

All outgoing 911 calls through this type of interface are treated the same by the E911 network, and the tools that enable Cisco Unified Communications Manager to control the ANI presented to the E911 network (such as calling party transformation masks) are irrelevant because the ANI can be only the POTS line's number.

Cisco Emergency Responder

Ease of administration for moves, adds, and changes is one of the key advantages of IP telephony technology. To provide for moves, adds, and changes that automatically update 911 information without user intervention, Cisco has developed a product called the Cisco Emergency Responder (Cisco ER).

Cisco ER provides the following primary functionality:

- Dynamic association of a phone to an Emergency Response Location (ERL), based on the detected physical location of the phone.
- Dynamic association of the Emergency Location Identification Number (ELIN) to the calling phone, for callback purposes. In contrast to non-ER scenarios outlined in preceding sections, Cisco ER enables the callback to ring the exact phone that initiated the 911 call.
- On-site notification to designated parties (by pager, web page, or phone call) to inform them that there is an emergency call in progress. The pager and web page notifications include the calling party name and number, the ERL, and the date and time details associated with the call. Phone notification provides the information about the calling number from which the emergency call was placed.

For more information on ERLs and ELINs, see [Emergency Response Location Mapping, page 10-10](#), and [Emergency Location Identification Number Mapping, page 10-11](#). For more information on Cisco ER, see [Cisco Emergency Responder Design Considerations, page 10-15](#), and refer to the Cisco ER product documentation available online at

http://www.cisco.com/en/US/products/sw/voicesw/ps842/tsd_products_support_series_home.html

The key functionality of Cisco ER relies on the detection of the phone's location by discovery of the network port (Layer 2 port, such as a Fast Ethernet switched port) from which the phone made the 911 call. The discovery mechanism relies on two main assumptions:

- The wired infrastructure of the enterprise is well established and does not change sporadically.
- The infrastructure is available for Cisco ER to browse; that is, Cisco ER can establish Simple Network Management Protocol (SNMP) sessions to the underlying network infrastructure and can scan the network ports for the discovery of connected phones.

Once Cisco ER discovers the originating port for the call, it associates the call with the pre-established ERL for the location of that port. This process also yields an association with a pre-established ELIN for the location and the selection of the appropriate egress point to the E911 infrastructure, based on the originating ERL.

Cisco ER also provides the capability to configure ERLs for IP subnets and to assign IP phone location by IP address. This capability may be used to locate wireless IP phones, IP softphones, and third-party SIP phones registered to Cisco Unified CM, which Cisco ER cannot locate by connected switch port. It may also be used instead of, or in addition to, connected switch port locations for wired Cisco IP phones. If both connected switch port and IP subnet locations are available for an IP phone, Cisco ER will prefer the connected switch port location because it is usually more specific than the IP subnet location. Using both connected switch port and IP subnet locations is a best practice because it provides assurance that an appropriate ERL will be assigned, even in case of any delay or error in detecting the connected switch port.

Cisco ER allows for the use of two or more ELINs per ERL. The purpose of this enhancement is to cover the specific case of more than one 911 call originating from a given ERL within the same general time period, as illustrated by the following examples.

Example 1

- Phone A and phone B are both located within ERL X, and ERL X is associated with ELIN X.
- Phone A makes a 911 call at 13:00 hours. ELIN X is used to route the call to PSAP X, and PSAP X answers and releases the call. Then, at 13:15 hours, phone B makes a 911 call. ELIN X is again used to route the call to PSAP X.
- PSAP X, after releasing the call from phone B, decides to call back phone A for further details pertaining to phone A's original call. The PSAP dials ELIN X, and gets phone B (instead of the desired phone A).

To work around this situation, Cisco ER allows you to define a pool of ELINs for each ERL. This pool provides for the use, in a round-robin fashion, of a distinct ELIN for each successive call. With the definition of two ELINs for ERL X in our example, we now have the situation described in Example 2.

Example 2

- Phone A and phone B are both located within ERL X. ERL X is associated with both ELIN X1 and ELIN X2.
- Phone A makes a 911 call at 13:00 hours. ELIN X1 is used to route the call to PSAP X, and PSAP X answers and releases the call. Then, at 13:15 hours, phone B makes a 911 call, and ELIN X2 is used to route this call to PSAP X.
- PSAP X, after releasing the call from phone B, decides to call back phone A for further details pertaining to phone A's original call. The PSAP dials ELIN X1 and gets phone A.

Of course, if a third 911 call were made but there were only two ELINs for the ERL, the situation would allow for callback functionality to properly reach only the last two callers in the sequence.

High Availability for Emergency Services

It is very important for emergency services to always be available to the user even under the most critical of conditions. Therefore, high availability planning must be done carefully when deploying emergency services in an enterprise.

Cisco Emergency Responder supports clustering with a maximum of two servers in active/standby mode. The data is synchronized between the primary and the secondary Cisco ER servers. To ensure that calls are routed to the secondary server if the primary server is unavailable, the system administrator must follow certain provisioning guidelines for configuring CTI route points and the DNs associated to those CTI route points in Cisco Unified CM. For more details on configuration, refer to the *Cisco Emergency Responder Administration Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps842/prod_maintenance_guides_list.html

If both of the Cisco ER servers are unavailable, a local route group (LRG) may be used to route the call to the appropriate PSAP with an appropriate ELIN/ERL (which might be less specific than what Cisco ER could have provided). Alternatively, the call may be routed to an internal security office to determine the caller's location. In either case, this provisioning must be done in Cisco Unified CM.

Apart from Cisco ER redundancy, Cisco Unified CM redundancy and gateway/trunk redundancy should also be considered where possible to route the 911 emergency calls and to avoid any single point of failure.

Capacity Planning for Cisco ER Clustering

In a Cisco ER cluster, the quantity of phones roaming outside the tracking domain of their home Cisco ER group is a scalability factor that you must keep within the limits set forth in the section on *Network Hardware and Software Requirements* in the *Cisco Emergency Responder Administration Guide*, available at:

http://www.cisco.com/en/US/products/sw/voicesw/ps842/prod_maintenance_guides_list.html

With the Cisco MCS 7845 server platform, a Cisco ER cluster can support a maximum of 3000 roaming phones. For deployments that have to exceed this limit (for instance, large campus deployments with multiple Unified CM clusters), phone movement can be tracked by IP subnets. By defining the IP subnets in each of the Cisco ER groups and by assigning each ERL with one ELIN per Cisco ER group, you can virtually eliminate roaming phones because all phones in the campus will be part of the tracking domain of their respective Cisco ER group.

To ensure proper sizing, use the Cisco Unified Communications Sizing Tool (Unified CST). This tool is available only to Cisco partners and employees, with appropriate login required, at <http://tools.cisco.com/cucst>. If you do not have access to this sizing tool, work with your Cisco account team or partner integrator to size your system appropriately.

Design Considerations for 911 Emergency Services

When planning 911 emergency services for a multi-line telephone system (MLTS) deployment, first establish all of the physical locations where phone services are needed. The locations can be classified as follows:

- Single building deployments, where all users are located in the same building
- Single campus deployments, where the users are located in a group of buildings situated in close proximity
- Multisite deployments, where users are distributed over a wide geographical area and linked to the telephony call processing site through WAN connectivity

The locations, or type of deployment, affect the criteria used to design and implement 911 services. The following sections describe the key criteria, along with typical and exceptional situations for each. When analyzing and applying these criteria, consider how they are affected by the phone locations in your network.

Emergency Response Location Mapping

The National Emergency Number Association (NENA) has proposed model legislation to be used by state and federal agencies in enacting the rules that govern 911 in enterprise telephony systems. One of the concepts in the NENA proposal is that of the emergency response location (ERL), which is defined as:

A location to which a 911 emergency response team may be dispatched. The location should be specific enough to provide a reasonable opportunity for the emergency response team to quickly locate a caller anywhere within it.

Rather than having to identify each phone's location individually, the requirement allows for the grouping of phones into a "zone," the ERL. The maximum size of the ERL may vary, depending upon local implementation of the legislation, but we will use 7000 square feet (sq ft) as a basis for discussion in this section. (The concepts discussed here are independent of the maximum ERL size that may be allowed in any given state or region.)

An emergency location identification number (ELIN) is associated with each ERL. The ELIN is a fully qualified E.164 number, used to route the call within the E911 network. The ELIN is sent to the E911 network for any 911 call originating from the associated ERL. This process allows more than one phone to be associated with the same fully qualified E.164 number for 911 purposes, and it can be applied to DID and non-DID phones alike.

**Note**

This document does not attempt to present the actual requirements of any legislation. Rather, the information and examples presented here are for the purposes of discussion only. The system planner is responsible for verifying the applicable local requirements.

For example, assume a building has a surface area of 70,000 sq ft and 100 phones. In planning for 911 functionality, the building can be divided into 10 zones (ERLs) of 7000 sq ft each, and each phone can be associated with the ERL where it is located. When a 911 call is made, the ERL (which could be the same for multiple phones) is identified by sending the associated ELIN to the PSAP. If the phones were evenly distributed in this example, each group of 10 phones would have the same ERL and, therefore, the same ELIN.

The various legislations define a minimum number of phones (for example, 49) and a minimum surface area (for example, 40,000 sq ft) below which the requirements for MLTS 911 are not applicable. But even if the legislation does not require 911 functionality for a given enterprise, it is always best practice to provision for it.

Emergency Location Identification Number Mapping

In general, you must associate a single fully qualified E.164 number, known as the emergency location identification number (ELIN), with each ERL. (However, if using Cisco Emergency Responder, you can configure more than one ELIN per ERL.) The ELIN is used to route the call across the E911 infrastructure and is used by the PSAP as the index into the ALI database.

ELINs must meet the following requirements:

- They must be routable across the E911 infrastructure. (See the examples in the section on [Interface Type, page 10-5](#).) If an ELIN is not routable, 911 calls from the associated ERL will, at best, be handled according to the default routing programmed in the E911 selective router.
- Once the ERL-to-ELIN mapping of an enterprise is defined, the corresponding ALI records must be established with the LEC so that the ANI and ALI database records serving the PSAP can be updated accurately.

The ELIN mapping process can be one of the following, depending on the type of interface to the E911 infrastructure for a given ERL:

- Dynamic ANI interface

With this type of interface, the calling party number identification passed to the network is controlled by the MLTS. The telephony routing table of the MLTS is responsible for associating the correct ELIN with the call, based on the calling phone's ERL. Within Cisco Unified Communications Manager, the calling party number can be modified by using transformation masks for calls made to 911. For example, all phones located in a given ERL can share the same calling search space that lists a partition containing a translation pattern (911) and a calling party transformation mask that would replace the phone's CPN with the ELIN for that location.

- Static ANI interface

With this type of interface, the calling party number identification passed to the network is controlled by the PSTN. This is the case if the interface is a POTS line. The ELIN is the phone number of the POTS line, and no further manipulation of the phone's calling party identification number is possible.

PSAP Callback

The PSAP might have to reach the caller after completion of the initial conversation. The PSAP's ability to call back relies on the information that it receives with the original incoming call.

The delivery of this information to the PSAP is a two-part process:

1. The Automatic Number Identification (ANI) is first sent to the PSAP. The ANI is the E.164 number used to route the call. In our context, the ANI received at the PSAP is the ELIN that the MLTS sent.
2. The PSAP then uses the ANI to query a database and retrieve the Automatic Location Identification (ALI). The ALI provides the PSAP attendant with information such as:
 - Caller's name
 - Address
 - Applicable public safety agency

- Other optional information, which could include callback information. For example, the phone number of the enterprise's security service could be listed, to aid in the coordination of rescue efforts.

Typical Situation

- The ANI information is used for PSAP callback, which assumes that the ELINs are dialable numbers.
- The ELINs are PSTN numbers associated with the MLTS. If someone calls the ELIN from the PSTN, the call will terminate on an interface controlled by the MLTS.
- It is the responsibility of the MLTS system administrator to program the call routing so that calls made to any ELIN in the system will ring a phone (or multiple phones) in the immediate vicinity of the associated ERL.
- Once the ERL-to-ELIN mapping is established, it needs to be modified only when there are changes to the physical situation of the enterprise. If phones are simply added, moved, or deleted from the system, the ERL-to-ELIN mapping and its associated ANI/ALI database records need not be changed.

Exceptional Situation

- Callback to the immediate vicinity of the originating ERL may be combined with (or even superseded by) routing the callback to an on-site emergency desk, which will assist the PSAP in reaching the original caller and/or provide additional assistance with the emergency situation at hand.
- The situation of the enterprise could change, for example, due to area code splits, city or county service changes requiring a new distribution of the public safety responsibilities, new buildings being added, or any other change that would affect the desired routing of a call for 911 purposes. Any of these events could require changes in the ERL-to-ELIN mapping and the ANI/ALI database records for the enterprise.

Dial Plan Considerations

It is highly desirable to configure a dial plan so that the system easily recognizes emergency calls, whether an access code (for example, 9) is used or not. The emergency string for North America is generally 911. Cisco strongly recommends that you configure the system to recognize both the strings 911 and 9911.

Cisco also strongly recommends that you explicitly mark the emergency route patterns with Urgent Priority so that Unified CM does *not* wait for the inter-digit timeout (Timer T.302) before routing the call.

Other emergency call strings may be supported concurrently on your system. Cisco highly recommends that you provide your telephony system users with training on the selected emergency call strings.

Also, it is highly desirable that users be trained to react appropriately if they dial the emergency string by mistake. In North America, 911 may be dialed in error by users trying to access a long distance number through the use of 9 as an access code. In such a case, the user should remain on the line to confirm that there is no emergency, and therefore no need to dispatch emergency personnel. Cisco ER's on-site notification capabilities can help in identifying the phone at the origin of such spurious 911 calls by providing detailed accounts of all calls made to 911, including calls made by mistake.

In a multisite deployment, the dial plan configuration should ensure that the emergency calls are always routed through the PSTN gateway local to the site, thereby making sure that the emergency call is routed to the nearest PSAP within the jurisdiction. One of the mechanism to achieve this could be to use the Local Route Group feature of Cisco Unified CM.

Also, in a multisite deployment it is very important to make sure that the emergency number is always reachable and routed through the local PSTN gateway for the mobility users (extension mobility and device mobility) independent of the implemented Class of Service (CoS). If the site/device approach is being used, the device calling search space (CSS) could be used to route the emergency calls.

Cisco recommends enabling Calling Party Modification on Cisco Emergency Responder. When this feature is enabled, the calling party number is replaced with the ELIN by Cisco ER for the emergency call. If Calling Party Modification is not enabled, either the DID will be sent to the PSAP or Cisco Unified CM must be configured to replace the calling party with the ELIN.

**Note**

Except for manually configured phones, E.164 numbers are supported with Cisco Emergency Responder. For manually configured phones, Cisco recommends configuring the phones on Cisco Unified CM with the E.164 numbers without the leading "+".

Gateway Considerations

Consider the following factors when selecting the gateways to handle emergency calls for your system:

- [Gateway Placement, page 10-13](#)
- [Gateway Blocking, page 10-14](#)
- [Answer Supervision, page 10-14](#)
- [Answer Supervision, page 10-14](#)

Gateway Placement

Within the local exchange carrier (LEC) networks, 911 calls are routed over a locally significant infrastructure based on the origin of the call. The serving Class 5 switches are connected either directly to the relevant PSAP for their location or to an E911 selective router, which itself is connected to a group of PSAPs significant for its region.

With Cisco's IP-based enterprise telephony architecture, it is possible to route calls on-net to gateways that are remotely situated. As an example, a phone located in San Francisco could have its calls carried over an IP network to a gateway situated in San Jose, and then sent to the LEC's network.

For 911 calls, it is critical to choose the egress point to the LEC network so that emergency calls are routed to the appropriate local PSAP. In the example above, a 911 call from the San Francisco phone, if routed to a San Jose gateway, could not reach the San Francisco PSAP because the San Jose LEC switch receiving the call does not have a link to the E911 selective router serving the San Francisco PSAP. Furthermore, the San Jose area 911 infrastructure would not be able to route the call based on a San Francisco calling party number.

As a rule of thumb, route 911 calls to a gateway physically co-located with the originating phone. Contact the LEC to explore the possibility of using a common gateway to aggregate the 911 calls from multiple locations. Be aware that, even if the 911 network in a given region lends itself to using a centralized gateway for 911 calls, it might be preferable to rely on gateways co-located with the calling phones to prevent 911 call routing from being impacted during WAN failures.

Gateway Blocking

It is highly desirable to protect 911 calls from "all trunks busy" situations. If a 911 call needs to be connected, it should be allowed to proceed even if other types of calls are blocked due to lack of trunking resources. To provide for such situations, you can dedicate an explicit trunk group just for 911 calls.

It is acceptable to route emergency calls exclusively to an emergency trunk group. Another approach is to send emergency calls to the same trunk group as the regular PSTN calls (if the interface permits it), with an alternative path to a dedicated emergency trunk group. This latter approach allows for the most flexibility.

As an example, we can point emergency calls to a PRI trunk group, with an alternate path (reserved exclusively for emergency calls) to POTS lines for overflow conditions. If we put 2 POTS lines in the alternate trunk group, we are guarantying that a minimum of two simultaneous 911 calls can be routed in addition to any calls that were allowed in the main trunk group.

If the preferred gateway becomes unavailable, it may be acceptable to overflow emergency calls to an alternate number so that an alternate gateway is used. For example, in North America calls dialed as 911 could overflow to an E.164 (non-911) local emergency number. This approach does not take advantage of the North American 911 network infrastructure (that is, there is no selective routing, ANI, or ALI services), and it should be used only if it is acceptable to the applicable public safety authorities and only as a last resort to avoid blocking the emergency call due to a lack of network resources.

Answer Supervision

Under normal conditions, calls made to an emergency number should return answer supervision upon connection to the PSAP. The answer supervision may, as with any other call, trigger the full-duplex audio connection between the on-net caller and the egress interface to the LEC's network.

With some North American LECs, answer supervision might not be returned when a "free" call is placed. This may be the case for some toll-free numbers (for example, 800 numbers). In exceptional situations, because emergency calls are considered "free" calls, answer supervision might not be returned upon connection to the PSAP. You can detect this situation simply by making a 911 test call. Upon connection to the PSAP, if audio is present, the call timer should record the duration of the ongoing call; if the call timer is absent, it is very likely that answer supervision was not returned. If answer supervision is not returned, Cisco highly recommends that you contact the LEC and report this situation because it is most likely not the desired functionality.

If this situation cannot be rectified by the Local Exchange Carrier, it would be advisable to configure the egress gateway *not* to require answer supervision when calls are placed to the LEC's network, and to cut through the audio in both directions so that progress indicator tones, intercept messages, and communications with the PSAP are possible even if answer supervision is not returned.

By default, Cisco IOS-based H.323 gateways must receive answer supervision in order to connect audio in both directions. To forego the need for answer supervision on these gateways, use the following commands:

- **progress_ind alert enable 8**

This command provides the equivalent of receiving a progress indicator value of 8 (in-band information now available) when alerting is received. This command allows the POTS side of the gateway to connect audio toward the origin of the call.

- **voice rtp send-recv**

This command allows audio cut-through in both the backward and forward directions before a Connect message is received from the destination switch. This command affects all Voice over IP (VoIP) calls when it is enabled.

Be advised that, in situations where answer supervision is not provided, the call detail records (CDRs) will not accurately reflect the connect time or duration of 911 calls. This inaccuracy can impede the ability of a call reporting system to document the relevant statistics properly for 911 calls.

In all cases, Cisco highly recommends that you test 911 call functionality from all call paths and verify that answer supervision is returned upon connection to the PSAP.

Cisco Emergency Responder Design Considerations

Device mobility brings about special design considerations for emergency calls. Cisco Emergency Responder (Cisco ER) can be used to track device mobility and to adapt the system's routing of emergency calls based on a device's dynamic physical location.

Device Mobility Across Call Admission Control Locations

In a centralized call processing deployment, Cisco ER can detect IP phone relocation and reassign relocated IP phones to appropriate ERLs automatically. However, Cisco Unified CM location-based call admission control for a relocated phone might not properly account for the WAN bandwidth usage of the phone in the new location, yielding possible over-subscription or under-subscription of WAN bandwidth resources. For example, if you physically move a phone from Branch A to Branch B, the phone's call admission control location remains the same (Location_A), and it is possible that calls made to 911 from that phone would be blocked due to call admission control denial if all available bandwidth to Location_A is in use for other calls. To avoid such blocking of calls, manual intervention might be required to adapt the device's location and region parameters.

Cisco Unified CM device mobility provides a way to update the phone's configuration automatically (including its calling search space and location information) in Unified CM to reflect its new physical location. If device mobility is not used, manual configuration changes may be necessary in Cisco Unified CM.

Default Emergency Response Location

If Cisco ER cannot directly determine the physical location of a phone, it assigns a default emergency response location (ERL) to the call. The default ERL points all such calls to a specific PSAP. Although there is no universal recommendation as to where calls should be sent when this situation occurs, it is usually desirable to choose a PSAP that is centrally located and that offers the largest public safety jurisdiction. It is also advisable to populate the ALI records of the default ERL's emergency location identification numbers (ELINs) with contact information for the enterprise's emergency numbers and to offer information about the uncertainty of the caller's location. In addition, it is advisable to mark those ALI records with a note that a default routing of the emergency call has occurred. Alternatively, the call may be routed to an internal security office to determine the caller's location.

Cisco Emergency Responder and Extension Mobility

Cisco ER supports Extension Mobility within a Cisco Unified CM cluster. It can also support Extension Mobility Cross-Cluster (EMCC), provided that both Cisco Unified CM clusters are supported either by a common Cisco ER server or group, or by two Cisco ER servers or groups configured as a Cisco ER cluster. In either case, the Cisco Unified CM clusters must not be configured to use the Adjunct Calling Search Space (CSS) associated with EMCC for 911 calls, but must be configured to use Cisco ER for all 911 calls in both Cisco Unified CM clusters.

Soft Clients

In cases where soft clients such as Cisco IP Communicator are used within the enterprise, Cisco ER can provide device mobility support. However, if the soft client is used outside the boundaries of the enterprise (for example, VPN access from a home office or hotel), Cisco ER will not be able to determine the location of the caller. Furthermore, it is unlikely that the Cisco system would have a gateway properly situated to allow sending the call to the appropriate PSAP for the caller's location.

It is a matter of enterprise policy to allow or not to allow the use of soft clients for 911 calls. It may be advisable to disallow 911 calls by policy for soft clients that can roam across the internet. Nevertheless, if such a user were to call 911, the best-effort system response would be to route the call to either an on-site security force or a large PSAP close to the system's main site.

The following paragraph is an example notice that you could issue to users to warn them that emergency call functionality is not guaranteed to soft client users:

Emergency calls should be placed from phones that are located at the site for which they are configured (for example, your office). A local safety authority might not answer an emergency call placed from a phone that has been removed from its configured site. If you must use this phone for emergency calls while away from your configured site, be prepared to provide the answering public safety authority with specific information regarding your location. Use a phone that is locally configured to the site (for example, your hotel phone or your home phone) for emergency calls when traveling or telecommuting.

Cisco ER also supports integration with Intrado V9-1-1, an emergency call delivery service that can reach almost any PSAP in the United States. With the combination of Cisco ER and Intrado V9-1-1, users of IP phones and softphones outside the enterprise can provide and update their locations through a web page provided by Cisco ER. Emergency calls from an off-premises location will then be delivered by Intrado to the appropriate PSAP for the caller's location.

Test Calls

For any enterprise telephony system, it is a good idea to test 911 call functionality, not only after the initial installation, but regularly, as a preventive measure.

The following suggestions can help you carry out the testing:

- Contact the PSAP to ask for permission before doing any tests, and provide them with the contact information of the individuals making the tests.
- During each call, indicate that it is *not* an actual emergency, just a test.
- Confirm the ANI and ALI that the call taker has on their screen.
- Confirm the PSAP to which the call was routed.
- Confirm that answer supervision was received by looking at the call duration timer on the IP phone. An active call timer is an indication that answer supervision is working properly.

PSAP Callback to Shared Directory Numbers

Cisco ER handles the routing of inbound calls made to emergency location identification numbers (ELINs). In cases where the line from which a 911 call was made is a shared directory number, the PSAP callback will cause all shared directory number appearances to ring. Any of the shared appearances can then answer the call, which means that it may not be the phone from which the 911 call originated.

Cisco Emergency Responder Deployment Models

Enterprise telephony systems based on multiple Unified CM clusters can benefit from the functionality of Cisco Emergency Responder (Cisco ER).

The *Cisco Emergency Responder Administration Guide* provides detailed descriptions of the terms used herein, as well as the background information required to support the following discussion. Of specific interest is the chapter on *Planning for Cisco Emergency Responder*. This documentation is available at

http://www.cisco.com/en/US/products/sw/voicesw/ps842/prod_maintenance_guides_list.html

**Note**

Cisco Emergency Responder does not support Cisco Unified Communication Manager Express (Unified CME) or Survivable Remote Mode Telephony (SRST). In case of SRST deployment, configure the appropriate dial-peer to route the 911 calls to the PSTN with the Site Published Number.

Single Cisco ER Group

A single Emergency Responder group can be deployed to handle emergency calls from two or more Unified CM clusters. The design goal is to ensure that any phone's emergency call is routed to the Cisco ER group, which will assign an ELIN and route the call to the appropriate gateway based on the phone's location.

One advantage of using a single Cisco ER group is that all ERLs and ELINs are configured into a single system. A phone registered on any cluster will be located by the single Cisco ER group because that group is responsible for polling all of the system's access switches. [Figure 10-1](#) illustrates a single Cisco ER group interfaced with two Unified CM clusters.

Figure 10-1 A Single Cisco ER Group Connected to Two Unified CM Clusters

132073

The single Cisco ER group in [Figure 10-1](#) interfaces with the following components:

- Each Unified CM cluster via SNMP, to collect information about their respective configured phones
- All of the enterprise's switches via SNMP, so that any cluster's phone, connected to any switch, can be located. This connection is not required if the phone locations are being identified based on IP subnets. For details on configuring IP subnet-based ERLs, refer to the chapter on Configuring Cisco Emergency Responder in the *Cisco Emergency Responder Administration Guide*, available at http://www.cisco.com/en/US/products/sw/voicesw/ps842/prod_maintenance_guides_list.html
- Each Unified CM cluster via JTAPI, to allow for the call processing required by any phone that dials 911 – for example, identification of the calling phone's ERL, assignment of the ELIN, redirection of the call to the proper gateway (based on the calling phone's location), and the handling of the PSAP callback functionality

The version of the JTAPI interface used by Cisco Emergency Responder is determined by the version of the Unified CM software to which it is connected. At system initialization, Cisco ER interrogates the Unified CM cluster and loads the appropriate JTAPI Telephony Service Provider (TSP). Because there can be only one version of JTAPI TSP on the Cisco ER server, all Unified CM clusters to which a single Cisco ER group is interfaced *must* run the same version of Unified CM software.

For some deployments, this software version requirement might present some difficulties. For instance, during a Unified CM upgrade, different clusters will be running different versions of software, and some of the clusters will be running a version of JTAPI that is not compatible with the version running on the Cisco ER servers. When this situation occurs, emergency calls from the cluster running a version of JTAPI different than that of the Cisco ER group might receive the call treatment provided by the Call Forward Busy settings of the emergency number's CTI Route Point.

When considering if a single Cisco ER group is appropriate for multiple Unified CM clusters, apply the following guidelines:

- Make Unified CM upgrades during an acceptable maintenance window when emergency call volumes are as low as possible (for example, after hours, when system use is at a minimum).
- Use a single Cisco ER group only if the quantity and size of the clusters allow for minimizing the amount of time when dissimilar versions of JTAPI are in use during software upgrades.

For example, a deployment with one large eight-server cluster in parallel with a small two-server cluster could be considered for use with a single Cisco ER group. In this case, it would be best to upgrade the large cluster first, thus minimizing the number of users (those served by the small cluster) that might be without Cisco ER service during the maintenance window of the upgrade. Furthermore, the small cluster's users can more appropriately be served by the temporary static routing of emergency calls in effect while Cisco ER is not reachable because they can be identified by the single ERL/ELIN assigned to all non-ER calls made during that time.

Multiple Cisco ER Groups

Multiple Cisco ER groups can also be deployed to support multi-cluster systems. In this case, each ER group interfaces with the following components:

- A Unified CM cluster via the following methods:
 - SNMP, to collect information about its configured phones
 - JTAPI, to allow for the call processing associated with redirection of the call to the proper gateway or, in the case of roaming phones, the proper Unified CM cluster
- The access switches (via SNMP) to which most of the phones associated with the Unified CM of the Cisco ER group are most likely to be connected

This approach allows Unified CM clusters to run different versions of software because each is interfaced to a separate Cisco ER group.

To allow phones to roam between various parts of the network and still be tracked by Cisco ER, you might have to configure the Cisco ER groups into a Cisco ER cluster. For details on Cisco ER clusters and groups, refer to the chapter on *Planning for Cisco Emergency Responder* in the *Cisco Emergency Responder Administration Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps842/prod_maintenance_guides_list.html

Figure 10-2 presents a sample topology illustrating some of the basic concepts behind Cisco ER clustering.

Figure 10-2 Multiple Cisco ER Groups

132074

Figure 10-2 illustrates the following topology:

- Cisco ER group A is interfaced to Unified CM cluster A to access switches A1 and A2, and it is deemed to be the home Cisco ER group of all phones registered to Unified CM cluster A.
- Likewise, Cisco ER group B is interfaced to Unified CM cluster B to access switches B1 and B2, and it is deemed to be the home Cisco ER group of all phones registered to Unified CM cluster B.

**Note**

Emergency Responder requires all ER groups in an ER cluster to run the same version of software.

Phone Movements Within the Tracking Domain of a Cisco ER Group

The emergency call processing for phones moving between access switches controlled by the same home Cisco ER group is the same as the processing done for a deployment with a single Unified CM cluster. For example, a phone moving between access switches A1 and A2 remains registered with Unified CM cluster A, and its location is determined by Cisco ER group A both before and after the move. The phone is still under full control of Cisco ER group A, for both the discovery of the phone by Unified CM cluster A and the determination of the phone's location by switch A2. The phone is therefore not considered to be an unlocated phone.

Phone Movements Between the Various Tracking Domains of a Cisco ER Cluster

A Cisco ER cluster is essentially a collection of Cisco ER groups that share location information. Each group shares the location of any phone it finds on an access switch or in an IP subnet.

Cisco ER groups also share information about phones that cannot be located within a Cisco ER group's tracking domain (in switches or IP subnets) but which are known to be registered in the group's associated Unified CM cluster. Such phones are deemed *unlocated*.

If a phone is roaming between access switches monitored by different Cisco ER groups, those groups must be configured in a Cisco ER cluster so they can exchange information about the phone's location. For example, phone A3 is registered with Unified CM cluster A, but it is connected to an access switch controlled by Cisco ER group B. Cisco ER group A is aware that phone A3 is registered with Unified CM cluster A, but group A cannot locate phone A3 in any of the site A switches. Therefore, phone A3 is deemed *unlocated* by Cisco ER group A.

Cisco ER group B, on the other hand, has detected the presence of phone A3 in one of the switches that it monitors. Because the phone is not registered with Unified CM cluster B, phone A3 is advertised through the Cisco ER LDAP database as an *unknown* phone.

Because the two Cisco ER groups are communicating through an LDAP database, they can determine that Cisco ER group B's *unknown* phone A3 is the same as Cisco ER group A's *unlocated* phone A3.

The Unlocated Phone page in Cisco ER group A will display the phone's host name along with the remote Cisco ER group (in this, case Cisco ER group B).

Emergency Call Routing within a Cisco ER Cluster

Cisco ER clustering also relies on route patterns that allow emergency calls to be redirected between pairs consisting of a Unified CM cluster and a Cisco ER. For more details, refer to the section on *Creating Route Patterns for Inter-Cisco Emergency Responder-Group Communications* in the *Cisco Emergency Responder Administration Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps842/prod_maintenance_guides_list.html

If phone A3 places an emergency call, the call signaling flow will be as follows:

1. Phone A3 sends the emergency call string to Unified CM cluster A for processing.
2. Unified CM cluster A sends the call to Cisco ER group A for redirection.
3. Cisco ER group A determines that phone A3 is located in Cisco ER group B's tracking domain, so it redirects the call to a route pattern that points to Unified CM cluster B.
4. Unified CM cluster A sends the call to Unified CM cluster B.
5. Unified CM cluster B sends the call to Cisco ER group B for redirection.
6. Cisco ER group B identifies the ERL and ELIN associated with phone A3's location and redirects the call to Unified CM cluster B. The calling number is transformed into the ELIN associated with the ERL of phone A3, and the called number is modified to route the call to the proper gateway.
7. Unified CM cluster B routes the call according to the new called number information obtained from Cisco ER group B.
8. Unified CM cluster B sends the call out the gateway toward the Emergency PSTN network.

WAN Deployment of Cisco Emergency Responder

The Cisco Emergency Responder Group can be located remotely from the Cisco Unified CM cluster (that is, over the WAN). Also, the primary and secondary Cisco ER servers can be placed in geographically separate sites over the WAN. For such deployments, the recommended round-trip time (RTT) is 40 msec or less, and the minimum bandwidth required between the Cisco ER Servers is 1.544 Mbps.

ALI Formats

In multi-cluster configurations, there might be instances where the physical locations of ERLs and ELINs defined in a single Cisco ER group span the territory of more than one phone company. This condition can lead to situations where records destined for different phone companies have to be extracted from a common file that contains records for multiple LECs.

Cisco ER exports this information in ALI records that conform to National Emergency Number Association (NENA) 2.0, 2.1, and 3.0 formats. However, many service providers do not use NENA standards. In such cases, you can use the ALI Formatting Tool (AFT) to modify the ALI records generated by Cisco ER so that they conform to the formats specified by your service provider. That service provider can then use the reformatted file to update their ALI database.

The ALI Formatting Tool (AFT) enables you to perform the following functions:

- Select a record and update the values of the ALI fields. AFT allows you to edit the ALI fields to customize them to meet the requirements of various service providers. Your service provider can then read the reformatted ALI files and use them to update their ELIN records.
- Perform bulk updates on multiple ALI records. Using the bulk update feature, you can apply common changes to all the records that you have selected, to one area code, or to one area code and one city code.
- Selectively export ALI records based on area code, city code, or a four-digit directory number. By selecting to export all the ALI records in an area code, for example, you can quickly access all the ELIN records for each service provider, thereby easily supporting multiple service providers.

Given the flexibility of the AFT, a single Cisco ER group can export ALI records in multiple ALI database formats. For a Cisco ER group serving a Unified CM cluster with sites in the territories of two LECs, the basic approach is as follows:

1. Obtain an ALI record file output from Cisco Emergency Responder in standard NENA format. This file contains the records destined for multiple LECs.
2. Make a copy of the original file for each required ALI format (one copy per LEC).
3. Using the AFT of the first LEC (for example, LEC-A), load a copy of the NENA-formatted file and delete the records of all the ELINs associated with the other LECs. The information to delete can usually be identified by NPA (or area code).
4. Save the resulting file in the required ALI format for LEC-A, and name the file accordingly.
5. Repeat steps 3 and 4 for each LEC.

For more information about the ALI formatting tools, refer to the online documentation available at

http://www.cisco.com/en/US/products/sw/voicesw/ps842/prod_maintenance_guides_list.html

For LECs not listed at this URL, the output from Unified CM can be formatted using standard text file editing tools, such as spreadsheet programs and standard text editors.

Call Admission Control

Revised: April 30, 2012; OL-21733-18

The call admission control function is an essential component of any IP telephony system, especially those that involve multiple sites connected through an IP WAN. In order to better understand what call admission control does and why it is needed, consider the example in [Figure 11-1](#).

Figure 11-1 Why Call Admission Control is Needed

As shown on the left side of [Figure 11-1](#), traditional TDM-based PBXs operate within circuit-switched networks, where a circuit is established each time a call is set up. As a consequence, when a legacy PBX is connected to the PSTN or to another PBX, a certain number of physical trunks must be provisioned. When calls have to be set up to the PSTN or to another PBX, the PBX selects a trunk from those that are available. If no trunks are available, the call is rejected by the PBX and the caller hears a network-busy signal.

Now consider the IP telephony system shown on the right side of [Figure 11-1](#). Because it is based on a packet-switched network (the IP network), no circuits are established to set up an IP telephony call. Instead, the IP packets containing the voice samples are simply routed across the IP network together

with other types of data packets. Quality of Service (QoS) is used to differentiate the voice packets from the data packets, but bandwidth resources, especially on IP WAN links, are not infinite. Therefore, network administrators dedicate a certain amount of "priority" bandwidth to voice traffic on each IP WAN link. However, once the provisioned bandwidth has been fully utilized, the IP telephony system must reject subsequent calls to avoid oversubscription of the priority queue on the IP WAN link, which would cause quality degradation for all voice calls. This function is known as call admission control, and it is essential to guarantee good voice quality in a multisite deployment involving an IP WAN.

To preserve a satisfactory end-user experience, the call admission control function should always be performed during the call setup phase so that, if there are no network resources available, a message can be presented to the end-user or the call can be rerouted across a different network (such as the PSTN).

This chapter discusses the following main topics:

- [Design Recommendations for Call Admission Control, page 11-126](#)
This section summarizes the key best practices, recommendations, and notes about call admission control for the readers who are already familiar with the principles and mechanisms described in the remainder of this chapter.
- [Call Admission Control Principles, page 11-3](#)
This section defines the two fundamental approaches to call admission control in an IP-based telephony system: topology-aware and topology-unaware call admission control.
- [Call Admission Control Architecture, page 11-12](#)
This section describes the call admission control mechanisms available through the various components of a Cisco IP Communications system, such as Cisco Unified Communications Manager locations, Cisco IOS gatekeeper, RSVP, and RSVP SIP Preconditions.
- [Design Considerations for Call Admission Control, page 11-70](#)
This section shows how to apply and combine the mechanisms described in the previous sections, based on the IP WAN topology (simple hub-and-spoke, two-tier hub-and-spoke, MPLS, or other topologies) and also based on the Cisco Unified Communications Manager deployment model adopted.

What's New in This Chapter

[Table 11-1](#) lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Table 11-1 *New or Changed Information Since the Previous Release of This Document*

| New or Revised Topic | Described in: | Revision Date |

Call Admission Control Principles

As mentioned previously, call admission control is a function of the call processing agent in an IP-based telephony system, so in theory there could be as many call admission control mechanisms as there are IP-based telephony systems. However, most of the existing call admission control mechanisms fall into one of the following two main categories:

- Topology-unaware call admission control — Based on a static configuration within the call processing agent
- Topology-aware call admission control — Based on communication between the call processing agent and the network about the available resources

The remainder of this section first analyzes the principles of topology-unaware call admission control and its limitations, and then presents the principles of topology-aware call admission control.

Topology-Unaware Call Admission Control

We define as topology-unaware call admission control any mechanism that is based on a static configuration within a call processing agent or IP-based PBX, aimed at limiting the number of simultaneous calls to or from a remote site connected via the IP WAN.

As shown in [Figure 11-2](#), most of these mechanisms rely on the definition of a logical "site" entity, which generally corresponds to a geographical branch office connected to the enterprise IP WAN.

After assigning all the devices located at each branch office to the corresponding site entity, the administrator usually configures a maximum number of calls (or a maximum amount of bandwidth) to be allowed in or out of that site.

Each time a new call needs to be established, the call processing agent checks the sites to which the originating and terminating endpoints belong, and verifies whether there are available resources to place the call (in terms of number of calls or amount of bandwidth for both sites involved). If the check

succeeds, the call is established and the counters for both sites are decremented. If the check fails, the call processing agent can decide how to handle the call based on a pre-configured policy. For example, it could send a network-busy signal to the caller device, or it could attempt to reroute the call over a PSTN connection.

Figure 11-2 Principles of Topology-Unaware Call Admission Control

Because of their reliance on static configurations, topology-unaware call admission control mechanisms can generally be deployed only in networks with a relatively simple IP WAN topology. In fact, most of these mechanisms mandate a simple hub-and-spoke topology or a simple MPLS-based topology (where the MPLS service is provided by a service provider), as shown in [Figure 11-3](#).

Figure 11-3 Domain of Applicability of Topology-Unaware Call Admission Control

In a hub-and-spoke network or MPLS-based network such as those shown in Figure 11-3, each spoke site is assigned to a "site" within the call processing agent, and the number of calls or amount of bandwidth for that "site" is configured to match the bandwidth available for voice (and/or video) on the IP WAN link that connects the spoke to the IP WAN.

Notice the absence of redundant links from the spoke sites to the hub site and of links directly connecting two spoke sites. The next section explains why such links create problems for topology-unaware call admission control.

Limitations of Topology-Unaware Call Admission Control

In today's enterprise networks, high availability is a common requirement, and it often translates into a desire to provide redundancy for the IP WAN network connectivity.

When considering the IP WAN topology in a typical enterprise network, you are likely to encounter a number of characteristics that complicate the assumption of a pure hub-and-spoke topology. Figure 11-4 shows several of these network characteristics in a single diagram. Obviously, only the largest enterprise networks present all these characteristics at once, but it is highly likely that most IP WAN networks feature at least one of them.

Figure 11-4 Topology Characteristics of Typical Enterprise Networks

As explained in the section on Design Considerations for Call Admission Control, page 11-70, it is sometimes possible to adapt a topology-unaware call admission control mechanism to a complex network topology, but there are limitations in terms of when this approach can be used and what behavior

153165

can be achieved. For example, consider the simple case of a branch site connected to a hub site via the IP WAN, where redundancy is a network requirement. Typically, redundancy can be achieved in one of the following ways:

- A single router with a primary and a backup link to the IP WAN
- A single router with two active WAN links in a load-balancing configuration
- Two router platforms, each connected to the IP WAN, with load-balanced routing across them

The examples [Figure 11-5](#) attempt to apply a topology-unaware call admission control mechanism to the case of a single router with a primary and backup link and the case of a single router with two active load-balanced links. (The case of two router platforms has the same call admission control implications as the latter example.)

Figure 11-5 Topology-Unaware Call Admission Control in Presence of Dual Links

For the first example in [Figure 11-5](#), branch office A is normally connected to the IP WAN via a primary link, whose Low Latency Queuing (LLQ) bandwidth is provisioned to allow a maximum of 10 simultaneous calls. When this primary link fails, a smaller backup link becomes active and preserves the connectivity to the IP WAN. However, the LLQ bandwidth of this backup link is provisioned to allow only up to 2 simultaneous calls.

In order to deploy a topology-unaware call admission control mechanism for this branch office, we must define a "site" A in the call processing agent and configure it for a certain number of calls (or amount of bandwidth). If we choose to use 10 calls as the maximum for site A, the backup link can be overrun during failures of the primary link, thereby causing bad voice quality for all active calls. If, on the other hand, we choose 2 calls as the maximum, we will not be able to use the bandwidth provisioned for the remaining 8 calls when the primary link is active.

Now consider branch office B, which has two active links connecting it to the IP WAN. Each of these links is provisioned to allow a maximum of 10 simultaneous calls, and the routing protocol automatically performs load-balancing between them. When deploying a topology-unaware call admission control mechanism for this branch office, we must define a "site" B in the call processing agent and configure it for a certain number of calls (or amount of bandwidth). Similar to the case of branch office A, if we choose to add up the capacity of the two links and use 20 calls as the maximum for site B, there is a potential to overrun the LLQ on one of the two links during failures of the other one. For example, if

link #2 fails, the system still allows 20 simultaneous calls to and from site B, which are now all routed via link #1, thus overrunning it and causing poor voice quality for all calls. On the other hand, if site B is configured for a maximum of 10 simultaneous calls, the available LLQ bandwidth is never fully utilized under normal conditions (when both links are operational).

These two simple examples show how IP WAN bandwidth provisioning in real enterprise networks is often too complex to be summarized in statically configured entries within the call processing agent. Deploying topology-unaware call admission control in such networks forces the administrator to make assumptions, develop workarounds, or accept sub-optimal use of network resources.

The optimal way to provide call admission control in the presence of a network topology that does not conform to a simple hub-and-spoke is to implement topology-aware call admission control, as described in the following section.

**Note**

Some IP telephony systems augment classic topology-unaware call admission control with a feedback mechanism based on observed congestion in the network, which forces calls through the PSTN when voice quality deteriorates. This approach is still not equivalent to true topology-aware call admission control because it is performed after the calls have already been established and because the call processing agent still does not have knowledge of exactly where congestion is occurring. As mentioned at the beginning of the chapter, in order to be effective, call admission control must be performed before the call is set up.

Topology-Aware Call Admission Control

We define as topology-aware call admission control any mechanism aimed at limiting the number of simultaneous calls across IP WAN links that can be applied to any network topology and can dynamically adjust to topology changes.

To accomplish these goals, topology-aware call admission control must rely on real-time communications about the availability of network resources between a call processing agent (or IP-based PBX) and the network. Because the network is a distributed entity, real-time communications require a signaling protocol.

The Resource Reservation Protocol (RSVP) is the first significant industry-standard signaling protocol that enables an application to reserve bandwidth dynamically across an IP network. Using RSVP, applications can request a certain amount of bandwidth for a data flow across a network (for example, a voice call) and can receive an indication of the outcome of the reservation based on actual resource availability.

In the specific case of call admission control for voice or video calls, an IP-based PBX can synchronize the call setup process with RSVP reservations between the two remote sites and can make a routing decision based on the outcome of the reservations. Because of its distributed and dynamic nature, RSVP is capable of reserving bandwidth across any network topology, thus providing a real topology-aware call admission control mechanism.

To better understand the basic principles of how RSVP performs bandwidth reservation in a network, consider the simple example depicted in [Figure 11-6](#). This example does not analyze the exact message exchanges and protocol behaviors, but rather focus on the end results from a functionality perspective. For more information on the RSVP message exchanges, see [RSVP Principles, page 11-18](#).

Assume that RSVP is enabled on each router interface in the network shown in [Figure 11-6](#) and that the numbers shown in the circles represent the amount of available RSVP bandwidth remaining on each interface.

Figure 11-6 Sample Network to Show RSVP Principles

Now consider an RSVP-enabled application that wants to reserve a certain amount of bandwidth for a data stream between two devices. This scenario is depicted in Figure 11-7, which shows a particular data stream that requires 24 kbps of bandwidth from Device 1 to Device 2.

Figure 11-7 RSVP Signaling for a Successful Reservation

The following considerations apply to [Figure 11-7](#):

- RSVP does not perform its own routing; instead it uses underlying routing protocols to determine where it should carry reservation requests. As routing changes paths to adapt to topology changes, RSVP adapts its reservations to the new paths wherever reservations are in place.
- The RSVP protocol attempts to establish an end-to-end reservation by checking for available bandwidth resources on all RSVP-enabled routers along the path from Device 1 to Device 2. As the RSVP messages progress through the network, the available RSVP bandwidth gets decremented by 24 kbps on the outbound router interfaces, as shown in [Figure 11-7](#).
- The available bandwidth on all outbound interfaces is sufficient to accept the new data stream, so the reservation succeeds and the application is notified.
- RSVP reservations are unidirectional (in this case, the reservation is established from Device 1 to Device 2, and not vice versa). In the presence of bidirectional applications such as voice and videoconferencing, two reservations must be established, one in each direction.
- RSVP provides transparent operation through router nodes that do not support RSVP. If there are any routers along the path that are not RSVP-enabled, they simply ignore the RSVP messages and pass them along like any other IP packet, and a reservation can still be established. (See [RSVP Principles, page 11-18](#), for details on protocol messages and behaviors.) However, in order to have an end-to-end QoS guarantee, you have to ensure that there is no possibility of bandwidth congestion on the links controlled by the non-RSVP routers.

After a reservation has been successfully established between Device 1 and Device 2, now assume that another application requests a 24-kbps reservation between Device 3 and Device 4, as depicted in [Figure 11-8](#).

Figure 11-8 RSVP Signaling for an Unsuccessful Reservation

126673

The following considerations apply to [Figure 11-8](#):

- The RSVP protocol attempts to establish an end-to-end reservation by checking for available bandwidth resources on all RSVP-enabled routers along the path from Device 3 to Device 4. As the RSVP messages progress through the network, the available RSVP bandwidth gets decremented by 24 kbps on the outbound router interfaces, as shown in [Figure 11-8](#).
- In this example, the available bandwidth on R5's outbound interface toward R6 is not sufficient to accept the new data stream, so the reservation fails and the application is notified. The available RSVP bandwidth on each outbound interface along the path is then restored to its previous value.
- The application can then decide what to do. It could abandon the data transfer or decide to send it anyway with no QoS guarantees, as best-effort traffic.

We can now apply the topology-aware call admission control approach based on RSVP to the examples of dual-connected branch offices A and B introduced in the previous section.

As shown in [Figure 11-9](#), branch office A has a primary link with an LLQ provisioned for 10 calls, while the backup link can accommodate only 2 calls. With this approach, RSVP is configured on both router interfaces so that the RSVP bandwidth matches the LLQ bandwidth. Branch A is also configured within the call processing agent to require RSVP reservations for all calls to or from other branches. Now calls are admitted or rejected based on the outcome of the RSVP reservations, which automatically follow the path determined by the routing protocol. Under normal conditions (when the primary link is active), up to 10 calls will be admitted; during failure of the primary link, only up to 2 calls will be admitted.

Policies can typically be set within the call processing agent to determine what to do in the case of a call admission control failure. For example, the call could be rejected, rerouted across the PSTN, or sent across the IP WAN as a best-effort call with a different DSCP marking.

Figure 11-9 Topology-Aware Call Admission Control for Dual Links

Similar considerations apply to branch B, connected to the IP WAN via two load-balanced links, as shown on the right side of [Figure 11-9](#). RSVP is enabled on each of the two router interfaces, with a bandwidth value that matches the LLQ configuration (in this case, enough bandwidth for 10 calls). Branch B is also configured within the call processing agent to request RSVP reservations for calls to or from other branches. Again, calls are admitted or rejected based on the actual bandwidth available along

the path chosen by the routing protocol. So in a case of perfectly even load-balancing across the two links, up to 20 calls could be admitted under normal conditions (when both links are operational); if one of the two links fails, only up to 10 calls would be admitted.

In the case that one of the two links failed while more than 10 calls were active, some calls would fail to re-establish a reservation on the new path. At this point, the call processing agent would be notified and could react based on the configured policy (for example, by dropping the extra calls or by remarking them as best-effort calls).

In conclusion, topology-aware call admission control allows administrators to protect call quality with any network topology, to automatically adjust to topology changes, and to make optimal use of the network resources under all circumstances.

Special Considerations for MPLS Networks

From the call admission control perspective, a network based on MPLS differs from one based on traditional Layer 2 WAN Services with respect to support for RSVP in the "hub" of the network. Hub sites of traditional Layer 2 wide-area networks consist, in most cases, of an enterprise-controlled router that can be enabled to participate in RSVP. Because the entire network (cloud) is the "hub site" in MPLS networks, there is no enterprise-controlled hub location to enable RSVP. (For more information, see [Simple MPLS Topologies, page 11-78](#).) Therefore, to provide topology-aware call admission control in an MPLS environment, the Customer Edge (CE) devices of the network must be configured for RSVP support.

Because RSVP must be enabled on the CE, control of this equipment is important. If this equipment is not under the control of the enterprise, you must work with your service provider to determine if they will enable RSVP on your WAN interface and if that implementation will support advanced features such as RSVP application ID.

RSVP messages will transparently pass across the RSVP-unaware MPLS cloud, so this does not pose a problem with end-to-end RSVP capability. Configuring RSVP on the CE WAN interface will ensure that its priority queue will not be overrun. Because RSVP reservations are unidirectional, the following rules must be observed to protect the priority queue on the Provider Edge (PE) router when RSVP is not enabled in the MPLS cloud:

- The media streams must be the same size in both directions.
- The media has to be symmetrically routed.

RSVP PATH messages record the egress IP address of the RSVP-aware routers they traverse. The information in the PATH message is used to send the RSVP RESV message back via the same route. Because of this mechanism, the WAN link between CE and PE must have routable IP addresses or the RSVP Reservations will fail.

If your MPLS network does not comply with these rules, contact your local Cisco account team for further assistance before implementing RSVP.

Call Admission Control Architecture

There are several mechanisms that perform the call admission control function in a Cisco IP Communications system. This section provides design and configuration guidelines for all of these mechanisms, according to their category:

- Topology-unaware mechanisms
 - [Unified CM Static Locations, page 11-12](#)
 - [Cisco IOS Gatekeeper Zones, page 11-15](#)
- Topology-aware mechanisms
 - [Unified CM RSVP-Enabled Locations, page 11-38](#)
 - [RSVP SIP Preconditions, page 11-50](#)

Unified CM Static Locations

Unified CM provides a simple mechanism known as *static locations* for implementing call admission control in the centralized call processing deployment. When you configure a device in Unified CM, the device can be assigned to a location. A certain amount of bandwidth will be allocated for calls to or from each location. The locations configured in Unified CM are virtual locations and not real, physical locations. Unified CM has no knowledge of the physical locations of devices. Therefore, if a device is moved from one physical location to another, the system administrator must perform a manual update on its location configuration so that Unified CM can correctly calculate bandwidth allocation for that device. Each device is in location Hub_None by default. Location Hub_None is a special location that is configured by default with unlimited audio and video bandwidth, and location Hub_None cannot be deleted. If the devices at a branch location are configured in the Hub_None location, none of the phone calls to or from that branch device will be subject to any call admission control.

Unified CM allows you to define a voice and video bandwidth pool for each location. If the location's audio and video bandwidth are configured as **Unlimited**, there will be unlimited bandwidth available for that location, and every audio or video call to or from that location will be permitted by Unified CM. On the other hand, if the bandwidth values are set to a finite number of kilobits per second (kbps), Unified CM will allow calls in and out of that location as long as the aggregate bandwidth used by all active calls is less than or equal to the configured values. If the video bandwidth for the location is configured as **None**, every video call to or from that location is denied but the video calls within the same location are not affected.

For video calls, the video location bandwidth takes into account both the video and the audio portions of the call. Therefore, for a video call, no bandwidth is deducted from the audio bandwidth pool.

The devices that can specify membership in a location include:

- IP phones
- CTI ports
- H.323 clients
- CTI route points
- Conference bridges
- Music on hold (MoH) servers
- Gateways
- Trunks

The static locations call admission control mechanism also takes into account the mid-call changes of call type. For example, if an inter-site video call is established, Unified CM will subtract the appropriate amount of video bandwidth from the respective locations. If this video call changes to an audio-only call via a transfer to a device that is not capable of video, Unified CM will return the allocated bandwidth to the video pool and allocate the appropriate amount of bandwidth from the audio pool. Calls that change from audio to video will cause the opposite change of bandwidth allocation.

Table 11-2 lists the amount of bandwidth requested by the static locations algorithm for various call speeds. For an audio call, Unified CM counts the media bit rates plus the Layer 3 overhead. For example, a G.711 audio call consumes 80 kbps allocated from the location's audio bandwidth pool. For a video call, Unified CM counts only the media bit rates for both the audio and video streams. For example, for a video call at a speed of 384 kbps, Unified CM will allocate 384 kbps from the video bandwidth pool.

Table 11-2 Amount of Bandwidth Requested by the Static Locations Algorithm

| Call Speed | Static Location Bandwidth Value |
|----------------------------|---------------------------------|
| G.711 audio call (64 kbps) | 80 kbps |
| G.729 audio call (8 kbps) | 24 kbps |
| 128-kbps video call | 128 kbps |
| 384-kbps video call | 384 kbps |
| 512-kbps video call | 512 kbps |
| 768-kbps video call | 768 kbps |

For a complete list of codecs and static location bandwidth values, refer to the bandwidth calculations information in the *Call Admission Control* section of the *Cisco Unified Communications Manager System Guide*, available at:

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

For example, assume that the configuration for the location Branch 1 allocates 256 kbps of available audio bandwidth and 384 kbps of available video bandwidth. In this case, the Branch 1 location can support up to three G.711 audio calls (at 80 kbps per call) or ten G.729 audio calls (at 24 kbps per call), or any combination of both that does not exceed 256 kbps. The location can also support different numbers of video calls depending on the video and audio codecs being used (for example, one video call requesting 384 kbps of bandwidth or three video calls with each requesting 128 kbps of bandwidth).

Note

Call admission control does not apply to calls between devices within the same location.

When a call is placed from one location to the other, Unified CM deducts the appropriate amount of bandwidth from both locations. For example, a G.729 call between two locations causes Unified CM to deduct 24 kbps from the available bandwidth at both locations. When the call has completed, Unified CM returns the bandwidth to the affected locations. If there is not enough bandwidth at either branch location, the call is denied by Unified CM and the caller receives the network busy tone. If the calling device is an IP phone with a display, that device also displays the message "Not Enough Bandwidth."

When an inter-site call is denied by call admission control, Unified CM can automatically reroute the call to the destination via the PSTN connection by means of the Automated Alternate Routing (AAR) feature. For detailed information on the AAR feature, see [Automated Alternate Routing, page 9-108](#).

**Note**

AAR is invoked only when the locations-based call admission control denies the call due to a lack of network bandwidth. AAR is not invoked when the IP WAN is unavailable or other connectivity issues cause the called device to become unregistered with Unified CM. In such cases, the calls are redirected to the target specified in the Call Forward No Answer field of the called device.

Locations and Regions Settings

Locations work in conjunction with regions to define the characteristics of a network link. Regions define the type of compression or bit rate (8 kbps or G.729, 64 kbps or G.722/G.711, and so forth) that is used on the link, and locations define the amount of available bandwidth for the link. You assign each device in the system to both a region (by means of a device pool) and a location (by means of a device pool or by direct configuration on the device itself).

You can configure *locations* in Unified CM to define:

- Physical locations (for example, a branch office)
- The amount of bandwidth that is available in the WAN for voice and fax calls coming into and going out from a location. This bandwidth value is used by Unified CM for locations-based call admission control.
- The amount of video bandwidth that is available in the WAN for calls coming into and going out from a location. This bandwidth value is used by Unified CM for locations-based call admission control.
- The settings for RSVP call admission control between locations. (Possible settings are No Reservation, Optional, Optional (Video Desired), Mandatory, and Mandatory (Video Desired).)

You can configure *regions* in Unified CM to define:

- The Max Audio Bit Rate used for intraregion calls
- The Max Audio Bit Rate used for interregion calls
- The Max Video Call Bit Rate (Includes Audio) used for intraregion calls and interregion calls
- The link loss type for interregion calls (Possible link loss types are Low Loss and Lossy.)

Unified CM Support for Locations and Regions

Cisco Unified Communications Manager supports 2000 locations and 2000 regions with Cisco MCS-7845 servers. To deploy up to 2000 locations and regions, you must configure the following service parameters in the **Clusterwide Parameters > (System - Location and Region)** and **Clusterwide Parameters > (System - RSVP)** configuration menus:

- Default Intraregion Max Audio Bit Rate
- Default Interregion Max Audio Bit Rate
- Default Intraregion Max Video Call Bit Rate (Includes Audio)
- Default Interregion Max Video Call Bit Rate (Includes Audio)
- Default Intraregion and Interregion Link Loss Type

When adding regions, you should then select **Use System Default** for the Max Audio Bit Rate and Max Video Call Bit Rate values. If you are using RSVP call admission control, you should also select **Use System Default** for the RSVP Setting parameter.

Changing these values for individual regions and locations from the default has an impact on server initialization and publisher upgrade times. Hence, with a total of 2000 regions and 2000 locations, you can modify up to 200 of them to use non-default values. With a total of 1000 or fewer regions and locations, you can modify up to 500 of them to use non-default values. Table 11-3 summarizes these limits.

Table 11-3 *Number of Allowed Non-Default Regions and Locations*

| Number of non-default regions and locations | Maximum number of regions | Maximum number of locations |
|---|---------------------------|-----------------------------|
| 0 to 200 | 2000 | 2000 |
| 200 to 500 | 1000 | 1000 |

Note

The Max Audio Bit Rate is used by both voice calls and fax calls. If you plan to use G.729 as the interregion codec, use T.38 Fax Relay for fax calls. If you plan to use fax pass-through over the WAN, change the default Interregion Max Audio Bit Rate to 64 kbps (G.722 or G.711), or else add a region for fax machines to each location with a non-default bit rate of 64 kbps (G.722 or G.711), subject to the limits in Table 11-3.

Note

Irrespective of the MCS model you are using, your Cisco Partner or Cisco Systems Engineer should always use the Cisco Unified Communications Sizing Tool (<http://tools.cisco.com/cucst>) to validate all designs that incorporate a large number of remote sites, because there are many interdependent variables that can affect Unified CM cluster scalability (such as regions, locations, gateways, media resources, and so forth). Use the Sizing Tool to accurately determine the number of servers or clusters required to meet your design criteria.

Cisco IOS Gatekeeper Zones

A Cisco IOS gatekeeper can provide call routing and call admission control between devices such as Cisco Unified CM, Cisco Unified Communications Manager Express (Unified CME), or H.323 gateways connected to legacy PBXs. It uses the H.323 Registration Admission Status (RAS) protocol to communicate with these devices and route calls across the network.

Gatekeeper call admission control is a policy-based scheme requiring static configuration of available resources. The gatekeeper is not aware of the network topology, so it is limited to simple hub-and-spoke topologies. Refer to the section on [Design Considerations for Call Admission Control, page 11-70](#), for detailed topology examples.

For a listing of the available Cisco IOS gatekeeper platforms and the features supported on each platform, refer to the *Cisco IOS H323 Gatekeeper Data Sheet* at

http://www.cisco.com/en/US/prod/collateral/voicesw/ps6788/vcallcon/ps4139/data_sheet_c78_561921.html

The call admission control capabilities of a Cisco IOS gatekeeper are based on the concept of gatekeeper *zones*. A zone is a collection of H.323 devices, such as endpoints, gateways, or Multipoint Control Units (MCUs), that register with a gatekeeper. There can be only one active gatekeeper per zone, and you can define up to 100 local zones on a single gatekeeper. A local zone is a zone that is actively handled by that gatekeeper – that is, all H.323 devices assigned to that zone register with that gatekeeper.

When multiple gatekeepers are deployed in the same network, a zone is configured as a local zone on only one gatekeeper. On the other gatekeepers, that zone is configured as a remote zone. This configuration instructs the gatekeeper to forward calls destined for that zone to the gatekeeper that "owns it" (that is, the gatekeeper on which that zone is configured as a local zone).

For details on configuring the gatekeeper, refer to the *Cisco IOS H.323 Configuration Guide* at

http://www.cisco.com/en/US/docs/ios/voice/h323/configuration/guide/15_0/vh_15_0_book.html

The bandwidth value deducted by the gatekeeper for every active call is double the bit-rate of the call, excluding Layer 2, IP, and RTP overhead. For example, a G.711 audio call that uses 64 kbps would be denoted as 128 kbps in the gatekeeper, and a 384-kbps video call would be denoted as 768 kbps.

Table 11-4 shows the bandwidth values used by the gatekeeper feature for some of the most popular call speeds.

Table 11-4 Gatekeeper Bandwidth Settings for Various Call Speeds

| Call Speed | Gatekeeper Bandwidth Value |
|----------------------------|----------------------------|
| G.711 audio call (64 kbps) | 128 kbps |
| G.729 audio call (8 kbps) | 16 kbps |
| 128-kbps video call | 256 kbps |
| 384-kbps video call | 768 kbps |
| 512-kbps video call | 1024 kbps |
| 768-kbps video call | 1536 kbps |

Note

Bandwidth calculations for the call Admission Request (ARQ) do not include compressed Real-Time Transport Protocol (cRTP) or any other transport overhead. See [Bandwidth Provisioning, page 3-47](#), for details on how to provision interface queues.

To better understand the application of the **bandwidth** commands in a real network, consider the example shown in [Figure 11-10](#).

Figure 11-10 Example of Cisco IOS Gatekeeper bandwidth Commands

Assuming that all calls are voice-only calls using the G.711 codec, and given the configuration commands shown in [Figure 11-10](#), the following statements hold true:

- The maximum amount of bandwidth requested by any device in zone A for a single call is 128 kbps, which means that calls trying to use codecs with a higher bit-rate than 64 kbps will be rejected.
- The maximum amount of bandwidth used by all calls involving devices in zone A (either within the zone or with other zones) is 384 kbps, which means that there can be at most three active calls involving devices in zone A.
- The maximum amount of bandwidth used by all calls between devices in zone B and devices in any other zone is 256 kbps, which means that there can be at most two active calls between devices in zone B and devices in zones A, C, and D.
- The maximum amount of bandwidth used by all calls between devices registered with gatekeeper GK 1 and devices registered with any other gatekeeper is 512 kbps, which means that there can be at most four active calls between devices in zones A and B and devices in zones C and D.

Unified Communications Architectures Using Resource Reservation Protocol (RSVP)

This section covers the various Unified Communications architectures that implement Resource Reservation Protocol (RSVP) as the call admission control mechanism. The section begins with an introduction to RSVP and an overview of the protocol architecture, concepts of RSVP and Quality of Service, Application ID, and a summary of the infrastructure design considerations and recommendations.

Next this section discusses Unified CM RSVP-enabled locations in a single-cluster Unified CM environment. The discussion covers the components involved as well as the provisioning of those components, Unified CM's use of RSVP policy and Application ID, and a recommended migration strategy from call admission control based on static locations.

The discussion then turns to distributed call processing architectures. The discussion begins with RSVP SIP Preconditions, with an overview of the feature and how it works to synchronize the RSVP layer and call control layer between the various call control applications such as Unified CM, Unified CME, and SIP-TDM Cisco IOS Gateways. Then each call control application is discussed in further detail with regard to RSVP SIP Preconditions, including feature notes and design recommendations and considerations.

Resource Reservation Protocol (RSVP)

The Resource Reservation Protocol (RSVP) is the first significant industry-standard protocol for dynamically setting up end-to-end QoS across a heterogeneous network. RSVP, which runs over IP, was first introduced by the IETF in RFC 2205, and it enables an application to reserve network bandwidth dynamically. Using RSVP, applications can request a certain level of QoS for a data flow across a network. Because of its distributed and dynamic nature, RSVP is capable of reserving bandwidth across any network topology, therefore it can be used to provide topology-aware call admission control for voice and video calls.

This section focuses on the RSVP protocol principles and its interactions with the WAN infrastructure, specifically the QoS aspects, while the motivation and the mechanisms for call admission control based on RSVP are described in other sections of this chapter.

This section covers the following specific topics:

- [RSVP Principles, page 11-18](#)
- [RSVP in MPLS Networks, page 11-21](#)
- [RSVP and QoS in WAN Routers, page 11-24](#)
- [RSVP Application ID, page 11-28](#)
- [RSVP Design Best Practices, page 11-33](#)

RSVP Principles

RSVP performs resource reservations for a given data flow across a network. RSVP reservations are unidirectional. Therefore, for a single audio call that contains two RTP streams, two RSVP reservations are generated, one for each RTP stream. The resource reservation is created by exchanging signaling messages between the source and destination devices for the data flow, and the messages are processed by intermediate routers along the path. The RSVP signaling messages are IP packets with the protocol number in the IP header set to 46, and they are routed through the network according to the existing routing protocols.

Not all routers on the path are required to support RSVP because the protocol is designed to operate transparently across RSVP-unaware nodes. On each RSVP-enabled router, the RSVP process intercepts the signaling messages and interacts with the QoS manager for the router's outbound interface involved in the data flow in order to "reserve" bandwidth resources. When the available resources are not sufficient for the data flow anywhere along the path, the routers signal the failure back to the application that originated the reservation request.

The principles of RSVP signaling can be explained by using the example shown in [Figure 11-11](#). In this diagram, an application wishes to reserve network resources for a data stream flowing from Device 1, whose IP address is 10.10.10.10, to Device 2, whose IP address is 10.60.60.60.

Figure 11-11 Example of RSVP Path and Resv Message Flow

141853

The following steps describe the RSVP signaling process for a single data flow, as shown by the example in Figure 11-11:

- The application residing on Device 1 originates an RSVP message called Path, which is sent to the same destination IP address as the data flow for which a reservation is requested (that is, 10.60.60.60) and is sent with the "router alert" option turned on in the IP header. The Path message contains, among other things, the following objects:
 - The "session" object, consisting of destination IP address, protocol number, and UDP/TCP port, which is used to identify the data flow in RSVP-enabled routers.
 - The "sender T-Spec" (traffic specification) object, which characterizes the data flow for which a reservation will be requested. The T-Spec basically defines the maximum IP bandwidth required for a call flow using a specific codec. The T-Spec is typically defined using values for the data flow's average bit rate, peak rate, and burst size. Details of the T-Spec are discussed later in this chapter.
 - The "P Hop" (or previous hop) object, which contains the IP address of the router interface that last processed the Path message. In this example, the P Hop is initially set to 10.10.10.10 by Device 1.
- By means of the "router alert" option, the Path message is intercepted by the CPU of the RSVP-aware router identified as 10.20.20.20 in Figure 11-11, which sends it to the RSVP process. RSVP creates a path state for this data flow, storing the values of the session, sender Tspec, and

P Hop objects contained in the Path message. Then it forwards the message downstream, after having replaced the P Hop value with the IP address of its outgoing interface (10.20.20.20 in this example).

3. Similarly, the Path message is intercepted by the CPU of the following RSVP-aware router, identified as 10.30.30.30 in [Figure 11-11](#). After creating the path state and changing the P Hop value to 10.30.30.30, this router also forwards the message downstream.
4. The Path message now arrives at the RSVP-unaware router identified as 10.40.40.40 in [Figure 11-11](#). Because RSVP is not enabled on this router, it just routes this message according to the existing routing protocols like any other IP packet, without any additional processing and without changing the content of any of the message objects.
5. Therefore, the Path message gets to the RSVP-aware router identified as 10.50.50.50, which processes the message, creates the corresponding path state, and forwards the message downstream. Notice that the P Hop recorded by this router still contains the IP address of the last RSVP-aware router along the network path, or 10.30.30.30 in this example.
6. The RSVP Receiver at Device 2 receives the Path message with a P Hop value of 10.50.50.50, and it can now initiate the actual reservation by originating a message called Resv. For this reason, RSVP is known as a receiver-initiated protocol. The Resv message carries the reservation request hop-by-hop from the receiver to the sender, along the reverse paths of the data flow for the session. At each hop, the IP destination address of the Resv message is the IP address of the previous-hop node, obtained from the path state. Hence, in this case Device 2 sends the Resv message with a destination IP address of 10.50.50.50. The Resv message contains, among other things, the following objects:
 - The "session" object, which is used to identify the data flow.
 - The "N Hop" (or next hop) object, which contains the IP address of the node that generated the message. In this example, the N Hop is initially set to 10.60.60.60 by Device 2.
7. When RSVP-aware router 10.50.50.50 receives the Resv message for this data flow, it matches it against the path state information using the received session object, and it verifies if the reservation request can be accepted based on the following criteria:
 - Policy control — Is this user and/or application allowed to make this reservation request?
 - Admission control — Are there enough bandwidth resources available on the relevant outgoing interface to accommodate this reservation request?
8. In this case, we assume that both policy and admission control are successful on 10.50.50.50, which means that the bandwidth provided by the Tspec in the path state for this session is reserved on the outgoing interface (in the same direction as the data flow, that is from Device 1 to Device 2), and a corresponding "reservation state" is created. Now router 10.50.50.50 can send a Resv message upstream by sending it as a unicast IP packet to the destination IP address stored in the P Hop for this session, which was 10.30.30.30. The N Hop object is also updated with the value of 10.50.50.50.
9. The Resv message now transits through the RSVP-unaware router identified as 10.40.40.40, which will route it toward its destination of 10.30.30.30 like any other IP packet. This mechanism allows RSVP signaling to work across a heterogeneous network where some nodes are not RSVP-enabled.
10. The RSVP-aware router identified as 10.30.30.30 receives the Resv message and processes it according to the mechanisms described in steps 7 and 8. Assuming policy and admission control are successful also at this hop, the bandwidth is reserved on the outgoing interface and a Resv message is sent to the previous hop, or 10.20.20.20 in this example.
11. After a similar process within the router identified as 10.20.20.20, the Resv finally reaches the RSVP sender, Device 1. This indicates to the requesting application that an end-to-end reservation has been established and that bandwidth has been set aside for this data flow in all RSVP-enabled routers across the network.

This example shows how the two main RSVP signaling messages, Path and Resv, travel across the network to establish reservations. Several other messages are defined in the RSVP standard to address error situations, reservation failures, and release of resources. In particular, the ResvErr message is used to signal failure to reserve the requested resources due to either policy control or admission control somewhere along the network. If, for example, admission control had failed at node 10.50.50.50 in [Figure 11-11](#), this node would have sent a ResvErr message back to Device 2, specifying the cause of the failure, and the application would have been notified.

Another important aspect of the RSVP protocol is that it adopts a soft-state approach, which means that for each session both the path state and the reservation state along the network need to be refreshed periodically by the application by sending identical Path and Resv messages. If a router does not receive refresh messages for a given session for a certain period of time, it deletes the corresponding state and releases the resources reserved. This allows RSVP to react dynamically to network topology changes or routing changes due to link failures. The reservations simply start flowing along the new routes based on the routing protocol decisions, and the reservations along the old routes time-out and are eventually deleted.

RSVP in MPLS Networks

In some MPLS service-provider networks, the IP addresses used on the links between the customer edge (CE) and the provider edge (PE) are not distributed to the rest of the MPLS network, thus ensuring that the subnets stay local to the PE and are not advertised beyond the PE (because they are not unique and are being reused elsewhere). This creates a situation where RSVP is not able to forward RSVP messages because the P Hop (Previous Hop) value of the RSVP message is unknown in the network. [Figure 11-12](#) illustrates this type of situation.

Figure 11-12 RSVP Over MPLS Without P Hop Overwrite

Figure 11-12 shows an enterprise network and a service provider MPLS network. CE1 and CE2 are RSVP-aware, and PE1 and PE2 are RSVP-unaware. The RSVP Path message contains a P Hop object. This object is rewritten at every RSVP hop. Its purpose is to enable an RSVP router (for example, CE1) to send a Path message to the next RSVP router (for example, CE2) to indicate that it (CE1) is the previous RSVP hop (or P Hop). This information is used by CE2 to forward the corresponding Resv message upstream hop-by-hop toward the sender.

In Cisco IOS, the RSVP Router always sets the P Hop address to the IP address of the egress interface onto which it transmits the Path message. There are situations where, although some IP addresses of CE1 are reachable, the IP address of its egress interface is not reachable from a remote RSVP Router CE2. The result is that the corresponding Resv message generated by CE2 never reaches CE1, thus the reservation is never established.

When a call is made from A1 to A2, A1 tries to set up an RSVP session and starts by sending a Path message to CE1. A1 will populate the P Hop object in the Path message of its outgoing interface IP (in this case, 10.10.10.10). CE1 will then receive the Path message, process it, create the corresponding path state, update the P Hop field of the message with its egress interface IP address (171.70.48.5), which is not a routable IP address, and forward the Path message downstream. This Path message will be tunneled across the service provider network and will be processed by CE2. Upon reception of the Path message, CE2 records the IP address of the P Hop object (CE1's egress interface IP address) and forwards the Path message downstream to A1. A1 will record and process the Path message and initiate an RSVP message

to CE2. CE2 will process the RSVP message and send its own RSVP message upstream to CE1. However, when CE2 replies with this Resv message, it will try to send it to the IP address that it had recorded earlier from the Path message received from CE1. Since this IP address (171.70.48.5) is not routable from CE2, the Resv message will fail, thus causing the reservation attempt to fail.

To resolve this behavior, a feature called Previous Hop Overwrite has been introduced in Cisco IOS Release 12.4.(20)T. P Hop Overwrite is a mechanism whereby the CE populates the Hop object in the Path message with an IP address from another interface on the router that is reachable in the customer VPN. In this way, the Resv message can find its way back toward the sender and reservations can be established. The P Hop Overwrite mechanism is illustrated in Figure 11-13.

Figure 11-13 RSVP P Hop Overwrite Feature in Cisco IOS 12.4(20)T

Describing Data Flow Characteristics in RSVP (TSpec)

RSVP was designed to support requesting Quality of Service (QoS) for any traffic flow, not just voice or video, across a wide range of Layer 2 technologies. To accomplish this, RSVP must be able to describe in detail the traffic flow for which it is requesting QoS, so that the intermediate routers can make admittance decisions correctly.

The bandwidth requirements for data flows for an RSVP session are characterized by senders in the TSpec (traffic specification) contained in Path messages and are mirrored in the RSpec (reservation specification) sent by receivers in Resv messages. The TSpec gets transported through the network to all intermediary routers and to the destination endpoint. The intermediate routers do not change this object, and the object gets delivered unchanged to the ultimate receiver(s).

The TSpec object contains the following elements:

- AverageBitRate (kbps)
- BurstSize (bytes)
- PeakRate (kbps)

Audio TSpec

For audio flows, the TSpec calculations specify the following measurements:

- AverageBitRate (kbps) — Including IP overhead
- BurstSize (bytes) — This value is calculated as the size of the packet times the number of packets in a burst. For audio flows, the burst usually specifies 1 to 2.
- PeakRate (bytes) — The peak rate, in bytes, refers to the maximum bytes per second that the endpoint transmits at any given time. If the burst is small, as is the case in audio streams, the peak rate can be calculated as 1.1 (or 1.2) times the tokenRate.

To avoid adjusting the bandwidth reservation upward when the call gets answered, Cisco Unified CM reserves the maximum bandwidth for each region codec at call setup time. Unified CM then modifies or adjusts the bandwidth based on the media capability of the connected parties when the call gets answered.

For more information on RSVP for Unified Communications, refer to the *Cisco Unified Communications Manager System Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

Note

This section focuses on providing an overview of RSVP principles and mechanisms. For more information on protocol behavior and extensions, complete message formats, and interactions with other protocols, refer to the numerous RFC documents related to RSVP, available at <http://www.ietf.org>.

RSVP and QoS in WAN Routers

RSVP has been supported in Cisco routers for many years, however most configurations recommended in this document are based on the RSVP Scalability Enhancements feature, which was first introduced in Cisco IOS Release 12.2(2)T.

By issuing the following Cisco IOS command in interface configuration mode on each Cisco IOS router interface, you can enable RSVP and define the maximum amount of bandwidth that it can control:

```
ip rsvp bandwidth [interface-kbps] [single-flow-kbps]
```

The *interface-kbps* parameter specifies the upper limit of bandwidth that RSVP can reserve on the given interface, while the *single-flow-kbps* parameter provides an upper bandwidth limit for each individual reservation (so that flows with higher bandwidth requests will be rejected even if there is bandwidth available on the interface).

**Note**

When RSVP is enabled on a router interface, all other interfaces in the router will drop RSVP messages unless they are also enabled for RSVP. To avoid dropping RSVP messages, enable RSVP on all interfaces through which you expect RSVP signaling to transit. If call admission control is not desired on an interface, set the bandwidth value to 75% of the interface bandwidth.

Within Cisco IOS, RSVP can be configured to operate according to two different models: the Integrated Services (IntServ) model, described in RFC 2210, or the Integrated Services/Differentiated Services (IntServ/DiffServ) model, described in RFC 2998. Both RFC documents are available on the IETF website at

<http://www.ietf.org>

Figure 11-14 shows the difference between these two approaches from the perspective of a Cisco IOS router.

Figure 11-14 The Two RSVP Operation Models: IntServ and IntServ/DiffServ

The IntServ Model

As shown on the left side of Figure 11-14, RSVP in the IntServ model involves both the control plane and the data plane. In the control plane, RSVP admits or denies the reservation request. In the data plane, it classifies the data packets, polices them based on the traffic description contained in the RSVP messages, and queues them in the appropriate queue. The classification that RSVP performs is based on the 5-tuple consisting of the source IP address, source port, destination IP address, destination port, and protocol number. In this model, all data packets transiting through the router must be intercepted by RSVP so that RSVP can inspect the 5-tuple and look for a match among the established reservations. If a match is found, the packets are scheduled and policed by RSVP according to the reservation's traffic specification.

As shown in Figure 11-15, when you combine the IntServ model with Low Latency Queuing (LLQ), the usable bandwidth is divided between RSVP and the predefined LLQ queues. RSVP controls the entrance criteria to the RSVP reserved bandwidth, while policy maps control the entrance criteria for the predefined queues.

Figure 11-15 Combining the IntServ Model with LLQ

To use the IntServ operation model on a Cisco IOS router, use the following commands in interface configuration mode:

```
ip rsvp resource-provider wfq [interface | pvc]
no ip rsvp data-packet classification
```

When these commands are active, RSVP admits or rejects new reservations, not only based on the upper bandwidth limit defined within the **ip rsvp bandwidth** command, but also based on the actual bandwidth resources available. For example, if there are LLQ classes with bandwidth statements, these amounts are deducted from the bandwidth pool that can be assigned to RSVP reservations. While LLQ classes statically allocate bandwidth at configuration time, RSVP does not allocate any amount until a reservation request is received. Therefore, it is important to ensure that an appropriate percentage of the available interface bandwidth is *not* allocated to LLQ classes, so that it can be used by RSVP as reservation requests are received.

Because the total maximum bandwidth that can be assigned to QoS mechanisms on a link is equal to 75% of the link speed, if you want to reserve 33% of the link bandwidth for RSVP-admitted flows, you have to make sure that the bandwidth assigned to LLQ classes does not exceed $(75 - 33) = 42\%$ of the link bandwidth.

Because RSVP is in control of assigning packets to the various queues within this model, it is possible to define a mechanism for RSVP to know whether or not to place flows in the Priority Queue (PQ) based on the data flow's T-Spec values by using the following Cisco IOS command in interface configuration mode:

```
ip rsvp pq-profile [r [b [p-to-r]]]
```

Cisco IOS RSVP uses the RSVP TSpec parameters r , b , and $p\text{-to-}r$ to determine if the flow being signaled for is a voice flow that needs PQ treatment. These parameters represent the following values:

- r = the average traffic rate in bytes per second
- b = the maximum burst of a flow in bytes
- $p\text{-to-}r$ = the ratio of peak rate to average rate, expressed as a percentage

If the traffic characteristics specified by the RSVP TSpec messages for a certain flow are less than or equal to the parameters in the Cisco IOS command, then RSVP will direct the flow into the PQ. If no parameters are provided with the command, the following values, representing the largest of the commonly used voice codecs (G.711), are used as default:

- r = 12288 bytes per second
- b = 592 bytes
- $p\text{-to-}r$ = 110%

The IntServ/DiffServ Model

As shown on the right side of [Figure 11-14](#), RSVP in the IntServ/DiffServ model involves only the control plane performing admission control but does not involve the data plane. This means that the call admission control function is separate from the scheduling and policing functions, which can be performed by the Low Latency Queuing (LLQ) algorithm according to predefined class maps, policy maps, and service policies.

With the IntServ/DiffServ model, it is therefore possible to add RSVP call admission control to a network that is already using a Differentiated Services approach to QoS. RSVP admits or rejects calls based on a preconfigured bandwidth amount, but the actual scheduling is based on the pre-existing LLQ criteria such as the DSCP value of each packet.

The entire usable bandwidth (75% of the link speed) can be assigned to LLQ classes, as shown in [Figure 11-16](#), as it normally is today. The policy maps define the traffic that is admitted into each queue. RSVP is typically configured to admit flows up to the amount of bandwidth defined for priority traffic, but keep in mind that RSVP in this model does not adjust the scheduling, so any traffic admitted by RSVP in excess of the predefined priority queue may be dropped or remapped to other lower-priority queues.

If all applications that send priority traffic are RSVP-enabled, you may configure the RSVP bandwidth to match the size of the priority queue. If, on the other hand, there are non-RSVP applications that also need to send priority traffic (such as Unified CM static locations or a gatekeeper), as shown in [Figure 11-16](#), the priority queue is divided into priority traffic that is controlled by non-RSVP mechanisms and priority traffic that is controlled by RSVP. The combined non-RSVP and RSVP admission control mechanisms must not use more bandwidth than is allocated to ensure that the priority queue is never over-subscribed.

Figure 11-16 LLQ Bandwidth Allocation with RSVP

To use the IntServ/DiffServ operation model on a Cisco IOS router, use the following commands in interface configuration mode:

```
ip rsvp resource-provider none
ip rsvp data-packet classification none
```

When these commands are active, RSVP admits or rejects new reservations uniquely based on the upper bandwidth limits defined within the **ip rsvp bandwidth** command, independently from the actual bandwidth resources available on the interface. Once admitted, the RSVP flows are subject to the same scheduling rules as all other non-RSVP traffic (for example, LLQ class and policy maps). Therefore, it is important to ensure that the RSVP-enabled traffic is marked with the appropriate DSCP value and that the bandwidth of the corresponding PQ or CBWFQ queues is provisioned to accommodate both RSVP-enabled traffic and all other traffic.

In this operating model, the **ip rsvp pq-profile** command is inactive because RSVP does not control the scheduling function.

RSVP Application ID

An application identity (app-id) is an RSVP object that can be inserted into the policy element of an RSVP message. This object is described in RFC 2872. This policy object helps to identify the application and associate it with the RSVP reservation request, thus allowing routers along the path to make appropriate decisions based on the application information.

The need for an app-id arises because RSVP is used to support multiple applications such as voice and video.

Without using an app-id, there is only one bandwidth value that is configurable per interface in RSVP. RSVP will admit requests until this bandwidth limit is reached. It does not differentiate between the requests and is not aware of the type of application for which the bandwidth is requested. As a result of

this, it is quite possible for RSVP to exhaust the allowed bandwidth by admitting requests representing just one type of application, thus causing all subsequent requests to be rejected due to unavailable bandwidth. In this way, a few video calls could prevent all or most of the voice calls from being admitted. For example, if an organization allocates 1000 units to RSVP, RSVP might exhaust a majority of this amount by admitting two 384-kbps video calls, thus leaving very little bandwidth for voice calls.

The solution to this problem is to configure separate bandwidth limits for individual applications or classes of traffic. Limiting bandwidth per application requires that an RSVP local policy matching the application bandwidth limit be applied to the router interface and that each reservation request flag the application to which it belongs so that it may be admitted against the appropriate bandwidth limit.

The app-id is not a single piece of information but multiple variable-length strings. As is described in RFC 2872, the object may include the following attributes:

- An identifier of the application (APP). This attribute is required.
- Global unique identifier (GUID). Optional.
- Version number of the application (VER). This attribute is required.
- Sub-application identifier (SAPP). An arbitrary number of sub-application elements can be included. Optional.

For example:

- APP = AudioStream
- GUID = CiscoSystems
- VER = 5.0.1.0
- SAPP = (not specified)

For more information on how Unified CM uses the Application ID, see [RSVP Application ID and Unified CM, page 11-48](#).

Cisco IOS Features

This section describes new Cisco IOS features that apply to the design of deployments using Cisco Unified CM 8.5 and later releases. These features are new in Cisco IOS Release 15.1(3)T, and it is important to use the correct Cisco IOS version to obtain these features.

RSVP Ingress Call Admission Control

As indicated in the section on [RSVP Principles, page 11-18](#), the RSVP protocol reserves the resources required by the source device to communicate with the destination device. The reservation is unidirectional. The source device signals the path message, which advertises the resource being requested. Upon receiving the path message, the destination device responds with the reservation message. The RESV message traverses the intermediate nodes between the source device and the destination device, hop-by-hop (only RSVP-aware hops), and determines if these nodes can allocate resources for the flow being requested. The reservation is checked against the resources on the outgoing interface only (egress with regard to the direction of the stream) while going downstream in the direction of the destination device.

In the following scenarios, the RESV message is not an indicator for guaranteed communication between the source device and destination device against the resource reserved:

Asymmetric Link Between Two RSVP-Aware Routers

In [Figure 11-17](#), the path message enters the RSVP-unaware cloud through a 10 MB link and goes out of the RSVP-unaware cloud into a 1 MB link. For the stream flowing from Site 1 to Site 2, only the egress interface of the RSVP-aware router at Site 1 is taken into consideration. Downstream, the 1 MB link at Site 2 is not accounted for while making the reservation. In most scenarios this is not an issue because every call has two streams, and a stream in the opposite direction (from Site 2 to Site 1) will reserve the bandwidth on the Site 2 RSVP-aware router.

Figure 11-17 Asymmetric Link Between RSVP-Aware Routers

Asymmetric Routing Path Such as a Dual-Attached Customer Equipment (CE) with Load Balancing

In [Figure 11-18](#), an audio call (two streams, one in each direction) is made between RSVP Agent A and RSVP Agent B. One stream in direction A to B flows over WAN 1, and the other stream in direction B to A flows over WAN 2. This is referred to as an asymmetrically routed call and is common in dual-attached networks with load balancing from a service provider. When RSVP is accounting on only the egress interface into a WAN network that is RSVP unaware, as is the case with service provider clouds for example, there is the potential to overrun the WANs provisioned bandwidth when traffic is load balanced.

Figure 11-18 Asymmetric Routing for a Dual-Attached Customer Equipment (CE) with Load Balancing

To overcome the limitations posed by the above scenarios and to conform with RFC 2205, use the Ingress Call Admission Control feature, which is supported in Cisco IOS Release 15.1(3)T. Ingress Call Admission Control allows the reservation of an RSVP request to be validated against a bandwidth pool on ingress into the router instead of upon egress only. (See Figure 11-19.) Note that egress bandwidth validation will continue to function as usual.

Figure 11-19 RSVP Ingress Call Admission Control

RSVP VPN Tunnel Support

Dynamic Multipoint Virtual Private Network (DMVPN) allows users to scale large and small IPsec VPNs by combining GRE tunnels, IPsec encryption, and Next Hop Resolution Protocol (NHRP). The RSVP VPN Tunnel feature supports the following types of configurations:

- RSVP over manually configured generic routing encapsulation (GRE) and multipoint generic routing encapsulation (mGRE) tunnels
- RSVP over manually configured GRE and mGRE tunnels in an IPsec protected mode
- RSVP over GRE and mGRE tunnels (IPsec protected and IPsec unprotected) in a DMVPN environment

For more information on DMVPN and the RSVP VPN Tunnel feature, refer to the *Cisco IOS Quality of Service Solutions Configuration Guide, Release 15.1*, available at

http://www.cisco.com/en/US/docs/ios/qos/configuration/guide/15_1/qos_15_1_book.html

RSVP for Flexible Bandwidth Interfaces

As indicated in the section on [RSVP Principles, page 11-18](#), when RSVP bandwidth is configured on an interface, the bandwidth value for that interface is fixed. This causes an issue with flexible interfaces (otherwise known as bundled interfaces) such as Multi-Link PPP, ATM IMA, FRF12, Gigabit EtherChannel (GEC), and so forth. The problem is that, when you configure a static RSVP bandwidth amount on a flexible bandwidth interface that contains bundles of links, if one or more of the links fail and the total bandwidth is reduced, the RSVP bandwidth remains fixed. This means that the ratio between the RSVP bandwidth and the total flexible interface bandwidth is no longer equal to the configured value, and this could cause oversubscription of that flexible bandwidth interface.

Note that Low Latency Queuing (LLQ) already allows for the Priority Queue and Class-Based Weighted Fair Queues to implement percentages; therefore, when applied to flexible bandwidth interfaces, LLQ parameters change in conjunction with the interface on which they are configured.

The Flexible Bandwidth Interfaces feature enhances the **ip RSVP bandwidth** command to allow for the configuration of a percentage of the interface bandwidth. This allows the RSVP bandwidth to change in parallel with the interface bandwidth, and it is applicable to interfaces that consist of a number of physical links that are bundled into one link.

For enterprise customers with sites that leverage bundled WAN interfaces either within their network or to a service provider, this feature allows them to fully maximize the bandwidth utilization for RSVP call admission control during complete up-time while also allowing them to use the same percentage of bandwidth on the bundle dynamically during link failures.

[Figure 11-20](#) and [Figure 11-21](#) illustrate the use of RSVP with flexible bandwidth interfaces.

Figure 11-20 Flexible Bandwidth Interfaces with 10 MB Total Bandwidth

```
ip RSVP bandwidth percent rsvp-bandwidth [max-flow-bw | percent flow-bandwidth]
```

254803

Figure 11-21 Flexible Bandwidth Interfaces with Total Bandwidth Reduced to 5 MB

```
ip RSVP bandwidth percent rsvp-bandwidth [max-flow-bw | percent flow-bandwidth]
```

254804

For more information on the use of RSVP with flexible bandwidth interfaces, refer to the *Cisco IOS Quality of Service Solutions Configuration Guide, Release 15.1*, available at

http://www.cisco.com/en/US/docs/ios/qos/configuration/guide/15_1/qos_15_1_book.html

RSVP Design Best Practices

When deploying RSVP in the IP WAN in conjunction with Unified CM, observe the following design best practices:

- Cisco recommends that you use the IntServ/DiffServ model if either of the following statements is true:
 - The only traffic destined for the Priority Queue (PQ) in the IP WAN interfaces is RSVP-enabled traffic.
 - All the non-RSVP traffic destined for the PQ can be deterministically limited to a certain amount by an out-of-band call admission control mechanism (such as Unified CM locations or a Cisco IOS gatekeeper).
- If all the PQ traffic is RSVP-enabled, the value specified in the **ip RSVP bandwidth** command and the **priority** command should match once Layer 2 overhead of the priority queue bandwidth has been taken into account.

- If RSVP is enabled on one or more interfaces of a router, all interfaces through which you expect RSVP signaling to transit should also be enabled for RSVP to ensure that RSVP messages do not get dropped. If call admission control is not desired on an interface, set the bandwidth value to 75% of the interface bandwidth.
- If some PQ traffic is not RSVP-enabled, you must ensure that the sum of the values specified in the **ip rsvp bandwidth** command and in the out-of-band call admission control mechanism do not exceed the bandwidth value specified in the **priority** command.
- Enable RSVP Application ID support if you need to limit the maximum amount of bandwidth used by voice and video calls. Application ID Support is introduced in Cisco IOS Release 12.4(6)T.
- Enable RSVP at the edge of the network, including the router WAN interfaces on both sides of the WAN link.
- Enable RSVP at all possible WAN congestion points, including redundant links of different speeds.
- If you do not have symmetric routing on load-balanced MPLS WAN links, ensure that ingress call admission control is configured (see [RSVP Ingress Call Admission Control, page 11-29](#)).
- RSVP is currently not available on most Catalyst Switching Platforms.

Bandwidth Provisioning for RSVP

This section discusses bandwidth provisioning as it relates to RSVP only. For a more general and complete discussion on bandwidth provisioning, see [Bandwidth Provisioning, page 3-47](#).

Calculating RSVP Bandwidth Values for Use with Unified CM

At the time Unified CM instructs the Cisco RSVP Agent to make the initial reservation for the call flow, the endpoints that are involved in the call have not fully exchanged their codec capabilities. Without this information, Unified CM must rely on the region settings to determine how to describe the traffic flow. The size of the traffic flow is a function of two things, the codec bit-rate and the sampling rate (or packets per second). The region settings contain the maximum codec bit rate but do not describe the sampling rate. The preferred sampling rates for audio codecs are defined in the following cluster-wide service parameters:

- Preferred G722 millisecond packet size: 20 ms by default
- Preferred G711 millisecond packet size: 20 ms by default
- Preferred G729 millisecond packet size: 20 ms by default

However, the codec type and codec sampling rate are negotiated for every call and might not be the preferred settings because they are not supported on one or more of the endpoints. To avoid having to increase the reservation size once the capabilities are fully exchanged, possibly causing a post-ring failure, this initial reservation is for the worst-case scenario (the largest codec bit rate using the smallest packet size) for that codec. Once media capabilities have been exchanged between the endpoints, then the reservation is revised to the correct bandwidth allocation. In most cases, the default sampling rate is used, resulting in the reservation being reduced.

Note

Unified CM does not include the SRTP overhead or the Layer 2 overhead in the RSVP Reservation. When compared to the RSVP T Spec bandwidth value, the Layer 3 IP RSVP bandwidth statement must take into account any SRTP traffic, and the Layer 2 priority queue value must also be over-provisioned if SRTP traffic is present. (See [Table 3-10](#) and [Table 3-11](#).)

Voice Bearer Traffic

Inter-region call with audio codec maximum set to G729, connecting using G.729:

- Initial request: 40 kbps using a 10 ms worst-case scenario
- Updated request: 24 kbps using the preferred sample size of 20 ms

Inter-region call with audio codec maximum set to G.728/iLBC, connecting using iLBC:

- Initial request: 48 kbps using a G.728 10 ms worst-case scenario
- Updated request: 31.2 kbps using iLBC with a preferred sample size of 20 ms

Inter-region call with audio codec set to G711, connecting using G.711:

- Initial request: 96 kbps using a 10 ms worst-case scenario
- Updated request: 80 kbps using the preferred sample size of 20 ms

Video Bearer Traffic

As with the audio stream, the initial reservation for the video stream will rely on the region settings because the endpoint codec capabilities will not be fully negotiated at the time of the reservation. The region settings for video calls include the bandwidth for the audio stream. (See [IP Video Telephony, page 12-1](#), for more information.) Because the audio stream has its own reservation, the final reservation for the video stream will be the region setting minus the audio codec bit-rate. However, because these codecs have not been fully negotiated, the video stream reservation will be for the worst-case scenario, which assumes no audio stream. Once media capabilities have been exchanged between the endpoints, then the reservation will be revised to the correct bandwidth allocation.

Because video is inherently bursty, it is necessary to add some overhead to the stream requirements. (See [Voice Bearer Traffic, page 3-48](#), for more information.) Unified CM uses the stream bandwidth to determine how to calculate the overhead, as follows:

- If the stream is < 256 kbps, then the overhead will be 20%
- If the stream is \geq 256 kbps, then the overhead will be 7%

Inter-region video call, with G.729 audio codec and video setting of 384 kbps:

- Initial request: $384 * 1.07 = 410$ kbps
- Updated request: $(384 - 8) * 1.07 = 402$ kbps

Inter-region video call, with G.711 audio codec and video setting of 384 kbps:

- Initial request: $384 * 1.07 = 410$ kbps
- Updated request: $(384 - 64) * 1.07 = 342$ kbps

Configuration Recommendation

Because the initial reservation will be larger than the actual packet flow, over-provisioning the RSVP and LLQ bandwidth is required to ensure that the desired number of calls can complete.

When provisioning the RSVP bandwidth value for N calls, Cisco recommends that the Nth value be the worst-case bandwidth to ensure that the Nth call gets admitted.

For example:

- To provision four G.729 streams:
 $(3 * 24) + 40 = 112$ kbps

- To provision four G.711 streams:
 $(3 * 80) + 96 = 336$ kbps
- To provision four 384 kbps video streams (G.729 audio)
 $(3 * (384 - 8) + 384) * 1.07 = 1618$ kbps
- To provision four 384 kbps video streams (G.711 audio)
 $(3 * (384 - 64) + 384) * 1.07 = 1438$ kbps

Configuring Cisco IOS Application ID Support

RSVP Application ID feature support was introduced in Cisco IOS Release 12.4(6)T, and that is the minimum release required for the following examples.

Combined Priority Queue

To utilize the functionality allowed in Unified CM's implementation of Application ID support (that is, allowing voice calls to consume all the bandwidth available in the priority queue), we must modify the previous recommendations that voice and video priority queues be kept separate. (See [RSVP Application ID and Unified CM, page 11-48](#).) To use this functionality, you should combine both the voice and video match criteria into one class-map. Because the requirements are to match either voice traffic or video traffic, be sure to make the class-map match criteria **match-any** instead of **match-all**, as follows:

```
class-map match-any IPC-RTP
  match ip dscp ef
  match ip dscp af41 af42
```

Configure the priority queue to support both the voice and video traffic. The following example configuration allocates 33% of the link bandwidth to the priority queue:

```
policy-map Voice-Policy
  class IPC-RTP
    priority percent 33
```

Mapping Application ID to RSVP Policy Identities

The RSVP Local Policy provides the mechanism for controlling a reservation based on an Application ID. Application IDs are mapped to RSVP Local Policies through the **ip rsvp policy identity** command. RSVP Local Policy identities are defined globally and are available to each interface for policy enforcement. Each identity can have one policy locator defined to match an Application ID.

To give the user as much flexibility as possible in matching application policy locators to local policies, the RSVP local policy command line interface (CLI) accepts application ID match criteria in the form of Unix-style regular expressions for the policy locator. Regular expressions are already used in the CLI for existing Cisco IOS components such as Border Gateway Protocol (BGP). Refer to the following documentation for more information on how regular expressions are used in Cisco IOS:

- *Access and Communication Servers Command Reference*
http://www.cisco.com/en/US/docs/ios/11_0/access/command/reference/arbook.html
- *Using Regular Expressions in BGP*
http://www.cisco.com/en/US/tech/tk365/technologies_tech_note09186a0080094a92.shtml
- *Regex Engine Performance Enhancement*
http://www.cisco.com/en/US/docs/ios/12_3t/12_3t4/feature/guide/gt_rexpe.html

RSVP Policy Identities for Matching the Default Unified CM Application IDs

```
ip rsvp policy identity rsvp-video policy-locator .*VideoStream.*
ip rsvp policy identity rsvp-voice policy-locator .*AudioStream.*
```

Interface RSVP Local Policies

Whether configuring Application ID support or not, for an interface to support RSVP, you must configure the **ip rsvp bandwidth** *<value>* command on that interface. This value cannot be exceeded by any one RSVP reservation or the sum of RSVP reservations on that interface, regardless of Application ID support. In fact, if a reservation passes the local policy check, it still must pass the interface RSVP bandwidth check before it is reserved.

Local policies based on Application ID are applied to an interface using the **ip rsvp policy local identity** command.

For reservations that match its policy locator value, a local policy has the ability to perform the following functions:

- Define the maximum amount of bandwidth the reservations can reserve as a group or as a single sender
- Forward or not forward RSVP messages
- Accept or not accept RSVP messages
- Define the maximum bandwidth the group or sender can reserve

For example, to limit the amount of video bandwidth to 384 kbps on a Serial T1, use the following commands:

```
interface Serial0/0/1:0
 ip rsvp bandwidth 506
 ip rsvp policy local identity rsvp-video
 maximum bandwidth group 384
 forward all
```

There is also a catch-all local policy called the default local policy. This local policy will match any RSVP reservation that did not match the other RSVP local policies configured on the link. The default local policy can be used to match reservations that are not tagged with an Application ID or reservations that are tagged with an Application ID that you want to treat as untagged traffic.

Example

The following example supports both voice and video calls using the model discussed in [How Unified CM Uses the Application ID, page 11-48](#). The voice calls are guaranteed 352 kbps of bandwidth while video calls are limited to 154 kbps of bandwidth. Voice calls can use all of the available RSVP bandwidth.

```
interface Serial0/0/1:0
 ip address 10.2.101.5 255.255.255.252
 service-policy output Voice-Policy
 ip rsvp bandwidth 506
 ip rsvp data-packet classification none
 ip rsvp resource-provider none
 ip rsvp policy local identity rsvp-voice
 maximum bandwidth group 506
 forward all
 ip rsvp policy local identity rsvp-video
 maximum bandwidth group 154
 forward all
 ip rsvp policy local default
 no accept all ! Will not show in the configuration
```

```
no forward all! Will not show in the configuration
```

In this example, if an RSVP reservation is received that does not have an Application ID or its Application ID does not match the two configured options, the reservation will fail. This configuration works if RSVP traffic originates only from Cisco RSVP Agents controlled by Unified CM. However, if there is intercluster RSVP traffic via an IP-IP gateway or if RSVP messages from a controller other than Unified CM are traversing this link, then the default local policy should be configured to accept and forward the reservations and a maximum bandwidth value should be configured on the policy. Note that it is possible to oversubscribe the RSVP bandwidth via the use of multiple RSVP local policies (if the sum of the policies is greater than the RSVP interface bandwidth), but reservations then become first-come, first-serve.

Provisioning for Call Control Traffic with RSVP and Centralized Call Processing

This section discusses bandwidth provisioning for call control traffic when RSVP is used as the call admission control mechanism in a centralized call processing deployment. For a more general discussion of bandwidth provisioning when RSVP is not used, see [.Provisioning for Call Control Traffic with Centralized Call Processing, page 3-52](#)

Considerations for Calls Using RSVP

In systems where call admission control uses RSVP, there is additional SCCP call control traffic between Unified CM and the Cisco RSVP Agents located at the branch when IP calls are placed across the WAN. To compute the associated bandwidth, use the following equation:

$$\text{Bandwidth (bps)} = (21 * \text{CHW}) * (\text{Number of IP phones and gateways in the branch})$$

Where CHW represents the number of calls placed across the IP WAN per hour per phone, including calls between IP phones at different branches as well as calls made through gateways located in a different site. For example, in a site where 20 phones each make 10 calls per hour, if 20% of the calls are placed across the IP WAN, then CHW = 2. The equation thus yields:
 $(21 * 2) * 20 = 840 \text{ bps}$.

The bandwidth calculated by this equation should be added to the required bandwidth for phone call control.

Unified CM RSVP-Enabled Locations

Cisco Unified CM provides a topology-aware call admission control mechanism based on the Resource Reservation Protocol (RSVP), which is applicable to any network topology and which eases the restriction of a traditional hub-and-spoke topology. The Cisco RSVP Agent is a Cisco IOS feature that enables Unified CM to perform the RSVP-based call admission control. For information on which Cisco IOS platforms support the Cisco RSVP Agent, refer to the *Cisco RSVP Agent Data Sheet*, available at

http://www.cisco.com/en/US/partner/products/ps6832/products_data_sheets_list.html

The Cisco RSVP Agent registers with Unified CM as either a media termination point (MTP) or a transcoder device with RSVP support. When an endpoint device makes a call in need of a bandwidth reservation, Unified CM invokes a Cisco RSVP Agent to act as a proxy for the endpoint to make the bandwidth reservation.

Figure 11-22 shows the signaling protocols used between Unified CM and various other devices, as well as the associated RTP streams for calls across the WAN in a given location. For any calls across the WAN, Unified CM directs the endpoint devices to send the media streams to their local Cisco RSVP Agent, which originates another call leg synchronized with an RSVP reservation to the Cisco RSVP Agent at the remote location. Figure 11-22 illustrates the following signaling protocols:

- Cisco RSVP Agents register to Unified CM via Skinny Client Control Protocol (SCCP).
- IP phones register with Unified CM via SCCP or Session Initiation Protocol (SIP).
- PSTN gateways register with Unified CM via Media Gateway Control Protocol (MGCP), SIP, or H.323 protocol.

Figure 11-22 Protocol Flows for Locations with RSVP

Figure 11-23 shows a typical Cisco RSVP Agent deployment within a Unified CM cluster, which includes three locations: Central Site, Branch 1, and Branch 2. The IP WAN connecting the three locations can be of any topology type and is not restricted to the hub-and-spoke topology. For any call between two locations that requires an RSVP reservation in the media path, a pair of Cisco RSVP Agents is invoked dynamically by Unified CM. The Cisco RSVP Agent acts as a proxy to make an RSVP reservation for the IP phone in the same location with the Cisco RSVP Agent. For example, when phone A in Branch 1 calls phone E in the Central Site, an RSVP reservation (illustrated as the red line in Figure 11-23) is established between Cisco RSVP Agents in the Branch 1 and Central Site locations.

There are three call legs for the media streams of this call. The first call leg is between phone A and the Branch 1 Cisco RSVP Agent, the second call leg is between the Branch 1 and Central Site Cisco RSVP Agents, and the third call leg is between the Central Site Cisco RSVP Agent and phone E. By the same token, when phone B in Branch 1 calls phone D in Branch 2, the RSVP reservation is established between the Branch 1 and Branch 2 Cisco RSVP Agents. Note that the media streams of a call between two branch locations are not sent through the Central Site in this case, which is different from a call made over the traditional hub-and-spoke topology using call admission control based on static locations.

**Note**

While RSVP-enabled locations and the use of Cisco RSVP Agent introduce support for arbitrary WAN topologies, they are based on static assignment of devices to a location, which means that every time a device is moved from one physical site to another, its configuration in Unified CM needs to be updated. Device Mobility can be used to update site-specific device configuration information automatically when the device moves to a new physical site. For more information, see the section on [Device Mobility](#), page 25-16.

Figure 11-23 Cisco RSVP Agent Concept

Cisco RSVP Agent Provisioning

The capacity of Cisco RSVP Agent in terms of simultaneous calls (also referred to as sessions) depends on the following factors:

- For software-based MTP functionality, the session capacity is determined by the router platform and the relative CPU load. (Refer to the *Cisco RSVP Agent Data Sheet*, available at http://www.cisco.com/en/US/products/ps6832/products_data_sheets_list.html.)
- For hardware-based MTP and transcoder functionality, the session capacity is limited by the number of DSPs available. (See [Media Resources](#), page 17-1, for DSP sizing considerations.)

For more information on supported platforms, requirements, and capacities, refer to the *Cisco RSVP Agent Data Sheet*, available at:

http://www.cisco.com/en/US/products/ps6832/products_data_sheets_list.html

For software-based MTP functionality, the *Cisco RSVP Agent Data Sheet* provides guidelines for session capacity based on a router dedicated to the Cisco RSVP Agent and 75% CPU utilization. These numbers apply to specific Cisco IOS releases and should be considered as broad guidelines. Different combinations of specific services, configurations, traffic patterns, network topologies, routing tables, and other factors can significantly affect actual performance for a specific deployment and hence reduce the number of concurrent sessions supported. Cisco recommends careful planning and validation testing prior to deploying a multi-service router in a production environment.

Cisco RSVP Agent Registration

The Cisco RSVP Agent registers with Unified CM as an MTP or transcoder device with RSVP support. The Cisco RSVP Agent does not have transcoding capability when registering as an MTP device. To have transcoding capability, the Cisco RSVP Agent must register with Unified CM as a transcoder device.

Registration Switchover and Switchback

If the primary Unified CM fails, the Cisco RSVP Agent switches over to the secondary Unified CM. When the primary Unified CM recovers from the failure, the Cisco RSVP Agent switches its registration back to the primary Unified CM. Use the following commands to configure the Cisco RSVP Agent registration switchover and switchback:

```
scp ccm group
  switchover method immediate
  switchback method guard timeout 7200
!
gateway
  timer receive-rtp 180
```

- The **switchover method immediate** command specifies the immediate registration switchover to the secondary Unified CM server after failure of the primary Unified CM server is detected. The available DSP resources become available immediately for new calls after the switchover has completed.
- The **switchback method guard timeout 7200** command specifies the registration switchback mechanism after the primary Unified CM recovers from its failure. With this command configured, the Cisco RSVP Agent starts to switch its registration gracefully back to the primary Unified CM after the last active call disconnects. If the graceful registration switchback has not initiated by the time the guard timer expires, the Cisco RSVP Agent will use the immediate switchback mechanism and register with the primary Unified CM right away. The default value of the guard timer is 7200 seconds, and it can be configured statically in the range of 60 to 172800 seconds.
- The **timer receiver-rtp** command in the gateway configuration mode defines the RTP clean-up timer for RSVP reservations. If a failure occurs, the RSVP reservation for the existing call will stay in place until the RTP clean-up timer expires. The default value of this timer is 1200 seconds. Cisco recommends that you configure this timer with its lowest allowed value, which is 180 seconds.

Maximum Sessions Support

The Cisco RSVP Agent supports a maximum number of calls or sessions, based on the software-based (CPU) and hardware-based (DSP) resources equipped on the Cisco RSVP Agent router. The **maximum sessions** command in the **dspfarm profile** configuration mode specifies the maximum number of calls

that the Cisco RSVP Agent is able to handle. The Cisco RSVP Agent notifies Unified CM of its session capacity based on this configuration. The maximum number of sessions decreases by one for every call going through the Cisco RSVP Agent. When the counter reaches zero, the Cisco RSVP Agent is regarded as having no resources available, and Unified CM skips that Cisco RSVP Agent for any subsequent calls.

Figure 11-24 shows a branch site with dual Cisco RSVP Agents. The Cisco RSVP Agents are co-resident with the WAN routers, and Cisco RSVP Agent redundancy is achieved by assigning two Cisco RSVP Agents to different MRGs in the same MRGL. If Agent-1 in MRG-1 is unavailable or out of session capacity, Unified CM will try to allocate Agent-2 in MRG-2 for RSVP calls to or from Branch 1. To ensure that Agent-2 is selected when Agent-1's capacity is reached, Cisco recommends configuring the maximum number of sessions to match exactly the number of calls supported by the **ip rsvp bandwidth** configured on the WAN interface of the Cisco RSVP Agent. In this example, both Cisco RSVP Agents need to be configured with **maximum sessions 1**. This recommendation is made on the assumption that all calls going across the WAN will use the same type of codec so that an accurate calculation of the number of calls across the WAN can be derived, which is done by dividing the total available RSVP bandwidth by the bandwidth requested per call.

Note

If the maximum number of sessions is higher than the number of calls supported by the **ip rsvp bandwidth** configuration, Unified CM will still send the call to the Cisco RSVP Agent but the RSVP reservation will fail because there is no bandwidth available, and Unified CM will follow the usual behavior for call admission control failure (that is, it will deny the call or invoke the AAR feature).

Figure 11-24 Configuring Maximum Sessions on the Cisco RSVP Agent

Pass-Through Codec

The pass-through codec enables a Cisco IOS Enhanced MTP device to terminate an RTP media stream received from an endpoint without knowing the media encoding of the stream. That is, the UDP packets of the media stream flow through the MTP without being decoded. This method enables the MTP to support every audio, video, and data codec that is defined in Unified CM. Because the MTP does not decode the media stream, the pass-through codec can also be used with encrypted (SRTP) media streams.

In fact, for video and SRTP media streams to use an MTP, it must support the pass-through codec. When configured with the pass-through codec, the Cisco RSVP Agent will substitute its own IP address for the source IP address in the IP/UDP headers of the packets and let them flow through.

The Cisco RSVP Agent will use the pass-through codec only if all of the following conditions are met:

- The two endpoint devices involved in the call have matching audio codec capability, and the region configuration permits the matching codec to be used for the call. In other words, no transcoder device needs to be inserted in the call.
- **MTP Required** is not configured for either endpoint device.
- All intermediate resource devices support the pass-through codec.

Note

If the Cisco RSVP Agent registers as an MTP device and a transcoder device needs to be inserted in the call, the codec configured in the Cisco RSVP Agent dspfarm MTP profile must match the inter-region codec configured in Unified CM Administration. For example, if the G.729 codec is the inter-region codec configured in Unified CM Administration, then the G.729 codec must also be configured in the dspfarm MTP profile.

The following example shows an Cisco RSVP Agent configuration on a Cisco 2800 IOS platform:

```
interface Loopback0
 ip address 10.11.1.100 255.255.255.255
!
sccp local Loopback0
sccp ccm 20.11.1.50 identifier 1 priority 1 version 8.0
sccp ccm 20.11.1.51 identifier 2 priority 2 version 8.0
sccp
!
sccp ccm group 1
 associate ccm 1 priority 1
 associate ccm 2 priority 2
 associate profile 1 register RSVPAgent
 switchover method immediate
 switchback method guard timeout 7200
!
dspfarm profile 1 mtp
 codec pass-through
 codec g729ar8
 rsvp
 maximum sessions software 100
 associate application SCCP
```

RSVP Policy

Unified CM can apply different RSVP policies to different location pairs. The RSVP policy can be configured in Unified CM Administration. The RSVP policy defines whether or not Unified CM will admit the call if the RSVP reservation attempt fails. The following RSVP policy settings can be configured between any two locations:

- **No Reservation**
No RSVP reservation attempt is made, and only static-locations call admission control is performed by Unified CM.

- **Mandatory**
Unified CM does not ring the terminating endpoint device until the RSVP reservation succeeds for the audio stream and, if the call is a video call, for the video stream as well.
- **Mandatory (Video Desired)**
A video call can proceed as an audio-only call if a reservation for the video stream cannot be reserved but the reservation for the audio stream succeeds.
- **Optional (Video Desired)**
A call can proceed as a best-effort audio-only call if it fails to obtain reservations for both its audio and video streams. The Cisco RSVP Agent re-marks the media packets as best-effort.
- **Use System Default**
The RSVP policy for the location pair matches the clusterwide RSVP policy. The default clusterwide RSVP policy is No Reservation. To change the default RSVP policy in Unified CM Administration, select **System > Service Parameters > Cisco CallManager Service.> Default Inter-location RSVP Policy**

**Note**

With the Optional (video desired) policy, IP WAN calls may proceed as best-effort not only if the RSVP reservation fails but also if the Cisco RSVP Agent is not available. In this case, Unified CM instructs SCCP and MGCP devices to re-mark their traffic as best-effort. However, this re-marking is not possible with H.323 and SIP devices, which will keep sending their traffic with the default QoS marking. To prevent over-subscribing the priority queue in the latter case, Cisco recommends configuring an access control list (ACL) on the IP WAN router to permit only packets marked with DSCP EF or AF41 if the source IP address is that of the Cisco RSVP Agent.

Figure 11-25 shows both the default and recommended configurations of the RSVP clusterwide parameters. Cisco recommends configuring the RSVP policy as **Mandatory** or **Mandatory (Video Desired)** because those settings guarantee the bandwidth reservation and the voice quality of the call. The most efficient method for setting the clusterwide RSVP policy is to configure the **Default Inter-location RSVP Policy** in the RSVP clusterwide parameters of the Cisco CallManager Service Service Parameter Configuration, and leave the RSVP configuration in the location configuration set to **Use System Default**.

Figure 11-25 *Setting RSVP Clusterwide Parameters*

| Clusterwide Parameters (System - RSVP) | | |
|---|---|--------------------------|
| Default inter-location RSVP Policy * | Mandatory | No Reservation |
| RSVP Retry Timer * | 60 | 60 |
| Mandatory RSVP Mid-call Retry Counter * | 1 | 1 |
| Mandatory RSVP mid call error handle option * | Call fails following retry counter exceeded | Call becomes best effort |

141857

In the clusterwide RSVP parameters configuration, there is a service parameter named **Mandatory RSVP mid call error handle option**. If the RSVP policy is configured as **Mandatory** or **Mandatory (Video Desired)**, this parameter specifies how Unified CM will treat an existing RSVP call based on the failure of a mid-call RSVP reservation attempt. The mid-call RSVP reservation attempt can be triggered by (but is not limited to) a network convergence after a WAN failure or by an existing voice-only call becoming a video call. A network convergence makes the Cisco RSVP Agent not only start to send the media streams over the newly converged path but also to try to make a new RSVP reservation over the new path.

The default setting of the **Mandatory RSVP mid call error handle option** is **Call Becomes Best Effort**. With the default option configured, Unified CM will maintain the existing call even though the mid-call RSVP reservation attempt fails, but the RTP streams will be marked as best effort (DSCP 0). Cisco recommends configuring this parameter with the **Call Fails Following Retry Counter Exceeded** option. With this option configured, Unified CM will fail the call if the RSVP reservation attempt keeps failing after a certain number of retries. The default value of the retry counter is 1, which is defined by the **RSVP Mandatory mid-call retry counter** service parameter, and the default value of **RSVP retry timer** is 60 seconds. Cisco recommends having both the retry counter and the retry timer service parameters configured with their default values. With both set to their default values, Unified CM will wait for 60 seconds before it disconnects the call if the RSVP mid-call retry fails. During this period, users might experience degraded voice quality because no RSVP reservation is in place and the RTP streams are marked as best effort.

Migrating from Static Locations to RSVP Call Admission Control

The example in this section illustrates the best practices for migrating from the traditional static-locations call admission control to the RSVP-based call admission control mechanism.

[Figure 11-26](#) shows a centralized call processing deployment with the static-locations call admission control mechanism. There are four locations in the Unified CM cluster, including the Hub_None location and three branches. For simplicity of illustration, the bandwidth used in this example refers only to the voice stream bandwidth. [Table 11-5](#) and [Table 11-6](#) show that every branch location is statically provisioned with 256 kbps of bandwidth, and the Hub_None location is provisioned with **Unlimited** bandwidth. The RSVP setting between any pair of locations is configured with **Use System Default**, and the clusterwide RSVP setting is configured with the default value **No Reservation**.

Figure 11-26 Configuration with Static Locations for Call Admission Control

Table 11-5 Locations and Bandwidth Settings for the Example in Figure 11-26

| Location Name | Bandwidth |
|---------------|-----------|
| Hub_None | Unlimited |
| Branch 1 | 256 kbps |
| Branch 2 | 256 kbps |
| Branch 3 | 256 kbps |

Table 11-6 *RSVP Policy for the Example in Figure 11-26*

| Locations Pair | | Policy |
|----------------|-----|----------------|
| Any | Any | No Reservation |

To migrate to RSVP-based call admission control, Cisco recommends migrating one location at a time. For example, if Branch 1 is the first location to be migrated, observe the following procedures:

- Set up a Cisco RSVP Agent in the Branch 1 location and assign it to the Branch 1 MRG and MRGL to associate it with the Branch 1 IP phones.
- Set up another Cisco RSVP Agent in the Hub_None location and include this Cisco RSVP Agent in the MRG and MRGL that is associated to all the IP phones in the remaining three locations, including the Hub_None location. Note that this Cisco RSVP Agent should not be included in the Null MRG or Branch 1 MRG, otherwise it is possible that a Branch 1 phone will use the Cisco RSVP Agent at the Hub_None location to make RSVP reservations.
- Configure the Branch 1 bandwidth as **Unlimited**.
- Configure the RSVP setting between Branch 1 and any other location as **Mandatory**. For example, for a call between Branch 1 and Branch 2 phones, the voice stream will still be hair-pinned through the Hub_None location. For the first call leg between the Branch 1 and Hub_None locations, a RSVP reservation will be made between the Branch 1 and Hub_None Cisco RSVP Agents. For the second call leg between the Hub_None and Branch 2 locations, Unified CM will perform call admission control based on static locations by checking the bandwidth availability for the Branch 2 location.

Table 11-7 and Table 11-8 show the location bandwidth and RSVP policy configuration after the migration at Branch 1.

Table 11-7 *Locations and Bandwidth Settings After Migration of Branch 1*

| Location Name | Bandwidth |
|---------------|-----------|
| Hub_None | Unlimited |
| Branch 1 | Unlimited |
| Branch 2 | 256 kbps |
| Branch 3 | 256 kbps |

Table 11-8 *RSVP Policy After Migration of Branch 1*

| Locations Pair | | Policy |
|---------------------|---------------------|----------------|
| Branch 1 | Any | Mandatory |
| All other locations | All other locations | No Reservation |

Table 11-9 and Table 11-10 show the location bandwidth and RSVP policy configurations after the clusterwide migration. With the clusterwide migration completed, any inter-site call will require a RSVP reservation to be made directly between two Cisco RSVP Agents, and the voice stream will be transported over the bandwidth reservation path.

The following procedures can be used to migrate Branch 2 and Branch 3 to RSVP call admission control:

- Set up a Cisco RSVP Agent in the Branch 2 location and assign it in the Branch 2 MRG and MRGL that is associated with the Branch 2 IP phones. Be sure to remove the Cisco RSVP Agent of the Hub_None location from the Branch 2 MRG so that the Cisco RSVP Agent in the Hub_None location will no longer be accessed by the IP phones in Branch 2.
- Configure the Branch 2 bandwidth as **Unlimited**.
- Configure the RSVP setting between Branch 2 and any other location as **Mandatory**.
- Set up a Cisco RSVP Agent in the Branch 3 location and assign it in the Branch 3 MRG and MRGL that is associated with the Branch 3 IP phones. Be sure to remove the Cisco RSVP Agent of the Hub_None location from the Branch 3 MRG so that the Cisco RSVP Agent of the Hub_None location will no longer be accessed by the IP phones in Branch 3.
- Configure the Branch 3 bandwidth as **Unlimited**.
- Configure the RSVP setting between Branch 3 and any other location as **Mandatory**.

Table 11-9 Locations and Bandwidth Settings After Migration Is Complete

| Location Name | Bandwidth |
|---------------|-----------|
| Hub_None | Unlimited |
| Branch 1 | Unlimited |
| Branch 2 | Unlimited |
| Branch 3 | Unlimited |

Table 11-10 RSVP Policy After Migration Is Complete

| Locations Pair | Policy |
|----------------|-----------|
| Any | Mandatory |

RSVP Application ID and Unified CM

The RSVP Application ID is a mechanism that enables Unified CM to add an identifier to both the voice and video traffic so that the Cisco RSVP Agent can set a separate bandwidth limit on either traffic based on the identifier received. To deploy the RSVP Application ID in the network, you must use a minimum version of Cisco IOS Release 12.4(6)T or higher on the Cisco RSVP Agent router. The RSVP Application ID strings can be configured via two service parameters in the clusterwide RSVP parameter configuration: **RSVP Audio Application ID** and **RSVP Video Application ID**.

Unified CM uses SCCP to convey the RSVP Application ID to the Cisco RSVP Agent. The Cisco RSVP Agent also inserts the RSVP Application ID into the RSVP signaling messages (such as the RSVP PATH and RESV messages) and sends those messages to the downstream or upstream RSVP routers.

How Unified CM Uses the Application ID

Unified CM has two cluster-wide service parameters that define the Application ID used to tag audio and video call reservations using RSVP:

- RSVP Audio Application ID (Default = AudioStream)
- RSVP Video Application ID (Default = VideoStream)

Figure 11-27 shows how Unified CM tags voice and video calls with an Application ID in RSVP.

Figure 11-27 Unified CM and RSVP Application ID

How Voice Calls Are Tagged

When a voice call is made between locations with an RSVP policy, the resulting reservations for the audio stream will be tagged with the RSVP Audio Application ID.

How Video Calls Are Tagged

When a video call is made between locations with an RSVP policy, the resulting reservations for the audio and video streams will both be tagged with the RSVP Video Application ID. A video call has both audio and video associated to the Video Application ID.

Note

This functionality is new in Cisco Unified CM 8.0, and it uses a model similar to the static locations model to separate the bandwidth of voice and video traffic. In static locations, the voice and video streams of a video call are both deducted from the video bandwidth counter. When using the RSVP Application ID in Unified CM 8.0, the same logic applies, and the voice and video streams of a video call are deducted from the video bandwidth Application ID.

RSVP Application ID Design Considerations and Best Practices

- The AudioStream Application ID is used for audio streams of audio-only calls.
- The VideoStream Application ID is used for both the audio and video streams of a video call.
- The Application ID does not currently differentiate between various types of video, such as telepresence video versus other video. All video in an RSVP session will be marked with the Video Application ID and the Video DSCP value.
- Unified CM currently has separate settings for both the Application ID and the DSCP values of the signaling and media streams. These are managed separately; however, Cisco recommends using the default values because they are configured to work in conjunction with one another.
- When video escalation occurs, the RSVP reservation for the audio stream is readmitted with the Video Application ID and configured DSCP value (PHB of AF41, by default). If the readmission for the audio stream fails due to insufficient bandwidth, the audio stream will continue as best-effort with a Video Application ID until the reservation into the Video Application ID pool succeeds.

- When video de-escalation occurs, the RSVP reservation for the audio stream is readmitted with the Audio Application ID and configured DSCP value (PHB of EF, by default). If the readmission for the audio stream fails due to insufficient bandwidth, the audio stream will continue as best-effort with an Audio Application ID until the reservation into the Audio Application ID pool succeeds.

Video Escalation Example with Application ID

An audio-only call is set up with the AudioStream Application ID, and the DSCP for the stream is set to a PHB value of EF. When the call is escalated video, the video streams are set up with the VideoStream Application ID. If the video stream reservation fails, the call will stay as an audio-only call with the AudioStream Application ID. However, if the video stream reservation succeeds, the audio stream will be readmitted from AudioStream Application ID to VideoStream Application ID. If the readmission succeeds, then both the video and audio streams will have the VideoStream Application ID set to a PHB value of AF41. If the readmission fails, then the video stream will have the VideoStream Application ID with a PHB value of AF41 while audio stream will have the VideoStream Application ID with a PHB set to 0 (video fail DSCP value).

See [Unified CM Video Calls with RSVP SIP Preconditions](#), page 11-57, for information on video escalation and de-escalation in distributed Unified CM environments with RSVP SIP Preconditions.

RSVP SIP Preconditions

RSVP SIP Preconditions is based on SIP Preconditions as defined in RFC 3312 and RFC 4032, and it offers the ability for Cisco call processing products to negotiate a level of Quality of Service and perform call admission control using the RSVP protocol. The term RSVP SIP Preconditions is used to identify the passing of policy information elements, or preconditions, over SIP signaling to negotiate a Quality of Service (QoS) policy. The actual RSVP message is not signaled over the SIP trunk; only the policy-related information elements are. The RSVP messages are then carried over by the RSVP Agent or RSVP-capable router. This use of SIP preconditions extends the negotiation of RSVP Quality of Service policy across Unified CM clusters as well as to Unified CM Express and SIP-TDM Cisco IOS gateways to allow for synchronization of the RSVP layer and call control layer between these various call control applications.

Overview of SIP Preconditions

As mentioned, SIP Preconditions provide for the negotiation of RSVP policy information across call control applications, thus allowing synchronization between these call control applications of the RSVP Layer for resource reservation and the call control layer for call setup and establishment.

The concept of a precondition in SIP signaling also avoids the potential for what is referred to as "ghost rings" across independent call control applications. Ghost rings can occur at session establishment time if the called party is rung without having first reserved the resources necessary to establish the media between the callers. In order to minimize ghost rings, network resources for the session must be reserved before the called party is alerted. However, the reservation of network resources frequently requires learning the IP address, port, and session parameters from the called party. This information is obtained as a result of the initial offer and answer exchange carried in SIP. This exchange normally causes the phone to ring, thus introducing a loop dilemma: resources cannot be reserved without performing an initial offer and answer exchange, but the initial offer and answer exchange cannot be done without performing resource reservation.

RSVP SIP Preconditions solves this dilemma by setting SIP Preconditions or constraints about the session that are introduced in the offer. The recipient of the offer generates an answer but does not alert the user or otherwise proceed with session establishment. Proceeding occurs only when the preconditions are met. This knowledge can be obtained through a local event, such as a confirmation of a resource reservation, or through a new offer sent by the calling party.

Figure 11-28 illustrates how these SIP Preconditions work in a generic SIP signaling call flow.

Figure 11-28 SIP with RSVP Between Call Agents

In Figure 11-28, a SIP user agent (SIP UA 1) starts the call by sending a SIP Invite message. The preconditions are in the SIP Invite in the Session Description Protocol (SDP), where the calling party's IP address and port number are identified. The preconditions stipulate a current QoS policy (`a=curr:qos`) and a desired QoS policy (`a=des:qos`). In this example, SIP UA 1 sends an invite to SIP UA 2 with a current QoS policy for the audio line set to **none** and the desired QoS policy is set to **mandatory e2e sendrecv**. This tells the receiver that an RSVP reservation is mandatory before offering the call (ringing the end device). The SIP UA 2 receiving the Invite then responds with a 183 session progress message with SDP stipulating a response to the preconditions sent. In this example, SIP UA 2 sends a current QoS policy as **none**, a desired QoS policy of **mandatory e2e sendrecv**, and a configured QoS policy (`a=conf:qos`) of **e2e recv**, indicating that it has received the request and will initiate a reservation using RSVP. At this point both user agents negotiate RSVP to reserve bandwidth for the media as described in the SDP. If this reservation succeeds, the UAs update one another with the updated QoS policy preconditions and then proceed with the call by ringing the end user. In the example, SIP UA 2 then

responds with a 180 Ringing message and the call can continue with normal establishment. If the reservation fails, then either SIP UA can terminate the call prior to ringing the called party. This avoids any "ghost ringing" condition.

Unified Communications Manager and RSVP SIP Preconditions

RSVP SIP Preconditions for Unified CM provides the functionality of intercluster call admission control in distributed Unified CM deployments. If you deploy RSVP SIP Preconditions in Unified CM, Cisco recommends having local RSVP-enabled locations-based call admission control fully functional prior to enabling RSVP SIP Preconditions. This approach is also recommended for migration purposes. For further details on enabling intra-cluster RSVP call admission control, see [Unified CM RSVP-Enabled Locations, page 11-38](#).

RSVP SIP Preconditions has two modes of configuration, local RSVP and end-to-end RSVP. These modes are configured on the SIP Trunk Profile in Unified CM administration pages.

Local RSVP

Local RSVP does not support reservations between two RSVP agents that are located in separate clusters. It uses two RSVP agents per cluster and does not use RSVP across the trunk that connects the clusters. This is the default configuration of the SIP Trunk Profile.

Figure 11-29 illustrates local RSVP in a distributed Unified CM deployment.

Figure 11-29 Local RSVP in a Distributed Unified CM Deployment

In [Figure 11-29](#), X indicates an endpoint in cluster 1, Y indicates an endpoint in cluster 2, and ICT1 and ICT2 indicate the intercluster trunks configured in clusters 1 and 2 respectively. The RSVP agents associated with the respective devices are also indicated. In this scenario, Cisco Unified CM cluster 1 controls the reservation between AgentBr1 and AgentHQ1, and Cisco Unified CM cluster 2 controls the reservation between AgentBr2 and AgentHQ2.

End-to-End RSVP

End-to-end RSVP configuration is available if the clusters are connected by a SIP trunk. End-to-end RSVP uses RSVP on the entire connection between the RSVP agents, and it uses only one RSVP agent per cluster.

[Figure 11-30](#) illustrates end-to-end RSVP in Unified CM.

Figure 11-30 End-to-End RSVP

In [Figure 11-30](#), X indicates an endpoint in cluster 1, Y indicates an endpoint in cluster 2, and ICT1 and ICT2 indicate the intercluster trunks configured in clusters 1 and 2 respectively. The RSVP agents associated with the respective devices are also indicated. In this scenario, Cisco Unified CM establishes an end-to-end RSVP connection directly between AgentBr1 and AgentBr2.

RSVP SIP Preconditions and Fallback to Local RSVP

Unified CM can be configured to fall back from end-to-end RSVP to local RSVP by configuring **Fall back to local RSVP** on the SIP Trunk profile. This fallback occurs only when the terminating side of the SIP trunk returns a SIP 420 response (Bad Extension), which indicates that the terminating side does not understand the preconditions. Fallback does not occur when a response such as a SIP 580 response

(Precondition Failed) is returned. In the case where an end-to-end RSVP SIP Preconditions failure occurs with a SIP 420 (Bad Extension) response during call establishment, Unified CM will invoke local RSVP. If this behavior is desired, a media resource group list with an RSVP Agent association must be assigned to the SIP intercluster trunk. If fallback to local RSVP is not configured, then Unified CM will continue down the route group and route list to another configured trunk or gateway (if configured), otherwise the call will fail.

This feature could be used in designs where a single SIP trunk could terminate to multiple destinations, where both SIP preconditions are supported and where they are not supported. An example might be with the Unified Proxy Server, where there is a single SIP trunk that is configured to a SIP proxy and the returned destination could be a terminating cluster that understands the SIP preconditions or a terminating cluster or SIP server that does not understand the SIP preconditions. Because there is only a single SIP trunk in this case, it would be enabled for RSVP SIP preconditions with fallback enabled. In cases where the terminating side does not understand the SIP preconditions, an RSVP agent can be associated to the SIP trunk in fallback mode so that, when a SIP 420 message (Bad Extension) is received and fallback occurs, a new SIP Invite will go out without the SIP preconditions. In cases where SIP preconditions are supported, the call will continue as explained in the [Overview of SIP Preconditions, page 11-50](#).

Cisco does *not* recommend enabling local RSVP fallback. Instead, a different route should be configured to reach the destination. Cisco recommends using a function such as Local Route Group or a similar function to reroute calls that fail RSVP call admission control to a gateway that is local to the calling device in order to extend the call over the PSTN.

Migration from Locations-Based Call Admission Control to RSVP SIP Preconditions

When migrating from locations-based call admission control to RSVP SIP Preconditions, it is important to first follow the migration recommendations in the section on [Migrating from Static Locations to RSVP Call Admission Control, page 11-45](#). Once migration of local static locations call admission control to local RSVP call admission control is complete, RSVP SIP Preconditions can be enabled on the SIP intercluster trunk.

The following steps are required to enable RSVP SIP Preconditions:

-
- Step 1** Configure a SIP intercluster trunk in each cluster, and direct it to the other cluster.
 - Step 2** Place the SIP intercluster trunks into their own location. All devices must be in a separate location from the SIP intercluster trunk location and have an inter-location RSVP policy of **Mandatory** or **Mandatory (Video Desired)**. The inter-location policy determines the RSVP policy that is sent over the SIP trunk in the preconditions. (See [Table 11-11](#), which lists the Unified CM inter-location policy that corresponds to the equivalent SIP audio and video precondition attributes.)
 - Step 3** Configure the intra-location RSVP policy of the SIP intercluster trunk to **Mandatory** or **Mandatory (Video Desired)**. Intra-location RSVP policy is accomplished by setting an inter-location RSVP policy of the specified location to itself. This is necessary for calls that are transferred back to the cluster on the same SIP intercluster trunk so that transfer does not fail.
 - Step 4** Configure the SIP profile of the SIP intercluster trunks on each Unified CM cluster by setting **RSVP Over SIP** to **E2E**, the **Fall back to local RSVP** field to your preference, and the **SIP Rel1XX Options** to **Send PRACK if 1XX contains SDP**.
-

**Note**

For the SIP trunk configuration, IPv6 is not supported on RSVP SIP Preconditions. Therefore, ensure that the IPv6 enablement checkbox **Enable ANAT for early offer calls** is not checked because it is not supported with RSVP SIP Preconditions.

**Note**

Unified CM ignores the **MTP Required** and **Use TRP** check boxes on the SIP trunk when it is configured for end-to-end RSVP.

As mentioned, the RSVP SIP Preconditions feature allows Unified CM endpoints to establish direct RSVP agent-to-agent reservations across clusters. [Figure 11-31](#) shows the components involved in a call made with RSVP SIP Preconditions.

Figure 11-31 RSVP SIP Preconditions, Distributed Unified CM Deployment Dual Cluster Design

[Figure 11-31](#) illustrates a typical dual cluster deployment with RSVP SIP Preconditions enabled. It includes four locations: Central Site 1, Branch 1, Central Site 2, and Branch 2. The IP WAN connecting the locations can be of any topology type and is not restricted to the hub-and-spoke topology. For any call between two clusters that requires an RSVP reservation in the media path, a Cisco RSVP Agent is invoked dynamically by each Unified CM cluster. The Cisco RSVP Agent acts as a proxy to make an RSVP reservation for the IP phone in the same location with the Cisco RSVP Agent. For example, when phone 1 in Branch 1 calls phone 2 in Branch 2, an RSVP reservation (illustrated as the red line in [Figure 11-31](#)) is established between Cisco RSVP Agents in the Branch 1 and Branch 2 locations. This

is similar to the media stream setup of a single cluster RSVP-enabled locations solution. The difference here is that the SIP trunk is passing the RSVP policy negotiation between the two Unified CM clusters so that only a single RSVP Agent is allocated per cluster location associated with the respective phones.

There are three call legs for the media streams of this call. The first call leg is between phone 1 and the Branch 1 Cisco RSVP Agent, the second call leg is between the Branch 1 and Branch 2 Cisco RSVP Agents, and the third call leg is between the Branch 2 Cisco RSVP Agent and phone 2. Note that the media streams of a call between two branch locations are not sent through the central site in this case, which is different from a call made over the traditional hub-and-spoke topology using call admission control based on static locations.

There are five call legs for the signaling of this same call. The first call leg is between phone 1 and Unified CM Cluster 1; the second leg is between the Branch 1 Cisco RSVP Agent and Unified CM Cluster 1; the third call leg is between Unified CM Cluster 1 and Unified CM Cluster 2; the fourth is between Unified CM Cluster 2 and the Branch 2 Cisco RSVP Agent; and the fifth and last call leg is between Unified CM Cluster 2 and phone 2.

In [Figure 11-31](#), Phone 1 in Cluster 1 Branch 1 calls a Phone 2 in Cluster 2 Branch 2. The call signaling between the phones and Unified CM could be SCCP or SIP, and the signaling between Unified CMs will be SIP with the RSVP SIP Preconditions feature enabled. When Phone 1 initiates a call to Phone 2, the Cluster 1 server allocates an RSVP Agent to Phone 1 based on the RSVP Agent located in Phone 1's media resource group and list, and it then extends the call over the SIP trunk to Cluster 2 with SIP preconditions (RSVP Policy). The preconditions that are advertised in the SIP INVITE to Cluster 2 are a derivative of the inter-location policy configured between the locations of Phone 1 and the SIP trunk in Cluster 1. So in this case, on Cluster 1 the inter-location policy between locations Branch 1 and HQ is set to Mandatory (Video Desired). For details about Unified CM policy, see [RSVP Policy, page 11-43](#). This inter-location policy determines the policy set on the outbound SIP INVITE to Cluster 2. At this point, Cluster 2 receives a SIP INVITE from Cluster 1 with preconditions set to Mandatory. Cluster 2 then allocates an RSVP Agent to Phone 2 based on its media resource group and list, and also checks the configured locations between the SIP trunk on Cluster 2 and Phone 2 in Branch 2. If this policy is also Mandatory, then Cluster 2 responds with a 183 SESSION PROGRESS message (followed by a PRACK) and starts the RSVP negotiation between the two RSVP Agents in Branch 1 and Branch 2. Once the RSVP Agents have successfully negotiated a reservation for the call, they will inform their respective clusters and the SIP signaling will progress through to ringing stage.

[Table 11-11](#) compares the Unified CM inter-location policy to the equivalent SIP audio and video precondition attribute. (For details about Unified CM RSVP Policy, see [RSVP Policy, page 11-43](#).)

Table 11-11 Unified CM RSVP Policy and Equivalent SIP Preconditions

| Unified CM RSVP Policy | SIP Precondition (Audio Call) | SIP Precondition (Video Call) |
|---------------------------|-------------------------------|--|
| No Reservation | audio = none | audio = none video = none |
| Optional (Video desired) | audio = optional | audio = optional video = optional |
| Mandatory | audio = mandatory | audio = mandatory video = mandatory |
| Mandatory (Video desired) | audio = mandatory | audio = mandatory video = optional |

Unified CM Video Calls with RSVP SIP Preconditions

Unified CM supports video escalation and de-escalation across Unified CM clusters with RSVP SIP Preconditions. Video escalation occurs when an ongoing audio-only call is escalated to video or when a video stream is added to the audio-only call. Conversely, de-escalation is the downgrading or de-escalating of a video call to an audio-only call.

In order to support video escalation and de-escalation across clusters with RSVP SIP Preconditions, Unified CM signals two media lines (or m-lines) in the SIP Preconditions within the SIP Session Description Protocol (SDP), one for the audio stream and one for the video stream. Having separate media lines for both audio and video allows each stream to have its own RSVP policy and status in SIP signaling. Because the audio and video streams have their own precondition attributes Unified CM, RSVP policies can be mapped easily into the preconditions. This function allows Unified CM to pass the successful status of an audio stream reservation while simultaneously passing the failed status of the video stream reservation, the potential of a Mandatory (Video Desired) policy, thus allowing the call to be downgraded from a video call to an audio-only call, without rejecting the call entirely.

The video bandwidth reserved for RSVP SIP Preconditions is set to the value configured between the region pair. In this case that would be the region of the endpoint and the SIP intercluster trunk region. Video bandwidth is then adjusted after the video channel is established. Cisco recommends ensuring a video bandwidth value that is greater than or equal to the expected negotiated bit rate of any two endpoints between the region pairs.

For mid-call video escalation, the video stream will be set up only after having video bandwidth reserved.

During hold/resume of a video call, video and audio bandwidth will continue to be reserved while connecting to music on hold.

For other supplementary services such as transfer, Unified CM triggers video reservation and video stream setup after the audio stream completes setup (this is also known as delayed video escalation).

Example 11-1 Delayed Video Escalation: Call transfer from audio-only to video call with RSVP SIP Preconditions

Video device A in cluster A calls audio device B in cluster B through a SIP trunk with RSVP SIP Preconditions enabled. The call is set up as an audio call whose audio streams are allocated to the audio pool with AudioStream Application ID and PHB (Per Hop Behavior) of EF.

Device B transfers the call to a video device C in cluster B. Audio streams between A and C are first established in the audio pool with AudioStream Application ID and PHB of EF.

Delayed video escalation happens between A and C only after the audio media connection is successful. The video streams are allocated to the video pool with VideoStream Application ID. If the video stream allocation fails, the call will stay as an audio-only call with AudioStream Application ID and PHB of EF. If the video stream reservation succeeds, the audio stream will be re-admitted from the audio pool to the video pool with the VideoStream Application ID. If the re-admission succeeds, then video and audio streams will have the VideoStream Application ID with a PHB of AF41. However, if the re-admission fails, then the video stream will have the VideoStream Application ID with a PHB of AF41 while the audio stream will have the VideoStream Application ID with PHB of 0 (video fail best effort value).

Unified CM and RSVP SIP Preconditions Best Practices and Design Considerations:

- The SIP trunk should always have both an inter-location and an intra-location RSVP policy. The inter-location policy ensures that the correct RSVP policy is set for inbound and outbound calls. The intra-location policy ensures that calls hair-pinned on the same trunk (due to intercluster forward and transfer operations) are ensured an end-to-end RSVP policy.
- Cisco recommends configuring a **Mandatory** or **Mandatory (Video Desired)** RSVP policy because those settings guarantee the bandwidth reservation and the voice quality of the call.
- Cisco recommends configuring the SIP trunk profile with the **SIP Rel1XX Options** field set to **Send PRACK if 1XX contains SDP**. A SIP PRACK message is required for RSVP SIP Preconditions operation, but only for 1XX messages containing SDP.
- Ensure the configuration of each cluster in an RSVP SIP Preconditions deployment is standardized across the solution so that the RSVP cluster service parameters, inter-location policies, and codecs used across the WAN as well as on the RSVP Agent are the same. It is important to ensure there is no mismatch in capabilities or configuration across the clusters when call establishment is being attempted.
- Unified CM with RSVP SIP Preconditions supports termination to shared lines across clusters, subject to the following guidelines and restrictions:
 - When setting up a call across clusters to a shared line, the RSVP reservation occurs between the calling device's RSVP Agent and the first RSVP Agent allocated for the shared line device. (This is not controllable by programming.) All other devices with this shared line in separate locations will only allocate an RSVP Agent and not establish a reservation.
 - One RSVP Agent is allocated to each location where one or more devices of the shared line exist.
 - If the device that had the first RSVP Agent allocated is the device that answers the call, then the call establishment will take place and the RSVP Agents that were allocated to other shared line devices in other locations will be released.
 - If a device that did not have a reservation established answers the call, then a new reservation will be initiated between the calling devices RSVP Agent and the one allocated for the answering device with an optional RSVP policy, and the RSVP Agents will continue to try the reservation for the duration of the call until a reservation is successful. During the time that the call is under an optional policy and the **Mandatory RSVP mid call error handle option** is set to **Call becomes best effort** (default), then the media stream between the two devices will be marked best-effort until a reservation succeeds, in which case the media will be re-marked to a PHB (Per Hop Behavior) value of EF (audio) or AF41 (video).
 - If the device that had the first RSVP Agent allocated fails the RSVP reservation with a Mandatory policy, then neither that device nor any device in that location will be rung. However, the shared line devices in all other location will be rung.
- Based on the above shared line limitations, Cisco recommends restricting a shared line to a group of devices within the same location.
- Unified CM with RSVP SIP Preconditions supports termination to Mobile Connect destinations (remote destinations), subject to the following guidelines and restrictions:
 - Local RSVP: For remote destinations to devices, gateways, or trunks that are remote to the calling device, gateway, or trunk, apply the same rules as explained above in the shared line support.
 - End-to-end RSVP: Remote destinations for any single line should not point to more than one RSVP SIP Preconditions destination. Unified CM supports only one RSVP SIP Preconditions call per line for remote destinations.

- If the MoH server is in the same location as the holding party (the party placing another party on hold), the initial reservation is reused and no new reservation is made.
- Hold/Resume functionality with RSVP SIP Preconditions will break the media streams across endpoints and RSVP agents, but the reservation will still be preserved.
- sRTP is supported with RSVP SIP Preconditions and is negotiated during media setup and after RSVP reservation. Unified CM does not signal RTP/SAVP and crypto attributes during the precondition phase.
- T.38 is supported with RSVP SIP Preconditions and negotiated from SIP, H.323, and MGCP endpoints supporting T.38 fax transmission. Unified CM will negotiate an initial reservation using the inter-region audio bandwidth (between the endpoint and SIP intercluster trunk). After call establishment and upon T.38 switchover, the bandwidth usage will be readjusted to 80 kbps if it is not already set.
 - Limitation: If the inter-region bit rate is set to less than 80 kbps, then after T.38 switchover occurs, the RSVP reservation will be readjusted to 80 kbps. This can cause failure if the new adjusted bandwidth cannot be reserved. In such cases, if the reservation fails after switchover, the call will continue because Unified CM will not signal this failure over the SIP intercluster trunk.
 - For the above reason, when deploying T.38 fax with RSVP SIP Preconditions, Cisco recommends using 80 kbps as the inter-region audio bit rate between T.38 endpoints and the intercluster trunk enabled for RSVP SIP Preconditions.
- To support RSVP SIP Preconditions for supplementary services such as hold/resume, transfer, and conference, media resources such as the music on hold servers, annunciators, and conference bridges must have a local RSVP agent assigned to their respective device pools' media resource group list (MRGL).

**Note**

In various call flows for supplementary services such as hold/resume or transfer and conference, different media resources are brought into the RSVP SIP Preconditions call. Those media resources such as conference bridges, music on hold servers, and annunciators also require an RSVP Agent association, just as any other device would when invoked into a RSVP SIP Preconditions or RSVP-enabled locations call. These media resources obtain an RSVP resource from the media resource group list associated to the configured device pool.

Architecture and Considerations for Extension Mobility Cross Cluster

Extension Mobility Cross Cluster (EMCC) enables users in one cluster to log into IP phones of another cluster. For more detailed information about Extension Mobility Cross Cluster with regards to feature function, high availability, and scalability, see [Extension Mobility Cross Cluster \(EMCC\), page 19-9](#). The rest of this section covers the EMCC feature as it applies to call admission control. It also assumes an understanding of the information covered in [Extension Mobility Cross Cluster \(EMCC\), page 19-9](#).

In EMCC deployments, RSVP-enabled locations with RSVP SIP Preconditions is the only form of call admission control supported. Static locations-based call admission control is not supported and will not function in EMCC environments.

EMCC and RSVP-Enabled Environments

In Unified CM RSVP-enabled deployments with either RSVP-enabled locations (for single cluster or intra-cluster) or RSVP SIP Preconditions (for distributed clusters or inter-cluster), a local RSVP Agent must be invoked into the call flow by Unified CM to accomplish the RSVP signaling on behalf of the IP

phone. This is accomplished in EMCC environments by the passing of call control information between the Unified CM clusters to enable an EMCC user logged in remotely to make both intra-cluster and inter-cluster calls with RSVP.

In an EMCC deployment, there are always two clusters for any given login or registration interaction. From the EMCC user's perspective, this would be a home cluster and a visiting cluster (see [Figure 11-32](#)). The home cluster is the user's originating cluster, and it is where the user information is stored. The visiting cluster is the phone's originating cluster, where an EMCC user roaming between clusters would log in and where the device information is stored.

When a user logs into a visiting clusters phone (visiting phone), that phone in turn registers directly with the EMCC user's home cluster. All calls that are then made from that user and visiting phone are made from the call control of the home cluster. The home cluster thus manages the visiting phone and provides this visiting phone with an EMCC roaming device pool. (See [Extension Mobility Cross Cluster \(EMCC\)](#), page 19-9, for further information on EMCC roaming device pools.)

The home cluster makes requests to the visiting cluster for an RSVP Agent when required, and it does this over the EMCC-enabled SIP trunk between the two clusters (specifically in SIP REFER messages). An RSVP Agent is requested from the visiting cluster only when the home cluster has determined that the endpoint requires an RSVP Agent for a call. This is determined by the home cluster from the inter-location RSVP policy between the visiting phone's location (from the EMCC roaming device pool) and the called party's location (from the called party device, gateway, or trunk).

Once the RSVP policy is determined, an RSVP Agent is requested from the visiting cluster for the visiting phone. In this request for the RSVP Agent, the home cluster sends the device name (sepxxxxxxxxxxxx) so that the visiting cluster can do a look up on the device name to determine the RSVP Agent (derived from the MRGL on the device itself or on the device pool). Once the home cluster has the information for the RSVP Agent to associate to the visiting phone, it can start the procedures to establish a local RSVP call (RSVP-enabled locations within a cluster) or an RSVP SIP Preconditions call (between clusters).

[Figure 11-32](#) illustrates the signaling and media connections between the various components involved in an EMCC call using RSVP over a SIP-enabled trunk.

Figure 11-32 EMCC Call Using RSVP over a SIP-Enabled Trunk

Best Practices

- Set the location policy between the EMCC roaming device pool location and all other locations to **Mandatory (Video Desired)**.
- RSVP-enabled locations-based call admission control should be functioning prior to enabling EMCC in conjunction with RSVP SIP Preconditions.
- Any IP phone to which an EMCC user can log in must have a local RSVP Agent associated to it.

Unified CM Interoperability and Feature Considerations

This section discusses interoperability considerations between Unified CM and Cisco IOS Gateways and Unified CME.

Cisco IOS Gateway and Unified CME

Both Cisco IOS SIP/TDM gateways and Cisco Unified Communication Manager Express (Unified CME) support RSVP SIP Preconditions. This support enables audio-only calls to be established between Unified CM and the Cisco IOS SIP/TDM gateway or Unified CME signaling RSVP policy over SIP signaling.

For further information regarding SIP RSVP features in Cisco IOS and restrictions for the RSVP SIP Preconditions feature on SIP/TDM Cisco IOS gateways and Unified CME, refer to the *Cisco IOS SIP Configuration Guide*, available at

http://www.cisco.com/en/US/docs/ios/voice/sip/configuration/guide/12_4t/sip_12_4t_book.html

Unified CM has two modes of configuration when interoperating with Cisco IOS gateways and Unified CME in RSVP deployments: local RSVP supporting MGCP, H.323, and SIP call signaling, and end-to-end RSVP supporting SIP signaling only. When interoperating with Cisco IOS gateways and Unified CME, Unified CM can support both of these methods of operation. There are, however, implications when using one method or the other, as described in the following sections.

Unified CM and Local RSVP with Cisco IOS Gateways and Unified CME

In local RSVP mode, Unified CM supports interoperating with Cisco IOS TDM gateways over MGCP, H.323, or SIP call signaling protocols and with Unified CME over H.323 or SIP. In this mode, Unified CM allocates an RSVP agent to the Cisco IOS TDM gateway for calls established to or from the gateway, and it does not signal preconditions or RSVP policy to the Cisco IOS TDM gateway. This is the default configuration for MGCP, H.323, and SIP in Unified CM.

Figure 11-33 illustrates local RSVP integration of Unified CM with a Cisco IOS TDM gateway and with Unified CME.

Figure 11-33 Local RSVP Integration of Unified CM with a Cisco IOS TDM Gateway and Unified CME

Advantages

This model provides the following advantages:

- Support for a wide variety of Cisco IOS gateway signaling protocols (MGCP, H.323, SIP).
- Support for both SIP and SCCP Unified CME endpoints.
- Centralized administration of RSVP policy and Application ID from Unified CM.

- With MGCP for a Cisco IOS TDM gateway, the media path is optimized in call transfer and forward supplementary service scenarios. For calls transferred or forwarded from the local system (Cisco IOS TDM gateway), both media and signaling are torn down and re-established to the transferred or forwarded party.

Disadvantages

This model has the following disadvantages:

- It uses RSVP Agent sessions (software or hardware, depending on session requirements and functionality such as session transcoding).
- With H.323 and SIP integrations for Cisco IOS TDM gateways and Unified CME, the media path is not optimized in transfer and forward supplementary service scenarios. This means that calls transferred or forwarded from the local system (Cisco IOS TDM gateway or Unified CME) hairpin both media and signaling on the local system, which results in double bandwidth consumption.

In this method, intra-cluster call admission control functions as explained in the section on [Unified CM RSVP-Enabled Locations](#), page 11-38.

Unified CM and End-to-End RSVP or RSVP SIP Preconditions with Cisco IOS Gateway and Unified CME

In end-to-end RSVP mode, Unified CM supports interoperating with Cisco IOS gateways and Unified CME using RSVP SIP Preconditions signaling. In this mode, Unified CM does not allocate an RSVP agent. The Cisco IOS gateway or Unified CME natively supports RSVP. This method reduces the usage of RSVP agent software sessions on a Cisco Integrated Services Router (ISR).

[Figure 11-34](#) illustrates an RSVP SIP Preconditions integration between Unified CM and a Cisco IOS TDM gateway or Unified CME.

Figure 11-34 *RSVP SIP Preconditions Integration Between Unified CM and Cisco IOS Gateway or Unified CME*

Advantages

This model provides the following advantages:

- Support for RSVP SIP Preconditions.
- Does not use RSVP Agent resources for SIP Cisco IOS TDM gateways or Unified CME.

Disadvantages

This model has the following disadvantages:

- It supports only SCCP Unified CME endpoints.
- It supports only SIP trunk implementations.
- The media path is not optimized in transfer and forward supplementary service scenarios. This means that calls that are transferred from the local system (SIP Cisco IOS TDM gateway or Unified CME) hairpin both media and signaling on the local system, which results in double bandwidth consumption.

Design Considerations for Unified CM Interoperability with SIP Cisco IOS TDM Gateway and Unified CME

When choosing between local RSVP and end-to-end RSVP deployments, determine the best option based on following criteria:

- The desired call signaling protocol (H.323, MGCP, or SIP). This could be based on many requirements outside of the scope of call admission control, such as dial-plan, PBX interoperability, and call signaling features, to name a few.
- Required supplementary services of call transfer and forward to destinations remote to the local system (SIP Cisco IOS TDM gateway and Unified CME). For example, these services might be required for forwarding of calls over the WAN to centralized voice messaging environments.
- Administration of the solution. Decide between centralized or distributed management of RSVP policy and application ID.
- Resource utilization. Consider the utilization of RSVP Agent sessions versus native RSVP. In some cases the number of sessions might require a dedicated platform and thus cannot reside on the SIP Cisco IOS TDM gateway or Unified CME.
- The SIP trunk configured on Unified CM pointing to the SIP Cisco IOS TDM gateway or Unified CME supporting RSVP SIP Preconditions should always have both an inter-location and an intra-location RSVP policy. The inter-location policy ensures that the correct RSVP policy is set for inbound and outbound calls. The intra-location policy ensures that calls hair-pinned on the same trunk (due to forward and transfer operations) are ensured an end-to-end RSVP policy.
- In Unified CM, Cisco recommends configuring a single separate location that can be applied to all Cisco IOS TDM gateways and Unified CMEs configured on a single cluster. That location should have an inter-location RSVP policy set to **Mandatory** or **Mandatory (Video Desired)** with all other locations including itself. An RSVP policy is required for the correct functioning of RSVP SIP Preconditions in these environments.

Note

Even IP phones that are in the same physical LAN as the SIP Cisco IOS TDM gateway require an RSVP policy between their location and the location on the SIP trunk. This will utilize RSVP Agent resources for the IP phones but will not deduct bandwidth over the WAN because the RTP stream remains local.

- Ensure that the RSVP policy configured on Unified CM matches the policy configured on the Cisco IOS TDM gateway. Use the following options under the **dial-peer** configuration when enabling RSVP reservations for the SIP Cisco IOS TDM gateway or Unified CME:

```
req-qos guaranteed-delay audio
acc-qos guaranteed-delay audio
```

This configuration ensures that, for each voice call, the SIP Cisco IOS TDM gateway will request an RSVP reservation using the guaranteed delay service. The fact that both the requested QoS and the acceptable QoS specify this RSVP service means that the RSVP reservation is mandatory for the call to succeed (that is, if the reservation cannot be established, the call will fail).

- Ensure that the Application ID configured in Unified CM matches the Application ID configured on the Cisco IOS TDM gateway and Unified CME.
- Ensure that inbound and outbound dial peers are correctly matched to ensure that the appropriate dial peers configured with SIP preconditions are utilized. For further information, refer to the *Cisco IOS SIP Configuration Guide*, available at

http://www.cisco.com/en/US/docs/ios/voice/sip/configuration/guide/12_4t/sip_12_4t_book.html

Cisco Unified Border Element and RSVP SIP Preconditions

With Cisco Unified Communications System 8.5 and later releases, Cisco Unified Border Element offers audio-only call support for RSVP SIP Preconditions. This support enables enterprises to use the Unified Border Element to integrate non-RSVP call control applications into an RSVP SIP Preconditions infrastructure. On the non-RSVP side of the call control, the Unified Border Element supports integrations with both H.323 and SIP. On the RSVP side of the call, SIP can be used with RSVP Preconditions to integrate with RSVP SIP Preconditions call control such as Unified CM, Unified CME, and SIP-TDM Cisco IOS Gateways. [Figure 11-35](#) illustrates this type of interworking.

Figure 11-35 Cisco Unified Border Element with RSVP over SIP Trunks

For SIP integrations on the non-RSVP side of call control, the Unified Border Element provides support for either Early Offer or Delayed Offer; and for H.323 integrations, either Fast Start or Slow Start is also supported. On the RSVP SIP Preconditions side of call control, SIP Early Offer is always sent in order to provide the preconditions required to negotiate the RSVP policy across call control applications; therefore, RSVP SIP Preconditions is always Early Offer.

For more information, refer to the *Cisco IOS SIP Configuration Guide*, available at

http://www.cisco.com/en/US/docs/ios/voice/sip/configuration/guide/12_4t/sip_12_4t_book.html

Service Advertisement Framework (SAF) and Call Control Discovery (CCD) Considerations

The Cisco Service Advertisement Framework (SAF) enables networking applications to advertise and discover information about networked services within an IP network. Call Control Discovery (CCD) uses SAF to distribute and maintain information about the availability of internal directory numbers (DNs) hosted by call control agents such as Unified CM and Unified CME. CCD also distributes the corresponding number prefixes that allow these internal directory numbers to be reached via the PSTN ("To PSTN" prefixes).

This section discusses SAF CCD as it relates to RSVP SIP Preconditions deployments. For more information on the Service Advertisement Framework and Call Control Discovery, refer to the chapters on [Network Infrastructure, page 3-1](#), [Unified Communications Deployment Models, page 5-1](#), and [Dial Plan, page 9-1](#).

SAF CCD and RSVP SIP Preconditions work together to provide an easy to manage dynamic dial plan for moves, adds, and changes and a topology-aware call admission control method for complex, multi-homed, multi-tiered networks, thus providing a dynamic replacement for a static gatekeeper infrastructure for both dial plan resolution and call admission control that reacts to changes in the network.

SAF CCD works together with RSVP SIP Preconditions call admission control to ensure that there is an alternate route to reach the destination in case of reservation failure. This function is referred to as Call Control Discovery automatic PSTN failover.

Call Control Discovery Automatic PSTN Failover

SAF CCD is different than standard call routing in that only a single IP route can be chosen for any given call; whereas with standard call routing, multiple IP paths may be defined and consecutively attempted for a single call by using route lists and route groups. For any call made using SAF learned routes, the following options exist:

- Take the selected IP path to reach the called number.
- If the IP path is not available, use the PSTN prefix to modify the called number as well as the automatic alternate routing (AAR) calling search space (CSS) from the calling device and route the call via the PSTN.

When RSVP SIP Preconditions is used on a SAF learned route, and if the reservation succeeds, then the call will be established according to normal call establishment on the IP path with RSVP. However, if the reservation fails over the IP route with a returned call termination cause code of Precondition Failure or Reservation Failure (SIP message 580) or Precondition Unsupported (SIP message 420), CCD automatic PSTN failover will occur. (It can also occur on other call termination cause codes, as described below.) CCD automatic PSTN failover is similar to automated alternate routing (see [Automated Alternate Routing, page 9-108](#)) in that, when a SAF CCD IP route fails due to a call admission control failure, CCD automatic PSTN failover occurs much like AAR would occur in an intracluster call admission control failure scenario. However, CCD automatic PSTN failover is different from AAR in that it can also occur for other routing failures apart from call admission control. CCD automatic PSTN failover will occur on any call to a learned pattern that fails prior to the alerting phase of the call and that has a call termination cause code other than normal call clearing, user busy, destination out of order, unallocated number, or geo-location mismatch.

CCD automatic PSTN failover uses the AAR CSS as well as the "To PSTN" prefixes (distributed by CCD) to reroute the call. This allows the administrator to leverage the same Class of Service used for AAR call rerouting for local call admission control as for CCD automatic PSTN failover. A key difference is that CCD automatic PSTN failover uses a prefix provided by SAF CCD distribution ("To PSTN" prefix) and not the AAR prefixes.

Figure 11-36 illustrates CCD automatic PSTN failover after RSVP SIP Preconditions call admission control failure.

Figure 11-36 CCD Automatic PSTN Failover with RSVP SIP Preconditions

There is also a difference in functionality between a CCD automatic PSTN failover from a SAF CCD learned route and a reroute by route list and route group functionality with a static route pattern. With a static route pattern pointing to a route group and route list, when a RSVP SIP Preconditions reservation failure occurs, Unified CM routes the call to the next trunk or gateway configured in the route group and list.

In either case (using SAF or a static route pattern), Cisco recommends ensuring that the next choice after call admission control failure is to route the call to a local route group. (See [Local Route Group](#), page 9-13, for more information on local route groups.) This has to be done in the constructs of the CCD automatic PSTN failover function. It is important to ensure that the correct calling search space is configured in the AAR CSS of the calling party to ensure that, when the CCD automatic failover occurs, the call is directed to a route pattern that will engage the local route group function and route the call to the local gateway. This route pattern can be a catch-all pattern used specifically for all CCD automatic failover conditions to ensure the routing of calls out the gateway local of the calling party.

Cisco Unified SIP Proxy Considerations

The Cisco Unified SIP Proxy is a high-performance, highly available stateless Session Initiation Protocol (SIP) server for centralized routing and SIP signaling normalization. By forwarding requests between call control domains, the Cisco Unified SIP Proxy provides the means for routing sessions within enterprise and service provider networks. The main purpose for the Unified SIP Proxy in Cisco Unified Communications deployments is the aggregation of SIP signaling, SIP normalization, and dial plan centralization. For more information on the Cisco Unified SIP Proxy and its features and functions, refer to the documentation at

http://www.cisco.com/en/US/prod/collateral/modules/ps2797/data_sheet_c78-521390_ps2797_Products_Data_Sheet.html

In a RSVP SIP Preconditions environment, the Unified SIP Proxy simply passes along the preconditions that are contained the SDP portion of various SIP messages and does not modify the preconditions in any way.

Adaptive Security Appliance (ASA) Considerations

When deploying a Cisco ASA between any of the Cisco Unified Communications call processing applications such as Unified CM, Unified CME, Unified SIP Proxy, or Cisco IOS SIP/TDM gateway with RSVP SIP Preconditions, both of the following inspections are required:

- SIP Inspection

The SIP inspection allows the SIP signaling from any Cisco SIP signaling product to traverse the ASA. The ASA subsequently opens the appropriate media pinholes that are recorded in the SDP of the various SIP messages. This is important when the ASA is in the media path between RSVP Agents that are reserving bandwidth and sourcing media flows for Unified Communications endpoints.

- IP Options Inspection

The IP Options inspection allows the RSVP signaling from RSVP Agent to RSVP Agent to traverse the ASA. All RSVP messages have the IP Router Alert Option set in the IP header of every packet. The ASA drops these packets by default unless the IP Router Alert Option is allowed in the IP Options inspection so that these packets are allowed to flow through the ASA.

Support for both SIP inspection and IP Options inspection specific to RSVP SIP Preconditions implementation is provided in ASA Software Release 8.3. Therefore, for compatibility reasons you must use ASA 8.3 or later software release in any RSVP SIP Preconditions deployment where the ASA is required to inspect the SIP signaling and/or pass RSVP packets.

For information on configuring the ASA for the SIP and IP Options inspections, refer to the *Cisco ASA 5500 Series Configuration Guide*, available at

http://www.cisco.com/en/US/products/ps6120/products_installation_and_configuration_guides_list.html

Design Considerations for Call Admission Control

This section describes how to apply the call admission control mechanisms to the various Unified CM call processing deployment models and to the following IP WAN topologies:

- [Simple Hub-and-Spoke Topologies, page 11-70](#)
- [Two-Tier Hub-and-Spoke Topologies, page 11-74](#)
- [Simple MPLS Topologies, page 11-78](#)
- [Generic Topologies, page 11-84](#)

For each topology, these sections present different sets of design considerations based on the Unified CM deployment model adopted.

Simple Hub-and-Spoke Topologies

[Figure 11-37](#) depicts a simple hub-and-spoke topology, also known as a star topology. In this type of network topology, all sites (called *spoke sites*) are connected via a single IP WAN link to a central site (called the *hub site*). There are no direct links between the spoke sites, and every communication between them must transit through the hub site.

Figure 11-37 A Simple Hub-and-Spoke Topology

The design considerations in this section apply to simple hub-and-spoke topologies that use traditional Layer 2 IP WAN technologies such as:

- Frame Relay
- ATM
- Frame Relay/ATM Service Interworking
- Leased Lines

For IP WAN deployments based on the MPLS technology, refer to the section on [Simple MPLS Topologies, page 11-78](#).

The remainder of this section contains design best practices for simple hub-and-spoke topologies according to the Unified CM deployment model adopted:

- [Centralized Unified CM Deployments, page 11-71](#)
One or more Unified CM clusters are located at the hub site, but only phones and gateways are located at the spoke sites.
- [Distributed Unified CM Deployments, page 11-72](#)
A Unified CM cluster or Cisco Unified Communications Manager Express (Unified CME) is located at each site.

Centralized Unified CM Deployments

In multisite WAN deployments with centralized call processing in a simple hub-and-spoke topology, use Unified CM static *locations* for implementing call admission control. Figure 11-38 shows an example of how to apply this mechanism to such a topology.

Figure 11-38 Call Admission Control for Simple Hub-and-Spoke Topologies Using Static Locations

Follow these guidelines when using static locations for call admission control:

- Configure a separate location in Unified CM for each spoke site.
- Configure the appropriate bandwidth limits for voice and video calls for each site according to the types of codecs used at that site. (See [Table 11-2](#) for recommended bandwidth settings.)
- Assign all devices at each spoke site to the appropriate location.
- Leave devices at the hub site in the Hub_None location.
- If you move a device to another location, change its location configuration as well.
- Unified CM supports up to 2000 locations.
- If you require automatic rerouting over the PSTN when the WAN bandwidth is not sufficient, configure the automated alternate routing (AAR) feature on Unified CM. (See [Automated Alternate Routing](#), page 9-108.)
- If multiple Unified CM clusters are located at the same hub site, leave the intercluster trunk devices in the Hub_None location. You may use a gatekeeper for dial plan resolution. However, gatekeeper call admission control is not necessary in this case because all IP WAN links are controlled by the locations algorithm.

**Note**

If one or more sites have dual connectivity to the IP WAN and you want to take full advantage of the bandwidth available on both links, Cisco recommends that you deploy topology-aware call admission control, as described in the section on [Generic Topologies, page 11-84](#). See also [Limitations of Topology-Unaware Call Admission Control, page 11-5](#), for more information.

Distributed Unified CM Deployments

For distributed call processing deployments on a simple hub-and-spoke topology, you can implement call admission control with a Cisco IOS gatekeeper. In this design, the call processing agent (which could be a Unified CM cluster, Cisco Unified Communications Manager Express (Unified CME), or an H.323 gateway) registers with the Cisco IOS gatekeeper and queries it each time the agent wants to place an IP WAN call. The Cisco IOS gatekeeper associates each call processing agent with a zone that has specific bandwidth limitations. Thus, the Cisco IOS gatekeeper can limit the maximum amount of bandwidth consumed by IP WAN voice calls into or out of a zone.

[Figure 11-39](#) illustrates call admission control with a gatekeeper. In brief, when the call processing agent wants to place an IP WAN call, it first requests permission from the gatekeeper. If the gatekeeper grants permission, the call processing agent places the call across the IP WAN. If the gatekeeper denies the request, the call processing agent can try a secondary path (the PSTN, for example) or can simply fail the call.

Figure 11-39 Call Admission Control for Hub-and-Spoke Topologies Using a Gatekeeper

153172

Follow these guidelines when deploying call admission control with a gatekeeper:

- In Unified CM, configure an H.225 gatekeeper-controlled trunk if you have a mixed environment with Cisco Unified Communications Manager Express (Unified CME) and H.323 gateways.
- In Unified CM, configure an intercluster gatekeeper-controlled trunk if you have an environment exclusively based on Unified CM clusters.
- Ensure that the zone configured in Unified CM matches the correct gatekeeper zone for the site.
- Each Unified CM subscriber listed in the device pool's Unified CM Redundancy Group registers a gatekeeper-controlled trunk with the gatekeeper. (Maximum of three.)
- Calls are load-balanced across the registered trunks in the Unified CM cluster.
- Unified CM supports multiple gatekeepers and trunks.
- You can place the trunk in a route group and route list construct to provide automatic PSTN failover. (See [Dial Plan](#), page 9-1, for more details.)
- Configure a separate zone in the gatekeeper for each site supporting Unified CMs, Unified CME, or H.323 gateways.
- Use the **bandwidth interzone** command on the gatekeeper to control bandwidth between Unified CM clusters, Unified CME servers, and H.323 devices registered directly with the gatekeeper. (See [Table 11-4](#) for bandwidth settings by codec type.)

- A single Cisco IOS gatekeeper can support up to 100 zones or sites.
- You can provide gatekeeper redundancy by using gatekeeper clustering (alternate gatekeeper) or Cisco Hot Standby Router Protocol (HSRP). Use HSRP only if gatekeeper clustering is not available in your software feature set.

**Note**

If one or more sites have dual connectivity to the IP WAN and you want to take full advantage of the bandwidth available on both links, Cisco recommends that you deploy topology-aware call admission control, as described in the section on [Generic Topologies, page 11-84](#). See also [Limitations of Topology-Unaware Call Admission Control, page 11-5](#), for more information.

Two-Tier Hub-and-Spoke Topologies

Figure 11-40 depicts a two-tier hub-and-spoke topology. This type of network topology consists of sites at three hierarchical levels: the first-tier hub site, the second-tier hub sites, and the spoke sites. A group of spoke sites are connected to a single second-tier hub site, and each second-tier hub site is in turn connected to the single first-tier hub site. As in the simple hub-and-spoke topology, there are no direct links between the spoke sites, and every communications between them must transit through the second-tier hub site. Similarly, there are no direct links between the second-tier hub sites, and all communications between them must transit through the first-tier hub site.

Figure 11-40 A Two-Tier Hub-and-Spoke Topology

The design considerations in this section apply to two-tier hub-and-spoke topologies that use traditional Layer 2 IP WAN technologies such as:

- Frame Relay
- ATM
- Frame Relay/ATM Service Interworking
- Leased Lines

For IP WAN deployments based on the MPLS technology, refer to the section on [Simple MPLS Topologies, page 11-78](#).

The remainder of this section contains design best practices for two-tier hub-and-spoke topologies according to the Unified CM deployment model adopted:

- [Centralized Unified CM Deployments, page 11-75](#)

One or more Unified CM clusters are located at the first-tier hub site, but only phones and gateways are located at the second-tier hub sites and the spoke sites.

- [Distributed Unified CM Deployments, page 11-77](#)

Unified CM clusters are located at the first-tier hub site and at the second-tier hub sites, while only endpoints and gateways are located at the spoke sites.

Centralized Unified CM Deployments

Figure 11-41 depicts a single centralized Unified CM cluster deployed in a two-tier hub-and-spoke IP WAN topology. In this scenario, the Unified CM cluster is located at the first-tier hub site, while all second-tier hub and spoke sites contain only endpoints and gateways.

Figure 11-41 Two-Tier Hub-and-Spoke Topology with Centralized Unified CM

This scenario requires that you deploy topology-aware call admission control, which for a single Unified CM cluster means using RSVP-enabled locations. Figure 11-42 shows how this mechanism can be deployed.

Figure 11-42 Call Admission Control for Two-Tier Hub-and-Spoke Topologies Using Locations with RSVP

The following guidelines apply to these deployments:

- Enable the Cisco IOS RSVP Agent feature on a Cisco IOS router at each site. At smaller sites, this router may coincide with the IP WAN router and PSTN gateway, while at larger sites they may be different platforms.
- In Unified CM, define a location for each site, and leave all bandwidth values as **Unlimited**.
- Assign all devices located at each site to the appropriate location (this includes endpoints, gateways, conferencing resources, and the Cisco RSVP Agent itself).
- Ensure that each Cisco RSVP Agent belongs to a media resource group (MRG) contained in the media resource group list (MRGL) of all devices at that site.
- In the Unified CM service parameters, set the **Default inter-location RSVP Policy** to **Mandatory** or **Mandatory (video desired)** and set the **Mandatory RSVP mid-call error handle option** to **Call fails following retry counter exceeded**.

- Enable RSVP on every WAN router interface in the network where congestion might occur, and configure the RSVP bandwidth based on the provisioning of the priority queue.
- If the Cisco RSVP Agent is not co-resident with the IP WAN router, enable RSVP on the LAN interfaces connecting the agent to the WAN router (as illustrated in Figure 11-42).

Distributed Unified CM Deployments

To provide call admission control in deployments that use a two-tier hub-and-spoke topology, with Unified CMs at the first-tier and second-tier hub sites, you can combine the static locations and gatekeeper zone mechanisms as illustrated in Figure 11-43.

Figure 11-43 Combining the Locations and Gatekeeper Mechanisms for Call Admission Control

Follow these recommendations when combining gatekeeper zones with static locations for call admission control:

- Use call admission control based on static locations for sites with no local Unified CM (that is, the spoke sites).
- Use gatekeeper-based call admission control between Unified CM clusters (that is, between the first-tier hub site and the second-tier hub sites).
- For each site without a local Unified CM, configure a location for that site in the Unified CM cluster supporting the site.
- Configure the appropriate bandwidth limits for voice and video calls at each site according to the type of codec used at that site. (See Table 11-2 and Table 11-4 for bandwidth settings.)
- Assign each device configured in Unified CM to a location. If you move a device to another location, change its location configuration as well.

- Unified CM supports up to 2000 locations.
- Each Unified CM cluster registers a gatekeeper-controlled trunk with the gatekeeper.
- On the gatekeeper, configure a zone for each Unified CM cluster, and use the **bandwidth interzone** command to control the number of calls to and from each cluster.

**Note**

If one or more sites have dual connectivity to the IP WAN and you want to take full advantage of the bandwidth available on both links, Cisco recommends that you deploy topology-aware call admission control, as described in the section on [Generic Topologies, page 11-84](#). See also [Limitations of Topology-Unaware Call Admission Control, page 11-5](#), for more information.

Simple MPLS Topologies

Figure 11-44 shows an IP WAN (from a service provider) based on the Multiprotocol Label Switching (MPLS) technology. The main design difference between traditional Layer 2 WAN services offered by service providers and services based on MPLS is that, with MPLS, the IP WAN topology does not conform to a hub-and-spoke but instead provides "full-mesh" connectivity between all sites.

This topology difference means that, from an IP routing perspective on the enterprise side of the network, each site is one IP hop away from all other sites. Thus, there is no need to transit through a hub site to reach any other site. In fact, there is no concept of a "hub site." All sites are considered equal, and the only difference between them is the amount of bandwidth that they are allowed to use across the IP WAN.

Figure 11-44 MPLS IP WAN from a Service Provider, and Its Topology Equivalent

Based on these considerations, it is easy to see that, from a call admission control perspective, a service-provider IP WAN service based on MPLS is in reality equivalent to a hub-and-spoke topology without a hub site. (See Figure 11-44.) In fact, the network itself could be considered as the hub site, while all the enterprise sites (including the headquarters, or central site) are equivalent to spoke sites. These differences have implications on how to perform call admission control, which are described in the remainder of this section.

An exception to the above considerations that is worth mentioning here is represented by multisite deployments where an MPLS-based WAN co-exists with an IP WAN based on a traditional Layer 2 technology, such as Frame Relay or ATM. Such a scenario could occur, for example, in the case of network migration phases, company mergers, or various other situations.

As shown in [Figure 11-45](#), integrating a hub-and-spoke IP WAN based on a traditional Layer 2 technology (such as Frame Relay) with an MPLS-based IP WAN results in a network topology that is neither a simple hub-and-spoke nor a full-mesh, but rather is equivalent to a two-tier hub-and-spoke.

In this case the first-tier hub site is represented by the MPLS network, the second-tier hub sites are represented by the MPLS-based sites as well as the MPLS-enabled Frame Relay hub site, and the spoke sites are represented by the Frame Relay spoke sites. Therefore, for design considerations on such deployments, refer to the section on [Two-Tier Hub-and-Spoke Topologies](#), [page 11-74](#).

Figure 11-45 Co-existence of MPLS Sites and Frame Relay Sites, and the Topology Equivalent

The remainder of this section contains design best practices for MPLS-based topologies according to the Unified CM deployment model adopted:

- [Centralized Unified CM Deployments](#), [page 11-80](#)

One or more Unified CM clusters are located at only one site, while only endpoints and gateways are located at all other sites.

- [Distributed Unified CM Deployments](#), [page 11-82](#)

Unified CM clusters are located at multiple sites, while endpoints and gateways are located at all other sites.

Note

This section focuses on enterprise deployments where the MPLS WAN service is provided by a service provider. In cases where the MPLS network is deployed by the enterprise itself, call admission control can be performed effectively if one of the following two conditions is satisfied: (1) routing in the MPLS network is configured so that it is equivalent to a hub-and-spoke, or (2) bandwidth in the core of the MPLS network is heavily over-provisioned so that congestion can occur only at the edge.

Note

If one or more sites have dual connectivity to the IP WAN and you want to take full advantage of the bandwidth available on both links, Cisco recommends that you deploy topology-aware call admission control, as described in the section on [Generic Topologies](#), [page 11-84](#). Particular care must be taken to

guarantee symmetric routing in the presence of load-balanced links. See also [Limitations of Topology-Unaware Call Admission Control, page 11-5](#), and [Special Considerations for MPLS Networks, page 11-11](#), for more information, and contact your local Cisco account team for further assistance.

Centralized Unified CM Deployments

In multisite WAN deployments with centralized call processing in an MPLS topology, use Unified CM static *locations* for implementing call admission control.

In a hub-and-spoke WAN topology (for example, Frame Relay or ATM), each link to and from a branch site terminates at the central site. For example, in a Frame Relay network, all permanent virtual circuits (PVCs) from the branch routers are aggregated at the central site's head-end router. In such a scenario, there is no need to apply call admission control to devices at the central site because the bandwidth accounting occurs at the branch ends of the WAN links. Therefore, within the Unified CM locations configuration, devices at the central site are left in the Hub_None location, while devices at each branch are placed in their appropriate location to ensure proper call admission control.

With an MPLS WAN network, all branches are deemed to be adjacent at Layer 3, thus they do not have to rely on the central site for connectivity. [Figure 11-46](#) illustrates a spoke-to-spoke call between two branch sites in this type of deployment.

Figure 11-46 Spoke-to-Spoke Calls in an MPLS Deployment

Also, in an MPLS WAN, the link connecting the central site to the WAN does not aggregate every branch's WAN link. By placing all the central site devices in their own call admission control location (that is, not in the Hub_None location), this configuration requires that call admission control be performed on the central site link independently of the branch links. (See [Figure 11-47](#).)

**Note**

Some devices such as trunks do not terminate media and are normally left in the Hub_None location. However, to avoid errors in call admission control when an MTP is required on a trunk, the trunk must be assigned to a location other than Hub_None and any MTP in the trunk's MRGL must be physically located at the site associated with that location. This configuration is required because an MTP cannot be assigned a location directly, so it inherits the location of the device that selected it.

Figure 11-47 Calls to and from the Hub in an MPLS Deployment

When all the available bandwidth for a particular site has been utilized, you can provide automatic failover to the PSTN by using the automated alternate routing (AAR) feature within Unified CM. (For more information on AAR, see [Automated Alternate Routing](#), page 9-108.)

Distributed Unified CM Deployments

In multisite deployments where a Unified CM cluster is present at more than one site without any branch locations and the sites are linked through an MPLS WAN, a gatekeeper can provide dial-plan resolution as well as call admission control between the sites, with each site being placed in a different gatekeeper zone. This is the same mechanism adopted for hub-and-spoke topologies based on Layer 2 WAN technologies. (See [Figure 11-48](#).)

Figure 11-48 Gatekeeper Call Admission Control in a Distributed Deployment with MPLS

In deployments where branch sites are required, a gatekeeper can be used for dial-plan resolution between clusters, but a gatekeeper is not recommended for call admission control.

When calls occur between branches belonging to different clusters, the audio path is established between the two branches directly, with no media transiting through each cluster's central site. Therefore, call admission control is required only on the WAN links at the two branches. (See [Figure 11-49](#).)

Figure 11-49 Multiple Clusters Connected by Intercluster Trunks (ICTs)

As in the centralized Unified CM deployments, devices that terminate media at each site (including the central sites for each cluster) must be placed in an appropriately configured location.

Note that the intercluster trunks are purely signaling devices, and there is no media transiting through them. Therefore, all intercluster trunks must be left in location Hub_None. The exception is when the trunk requires an MTP, in which case the trunk and MTP should both be in the location of the site in which they reside.

When all the available bandwidth for a particular site has been used, you can provide automatic failover to the PSTN by using a combination of the following two methods:

- The route list and route group construct for calls across multiple Unified CM clusters
- The automated alternate routing (AAR) feature for calls within a Unified CM cluster (For more information on AAR, see [Automated Alternate Routing, page 9-108.](#))

Generic Topologies

In the context of this chapter, a generic topology is a network topology that cannot be reduced to a simple hub-and-spoke, a two-tier hub-and-spoke, or a simple MPLS-based network.

As Figure 11-50 illustrates, a generic topology can present full-mesh features, hub-and-spoke features, partial-mesh features, or possibly all of them combined in a single network. It may also present dual connections between sites, as well as multiple paths from one site to another.

Figure 11-50 A Generic Topology

The complex nature of these networks requires the adoption of topology-aware call admission control mechanisms based on RSVP. In particular, these mechanisms can properly control bandwidth in presence of any of the following topology aspects:

- Remote sites dual-homed to different hub sites
- Multiple IP WAN links between any two sites, either in a primary/backup configuration or in an active/active load-balanced configuration
- Redundant hubs or data centers with a dedicated connection
- Fully-meshed core networks
- Multiple equal-cost IP paths between any two sites
- Multi-tiered architectures

The remainder of this section contains design best practices for generic network topologies according to the Unified CM deployment model adopted:

- [Centralized Unified CM Deployments, page 11-85](#)
One or more Unified CM clusters are located at a given site, but only endpoints and gateways are located at all other sites.
- [Distributed Unified CM Deployments, page 11-72](#)
Unified CM clusters are located at multiple sites, and endpoints and gateways are located at all other sites.
- [Distributed Mixed Call Processing Deployments, page 11-90](#)
Call control applications are distributed in various topologies.

Centralized Unified CM Deployments

Centralized Unified CM deployments using a generic topology can be categorized into two sub-types:

- [Single Unified CM Cluster, page 11-85](#)
- [Co-Located Unified CM Clusters, page 11-86](#)

Single Unified CM Cluster

The recommendations in this section apply to a single Unified CM cluster deployed in a generic network topology, as illustrated in [Figure 11-51](#).

Figure 11-51 A Single Unified CM Cluster in a Generic Topology

The following guidelines apply to this type of deployment:

- Enable the Cisco IOS RSVP Agent feature on a Cisco IOS router at each site, including the central site where Unified CM resides. At smaller sites, this router may coincide with the IP WAN router and PSTN gateway, while at larger sites they may be different platforms.
- In Unified CM, define a location for each site, and leave all bandwidth values as **Unlimited**.
- Assign all devices located at each site to the appropriate location (this includes endpoints, gateways, conferencing resources, and the Cisco RSVP Agents themselves).
- Ensure that each Cisco RSVP Agent belongs to a media resource group (MRG) contained in the media resource group list (MRGL) of all devices at that site.
- In the Unified CM service parameters, set the **Default inter-location RSVP Policy** to **Mandatory** or **Mandatory (video desired)** and set the **Mandatory RSVP mid-call error handle option** to **Call fails following retry counter exceeded**.
- Enable RSVP on every WAN router interface in the network where congestion might occur, and configure the RSVP bandwidth based on the provisioning of the priority queue. (See [RSVP Design Best Practices](#), page 11-33.)
- If you need to provision bandwidth separately for voice and video calls, also configure an RSVP application ID on the same WAN router interfaces.
- If the Cisco RSVP Agent is not co-resident with the IP WAN router, enable RSVP on the LAN interfaces connecting the agent to the WAN router.

Co-Located Unified CM Clusters

The recommendations in this section apply to deployments where multiple Unified CM clusters are located on the same LAN or MAN. However, the same considerations may also be valid if the sites where the Unified CM clusters reside are connected via a lower bandwidth link. Due to the design, any call cluster-to-cluster will engage an RSVP Agent for an endpoint in each cluster.

[Figure 11-52](#) illustrates a deployment with two Unified CM clusters located at a given site (HQ) and a number of remote sites with endpoints and gateways, which are controlled either by Cluster 1 (for example, Branch 1) or Cluster 2 (for example, Branch 2).

Figure 11-52 Co-Located Unified CM Clusters in a Generic Topology

The following guidelines apply to the deployment in [Figure 11-52](#):

- Enable the Cisco IOS RSVP Agent feature on a Cisco IOS router at each site, including the central site where Unified CM resides. At smaller sites, this router may coincide with the IP WAN router and PSTN gateway, while at larger sites they may be different platforms.
- Depending on the amount of call traffic between the central site and remote sites and between clusters, consider co-locating the RSVP Agents for both clusters at the central site on a single or multiple Cisco Integrated Services Routers (ISR). A single ISR can host multiple RSVP Agents controlled by different clusters.
- In each Unified CM cluster, define a location for each site, and leave all bandwidth values as unlimited.
- Assign all devices located at each site to the appropriate location. This includes endpoints, gateways, conferencing resources, and the Cisco RSVP Agents themselves.
- Ensure that each Cisco RSVP Agent belongs to a media resource group (MRG) contained in the media resource group list (MRGL) of all devices at that site.
- In the Unified CM service parameters, set the **Default inter-location RSVP Policy** to **Mandatory** or **Mandatory (video desired)** and set the **Mandatory RSVP mid-call error handle option** to **Call fails following retry counter exceeded** on both clusters.
- Enable RSVP on every WAN router interface in the network where congestion might occur, and configure the RSVP bandwidth based on the provisioning of the priority queue. (See [RSVP Design Best Practices](#), page 11-33.)

- If you need to provision bandwidth separately for voice and video calls, also configure an RSVP application ID on the same WAN router interfaces.
- If the Cisco RSVP Agent is not co-resident with the IP WAN router, enable RSVP on the LAN interfaces connecting the agent to the WAN router.
- Ensure that RSVP SIP Preconditions is enabled on the SIP intercluster trunks (see [Migration from Locations-Based Call Admission Control to RSVP SIP Preconditions, page 11-54](#), for the steps).
- Ensure that an inter-location RSVP policy of **Mandatory** or **Mandatory (video desired)** is set between the SIP intercluster trunk location and all locations, including itself (see intra-location RSVP policy below).
- Ensure that an intra-location RSVP policy of **Mandatory** or **Mandatory (Video Desired)** is set on the SIP intercluster trunk. An intra-location RSVP policy is set by selecting the location and configuring a policy for itself. This effectively ensures that calls within this location will engage RSVP call admission control. This is important for calls hairpinned on the trunk from call transfers or forwards back to the originating cluster.
- For calls from cluster to cluster within the central site, RSVP Agents will be engaged. This is due to the design and the ability for supplementary services to function across clusters, keeping intact end-to-end RSVP across the clusters. There are a few variations that can be supported. Consult with your Cisco account team to determine the best possible call admission control design for co-located clusters.

Distributed Unified CM Deployments

RSVP SIP Preconditions provides call admission control for distributed deployments of Unified Communication Manager clusters in a generic network topology. This section contains an example of a dual-cluster deployment with RSVP SIP Preconditions support between the clusters (see Figure 11-53). Hybrids and variations of this model are expected, and this is only a high-level example of a simple design, with best practices and design considerations called out.

Figure 11-53 Distributed Unified CM Deployment

The following guidelines apply to the deployment in Figure 11-53:

- Enable the Cisco IOS RSVP Agent feature on a Cisco IOS router at each site, including the central site where Unified CM resides. At smaller sites, this router may coincide with the IP WAN router and PSTN gateway, while at larger sites they may be different platforms.
- In each Unified CM cluster, define a location for each site, and leave all bandwidth values as unlimited.
- Assign all devices located at each site to the appropriate location. This includes endpoints, gateways, conferencing resources, and the Cisco RSVP Agents themselves.
- Ensure that each Cisco RSVP Agent belongs to a media resource group (MRG) contained in the media resource group list (MRGL) of all devices at that site.
- In the Unified CM service parameters, set the **Default inter-location RSVP Policy** to **Mandatory** or **Mandatory (video desired)**, and set the **Mandatory RSVP mid-call error handle option** to **Call fails following retry counter exceeded** on both clusters.

- Enable RSVP on every WAN router interface in the network where congestion might occur, and configure the RSVP bandwidth based on the provisioning of the priority queue. (See [RSVP Design Best Practices, page 11-33](#).)
- If you need to provision bandwidth separately for voice and video calls, also configure an RSVP application ID on the same WAN router interfaces.
- If the Cisco RSVP Agent is not co-resident with the IP WAN router, enable RSVP on the LAN interfaces connecting the agent to the WAN router.
- Ensure that RSVP SIP Preconditions is enabled on the SIP intercluster trunks (see [Migration from Locations-Based Call Admission Control to RSVP SIP Preconditions, page 11-54](#), for the steps).
- Ensure that an inter-location RSVP policy of **Mandatory** or **Mandatory (video desired)** is set between the SIP intercluster trunk location and all locations, including itself (see intra-location RSVP policy below).
- Ensure that an intra-location RSVP policy of **Mandatory** or **Mandatory (Video Desired)** is set on the SIP intercluster trunk. An intra-location RSVP policy is set by selecting the location and configuring a policy for itself. This effectively ensures that calls within this location will engage RSVP call admission control. This is important for calls hairpinned on the trunk from call transfers or forwards back to the originating cluster.

Distributed Mixed Call Processing Deployments

RSVP SIP Preconditions provides call admission control for distributed deployments of Unified Communications call control applications in a generic network topology.

This section contains a list of the supported RSVP SIP Preconditions deployment models. Hybrids and variations of these models are expected, and these are only high-level examples of the design possibilities, with best practices and design considerations called out. (Consult the specific product documentation for more information on configuration of these features.)

The following guidelines apply to the deployments in [Figure 11-54](#):

- The deployment supports Unified CME SCCP integration for audio-only calls.
- Enable RSVP on every WAN router interface in the network where congestion might occur, and configure the RSVP bandwidth based on the provisioning of the priority queue. (See [RSVP Design Best Practices, page 11-33](#).)
- If you need to provision bandwidth separately for voice and video calls, also configure an RSVP application ID on the same WAN router interfaces.
- Follow the recommendations listed in the [Design Considerations for Unified CM Interoperability with SIP Cisco IOS TDM Gateway and Unified CME, page 11-65](#).

Figure 11-54 Unified CM to Cisco IOS Gateway (TDM) and to Unified CME (SCCP)

The following guidelines apply to the deployments in Figure 11-55:

- Follow the guidelines, best practices, limitations, and restrictions for SIP Cisco IOS TDM gateway and Unified CME interoperability listed in the *Cisco IOS SIP Configuration Guide*, available at http://www.cisco.com/en/US/docs/ios/voice/sip/configuration/guide/12_4t/sip_12_4t_book.html
- Ensure that the RSVP policy configured on each Unified CME or SIP Cisco IOS TDM gateway is consistent in order to avoid failed or unprotected calls. Use the following options under the **dial-peer** configuration when enabling RSVP reservations for the SIP Cisco IOS TDM gateway or Unified CME:

```
req-qos guaranteed-delay audio
acc-qos guaranteed-delay audio
```

This configuration ensures that for each voice call, the SIP Cisco IOS TDM gateway will request an RSVP reservation using the guaranteed delay service. The fact that both the requested QoS and the acceptable QoS specify this RSVP service means that the RSVP reservation is mandatory for the call to succeed. (That is, if the reservation cannot be established, the call will fail.)

- If Application ID is used, ensure that it is consistent across all of products in the solution (SIP Cisco IOS TDM gateway and Unified CME).
- Ensure that inbound and outbound dial peers are correctly matched to ensure that the appropriate dial peers configured with SIP Preconditions are utilized. For further information, refer to the *Cisco IOS SIP Configuration Guide*, available at http://www.cisco.com/en/US/docs/ios/voice/sip/configuration/guide/12_4t/sip_12_4t_book.html

Figure 11-55 Unified CME to Unified CME, Unified CME to Cisco IOS Gateway, and Cisco IOS Gateway to Cisco IOS Gateway

The following guidelines apply to the deployments in [Figure 11-56](#):

- Follow the guidelines stipulated for [Figure 11-54](#) for Unified CM in distributed call processing deployments, and follow the guidelines stipulated for [Figure 11-55](#) for Unified CME and SIP Cisco IOS TDM Gateways.
- Each Unified CM cluster will typically have a single trunk directed to the Cisco Unified SIP Proxy. Ensure that RSVP SIP Preconditions (end-to-end RSVP) is enabled on that trunk.
- Ensure that RSVP SIP Preconditions is enabled on the SIP trunk to the Cisco Unified SIP Proxy (see [Migration from Locations-Based Call Admission Control to RSVP SIP Preconditions](#), page 11-54, for the steps).
- Ensure that an inter-location RSVP policy is configured on each Unified CM cluster between the IP phone locations and the SIP trunk location. This ensures that the SIP preconditions will be enabled for all calls engaged on the SIP trunk to the Cisco Unified SIP Proxy.
- If there are potential SIP destinations that do not support RSVP SIP Preconditions, then ensure that RSVP SIP Preconditions fallback to local RSVP is configured on the SIP trunk to allocate an RSVP Agent for those call flows. And if RSVP SIP Preconditions fallback is enabled, ensure that the RSVP Agent associated to the SIP trunk is in a physical site that will ensure RSVP path protection for those call flows.
- Unified CME and SIP Cisco IOS TDM gateways will also typically have a single SIP dial peer directed to the Cisco Unified SIP Proxy. Ensure that RSVP SIP Preconditions (SIP Preconditions support) is configured on those dial peers, as stipulated in the *Cisco IOS SIP Configuration Guide*, available at

http://www.cisco.com/en/US/docs/ios/voice/sip/configuration/guide/12_4t/sip_12_4t_book.html

- For information on configuration, guidelines, best practices, limitations, and restrictions for Cisco Unified SIP Proxy, refer to the documentation at http://www.cisco.com/en/US/prod/collateral/modules/ps2797/data_sheet_c78-521390_ps2797_Products_Data_Sheet.html

Figure 11-56 All Components Capable of RSVP SIP Preconditions via Cisco Unified SIP Proxy

The following guidelines apply to the deployments in [Figure 11-57](#):

- Follow the guidelines stipulated for [Figure 11-54](#) for Unified CM in distributed call processing deployments, and follow the guidelines stipulated for [Figure 11-55](#) for Unified CME and SIP Cisco IOS TDM Gateways.
- Ensure that Services Advertisement Framework (SAF) and Call Control Discovery (CCD) are enabled in the network and functioning across the deployed products: For details on SAF configuration, refer to the following documents:
 - *Cisco IOS Service Advertisement Framework Configuration Guide*
http://www.cisco.com/en/US/docs/ios/saf/configuration/guide/15_0/saf_15_0_book.html
 - *Cisco Unified Communications Manager Features and Services Guide*
http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html
- Enable RSVP SIP Preconditions on the SAF-enabled SIP trunk (see [Migration from Locations-Based Call Admission Control to RSVP SIP Preconditions](#), page 11-54, for the steps).
- Enable RSVP SIP Preconditions on the SAF-enabled SIP trunk. Ensure that only SAF-enabled SIP trunks are used with Call Control Discovery in an RSVP SIP Preconditions deployment. SAF-enabled H.323 trunks will not function in an RSVP SIP Preconditions deployment.
- Ensure that an inter-location RSVP policy of **Mandatory** or **Mandatory (video desired)** is set between the SAF-enabled SIP trunk location and all locations, including itself (see the intra-location RSVP policy below). This ensures that the SIP preconditions will be enabled for all calls engaged on the SIP trunk to and from the SAF network.

- Ensure that an intra-location RSVP policy of **Mandatory** or **Mandatory (Video Desired)** is set on the SAF-enabled SIP trunk. An intra-location RSVP policy is set by selecting the location and configuring a policy for itself. This effectively ensures that calls within this location will engage RSVP call admission control. This is important for calls hairpinned on the trunk from call transfers or forwards back to the originating cluster.
- When using SAF-enabled SIP trunks in RSVP SIP Preconditions environments, Cisco recommends ensuring that CCD Automatic Failover is enabled and that calls that fail call admission control are routed to a local route group. For more information see the section on Call Control Discovery Automatic PSTN Failover as well as the DP chapter Local Route Group.

Figure 11-57 All Components Capable of RSVP SIP Preconditions via Service Advertisement Framework (SAF) and Call Control Discovery (CCD)

Call Admission Control Design Recommendations for TelePresence Video Interoperability Architectures

Video interoperability refers to the support for point-to-point video calls between Cisco TelePresence endpoints, Cisco Unified Communications video endpoints, and third-party video endpoints without requiring a Multipoint Control Unit (MCU). In order to offer support for these call scenarios, testing was required to validate the support and determine the design and deployment considerations. This section discusses the design considerations and recommendations applicable to Quality of Service (QoS) and call admission control (CAC) for interoperable video calls. The TelePresence system should be designed according to the guidelines indicated in the *Cisco TelePresence Network Systems Design Guide*, available at

http://www.cisco.com/en/US/solutions/ns340/ns414/ns742/ns819/landing_vid_tPresence.html

This section explains how to supplement the design to allow for video interoperation between Unified Communications and TelePresence endpoints. For information on Unified Communications endpoints, refer to the chapter on [Unified Communications Endpoints, page 18-1](#); and for information on TelePresence endpoints, refer to the Cisco TelePresence Endpoints product documentation at <http://www.cisco.com/en/US/products/ps7060/index.html>.

Note

Third-party video endpoints should follow the same guidelines and recommendations as Cisco Unified Communications endpoints. Throughout this section, the term *UC endpoints* is used to refer to both third-party endpoints and Cisco Unified Communications Endpoints.

The current release of Cisco TelePresence does not provide a mechanism for reserving network bandwidth or performing call-by-call CAC for TelePresence endpoints. Therefore, if the number of TelePresence rooms deployed at a given site exceeds the bandwidth available to/from that site, it is possible that too many TelePresence meetings could occur simultaneously and QoS policies in the network will begin dropping TelePresence packets, resulting in poor audio and video quality for all calls traversing that network link. Existing call admission control techniques include locations-based CAC and Resource Reservation Protocol (RSVP), both of which are administered by Cisco Unified Communications Manager (Unified CM), but they are not recommended nor supported for Cisco TelePresence end-to-end calls. Therefore, the current recommendation is to use manual capacity planning to provide sufficient bandwidth to support all possible TelePresence meetings that can occur simultaneously across the network infrastructure. TelePresence video interoperability addresses the CAC requirements and design considerations in order to ensure CAC for the UC endpoints and native interoperable calls.

It is important to be familiar with locations CAC and RSVP CAC prior to designing TelePresence video interoperability. This section addresses both locations CAC and RSVP with regards to TelePresence video interoperability, and each CAC mechanism has its own benefits, design considerations, and requirements.

Additionally, TelePresence video interoperability in Unified CM enables Cisco Telepresence System (CTS) endpoints to communicate with non-CTS endpoints, provided that the installed CTS software supports such interoperability. For further information, refer to the document on *Interoperability Between CTS Endpoints and Other Cisco Endpoints or Devices*, available at

http://www.cisco.com/en/US/docs/telepresence/interop/endpoint_interop.html

Supported CAC Deployment Scenarios and Design Considerations

The design considerations for TelePresence video interoperability CAC are based on the following main deployment scenarios:

- **Mixed Single Cluster** — Mixed UC video endpoints and TelePresence endpoints registered to a single cluster

This is a single-cluster design where TelePresence and UC video endpoints are registered to the same cluster. The call processing deployment model can be any of the single-cluster designs such as clustering over the WAN, multi-site centralized call processing, or single campus designs.

- **Dedicated Multi-Cluster** — UC video endpoints and TelePresence endpoints on separate dedicated clusters

This is a multi-cluster design where the TelePresence endpoints are registered to a different cluster than the UC video endpoints. The call processing deployment model can be multi-site centralized or multi-site distributed cluster designs. All releases of Cisco Unified CM 8.x support this model for deploying UC and TelePresence in the same enterprise. However, only Unified CM 8.6 and later releases support the new capability for UC video and TelePresence call interoperability in point-to-point video calls without the use of a video MCU.

- **Mixed Multi-Cluster** — UC video endpoints and TelePresence endpoints mixed in multi-cluster distributed deployments

This is a multi-cluster design where TelePresence endpoints are spread across multiple clusters serviced by a single Cisco TelePresence System Manager (CTS-Manager). There are also deployment scenarios where some TelePresence endpoints can be co-located with the same Unified CM cluster as the UC endpoints (mixed single cluster model) while other TelePresence endpoints are registered to a dedicated cluster, and both clusters are serviced by a single CTS-Manager for TelePresence. The call processing deployment model can be multi-site, multi-cluster centralized, or multi-site/multi-cluster distributed designs. This is a hybrid model that combines aspects of the dedicated multi-cluster model with mixed single-cluster model where all endpoints are registered to the same cluster.

Cisco Unified Communications Manager Session Management Edition (SME) is also supported in the multi-cluster models. However, because Session Management Edition is a variation of the multi-site distributed call processing deployment model and is typically employed to interconnect large numbers of Unified Communications systems through a single front-end system, there are no specific guidelines for it with regard to TelePresence video interoperability.

Locations CAC Design Considerations and Recommendations

In designing locations CAC, the goal is to ensure CAC for UC endpoints while avoiding CAC for TelePresence endpoints. To achieve this goal, UC endpoints are placed in locations that track audio and video bandwidth in order to ensure that the media traffic across the WAN is not oversubscribed, while TelePresence endpoints are placed in locations that are set to unlimited bandwidth so that TelePresence traffic is not subject to CAC but is controlled through the correct QoS marking of media and bandwidth provisioning of the WAN uplinks.

Design Recommendations

The following design recommendations apply to TelePresence video interoperability solutions that employ locations CAC:

- Locations CAC for TelePresence video interoperability is supported in all three deployment models: mixed single cluster, dedicated multi-cluster, and mixed multi-cluster.
- TelePresence endpoints should always be placed in a separate CAC location with unlimited audio and video bandwidth, such as the `hub_none` location or an equivalent.
- Cross-cluster call transfer and forward between UC and TelePresence endpoints requires either QSIG path replacement to optimize the call signaling path and avoid incorrect bandwidth adjustments or [Location-Based Call Admission Control Over Intercluster Trunk, page 11-114](#). QSIG Tunneling with path replacement can be configured on both H.323 and SIP intercluster trunks. For more information on location-based call admission control over intercluster trunks, refer to the call admission control information in the *Cisco Unified Communications Manager System Guide*, available at http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html.
- Intercluster trunks should be associated with a CAC location where the video bandwidth is set to unlimited, and bandwidth deductions for calls are tracked from an endpoint's association to a bandwidth-limited location. This applies to both mixed multi-cluster and dedicated multi-cluster deployments.
- Only point-to-point video calls are supported between UC and TelePresence endpoints. No ad-hoc conferencing is supported unless a video MCU is available.
- Cisco Unified CM 8.x uses two different cluster-wide QoS service parameter to differentiate between the Differentiated Services Code Point (DSCP) settings of UC video endpoints and TelePresence endpoints. TelePresence endpoints use the **DSCP for Telepresence calls** QoS parameter while the Cisco UC video endpoints use the **DSCP for video calls** QoS service parameter.
- For sites that deploy only UC endpoints and no TelePresence endpoints, ensure that the CS4 DSCP class is added to the AF41 QoS traffic class on inbound WAN QoS configurations to account for the inbound CS4 marked traffic, thus ensuring QoS treatment of CS4 marked media. See [Figure 11-61](#) and its associated design considerations for more details about this scenario.
- For sites that deploy only UC TelePresence endpoints and no UC endpoints, ensure that the AF41 DSCP class is added to the CS4 QoS traffic class on inbound WAN QoS configurations to account for the inbound AF41 marked traffic, thus ensuring QoS treatment of AF41 marked media. See [Figure 11-64](#) and its associated design considerations for more details about this scenario.

Design Considerations

When deploying locations CAC for TelePresence video interoperable calls, consider the following major factors:

- [DSCP QoS Marking, page 11-98](#)
- [Bandwidth Accounting for Calls Between Multiple Sites, page 11-98](#)
- [Bandwidth Accounting for Calls within a Single Site, page 11-105](#)

DSCP QoS Marking

The Differentiated Services Code Point (DSCP) QoS markings for TelePresence video interoperable calls are asymmetric, with AF41 used for the UC endpoints and CS4 for the TelePresence endpoints. AF41 and CS4 are default configurations in Unified CM, and changes to these defaults should align with the QoS configuration in the network infrastructure, as applicable. TelePresence endpoints mark video calls with a DSCP value of CS4, which is consistent with the default **DSCP for Telepresence calls** setting. UC endpoints mark calls with a DSCP value of AF41, which is consistent with the default **DSCP for Video calls** setting. [Figure 11-58](#) illustrates the media marking and bandwidth accounting.

Figure 11-58 *Bandwidth Deductions and Media Marking in a Multi-Site Deployment with Locations CAC*

Bandwidth Accounting for Calls Between Multiple Sites

Locations CAC for TelePresence video interoperable calls deducts bandwidth only from the UC endpoint's location and not from the TelePresence endpoint's location, as illustrated in [Figure 11-58](#). This is by design to ensure that TelePresence endpoints are not restricted by bandwidth for the end-to-end TelePresence calls. This manner of bandwidth accounting on one side for the AF41 QoS class and provisioning on the other side for the CS4 QoS class has a few side effects.

Locations CAC accounts for the bidirectional media of AF41 class traffic. In asymmetrically marked flows, however, the full allocated bandwidth of the AF41 class is used in one direction but not the other. In the other direction, the traffic is marked CS4. This does not represent additional bandwidth

consumption but simply a difference in marking. This difference in marking, and the bandwidth accounting on UC endpoint locations but not on TelePresence endpoint locations, lead to the QoS design considerations in the following two distinct call scenarios.

Call Scenario 1: Calls Between a Dedicated UC Site and a Co-Located Site

Figure 11-59 depicts a multi-site deployment where one site contains only UC endpoints and another site contains both UC and TelePresence endpoints co-located.

Figure 11-59 Bandwidth Accounting Between a Dedicated UC Site and a Co-Located Site with Locations CAC

If there is a site with UC endpoints associated with one CAC location and TelePresence endpoints associated with a separate CAC location, the CAC location for the UC endpoints will not deduct bandwidth for the inbound AF41 streams for calls to TelePresence endpoints from other remote UC endpoint locations. This case is illustrated in Figure 11-60.

Figure 11-60 Bandwidth Deductions and Media Marking Between a Dedicated UC Site and a Co-Located Site with Locations CAC

Video interoperability call, co-located UC and TelePresence site:

- CS4 marked media outbound and AF41 marked media inbound.
- Inbound AF41 marked media is not accounted for in Locations A or B.
- An equal quantity of bandwidth of CS4 traffic class is unused inbound and thus available in the WAN for the inbound AF41 marked stream.

-----> RTP Marked CS4
 —————> RTP Marked AF41

The bandwidth accounting error in [Figure 11-60](#) is unavoidable but relatively minor because the asymmetry also results in the same quantity of CS4 bandwidth going unused and thus it is still available. The error is problematic only in situations where CS4 and AF41 traffic take diverse paths. It should be noted that the available bandwidth for CS4 class in this case is available for all traffic types on the link and not just AF41. Therefore, potential contention can still occur in the AF41 class during busy hours of WAN utilization.

If there are sites containing only UC endpoint that expect to engage in video calls with TelePresence endpoints at other sites, asymmetrically marked media will be expected on the WAN uplink of the UC-only site. To ensure that the CS4 DSCP class is treated appropriately in QoS, CS4 DSCP should be added to the AF41 QoS traffic class in inbound WAN QoS configurations, thus accounting for this inbound CS4 marked traffic and ensuring proper QoS treatment. Note that extra bandwidth is not required here for the added QoS traffic class. This case is illustrated in [Figure 11-61](#).

Figure 11-61 Media Marking to Ensure Proper QoS Treatment of Calls Between Dedicated UC Sites and Co-Located Sites with Locations CAC

Call Scenario 2: Calls Between a Dedicated TelePresence Site and a Co-Located Site

Figure 11-62 depicts a multi-site deployment where one site contains only TelePresence endpoints and another site contains both UC and TelePresence endpoints co-located.

Figure 11-62 Bandwidth Accounting Between a Dedicated TelePresence Site and a Co-Located Site with Locations CAC

In the case where a TelePresence call comes to a UC endpoint location in a site that contains both TelePresence and UC endpoints, bandwidth is deducted for the AF41 QoS class but inbound media is marked CS4. This CS4 traffic is not accounted for in the provisioning of the WAN uplink for local TelePresence endpoints. As in the previous case, this accounting error is also unavoidable but relatively minor because the asymmetry also results in the same quantity of AF41 bandwidth going unused and thus it is still available. The error is problematic only in situations where CS4 and AF41 traffic take diverse paths. It should be noted that the available bandwidth for the AF41 class in this case is available for all traffic types on the link and not just CS4. Therefore, potential contention can still occur in the CS4 class during busy hours of WAN utilization. This case is illustrated in Figure 11-63.

Figure 11-63 *Bandwidth Deductions and Media Marking Between a Dedicated TelePresence Site and a Co-Located Site with Locations CAC*

Video interoperability call, co-located UC and TelePresence site:

- CS4 marked media inbound.
- AF41 marked media outbound.
- CS4 marked media is not accounted for in TelePresence endpoint's QoS provisioning; however, an equal quantity of bandwidth of AF41 traffic class is unused inbound and thus available in the WAN for the inbound CS4 media.

-----> RTP Marked CS4
 —————> RTP Marked AF41

For TelePresence-only sites expecting to engage in video calls with UC endpoint sites, asymmetrically marked media is expected on the WAN uplink of the TelePresence-only site. To ensure that the AF41 DSCP class is treated appropriately in QoS, AF41 DSCP should be added to the CS4 QoS traffic class in inbound WAN QoS configurations, thus accounting for this inbound AF41 marked traffic and ensuring proper QoS treatment. Note that extra bandwidth is not required here for the added QoS traffic class. This case is illustrated in [Figure 11-64](#).

Figure 11-64 Media Marking to Ensure Proper QoS Treatment of Calls Between Dedicated TelePresence Sites and Co-Located Sites with Locations CAC

Bandwidth Accounting for Calls within a Single Site

In cases where UC endpoints and TelePresence endpoints are in the same physical site, they will still be associated with separate CAC locations according to the design guidelines. For calls between TelePresence and UC endpoints in the same physical site, bandwidth is deducted from the UC endpoints' CAC location because this is an inter-location call; however, media will not traverse the WAN because the devices are located in the same physical site. This case is illustrated in [Figure 11-65](#).

Figure 11-65 *Bandwidth Deductions and Media Marking for Calls Between UC and TelePresence Endpoints in the Same Site with Locations CAC*

This is a limitation of locations CAC for TelePresence and UC endpoints calling one another when they are located in the same physical site or campus. This limitation is due to how locations CAC currently functions and to the requirement to place TelePresence endpoints into a separate CAC location where bandwidth is unlimited.

For Session Management Edition deployments, follow the guidelines in the section on [Session Management Edition Managing the CAC Domain with Locations CAC](#), page 11-110.

RSVP CAC Design Considerations and Recommendations

In an RSVP solution for TelePresence video interoperability, the goal is to ensure RSVP CAC for both end-to-end UC endpoint calls and TelePresence video interoperability calls, while also ensuring that end-to-end TelePresence calls never invoke RSVP (RSVP Agent) because it is not currently supported and can cause specific TelePresence features to fail.

TelePresence video interoperability in RSVP deployments is very easy to achieve and provides better CAC support than locations CAC solutions, provided that a few design rules and deployment models are adhered to. The supported designs are the mixed single cluster and dedicated multi-cluster designs. The mixed multi-cluster designs are not recommended due to the configuration complexity of ensuring that end-to-end TelePresence calls across clusters do not invoke RSVP and that all other interoperable point-to-point call scenarios do invoke RSVP.

For details about RSVP architecture and general design and deployment considerations, see the section on [Unified Communications Architectures Using Resource Reservation Protocol \(RSVP\)](#), page 11-17. It is important to understand the RSVP principles and solution prior to reading this section independently as this section will uniquely cover recommendations and considerations specific to Telepresence video interoperability with regards to RSVP.

Design Recommendations

The following design recommendations apply to TelePresence video interoperability solutions that employ RSVP for call admission control:

- Locations-based RSVP is supported in mixed single cluster and dedicated multi-cluster designs. As mentioned previously, a mixed multi-cluster design can be used but at the cost of complex configuration of trunks, dial plan, and locations-based RSVP policy. Therefore, mixed multi-cluster designs are not recommended and will not be treated in these design recommendations.
- Both Local RSVP and RSVP SIP Preconditions are supported for intercluster calls, provided they are designed and configured according to the guidelines in the relevant sections of this chapter.
- When designing solutions for TelePresence video interoperability with RSVP, ensure that TelePresence-to-TelePresence calls never invoke RSVP because that functionality is not currently supported and can cause specific TelePresence features to fail. However, for TelePresence calls to/from UC video endpoints, RSVP should be invoked. To achieve this, ensure the following:
 - TelePresence endpoints are in CAC locations separate from UC endpoints.
 - TelePresence locations set their RSVP policy to **no reservation** for the location pairing with other TelePresence locations as well as their own location. For more information on RSVP Policy for location pairs, see the section on [RSVP Policy](#), page 11-43.
 - TelePresence locations set their RSVP policy to **mandatory** or **mandatory video desired** for the location pairings with UC video endpoint locations.
 - For dedicated multi-cluster deployments, intercluster trunks require an RSVP policy pairing between UC endpoint locations as well as TelePresence endpoint locations.

For dedicated TelePresence clusters, intercluster trunks pointing to dedicated UC endpoint clusters should have an RSVP policy location pairing with TelePresence endpoints set to **mandatory** or **mandatory video desired**. Intercluster trunks pointing to TelePresence clusters should have an RSVP policy location pairing with TelePresence endpoints set to **no reservation**.

For dedicated UC endpoint clusters, intercluster trunks pointing to both dedicated UC clusters and TelePresence clusters should have an RSVP policy location pairing with UC endpoints set to **mandatory** or **mandatory video desired**.

Design Considerations

When deploying RSVP CAC for TelePresence video interoperable solutions, consider the following major factors:

RSVP Performs CAC for Both UC and TelePresence Endpoints

Unlike locations CAC, RSVP performs CAC for both the TelePresence and UC endpoints for TelePresence video interoperating calls. It also overwrites the endpoint QoS marking, thus ensuring the correct QoS marking from agent to agent. [Figure 11-66](#) illustrates this point

Figure 11-66 Bandwidth Deductions and Media Marking in a Multi-Site Deployment with RSVP CAC

[Figure 11-66](#) illustrates a call between a TelePresence endpoint and a Cisco Unified IP Phone 9900 Series video phone, where RSVP Agents are invoked for RSVP CAC. Two salient points are illustrated here:

- RSVP Agents re-mark the RTP media traffic so that the media is marked symmetrically between RSVP Agents with a DSCP value of AF41, which is consistent with the **DSCP for Video calls** setting. This provides symmetrically marked RTP traffic between endpoints, which is something that the locations CAC solution cannot achieve.
- RSVP deduces bandwidth over the media path between the RSVP Agents for the UC endpoint and the TelePresence endpoint. This provides CAC for audio and video streams in both directions for TelePresence video interoperability calls. This is also something that locations CAC inherently cannot achieve.

RSVP Should Not Be Used on Calls Between Endpoints Located in the Same Physical Site in a Mixed Single-Cluster Deployment

When deploying mixed single-cluster designs, where TelePresence endpoints and UC video endpoints are registered to the same Unified CM cluster and located in the same physical site or campus, it is important not to engage RSVP for calls between these devices. The RSVP policy location pair between the UC endpoint's location and the TelePresence endpoint's location should be set in these cases to **no reservation**. This is illustrated in [Figure 11-67](#).

Figure 11-67 RSVP Policy Setting for Calls Between UC and TelePresence Endpoints in the Same Site

[Figure 11-67](#) illustrates a TelePresence endpoint and a Cisco Unified IP Phone 9900 Series video phone in the same physical site but in separate CAC locations. The location pair policy is set to **no reservation** so that calls between TelePresence and UC endpoints in the same physical site or campus do not invoke RSVP. Note that the RTP streaming is asymmetrical. This will be the case but is usually inconsequential over the LAN.

RSVP Should Be Used on Calls Between Endpoints in Different Clusters

For dedicated multi-cluster deployments it is necessary to invoke RSVP even when the UC endpoint and the TelePresence endpoint are located in the same physical site. This will utilize RSVP Agent resources but the media will not be routed over the WAN uplink. [Figure 11-68](#) illustrates this point.

Figure 11-68 *Bandwidth Deductions and Media Marking in a Multi-Cluster, Single-Site Deployment with RSVP CAC*

Note that the RSVP Agents as well as the WAN edge router in [Figure 11-68](#) could all be either co-located or separated as depicted. For information on co-locating multiple RSVP Agents registered to separate clusters, see the section on [Multiple Clusters Sharing a Single Platform for RSVP Agent](#), page 11-124.

Guidelines for Session Management Edition Deployments

For Session Management Edition deployments, follow the same guidelines that are stipulated in the section on [Unified CM Session Management Edition with RSVP Deployments](#), page 11-120. Keep in mind, however, that RSVP is not recommended in mixed multi-cluster deployments.

Call Admission Control Design Recommendations for Unified CM Session Management Edition Deployments

Cisco Unified Communications Manager Session Management Edition (SME) has two main forms of call admission control available to it for admitting trunk-to-trunk audio and video calls: one is Locations call admission control (CAC) and the other is Resource Reservation Protocol (RSVP) using RSVP-enabled Locations. This section covers design guidelines and best practices specific to Session Management Edition deployments. It does not cover the basic functions of Locations CAC, Locations-based RSVP, or RSVP SIP Preconditions. Cisco highly recommends that you become familiar with the applicable sections of this chapter as a prerequisite to understanding the following design guidelines.

The term "CAC domain" is used in this section to describe an area of the network that is managed by a single CAC mechanism such as Locations CAC or RSVP. In cases involving Locations CAC, the CAC domain is managed by a single cluster, be it a leaf cluster or a Session Management Edition cluster, because Locations CAC is aware of only a single cluster and Locations information is not communicated between clusters. There is a mechanism referred to as "Location-based call admission control over intercluster trunk" that allows clusters to communicate Location information from cluster to cluster, but this mechanism is limited in scope and is referred to specifically where it applies.

Session Management Edition Managing the CAC Domain with Locations CAC

Unified CM Session Management Edition can leverage Locations CAC to do bandwidth management on behalf of leaf clusters, third-party IP PBXs, and TDM gateways in a limited fashion. Locations CAC is a basic static CAC mechanism that tracks bandwidth for audio and video calls made between devices in different Locations within a cluster. A Location is equivalent to a physical site with a single WAN uplink. Locations CAC is not communicated across clusters, so it is applicable only within a given cluster. Therefore, there are a number of limitations to supporting a multi-cluster distributed Unified CM deployment with Locations CAC. Unified CM Session Management Edition can, however, leverage Locations CAC by associating a location to a trunk or set of trunks whose media originates from or terminates on leaf cluster devices located in a campus.

[Figure 11-69](#) shows an example of Unified CM Session Management Edition managing the CAC domain for two campus sites. Two leaf clusters, co-located in the campus site on the left, manage endpoints and devices in that same physical campus. Another leaf cluster resides in another campus deployment. Any inter-site and inter-cluster calling is sent to Session Management Edition for handling. In this case the Session Management Edition cluster has two Locations configured: LOCATION 1 associated to the trunks for both leaf clusters 1 and 2, and LOCATION 2 associated to the trunk for leaf cluster 3.

In this design, Unified CM Session Management Edition manages CAC for the campus sites' WAN edge uplinks by means of associating a Location to the trunks pointing to the leaf clusters in the respective campuses.

Figure 11-69 Unified CM Session Management Edition Managing the CAC Domain for Two Campus Sites

Any calls from Leaf 1 to Leaf 2 are not subject to call admission control because both Leaf 1 and Leaf 2 trunks are in the same Location in the Session Management Edition configuration. Any calls to/from Leaf 3 to/from Leaf 1 or 2 are deducted from the respective Locations' audio or video pools.

Leaf Clusters Managing the CAC Domain with Locations CAC

In Session Management Edition designs, leaf clusters can also maintain and manage their own CAC domain with Locations CAC, in which case Session Management Edition is transparent to the admission control management of the leaf clusters. In these designs there are a few guidelines that are important to follow to ensure that Locations CAC functions correctly in each cluster:

- Cisco does not recommend having more than one cluster to protect the bandwidth of a single WAN edge. This can occur in designs where there are endpoints that are registered to different Unified CM leaf clusters but reside in the same physical site and utilize the same WAN edge uplink for inter-site calling. If Locations CAC is used in these cases, the bandwidth managed by each cluster is not communicated between clusters. Therefore, the only way to effectively manage this scenario is to partition the WAN edge bandwidth between clusters and have each cluster manage its own portion of the WAN edge bandwidth. This can, however, lead to bandwidth deductions for intercluster calls when the media does not traverse the WAN edge and remains on the site's LAN. While this will not oversubscribe the WAN edge, it is inefficient use of WAN edge bandwidth and thus not recommended.

- For intercluster calls it is important to avoid double bandwidth counting in cases of call forwarding or transfers. This is the case if a call is transferred or forwarded back to the originating leaf cluster and the originating Location. In such call scenarios the signalling is hair-pinned on the transferring/forwarding leaf cluster. [Figure 11-70](#) and [Figure 11-71](#) depict this scenario.

Figure 11-70 Leaf Clusters Managing CAC for an Intercluster Call

In [Figure 11-70](#) a call is established between a device in Location B (Branch 1, Cluster 1) and Location F (Branch 2, Cluster 2). Cluster 1 has deducted 80 kbps from Location B, and Cluster 2 has deducted 80 kbps from Location F (a G.711 audio call between clusters). Notice that the intercluster trunks (ICT) to Session Management Edition and from Session Management Edition to the leaf clusters are located in the Hub_none Location, where Locations bandwidth is set to unlimited (default and non-configurable). Unlike the signalling, however, the media is direct between the two branches and thus it is important to protect only each branch WAN edge with Locations CAC.

Figure 11-71 Leaf Clusters Managing CAC for a Transferred Call

In Figure 11-71 the endpoint in Location F transfers the call to another endpoint in Location B (Branch 1, Cluster 1). At this point Cluster 2 removes the bandwidth deduction from Location F because that endpoint is no longer in the call signalling process. However, the new call from Cluster 2 to Cluster 1 is hair-pinned across the Cluster 2 trunk to Session Management Edition and is seen as a new call by both Session Management Edition and subsequently Cluster 1. So in this case Cluster 1 deducts another 80 kbps of bandwidth for the new call to the endpoint in Location B, for a total of 160 kbps of bandwidth deducted from Location B for a call between two devices in Location B. This inefficient call signalling path creates this situation where Cluster 1 believes it has two separate calls established between an endpoint in Location B and the intercluster trunk to Session Management Edition, when in fact the media is not traversing the WAN edge because the two endpoints in Location B have their media established to one another. This is due to the call signalling being hair-pinned on Cluster 2.

There are two effective ways to work around this double bandwidth counting scenario when Locations CAC is managed on the leaf clusters:

- [Location-Based Call Admission Control Over Intercluster Trunk](#), page 11-114, (also known as *phantom location*)
- [QSIG Path Replacement Over Intercluster Trunks](#), page 11-116

Location-Based Call Admission Control Over Intercluster Trunk

When a call is made across clusters through an intercluster trunk (ICT) and gets hair-pinned back to the same location or site of the same cluster, although the media gets exchanged between two endpoints in the same site or location, the previous design of Unified CM Locations call admission control (CAC) deducted location bandwidth twice, once for the outbound call and again for the inbound call. The result did not correctly reflect the bandwidth consumption, which eventually caused denial of a new call to or from the site or location when ample bandwidth still existed.

To resolve the bandwidth calculation problem, the phantom location feature enables Unified CM to pass location information (the primary key ID (PKID) of location record and location name) as a proprietary information element (IE) between the calling and called parties through an ICT, either in the H.323 or SIP protocols. Thus, either cluster knows the true location information of the party or endpoint, not the location information of the ICT. (See [Figure 11-72](#) and [Figure 11-73](#) for use case examples.)

A Unified CM location designated as the phantom location is created for the ICT for this type of application. The locations server does not deduct bandwidth for a device that is assigned to the phantom location. A device such as the ICT that is assigned to the phantom location uses the true location of the connected device across the cluster.

[Figure 11-72](#) depicts the scenario for a call established between a device in Location B (Branch 1, Cluster 1) and Location F (Branch 2, Cluster 2). Cluster 1 has deducted 80 kbps from Location B, and Cluster 2 has deducted 80 kbps from Location F (a G.711 audio call between clusters). When the call signalling is sent from Cluster 1 to Session Management Edition Location B, information will be sent in an information element (step 1 in [Figure 11-72](#)) and this same information is then sent again from Session Management Edition to Cluster 2 (step 2 in [Figure 11-72](#)). Information about the device in Location F is also sent from Cluster 2 to Cluster 1 through Session Management Edition in the same manner. Only Location B information is illustrated for this example, but keep in mind that this Location information exchange happens in both directions.

Figure 11-72 Intercluster Call with Phantom Location CAC

Notice that the intercluster trunks (ICTs) to Session Management Edition and from Session Management Edition to leaf clusters are in the phantom location, where Locations bandwidth is set to unlimited (effectively not being tracked for CAC) and where location information about the calling party in Location B is sent across the ICT.

At this point Cluster 2 knows that the call it received from Session Management Edition is associated to Location B. Cluster 2 uses this information only to associate that specific call on its ICT to that Location identifier and does not handle any bandwidth deductions for Location B.

Figure 11-73 shows the case of a transferred call. After the transfer, Cluster 2 hairpins the call over the ICT and sends Cluster 1 (through Session Management Edition; steps 3 and 4 in Figure 11-73) the Location B information that it originally received from Cluster 1 (through Session Management Edition; steps 1 and 2 in Figure 11-73). This lets Cluster 1 know that the incoming call it receives from Cluster 2 originated from a device in Location B in Cluster 1. This allows Cluster 1 to return the bandwidth that it deducted for the two calls it has for the two endpoints in the same Location.

In [Figure 11-74](#), phone 1000 calls phone 4000, and the following events occur:

- A signaling call leg is established from the 1XXX cluster through Session Management Edition to the 4XXX cluster.
- Call admission control deducts the bandwidth for a call from 1XXX to 4XXX.
- An RTP media path is established directly between the two phones over the WAN.

Figure 11-74 QSIG Path Replacement Between Clusters – Initial Call

209625

In [Figure 11-75](#), phone 4000 transfers a call to phone 1001, and the following events occur:

- A new signaling call leg is established from the 4XXX cluster through Session Management Edition to the 1XXX cluster.
- Call admission control deducts the bandwidth for a call from 4XXX to 1XXX.
- The resulting media path is established directly between phone 1000 and phone 1001.

Figure 11-75 QSIG Path Replacement Between Clusters – Transferred Call

As illustrated in Figure 11-76, QSIG path replacement for tromboned calls clears redundant signaling and releases unused call admission control bandwidth.

Figure 11-76 QSIG Path Replacement Between Clusters – Signaling Path Optimized

In QSIG deployments with Session Management Edition, called, calling and diverting numbers sent in QSIG application protocol data units (APDUs) are not modified by translation and transformation patterns. For Session Management Edition deployments using QSIG-enabled trunks, numbers sent in QSIG APDUs (particularly dialed numbers, since the user dialing behavior may vary from cluster to cluster) can impact the delivery of QSIG-based features. QSIG features such as Call Back and Path Replacement can use the called and calling numbers for a given call(s) to determine if and when these features can be invoked. To avoid the dependency of called and calling numbers for QSIG feature invocation, configure the following values for the Unified CM Service Parameter that apply to QSIG features.

Clusterwide Parameters (Feature – Path Replacement)

Because the QSIG protocol passes the extension number or directory number but does not pass translated or inserted numbers, use QSIG features such as path replacement in a Unified Communications network with a uniform dial plan. When a Unified Communications network uses non-unique directory numbers in the dial plan (and/or variable user dialing habits), you must reroute calls using a PINX ID, which is a unique directory number for every PINX (that is, every QSIG-capable Unified Communications system) in the Unified Communications network. The path replacement feature uses the PINX ID, if configured, instead of the called or calling party number. To configure the PINX ID, perform the following tasks in Cisco Unified Communications Manager Administration:

- Configure the PINX ID service parameter(s) for the Path Replacement feature. (The Path Replacement feature uses the Cisco CallManager service.)
- Create a call pickup group that includes only the PINX ID.

Cisco Unified Communications Manager provides the Path Replacement Calling Search Space service parameter, so you can configure the calling search space that the cooperating PINX uses to send the outbound SETUP message to the requesting PINX. If you do not specify a value for the Path Replacement Calling Search Space service parameter, the requesting PINX uses the calling search space of the end user that is involved in the call.

For more information Path Replacement over QSIG Trunks, refer to the Path Replacement information in the IP telephony protocol section of the *Cisco Unified Communications Manager System Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

Call Diversion

Cisco Unified Communications Manager supports call diversion by rerouting and call diversion by forward switching. When call diversion by rerouting occurs, the originating PINX receives a request from the receiver of the call to divert the call to another user. The default Clusterwide Parameters (Feature - Forward) setting is to use Call Forward by Forward Switching (Forward By Reroute is disabled). As a general recommendation for Session Management Edition deployments, if you do not use a uniform dial plan for your Unified Communications network, use call diversion by forward switching and path replacement to optimize the path between the originating and terminating users.

For more information on QSIG Call Diversion, refer to the Call Diversion information in the IP telephony protocol section of the *Cisco Unified Communications Manager System Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

Unified CM Session Management Edition with RSVP Deployments

Unified CM Session Management Edition can be deployed in a number of RSVP deployments either with SIP Preconditions support between clusters or without it. For an overview of RSVP in Unified Communications designs and as a prerequisite to understanding the following content, see the section on [Unified Communications Architectures Using Resource Reservation Protocol \(RSVP\)](#), page 11-17, which includes detailed sections on Unified CM RSVP-enabled Locations and RSVP SIP Preconditions.

Session Management Edition Design with Leaf Clusters without RSVP SIP Precondition Support

Unified CM Session Management Edition can be deployed with leaf clusters that maintain their own CAC support locally within the leaf cluster. In such deployments where the leaf clusters manage their own CAC mechanism for their own devices in remote sites, or where those leaf clusters are in a campus deployment and do not require CAC for intra-cluster calls (calls that remain within the leaf cluster), Session Management Edition can be leveraged to manage CAC for audio and video calls between those leaf clusters (intercluster calls) with RSVP. In these cases Session Management Edition is leveraging the Cisco RSVP Agents to handle CAC across the links between the leaf clusters but is not managing CAC for the links that the leaf clusters manage for their intra-cluster calls.

Requirements

- Intra-cluster calls are managed by the leaf cluster CAC.
- Intercluster calls are managed by Session Management Edition RSVP-enabled Locations CAC.
- Cisco highly recommends that the WAN bandwidth managed by Session Management Edition for intercluster calls should not be shared with the WAN bandwidth for intra-cluster calls managed by the leaf clusters. If the bandwidth from the same WAN links is managed by two separate CAC mechanisms, then there is the potential for double bandwidth counting because the two separate CAC mechanisms are not aware of each other.

Figure 11-77 depicts two leaf clusters deployed in different regional sites connecting to one another through Session Management Edition for intercluster connectivity. Leaf cluster 1 is using Locations CAC to manage any remote sites in its CAC domain, while Leaf cluster 2 is using RSVP to manage any remote sites under its CAC domain. Session Management Edition in this case leverages RSVP-enabled Locations to manage the CAC domain between leaf clusters using remote RSVP Agents. The remote RSVP Agents are simply standard RSVP Agents registered with Session Management Edition and associated to the leaf cluster trunk(s) through media resource group (MRG) and media resource group list (MRGL) functions, but they are physically located at a campus site and/or co-located with the leaf cluster and thus could be "remote" from the Session Management Edition cluster. These RSVP Agents should be at a head-end network WAN that interconnects the leaf clusters and is enabled to support RSVP.

Figure 11-77 Session Management Edition Deployment with Leaf Clusters without SIP Precondition Support

209628

In a call setup between Leaf 1 and Leaf 2, the call flow works as follows (see [Figure 11-78](#)):

1. Leaf 1 sets up a call to Session Management Edition. This is done over an H.323 or SIP intercluster trunk. QSIG Path Replacement support is preferred for H.323 prior to Unified CM 8.5 and SIP with Unified CM 8.5 and later releases.
2. Session Management Edition receives the call from Leaf 1 and allocates two RSVP Agents. The RSVP Agents are associated to the trunks through the media resource group and list functions (see [Figure 11-77](#)). Once allocated, the RSVP Agents reserve the bandwidth over the path between them.
3. If the bandwidth request is successful, the call is extended from Session Management Edition to Leaf 2 over the SIP or H.323 intercluster trunk. If the reservation fails, then the call is not extended to Leaf 2 and, depending on the configuration of call processing in Session Management Edition, the call could be extended elsewhere or torn down from Leaf 1.

Figure 11-78 Call Flow for Session Management Edition Deployment with Leaf Clusters without SIP Precondition Support

The following notes apply to [Figure 11-78](#):

- If the call is extended to Leaf 2 in step 3, then Leaf 2 can use Locations CAC or RSVP as the admission control for that call leg. If using RSVP as in [Figure 11-78](#), then Leaf 2 will associate an RSVP Agent to the SIP trunk pointing to Session Management Edition and will associate another RSVP Agent with the called party endpoint.
- In cases where the leaf cluster is doing RSVP locally and not with SIP Preconditions, the Session Management Edition Remote RSVP Agent and the leaf cluster RSVP Agent associated with the trunk to Session Management Edition can be co-located on the same routing platform. See [Multiple Clusters Sharing a Single Platform for RSVP Agent](#), page 11-124, for further information.

Session Management Edition Design with Leaf Clusters with SIP Precondition Support

Unified CM Session Management Edition can also be deployed with leaf clusters that manage their CAC domain with RSVP and support RSVP SIP Preconditions. Session Management Edition in this case enables its intercluster trunks with RSVP SIP Preconditions and passes the SIP Preconditions from leaf cluster to leaf cluster, thus providing an end-to-end RSVP Agent deployment.

Requirements

- Leaf clusters with Unified CM 8.0 and later releases (preferably Unified CM 8.6.1 or later)
- Intra-cluster calls managed by the leaf cluster using Unified CM RSVP-enabled Locations
- Intercluster calls managed by Session Management Edition with SIP intercluster trunks (ICTs) configured to pass RSVP SIP Preconditions from leaf cluster to leaf cluster
- QSIG with path-replacement enabled on *all* SIP intercluster trunks (ICTs) to optimize call signalling for transferred and forwarded calls (requires Unified CM 8.5 or later release)

Figure 11-79 depicts the described solution where leaf clusters have Unified CM RSVP-enabled Locations for intra-cluster calls, and Session Management Edition as well as the SIP ICTs configured on both of the leaf clusters are enabled with RSVP SIP Preconditions. Session Management Edition in turn passes the SIP Preconditions along from leaf Unified CM to leaf Unified CM, which in turn pass those preconditions down to the branch RSVP Agents, thus providing an end-to-end RSVP reservation directly from branch to branch across multiple cluster boundaries.

Figure 11-79 Session Management Edition Deployment with Leaf Clusters with SIP Precondition Support

209630

Session Management Edition Design with Mixed Leaf Clusters (with and without SIP Precondition Support)

Unified CM Session Management Edition can also support a mixed environment where on one trunk it is supporting RSVP SIP Preconditions on the trunk to a leaf cluster that supports RSVP locally and RSVP SIP Preconditions (see example Leaf 2 in Figure 11-80) and on another trunk Session Management Edition associates an RSVP Agent and is doing RSVP locally to the trunk to a cluster that does not support RSVP SIP Preconditions (see Leaf 1 in Figure 11-80).

Figure 11-80 Session Management Edition Design with Mixed Leaf Clusters (with and without SIP Precondition Support)

Multiple Clusters Sharing a Single Platform for RSVP Agent

In some cases there might be the need to share a single router platform supporting RSVP Agent across multiple Unified CM clusters. In this case a single router platform supporting RSVP Agent, such as a Cisco Integrated Services Router (ISR), can be configured with multiple RSVP Agents, with each agent registered to a separate Unified CM cluster, each with dedicated software sessions. For information on the number of supported RSVP Agent sessions per platform, refer to the *Cisco RSVP Agent Data Sheet*, available at

http://www.cisco.com/en/US/products/ps6832/products_data_sheets_list.html

Figure 11-81 illustrates this with a Session Management Edition deployment co-located with two leaf clusters at the headquarters site. In this example one leaf cluster is Unified CM 7.x while the other leaf cluster and the Session Management Edition cluster is version 8.5. Each of the three clusters is configured with an RSVP Agent that supports 300 software sessions at the headquarters, and both leaf clusters share a Cisco ISR platform for RSVP Agent supporting 100 sessions each at two remote locations.

Figure 11-81 Session Management Edition Co-Located with Leaf Clusters (Multiple Clusters Sharing a Single Platform)

246858

Design Recommendations for Call Admission Control

This section briefly summarizes the best practices for providing call admission control in various Cisco Unified Communications Manager (Unified CM) deployments.

The following recommendations apply to deployments with a single Unified CM cluster:

- For simple hub-and-spoke topologies with no dual links, use Unified CM static locations. Leave the hub site devices in the Hub_None location.
- For Multiprotocol Label Switching (MPLS) topologies with no dual links, use Unified CM static locations, with devices at every site (including the central site) assigned to a location.
- For any other topology, use Unified CM RSVP-enabled locations. Cisco recommends the **Mandatory** or **Mandatory (video desired)** policy as the default RSVP policy between sites. The Cisco RSVP Agent feature may reside on the IP WAN router in smaller sites or run on standalone platforms in larger sites.

The following recommendations apply to deployments with multiple Unified CM clusters:

- For simple hub-and-spoke topologies with no dual links, use Cisco IOS gatekeeper zones between sites where Unified CM clusters reside.
- For two-tier hub-and-spoke topologies with no dual links where Unified CM clusters are located at the first and second level hub sites, use Cisco IOS gatekeeper zones for the links between first- and second-level hub sites and use Unified CM static locations for the links between second-level hub sites and spoke sites.
- For MPLS topologies with no dual links, use Unified CM static locations, with every site in a location and with no gatekeeper zones. Leave intercluster trunks in the Hub_None location unless an MTP is required. You may use a gatekeeper for intercluster call routing, but it is not needed for call admission control.
- For any other topology, use RSVP.

CHAPTER 12

IP Video Telephony

Revised: April 30, 2012; OL-21733-18

Enterprises with Unified Communication systems may have widely deployed voice services such as point-to-point calls and conferencing within the enterprise as well as calls to the PSTN for external connectivity. When adding video to such networks, the following approaches can be used:

- [Enable Voice Devices to Support Video Calls, page 12-1](#)
- [Integrating Voice Network with Existing Video Network, page 12-1](#)

Enable Voice Devices to Support Video Calls

An enterprise may enable existing IP phones to support cameras or use software on PC-based systems to provide video capability in conjunction with IP phones. Where possible, newer devices that support video can be deployed, thus keeping the existing call control infrastructure intact.

This approach has the following advantages:

- Existing dial plan — Enterprises can use the existing dial plan and existing call agents to support video calls in the network.
- Call admission control — A single call admission control entity in the enterprise provides a way to optimize use of the network bandwidth.
- Existing network — The enterprise can use the existing network topology by adding the needed bandwidth to accommodate video on its network.
- Users — Enterprises can enable all existing users to make video calls.
- Video codec — A standardizing video codec enables the enterprise to optimize bandwidth usage for video calls, thus reducing the need for transcoding or transrating resources.
- Existing IP phones — The enterprise can leverage existing IP phones to add video by using soft clients or by connecting cameras IP phones.

Integrating Voice Network with Existing Video Network

An enterprise that has an existing video network used for conference room video calls or for video devices for executives, can integrate the video network with its voice network, thus enabling enterprise users to call video devices.

This approach has the following advantages:

- Separate dial plans — A separate dial plan for the video network enables enterprises to plan for video resources such as videoconferencing bridges and video PSTN gateways. Users can dial a prefix to access resources from the other network.

- Existing network — The enterprise can use the existing overlapped network topology as separate video and voice networks.
- Management and monitoring — Separate management and monitoring for voice and video make troubleshooting and problem isolation easier.
- Trunk protocol — Enterprises can choose the desired protocol to interwork between the voice and video call agents. This can enable enterprises to use similar methods for call transfers, DTMF, MWI, or other functionality.
- Independence from call agent features — Enterprises can leverage capabilities that video call agents provide for video endpoints, such as optimizing the bit rate of video traffic for calls, and those capabilities may be independent of the features of voice call agents.

An enterprise can choose either of the above approaches or can combine them to achieve its objective of enabling its users to make video calls.

Video is now fully integrated into Cisco Unified Communications Manager (Unified CM), and there are also many video endpoints available from Cisco and its strategic partners. For example, Cisco Unified Video Advantage is just as easy to deploy, manage, and use as a Cisco Unified IP Phone.

What's New in This Chapter

[Table 12-1](#) lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Table 12-1 *New or Changed Information Since the Previous Release of This Document*

| New or Revised Topic | Described in: | Revision Date |
|------------------------------------|--|--------------------|
| Video interoperability | Video Interoperability, page 12-44 | April 30, 2012 |
| Minor corrections and changes | Various sections throughout this chapter | September 30, 2011 |
| Minor corrections and changes | Various sections throughout this chapter | June 2, 2011 |
| SIP clients | Endpoints, page 12-5 | November 15, 2010 |
| Trunks for video calls | Trunks, page 12-15 | November 15, 2010 |
| Video endpoints | Endpoints, page 12-5 | November 15, 2010 |
| Cisco Unified IP Phone 9900 Series | Various sections throughout this chapter | April 2, 2010 |

IP Video Telephony Solution Components

The Cisco IP Video Telephony solution consists of Cisco Unified Communications Manager (Unified CM); Cisco Unified Videoconferencing 3500 and 5000 Series Multipoint Control Units (MCUs) for H.323, Session Initiation Protocol (SIP), and Skinny Client Control Protocol (SCCP) conference calls; Cisco Unified Videoconferencing 3500 Series H.320 Gateways; Cisco IOS H.323 Gatekeeper; Cisco Unified IP Phones 9900 Series; Cisco IP Video Phone E20; Cisco Unified Personal Communicator; Cisco Unified Video Advantage; Cisco Unified IP Phone 7985; third-party SCCP video endpoint solutions; and the existing range of H.323 or SIP-compliant products from partners such as Polycom, Lifesize, Sony, and others. (See [Figure 12-1](#).)

Figure 12-1 IP Video Telephony Components

Administration Considerations

This section discusses the following configuration elements in Unified CM Administration that pertain to Video Telephony:

- [Protocols, page 12-3](#)
- [Endpoints, page 12-5](#)
- [Regions, page 12-5](#)
- [Topology-Aware Locations, page 12-8](#)
- [Retry Video Call as Audio, page 12-10](#)
- [Wait for Far-End to Send TCS, page 12-13](#)
- [Trunks, page 12-15](#)

Protocols

Unified CM supports a large number of protocols. Any device can call any other device, but video is supported only on SCCP, H.323, and SIP devices. Specifically, video is not supported in the following protocols in Cisco Unified CM Release 8.x:

- Computer Telephony Integration (CTI) applications (TAPI and JTAPI)
- Media Gateway Control Protocol (MGCP)

Therefore, Unified CM currently supports the types of calls listed in [Table 12-2](#).

Table 12-2 Types of Calls Supported in Unified CM Release 8.x

| Calling Device Type | Called Device Type | | | | |
|---------------------|--------------------|-----------------|------------|------------|-----------------|
| | SCCP | H.323 | MGCP | TAPI/JTAPI | SIP |
| SCCP | Audio and video | Audio and video | Audio only | Audio only | Audio and video |
| H.323 | Audio and video | Audio and video | Audio only | Audio only | Audio and video |
| MGCP | Audio only | Audio only | Audio only | Audio only | Audio only |
| TAPI/JTAPI | Audio only | Audio only | Audio only | Audio only | Audio only |
| SIP | Audio and video | Audio and video | Audio only | Audio only | Audio and video |

Table 12-3 lists the audio and video algorithms and protocols currently supported in Unified CM.

Table 12-3 Capabilities Supported in Unified CM Release 8.x

| H.323 | SCCP | SIP |
|---|---|---|
| H.261 | H.261 | H.261 |
| H.263, H.263+ | H.263, H.263+ | H.263, H.263+ |

Endpoints

IP phones are the most common video endpoints within the Cisco Unified Communications System. To add video to the IP phones for users, enterprises can use a camera for the Cisco Unified IP Phone 9971, use endpoints such as the Cisco E20 Video Phone, or connect the IP phone to a PC running Cisco Unified Video Advantage. Enterprises can also deploy soft clients such as Cisco Unified Personal Communicator.

Endpoints that support protocols such as H.323 and SIP can also be deployed with Cisco Unified CM. The decision to use H.323 is primarily determined by the use of H.239 for data sharing (for example, sharing PC screens during video calls) or if H.235 is used to pass secure tokens between endpoints for a video call with secure media between the endpoints. The type of user features, such as presence, also govern the type of protocol used for the endpoints, and the protocol choice is primarily dependent on the support for the features needed on the endpoints.

SIP video devices supported by Cisco Unified CM include the Cisco 9900 Series IP Phones, Cisco E20 Video Phone, Cisco Cius, third-party SIP devices (advanced), or the generic desktop and room system video device. Video can be enabled on the Cisco 9900 Series IP Phones by means of the video capabilities configuration for the devices. Configuration for the Cisco E20 Video Phone is on the phone itself. Cius supports video for calls with its front facing camera. The third-party SIP device (advanced) phone type or the generic video devices are additional options for endpoints from Polycom, Lifesize, Sony, and other manufacturers. While the configuration on Unified CM for these endpoints has not changed from earlier versions, the operation of Unified CM has been optimized to support the Cisco E20 Video Phone, Cisco Cius, Tandberg endpoints, and third-party endpoints more efficiently. Features such as the ability to process Early Offer from the endpoints and process them across SIP trunks without the use of MTP resources provide call signaling optimization and reduce the time to establish media for the call. Unified CM can also now support HD calls from these endpoints so that additional signaling (such as RTCP or parameters passed between the endpoints) is processed and sent across to achieve an optimal video call between the two devices. While Cius needs additional consideration due to its flexible use as a video phone when docked and as a Wi-Fi tablet when undocked, a Wi-Fi network is recommended for audio, and appropriate bandwidth should be used for calls. For additional information on wireless deployments, see the chapter on [Mobile Unified Communications, page 25-1](#).

For detailed information on the capabilities of the various IP phones and Cisco Unified Video Advantage, see the chapter on [Unified Communications Endpoints, page 18-1](#). For additional information on soft clients such as Cisco Unified Personal Communicator and the Client Services Framework, see the chapter on [Cisco Collaboration Clients and Applications, page 24-1](#).

Selecting the appropriate IP phones and endpoints for users to make video calls depends on the features desired and capabilities needed for video calls. The available options provide flexibility for designing and deploying clients for different types of users.

Regions

When configuring a region, you set two fields in Unified CM Administration: the Audio Codec and the Video Bandwidth. The audio setting specifies a codec type, while the video setting specifies the amount of bandwidth per call. However, even though the notation is different, the Audio Codec and Video Bandwidth fields actually perform similar functions. The Audio Codec field defines the maximum bit-rate allowed for audio-only calls as well as for the audio channel in video calls. For instance, if you set the Audio Codec for a region to G.711, Unified CM allocates 64 kbps as the maximum bandwidth allowed for the audio channel for that region. In this case, Unified CM will permit calls using either G.711, G.722, G.728, iLBC, or G.729. However, if you set the Audio Codec to G.729, Unified CM allocates only 8 kbps as the maximum amount of bandwidth allowed for the audio channel, and it will permit calls using only G.729 because iLBC, G.728, G.711, and G.722 all take more than 8 kbps.

**Note**

If both endpoints support G.711 and G.722, then G.722 will be negotiated because it is a wideband codec.

The Video Bandwidth field defines the maximum bit-rate allowed for the video channel of the call. However, for historical continuity with the practices used in traditional videoconferencing products, the value used in this field also includes the bandwidth of the audio channel. For instance, if you want to allow calls at 384 kbps using G.711 audio, you would set the Video Bandwidth field to 384 kbps and not 320 kbps.

**Note**

The Audio Codec setting also applies to the audio channel of video calls.

In summary, the Audio Codec field defines the maximum bit-rate used for audio-only calls and for the audio channel of video calls, while the Video Bandwidth field defines the maximum bit-rate allowed for video calls and should include the audio portion of the call.

Choosing the correct audio codec bandwidth limit is very important because each device supports only certain audio codecs, as shown in [Table 12-4](#). (For the most recent list of codecs supported by a particular endpoint, refer to the product documentation for that endpoint.)

Table 12-4 Types of Audio Codecs Supported by Endpoint Devices

| Codec Type | Cisco 7900 and 9900 Series IP Phones | SCCP Third-Party Video Endpoints | Typical H.323 or SIP Endpoints | Cisco Unified Videoconferencing 3500 Series Gateways | Cisco Unified Videoconferencing 3500 and 5000 Series MCUs |
|------------|--------------------------------------|----------------------------------|--------------------------------|--|---|
| G.729 | Yes | Yes, depending on the model | No | No | Yes, depending on the model |
| G.728 | No | Yes, depending on the model | Yes | Yes | Yes, depending on the model |
| G.711 | Yes | Yes | Yes | Yes | Yes |
| G.722 | Yes, depending on the model | Yes | Yes | Yes | Yes, depending on the model |

As [Table 12-4](#) indicates, if you set the region to G.729, not all videoconferencing devices are able to support this type of codec. For example, calls between a Cisco Unified Video Advantage endpoint and a Tandberg T1000 endpoint would fail, or Unified CM would allocate an audio transcoding resource for the call.

Cisco Unified CM Release 5.0 introduced audio transcoding resources based on Cisco IOS Enhanced Media Termination Point, which are able to support transcoding the audio stream of a video call while still supporting the video stream via a pass-through codec. The pass-through codec is used only for the video stream because the pass-through codec cannot be used for a stream that requires transcoding. The following three conditions must all be true for the pass-through codec to be used:

- The two endpoint devices have a matching CODEC capability.
- **MTP Required** is *not* checked for either endpoint.
- All intermediate resource devices (MTPs and transcoders) support the pass-through codec.

Traditional transcoders do not currently support the pass-through capability, so the call would connect as audio-only and would be transcoded between G.729 and G.711. To avoid this situation without using Cisco IOS Enhanced Transcoders, you would have to set the region to use G.711 instead. However, a region set for G.711 would also use G.711 for audio calls between two IP phones, which you might not want due to the increased consumption of bandwidth over the WAN.

If you want to use G.729 for audio-only calls to conserve bandwidth and to use G.711 for video calls, then you should configure one region to use G.711 for video endpoints that do not support G.729 and a separate region (or regions) to use G.729 for IP phones. (See Figure 12-2.) This method increases the number of regions needed but provides the desired codec and bandwidth allocations.

Figure 12-2 Using G.711 for Video Calls and G.729 for Audio-Only Calls

Note

It is possible to configure a pair of regions to prohibit video. If two video-capable devices in that region pair try to call each other, they will connect as audio-only unless Retry Video Call as Audio is not checked, in which case AAR rerouting logic will take over.

Table 12-5 lists some example configurations and their outcomes.

Table 12-5 Scenarios for Various Region Settings

| Region Setting | Setting of Retry Video as Audio | Result |
|-----------------------------|---------------------------------|---|
| Region allows video | Enabled | Video calls allowed |
| Region allows video | Disabled | Video calls allowed |
| Region does not allow video | Enabled | Video calls will proceed as audio |
| Region does not allow video | Disabled | If AAR is not configured, video calls fail (with busy tone and "Bandwidth Unavailable" message displayed) |

The Video Call Bandwidth field accepts values in the range of 1 to 32,256 kbps. However, to allow for compatibility with H.323 and H.320 videoconferencing devices, Cisco recommends that you always enter values for this field in increments of either 56 or 64 kbps. Therefore, valid values for this field include 112 kbps, 128 kbps, 224 kbps, 256 kbps, 336 kbps, 384 kbps, and so forth.

When the call speed requested by the endpoint exceeds the bandwidth value configured for the region, Unified CM automatically negotiates the call down to match the value allowed in the region setting. For instance, assume that an H.323 endpoint calls another H.323 endpoint at 768 kbps, but the region is set to allow a maximum of 384 kbps. The incoming H.225 setup request from the calling party would indicate that the call speed is 768 kbps, but Unified CM would change that value to 384 kbps in the outgoing H.225 setup message to the called party. Thus, the called endpoint would think that it was a 384-kbps call to begin with, and the call would be negotiated at that rate. The calling endpoint would show the requested bandwidth as 768 kbps, but the negotiated bandwidth would be 384 kbps.

However, if you set the Video Bandwidth to "None" in the region, Unified CM will either terminate the call (and send an H.225 Release Complete message back to the calling party) or will allow the call to pass as an audio-only call instead, depending on whether or not the called device has the Retry Video Call as Audio option enabled. (See [Retry Video Call as Audio, page 12-10](#).)

As the video resolution for the calls increases, so does the need for bandwidth. For video bandwidth in the region settings, the suggested values are 384 kbps for calls where CIF video resolution is desired, 768 kbps where VGA resolution is desired, and 1.5 Mbps for 720p resolution video calls. While most video endpoints have variable bit-rate encoders, video phones such as the Cisco Unified IP Phone 9900 Series have a constant bit-rate encoder for video. The constant bit-rate encoder provides better motion video and error resiliency.

Some endpoints such as the Cisco Unified Video Advantage use CIF resolution for calls. To restrict CIF resolution for video calls from such devices, the region configuration for video call bandwidth can be configured to 384 kbps and the devices can be associated to this region. Thus, calls to endpoints with higher resolution or conferences to MCUs negotiate CIF resolution for video.

Some Unified Communications endpoints with wireless capabilities (for example, Cisco Unified IP Phones 9900 Series and Cisco Cius) allow configuration of different bandwidth settings for the wireless media. For further details and design considerations, see [Wireless LAN Infrastructure, page 3-57](#).

Topology-Aware Locations

There are two methods to limit the amount of bandwidth available for calls between locations. Cisco Unified CM 4.0 introduced support for video calls in locations. More specifically, the location option in Cisco Unified CM defines the aggregate bandwidth allowed for all calls between that location and all other locations. This aggregate bandwidth value maps well to traditional hub-and-spoke network topologies. Cisco Unified CM Release 5.x introduced the option to use topology-aware locations based on Resource Reservation Protocol (RSVP) to determine if enough bandwidth is available along the path between two sites. RSVP enables per-hop checking that accommodates complex topologies while supporting the separation of audio bandwidth and video bandwidth via the use of RSVP Application IDs.

**Note**

Static locations and RSVP-based locations use different models to separate voice and video calls. For more details, see [Call Admission Control, page 11-1](#).

RSVP-based locations introduce the concept of an RSVP policy. While there are numerous policy options, there are two main categories:

- The RSVP reservation for the video stream is mandatory for the call to complete. The call will either fail (with busy tone played and the "Bandwidth Unavailable" message displayed to the user) or Automated Alternate Routing (AAR) will try to reroute the call.

Note While the call is being rerouted through the PSTN, no video will be available.

- The RSVP reservation for the video stream is desired.

First, the audio codec and the video bandwidth set in the region define the maximum speed (bit rate) of the video call. An RSVP reservation is sent from the Cisco RSVP Agent for the audio and video stream of the call using the maximum bit rate as the reservation requirement. If the RSVP reservation for the video stream fails, Unified CM checks the setting of RSVP policy to determine how to handle that call. If the policy for the audio stream is optional, the call will continue as audio-only. Otherwise, if the RSVP policy for the audio stream is mandatory, the call will continue as audio-only unless the audio stream also fails to get an RSVP Reservation. In that case, the call will either fail (with busy tone played and the "Bandwidth Unavailable" message displayed to the user) or Automated Alternate Routing (AAR) will try to reroute the call. (For more details on topology-aware locations, see [Call Admission Control, page 11-1.](#))

Note

If the video reservation fails while using a video-desired policy, the call will complete as audio-only. However, the user will not have any visual or audible feedback to indicate why the video failed.

When configuring static locations, you also set two fields in Unified CM Administration: the Audio Bandwidth and the Video Bandwidth. Unlike regions however, the Audio Bandwidth for static locations applies only to audio-only calls, while the Video Bandwidth applies to both the audio and video channels of video calls. The audio and video bandwidth are kept separate because, if both types of calls shared a single allocation of bandwidth, then it is very likely that audio calls would take all the available bandwidth and leave no room for any video calls, or vice versa. Also, separate bandwidth pools for audio and video correspond to the way queues are configured in the switches and routers in the network, which typically have a priority queue for voice traffic and a separate priority queue or a Class-Based Weighted Fair Queue for video traffic. (See [WAN Quality of Service \(QoS\), page 3-40](#), for more details.)

Both the Audio Bandwidth and the Video Bandwidth fields offer three options: None, Unlimited, or a field that accepts numeric values. However, the values entered in these fields use two different calculation models. For the Audio Bandwidth field, the values entered should include the Layers 3 to 7 overhead required for the call. For instance, if you want to permit a single G.729 call to or from a location, you would enter the value of 24 kbps. For a G.711 call, you would enter the value of 80 kbps. The Video Bandwidth field, by contrast, should be entered without the overhead included. For instance, for a 128-kbps call you would enter 128 kbps, and for a 384-kbps call you would enter 384 kbps. As with the values used in the Video Bandwidth field for regions, Cisco recommends that you always use increments of 56 kbps or 64 kbps for the Video Bandwidth field for locations as well.

For example, assume that a company has a three-site network. The San Francisco location has a 1.544-Mbps T1 circuit connecting it to the San Jose main campus. The system administrator wants to allow four G.729 voice calls and one 384-kbps (or two 128-kbps) video calls to/from that location. The Dallas location has two 1.544-Mbps T1 circuits connecting it to the San Jose main campus, and the

administrator wants to allow eight G.711 voice calls and two 384-kbps video calls to/from that location. For this example, the administrator would set the San Francisco and Dallas locations to the following values:

| Location | Number of Audio Calls Desired | Audio Bandwidth Field Value | Number of Video Calls Desired | Video Bandwidth Field Value |
|---------------|-------------------------------|-----------------------------|-------------------------------|-----------------------------|
| San Francisco | 4 using G.729 | 96 kbps (4 * 24 kbps) | 1 at 384 kbps | 384 kbps |
| Dallas | 8 using G.711 | 640 kbps (8 * 80 kbps) | 2 at 384 kbps | 768 kbps |

When the call speed requested by the endpoint exceeds the value configured for the location, Unified CM will *not* automatically negotiate the call speed (as it does for regions) to match the value allowed in the location setting. Instead, the call will be rejected or will be retried as an audio-only call (if the Retry Video as Audio setting is enabled on the called device). Therefore, you should always set the region's video bandwidth to a value lower than the location's video bandwidth value. For example, if you have two regions (region A and region B) and you set the video bandwidth between those two regions to 768 kbps but the devices in region A are in a location that has a video bandwidth set to 384 kbps, then all calls between those two regions will fail or will result in audio-only calls (depending on the Retry Video Call as Audio setting).

Retry Video Call as Audio

This check-box is available on all SCCP endpoint types that support video, including Cisco Unified IP Phones 7940, 7941, 7942, 7945, 7960, 7961, 7962, 7965, 7970, 7971, 7975, and Cisco IP Video Phone 7985, as well as third-party SCCP video endpoints, and all H.323 and SIP devices (clients, gateways and all types of H.323 trunks). When this option is activated (checked), if there is not enough bandwidth to reach the device (for example, if the Unified CM regions or locations do not allow video for that call), then Unified CM will retry the call as an audio-only call. When this option is deactivated (unchecked), Unified CM will not retry the call as audio-only but instead will either fail the call or reroute the call by whatever automated alternate routing (AAR) path is configured. By default, this retry option is enabled (checked).

This feature applies to the following scenarios only:

- The region is configured not to allow video.
- The location is configured not to allow video, or the requested video speed exceeds the available video bandwidth for that location when locations are not using an RSVP Policy.
- For calls between Unified CM clusters, the requested video speed exceeds the gatekeeper's zone bandwidth limits.

The Retry Video Call as Audio option takes effect only on the terminating (called) device, thus allowing the flexibility for the calling device to have different options (retry or AAR) for different destinations.

If the video call fails due to bandwidth limitations but automated alternate routing (AAR) is enabled, Unified CM will attempt to reroute the failed call as a video call to the AAR destination. If AAR is not enabled, the failed call will result in a busy tone and an error message being sent to the caller. (See [Figure 12-3](#).) Depending on the type of device that is calling, the failed call will result in one of the following conditions:

- If the calling device is an SCCP endpoint with an LCD screen, the caller will hear busy tone and will see the message "Bandwidth Unavailable" displayed on the device.
- If the calling device is an SCCP endpoint without an LCD screen (such as a Cisco Unified IP Phone 7902), the caller will hear busy tone.
- If the calling device is an H.323 or SIP device or a PSTN device connected through a gateway, the caller will hear busy tone and Unified CM will send the appropriate error message (such as a Q.931 Network Congestion cause code) back to the H.323, SIP, or MGCP device.

Figure 12-3 Possible Scenarios for a Video Call

See the chapter on [Call Admission Control](#), page 11-1, for further details on the use of AAR.

Figure 12-4 illustrates the steps of a call between two clusters using non-gatekeeper controlled intercluster trunks.

Figure 12-4 Call Flow Between Two Clusters Using Non-Gatekeeper Controlled Intercluster Trunks

Wait for Far-End to Send TCS

This check-box is available on all H.323 devices, including H.323 clients, H.323 gateways, and H.225 gatekeeper-controlled trunks. This feature pertains to the H.245 capabilities-exchange phase of H.323 calls. When this feature is enabled, Unified CM waits for the remote H.323 device to send its Terminal Capabilities Set (TCS) to Unified CM before Unified CM will send its TCS to the H.323 device. When the option is disabled, Unified CM does not wait but sends its TCS to the remote H.323 device immediately.

By default, the Wait for Far-End to Send TCS option is enabled (checked). However, you must uncheck (disable) it in the following circumstances:

- When the H.323 device communicating with Unified CM is also waiting for the far-end to send its TCS

In this case, a stalemate occurs because neither side sends its TCS, and the H.245 connection times out after a few seconds. Examples of devices that also wait for the far-end to send TCS are some H.323 routed-mode gatekeepers, H.320 gateways, H.323 proxies (or IP-to-IP gateways) and some H.323 multipoint conference bridges. These devices wait for the far-end to send TCS for the same reason Unified CM does: because they are waiting for both sides of the connection to send their TCSs before forwarding them to the other side.

- When communicating with another Unified CM cluster over an intercluster trunk

**Note**

For intercluster trunks and gatekeeper-controlled intercluster trunks, the Wait for Far-End to Send TCS option is always disabled and cannot be enabled.

In many scenarios, Unified CM performs the role of a software switch connecting two endpoint devices (such as two H.323 clients that are trying to call each other). In such cases, it is best if Unified CM waits until both devices have sent their TCS messages so that it knows the capabilities of each device and can therefore make the most intelligent decision about what TCS to send back to each party (depending on region and location configurations, among other things). In these cases, the Wait for Far-End to Send TCS feature should be enabled.

However, some other H.323 devices (such as an H.320 gateway, which connects an H.323 device to an H.320 device) also perform the function of connecting two or more parties together. The gateway also prefers to wait until both ends send their TCS messages, so that it can make the most intelligent choice about how to set up the call. A stalemate could result if Unified CM and the gateway both wait for the other side to send their TCSs. To avoid this stalemate situation, disable (uncheck) the Wait for Far-End to Send TCS feature.

For instance, consider the following call scenarios illustrated in [Figure 12-5](#):

- Scenario 1 — Cisco Unified Video Advantage calls an H.320 endpoint
- Scenario 2 — An H.323 client calls an H.320 endpoint

In both of these scenarios, Wait for Far-End to Send TCS feature can be left at its default setting of enabled (checked)

Figure 12-5 Scenarios with the Wait for Far-End to Send TCS Feature Enabled (Checked)

In Scenario 1 from Figure 12-5, Unified CM already knows the capabilities of the Cisco Unified Video Advantage client because SCCP devices provide Unified CM with their media capabilities during registration. But Unified CM does not know the capabilities of the H.323 gateway until the gateway sends its TCS to Unified CM during the H.245 phase of the call. Likewise, the H.323 gateway does not know what TCS to send to Unified CM until the H.323 endpoint sends its TCS to the gateway. In this case it is better to leave the Wait for Far-End to Send TCS feature enabled because the H.323 endpoint will send its TCS to the gateway, the gateway will send its TCS to Unified CM, and Unified CM will then have the TCSs from both endpoints with which to make a decision.

Figure 12-6 shows the following call scenarios, in which the call will fail unless the Wait for Far-End to Send TCS feature is disabled:

- Scenario 1 — Cisco Unified Video Advantage calls another Cisco Unified Video Advantage in a remote cluster via the ISDN network
- Scenario 2 — An H.323 client calls another H.323 client in the remote cluster via the ISDN network

Figure 12-6 Scenarios with the Wait for Far-End to Send TCS Feature Disabled (Unchecked)

In both scenarios from Figure 12-6, there will be a stalemate because both Unified CMs will wait to receive the TCSs from the gateways, and the gateways will both wait to receive the TCS from the ISDN side as well. The call will time-out after a few seconds and fail. From the perspective of the users, the

caller will hear ringback tone indicating that the call is progressing and the called party will hear a ring indicating an incoming call. When the called party attempts the answer the call, the H.245 phase will fail due to the stalemate, and the call will then fail by hanging up on both parties.

To work around this issue in scenarios such as these, Cisco recommends that you disable (uncheck) the Wait for Far-End to Send TCS option on the device representing the H.320 gateway in Unified CM. This device could be an H.225 gatekeeper-controlled trunk or an H.323 gateway device, depending on how you have configured Unified CM to reach the H.320 gateway.

However, if the Wait for Far-End to Send TCS option is disabled, there is a possibility that the initial capabilities exchanged will not work for the remote device. For instance, the Unified CM region might be set to 768-kbps video but the H.320 device might only support 384 kbps, or the selected audio codec might not work for the remote party. In such cases, the initially negotiated logical channels might have to be torn down and reopened with the correct speed and codec. Many legacy H.323 and H.320 devices do not handle this situation well and will disconnect the call when Unified CM sends a CloseLogicalChannel message to renegotiate the channel to a different value. Thus, you must be careful where and when you disable the Wait for Far-End to Send TCS option.

Trunks

Cisco Unified CM supports various types of trunks. H.323 trunks have been most popular for video deployments due to the large number of H.323 endpoint deployments, and it can be used to interwork with H.323 gatekeepers that route calls to video endpoints and gateways. H.323 trunks also provide a pass-through functionality for a number of video features used by the H.323 video endpoints, such as H.239 and H.235. The RASAggregator trunk enables Unified CM to provide advanced features such as call restrictions and bandwidth enforcement for calls for the endpoints registered to a Cisco IOS gatekeeper.

SIP trunks can provide interconnection to SIP networks. These trunks support video and SRTP across the trunks. Unified CM can provide a much tighter integration for video communication servers such as the Cisco TelePresence Video Communication Server (VCS). This capability expands the support for high-definition calls so that advanced signaling needed by Cisco VCS, Cisco Video devices, and third-party video endpoints can also work through Unified CM. In addition, Cisco Unified CM SIP trunks support Early Offer for video calls without the need of a media termination point (MTP). This can be important for deployments where calls go through multiple call control servers or where call cut-through time for establishing a bidirectional media path is important. For additional information, see the chapter on [Cisco Unified CM Trunks, page 14-1](#).

Some deployments may use DNS SRV in their networks. For Cisco TelePresence VCS deployments that use DNS SRV, Unified CM SIP trunks can also use DNS SRV. In such deployments, you need to consider the DNS server scalability and redundancy and also note that the load balancing and redundancy ability is dependent on the DNS server servicing the requests. Thus, the Unified CM trunk load balancing and redundancy will be in addition to the DNS server load balancing and redundancy.

Multipoint Conferencing

Whenever three or more parties want to engage in the same video call together, a Multipoint Control Unit (MCU) is required. An MCU consists of the following main components:

- Multipoint Controller (MC)
- Multipoint Processor (MP)

The MC handles all aspects of call setup and teardown for the conference, including media negotiation, call signaling, and choosing which MP to use for the call. The MP processes all the audio and video packets. The MC controls the MP, and one MC can control multiple MPs. The MP can be either software-based or hardware-based. Software-based MPs are typically not capable of advanced transcoding, transrating (multiple speeds), or composition features.

Cisco MCUs also support the Skinny Client Control Protocol (SCCP). This enables the MCU to be integrated with Unified CM as a video conference bridge similar to how the Cisco IOS conference bridges can be integrated for audio conferencing.

Cisco Unified Videoconferencing products have the Multipoint Controller (MC) and the Multipoint Processor (MP) functions built into the Multipoint Conference Units (MCUs) as an integrated device. Chassis-based MCUs provide flexibility and scalability by using an MCU module that manages and controls the Enhanced Media Processor (EMP) modules that do the video conferencing.

Note

An EMP is required for the Cisco 3545 and 5200 MCUs because they do not have a software-based MP. An MCU module is needed to control the EMPs in the MCU chassis.

Cisco Unified CM supports the Cisco Unified Videoconferencing MCUs in SCCP, H.323, and SIP modes. Each protocol offers different features and is used for different reasons, so each of these MCUs is equipped to run all three protocols. The Cisco Unified Videoconferencing MCUs can be configured to run all three protocols simultaneously and divide the total number of available MP resources between the three.

Regardless of signaling protocol, the MCU provides the same basic function of receiving the audio and video streams from each participant and sending those streams back out to all other participants in some sort of combined view. There are two types of views in a multipoint video conference:

- Voice-activated (switched)
- Continuous presence

Voice Activation

Voice-activated conferences take in the audio and video streams of all the participants, decide which participant is the dominant speaker, and send only the dominant speaker's video stream back out to all other participants. The participants then see a full-screen image of the dominant speaker (and the current speaker sees the previous dominant speaker). The audio streams from all participants are mixed together, so everyone hears everyone else, but only the dominant speaker's video is displayed.

You can use any of the following methods to select the dominant speaker:

- Voice activation mode

Using this mode, the MCU automatically selects the dominant speaker by determining which conference participant is speaking the loudest and the longest. To determine loudness, the MCU calculates the strength of the voice signal for each participant. As conditions change throughout the conversation, the MCU automatically selects a new dominant speaker and switches the video to

display that participant. A hold timer prevents the video from switching too hastily. To become the dominant speaker, a participant has to speak for a specified number of seconds and be more dominant than all other participants.

- Manual selection of the dominant speaker through the MCU's web-based conference control user interface

The conference controller (or chairperson) can log onto the MCU's web page, highlight a participant, and select that person as the dominant speaker. This action disables voice activity detection, and the dominant speaker remains constant until the chairperson either selects a new dominant speaker or re-enables voice activation mode.

- Configuring the MCU to cycle through the participant list automatically, one participant at a time
- With this method, the MCU stays on each participant for a configured period of time and then switches to the next participant in the list. The conference controller (or chairperson) can turn this feature on and off (re-enable voice activation mode) via the web interface.

Continuous Presence

Continuous-presence conferences display some or all of the participants together in a composite view. The view can display from 2 to 16 squares (participants) in a variety of different layouts. Each layout offers the ability to make one of the squares voice-activated, which is useful if there are more participants in the conference than there are squares to display them all in the composite view. For instance, if you are using a four-way view but there are five participants in the call, only four of them will be displayed at any given time. You can make one of the squares in this case voice-activated so that participants 4 and 5 will switch in and out of that square, depending on who is the dominant speaker. The participants displayed in the other three squares would be fixed, and all of the squares can be manipulated via the conference control web-based user interface.

Note

Continuous presence requires the use of an Enhanced Media Processor (EMP) in the Cisco Unified Videoconferencing MCU.

MP Resources

For both types of conferences, the type of MP resource determines which video formats, transrating, and transcoding capabilities the MCU can support. If endpoints connect to the conference at different speeds, a transrating-capable MP is required. The RM and EMP modules are both capable of transrating between speeds. If a transrating-capable MP is not available, the MCU will send out flow-control messages to all the endpoints, instructing them to lower their transmit speed to match the maximum receive rate of the slowest endpoint. For example, if three participants are connected in a 384-kbps conference and a fourth participant joins at 128 kbps, the MCU will send flow-control messages to the other three participants instructing them to lower their transmit rates to match the 128-kbps participant. This method causes all participants to suffer degraded quality because one participant is less capable. A transrating-capable MP would, instead, convert the 128-kbps stream to 384 kbps, and vice versa, so that each participant can enjoy the best quality their connection allows.

For continuous-presence conferences, a transrating-capable MP is also very important. The software-based MP built into the MCU combines all the input streams and sends the resulting combination back out to each participant. For instance, if four participants are connected in a continuous-presence conference at 384 kbps using G.711 audio, each participant will transmit 320 kbps of video and 64 kbps of audio into the MCU. The MCU will take these four input video streams and combine them into the four-way composite view. The MCU will then transmit 1280 kbps of video back to each endpoint, along with the mixed 64 kbps of audio, for a total of 1344 kbps per endpoint. This method is known as Asynchronous Continuous Presence, and it can have a negative impact on bandwidth requirements, call admission control mechanisms, and interoperability with certain devices.

**Note**

Cisco strongly advises against the use of Asynchronous Continuous Presence.

With the RM or EMP modules, the MCU is capable of transrating each input stream before combining them, so that the total output bandwidth matches the input bandwidth. For instance, if the MCU is using the four-quadrant layout and each participant transmits 320 kbps of video and 64 kbps of audio into the MCU, the MCU would essentially transrate each input stream down to 80 kbps, combine them so that the resulting four-quadrant view is 320 kbps of video (4 * 80 kbps), combine this video with the mixed 64 kbps audio, and transmit the final combination back to each participant. This method is known as Synchronous Continuous Presence. Cisco strongly recommends that all continuous-presence conferences use the Synchronous Continuous Presence mode. However, use of this mode means that each MCU must have a transrating-capable MP (such as an RM or EMP) available, which does increase the cost of the MCU.

**Note**

For H.323 and SIP clients with built-in MCUs, Unified CM does not allow an H.323 client to generate a second call, thereby negating the functionality of the built-in MCU.

MCU Resources for Ad-Hoc Conferences

As stated previously, the Cisco Unified Videoconferencing MCUs offer support for SCCP beginning with software version 3.2+ for those models and with Cisco Unified CM Release 4.0. When configured in SCCP mode, Unified CM provides the MC function while the MCU provides the MP function. The SCCP MCU is controlled completely by Unified CM. Cisco Unified CM 8.6 and later releases support SIP-based TelePresence MCUs through conference bridges, thus providing an additional method of MCU integration for ad-hoc conferences that can support higher resolution.

Only the following events invoke ad-hoc MCU resources:

- The user of an SCCP or SIP endpoint (such as an IP Phone or a third-party SCCP video endpoint) presses the Conf, Join, or cBarge softkeys to invoke an ad-hoc conference
- The user of an SCCP or SIP endpoint (such as an IP Phone or a third-party SCCP video endpoint) presses the MeetMe softkey to invoke a reservationless meet-me conference.
- The user of Cisco Cius or Cisco Unified Personal Communicator in softphone mode uses the Join or Conference feature to join multiple calls into a conference.

Participants in either of these types of conferences can include any type of endpoint (that is, video and non-video devices using any signaling protocol that Unified CM supports via any supported gateway type); however, only SCCP endpoints, SIP Cisco IP Phones, or Cisco Unified Personal Communicator can invoke the ad-hoc MCU resources. In other words, an H.323 video endpoint cannot invoke an ad-hoc MCU resource, but an SCCP video endpoint can invoke the resource and then join an H.323 video participant to the call. For example, the user at the SCCP endpoint could press the Conf softkey, dial the directory number of an H.323 client, and then press the Conf softkey again to complete the transaction. The H.323 client will be joined as a participant on the SCCP MCU conference.

**Note**

Earlier versions of this document described alternative configurations for H.323 devices that do not support supplementary services (such as placing a call on hold). For details, refer to the section on *SCCP MCU Resources* in the *Cisco Unified Communications SRND Based on Cisco Unified Communications Manager 7.x*, available at http://www.cisco.com/en/US/docs/voice_ip_comm/cucm/srnd/7x/uc7_0.html.

For reservationless conferences via the MeetMe softkey, the signaling protocol used by the other endpoints does not have to support being placed on hold and transferred. For these types of conferences, each endpoint dials the MeetMe dial-in number arranged by the SCCP client who initiated the conference.

Figure 12-7 illustrates how H.323 endpoints and Cisco IP Phones can participate in the same ad-hoc conference. In this example, the conference was initiated by an SCCP endpoint using the Conf softkey to invite the three members.

Figure 12-7 Ad-Hoc Conference Between SCCP, SIP, and H.323 Endpoints

Ad-hoc conferences support voice-activated mode as well as continuous presence, depending on the conferencing bridge used.

Media Resource Groups and Lists

When a user of an SCCP or SIP phone activates the Conf, Join, or MeetMe softkey, Unified CM uses the Media Resource Manager to select conference bridges. Conference bridges or MCUs resources are configured in the media resource groups (MRGs). The media resource group lists (MRGLs) specify a prioritized list of MRGs and can be associated with the endpoints. The Media Resource Manager uses MRGLs of the endpoints for selecting the conference bridge. How you group the resources is completely at your discretion, but it is typically done either by geographical placement (so that all endpoints at a given site use the conference bridges closest to them) or by endpoint type (so that video-capable endpoints use a video-capable MCU while audio-only endpoints use a different conference bridge resource).

Cisco Unified CM has the Intelligent Bridge Selection feature, which provides a method for selecting conference resources based on the capabilities of the endpoints in the conference. If there are two or more video endpoints when the conference is invoked and a videoconferencing resource is available, Intelligent Bridge Selection chooses that resource for the conference. On the other hand, if no videoconferencing resource is available or if there are no video-capable endpoints in the conference, Intelligent Bridge Selection chooses an available audio resource for the conference. Intelligent Bridge Selection provides an added functionality to select secure conference bridges for secure conferences. However, secure conference bridge selection is dependent on device capabilities. Unified CM may decide to allocate secure conference bridges in lieu of video or audio conference bridges. Flexibility to change the behavior of the Intelligent Bridge Selection functionality is provided through service parameter configurations in Unified CM.

For the purposes of Intelligent Bridge Selection, the following types of endpoints are considered to be video-capable:

- Cisco Unified Video Advantage (Should be running on a PC connected to the PC port of an IP phone)
- Cisco Unified IP Phone 7985G and 9900 Series
- Cisco Unified Personal Communicator or the Client Services Framework clients
- H.323 client (Third-party video endpoints)
- SIP Advanced endpoint (Third-party video endpoints)
- SIP trunk with no media termination point (MTP) for video calls
- H.323 trunk with no MTP for video calls

Intelligent Bridge Selection has the following advantages over other methods of conference bridge selection:

- Conference bridge selection by conference type – either secure, video, or audio conferences
- Simplified media resource configuration
- Optimized use of MCU video ports that potentially would have been used for audio-only conferences with other methods of bridge selection

All the conference bridge resources and MCUs can be in one MRGL, and Intelligent Bridge Selection will then select the conference bridge based on the need to do just an audio conference or a video conference.

Unified CM also supports an alternate way of selecting conference bridges, which can be specified by service parameter configurations. In this mode, Unified CM applies the following criteria to select the conference bridge resource to use, in the order listed here:

1. The priority order in which the media resource groups (MRGs) are listed in the media resource group list (MRGL)
2. Within the selected MRG, the resource that has been used the least

If the MCU is placed at the top of the MRGL for the phone, the MCU will always be chosen even for audio-only conferences that do not involve any video-capable participants. In this scenario, the MCU resources might be wasted on audio-only conferences and not be available to satisfy the request for a video conference when it occurs.

Note

Meet-me conferences do not use the Intelligent Bridge Selection feature.

Intelligent Bridge Selection

Cisco Unified CM includes the Intelligent Bridge Selection feature, which provides a method for selecting conference resources based on the capabilities of the endpoints in the conference. If there are two or more video endpoints when the conference is invoked and a videoconferencing resource is available, Intelligent Bridge Selection chooses that resource for the conference. On the other hand, if no videoconferencing resource is available or if there are no video-capable endpoints in the conference, Intelligent Bridge Selection chooses an available audio resource for the conference.

Intelligent Bridge Selection provides an added functionality to select secure conference bridges for secure conferences. However, secure conference bridge selection is dependent on device capabilities. Unified CM may decide to allocate secure conference bridges in lieu of video or audio conference bridges. Flexibility to change the behavior of the Intelligent Bridge Selection functionality is provided through service parameter configurations.

For the purposes of Intelligent Bridge Selection, the following types of endpoints are considered to be video-capable:

- Cisco Unified Video Advantage (Should be running on a PC connected to the PC port of an IP phone)
- Cisco Unified IP Phone 7985G
- Cisco Unified Personal Communicator
- H.323 client (Third-party video endpoints)
- SIP Advanced endpoint (Third-party video endpoints)
- SIP trunk with no media termination point (MTP) for video calls
- H.323 trunk with no MTP for video calls

Intelligent Bridge Selection has the following advantages over other methods of conference bridge selection:

- Conference bridge selection by conference type – either secure, video, or audio conferences
- Simplified media resource configuration
- Optimized use of MCU video ports that potentially would have been used for audio-only conferences with other methods of bridge selection

**Note**

Meet-me conferences do not use the Intelligent Bridge Selection feature.

H.323 and SIP MCU Resources

When configured in H.323 or SIP mode, the MCU provides the MC function and behaves like an H.323 or SIP peer to Unified CM. H.323 and SIP MCU conferences can be invoked in a number of different ways, but they all fall into two major categories:

- Scheduled
- Reservationless

A scheduled conference uses a scheduling application to reserve the MCU resources in advance of the call. The scheduling function typically is provided through a web-based user interface such as Cisco Unified MeetingPlace, or Cisco Unified Video Conferencing Manager. The scheduling application usually generates an invitation that provides the user with the date and time of the conference, the number of ports reserved for the conference, and the dial-in information. Alternatively, the scheduling system can be configured to dial out to some or all of the participants at the beginning of the conference.

For a reservationless conference, the MCU has a certain number of resources that are available on demand. To create a conference, a user simply dials into the MCU at any time. If that user is the first participant to dial in, the MCU dynamically creates a new conference using the settings defined in the service template. (For more information on service templates, see [Service Templates and Prefixes](#), page 12-22.) Subsequent users who dial into the same conference number are joined to that conference.

Any type of endpoint can create and participate in scheduled and reservationless H.323 or SIP conferences. For instance, an SCCP endpoint can dial into the H.323 MCU to create a reservationless conference just as well as an H.323 endpoint can.

Figure 12-8 illustrates how H.323 and SCCP endpoints can participate in the same H.323 conference. In this example, the conference was initiated by an SCCP endpoint that dialed into the H.323 MCU to create a new reservationless conference, and the other two parties subsequently dialed into that conference.

Figure 12-8 *SCCP and H.323 Endpoints in a Reservationless Conference*

H.323 and SIP conferences support both voice-activated and continuous-presence modes. Furthermore, H.323 conferences support all of the MP types, including the integrated software-based MP of the MCU, the Rate Matching (RM) module, and the Enhanced Media Processor (EMP) module.

Service Templates and Prefixes

A service on the MCU defines the settings that pertain to each conference. You can have different services defined for the different types of conferences. Each service defines, at a minimum, the following settings:

- Speed of the conference (the video bit-rate)
This setting might include multiple speeds if a transrating-capable MP is used.
- Minimum and/or maximum number of participants
The minimum number defines how many ports will be reserved at the beginning of the conference. The maximum number defines the maximum number of participants that the MCU will allow to join this conference.
- Video codec type (H.261, H.263, or H.264)
- Frame rate (15 or 30 fps)
- Resolution (QCIF or CIF)
- MP resource (Auto, MP, RM, or EMP)
- Video layout to be displayed (voice activated or continuous presence)

A conference can include multiple layouts or even dynamic layouts that change as the number of participants in the conference increases or decreases.

- H.323 and SIP, or SCCP

When the "SCCP service" check-box is enabled (checked), the service is used for SCCP conferences. When this box is disabled (unchecked), the service is used for H.323 and SIP conferences.

For H.323 and SIP services, each service is assigned a service prefix that is dialed by the endpoints to reach that particular service. The service prefix forms the leading digits of the conference number, and the trailing digits define the conference ID. This format allows multiple conferences to run simultaneously using the same service prefix. For instance, you can have a service prefix of 555, while the full dial string of the conference is seven digits. This scheme would allow for conference numbers in the range of 5550000 through 5559999, with four digits for the conference ID. The user must dial the full string to access the conference. When the call is received by the MCU, the MCU parses the dialed digits to try to match a service prefix. Once it determines which service prefix is being dialed, the MCU then uses the remaining digits as the conference ID. If the conference ID does not exist yet, the MCU creates a new reservationless conference with that ID. If the conference already exists, the user is added to that conference.

It is important to note that, if both H.323 and SIP are enabled on the MCU at the same time, the dial plan must be the same for both protocols. There is no separation between H.323 and SIP as there is with SCCP. If a conference is created using SIP, the MCU will register that conference via H.323. If the gatekeeper or SIP proxy rejects the registration, the conference will fail.

SCCP services must also have a service prefix defined, but the digits themselves do not mean anything because users do not "dial" into an SCCP service. The prefix is used only in the SCCP registration messages between Unified CM and the SCCP MCU resource. Users either use the Conf, Join, or cBarge softkeys to access the SCCP MCU conference (ad hoc), or they dial a MeetMe number assigned by Unified CM to join the conference (reservationless). Therefore, the digits you specify for the SCCP service prefix do not matter and can be any digits you wish, such as 999999 for instance. This prefix is not exposed outside of the SCCP signaling between the MCU and Unified CM (that is, it cannot be dialed, it is not included in the MCU's registration with the gatekeeper, and so forth).

**Note**

The Cisco MeetingPlace Express media server has support for SCCP. Using this integration, the Cisco MeetingPlace Express media server can provide ad-hoc conference bridges with Unified CM, similar to the way the Cisco Unified Videoconferencing MCUs do.

Sizing the MCU

There are several factors involved in determining the types and number of conferences that an MCU can support. These sizing factors are different for different models of MCUs. MCUs can also make available more ports when using desktop conferencing mode as compared to the high definition (HD) mode.

Calculating the size of MCUs depends on the following factors:

- The type of resolution for the video conference
- The total number of ports that the MCU can support
- The number of ports that the MCU can dedicate to each protocol
- Whether cascading conferences are needed between MCUs or between EMP cards

**Note**

A single SCCP conference cannot span multiple EMPs. Each SCCP conference can support up to 24 participants.

For specific information about the number of ports supported, refer to the product documentation for your MCU hardware, available on Cisco.com. Due to the almost infinite number of possible variations, it is very difficult to provide any concrete design guidance in this document. Many customers end up with a mixture of SCCP ad-hoc conferences, H.323 and SIP reservationless conferences, and H.323 and SIP scheduled conferences. The MCUs must be sized to accommodate all of those types of conferences at the correct speeds and video layouts. Needless to say, this can become quite complex to determine. Please consult with your Cisco sales representative for assistance on sizing the MCUs for your particular environment.

IVR for Dial-In Conference

Dial-in conferences typically use an interactive voice response (IVR) system to prompt users to enter the conference ID and the password (if one is configured) of the conference they want to join. You can use either of the following types of IVRs with the Cisco Unified Videoconferencing 3500 Series MCUs:

- The IVR built into the MCU
- Cisco Unified IP IVR

The built-in IVR of the MCU has the following characteristics:

- Can prompt to create a conference or join by conference ID
- Can prompt for the password of the conference
- Supports both in-band and out-of-band (H.245 alpha-numeric) DTMF
- Cannot be customized to provide more flexible menus or functionality

The only thing that can be customized is the recorded audio file that is played to the user.

If you want to have a single dial-in number and then prompt the user for the conference ID, you can use Cisco Unified IP IVR in conjunction with the MCU.

Cisco Unified IP IVR has the following characteristics:

- Can prompt for the conference ID and the password (among other things)
- Supports only out-of-band DTMF

That is, the calling device must support an out-of-band DTMF method, such as H.245 alpha-numeric on H.323 devices. These out-of-band DTMF messages are then relayed by Unified CM to the Cisco IP IVR server. If the calling device supports only in-band DTMF tones, the Cisco IP IVR server will not recognize them and the calling device will be unable to enter the conference.

- Can be highly customized to provide more flexible menus and other advanced functionality

Customizations can include such things as verifying the user's account against a back-end database before permitting that user to enter into the conference, or queuing the participants until the chairperson joins.

Note

Because Cisco Unified IP IVR supports only out-of-band signaling, it will not work with H.323 endpoints that use in-band DTMF tones.

With Cisco Unified IP IVR, users dial a CTI route point that routes the call to the Cisco Unified IP IVR server instead of dialing a route pattern that routes directly to the MCU. After collecting the DTMF digits of the conference ID, the Cisco Unified IP IVR then transfers the call to the route pattern that routes the call to the MCU. This transfer operation requires that the calling device supports having its media channels closed and reopened to a new destination. For example, an H.323 video device that calls the

Cisco Unified IP IVR will initially negotiate an audio channel to the Cisco Unified IP IVR server and then, after entering the appropriate DTMF digits, it will be transferred to the MCU, at which point Unified CM will invoke the Empty Capabilities Set (ECS) procedure described earlier in this chapter to close the audio channel between the endpoint and the Cisco Unified IP IVR server and open new logical channels between the endpoint and the MCU. If the H.323 video endpoint does not support receiving an ECS from Unified CM, it will react by disconnecting the call or, worse, crashing and/or rebooting.

Gatekeepers

Prior to the introduction of video support in Unified CM, H.323 videoconferencing networks relied on gatekeepers to perform device registration management, call routing, and bandwidth control. The Cisco IOS Gatekeeper, formerly known as the Multimedia Conference Manager (MCM), provides these functions. However, most gatekeepers, including Cisco's, offer only rudimentary call routing capabilities compared to what might be expected in a typical enterprise-class PBX. When used to route H.323 video calls, Unified CM supplements the basic gatekeeper features and provides full enterprise-class PBX functionality to H.323 video calls.

Unified CM and the gatekeeper work as a team to manage H.323 video endpoints. The gatekeeper handles all Registration, Admission, and Status (RAS) signaling, while Unified CM handles all of the H.225 call signaling and H.245 media negotiations. Therefore, you have to deploy gatekeepers along with the Unified CM servers if RAS signaling procedures are required for the H.323 endpoints in your network, as illustrated in [Figure 12-9](#).

Figure 12-9 Unified CM and Cisco IOS Gatekeeper Provide RAS Signaling for H.323 Endpoints

RAS signaling is required any time either of the following conditions exists:

- The endpoint does not use a fixed IP address.

If the endpoint uses a static IP address, Unified CM does not require RAS procedures to locate the endpoint. Instead, the endpoint is provisioned in Unified CM Administration with its static IP address, and calls to that H.323 client's directory number are routed directly to that static IP address. If the endpoint does not use a static IP address, then Unified CM must query the gatekeeper to obtain the endpoint's current IP address each time Unified CM extends a call to the endpoint.

- The endpoint requires RAS procedures to place calls to E.164 addresses.

Most H.323 videoconferencing endpoints are capable of dialing another endpoint directly only when dialing by IP address (that is, the user enters the IP address of the destination endpoint in dotted-decimal format and then pushes the call button). However, if the user dials an

E.164-formatted number (a numeric value not in the dotted-decimal format of an IP address) or an H.323-ID (in the format of *username* or *username@domain*), most endpoints today provide only one way to resolve these types of destinations – by a RAS query to their gatekeeper. A growing number of endpoints, however, can be configured so that, for any call to an E.164 address, they skip any RAS procedures and instead send an H.225 SETUP message directly to a specified IP address. This method of operation is known as peer-to-peer mode. Tandberg H.323 endpoints are one example that use this mode, in which you can either configure a gatekeeper address for them to register with, or configure the IP address of the Unified CM server they should use. In the latter case, the endpoint sends all calls directly to the specified IP address, bypassing the need for RAS procedures with any gatekeeper.

In addition to managing RAS procedures for H.323 video endpoints, gatekeepers also continue to play an important role in managing dial plan resolution and bandwidth restrictions between Unified CM clusters in large multisite distributed call processing environments. A gatekeeper can also integrate with large numbers of H.323 VoIP gateways within the organization, or it can act as a session border controller between an enterprise IP Telephony network and a service provider VoIP transport network.

Therefore, as it pertains to Cisco IP Video Telephony deployments, the Cisco IOS Gatekeeper can perform one or both of the following roles:

- Endpoint gatekeeper

An endpoint gatekeeper is configured to manage all RAS procedures for calls to, from, and between H.323 clients, MCUs, and H.320 video gateways. The endpoint gatekeeper directs all such calls to the appropriate Unified CM cluster so that Unified CM can perform all of the H.225 call routing and H.245 media negotiations.

- Infrastructure gatekeeper

An infrastructure gatekeeper is configured to manage all dial plan resolution and bandwidth restrictions (call admission control) between Unified CM clusters, between a Unified CM cluster and a network of H.323 VoIP gateways, or between a Unified CM cluster and a service provider's H.323 VoIP transport network.

In previous Cisco Unified CM releases, the endpoint gatekeeper and the infrastructure gatekeeper had to run on separate routers, and each endpoint gatekeeper could service only a single Unified CM cluster. If multiple Unified CM clusters existed within the enterprise, a separate endpoint gatekeeper had to be deployed for each Unified CM cluster. With the current Cisco Unified CM release, it is possible to combine these roles on a single gatekeeper, using it as an endpoint gatekeeper for one or more Unified CM clusters and as the infrastructure gatekeeper for managing calls between clusters or between a cluster and other H.323 VoIP networks. However, for the following reasons (among others), Cisco recommends that you still separate these roles onto two or more gatekeepers:

- Scalability

Depending on the Cisco IOS router platform you choose to deploy and your estimated busy hour call volume, you might need several gatekeepers to handle the load.

- Geographical resiliency

Putting all of your eggs into one basket may not be wise in a large, multi-national VoIP network. Having gatekeepers placed throughout your network (typically by geography) can provide better fault isolation in the event of a gatekeeper failure.

- Incompatibilities

Some configuration aspects of the gatekeeper are global in nature (they pertain to all endpoints registered with that gatekeeper). For example, the command **arq reject-unknown-prefix**, which may be useful in some H.323 VoIP transport environments, conflicts with the use of the **gw-type-prefix <prefix> default-technology** command, which is used in endpoint gatekeepers to route calls to Unified CM. While Cisco IOS does not stop you from configuring both commands on

the same gatekeeper, the **arq reject-unknown-prefix** command takes precedence and, therefore, calls to unknown numbers will be rejected instead of being routed to Unified CM. In this case, you would have to use one gatekeeper for the H.323 VoIP transport network and another gatekeeper for the Unified CM cluster(s).

Another example of incompatibility can occur in the way you configure the gatekeeper for redundancy. Most Cisco H.323 voice devices, including Cisco Voice Gateways and Unified CM, support the H.323v3 Alternate Gatekeeper feature, which would allow you to configure the gatekeepers as a gatekeeper cluster using the Gatekeeper Update Protocol (GUP) to keep in sync with each other. However, many H.323 video endpoints do not support Alternate Gatekeeper, so the gatekeepers must be configured to use Hot Standby Routing Protocol (HSRP) for redundancy. You cannot mix and match these two redundancy methods on the same gatekeeper. In this case, you might decide to use a gatekeeper cluster for those endpoints that support Alternate Gatekeeper and an HSRP pair of gatekeepers for those that do not.

Figure 12-10 illustrates a network scenario with two Unified CM clusters. Each cluster consists of SCCP and H.323 clients, H.323 MCUs, and H.320 gateways. To manage the RAS aspects of the H.323 clients, MCUs, and H.320 gateways, an endpoint gatekeeper is deployed with each cluster. A separate infrastructure gatekeeper manages dial plan resolution and bandwidth between the clusters. Gatekeeper redundancy is not shown in the figure, although each of these gatekeepers may actually be multiple gatekeepers configured for either Alternate Gatekeeper or HSRP-based redundancy.

Figure 12-10 Two Unified CM Clusters with Required Gatekeepers

Endpoint Gatekeepers

An endpoint gatekeeper is required any time both of the following conditions are met:

- The cluster contains H.323 clients, H.323 MCUs, or H.320 gateways (collectively referred to as H.323 endpoints). If none of these types of endpoints exists (for example, if all clients are SCCP endpoints and there are no MCUs or H.320 gateways), then an endpoint gatekeeper is not needed.
- And either of the following conditions is true:
 - The H.323 endpoints require RAS procedures to initiate calls to E.164 addresses. As mentioned earlier, a growing number of devices are capable of peer-to-peer call signaling, in which case there is no need for those devices to register with a gatekeeper.
 - The H.323 endpoints do not use static IP addresses.

The role of the endpoint gatekeeper is simply to handle the RAS aspects of communications with the endpoints, providing a place for these H.323 endpoints to register. The endpoint gatekeeper responds to all call requests made to, from, or between these endpoints by directing the call to the appropriate Unified CM server(s) so that Unified CM can perform all of the call routing and bandwidth control functions. To accomplish this call routing and bandwidth control, you configure Unified CM to register H.323 trunk(s) with the gatekeeper and configure the gatekeeper to route calls to those trunks for all calls to, from, or within that zone.

Cisco Unified CM should register to endpoint gatekeepers using a type of H.323 trunk called the RASAggregator trunk. This type of trunk is used for all H.323 client, H.323 MCU, or H.320 gateway zones, while the gatekeeper-controlled intercluster trunk and gatekeeper-controlled H.225 trunk are used to integrate with infrastructure gatekeepers.

Provisioning H.323 Clients

H.323 clients are provisioned much the same way as other phones are, in that you create a new phone (model type = H.323 Client), assign a directory number to it, and assign it a calling search space, device pool, and so forth. You configure the H.323 clients in Unified CM in one of the following ways. The method you use depends on whether or not the client uses a static IP address and whether or not the client requires RAS procedures to dial E.164 addresses.

- Gatekeeper controlled

This type of configuration is used for clients that do not have a static IP address assigned to them (they use a DHCP-assigned address) and that require RAS procedures to dial E.164 addresses. A RASAggregator trunk is used to communicate to and from these clients. (See [Figure 12-11](#) and [Figure 12-12](#).)
- Non-gatekeeper controlled, asynchronous

This type of configuration is used for clients that have a static IP address assigned to them but that require RAS procedures to dial E.164 addresses. While Unified CM can signal directly to them without the need of a gatekeeper to resolve their IP addresses, they are not able to signal directly to Unified CM but instead must query the gatekeeper to resolve the E.164 address they are trying to dial (thus, asynchronous communications). To support these types of clients, you must have at least one gatekeeper-controlled client defined in Unified CM for each zone on the gatekeeper, even if all the clients actually use static IP addresses. In this case, the non-gatekeeper controlled client may be a "dummy" client that does not actually exist. Its purpose is merely to create the RASAggregator trunk so that the gatekeeper will be able to route calls from the clients to Unified CM. (See [Figure 12-13](#) and [Figure 12-14](#).)

- Non-gatekeeper controlled, synchronous

This type of configuration is used for clients that have a static IP address and are also capable of peer-to-peer signaling (that is, they do not require RAS procedures to dial E.164 numbers). Unified CM signals directly to them, and they signal directly to Unified CM (thus, synchronous communications). No gatekeeper or RASAggregator trunk is needed for this type of client. (See Figure 12-15 and Figure 12-16.)

Figure 12-11 through Figure 12-16 illustrate the call signaling flows used in these three scenarios.

Gatekeeper-Controlled Clients

When you configure an H.323 client as gatekeeper-controlled, you may enter any alpha-numeric string (such as a descriptive name) in the Device Name field, check the **Gatekeeper-controlled** box, and fill in the following fields:

- **Device Pool**
The device pool you want the client to use. All H.323 clients (whether gatekeeper-controlled or non-gatekeeper controlled) that are registered in the same zone must use the same device pool. If you accidentally assign different device pools across the endpoints, Unified CM will register multiple RASAggregator trunks within the zone, and an inbound call might be rejected by Unified CM if the call is directed to the wrong RASAggregator trunk.
- **Gatekeeper**
A drop-down list of gatekeeper IP addresses. You must define the gatekeeper in Unified CM before configuring any gatekeeper-controlled H.323 clients.
- **Technology Prefix**
The technology prefix used by the RASAggregator trunk to register in the client zone on the gatekeeper. This technology prefix must match what is configured as the default technology prefix on the gatekeeper. All gatekeeper-controlled H.323 clients that are registered in the same zone must use the same technology prefix. If you accidentally assign different technology prefixes across the endpoints, Unified CM will register multiple RASAggregator trunks within the zone, and an inbound call might be rejected by Unified CM if the call is directed to the wrong RASAggregator trunk. Cisco recommends that you use **1#** for this prefix.

- Zone Name

The (case-sensitive) name of the client zone as configured in the gatekeeper. All gatekeeper-controlled H.323 clients that are registered in the same zone must use the same zone name. If you accidentally assign different zone names (remember, the field is case sensitive) across the endpoints, Unified CM will attempt to register multiple RASAggregator trunks with the gatekeeper (but the one with the incorrect zone name will fail to register), and an inbound call might be rejected by Unified CM if the call is directed to the wrong RASAggregator trunk.

Also, you must set the Unified CM service parameter **Send Product ID and Version ID** to **True**. This parameter allows the RASAggregator trunk to register with the gatekeeper as an H323-GW, so that the gatekeeper can direct all H.323 calls to, from, or within the client zone to the RASAggregator trunk.

Non-Gatekeeper Controlled Clients

When provisioning an H.323 client as non-gatekeeper controlled, you must enter the static IP address of the client into the Device Name field and leave all of the settings under the Gatekeeper-controlled section blank (unchecked). Unified CM then uses the static IP address to reach the client any time a call is extended to its directory number.

If the client is configured to use peer-to-peer mode, then no further configuration is required. If the client requires RAS procedures to place calls to E.164 addresses, then you must also configure a dummy gatekeeper-controlled H.323 client in order to create the RASAggregator trunk, by filling in the following fields:

- Device Name

A descriptive name that identifies this client as a dummy client used for the purpose of creating the RASAggregator trunk for the client zone.

- Device Pool

The device pool you chose when configuring the non-gatekeeper controlled H.323 client(s). If the device pool assigned to the dummy client is different than that assigned to the real clients, inbound calls from the real clients might be rejected by Unified CM.

- Gatekeeper

A drop-down list of gatekeeper IP addresses. You must define the gatekeeper in Unified CM before configuring the dummy gatekeeper-controlled H.323 client.

- Technology Prefix

The technology prefix used by the RASAggregator trunk to register in the client zone on the gatekeeper. This technology prefix must match what is configured as the default technology prefix on the gatekeeper. Cisco recommends that you use **1#** for this prefix.

- Zone Name

The (case-sensitive) name of the client zone as configured in the gatekeeper.

Also, you must set the Unified CM service parameter **Send Product ID and Version ID** to **True**. This parameter allows the RASAggregator trunk to register with the gatekeeper as an H323-GW, so that the gatekeeper can direct all H.323 calls to, from, or within the client zone to the RASAggregator trunk.

Provisioning H.323 MCUs

H.323 MCUs are provisioned in Unified CM as H.323 gateways, and then route patterns are configured to extend calls to these devices. When provisioning an H.323 gateway, you must enter the static IP address and TCP signaling port of the MCU into the Device Name field. Unified CM then uses the static IP address and TCP port to reach the MCU any time a call matches the route pattern(s) associated with it.

**Note**

The Cisco Unified Videoconferencing 3500 and 5000 Series MCUs do not listen on TCP port 1720 by default. (The Cisco Unified Videoconferencing 3500 and 5000 Series MCUs listen on port 2720 by default.) You must verify which TCP port they are listening on, and either change it to 1720 or provision the correct port in Unified CM.

If the MCU is configured to use peer-to-peer mode, then no further configuration is required. (Cisco Unified Videoconferencing MCUs do not currently support peer-to-peer mode, but some third-party MCUs do.) If the MCU requires RAS procedures to place calls to E.164 addresses, then you must also configure a dummy gatekeeper-controlled H.323 client in order to create the RASAggregator trunk, by filling in the fields for Device Name, Device Pool, Gatekeeper, Technology Prefix, and Zone Name as discussed in the section on [Non-Gatekeeper Controlled Clients](#), page 12-33.

MCU Service Prefixes

H.323 MCUs can use either E.164 addresses or technology prefixes (also referred to as service prefixes in the MCU) as the dial-in number(s) to reach reservationless or scheduled H.323 conferences running on them. Cisco recommends that you configure the MCUs to use E.164 addresses by setting the MCU Mode to **MCU** instead of **Gateway** in the MCU administration screens. If the **MCU** setting is not available on the model of MCU you are using, then you must use the following special configuration to properly route calls placed from other H.323 endpoints to the MCU:

If the MCU is configured in **Gateway** mode or is another vendor's MCU that (for whatever reason) requires its conference IDs to register as technology prefixes instead of as E.164 addresses, then the service prefix(s) of the MCU must begin with a # character. For example, if the MCU's service prefix is 8005551212, then you must provision the service prefix on the MCU as #8005551212. Thus, when other H.323 endpoints dial 8005551212, the gatekeeper will not find a matching technology prefix registered and will instead route the call to the RASAggregator trunk that is registered with the default technology prefix in the zone of the endpoint that is placing the call. Unified CM must then prepend the # character to the beginning of the called number before extending the call to the MCU. This character is prepended on the route pattern(s) associated with the H.323 gateway representing the MCU. Calls to the MCU from SCCP clients will therefore also have this # character prepended to the calling number.

If the MCU is configured in **MCU** mode or is another vendor's MCU that uses E.164 addresses for its conference IDs, then you do not have to prepend the # character. Also note that, if the MCU uses peer-to-peer mode and hence does not need to register its technology prefixes with any gatekeeper, then this situation does not apply and you do not have to prepend a # character.

Provisioning H.320 Gateways

As with H.323 MCUs, H.320 gateways are provisioned in Unified CM as H.323 gateways, and then route patterns are configured to extend calls to these devices. When provisioning an H.323 gateway, you must enter the static IP address and TCP signaling port of the H.320 gateway into the Device Name field. Unified CM then uses the static IP address and TCP port to reach the gateway any time a call matches the route pattern(s) associated with it.

**Note**

The Cisco Unified Videoconferencing 3500 and 5000 Series Gateways do not listen on TCP port 1720 by default. (The Cisco Unified Videoconferencing 3500 and 5000 Series Gateways listen on port 1820 by default.) You must verify which TCP port they are listening on, and either change it to 1720 or provision the correct port in Unified CM.

If the gateway is configured to use peer-to-peer mode, then no further configuration is required. If the gateway requires RAS procedures to place calls to E.164 addresses, then you must also configure a dummy gatekeeper-controlled H.323 client in order to create the RASAggregator trunk, by filling in the fields for Device Name, Device Pool, Gatekeeper, Technology Prefix, and Zone Name as discussed in the section on [Non-Gatekeeper Controlled Clients](#), page 12-33.

Gateway Service Prefixes

H.320 gateways use technology prefixes (also referred to as service prefixes in the gateway) as the prefix that users should dial to reach an ISDN destination. For calls to route correctly, you must configure the service prefix(s) of the gateway to begin with a # character. For example, if the gateway's service prefix that clients dial to reach an ISDN number is 9, then you must provision the service prefix on the gateway as #9. In this way, when H.323 clients dial 9 plus the PSTN number (such as 918005551212), the gatekeeper will not find a matching technology prefix registered and will instead route the call to the Unified CM trunk that is registered with the default technology prefix. Unified CM must then prepend the # character to the beginning of the called number before extending the call to the gateway. Note that, if the gateway uses peer-to-peer mode and hence does not need to register its technology prefixes with any gatekeeper, then this situation does not apply and you do not have to prepend a # character.

Gatekeeper Zone Configuration

The preceding sections discuss how to provision the endpoints in Unified CM Administration. You must also configure the endpoint gatekeeper(s) with the appropriate zone definitions. You must configure a zone for each type of endpoint (client, MCU, or gateway) and, optionally, for each device pool associated with these endpoints in Unified CM.

Each zone is configured to route all calls placed to, from, or within the zone to the RASAggregator trunk registered in that zone. You configure the zones on the endpoint gatekeeper by using the following command syntax:

```
zone local <zone_name> <domain_name> <ip_address> invia <zone_name>
outvia <zone_name> enable-intrazone
```

The command argument **invia** applies to calls placed to the zone from any other zone, **outvia** applies to calls placed from the zone to any other zone, and **enable-intrazone** applies to calls placed within the zone. The following sections illustrate the use of these commands.

Client Zones

The number of client zones you have to configure within each endpoint gatekeeper depends on the following factors:

- The device pools to which the H.323 clients are associated
 - The device pool determines which Unified CM servers are primary, secondary, and tertiary servers for each H.323 client. If you assign all H.323 clients to the same device pool, then you need to define only a single client zone in the endpoint gatekeeper. In other words, for each device pool used by H.323 clients, you must configure a separate client zone in the gatekeeper.
- Whether the endpoint gatekeeper provides services for a single Unified CM cluster or multiple Unified CM clusters

Each client zone is configured to route calls to a particular RASAggregator trunk. Therefore, if one endpoint gatekeeper is used to service multiple Unified CM clusters, then you must define a separate client zone for each cluster that the gatekeeper services.

To illustrate, the following examples show how client zones may be configured. [Example 12-1](#) shows a single client zone defined for a single Unified CM cluster in which all H.323 clients are associated with the same device pool. [Example 12-2](#) shows a single Unified CM cluster in which the H.323 clients are divided between two different device pools.

**Note**

Some of the commands shown in the following examples are the default values applied in the Cisco IOS Gatekeeper and, therefore, would not have to be configured explicitly, nor would they appear in the running configuration. They are included here for thoroughness but are marked by a ! at the beginning of the command line.

Example 12-1 Client Zone for a Single Unified CM Cluster and Single Device Pool

```
gatekeeper
zone local clients domain.com invia clients outvia clients enable-intrazone
gw-type-prefix 1# default-technology
no use-proxy clients default inbound-to terminal
no use-proxy clients default outbound-from terminal
! no arg reject-unknown-prefix
endpoint ttl 60
no shutdown
```

Example 12-2 Client Zones for a Single Unified CM Cluster and Two Device Pools

```
gatekeeper
zone local dp1-clients domain.com invia dp1-clients outvia dp1-clients enable-intrazone
zone local dp2-clients domain.com invia dp2-clients outvia dp2-clients enable-intrazone
gw-type-prefix 1# default-technology
no use-proxy dp1-clients default inbound-to terminal
no use-proxy dp1-clients default outbound-from terminal
no use-proxy dp2-clients default inbound-to terminal
no use-proxy dp2-clients default outbound-from terminal
! no arg reject-unknown-prefix
endpoint ttl 60
no shutdown
```

Disabling The Use of Proxy

The Cisco IOS Gatekeeper, formerly known as the Cisco Multimedia Conference Manager (MCM), previously offered an H.323 proxy function that has been at End of Life (EOL) for some time and is not compatible with Unified CM, but the commands in the gatekeeper to use a proxy for all calls to and from terminals (clients) are still enabled by default. You must disable this function for each client zone by using the following command syntax:

```
gatekeeper
no use-proxy <zone_name> default [inbound-to | outbound-from] terminals
```

The Cisco MCM proxy was replaced by a solution called the Cisco IOS Multiservice IP-to-IP Gateway and the associated via-zone-enabled Cisco IOS Gatekeeper. This document does not discuss the IP-to-IP Gateway, but Cisco Unified CM leverages the via-zone and IP-to-IP gateway constructs by registering its RASAggregator trunks with the gatekeeper, effectively mimicking an IP-to-IP gateway so that the gatekeeper will route all invia, outvia, and enable-intrazone calls to the RASAggregator trunk as if it were an IP-to-IP gateway.

Client Zone Prefixes

For H.323 client zones, there is no need to configure zone prefixes or technology prefixes of any kind, except for the default technology prefix. Instead, the **invia**, **outvia**, **enable-intrazone**, and **gw-type-prefix <I#> default-technology** commands ensure that all calls placed are routed to the RASAggregator trunk associated with the zone in which the call originated.

MCU Zones

The number of MCU zones you have to configure within each endpoint gatekeeper depends on the following factors:

- The device pools to which the MCUs are associated

The device pool determines which Unified CM servers are primary, secondary, and tertiary servers for each MCU. If you assign all MCUs to the same device pool, then you need to define only a single MCU zone in the endpoint gatekeeper. In other words, for each device pool used by MCUs, you must configure a separate MCU zone in the gatekeeper.
- Whether the endpoint gatekeeper provides services for a single Unified CM cluster or multiple Unified CM clusters

Each MCU zone is configured to route calls to a particular RASAggregator trunk. Therefore, if one endpoint gatekeeper is used to service multiple Unified CM clusters, then you must define a separate MCU zone for each cluster that the gatekeeper services.

Gatekeeper configuration for MCU zones is similar to the configurations shown in [Example 12-1](#) and [Example 12-2](#) for MCUs.

Disabling The Use of Proxy

By default, the Cisco IOS Gatekeeper is set to not use a proxy for calls to and from MCUs or gateways. However, if you have enabled the use of proxy for those types of endpoints, you must disable it for each MCU zone by using the following command syntax:

```
gatekeeper
no use-proxy <zone_name> default [inbound-to | outbound-from] [MCU | gateway]
```

If your MCU is registering as an MCU, then use the **MCU** argument at the end of the **no use-proxy** command; if your MCU is registering as a gateway, then use the **gateway** argument instead.

MCU Zone Prefixes

For H.323 MCU zones, there is no need to configure zone prefixes or technology prefixes of any kind, except for the default technology prefix. Instead, the **invia**, **outvia**, **enable-intrazone**, and **gw-type-prefix <I#> default-technology** commands ensure that all calls placed are routed to the RASAggregator trunk associated with the zone in which the call originated.

If your MCUs are registering their service prefixes as technology prefixes instead of E.164 addresses, use the special configuration described previously for prepending a # character to the MCU's service prefixes (see [MCU Service Prefixes, page 12-34](#)). Due to the way the Cisco IOS Gatekeeper selects a via-zone for calls to a technology prefix, when the endpoint dials the service prefix of the MCU, the call will fail if the gatekeeper finds a matching technology prefix registered. You must ensure that the client does not dial the # character, so that the gatekeeper will not find a matching technology prefix and will instead route the call to the RASAggregator trunk associated with the zone in which the call originated.

H.320 Gateway Zones

The number of H.320 gateway zones you have to configure within each endpoint gatekeeper depends on the following factors:

- The device pools to which the H.320 gateways are associated

The device pool determines which Unified CM servers are primary, secondary, and tertiary servers for each H.320 gateway. If you assign all gateways to the same device pool, then you need to define only a single gateway zone in the endpoint gatekeeper. In other words, for each device pool used by H.320 gateways, you must configure a separate gateway zone in the gatekeeper.

- Whether the endpoint gatekeeper provides services for a single Unified CM cluster or multiple Unified CM clusters

Each gateway zone is configured to route calls to a particular RASAggregator trunk. Therefore, if one endpoint gatekeeper is used to service multiple Unified CM clusters, then you must define a separate gateway zone for each cluster that the gatekeeper services.

Gatekeeper configuration for gateway zones is similar to the configurations shown in [Example 12-1](#) and [Example 12-2](#) for gateways.

Disabling The Use of Proxy

By default, the Cisco IOS Gatekeeper is set to not use a proxy for calls to and from gateways. However, if you have enabled the use of proxy for those types of endpoints, you must disable it for each H.320 gateway zone by using the following command syntax:

```
gatekeeper
no use-proxy <zone_name> default [inbound-to | outbound-from] gateway
```

Gateway Zone Prefixes

There is no need to configure zone prefixes of any kind for H.320 gateway zones. Instead, the **invia**, **outvia**, **enable-intrazone**, and **gw-type-prefix <1#> default-technology** commands ensure that all calls placed are routed to the RASAggregator trunk associated with the zone in which the call originated.

You must also use the special configuration described previously for prepending a # character to the gateway's service prefixes (see [Gateway Service Prefixes, page 12-35](#)). Due to the way the Cisco IOS Gatekeeper selects a via-zone for calls to a technology prefix, when the endpoint dials the service prefix of the gateway, the call will fail if the gatekeeper finds a matching technology prefix registered. You must ensure that the client does not dial the # character, so that the gatekeeper will not find a matching technology prefix and will instead route the call to the RASAggregator trunk associated with the zone in which the call originated.

Zone Subnets

As mentioned previously, the H.323 specification permits a single gatekeeper to manage multiple zones. However, the gatekeeper needs a way to decide which zone an endpoint should be placed in when it receives a Registration Request (RRQ) from that device. The RRQ message contains a Gatekeeper Identifier field that enables the endpoint to indicate the zone in which it would like to register. However, many H.323 video endpoints do not populate this field, and if the gatekeeper has multiple zones defined, it will not know which zone to place the endpoint into. Therefore, you must use of the **zone subnet** command to tell the gatekeeper which zone to associate with the endpoint. This command defines which IP addresses or IP address ranges are permitted to register in each zone. The command syntax requires that you enter a network mask. Therefore, you can specify either a particular host address by entering a 32-bit (/32) network mask or a range of addresses by specifying a smaller network mask.

Because MCUs, H.320 gateways, and Unified CM servers typically use fixed IP addresses but H.323 clients can use DHCP addresses, Cisco recommends that you define **zone subnet** commands only for the MCU and gateway zones but leave the client zones open so that any IP address is permitted in them. Note that you must also permit the Unified CM servers to register in the MCU and gateway zones, as illustrated in [Example 12-3](#).

**Note**

Some of the commands shown in the following example are the default values applied in the Cisco IOS Gatekeeper and, therefore, would not have to be configured explicitly, nor would they appear in the running configuration. They are included here for thoroughness but are marked by a ! at the beginning of the command line.

Example 12-3 Defining Zone Subnets

```
gatekeeper
no zone subnet MCUs default enable
zone subnet MCUs [MCUs_IP_addr]/32 enable
zone subnet MCUs [RASAggregators_IP_addr]/32 enable
no zone subnet gateways default enable
zone subnet gateways [gateways_IP_addr]/32 enable
zone subnet gateways [RASAggregators_IP_addr]/32 enable
! zone subnet clients default enable
no zone subnet clients [MCUs_IP_addr]/32 enable
no zone subnet clients [gateways_IP_addr]/32 enable
```

The configuration in [Example 12-3](#) explicitly permits the MCU and the RASAggregator for the MCU zone to register in the MCU zone, and it explicitly permits the gateway and RASAggregator for the gateway zone to register in the gateway zone. It also explicitly denies the MCU and gateway from registering in the client zone, while implicitly permitting all other IP addresses (including the RASAggregator for the client zone) to register in the client zone.

Endpoint Time to Live

Endpoints send lightweight Registration Requests (RRQs) to their gatekeeper periodically to maintain their registration status. The frequency with which they send these RRQs is referred to as the Time to Live (TTL) value. The endpoint may specify the TTL it wishes to use in the body of its RRQs. The gatekeeper may then honor the endpoint's requested TTL value by echoing it in the Registration Confirm (RCF) response or, alternatively, may override the endpoint's request by specifying a different TTL value in the RCF.

If the TTL value is not specified in the RRQ, the gatekeeper should specify one in its RCF response. The endpoint should then honor the TTL specified by the gatekeeper. The Cisco IOS Gatekeeper honors all TTL values specified by the endpoints. However, many H.323 video endpoints do not specify a TTL value in their RRQs. In such cases, the Cisco IOS Gatekeeper defaults to specifying a TTL value of 1800 seconds (30 minutes). The Cisco IOS Gatekeeper will flush the endpoint's registration after three TTL intervals have passed without receiving any messages from the endpoint (3 * 30 minutes = 90 minutes).

A large TTL value can cause problems with H.323 clients that do not use static IP addresses. For example, with the default TTL value of 1800 seconds, if you disconnect the client from the network and move it to another location in which it receives a different DHCP address, it will fail to register with the gatekeeper (Registration Reject (RRJ) cause value "duplicate alias") until three TTL intervals have passed, and the gatekeeper will flush that endpoint's original registration.

Therefore, Cisco recommends that you consider reducing the TTL value to as low a number as possible without causing any negative effect on your network. The Cisco IOS Gatekeeper permits you to set the TTL value anywhere in the range of 60 seconds to 3600 seconds. In most cases, 60 seconds should work well. However, if your gatekeeper is already heavily utilized, adjusting the TTL from the default of 1800 seconds to 60 seconds might cause it to become overwhelmed.

Use the following command syntax to set the TTL value:

```
gatekeeper
endpoint ttl <seconds>
```

Supported Gatekeeper Platforms

To act as an endpoint gatekeeper with Cisco Unified CM, the Cisco IOS Gatekeeper must run Cisco IOS Release 12.3(11)T or greater. For minimum Cisco IOS release requirements on the infrastructure gatekeeper, refer to the latest *Cisco Unified Communications System Release Notes for IP Telephony* available at:

<http://www.cisco.com/go/unified-techinfo>

To determine which release and feature set you should use for your router platform, use the Cisco Feature Navigator (requires a Cisco.com login account), available at:

<http://tools.cisco.com/ITDIT/CFN/jsp/index.jsp>

For more information, also refer to the *Cisco IOS H323 Gatekeeper Data Sheet*, available at:

http://www.cisco.com/en/US/prod/collateral/voicesw/ps6788/vcallcon/ps4139/data_sheet_c78_561921.html

Summary of Endpoint Gatekeepers

This section summarizes some key points to remember about endpoint gatekeepers and provides some example configurations that combine techniques used in the previous examples.

- Configure a separate zone in the endpoint gatekeeper for each type of endpoint (clients, MCUs, and H.320 gateways). If the endpoints are associated with multiple device pools, configure multiple zones for each type of endpoint.
- Configure a RASAggregator trunk to register in each zone. This trunk is automatically created when you configure gatekeeper-controlled H.323 clients in Unified CM Administration. However, for non-gatekeeper controlled H.323 clients, H.323 MCUs, and H.320 gateways, you must configure a dummy gatekeeper-controlled H.323 client in order to create the RASAggregator trunk for that zone.
- Set the service parameter **Send Product ID and Version ID** to **True** in order for the RASAggregator trunk to register with the gatekeeper as an IP-to-IP gateway. This setting enables the RASAggregator to be selected by the gatekeeper for all calls placed to, from, or within each zone due to the use of the **invia**, **outvia**, **enable-intrazone**, and **gw-type-prefix <I#> default-technology** commands applied to each local zone definition.
- You do not have to associate any zone prefixes for any of the endpoint zones. No matter what the endpoint dials, the gatekeeper should not find a matching zone prefix or technology prefix but should instead route the call to the RASAggregator trunk associated with the zone from which the call originated. To avoid having the gatekeeper accidentally match the dialed number to the technology prefix of your MCUs or gateways, mask all MCU and gateway service prefixes with a # character, and then prepend the # character in the route pattern associated with that MCU or gateway.

- Configure zone subnets if any of the H.323 endpoints do not support the ability to specify the Gatekeeper Identifier (name of the zone) with which they wish to register.
- Disable the use of the old MCM Proxy for all zones.
- Set the endpoint registration Time to Live (TTL) to as low of a value as you can without creating undo stress on the gatekeeper. In extreme cases where the gatekeeper is serving hundreds of endpoint registrations, setting the TTL to 60 seconds might cause an unmanageable amount of RAS traffic. In smaller environments, setting it to 60 seconds should work well.

[Example 12-4](#) shows a configuration for an endpoint gatekeeper servicing a single Unified CM cluster in which a single device pool is used to service all H.323 video endpoint types.

Note

Some of the commands shown in the following examples are the default values applied in the Cisco IOS Gatekeeper and, therefore, would not have to be configured explicitly, nor would they appear in the running configuration. They are included here for thoroughness but are marked by a ! at the beginning of the command line.

Example 12-4 Endpoint Gatekeeper Configuration for a Single Cluster and a Single Device Pool

```
gatekeeper
zone local clients domain.com invia clients outvia clients enable-intrazone
zone local MCUs domain.com invia MCUs outvia MCUs enable-intrazone
zone local gateways domain.com invia gateways outvia gateways enable-intrazone
! zone subnet clients default enable
no zone subnet clients [MCUs_IP_addr]/32 enable
no zone subnet clients [gateways_IP_addr]/32 enable
no zone subnet MCUs default enable
zone subnet MCUs [MCUs_IP_addr]/32 enable
zone subnet MCUs [RASAggregators_IP_addr]/32 enable
no zone subnet gateways default enable
zone subnet gateways [gateways_IP_addr]/32 enable
zone subnet gateways [RASAggregators_IP_addr]/32 enable
no use-proxy clients inbound-to terminals
no use-proxy clients outbound-from terminals
! no use-proxy MCUs inbound-to [MCU | gateway]
! no use-proxy MCUs outbound-from [MCU | gateway]
! no use-proxy gateways inbound-to gateway
! no use-proxy gateways outbound-from gateway
gw-type-prefix 1# default-technology
! no arq reject-unknown-prefix
endpoint ttl 60
no shutdown
```

Applications

Cisco IP Communications provides an expanding portfolio of applications that extend the features of Unified CM and provide advanced capabilities and integration with other communication media. Many of these applications can be used in conjunction with IP Video Telephony devices, even if they do not specifically support video. For instance, Cisco Unified CM does not support the negotiation of video channels for CTI applications using the TAPI/JTAPI protocols, but that does not necessarily preclude using a CTI application in conjunction with a video call. This section reviews some of the Cisco and third-party applications and discusses whether or not they can be used to provide advanced call treatment for video calls.

CTI Applications

The following applications are based on the Computer Telephony Integration (CTI) interface.

Cisco Emergency Responder

Cisco Emergency Responder (ER) routes emergency (911) calls to the correct Public Safety Answering Point (PSAP). It also provides the PSAP with the correct calling line ID of the originating device so that the PSAP can respond to the correct physical location of the incident and call the party back in the event that the call is disconnected. Cisco ER uses JTAPI to integrate with Unified CM. Emergency calls are routed to Cisco ER via a CTI route point, then Cisco ER decides which PSAP to forward the call to and what calling line ID to display. Cisco ER tracks each endpoint on the network to determine its physical location by using Simple Network Management Protocol (SNMP) and Cisco Discovery Protocol (CDP) to discover the physical port and specific Cisco Catalyst Ethernet switch to which the endpoint is connected. If CDP is not available, Cisco ER can be configured to locate endpoints by their IP subnet instead. Cisco ER then correlates this information with the physical location of the switch and stores the information in its database.

Both Cisco Unified Video Advantage and the Cisco IP Video Phone 7985 support CDP for the purpose of Cisco ER discovery. Cisco Unified Video Advantage does not send CDP messages to the switch directly but relies on its associated Cisco Unified IP Phone for this support. Therefore, if a Video Telephony user dials 911, Cisco ER is able to route the call to the correct PSAP.

Because third-party SCCP video endpoints do not support CDP, Cisco ER must track these endpoints by their IP subnet. Cisco ER is therefore able to route the call to the correct PSAP.

Because H.323 videoconferencing clients do not support CDP, Cisco ER must track them by their IP subnet. Cisco ER is therefore able to route the call to the correct PSAP. However, the H.323 device must support the Empty Capabilities Set (ECS) procedure in order to have its call routed by Cisco ER. If the H.323 endpoint does not support receiving an ECS from Unified CM, calls to 911 that are handled by Cisco ER will fail.

When Cisco Cius is connected to Unified CM through a 3G or 4G connection, Cisco ER will not be able to locate the appropriate PSAP for the user's location. Cisco Cius users should be instructed to use alternate means to call 911 while roaming with 3G or 4G connections.

Cisco Unified Communications Manager Assistant

Cisco Unified Communications Manager Assistant enables administrative assistants to provide coverage for the managers with whom they are associated. Unified CM Assistant uses JTAPI to integrate with Unified CM. While Unified CM Assistant is not specifically video-capable, there is nothing stopping Unified CM Assistant from being used with phones that are video-enabled. Once Unified CM Assistant has handled the call and the call is transferred to the final destination device, the two devices in the call communicate with each other directly and could establish video channels at that point. For example, if a video-capable endpoint dialed the directory number of a Manager, and the Assistant covered the call using the Unified CM Assistant application, there might not be any video established during the initial handling of the call. But once the Assistant transferred the caller to the Manager, Unified CM could then negotiate video channels. However, H.323 devices must support the Empty Capabilities Set (ECS) procedure in order to interoperate with Unified CM Assistant. If the H.323 endpoint does not support receiving an ECS from Unified CM, calls that are intercepted by Unified CM Assistant will fail when the Assistant attempts to transfer the call to the Manager.

Cisco Unified IP Interactive Voice Response and Cisco Unified Contact Center

Cisco Unified IP Interactive Voice Response (Unified IP IVR) and Cisco Unified Contact Center (Unified CC) use JTAPI to integrate with Unified CM. If a video-capable device calls into an IVR application (such as a help desk), the communication is audio-only while the caller is connected to the application server (that is, while the caller browses the IVR menu or waits in queue for a help-desk member to take the call). However, once the IVR application transfers the call to its final destination, video channels can be negotiated at that time. H.323 devices must support the Empty Capabilities Set (ECS) procedure in order to interoperate with Cisco Unified IP IVR and Unified CC. If the H.323 endpoint does not support receiving an ECS from Unified CM, calls that are intercepted by Cisco Unified IP IVR or Unified CC will fail when the application attempts to transfer the caller to the final destination.

IVR applications often use DTMF tones to select options in the IVR menu. An alternative is speech recognition, which enables the caller to speak commands to the IVR server instead of pressing keys on the phone. Because Cisco Unified IP IVR and Unified CC both use JTAPI to integrate with Unified CM, they pass DTMF tones through out-of-band signaling messages. Many H.323 devices on the market today use in-band DTMF tones, and these H.323 clients would not be able to use DTMF to navigate an IP IVR or Unified CC menu. However, these H.323 clients could use speech recognition if the IVR server is enabled for it. Video-capable devices such as Cisco Unified Video Advantage, third-party SCCP video devices, and any H.323 endpoint that uses H.245 alphanumeric out-of-band signaling for DTMF, can navigate the IVR menus using DTMF tones.

Cisco Unified Enterprise Attendant Console

The Cisco Unified Enterprise Attendant Console uses JTAPI to integrate with Unified CM. The Unified Enterprise Attendant Console is used as a front-office device to handle incoming calls. Although the Unified Enterprise Attendant Console does not specifically support video, video channels can be negotiated once the call is transferred to its final destination. However, H.323 devices must support the Empty Capabilities Set (ECS) procedure in order to interoperate with the Unified Enterprise Attendant Console. If the H.323 endpoint does not support receiving an ECS from Unified CM, calls that are intercepted by a Unified Enterprise Attendant Console will fail when the attendant attempts to transfer the caller to the final destination.

Cisco IP Communicator

Cisco IP Communicator is an SCCP software phone, and it does not support video. Video can be provided by associating the Cisco Unified Video Advantage client with Cisco IP Communicator. As of version 2.0, Cisco IP Communicator can associate to Cisco Unified Video Advantage 2.0 when both applications reside on the same PC. For more information, refer to the chapter on [Unified Communications Endpoints](#), page 18-1.

Cisco IP Communicator 2.1 and later releases also provide a SIP device protocol option for creating or adding a Cisco IP Communicator device. However, Cisco Unified Video Advantage is not supported for Cisco IP Communicator using SIP protocol.

Collaboration Solutions

The following technologies are sometimes used to provide video communications between endpoints.

T.120 Application Sharing

Some videoconferencing endpoints use the T.120 protocol to share documents, whiteboards, and text among participants in a conference. Unified CM does not support negotiating a T.120 channel. Instead of T.120, Cisco recommends using web-based collaboration solutions such as Cisco MeetingPlace or other third-party collaboration solutions.

Cisco Unified MeetingPlace

Cisco Unified MeetingPlace combines a high-end audio and video conferencing solution with a web-based front end for scheduling and participating in conferences. For more information, see [Cisco Unified MeetingPlace, page 22-13](#).

Video Interoperability

Video interoperability is the audio and video support for point-to-point calls between Cisco TelePresence System (CTS) endpoints, other Cisco Unified Communications (UC) video endpoints, and third-party video endpoints. Prior to Cisco Unified CM 8.5, video interoperability between the different families of video endpoints was possible only with the insertion of a video component between endpoints, such as a video transcoder or a multipoint control unit (MCU).

Cisco Unified CM 8.5 and later releases not only offer native video interoperability between different video endpoint family types, point-to-point, but also provide better video interoperability in general with H.264 codec negotiation in SIP and H.323 protocols and enable the endpoints to negotiate high definition (HD) resolutions when available.

As stated earlier, video interoperability in Unified CM also enables Cisco TelePresence System (CTS) endpoints to communicate with non-CTS endpoints, provided that the installed CTS software supports such interoperability. For further information, refer to *Interoperability Between CTS Endpoints and Other Cisco Endpoints or Devices*, available at

http://www.cisco.com/en/US/docs/telepresence/interop/endpoint_interop.html

The primary motivation for this newly added support is to facilitate the interaction of a diverse set of video endpoints without the need for deploying an expensive DSP infrastructure that would otherwise be required.

The following sections present general considerations and recommendations for the use of video interoperability:

- [Video Interoperability Architecture, page 12-44](#)
- [Design Considerations for Video Interoperability, page 12-45](#)

Video Interoperability Architecture

The video interoperability architecture includes the following elements:

- Video interoperability support is available only in Cisco Unified CM 8.5 and later releases.
- Two different video endpoint family types (Cisco TelePresence endpoints, Cisco UC endpoints, or third-party endpoints) engaged in a video call.

The following sections offer further information about the scope of the video interoperability support:

- [Video Interoperability Test Cases, page 12-45](#)
- [Limitations of Video Interoperability, page 12-45](#)

Video Interoperability Test Cases

In most cases a video endpoint that supports SIP or H.323 without using proprietary signaling would be able to interoperate with a Cisco UC video endpoint that supports video interoperability. For specific information on the scope of the interoperability between common sets of deployed devices and general information about the testing that was conducted to validate these more common examples of interoperability, refer to the *Cisco Unified Communications System Test Results for IP Telephony*, available at

http://www.cisco.com/en/US/docs/voice_ip_comm/uc_system/unified/communications/system/uc tart.htm

Limitations of Video Interoperability

While video interoperability support attempts to enable any-to-any point-to-point video call interoperability, it is important to note that not all features of an individual video endpoint can be supported when interoperating with another endpoint. There are many reasons for this. For example, incompatibilities between different call control protocols could render a feature unavailable or offer a different representation of that feature. H.264 video media parameters can be represented differently in H.323 than in SIP, as another example. H.323 also does not have support for presence, but presence is quite commonly supported in SIP. Skinny Client Control Protocol (SCCP) does not have any notion of application sharing, which is commonly available in SIP and H.323 endpoint implementations. For instance, an SCCP user trying to share his/her PC screen would be hampered because Binary Flow Control Protocol (BFCP) and H.239 are not available in SCCP.

Design Considerations for Video Interoperability

Because Unified CM video interoperability decreases the reliance on video transcoding to achieve any-to-any video calling, some call flows might change substantially. That is not to say that video transcoding is unnecessary for all call flows, but it is no longer needed for the ones where the video interoperability capabilities of Unified CM can be employed. Therefore, enabling video interoperability reduces the need for DSP resources.

Additionally, the following areas should be considered when implementing the video interoperability capabilities of Unified CM:

- [Guideline and Restrictions for Video Interoperability, page 12-45](#)
- [Quality of Service \(QoS\) and Call Admission Control Considerations for Video Interoperability, page 12-46](#)

Guideline and Restrictions for Video Interoperability

The following guidelines and restrictions apply with regard to video interoperability in a Unified CM deployment:

- If H.323 or SCCP protocols are used in conjunction with video interoperability, Unified CM will support only a single H.264 payload and the packetization mode is treated as 0. An example side effect (but not the only one) of this circumstance is the fact that 1080p resolution is not available with these protocols because 1080p requires packetization mode 1.
- If multiple payloads are presented by an H.323 or SCCP endpoint engaged in a video interoperability call, Unified CM will use only the payload with the lowest codec profile. This, in turn, could result in less than the highest supported resolution being selected for the call.

- If a SIP endpoint omits the **level-asymmetry-allowed** parameter in the Session Description Protocol (SDP), Cisco products will assume that the endpoint can support asymmetric resolution transmission. Therefore, different receiving and sending video resolutions could be negotiated during a call.
- If a call is processed with video interoperability while Unified CM is performing protocol interworking with SIP and H.323, the H.323 endpoint must honor the proposed dynamic payload number specified by the SIP side, which means that no re-negotiation to a different payload would be supported.
- Unified CM will not negotiate Real-Time Transport Control Protocol (RTCP) feedback if the video call invokes a media termination point (MTP) or transcoder.

Quality of Service (QoS) and Call Admission Control Considerations for Video Interoperability

There are no changes to the configuration of regions and locations in Unified CM as a result of video interoperability support. However, regions play a significant role in determining the resolution between groups of endpoints, and they can be used to maximize or minimize the resolution that these devices use when interoperating. The **Max Video Call Bit Rate** field in the regions settings is used to determine the amount of bandwidth and, thus, the resolution that endpoints are able to negotiate.

For further information about QoS and call admission control with native video interoperability, see the section on [Call Admission Control Design Recommendations for TelePresence Video Interoperability Architectures](#), page 11-95.

Wireless Networking Solutions

Because video is so bandwidth intensive, Cisco does *not* recommend using a shared wireless medium such as 802.11b/g for video endpoints.

Take care to ensure that video endpoints do not share the wireless bandwidth with any production IP Phones because video will consume much of the bandwidth and make it difficult to support video, audio, and data all on the same wireless medium.

Cisco Unified Video Advantage relies on a physical Ethernet connection to the physical IP Phone with which it is associated. It is not uncommon for a user to have both a physical Ethernet interface and an Aironet 802.11b Wireless Adapter installed in the same PC. This configuration could cause problems for Cisco Unified Video Advantage if the wireless interface happens to be the preferred path to the network because Cisco Unified Video Advantage will not associate over that interface. Cisco recommends that you always make the physical Ethernet interface the preferred path. Also, when users connect to the PC port on the back of the IP Phone, instruct them to disable their Aironet Adapter to keep it from accidentally taking precedence.

Cisco Unified Wireless IP Phones 7925G and 7921G

The Cisco Unified Wireless IP Phones 7925G and 7921G do not support video. Nothing prevents a video endpoint from calling a Cisco Unified Wireless IP Phone; however, it will negotiate as an audio-only call. The Wireless IP Phone user can then put the call on hold, transfer it, or conference it. If the caller is an H.323 video endpoint, it must support the Empty Capabilities Set (ECS) procedure in order for these supplementary services to work.

XML Services

Currently there are no XML applications specifically written for the Cisco Unified Video Advantage client solution, Cisco IP Video Phone 7985, or third-party SCCP video endpoints. However, with the exception of a few third-party endpoints, these endpoints do support XML applications. Cisco Unified Video Advantage uses a Cisco Unified IP Phone, so any XML application supported on those phone models should also work with Unified Video Advantage.

Most third-party SCCP video endpoints support XML, but not all XML applications currently work on those endpoints. For example, Cisco Extension Mobility and the Berbee InformaCast product are two popular XML applications that currently do not work on the third-party SCCP endpoints. Support for these applications will require firmware upgrades to the endpoints as well as changes in Unified CM Administration in some cases.

CHAPTER 13

Gateways

Revised: September 30, 2011; OL-21733-18

Gateways provide a number of methods for connecting an IP telephony network to the Public Switched Telephone Network (PSTN), a legacy PBX, or key systems. Gateways range from specialized, entry-level and stand-alone voice gateways to high-end, feature-rich integrated router and Cisco Catalyst gateways.

This chapter explains important factors to consider when selecting a Cisco gateway to provide the appropriate protocol and feature support for your IP Telephony network. The main topics discussed in this chapter include:

- [Traffic Patterns and Gateway Sizing, page 13-2](#)
- [TDM and VoIP Trunking Gateways, page 13-7](#)
- [Understanding Cisco Gateways, page 13-8](#)
- [Gateway Selection, page 13-9](#)
- [Fax and Modem Support, page 13-19](#)
- [Gateways for Video Telephony, page 13-27](#)

What's New in This Chapter

[Table 13-1](#) lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Table 13-1 ***New or Changed Information Since the Previous Release of This Document***

| New or Revised Topic | Described in | Revision Date |
|---|--|----------------------|
| Gateway configuration examples were removed from this document but can be found in the <i>Cisco IOS Fax, Modem, and Text Support over IP Configuration Guide</i> , which is available at http://www.cisco.com/en/US/docs/ios/voice/fax/configuration/guide/12_4t/vf_12_4t_book.html | Gateway Configuration Examples, page 13-26 | September 30, 2011 |
| Video telephony gateways | Gateways for Video Telephony, page 13-27 | November 15, 2010 |
| Fax and modem support | Fax and Modem Support, page 13-19 | April 2, 2010 |

Traffic Patterns and Gateway Sizing

This section presents a high-level discussion of the differences between various traffic models or patterns and how they can affect voice gateway selection. The emphasis is on traffic patterns and gateway sizing for traffic-intensive deployments.

Definitions and Terminology

This section uses the following terms and definitions:

- **Simultaneous calls**
The number of calls that are all active in the system at the same time.
- **Maximum simultaneous calls**
The maximum number of simultaneous calls in active (talk) state that the system can handle. The number of calls expected to be active simultaneously during the *busy hour* of the day should not exceed this number.
- **Calls per second (cps)**
The call arrival rate, described as the number of calls that arrive (that is, new call setup attempts) in one second. Call arrival rates are also often quoted in calls per hour, but this metric is looser in the sense that 100 calls arriving in the last five seconds of an hour provides an average call arrival rate of 100 calls per hour (which is an extremely low rate for a communications system), while it also provides an arrival rate of 20 calls per second (which is a high rate). Sustaining 20 calls per second for an entire hour would result in 72,000 calls per hour. Therefore calls-per-hour is not a very useful metric for ascertaining a system's ability to handle bursty call arrival traffic patterns.
- **Busy Hour Call Attempts (BHCA)**
The number of calls attempted during the busiest hour of the day (the peak hour). This is the same as the calls-per-second rating for the busiest hour of the day, but it is expressed over a period of an hour rather than a second. For example, 10 cps would be equal to 36,000 calls per hour. There is also a metric for Busy Hour Call Completions (BHCC), which can be lower than the BHCA (call attempts) under the assumption that not all calls are successful (as when a blocking factor exists). This chapter assumes 100% call completions, so that $BHCA = BHCC$.
- **Bursty traffic**
Steady arrival means the call attempts are spaced more or less equally over a period of time. For example, 60 calls per hour at a steady arrival rate would present one call attempt roughly every minute (or approximately 0.02 cps). With bursty arrival, the calls arriving over a given period of time (such as an hour) are not spaced equally but are clumped together in one or more spikes. In the worst case, an arrival rate of 60 calls per hour could offer all 60 calls in a single second of the hour, thus averaging 0 cps for most of the hour with a peak of 60 cps for that one second. This kind of traffic is extremely stressful to communications systems.
- **Hold time**
This is the period of "talk time" on a voice call; that is, the period of time between call setup and call teardown when there is an open speech path between the two parties. A hold time of 3 minutes (180 seconds) is an industry average used for traffic engineering of voice systems. The shorter the hold time on the average call, the greater the percentage of system CPU time spent on setting up and tearing down calls compared to the CPU time spent on maintaining the speech path.

PSTN Traffic Patterns

Traffic, when used in the context of voice communication systems, refers to the volume of calls being sent and/or received. Of particular importance is the traffic carried by external circuits such as the public switched telephone network (PSTN). Traffic is measured in Erlangs, and an Erlang is defined as one call lasting for one hour. This section does not go into any further detail on Erlangs other than to say that there are mathematical tables (Erlang-B and Erlang-C) that are used to calculate how many circuits are required for a given amount of offered traffic.

The amount of traffic received and generated by your business determines the size of the external circuits required. However, many customers typically continue to use the same number of circuits for their IP-based communications system as they previously used for a TDM-based system. While this sizing method might work if no issues are encountered, the process of ongoing system traffic analysis should be part of any routine maintenance practices. Traffic analysis can show that the system is over-provisioned for the current levels of traffic (and, therefore, the customer is paying for circuits that are not needed) or, conversely, that the system is under-provisioned and may be suffering from occasional blocked and/or lost calls, in which case increasing the number of circuits will remedy the situation.

Normal Business Traffic Profile

Most customers have a normal traffic profile, which means that they typically have two *busy hours* per day, one occurring during the morning from 10:00 to 11:00 and the other in the afternoon from 14:00 to 15:00. These busy-hour patterns can often be attributed to such things as employees starting the work day or returning from a lunch break. The calls themselves tend to have longer hold times and they tend to arrive and leave in a steady manner. A generally accepted industry average holding time to use for traffic calculations is 3 minutes.

Assuming that the communications system is engineered with the busy-hour traffic in mind, no issues should arise. Engineering a system below these levels will result in blocked and/or lost calls, which can have a detrimental effect on business.

Contact Center Traffic Profile

Contact centers present somewhat different patterns of traffic in that these systems typically handle large volumes of calls for the given number of agents or interactive voice response (IVR) systems available to service them. Contact centers want to get the most out of their resources, therefore their agents, trunks, and IVR systems are kept busy all the while they are in operation, which usually is 24 hours a day. Call queuing is typical (when incoming call traffic exceeds agent capacity, calls wait in queue for the next available agent), and the agents are usually dedicated during their work shifts to taking contact center calls.

Call holding times in contact centers are often of a shorter average duration than normal business calls. Contributing to the shorter average call holding time is the fact that many calls interact only with the IVR system and never need to speak to a human agent (also termed self-service calls). A representative holding time for self-service calls is about 30 seconds, while a call that talks to an agent has an average holding time of 3 minutes (the same as normal business traffic), making the overall average holding time in the contact center shorter than for normal business traffic.

The goal of contact centers to optimize resource use (including IVR ports, PSTN trunks, and human agents), combined with the fact that contact centers are systems dedicated to taking telephone calls, also presents the system with higher call arrival rates than in a typical business environment. These call arrival rates can also peak at different times of day and for different reasons (not the usual busy hour) than normal business traffic. For example, when a television advertisement runs for a particular holiday

package with a 1-800 number, the call arrival rate for the system where those calls are received will experience a peak of traffic for about 15 minutes after the ad airs. This call arrival rate can exceed the average call arrival rate of the contact center by an order of magnitude.

Gateway Sizing for Contact Center Traffic

Short call durations as well as bursty call arrival rates impact the PSTN gateway's ability to process the traffic. Under these circumstances the gateway needs more resources to process all calls in a timely manner, as compared to gateways that receive calls of longer duration that are presented more uniformly over time. Because gateways have varying capabilities to deal with these traffic patterns, careful consideration should be given to selecting the appropriate gateway for the environment in which it will operate. Some gateways support more T1/E1 ports than others, and some are more able than others to deal with multiple calls arriving at the same time.

For a traffic pattern with multiple calls arriving in close proximity to each other (that is, high or bursty call arrival rates), a gateway with a suitable rating of calls per second (cps) is the best fit. Under these conditions, using calls with 15-second hold times, the Cisco AS5400XM Universal Gateway can maintain 16 cps with 250 calls active at once, the Cisco 3845 Integrated Services Router can maintain 13 cps with 200 calls active at once, and the Cisco 3945 Integrated Services Router can maintain 28 cps with 420 calls active at once. The performance of the Cisco AS5350XM Universal Gateway is identical to that of the AS5400XM in terms of calls per second.

For traffic patterns with a steady arrival rate, the maximum number of active calls that a gateway can handle is generally the more important consideration. Under these conditions, using calls with 180-second hold times, the Cisco AS5400XM Universal Gateway can maintain 600 simultaneously active calls with a call arrival rate of up to 3.3 cps, the Cisco 3845 Integrated Services Router can maintain 450 simultaneously active calls with a call arrival rate of up to 2.5 cps, and the Cisco 3945 Integrated Services Router can maintain 720 simultaneously active calls with a call arrival rate of up to 4 cps).

These numbers assume that all of the following conditions apply:

- CPU utilization does not exceed 75%.
- PSTN gateway calls are made with ISDN PRI trunks using H.323.
- Real Time Control Protocol (RTCP) timer is set to the default value of 5 seconds.
- Voice Activity Detection (VAD) is off.
- G.711 uses 20 ms packetization.
- Cisco IOS Release 15.0.1M is used.
- Dedicated voice gateway configurations are used, with ethernet (GE) egress and no QoS features. (Using QoS-enabled egress interfaces or non-ethernet egress interfaces, or both, will consume additional CPU resources.)
- No supplementary call features or services are enabled – such as general security (for example, access control lists or firewalls), voice-specific security (TLS, IPsec and/or SRTP), AAA lookups, gatekeeper-assisted call setups, VoiceXML or TCL-enabled call flows, call admission control (RSVP), and SNMP polling/logging. Such extra call features will use additional CPU resources.

Voice Activity Detection (VAD)

VAD is a digital signal processing feature that suppresses the creation of most of the IP packets during times when the speech path in a particular direction of the call is perceived as being silent. Typically only one party on a call speaks at a time, so that packets need flow in only one direction, and packets in

the reverse (or silent) direction need not be sent except as an occasional keepalive measure. VAD can therefore provide significant savings in the number of IP packets sent for a VoIP call, and thereby save considerable CPU cycles on the gateway platform. While the actual packet savings that VAD can provide varies with the call flow, the application, and the nature of speaker interactions, it tends to use 10% to 30% fewer packets than would be sent for a call made using a VAD-off configuration.

VAD is most often turned off in endpoints and voice gateways deployed in Unified CM networks; VAD is most often turned on in voice gateways in other types of network deployments.

Codec

Both G.711 and G.729A use as their default configuration a 20 ms sampling time, which results in a 50 packets per second (pps) VoIP call in each direction. While a G.711 IP packet (200 bytes) is larger than a G.729A packet (60 bytes), this difference has not proven to have any significant effect on voice gateway CPU performance. Both G.711 and G.729 packets qualify as "small" IP packets to the router, therefore the packet rate is the salient codec parameter affecting CPU performance.

Performance Overload

Cisco IOS is designed to have some amount of CPU left over during peak processing, to handle interrupt-level events. The performance figures in this section are designed with the processor running at an average load of approximately 75%. If the load on a given Cisco IOS gateway continually exceeds this threshold, the following will result:

- The deployment will not be supported by Cisco Technical Assistance Center (TAC).
- The Cisco IOS Gateway will display anomalous behavior, including Q.921 timeouts, longer post-dial delay, and potentially interface flaps.

Cisco IOS Gateways are designed to handle a short burst of calls, but continual overloading of the recommended call rate (calls per second) is not supported.

Note

With any gateway, you might be tempted to assign unused hardware ports to other tasks, such as on a CMM gateway where traffic calculations have dictated that only a portion of the ports can be used for PSTN traffic. However, the remaining ports *must* remain unused, otherwise the CPU will be driven beyond supported levels.

Performance Tuning

The CPU utilization of a Cisco IOS Voice gateway is affected by every process that is enabled in a chassis. Some of the lowest level processes such as IP routing and memory defragmentation will occur even when there is no live traffic on the chassis.

Lowering the CPU utilization can help to increase the performance of a Cisco IOS Voice Gateway by ensuring that there are enough available CPU resources to process the real-time voice packets and the call setup instructions. Some of the techniques for decreasing CPU utilization are described in [Table 13-2](#).

Table 13-2 Techniques for Reducing CPU Utilization

| Technique | CPU Savings | Description |
|--|-------------|--|
| Enable Voice Activity Detection (VAD) | Up to 20% | Enabling VAD can result in up to 45% fewer voice packets in typical conversations. The difficulty is that, in scenarios where voice recognition is used or there are long delays, a reduction in voice quality can occur. Voice appears to "pop" in at the beginning and "pop" out at the end of talk spurts. |
| Disable Real Time Control Protocol (RTCP) | Up to 5% | Disabling RTCP results in less out-of-band information being sent between the originating and terminating gateways. This results in lower quality of statistics displayed on the paired gateway. This can also result in the terminating gateway having a call "hang" for a longer period of time if RTCP packets are being used to determine if a call is no longer active. |
| Disable other non-essential functions such as: Authentication, Authorization, and Accounting (AAA); Simple Network Management Protocol (SNMP); and logging | Up to 2% | Any of these processes, when not required, can be disabled and will result in lower CPU utilization by freeing up the CPU to provide faster processing of real-time traffic. |
| Change call pattern to increase the length of the call (and reduce the number of calls per second) | Varies | This can be done by a variety of techniques such as including a long(er) introduction prompt played at the beginning of a call or adjusting the call script at the call center. |

Additional Information

Considerations for Gateway Redundancy

When deploying a gateway solution, give careful consideration to redundancy when compared with scalability. For example, the Cisco VGD 1T3 Voice Gateway is capable of delivering 28 T1 lines in one physical circuit. However, considering the inherent need for redundancy with PSTN services, multiple smaller gateways delivering the same overall physical quantity of service may be more appropriate. Multiple gateways further allows for placement in different physical locations, thus allowing for another level of redundancy, in this case spatial redundancy.

Gateway deployments involving contact with emergency services must also be considered, and sometimes more than one solution may be necessary. For example, consider a small branch location connected to the PSTN through a SIP trunk located at a remote headquarters. If there is either a WAN or SIP trunk failure, the branch location must still be able to contact the emergency services. In this case the best solution would be either a local analog or PRI service (that is, either a standalone analog service or a PRI service terminated on the branch router).

TDM and VoIP Trunking Gateways

Until approximately 2006, the only choice for an enterprise to connect its internal VoIP network to voice services outside the enterprise was via TDM gateways to the traditional PSTN. Cisco offers a full range of TDM gateways with analog and digital connections to the PSTN as well as to PBXs and key systems. TDM connectivity covers a wide variety of low-density analog (FXS and FXO), low density digital (BRI), and high-density digital (T1, E1, and T3) interface choices.

Starting around 2006, new voice service options to an enterprise started to become available from service providers, most often referred to as SIP trunk services. Using a SIP trunk for connecting to PSTN and other destinations outside the enterprise involves an IP-to-IP connection at the edge of the enterprise's VoIP network. The same functions traditionally fulfilled by a TDM gateway are still needed at this interconnect point, including demarcation, call admission control, ensuring QoS, a troubleshooting boundary, security checks, and so forth. For SIP trunking connections, the Cisco Unified Border Element fulfills these functions as a session border controller (SBC) at the interconnect

point between the enterprise and the service provider network. Cisco Unified Border Element also performs protocol translation functions to interconnect H.323 and SIP equipment, or to interconnect SIP equipment using different variations of SIP implementations. Cisco Unified Border Element can also perform transcoding. If used for one of these functions, Cisco Unified Border Element may also be used internal to the enterprise network at interconnect points between equipment that cannot interoperate without a protocol translation or transcoding service.

TDM gateway platforms are discussed in detail in the remainder of this chapter. Cisco Unified Border Element is discussed in greater detail in the chapter on [Cisco Unified CM Trunks, page 14-1](#). Both functions can be enabled on the same Cisco Integrated Services Router (ISR) platform at the same time.

Understanding Cisco Gateways

Cisco access gateways enable Cisco Unified Communications Manager (Unified CM) to communicate with non-IP telecommunications devices. There are two types of Cisco access gateways, analog and digital.

Cisco Access Analog Gateways

There are two categories of Cisco access analog gateways, trunk gateways and station gateways.

- Access analog station gateways

Analog station gateways connect Unified CM to Plain Old Telephone Service (POTS) analog telephones, interactive voice response (IVR) systems, fax machines, and voice mail systems. Station gateways provide Foreign Exchange Station (FXS) ports.

- Access analog trunk gateways

Analog trunk gateways connect Unified CM to PSTN central office (CO) or PBX trunks. Trunk gateways provide Foreign Exchange Office (FXO) ports for access to the PSTN, PBXs, or key systems, and E&M (recEive and transMit, or ear and mouth) ports for analog trunk connection to a legacy PBX. Whenever possible, use digital gateways to minimize any answer and disconnect supervision issues. Analog Direct Inward Dialing (DID) and Centralized Automatic Message Accounting (CAMA) are also available for PSTN connectivity.

Cisco Access Digital Trunk Gateways

A Cisco access digital trunk gateway connects Unified CM to the PSTN or to a PBX via digital trunks such as Primary Rate Interface (PRI), Basic Rate Interface (BRI), or T1 Channel Associated Signaling (CAS). Digital T1 PRI trunks may also be used to connect to certain legacy voice mail systems.

Tuning Gateway Gain Settings

Connecting a Cisco Unified Communications network to the PSTN through gateways requires that you properly address voice quality issues arising from echo and signal degradation due to power loss, impedance mismatches, delay, and so forth. For this purpose, you must establish a Network Transmission Loss Plan (NTLP), which provides a complete picture of signal loss in all expected voice paths. Using this plan, you can identify locations where signal strength must be adjusted for optimum loudness and effective echo cancellation. Note that not all carriers use the same loss plan, and that the

presence of cellular networks adds further complexity in creating the NTLP. Cisco does not recommend adjusting input gain and output attenuation on gateways without first completing such an NTLP. For more information, refer to *Echo Analysis for Voice Over IP*, available at

http://www.cisco.com/en/US/docs/ios/solutions_docs/voip_solutions/EA_ISD.pdf

Gateway Selection

When selecting an IP telephony gateway, consider the following factors:

- [Core Feature Requirements, page 13-9](#)
- [Gateway Protocols, page 13-10](#)
- [Gateway Protocols and Core Feature Requirements, page 13-10](#)
- [Site-Specific Gateway Requirements, page 13-17](#)

Core Feature Requirements

Gateways used in IP telephony applications must meet the following core feature requirements:

- **Dual tone multifrequency (DTMF) relay capabilities**
DTMF relay capability, specifically out-of-band DTMF, separates DTMF digits from the voice stream and sends them as signaling indications through the gateway protocol (H.323, SCCP, MGCP, or SIP) signaling channel instead of as part of the voice stream or bearer traffic. Out-of-band DTMF is required when using a low bit-rate codec for voice compression because the potential exists for DTMF signal loss or distortion.
- **Supplementary services support**
Supplementary services are typically basic telephony functions such as hold, transfer, and conferencing.
- **Fax/modem support**
Fax over IP enables interoperability of traditional analog fax machines with IP telephony networks. The fax image is converted from an analog signal and is carried as digital data over the packet network. For more information, see [Fax and Modem Support, page 13-19](#)
- **Unified CM redundancy support**
Cisco Unified Communications is based on a distributed model for high availability. Unified CM clusters provide for Unified CM redundancy. The gateways must support the ability to “re-home” to a secondary Unified CM in the event that a primary Unified CM fails. Redundancy differs from call survivability in the event of a Unified CM or network failure.

Refer to the gateway product documentation to verify that any IP Telephony gateway you select for an enterprise deployment can support the preceding core requirements. Additionally, every IP Telephony implementation has its own site-specific feature requirements, such as analog or digital access, DID, and capacity requirements (see [Site-Specific Gateway Requirements, page 13-17](#)).

Gateway Protocols

Cisco Unified CM (Release 3.1 and later) supports the following gateway protocols:

- H.323
- Media Gateway Control Protocol (MGCP)

Cisco Unified CM Release 4.0 and later supports Session Initiation Protocol (SIP) on the trunk side. The SIP trunk implementation has been enhanced in Cisco Unified CM releases 5.0 through 7.x to support more features.

Protocol selection depends on site-specific requirements and the installed base of equipment. For gateway configuration, MGCP might be preferred over H.323 or SIP due to simpler configuration. On the other hand, H.323 or SIP might be preferred over MGCP because of the robustness of the interfaces supported.

Simplified Message Desk Interface (SMDI) is a standard for integrating voice mail systems to PBXs or Centrex systems. Connecting to a voice mail system via SMDI and using either analog FXS or digital T1 PRI would require either SCCP or MGCP protocol because H.323 or SIP devices do not identify the specific line being used from a group of ports. Use of H.323 or SIP gateways for this purpose means the Cisco Message Interface cannot correctly correlate the SMDI information with the actual port or channel being used for an incoming call.

In addition, the Unified CM deployment model being used can influence gateway protocol selection. (Refer to the chapter on [Unified Communications Deployment Models](#), page 5-1.)

**Note**

Prior to deployment, check the Cisco IOS software release notes to confirm feature or interface support.

Gateway Protocols and Core Feature Requirements

This section describes how each protocol (SCCP, H.323, MGCP, and SIP) supports the following gateway feature requirements:

- [DTMF Relay](#), page 13-10
- [Supplementary Services](#), page 13-12
- [Unified CM Redundancy](#), page 13-15

DTMF Relay

Dual-Tone Multifrequency (DTMF) is a signaling method that uses specific pairs of frequencies within the voice band for signals. A 64 kbps pulse code modulation (PCM) voice channel can carry these signals without difficulty. However, when using a low bite-rate codec for voice compression, the potential exists for DTMF signal loss or distortion. An out-of-band signaling method for carrying DTMF tones across a Voice over IP (VoIP) infrastructure provides an elegant solution for these codec-induced symptoms.

SCCP Gateways

The Cisco VG248 carries DTMF signals out-of-band using Transmission Control Protocol (TCP) port 2002. Out-of-band DTMF is the default gateway configuration mode for the VG248.

H.323 Gateways

The H.323 gateways, such as the Cisco 3800 series products, can communicate with Unified CM using the enhanced H.245 capability for exchanging DTMF signals out-of-band. The following is an example out-of-band DTMF configuration on a Cisco IOS gateway:

```
dial-peer voice 100 voip
destination-pattern 555...
session target ipv4:10.1.1.1
CODEC g729ar8
dtmf-relay h245-alphanumeric
preference 0
```

MGCP Gateway

The Cisco IOS-based platforms use MGCP for Unified CM communication. Within the MGCP protocol is the concept of *packages*. The MGCP gateway loads the DTMF package upon start-up. The MGCP gateway sends *symbols* over the control channel to represent any DTMF tones it receives. Unified CM then interprets these signals and passes on the DTMF signals, out-of-band, to the signaling endpoint. The global configuration command for DTMF relay is:

```
mgcp dtmf-relay VOIP codec all mode out-of-band
```

You must enter additional configuration parameters in the Unified CM MGCP gateway configuration interface.

DTMF relay is enabled by default and does not need additional configuration.

**Note**

Use the **fm-package** command to enable DTMF via RFC 2833, available as of Cisco IOS Release 12.4(6)T.

SIP Gateway

The Cisco IOS-based platforms can use SIP for Unified CM communication. They support various methods for DTMF, but only the following methods can be used to communicate with Unified CM:

- Named Telephony Events (NTE), or RFC 2833
- Unsolicited SIP Notify (UN)
- Key Press Markup Language (KPML)

The following example shows a configuration for NTE:

```
dial-peer voice 100 voip
destination-pattern 555...
session target ipv4:10.1.1.1
session protocol sipv2
dtmf-relay rtp-nte
```

The following example shows a configuration for UN:

```
dial-peer voice 100 voip
destination-pattern 555...
session target ipv4:10.1.1.1
session protocol sipv2
dtmf-relay sip-notify
```

For more details on DTMF method selection, see the chapter on [Media Resources](#), page 17-1.

Supplementary Services

Supplementary services provide user functions such as hold, transfer, and conferencing. These are considered fundamental requirements of any voice installation. Each gateway evaluated for use in an IP telephony network should provide support for supplementary services natively, without the use of a software media termination point (MTP).

SCCP Gateways

The Cisco SCCP gateways provide full supplementary service support. They also support FXS SCCP ports with Cisco IOS Release 12.4.9T. The SCCP gateways use the Gateway-to-Unified CM signaling channel and SCCP to exchange call control parameters.

H.323 Gateways

H.323v2 implements Open/Close LogicalChannel and the emptyCapabilitySet features. The use of H.323v2 by H.323 gateways, beginning in Cisco IOS Release 12.0(7)T and Cisco Unified CM Release 3.0 and later, eliminates the requirement for an MTP to provide supplementary services. With Unified CM Release 3.1 and later, a transcoder is allocated dynamically only if required during a call to provide access to G.711-only devices while still maintaining a G.729 stream across the WAN. Full support for H.323v2 is available in Cisco IOS Release 12.1.1T.

Once an H.323v2 call is set up between a Cisco IOS gateway and an IP phone, using the Unified CM as an H.323 proxy, the IP phone can request to modify the bearer connection. Because the Real-Time Transport Protocol (RTP) stream is directly connected to the IP phone from the Cisco IOS gateway, a supported voice codec can be negotiated.

[Figure 13-1](#) and the following steps illustrate a call transfer between two IP phones:

1. If IP Phone 1 wishes to transfer the call from the Cisco IOS gateway to Phone 2, it issues a transfer request to Unified CM using SCCP.
2. Unified CM translates this request into an H.323v2 CloseLogicalChannel request to the Cisco IOS gateway for the appropriate SessionID.
3. The Cisco IOS gateway closes the RTP channel to Phone 1.
4. Unified CM issues a request to Phone 2, using SCCP, to set up an RTP connection to the Cisco IOS gateway. At the same time, Unified CM issues an OpenLogicalChannel request to the Cisco IOS gateway with the new destination parameters, but using the same SessionID.
5. After the Cisco IOS gateway acknowledges the request, an RTP voice bearer channel is established between Phone 2 and the Cisco IOS gateway.

Figure 13-1 H.323 Gateway Supplementary Service Support

MGCP Gateway

The MGCP gateways provide full support for the hold, transfer, and conference features through the MGCP protocol. Because MGCP is a master/slave protocol with Unified CM controlling all session intelligence, Unified CM can easily manipulate MGCP gateway voice connections. If an IP telephony endpoint (for example, an IP phone) needs to modify the session (for example, transfer the call to another endpoint), the endpoint would notify Unified CM using SCCP. Unified CM then informs the MGCP gateway, using the MGCP User Datagram Protocol (UDP) control connection, to terminate the current RTP stream associated with the Session ID and to start a new media session with the new endpoint information. [Figure 13-2](#) illustrates the protocols exchanged between the MGCP gateway, endpoints, and Unified CM.

Figure 13-2 MGCP Gateway Supplementary Service Support

77300

SIP Gateway

The Unified CM SIP trunk interface to Cisco IOS SIP gateways supports supplementary services such as hold, blind transfer, and attended transfer. The support for supplementary services is achieved via SIP methods such as INVITE and REFER. For more details, refer to the following documentation:

- *Cisco Unified Communications Manager System Guide*, available at http://www.cisco.com/en/US/products/sw/voicew/ps556/prod_maintenance_guides_list.html
- *Cisco IOS SIP Configuration Guide*, available at http://www.cisco.com/en/US/docs/ios/voice/sip/configuration/guide/12_4t/sip_12_4t_book.html

Unified CM Redundancy

An integral piece of the IP telephony architecture is the provisioning of low-cost, distributed PC-based systems to replace expensive and proprietary legacy PBX systems. This distributed design lends itself to the robust fault tolerant architecture of clustered Unified CMs. Even in its most simplistic form (a two-system cluster), a secondary Unified CM should be able to pick up control of all gateways initially managed by the primary Unified CM.

SCCP Gateways

Upon boot-up, the Cisco VG224, VG248, and ATA 188 gateways are provisioned with Unified CM server information. When these gateways initialize, a list of Unified CMs is downloaded to the gateways. This list is prioritized into a primary Unified CM and secondary Unified CM. In the event that the primary Unified CM becomes unreachable, the gateway registers with the secondary Unified CM.

H.323 VoIP Call Preservation for WAN Link Failures

H.323 VoIP call preservation enhancements for WAN link failures sustain connectivity for H.323 topologies where signaling is handled by an entity that is different from the other endpoint, such as a gatekeeper that provides routed signaling or a call agent (such as the Cisco BTS 10200 Softswitch, Cisco PGW2200 Softswitch, or Cisco Unified CM) that brokers signaling between the two connected parties. Call preservation is useful when a gateway and the other endpoint (typically a Cisco Unified IP Phone) are located at the same site but the call agent is remote and therefore more likely to experience connectivity failures.

H.323 call preservation covers the following types of failures and connections.

Failure Types:

- WAN failures that include WAN links flapping or degraded WAN links.
- Cisco Unified CM software failure, such as when the ccm.exe service crashes on a Unified CM server.
- LAN connectivity failure, except when a failure occurs at the local branch.

Connection Types:

- Calls between two Cisco Unified CM controlled endpoints under the following conditions:
 - During Unified CM reloads.
 - When a Transmission Control Protocol (TCP) connection used for signaling H.225.0 or H.245 messages between one or both endpoints and Unified CM is lost or flapping.
 - Between endpoints that are registered to different Unified CMs in a cluster, and the TCP connection between the two Unified CMs is lost.
 - Between IP phones and the PSTN at the same site.
- Calls between a Cisco IOS gateway and an endpoint controlled by a softswitch, where the signaling (H.225.0, H.245 or both) flows between the gateway and the softswitch and media flows between the gateway and the endpoint:
 - When the softswitch reloads.
 - When the H.225.0 or H.245 TCP connection between the gateway and the softswitch is lost, and the softswitch does not clear the call on the endpoint.
 - When the H.225.0 or H.245 TCP connection between softswitch and the endpoint is lost, and the softswitch does not clear the call on the gateway.

- Call flows involving a Cisco Unified Border Element (formerly, Cisco Multiservice IP-to-IP Gateway) running in media flow-around mode that reload or lose connection with the rest of the network.

Note that, after the media is preserved, the call is torn down later when either one of the parties hangs up or media inactivity is detected. In cases where there is a machine-generated media stream, such as music streaming from a media server, the media inactivity detection will not work and the call might hang. Cisco Unified CM addresses such conditions by indicating to the gateway that such calls should not be preserved, but third-party devices or the Cisco Unified Border Element would not do this.

Flapping is defined for this feature as the repeated and temporary loss of IP connectivity, which can be caused by WAN or LAN failures. H.323 VoIP calls between a Cisco IOS gateway and Cisco Unified CM may be torn down when flapping occurs. When Unified CM detects that the TCP connection is lost, it clears the call and closes the TCP sockets used for the call by sending a TCP FIN, without sending an H.225.0 Release Complete or H.245 End Session message. This is called *quiet clearing*. The TCP FIN sent from Unified CM could reach the gateway if the network comes up for a short duration, and the gateway will tear down the call. Even if the TCP FIN does not reach the gateway, the TCP keepalives sent from the gateway could reach Unified CM when the network comes up. Unified CM will send TCP RST messages in response to the keepalives because it has already closed the TCP connection. The gateway will tear down H.323 calls if it receives the RST message.

Configuration of H.323 VoIP call preservation enhancements for WAN link failures involves configuring the **call preserve** command. If you are using Cisco Unified Communications Manager, you must enable the Allow Peer to Preserve H.323 Calls parameter from the Service Parameters window.

The **call preserve** command causes the gateway to ignore socket closure or socket errors on H.225.0 or H.245 connections for active calls, thus allowing the socket to be closed without tearing down calls using those connections.

Example of H.323 VoIP Call Preservation for All Calls

The following configuration example enables H.323 VoIP call preservation for all calls:

```
voice service voip
  h323
    call preserve
```

MGCP Gateway

MGCP gateways also have the ability to fail over to a secondary Unified CM in the event of communication loss with the primary Unified CM. When the failover occurs, active calls are preserved.

Within the MGCP gateway configuration file, the primary Unified CM is identified using the **call-agent <hostname>** command, and a list of secondary Unified CM is added using the **ccm-manager redundant-host** command. Keepalives with the primary Unified CM are through the MGCP application-level keepalive mechanism, whereby the MGCP gateway sends an empty MGCP notify (NTFY) message to Unified CM and waits for an acknowledgement. Keepalive with the backup Unified CMs is through the TCP keepalive mechanism.

If the primary Unified CM becomes available at a later time, the MGCP gateway can “re-home,” or switch back to the original Unified CM. This re-homing can occur either immediately, after a configurable amount of time, or only when all connected sessions have been released. This is enabled through the following global configuration commands:

```
ccm-manager redundant-host <hostname1 | ipaddress1 > <hostname2 | ipaddress2>
[no] call-manager redundancy switchback [immediate|graceful|delay <delay_time>]
```

SIP Gateway

Redundancy with Cisco IOS SIP gateways can be achieved similarly to H.323. If the SIP gateway cannot establish a connection to the primary Unified CM, it tries a second Unified CM defined under another dial-peer statement with a higher preference.

By default the Cisco IOS SIP gateway transmits the SIP INVITE request 6 times to the Unified CM IP address configured under the dial-peer. If the SIP gateway does not receive a response from that Unified CM, it will try to contact the Unified CM configured under the other dial-peer with a higher preference.

Cisco IOS SIP gateways wait for the SIP 100 response to an INVITE for a period of 500 ms. By default, it can take up to 3 seconds for the Cisco IOS SIP gateway to reach the backup Unified CM. You can change the SIP INVITE retry attempts under the **sip-ua** configuration by using the command **retry invite <number>**. You can also change the period that the Cisco IOS SIP gateway waits for a SIP 100 response to a SIP INVITE request by using the command **timers trying <time>** under the **sip-ua** configuration.

One other way to speed up the failover to the backup Unified CM is to configure the command **monitor probe icmp-ping** under the **dial-peer** statement. If Unified CM does not respond to an Internet Control Message Protocol (ICMP) echo message (ping), the dial-peer will be shut down. This command is useful only when the Unified CM is not reachable. ICMP echo messages are sent every 10 seconds.

The following commands enable you to configure Unified CM redundancy on a Cisco IOS SIP gateway:

```
sip-ua
  retry invite <number>
  timers trying <time>

dial-peer voice 101 voip
  destination-pattern 2...
  session target ipv4:10.1.1.101
  preference 0
  monitor probe icmp-ping
  session protocol sipv2

dial-peer voice 102 voip
  destination-pattern 2...
  session target ipv4:10.1.1.102
  preference 1
  monitor probe icmp-ping
  session protocol sipv2
```

Site-Specific Gateway Requirements

Each IP Telephony implementation has its own site-specific requirements. The following questions can help you with IP Telephony gateway selection:

- Is the PSTN (or PBX) access analog or digital?
- What type of analog (FXO, FXS, E&M, DID, CAMA) or digital (T1, E1, CAS, CCS) interface is required for the PSTN or PBX?
- If the PSTN access is digital, what type of signaling is required (T1 CAS, Q.931 PRI, E1 CAS, or R2)?

- What type of signaling does the PBX currently use?
 - FXO or FXS: loop start or ground start
 - E&M: wink-start, delay-start, or immediate-start
 - E&M: type I, II, III, IV, or V
 - T1: CAS, Q.931 PRI (User-Side or Network-Side), QSIG, DPNSS, or Proprietary d-channel (CCS) signaling
 - E1: CAS, R2, Q.931 PRI (User-Side or Network-Side), QSIG, DPNSS, Proprietary d-channel (CCS) signaling
- What type of framing (SF, ESF, or G.704) and line encoding (B8ZS, AMI, CRC-4, or HDB3) does the PBX currently use?
- Does the PBX require passing proprietary signaling? If so, which time slot is the signaling passed on, and is it HDLC-framed?
- What is the required capacity of the gateway; that is, how many channels are required? (Typically, if 12 or more voice channels are required, then digital is more cost effective than an analog solution.)
- Is Direct Inward Dialing (DID) required? If so, specify analog or digital.
- Is Calling Line ID (CLID) needed?
- Is Calling Name needed?
- What types of fax and modem support are required?
- What types of voice compression are required?
- What types of supplementary services are required?
- Will the PBX provide clocking, or will it expect the Cisco gateway to provide clocking?
- Is rack space available for all needed gateways, routers, and switches?

**Note**

Direct Inward Dial (DID) refers to a private branch exchange (PBX) or Centrex feature that permits external calls to be placed directly to a station line without use of an operator.

**Note**

Calling Line Identification (CLI, CLID, or ANI) refers to a service available on digital phone networks to display the calling number to the called party. The central office equipment identifies the phone number of the caller, enabling information about the caller to be sent along with the call itself. CLID is synonymous with Automatic Number Identification (ANI).

Cisco Unified Communications gateways are able to inter-operate with most major PBX vendors, and they are EIA/TIA-464B compliant.

The site-specific and core gateway requirements are a good start to help narrow the possible choices. Once you have defined the required features, you can make a gateway selection for each of the pertinent configurations, whether they are single-site enterprise deployments of various sizes and complexities or multisite enterprise deployments.

The following tables summarize the features and interface types supported by the various Cisco gateway models.

**Note**

In the following tables, the Cisco IOS and Unified CM release numbers refer to the minimum release that can support the listed feature on a particular gateway platform. For more information about Cisco IOS features, refer to the Cisco Feature Navigator located at <http://tools.cisco.com/ITDIT/CFN/jsp/index.jsp>.

Fax and Modem Support

This section describes the fax and modem support available with Unified CM and Cisco voice gateways. This section first presents brief overviews of fax and modem support on Cisco voice gateways, followed by a listing of supported platforms and example configuration files.

Gateway Support for Fax Passthrough and Fax Relay

Fax over IP enables interoperability of traditional analog fax machines with IP Telephony networks. The fax image is converted from an analog signal and is carried digitally over the packet network.

In its original form, fax data is digital and is contained in High-Level Data Link Control (HDLC) frames. However, to transmit across a traditional PSTN, these digital HDLC frames are modulated onto an analog carrier. While this analog carrier is necessary for effective faxing in PSTN environments, it is not ideal for the type of digital transport used by IP packet networks. Therefore, specific transport methods have been devised for successful transport of fax transmissions over an IP infrastructure.

The two main methods for transporting fax over IP are passthrough and relay. Passthrough is the simplest method, and it works by sampling and digitizing the analog fax signal just like a voice codec does for human speech. While there are a number of codecs available, passthrough on Cisco voice gateways always uses the G.711 codec for carrying fax information because it offers the least distortion of the analog fax signals. If a high-compression codec is being used by the original voice call, then passthrough uses an upspeed feature to change the codec to G.711. Passthrough is also commonly referred to as Voice Band Data (VBD), and Cisco provides two versions of passthrough: modem passthrough and fax pass-through. The names of these two passthrough versions are derived from how they are configured in the Cisco IOS command line interface (CLI). Additional differences between these passthrough versions center around their switchovers and triggering tones, and these are discussed in more detail in the following paragraphs.

Modem passthrough typically uses Cisco proprietary Named Signaling Event (NSE) packets to switch the call from voice mode to passthrough mode in what is commonly termed an NSE-based switchover. This switchover from voice mode to passthrough is an important concept for fax pass-through and relay as well. Every call on a Cisco voice gateway starts as a voice call, and the proper switchover occurs only when the gateway determines that the call is truly a fax call.

The modem passthrough feature is triggered by a 2100 Hz CED or ANSam tone at the beginning of a fax or modem call. The CED tone is associated with G3 faxes and low-speed modems, while the ANSam tone is used by SG3 faxes and high-speed modems. Historically, when the ANSam or CED tone was detected, modem passthrough used Cisco proprietary NSE packets to signal the remote voice gateway of the switchover from voice mode to modem passthrough. Now, however, in addition to an NSE-based switchover, modem passthrough also supports a protocol-based switchover using the H.323 or SIP call control protocols. When modem passthrough is configured to handle the switchover using H.323 or SIP, it also will use a standards-based NTE message to optionally signal the remote voice gateway to disable its echo cancellers. These enhancements to modem passthrough allow for increased interoperability with third-party devices and are found in Cisco IOS Release 12.4(24)T and higher.

Despite its name, modem passthrough is also widely used for fax calls. You can activate it in the Cisco IOS command line interface (CLI) by using the **modem passthrough** command for H.323, SIP, and SCCP voice gateways or the **mgcp modem passthrough** command for MGCP voice gateways.

Fax pass-through does not support an NSE-based switchover as modem passthrough does. Instead, it always relies on the underlying call control protocol to switch the call from voice mode to fax pass-through. Fax pass-through supports only a protocol-based switchover using the call control protocols of H.323 and SIP. Because fax pass-through utilizes the call control protocol for its switchover, it will typically interoperate with third-party devices.

Fax pass-through is triggered by the detection of V.21 flags associated with G3 fax calls. Therefore, this transport method does not work for modems or SG3 fax calls. The command to enable fax pass-through on H.323 and SIP voice gateways is **fax protocol pass-through**.

Figure 13-3 highlights the two different passthrough implementations employed by Cisco voice gateways for fax calls.

Figure 13-3 Cisco Passthrough Implementations for Fax Calls

Relay is the other main method for transporting fax over IP, and its implementation is a bit more complicated than passthrough. Relay strips off the analog carrier from the fax signal in a process known as *demodulation* to expose the fax HDLC data frames. The pertinent information in these HDLC frames is then removed and efficiently packaged in a fax relay protocol to be transported to the gateway on the other side. When received on the other side, the fax information is pulled from the relay protocol, reconstructed back into fax HDLC frames, and modulated onto an analog carrier for transmission to a fax machine.

Cisco supports two versions of fax relay, T.38 and Cisco fax relay. An ITU standard, T.38 allows Cisco gateways to interoperate with third-party devices that also support the T.38 specification. In most scenarios, T.38 fax relay uses the call control protocol to switch from voice mode to T.38 fax relay mode, and this is referred to as protocol-based or standards-based T.38 fax relay. However, it is also possible to configure T.38 fax relay to switch over using Cisco proprietary NSEs in what is termed NSE-based T.38 fax relay. To ensure third-party interoperability, protocol-based T.38 must be utilized.

Cisco fax relay is a pre-standard implementation, and it is proprietary to Cisco voice gateways. It is also the default fax transport configuration on nearly all Cisco voice gateways. Unlike the NSE or protocol-based methods used by T.38 fax relay and passthrough, Cisco fax relay transitions from voice to relay mode utilizing specific RTP dynamic payload types (PT). Figure 13-4 illustrates the Cisco fax relay methods.

Figure 13-4 Cisco Relay Implementations for Fax Calls

Fax relay mode, and more specifically T.38, is the preferred method to transport fax traffic. However, if T.38 fax relay is not supported, then Cisco fax relay or passthrough can be used as an alternative.

Best Practices

The following recommendations and guidelines can assist you in best implementing fax support on Cisco voice gateways:

- When using QoS, make every effort to minimize the following:
 - Packet loss
 - Delay
 - Delay variation (jitter)

All transmissions of fax over IP are extremely sensitive to packet loss. Even minimal packet loss can cause fax failures. If packet loss is a problem in your network, then you should use the redundancy feature in T.38 fax relay. Also, ensure that constant packet delay on the network does not exceed 1 second and that delay variation (jitter) does not exceed 300 milliseconds for T.38 and Cisco fax relay. When passthrough is used, the jitter should follow VoIP design best practices and not exceed 30 ms. For detailed information about implementing QoS in a Cisco Unified Communications network, refer to the *Enterprise QoS Solution Reference Network Design Guide*, available at

<http://www.cisco.com/go/designzone>

- The following tips can help ensure the integrity of the fax calls:
 - Use call admission control (CAC) to ensure that calls are not admitted if they exceed the specified total bandwidth limit. The following table lists approximate fax call bandwidth usage for the common fax transport methods.

| Fax Transport Method | Bandwidth ¹ |
|---|------------------------|
| Modem Passthrough or Fax Pass-through (G.711) | 83 kbps |
| Modem Passthrough with Redundancy | 170 kbps |
| T.38 (no redundancy) | 25 kbps |

| Fax Transport Method | Bandwidth ¹ |
|---|------------------------|
| T.38 (high-speed redundancy level set to 1) | 41 kbps |
| T.38 (high-speed redundancy level set to 2) | 57 kbps |
| Cisco Fax Relay | 48 kbps |

1. Bandwidth values are approximate with Ethernet or Frame Relay L2 headers. T.38 and Cisco fax relay bandwidth values are peak and occur only during the sending of a fax page at 14.4 kbps.

- Disable call waiting on all dedicated modem and fax ports.
- T.38 fax relay provides the best fax performance based on network considerations and is the recommended transport method for fax traffic.

To insure interoperability with other vendor's T.38 products, use protocol-based T.38.

NSE-based T.38 must be used for communicating with certain Cisco voice gateways, such as the Cisco VG248 and any Cisco IOS SCCP gateways. For older versions of Unified CM with limited support for protocol-based T.38, NSE-based T.38 fax relay is a valid alternative.

In Unified CM scenarios where T.38 is to be deployed among gateways running a variety of call signaling protocols, protocol-based T.38 should be the first choice. The latest release of Cisco Unified CM supports protocol-based T.38 with H.323, SIP, and MGCP call control protocols. If protocol-based T.38 is not supported in your installed version of Cisco Unified CM or if SCCP gateways are involved, then NSE-based T.38 should be used. To verify if your version of Unified CM supports protocol-based T.38, refer to the Cisco Unified Communications Manager release notes available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_release_notes_list.html

- T.38 fax relay is supported on most of the current Cisco voice gateways, especially those running Cisco IOS. For details, refer to the product data sheets for your specific gateway models.
- Error Correction Mode (ECM) is a negotiated feature on fax calls, and it ensures that fax pages are received error-free. However, in its effort to retransmit any errors, ECM can lead to increased fax transmission times and call failures. If desired, you can disable ECM on the gateway itself rather than disabling it on multiple fax machines. However, if packet drops or other IP or PSTN impairments occur, the fax image quality might deteriorate. Therefore, you should disable ECM only after considering whether you want to risk compromising image quality rather than experiencing longer call durations or dropped calls. You should also monitor and evaluate the network to identify and resolve the impairments that are causing the fax page errors.

Super Group 3 Fax Support

Commonly referred to as "high-speed" fax or V.34 fax, the Super Group 3 (SG3) classification uses V.34 modulation to increase the maximum fax page transmission speed to 33.6 kbps. SG3 fax machines are backward compatible with standard G3 fax machines that support a maximum page transmission speed of 14.4 kbps.

Cisco IOS gateways with Cisco IOS Release 12.4.4T and later offer support for Super Group 3 (SG3) fax transmissions when T.38 or Cisco fax relay are configured; however, only Group 3 speeds are negotiated. For more information on this feature, refer to *Cisco IOS Fax, Modem, and Text Support over IP Configuration Guide, Cisco IOS Release 15.1M&T*, available at

http://www.cisco.com/en/US/docs/ios/voice/fax/configuration/guide/15_1/vf_15_1_book.html

If it is necessary to transport SG3 high-speed faxes at their native speeds, then modem passthrough must be used. With the release of Cisco IOS version 15.1.1T, a new feature will provide native support for SG3 faxes by T.38 fax relay.

Gateway Support for Modem Passthrough and Modem Relay

In general, there are three mechanisms for supporting modem sessions over an IP network using voice gateways:

- Modem passthrough
- Cisco Modem Relay
- Secure Modem Relay (Secure Communication Between STE Endpoints)

Each of these mechanisms can transport modem calls, but the relay methods are restrictive in that only certain modem modulations are supported. Modem passthrough, on the other hand, can usually handle any modulation.

An important concept to understand when dealing with the transport of modem signals across IP networks is the switchover that must occur on the gateway. Every call on a Cisco gateway begins as a voice call initially. Even if the call is between modems, the call will be set up as a voice call first. Then, once the gateway is sure that the call is truly a modem call, a switchover occurs that converts the gateway from voice call mode to a modem passthrough or modem relay mode. There are various switchover methods to transition a call from voice mode to modem passthrough or relay.

As discussed previously in the section on [Gateway Support for Fax Passthrough and Fax Relay, page 13-19](#), modem passthrough uses proprietary NSE packets or the H.323/SIP protocol stack to switch a voice call into passthrough mode. When modem signals are detected, the gateways can use these NSE messages to inform each other of the impending modem call. Special messages within the H.323 or SIP call control protocols can also be used. The gateways then make adjustments to better handle the transport of the modem signals. These adjustments include up-speeding the voice codec to G.711, disabling Voice Activity Detection (VAD), and disabling the echo cancellers if necessary. Because modem passthrough simply samples the analog modem signal using the G.711 codec, it should handle any modem modulation, but not always at the highest speeds.

Cisco Modem Relay is a proprietary implementation that efficiently transports V.34 modem calls over an IP network. V.90 calls are also supported, but they are forced to train down to V.34 speeds. As with modem passthrough, NSE packets are used to handle the switchover to Cisco Modem Relay from voice mode.

Secure modem relay, which is also referred to as Secure Communication Between STE Endpoints, allows for the transport of secure telephone calls over an IP infrastructure. Special devices known as Secure Terminal Equipment (STE) transmit encrypted voice using the V.32 modulation. Secure modem relay is designed to handle the transport of information between STEs in Unified CM environments with SCCP and MGCP gateways. Secure modem relay is not compatible with Cisco Modem Relay. One of the main reasons is that the switchover for secure modem relay does not use NSEs but instead uses V.150.1-based State Signaling Event (SSE) messages.

Secure modem relay is designed specifically for transporting STE signals and is almost never used outside of government or defense-related deployments. In most cases, Cisco Modem Relay or modem passthrough should be used for transporting modem calls. For more information on secure modem relay, refer to *Secure Communication Between IP-STE Endpoint and Line-Side STE Endpoint*, available at

http://www.cisco.com/en/US/docs/ios/12_4t/12_4t4/htv1501.html

Figure 13-5 summarizes the Cisco modem transport implementations. Modem relay should be used whenever possible because it offers the most bandwidth efficiency and tolerance for network impairments when compared to modem passthrough. The disadvantage of modem relay is that it is quite restrictive on the modulations supported, while modem passthrough can handle any modem modulation.

Figure 13-5 Cisco Passthrough and Relay Implementations for Modem Calls

Best Practices

Observe the following recommended best practices to ensure optimum performance of modem traffic transported over an IP infrastructure:

- Ensure that the IP network is enable for Quality of Service (QoS) and that you adhere to all of the recommendations for providing QoS in the LAN, MAN, and WAN environments. Every effort should be made to minimize the following parameters:
 - Packet loss — Fax and modem traffic requires an essentially loss-free transport. A single lost packet can result in retransmissions.
 - Delay
 - Delay variation (jitter)

For more information, refer to the *Enterprise QoS Solution Reference Network Design Guide*, available at

<http://www.cisco.com/go/designzone>

- Use call admission control (CAC) to ensure that calls are not admitted if they exceed the specified total bandwidth limit. For planning purposes, assume that modem passthrough calls will always consume approximately 83 kbps of bandwidth, or 170 kbps with redundancy enabled, regardless of the modem modulation being transported. Modem relay bandwidth is sporadic because of the nature of modem communications, but plan for peaks of about 45 kbps for the maximum V.34 connection speed of 33.6 kbps. The bandwidth values cited here are approximations and assume Ethernet or frame relay as the L2 transport.
- Use modem relay whenever possible. Modem passthrough should be used for any modulations not supported by modem relay.

- Do not use the IP network to connect modems that will be used to troubleshoot or diagnose problems with the IP network. In this case, the modems used to troubleshoot the devices that compose the IP infrastructure should be connected to a plain old telephone service (POTS).
- Because of the NSE switchover utilized by Cisco modem relay and modem passthrough, gateways using different call control protocols can easily communicate with one another. For example, an MGCP gateway and an H.323 gateway connected to Unified CM can successfully negotiate Cisco modem relay or modem passthrough because the NSE switchover occurs within the RTP voice media stream that has already been set up by Unified CM.
- Disable call waiting on all dedicated modem and fax ports.

V.90 Support

Currently, Cisco equipment supports only V.34 modems. Although V.90 modems will function on existing hardware, and speeds higher than V.34 speeds can be achieved, full V.90 support cannot be guaranteed.

Supported Platforms and Features

The following Cisco platforms support fax and modem features:

- Cisco IOS Gateways support:
 - Modem passthrough
 - Fax passthrough for the H.323 and SIP protocols
 - T.38 fax relay. Both NSE and protocol-based switchovers for T.38 are supported, except in the case of SCCP where only NSE-based T.38 fax relay is supported.
 - Cisco fax relay. The Cisco AS5350, AS5400, and AS5850 using Nextport DSP cards do not support Cisco fax relay. The PVDM3 DSP modules also do not support Cisco fax relay.
 - Cisco modem relay
- Cisco non-IOS gateways:
 - The Cisco VG248 supports modem passthrough, NSE-based T.38 fax relay, and Cisco fax relay.
 - The Cisco 6608 and 6624 support only modem passthrough and Cisco fax relay.
 - The Cisco ATAs support modem passthrough for fax calls only. Using modem passthrough with an ATA for modem calls is not officially supported.

**Note**

The fax and modem support information presented here is valid beginning with Cisco IOS Release 12.4(9)T for the Cisco IOS gateways and Release 1.3.1 of the Cisco VG248 Analog Phone Gateway.

Platform Protocol Support

Common call control protocols used today in enterprise solutions include H.323, Session Initiation Protocol (SIP), Media Gateway Control Protocol (MGCP), and Skinny Client Control Protocol (SCCP). Not all Cisco voice platforms support all of these protocols or all of the fax and modem features, thus raising interoperability issues. Additional interoperability issues occur when mixing Cisco IOS

gateways such as the Cisco 2800 Series or the Cisco 3800 Series with non-IOS gateways such as the VG248. This section lists the combinations of gateways that provide support for interoperability of fax, modem, and protocol features.

Some of the common combinations of protocols in a network include: MGCP and H.323; SCCP and H.323; SCCP and SIP; MGCP and SIP; H.323 and SIP; and SCCP and MGCP.

Table 13-3 lists the protocol combinations that currently support fax and modem interoperability.

Table 13-3 Fax and Modem Features Supported with Various Combinations of Call Control Protocols

| Protocol Combinations | Modem Relay | Modem Passthrough ¹ | T.38 Fax Relay | Cisco Fax Relay | Fax Passthrough |
|---|-------------|--------------------------------|------------------|-----------------|-----------------|
| Unified CM using MGCP combined with Unified CM using H.323 or SIP | Yes | Yes | Yes ² | Yes | No |
| Unified CM using MGCP combined with Unified CM using MGCP | Yes | Yes | Yes ² | Yes | No |
| SCCP combined with Unified CM using H.323 or SIP | Yes | Yes | Yes ³ | Yes | No |
| SCCP combined with Unified CM using MGCP | Yes | Yes | Yes ³ | Yes | No |
| Unified CM using H.323 combined with H.323 or SIP | Yes | Yes | Yes ² | Yes | Yes |
| Unified CM using SIP combined with H.323 or SIP | Yes | Yes | Yes ² | Yes | Yes |

1. Modem passthrough works for both modem and fax passthrough calls.
2. NSE-based T.38 fax relay works, but protocol-based T.38 fax relay depends on the version of Unified CM. For version information, refer to the Cisco Unified Communications Manager release notes available at http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_release_notes_list.html.
3. SCCP protocol works only with NSE-based T.38 fax relay.

Note

Table 13-3 is a general reference. You should be aware that specific products might have limitations that are not listed in this table. For example, the Cisco ATA supports H.323, SIP, and SCCP call control protocols, but only modem passthrough is supported no matter which call control protocol is used.

Gateway Configuration Examples

For detailed configuration information about fax and modem support on Cisco gateways, refer to the *Cisco IOS Fax, Modem, and Text Support over IP Configuration Guide*, which is available at

http://www.cisco.com/en/US/docs/ios/voice/fax/configuration/guide/12_4t/vf_12_4t_book.html

Gateways for Video Telephony

Video gateways terminate video calls into an IP telephony network or the PSTN. Video gateways are different from voice gateways because they have to interact with the ISDN trunks that support video and convert that call to a video call on the IP network using protocols such as H.323 or SIP. Enterprises can consider separate gateways for voice calls and video calls, or they can have integrated gateways that route both voice and video calls.

The following key considerations can help you decide if you need separate gateways for voice and video or an integrated gateway:

- **Dial plan** — If the enterprise has the flexibility of a separate dial plan for video users, it can use separate video gateways that allow it to keep existing enterprise dial plans.
- **Video users** — If the enterprise has a large number of users who primarily use voice rather than video, then Cisco recommends using separate video gateways to service the video call users.
- **Locations** — If the enterprise has a large number of distributed locations with video users at many locations, then Cisco recommends using an integrated gateway to reduce total cost of ownership (TCO).
- **Additional video capabilities** such as video IVR, auto attendant, and bonding across trunks — Dedicated video gateways might support advanced features that integrated gateways do not support.
- **Protocol** — Gateway protocol can be an important factor to align with enterprise policies and standards.
- **Capacity** — Dedicated gateways might support lower simultaneous call volumes, while integrated gateways should have higher capacity because they can support voice calls in addition to video.
- **Device management** — Ease of maintenance, management, and troubleshooting can be an important factor. Dedicated gateways provide a better user interface (GUI) for management and configuration, while integrated gateways can provide better troubleshooting. However, these factors are dependent on the respective products.

Dedicated Video Gateways

Enterprises that have an extensive voice infrastructure with voice gateways can add video gateways so that users can make video calls through them to the PSTN. The Cisco Unified Videoconferencing 3500 and 5200 Series Video Gateways can be used for that purpose.

[Figure 13-6](#) shows an enterprise deployment that can use existing protocols for its voice gateways and add video gateways so that Unified CM users can make voice and video calls to the PSTN.

Figure 13-6 Unified CM System with Separate PSTN Lines for Voice and IP Video Telephony

The Unified Videoconferencing gateways, while excellent for video calls, do not support all of the features that Cisco Voice Gateways offer. The Unified Videoconferencing gateways have the following characteristics:

- They support only H.323 and H.320.
- They are standalone devices that cannot be integrated into Cisco IOS Routers or Cisco Catalyst Switches.
- They support only T1/E1-PRI and ISDN BRI.
- They support H.261, H.263, and H.264 video codecs
- They support only G.711, G.722, G.722.1, G.723.1 and G.728; they do not support G.729 audio.
- They support the H.245 Empty Capabilities Set (ECS).
- They support T.120 and H.239 data sharing protocol
- They support H.235 encryption
- They do not support many of the manageability and troubleshooting capabilities inherent in Cisco Voice Gateways.

As a result of these differences in the products, Cisco Unified Videoconferencing 3500 Series gateways are not recommended as replacements for Cisco Voice Gateways. IP Telephony customers who want to add video to their communications environment should deploy both types of gateways and use the Cisco Voice Gateways for all voice calls and use the Cisco Unified Videoconferencing 3500 Series gateways for video calls only. Customers might also have to procure separate circuits for voice and video from their PSTN service provider, depending on which model of Cisco IOS Gateway is deployed.

With separate voice and video gateways (see [Figure 13-6](#)), the route plans must also be separate for both inbound and outbound calls. For inbound calls, there is no way to have a single Direct Inward Dial (DID) extension for a user who wants to be able to receive both voice and video calls. Typically, each user will already have a DID for voice calls. When you introduce video into the scenario, users will have to be dialed some other way, such as via a second DID number or by dialing the main number of the video gateway and then entering the users video extension when prompted by the Interactive Voice Response (IVR). For outbound calls, there is no way to have a single PSTN access code for both voice and video calls. Typically, users will already have a well-known access code for voice (such as 9 in most US enterprises), but when you introduce video into the scenario, they will have to dial some other access code to place outbound video calls.

Another consideration for deploying two types of gateways is the placement of those gateways. Typically, enterprises have many PSTN gateway resources consolidated at their central site(s), and each branch office has some local gateway resources as well. For instance, Cisco Catalyst 6500 gateways may be deployed at the central site with several T1/E1 circuits connected to them, while Cisco Integrated Services Routers (ISRs) may be deployed at each branch office with either analog or digital trunks to the local CO. When video is introduced into this scenario, the customer must also determine the number of PSTN circuits they will need for video and where the video gateways will be placed. For instance, will they deploy only a few Cisco Unified Videoconferencing video gateways at the central site, or will they also deploy them at each branch office?

Finally, consider how calls will be routed across the IP network to a remote gateway for the purpose of providing toll bypass, and how calls will be re-routed over the PSTN in the event that the IP network is unavailable or does not have enough bandwidth to complete the call. More specifically, do you want to invoke automated alternate routing (AAR) for video calls?

Integrated Video Gateways

Enterprises may consider an integrated device for voice and video gateway functionality. This provides the enterprise the advantages of managing fewer devices and keeping the dial plan simple. The gateway processes the call as a voice call if it is voice and as a video call if it is video.

The Cisco IOS Integrated Video Gateway has the following characteristics:

- Supports Cisco ISO-13871 bonding
- Provides H.320, H.323, and SIP support
- Supports existing voice codec and H.264 video codec
- Provides extensive called and calling transformation capabilities
- Provides extensive logging and troubleshooting capabilities

The following considerations apply for deploying Cisco IOS Integrated Video gateways:

- Consider the capacity needed on PSTN links for additional video calls.
- Consider the need of devices to use data applications such as T.120 and the additional bandwidth that will be used on the IP network.
- Consider if users need features such far-end camera control or DTMF that is used for conferences that the H.320 gateway needs to support.

Routing Inbound Calls from the PSTN

Use one of the following methods to route inbound calls from the PSTN:

- Assign at least two different directory numbers to each video-enabled device in the Unified CM cluster, with one line for audio and another line for video. With this method, the outside (PSTN) caller must dial the correct number to enable video.
- For video calls, have outside callers dial the main number of the video gateway. Cisco Unified Videoconferencing gateways offer an integrated IVR that prompts the caller to enter the extension number of the party they are trying to reach. Unified CM will then recognize that it is

a video call when ringing the destination device. This method relieves the caller from having to remember two different DID numbers for each called party, but it adds an extra step to dialing an inbound video call.

Note The outside video endpoints must support DTMF in order to enter the extension of the called party at the IVR prompt.

The following example illustrates the second method:

A user has a Cisco Unified IP Phone 7960 attached to a PC running Cisco Unified Video Advantage. The extension of the IP Phone is 51212, and the fully qualified DID number is 1-408-555-1212. To reach the user from the PSTN for a voice-only call, people simply dial the DID number. The CO sends calls to that DID number through T1-PRI circuit(s) connected to a Cisco Voice Gateway. When the call is received by the gateway, Unified CM knows that the gateway is capable of audio only, so it negotiates only a single audio channel for that call. Conversely, for people to reach the user from the PSTN for a video call, they must dial the main number of the video gateway and then enter the user's extension. For example, they might dial 1-408-555-1000. The CO would send calls to that number through the T1-PRI circuit(s) connected to a Cisco Unified Videoconferencing 3500 Series video gateway. When the call is received by the gateway, an IVR prompt asks the caller to enter the extension of the person they are trying to reach. When the caller enters the extension via DTMF tones, Unified CM knows that the gateway is capable of video, so it negotiates both audio and video channels for that call.

Gateway Digit Manipulation

The Cisco Unified Videoconferencing 3500 Series Gateways cannot manipulate digits for calls received from the PSTN. It takes the exact number of digits passed to it in the Q.931 Called Party Number field and sends them all to Unified CM. Therefore, Unified CM must manipulate the digits in order to match the directory number (DN) of the destination device. For instance, if the circuit from the CO switch to the gateway is configured to pass 10 digits but the extension of the called party is only five digits, Unified CM must strip off the leading five digits before attempting to find a matching DN. You can implement this digit manipulation in one of the following ways:

- By configuring the Significant Digits field on the H.323 gateway device or on the H.225 gatekeeper-controlled trunk that carries the incoming calls from the Cisco Unified Videoconferencing gateway

This method enables you to instruct Unified CM to pay attention to only the least-significant N digits of the called number. For example, setting the Significant Digits to 5 will cause Unified CM to ignore all but the last 5 digits of the called number. This is the easiest approach, but it affects all calls received from that gateway. Thus, if you have variable-length extension numbers, this is not the recommended approach.

- By configuring a translation pattern and placing it in the calling search space of the H.323 gateway device or of the H.225 gatekeeper-controlled trunk that carries the incoming calls from the Cisco Unified Videoconferencing gateway

This method enables Unified CM to match calls to the full number of digits received, to modify the called number, and then to continue performing digit analysis on the resulting modified number. This approach is slightly more complex than the preceding method, but it is more flexible and enables you to use a finer granularity for matching calls and for specifying how they will be modified.

Routing Outbound Calls to the PSTN

Use one of the following methods to route outbound calls to the PSTN:

- Assign different access codes (that is, different route patterns) for voice and video calls. For example, when the user dials 9 followed by the PSTN telephone number they are trying to reach, it could match a route pattern that directs the call out a voice gateway. Similarly, the digit 8 could be used for the route pattern that directs calls out a video gateway.
- Assign at least two different directory numbers on each video-enabled device in the Unified CM cluster, with one line for audio and another line for video. The two lines can then be given different calling search spaces. When users dial the access code (9, for example) on the first line, it could be directed out a voice gateway, while dialing the same access code on the second line could direct the call out a video gateway. This method alleviates the need for users to remember two different access codes but requires them to press the correct line on their phones when placing calls.

Gateway Service Prefixes

The Cisco Unified Videoconferencing Gateways use service prefixes to define the speed for outbound calls. When you configure a service prefix in the gateway, you must choose one of the following speeds:

- Voice-only
- 128 kbps
- 256 kbps
- 384 kbps
- 768 kbps
- Auto (dynamically determined; supports any call speed in the range of 128 kbps to 768 kbps)

Note

Each of the above speeds represents a multiple of 64 kbps. For 56-kbps dialing, there is a check-box on the service prefix configuration page to restrict each channel to 56 kbps. Therefore, a 128-kbps service with restricted mode enabled would result in a 112-kbps service; a 384 kbps service with restricted mode enabled would result in a 336-kbps service; and so on.

Calls from an IP endpoint toward the PSTN must include the service prefix at the beginning of the called number in order for the gateway to decide which service to use for the call. Optionally, you can configure the default prefix to be used for calls that do not include a service prefix at the beginning of the number. This method can become quite complex because users will have to remember which prefix to dial for the speed of the call they wish to make, and you would have to configure multiple route patterns in Unified CM (one for each speed). Fortunately, the Auto speed enables you to minimize this effort. If the majority of your calls are made using 64 kbps per channel (for example, 128 kbps, 384 kbps, 512 kbps, 768 kbps, and so on), you could use the Auto service in that case. You would then need to create only one other service for the rare case in which someone makes a call using 56 kbps per channel (for example, 112 kbps, 336 kbps, and so on).

Cisco recommends that you always use a # character in your service prefixes because the gateway recognizes the # as an end-of-dialing character. By placing this character in the service prefix, you block people from attempting to use the gateway for toll fraud by dialing the main number of the gateway, reaching the IVR, and then dialing out to an off-net number. The # can either be at the beginning (recommended) or the end of the service prefix. For example, if your access code to reach the PSTN is 8 for video calls, Cisco recommends that you configure the service prefix as #8 or 8#. Or, if you have two service prefixes as described above, you might use #80 for the Auto 64-kbps service and #81 for the Auto 56-kbps service.

The ramification of using a service prefix is that Unified CM must prepend the service prefix to the called number when sending calls to the Cisco Unified Videoconferencing gateway. Because forcing users to dial the # would not be very user-friendly, Cisco recommends that you configure Unified CM to prepend the # to the dialed number. For example, if the access code to dial a video call to the PSTN is 8, you could configure a route pattern as 8.@ in Unified CM, and in the route pattern configuration you would configure the called number translation rule to prepend #8 whenever that route pattern is dialed. Or, if you have two service prefixes as described above, you might use 80.@ for the Auto 64-kbps service (prefixing # to the called number) and 81.@ for the Auto 56-kbps service (prefixing # to the called number).

Automated Alternate Routing (AAR)

When the IP network does not have enough bandwidth available to process a call, Unified CM uses its call admission control mechanism to determine what to do with the call. As described in the chapter on [IP Video Telephony, page 12-1](#), Unified CM performs one of the following actions with the call, depending on how you have configured it:

- Fail the call, playing busy tone to the caller and displaying a Bandwidth Unavailable message on the caller's screen
- Retry the video call as an audio-only call
- Use automated alternate routing (AAR) to re-route the call over an alternative path, such as a PSTN gateway

The first two options are covered in the chapter on [IP Video Telephony, page 12-1](#), and this section covers the AAR option.

To provide AAR for voice or video calls, you must configure the calling and called devices as members of an AAR group and configure an External Phone Number Mask for the called device. The External Phone Number Mask designates the fully qualified E.164 address for the user's extension, and the AAR group indicates what digits should be prepended to the External Phone Number Mask of the called device in order for the call to route successfully over the PSTN.

For example, assume that user A is in the San Jose AAR group and user B is in the San Francisco AAR group. User B's extension is 51212, and the External Phone Number Mask is 6505551212. The AAR groups are configured to prepend 91 for calls between the San Jose and San Francisco AAR groups. Thus, if user A dials 51212 and there is not enough bandwidth available to process the call over the IP WAN between those two sites, Unified CM will take user B's External Phone Number Mask of 6505551212, prepend 91 to it, and generate a new call to 916505551212 using the AAR calling search space for user A.

This same logic applies to video calls as well, with one additional step in the process. For video-capable devices, there is a field called Retry Video Call as Audio. As described in the chapter on [IP Video Telephony, page 12-1](#), if this option is enabled (checked), Unified CM does not perform AAR but retries the same call (that is, the call to 51212) as a voice-only call instead. If this option is disabled (unchecked), Unified CM performs AAR. By default, all video-capable devices in Unified CM have the Retry Video Call as Audio option enabled (checked). Therefore, to provide AAR for video calls, you must disable (uncheck) the Retry Video Call as Audio option. Additionally, if a call admission control policy based on Resource Reservation Protocol (RSVP) is being used between locations, the RSVP policy must be set to Mandatory for both the audio and video streams.

Furthermore, Unified CM looks at only the called device to determine whether the Retry Video Call as Audio option is enabled or disabled. So in the scenario above, user B's phone would have to have the Retry Video Call as Audio option disabled in order for the AAR process to take place.

Finally, devices can belong to only one AAR group. Because the AAR groups determine which digits to prepend, AAR groups also influence which gateway will be used for the rerouted call. Depending on your choice of configuration for outbound call routing to the PSTN, as discussed in the previous section, video calls that are rerouted by AAR might go out a voice gateway instead of a video gateway. Therefore, carefully construct the AAR groups and the AAR calling search spaces to ensure that the correct digits are prepended and that the correct calling search space is used for AAR calls.

While these considerations can make AAR quite complex to configure in a large enterprise environment, AAR is easier to implement when the endpoints are strictly of one type or the other (such as IP Phones for audio-only calls and systems such as the Tandberg T-1000 dedicated for video calls). When endpoints are capable of both audio and video calls (such as Cisco Unified Video Advantage or a Cisco IP Video Phone 7985G), the configuration of AAR can quickly become unwieldy. Therefore, Cisco recommends that large enterprise customers who have a mixture of voice and video endpoints give careful thought to the importance of AAR for each user, and use AAR only for select video devices such as dedicated videoconference rooms or executive video systems. Table 13-4 lists scenarios when it is appropriate to use AAR with various device types.

Table 13-4 When to Use AAR with a Particular Device Type

| Device Type | Device is used to call: | Enable AAR? | Comments |
|--|---|-------------|--|
| IP Phone | Other IP Phones and video-capable devices | Yes | Even when calling a video-capable device, the source device is capable of audio-only, thus AAR can be configured to route calls out a voice gateway. |
| IP Phone with Cisco Unified Video Advantage, or Cisco IP Video Phone 7985G | Other video-capable devices only | Yes | Because the device is used strictly for video calls, you can configure the AAR groups accordingly. |
| | IP Phones and other video-capable devices | No | It will be difficult to configure the AAR groups to route audio-only calls differently than video calls. |
| Sony or Tandberg SCCP endpoint | Other video-capable devices only | Yes | Because the device is used strictly for video calls, you can configure the AAR groups accordingly. |
| | IP Phones and other video-capable devices | No | It will be difficult to configure the AAR groups to route audio-only calls differently than video calls. |
| H.323 or SIP client | Other video-capable devices only | Yes | Because the device is used strictly for video calls, you can configure the AAR groups accordingly. |
| | IP Phones and other video-capable devices | No | It will be difficult to configure the AAR groups to route audio-only calls differently than video calls |

Least-Cost Routing

Least-cost routing (LCR) and tail-end hop-off (TEHO) are very popular in VoIP networks and can be used successfully for video calls as well. In general, both terms refer to a way of configuring the call routing rules so that calls to a long-distance number are routed over the IP network to the gateway closest

to the destination, in an effort to reduce toll charges. (For Cisco Unified CM Release 4.1, LCR basically means the same thing as TEHO.) Unified CM supports this feature through its rich set of digit analysis and digit manipulation capabilities, including:

- Partitions and calling search spaces
- Translation patterns
- Route patterns and route filters
- Route lists and route groups

Configuring LCR for video calls is somewhat more complicated than for voice calls, for the following reasons:

- Video calls require their own dedicated gateways, as discussed previously in this chapter
- Video calls require much more bandwidth than voice calls

With respect to dedicated gateways, the logic behind why you might or might not decide to use LCR for video calls is very similar to that explained in the section on [Automated Alternate Routing \(AAR\)](#), [page 13-32](#). Due to the need to have different types of gateways for voice and video, it can become quite complex to configure all the necessary partitions, calling search spaces, translation patterns, route patterns, route filters, route lists, and route groups needed for LCR to route voice calls out one gateway and video calls out another.

With respect to bandwidth requirements, the decision to use LCR depends on whether or not you have enough available bandwidth on your IP network to support LCR for video calls to/from a given location. If the current bandwidth is not sufficient, then you have to determine whether the benefits of video calls are worth the cost of either upgrading your IP network to make room for video calls or deploying local gateways and routing calls over the PSTN. For example, suppose you have a central site with a branch office connected to it via a 1.544-Mbps T1 Frame Relay circuit. The branch office has twenty video-enabled users in it. A 1.544-Mbps T1 circuit can handle at most about four 384-kbps video calls. Would it really make sense in this case to route video calls up to the central site in order to save on toll charges? Depending on the number of calls you want to support, you might have to upgrade your 1.544-Mbps T1 circuit to something faster. Is video an important enough application to justify the additional monthly charges for this upgrade? If not, it might make more sense to deploy a Cisco Unified Videoconferencing gateway at the branch office and not bother with LCR. However, placing local Cisco Unified Videoconferencing gateways at each branch office is not inexpensive either, so ultimately you must decide how important video-to-PSTN calls are to your business. If video is not critical, perhaps it is not worth upgrading the bandwidth or buying video gateways but, instead, using the Retry Video Call as Audio feature to reroute video calls as voice-only calls if they exceed the available bandwidth. Once a call is downgraded to voice-only, local gateway resources and bandwidth to perform LCR become more affordable and easier to configure.

ISDN B-Channel Binding, Rollover, and Busy Out

With Cisco IOS Release 12.4.20T or later releases, Cisco IOS H.320 gateways support the ISO-13871 bonding technique, which supports video calls at speeds up to 1 Mbps for video calls. With this functionality the Cisco IOS router can be used as an integrated gateways for both voice and video calls.

H.320 video uses multiple ISDN channels bound together to achieve the speeds needed to pass full-motion video. One of the problems with this bonding mechanism is that, when an inbound ISDN video call is received, the gateway does not know how many channels will be requested for that call until after it accepts the call and the source device indicates how many additional channels are required. If there are not enough B-Channels to satisfy the request, the call is disconnected. Therefore, careful traffic engineering is required to minimize the possibility that this situation will occur. Essentially, you want to ensure that there are always enough B-Channels available to handle the next call that might come in.

This B-Channel issue occurs in two cases:

- Inbound calls from the PSTN to the IP network
- Outbound calls from the IP network to the PSTN

Inbound Calls

For inbound calls, consider the following scenario:

A company has a Cisco Unified Videoconferencing 3527 Gateway with an ISDN PRI circuit connecting it to a central office (CO) switch. The ISDN PRI circuit in this case offers 23 B-Channels. A video call is received from the PSTN at 384 kbps. This call takes six B-Channels, leaving 17 available. A second and third 384-kbps call are received on the line while the first one is still active. These each take an additional six channels, leaving five channels available. When the fourth 384-kbps call is received, the gateway will answer the call but, recognizing that it does not have enough B-Channels available (it only has five left but the call requires six), it will disconnect (by sending a Q.931 RELEASE COMPLETE with "16: Normal Call Clearing" as the reason). The caller attempting to make the fourth call will not know why the call failed and might redial the number repeatedly, trying to make the call work.

On Cisco Unified Videoconferencing gateways, you can minimize your chances of running into this issue by configuring the gateway to send a request to the CO to busy-out the remaining B-Channels (in this example, five channels) whenever the gateway reaches a certain threshold of utilization (configured as a percentage of total bandwidth).

In addition, you can have the CO provision multiple ISDN circuits in a trunk group. When the first circuit reaches the busy-out threshold, calls will roll over to the next PRI in the group. The Cisco Unified Videoconferencing 3500 Series Gateway offers two ISDN PRI connections and supports bonding channels across both ports. For example, port 1 might have only five channels available while port 2 is sitting idle and, therefore, has 23 channels available. By taking the five channels from port 1 and one channel from port 2 and bonding them together, the fourth 384-kbps call can succeed. This leaves 22 channels available on controller 2, and at some point additional inbound calls would reach the busy-out threshold again. At that point the remaining channels on port 2 will be busied out, and all further inbound calls will be rejected with cause code "Network Congestion." Cisco Unified Videoconferencing gateways cannot bond channels across different gateways or across different Cisco 3500 Series gateway models in the same Cisco 3545 chassis, so two ports is the maximum that you can bond together. The CO switch can still roll calls over to a third or fourth PRI in the trunk group (most COs support trunk groups of up to 6 circuits), but you cannot bond channels between PRI number one and PRI number three, for example, as you can between PRI number one and PRI number two.

The busy-out logic described above depends on the assumption that all calls take place at the same speed. Suppose, for example, that two 384-kbps calls are active on a port and a 128-kbps call came in. This call would take only two channels, using a total of 14 channels for the three calls ($6+6+2 = 14$) and leaving nine channels available on the circuit. However, if the busy-out threshold is set at 18 channels (assuming that all calls would take place at 384-kbps), only four channels are still available under this busy-out threshold. If another 384 kbps call comes in at this point, the call will fail because the remaining four channels are not enough to support the call. Also, because the busy-out threshold of 18 channels has not been reached yet (only 14 channels are used), the circuit is not busied out and calls will not roll over to the next circuit. This condition will persist until one of the existing calls is disconnected. To avoid such situations, it is important to try to standardize on a single call speed for all calls.

Outbound Calls

Outbound calls encounter the same potential situations as inbound calls, but the way in which the busy-out occurs is different. The Cisco Unified Videoconferencing 3500 Series Gateways support messages called Resource Availability Indicator and Resource Availability Confirm (RAI/RAC). The RAI/RAC messages are defined under the H.225 RAS specification and are used by the gateways to tell the gatekeeper that they are full and to no longer route any more calls to them. When the gateway reaches the busy-out threshold, it sends an RAI message with a status of True to the gatekeeper. True means "Do not send me any more calls;" False means "I am available." The gateway sends an RAI=False as soon as it is no longer at its busy-out threshold. The busy-out threshold for outbound calls is separate from the busy-out threshold for inbound calls, and you can configure them differently so that inbound calls will roll over to the next available circuit but outbound calls will still be accepted, or vice versa. For example, you could configure the RAI threshold to 12 channels but the ISDN busy-out threshold to 18 channels. When two 384 kbps are active, outbound calls will roll over to the next available gateway, but a third 384-kbps inbound call could still be received. An equally efficient method of achieving outbound call busy-out failover is to use Unified CM's route group and route list construct, as described in the following section, instead of the RAI/RAC method.

Configuring the Gateways in Unified CM

You can configure a Unified Videoconferencing gateway in either of the following ways in Unified CM:

- Configure it as an H.323 gateway, and Unified CM will route calls directly to the gateway.
- Configure an H.225 gatekeeper-controlled trunk to the gatekeeper, and route calls to the gateway through the gatekeeper.

If you have only one gateway, it is probably easier to configure it directly in Unified CM instead of going through a trunk to get to it. If you have multiple gateways for load balancing and redundancy, you can either configure them all in Unified CM and place them into a route group(s) and route list, or configure an H.225 trunk to the gatekeeper and rely on RAI/RAC between the gateways and the gatekeeper to tell Unified CM which gateway it should send a given call to.

For inbound calls from the PSTN to Unified CM, the Cisco Unified Videoconferencing gateways can either register with a gatekeeper or be configured with the IP addresses of up to three Unified CM servers to which they should send all inbound call requests. This method is known as peer-to-peer mode. Either way, the goal is have all inbound calls received by the gateways sent to Unified CM so that Unified CM can decide how to route the calls. See [Gatekeepers, page 12-25](#), for more details on how to configure the gatekeeper to route calls from the gateways to Unified CM.

Call Signaling Port Numbers

By default, the Cisco Unified Videoconferencing Gateways listen on TCP port 2720 instead of the well-known port 1720. However, also by default, Unified CM sends H.323 calls to port 1720. You can change the port that the gateway listens on or you can change the port that Unified CM sends to in the H.323 gateway device configuration in Unified CM. Either way, both sides have to match in order for outbound calls to the gateway to succeed.

In the inbound direction, when configured to operate in peer-to-peer mode, the Cisco Unified Videoconferencing Gateways will send the call to Unified CM on port 1720. When configured to register with a gatekeeper, Unified CM uses a randomly generated port number for all gatekeeper-controlled trunks. This method enables Unified CM to have multiple trunks to the same gatekeeper. This port number is included in the Registration Request (RRQ) from Unified CM to the gatekeeper, so the inbound H.225 setup message from the gateway to Unified CM will be sent to this

port number. However, if the gateway is configured directly in Unified CM as an H.323 gateway device, Unified CM will ignore the fact that the call came in on the TCP port of the H.225 trunk and will instead match the source IP address to the H.323 gateway device configured in its database. If it does not find a matching device, Unified CM will treat the call as if it came in on the trunk.

In the outbound direction, if Unified CM uses a gatekeeper-controlled H.225 trunk to reach the gateway, the gatekeeper will tell Unified CM which TCP port to use to reach the gateway. If the gateway is configured in Unified CM as an H.323 gateway device (that is, peer-to-peer mode), then Unified CM must be configured to send calls either to port 2720 (default) or to 1720 (if the listening port on the gateway has been modified).

Call Signaling Timers

Due to the delay inherent in H.320 bonding, video calls can take longer to complete than voice calls. Several timers in Unified CM are tuned, by default, to make voice calls process as fast as possible, and they can cause video calls to fail. Therefore, you must modify the following timers from their default values in order to support H.320 gateway calls:

- H.245TCSTimeout
- Media Exchange Interface Capability Timer
- Media Exchange Timer

Cisco recommends that you increase each of these timers to 25 by modifying them under the Service Parameters in Unified CM Administration. Note that these are cluster-wide service parameters, so they will affect calls to all types of H.323 devices, including voice calls to existing H.323 Cisco Voice Gateways.

Bearer Capabilities of Voice Gateways

H.323 calls use the H.225/Q.931 Bearer Capabilities Information Element (bearer-caps) to indicate what type of call is being made. A voice-only call has its bearer-caps set to "speech" or "3.1 KHz Audio" while a video call has its bearer-caps set to "Unrestricted Digital Information." Some devices do not support Unrestricted Digital Information bearer-caps. Calls to these devices might fail if Unified CM attempts the call as a H.323 video call.

Unified CM decides which bearer-caps to set, based on the following factors:

- Whether the calling and/or called devices are video-capable
- Whether the region in Unified CM is configured to allow video for calls between those devices

Unified CM supports retrying the video call as audio, and this feature can be enabled through configuration. When Unified CM makes a video call with bearer-caps set to "Unrestricted Digital" and the call fails, Unified CM then retries the same call as an audio call with the bearer-caps set to "speech."

When using H.323, Cisco IOS gateways can service calls as voice or video, based on the bearer capabilities it receives in the call setup. When using SIP, the gateway translates the ISDN capabilities into SDP for call negotiations.

If the Cisco voice gateway uses MGCP to communicate with Unified CM, the problem will not occur because Unified CM does not support video on its MGCP protocol stack and because, in MGCP mode, Unified CM has complete control over the D-Channel signaling to the PSTN.

CHAPTER 14

Cisco Unified CM Trunks

Revised: July 31, 2012; OL-21733-18

A trunk is a communications channel on Cisco Unified Communications Manager (Unified CM) that enables Unified CM to connect to other servers. Using one or more trunks, Unified CM can receive or place voice, video, and encrypted calls, exchange real-time event information, and communicate in other ways with call control servers and other external servers.

Trunks are an integral and a crucial part of a Cisco Unified Communications deployment, hence it is important to understand the types of trunks available, their capabilities, and design and deployment considerations such as resiliency, capacity, load balancing, and so forth.

There are two basic types of trunks that can be configured in Unified CM:

- SIP and H.323 trunks, both of which can be used for external communications
- Intercluster trunks (ICTs)

This chapter describes the general capabilities and functions of these trunks. Additional discussion on specific applications of Unified CM trunks can be found in other pertinent chapters of this document.

This chapter discusses the following topics:

- [A Comparison of SIP and H.323 Trunks, page 14-3](#)
- [SIP Trunks Overview, page 14-6](#)
- [H.323 Trunks Overview, page 14-36](#)
- [General SIP and H.323 Trunk Design Considerations, page 14-55](#)
- [IP PSTN and IP Trunks to Service Provider Networks, page 14-58](#)
- [Trunk Aggregation Platforms, page 14-59](#)

For more details on the applications of Unified CM trunks, refer to their respective sections in the following chapters:

- [Unified Communications Deployment Models, page 5-1](#)
- [Media Resources, page 17-1](#)
- [Call Admission Control, page 11-1](#)

Unified CM Trunks Solution Architecture

Unified CM uses the mechanism of IP trunks to exchange call-related information with other components of a Unified Communications solution. Given their importance in this respect, it is important to develop the system architecture of the IP trunks with proper regard to the protocol, feature and service expectations, performance requirements, and so forth.

Figure 14-1 illustrates the role of IP trunks in system connectivity. The illustration does not show all possible connections from the Unified CM cluster.

Figure 14-1 IP Trunks Provide Connections to Unified CM

Calls are directed toward trunks as defined by the dial plan using the route pattern construct. A route pattern can use a trunk either directly or through a route list. The route list, if used, consists of one or more route groups, each of which contains one or more trunks. An individual trunk within a route group may be configured to be selected in either a top-down or circular fashion. For outgoing calls, Unified CM selects one of the trunks associated in this fashion with the route pattern. Before it accepts an incoming call, Unified CM verifies whether a trunk is defined to the remote address from which the call is received.

A Comparison of SIP and H.323 Trunks

Cisco Unified CM trunk connections support both SIP and H.323. In many cases, the decision to use SIP or H.323 is driven by the unique feature(s) offered by each protocol. There are also a number of external factors that can affect the choice of trunk protocol, such as customer preference or the protocol's maturity and degree of interoperability offered between various vendors' products.

For trunk connections between Cisco devices, this decision is relatively straightforward. For trunk connections to other vendors' products and to service provider networks, it is important to understand which features are required by the customer and the extent of interoperability between any two vendors' products.

[Table 14-2](#) compares some of the features offered over SIP and H.323 trunks between Unified CM clusters.

1. H.323 trunks support signaling of RFC 2833 for certain connection types.

SIP Trunks Overview

SIP trunks provide connectivity to other SIP devices such as gateways, Cisco Unified CM Session Management Edition, SIP proxies, Unified Communications applications, and other Unified CM clusters. Today, SIP is arguably the most commonly chosen protocol when connecting to service providers and Unified Communications applications. Cisco Unified CM 8.5 and later releases provide the following SIP trunk and call routing enhancements:

- Can run on all Unified CM nodes
- Up to 16 destination IP addresses per trunk
- SIP OPTIONS ping keepalives
- SIP Early Offer support for voice and video calls (insert MTP if needed)
- QSIG over SIP
- SIP trunk normalization and transparency
- Supports the use of route lists on all Unified CM nodes

The SIP trunk features available in the current release of Unified CM make SIP the preferred choice for new and existing trunk connections. The QSIG over SIP feature provides parity with H.323 intercluster trunks and can also be used to provide QSIG over SIP trunk connections to Cisco IOS gateways (and on to QSIG-based TDM PBXs). The ability to run on all Unified CM nodes and to handle up to 16 destination IP addresses improves outbound call distribution from Unified CM clusters and reduces the number of SIP trunks required between clusters and devices. SIP OPTIONS ping provides dynamic reachability detection for SIP trunk destinations, rather than per-call reachability determination. SIP Early Offer support for voice and video calls (insert MTP if needed) can reduce or eliminate the need to use MTPs and allows voice, video, and encrypted calls to be made over SIP Early Offer trunks.

SIP trunk normalization and transparency improve native Unified CM interoperability with and between third-party unified communications systems. Normalization allows inbound and outbound SIP messages and SDP information to be modified on a per-SIP-trunk basis. Transparency allows Unified CM to pass SIP headers, parameters, and content bodies from one SIP trunk call leg to another, even if Unified CM does not understand or support the parts of the message that are being passed through.

These features are discussed in detail later in this section.

For the complete list of new enhancements for SIP trunks, refer to the Cisco Unified Communications Manager product release notes available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_release_notes_list.html

General Deployment Considerations

Unified CM SIP trunks offer a greater set of features in comparison with H.323 intercluster trunks, thus making SIP the protocol of choice for intercluster trunk connections (although H.323 Annex M1 may still be preferred for intercluster trunk connections to Unified CM clusters using earlier software versions). Also, given the wide support of SIP in the industry, SIP trunks are usually a good choice for connectivity to third-party applications and service providers.

SIP Trunk Features and Operation

This section explains how Unified CM SIP trunks operate and describes several key SIP trunk features that should be taken into account when designing and deploying Unified CM SIP trunks.

SIP Trunks Can Run on All Active Unified CM Nodes

When the **Run on all Active Unified CM Nodes** option is checked on a SIP trunk, Unified CM creates an instance of the SIP trunk daemon on every call processing subscriber within the cluster, thus allowing SIP trunk calls to be made or received on any call processing subscriber. (Prior to this feature, up to three nodes could be selected per trunk by using Unified CM Groups.) With **Run on all Active Unified CM Nodes** enabled, outbound SIP trunk calls originate from the same node on which the inbound call (for example, from a phone or trunk) is received. As with all Unified CM SIP trunks, the SIP daemons associated with the trunk will accept inbound calls only from end systems with IP addresses that are defined in the trunk's destination address fields. Running SIP trunks on all nodes is recommended where the SIP trunk is required to process a large number of calls so that outbound and inbound call distribution can be evenly spread across all call processing subscribers within a cluster. Also, when multiple SIP trunks to the same destination(s) are using the same subscriber, a unique incoming and destination port number must be defined per trunk to allow each trunk to be identified uniquely.

Up to 16 SIP Trunk Destination IP Addresses

SIP trunks can be configured with up to 16 destination IP addresses, 16 fully qualified domain names, or a single DNS SRV entry. Support for additional destination IP addresses reduces the need to create multiple trunks associated with route lists and route groups for call distribution between two Unified Communications systems, thus simplifying Unified CM trunk design. (See [Figure 14-2](#).) This feature can be used in conjunction with the **Run on all Active Unified CM Nodes** feature or with a SIP trunk that uses standard Unified CM Groups to create a SIP daemon on up to three nodes within the cluster. Bear in mind, however, that the SIP daemons associated with a Unified CM SIP trunk will accept inbound calls only from end systems with IP addresses that are defined in the trunk's destination address fields.

Figure 14-2 SIP Trunks with Multiple Destination IP Addresses Running on All Active Nodes

SIP OPTIONS Ping

The SIP OPTIONS Ping feature can be enabled on the SIP Profile associated with a SIP trunk to dynamically track the state of the trunk's destination(s). When this feature is enabled, each node running the trunk's SIP daemon will periodically send an OPTIONS Request to each of the trunk's destination IP addresses to determine its reachability and will send calls only to reachable nodes. A destination address is considered to be "out of service" if it fails to respond to an OPTIONS Request, if it sends a Service Unavailable (503) response or Request Timeout (408) response, or if a TCP connection cannot be established. The trunk state is considered to be "in service" when at least one node receives a response (other than a 408 or 503) from a least one destination address. SIP trunk nodes can send OPTIONS Requests to the trunk's configured destination IP addresses or to the resolved IP addresses of the trunk's DNS SRV entry. Enabling SIP OPTIONS Ping is recommended for all SIP trunks because it allows Unified CM to dynamically track trunk state rather than determining trunk state on a per-call and timeout basis.

SIP Early Offer Support over Unified CM SIP Trunks

SIP negotiates media exchange by means of the Session Description Protocol (SDP), where one side offers a set of capabilities to which the other side answers, thus converging on a set of media characteristics. SIP allows the initial offer to be sent either by the caller in the initial INVITE message (Early Offer) or, if the caller chooses not to, the called party can send the initial offer in the first reliable response (Delayed Offer).

By default, Unified CM SIP trunks send the INVITE without an initial offer (Delayed Offer). In general SIP Delayed Offer is preferred for Unified CM SIP trunks because MTPs are not needed to establish a Delayed Offer call for voice, video, or encrypted media. If SIP Early Offer is desired, Unified CM has two configurable options to enable a SIP trunk to send the offer in the INVITE:

- [Media Termination Point Required, page 14-9](#)
- [Early Offer Support for Voice and Video Calls \(Insert MTP If Needed\), page 14-9](#)

Media Termination Point Required

Enabling the **Media Termination Point Required** option on the SIP trunk assigns an MTP from the trunk's media resources group (MRG) to every outbound call. (See [Figure 14-3](#).) This statically assigned MTP supports only the G.711 or G.729 codecs, thus limiting media to voice calls only.

Figure 14-3 SIP Early Offer with Media Termination Point Required

Early Offer Support for Voice and Video Calls (Insert MTP If Needed)

Enabling **Early Offer support for voice and video calls (insert MTP if needed)** on the SIP Profile associated with the SIP trunk inserts an MTP only if the calling device cannot provide Unified CM with the media characteristics required to create the Early Offer. In general, **Early Offer support for voice and video calls (insert MTP if needed)** is recommended over **Media Termination Point Required** because this configuration option reduces MTP usage (see [Figure 14-4](#)). Calls from older SCCP-based phones registered to Unified CM over SIP Early Offer trunks configured with this option will use an MTP to create the Offer SDP, and these calls support voice, video, and encrypted media (see [Endpoint Features Summary, page 18-55](#)). Inbound calls to Unified CM from SIP Delayed Offer trunks or H.323 Slow Start trunks that are extended over an outbound SIP Early Offer trunk will use an MTP to create the Offer SDP; however, these calls support audio only in the initial call set up but can be escalated mid-call to support video and SRTP if the call media is renegotiated (for example, after hold/resume). For guidance on when to use **Early Offer support for voice and video calls (insert MTP if needed)**, see [Design Considerations for SIP Trunks, page 14-27](#).

Note

MTP resources are not required for incoming INVITE messages, whether or not they contain an initial offer SDP.

Figure 14-4 Early Offer Support for Voice and Video Calls

254786

Unified CM does not need to insert an MTP to create an outbound Early Offer call over a SIP trunk if the inbound call to Unified CM is received by any of the following means:

- On a SIP trunk using Early Offer
- On an H.323 trunk using Fast Start
- On an MGCP trunk
- From a SIP-based IP phone registered to Unified CM
- From newer SCCP-based Cisco Unified IP Phone models registered to Unified CM (see the [Endpoint Features Summary, page 18-55](#), for details)

For the above devices, Unified CM uses the media capabilities of the endpoint and applies the codec filtering rules based on the region-pair of the calling device and outgoing SIP trunk to create the offer SDP for the outbound SIP trunk call. In most cases, the offer SDP will have the IP address and port number of the endpoint initiating the call. This is assuming that Unified CM does not have to insert an MTP for other reasons such as a DTMF mismatch, TRP requirements, or a transcoder requirement when there is no common codec between the regions of the calling device and the SIP trunk.

When **Early Offer support for voice and video calls (insert MTP if needed)** is configured on a trunk's SIP Profile, calls from older SCCP-based phones (see [Endpoint Features Summary, page 18-55](#)), SIP Delayed Offer trunks, and H.323 Slow Start trunks will cause Unified CM to allocate an MTP if an MTP or transcoder has not already been allocated for that call for another reason. The MTP is used to generate an offer SDP with a valid media port and IP address. The MTP will be allocated from the media resources associated with the calling device rather than from the outbound SIP trunk's media resources. (This prevents the media path from being anchored to the outbound SIP trunk's MTP). If the MTP cannot be allocated from the calling device's media resource group list (MRGL), then the MTP allocation is attempted from the SIP trunk's MRGL.

For calls from older SCCP phones (see [Endpoint Features Summary, page 18-55](#)) registered to Unified CM, some of the media capabilities of the calling device (for example, supported voice codecs, video codecs, and encryption keys if supported) are available for media exchange through the Session Description Protocol (SDP). Unified CM will create a superset of the endpoint and MTP codec

capabilities and apply the codec filtering based on the applicable region-pair settings. The outbound Offer SDP will use the MTP's IP address and port number and can support voice, video, and encrypted media. Note that the MTP should be configured to support the pass-through codec.

When Unified CM receives an inbound call on an H.323 Slow Start or SIP Delayed Offer trunk, the media capabilities of the calling device are not available when the call is initiated. In this case, Unified CM must insert an MTP and will use its IP address and UDP port number to advertise all supported audio codecs (after region pair filtering) in the Offer SDP of the initial INVITE sent over the outbound SIP trunk. When the Answer SDP is received on the SIP trunk, if it contains a codec that is supported by the calling endpoint, then no additional offer-answer transaction is needed. In case of codec mismatch, Unified CM can either insert a transcoder to address the mismatch or send a reINVITE or UPDATE to trigger media negotiation. Calls from H.323 Slow Start or SIP Delayed Offer trunks support audio only in the initial call setup, but they can be escalated mid-call to support video and SRTP if the call media is renegotiated (for example, after Hold/Resume).

QSIG over SIP Trunks

Unified CM can encapsulate QSIG content in SIP messages, thus allowing features such as Call Back, MWI, and Path Replacement to be invoked over SIP QSIG intercluster trunks and over SIP QSIG trunks to Cisco IOS gateways. (See [Figure 14-5](#).) QSIG over SIP trunks provides parity with the QSIG feature set on H.323 Annex M1 intercluster trunks and MGCP QSIG trunks. (ISO and ECMA variants of QSIG are supported on a per-trunk basis.)

Figure 14-5 QSIG over SIP Trunks

254787

SIP Trunk Message Normalization and Transparency

Normalization and transparency provide powerful script-based functionality for SIP trunks that can be used to transparently forward and/or modify SIP messages and message body contents as they traverse Unified CM. Normalization and transparency scripts are designed to address SIP interoperability issues, allowing Unified CM to interoperate with SIP-based third-party PBXs, applications, and IP PSTN services.

SIP Trunk Normalization

Normalization allows incoming and outgoing SIP messages to be modified on their way through Unified CM. Normalization applies to all calls that traverse a SIP trunk with an associated script, regardless of what protocol is being used for the other endpoint involved in the call. For example, a SIP trunk normalization script can operate on a call from a SIP line device to a SIP trunk, from an SCCP-based device to a SIP trunk, from MGCP to SIP trunk, from H.323 to SIP trunk, and so forth. (See [Figure 14-6](#).) Normalization does not require end-to-end SIP.

Figure 14-6 SIP Trunk Normalization

SIP Trunk Transparency

Transparency allows Unified CM to pass SIP headers, parameters, and content bodies from one SIP trunk call leg to another, even if Unified CM does not understand or support the parts of the message that are being passed through. Transparency (or transparent pass-through) is applicable only when the call through Unified CM is from SIP trunk to SIP trunk, as illustrated in Figure 14-7.

Figure 14-7 SIP Trunk Transparency

Normalization and transparency scripts use Lua, a powerful, fast, lightweight, embeddable scripting language to modify SIP messages and SDP body content on SIP trunks. (For more information on Lua, refer to the documentation available at <http://lua-users.org/wiki/LuaOrgGuide>.)

Cisco has created a library of Lua-based SIP Message APIs that allow specified information in the SIP message and SDP body to be retrieved, modified, replaced, removed, passed through, ignored, appended to, transformed, and so on. The underlying Lua language allows retrieved information to be stored as variables and operated on using a series of operations such as: If, elseif, while, do, <, >, =, and so forth. The scripting approach naturally supports multiple variables and state-specific contexts for making

script decisions. The combination of Cisco's SIP Message Library APIs and the functionality underlying the Lua language creates a very powerful scripting environment that allows almost any SIP message and/or its SDP body content to be modified.

For inbound messages on a SIP trunk, normalization and transparency script processing occurs immediately after receiving the message from the network. For outbound messages, script processing occurs immediately before sending the message to the network.

Within a Lua script, callback functions (also known as message handlers) are used to request message types of interest. The Cisco Lua environment constructs the name of the message handler based on the message direction and method for requests (for example, `inbound_INVITE`) and based on the message direction, response code, and method (from the CSeq header) for responses (for example, `outbound_180_INVITE`). A message object (for example, `msg`) is passed to the message handler, thereby allowing the script to modify the message (for example, `inbound_INVITE(msg)`).

Callback Function (message Handler) examples:

| | |
|-----------------------------------|------------------------------------|
| <code>inbound_INVITE()</code> | <code>outbound_INVITE()</code> |
| <code>inbound_UPDATE()</code> | <code>outbound_SUBSCRIBE()</code> |
| <code>inbound_3XX_INVITE()</code> | <code>outbound_180_INVITE()</code> |

The Lua script then uses APIs defined in the Cisco SIP Message library to access and manipulate message parameters. For example:

- **getHeader**(*header-name*) returns header-value or ""
- **getHeaderValues**(*header-name*) returns a table of header values
- **addHeaderValueParameter**(*header-name, parameter-name, [parameter-value]*)
- **getUri**(*header-name*) retrieves the URI from the specified header
- **block**() blocks the specified SIP message
- **applyNumberMask**(*header-name, mask*) retrieves the specified header and applies the specified number mask to the URI
- **getSdp**() returns the SDP content
- **sdp:getLine**(**start of line, line contains**) returns line in SDP that starts with "start of line" and also has string "line contains"
- **sdp:modifyLine**(**start of line, line contains, new-line**) finds the in SDP that starts with "start of line", the line matching "line contains" is replaced with the *new-line* parameter

The following examples illustrate the use of SIP Message API scripts.

Example 14-1 SIP Message API – getRequestLine

getRequestLine() returns the method, request-uri, and version.

This method returns three values:

- The method name
- The request-uri
- The protocol version

Example script:

| | |
|--------|--|
| Line 1 | M = {} |
| Line 2 | function M.outbound_INVITE(message) |
| Line 3 | local method, ruri, ver = message:getRequestLine() |
| Line 4 | end |
| Line 5 | return M |

Line 1 initializes the set of callback functions to an empty value. This set of callback functions, named M, is essentially a Lua table.

Lines 2 to 4 define a message handler. This callback function is executed when an outbound INVITE is sent from Unified CM. The script then gets the method, request-uri, and version from the request line and stores these values.

The script can define multiple message handlers. The name of the message handler dictates which message handler is invoked (if any) for a given SIP message.

The last line returns the set of callbacks. This line is absolutely required.

Message:

```
INVITE sip:1234@10.10.10.1 SIP/2.0
```

Output and result:

```
method == "INVITE"
ruri == "sip:1234@10.10.10.1"
version == "SIP/2.0"
```

Example 14-2 A script that simply removes the "Cisco-Guid" header in an outbound INVITE

| | |
|--------|-------------------------------------|
| Line 1 | M = {} |
| Line 2 | function M.outbound_INVITE(message) |
| Line 3 | message:removeHeader("Cisco-Guid") |
| Line 4 | end |
| Line 5 | return M |

Line 1 initializes the set of callback functions to an empty value. This set of callback functions, named M, is essentially a Lua Table.

Lines 2 to 4 define a message handler. This callback function is executed when an outbound INVITE is sent from Unified CM. The script can define multiple message handlers. The name of the message handler dictates which message handler is invoked (if any) for a given SIP message.

The last line returns the set of callbacks. This line is absolutely required.

Message:

```
INVITE sip:1234@10.10.10.1 SIP/2.0
.
P-Asserted-Identity: "1234" <1234@10.10.10.1>
Cisco-Guid: 1234-4567-1234
Session-Expires: 1800
```

Output and results:

```
INVITE sip:1234@10.10.10.1 SIP/2.0
.
P-Asserted-Identity: "1234"
```

For more information on SIP trunk normalization and transparency scripts, refer to the *Developer Guide for SIP Transparency and Normalization*, available at

http://www.cisco.com/en/US/docs/voice_ip_comm/cucm/sip_tn/8_5_1/sip_t_n.html

Route Lists Run on All Active Unified CM Nodes

Although this is not specifically a SIP trunk feature, running route lists on all nodes provides benefits for trunks in route lists and route groups. Running route lists on all nodes improves outbound call distribution by using the "route local" rule to avoid unnecessary intra-cluster traffic.

For route lists, the route local rule operates as follows:

For outbound calls that use route lists (and associated route groups and trunks), when a call from a registered phone or inbound trunk arrives at the node with the route list instance, Unified CM checks to see if an instance of the selected outbound trunk exists on the same node as the route list. If so, Unified CM will use this node to establish the outbound trunk call.

If both the route list and the trunk have **Run on all Active Unified CM Nodes** enabled, outbound call distribution will be determined by the node on which the inbound call arrives. When the selected outbound trunk uses Unified CM Groups instead of running on all nodes, Unified CM will apply the route local rule if an instance of the selected outbound trunk exists on the same node on which the inbound call arrived. If an instance of the trunk does not exist on this node, then Unified CM will forward the call (within the cluster) to a node where the trunk is active.

If the route list does not have **Run on all Active Unified CM Nodes** enabled, an instance of the route list will be active on one node within the cluster (the primary node of the route list's Unified CM Group) and the route local rule will be applied on this node. With this configuration, Cisco recommends that you do not use the primary node of the route list's Unified CM Group in the Unified CM Group of any of the trunks associated with the route list because this can result in sub-optimal outbound call distribution.

As a general recommendation, **Run on all Active Unified CM Nodes** should be enabled for all route lists. (See [Figure 14-8](#).)

Figure 14-8 Route Lists Running on All Active Unified CM Nodes

SIP Trunks Using DNS

Using a DNS SRV entry as the destination of a SIP trunk might be preferable to defining multiple destination IP addresses in certain situations such as the following:

- SRV host prioritization is required
- SRV host weighting is required
- More than 16 destination IP addresses are required
- DNS SRV resolution is a requirement of the destination Unified Communications system

Note

If the configuration option **Destination Address is an SRV** is selected, only a single SRV entry can be added as the trunk destination. (For example, Destination Address = cluster1.cisco.com. Port = 0.)

Figure 14-9 shows the call flow for a SIP trunk using DNS SRV to resolve the addresses to a destination Unified CM cluster. However, this destination could also be a third-party unified communications system.

Figure 14-9 Call Flow for Intercluster SIP Trunk Using DNS SRV

Note: The DNS A Lookup has been removed from this call flow

Figure 14-9 illustrates the following steps in the call flow:

1. The IP phone in Cluster1 calls 87522001.
2. The call matches a route pattern of 8752XXXX that is pointing to the SIP trunk with DNS SRV of cluster2.foo.com. CCM3 in Cluster1 is the node handling this call because the SIP trunk is registered to it. CCM3 sends a DNS SRV lookup for cluster2.foo.com
3. The DNS server replies with two records: CCM-A.cluster2.foo.com and CCM-B.cluster2.foo.com. Because CCM-A.cluster2.foo.com has a higher priority, the call is attempted to this Unified CM. Before sending the SIP Invite, another DNS lookup is done for CCM-A.cluster2.foo.com.
4. CCM3 sends a SIP Invite to 87522001@cluster2.foo.com, with destination address set to the IP address of CCM-A.
5. Unified CM interprets this call as a local call because the host portion of the uniform resource identifier (URI) matches the Cluster FQDN enterprise parameter. Cluster2 does not have any SIP trunk configured with a destination of CCM3, so it does a DNS SRV lookup for all domains configured under the SIP trunks with DNS SRV. In this case, the example shows a single trunk with a DNS SRV destination of cluster1.foo.com

6. The DNS server returns two entries, and one of them matches the source IP address of the Invite. The cluster accepts the call and extends it to extension 87522001.

High Availability for SIP Trunks

A variety of Unified CM options is available for configuring high availability with SIP trunks, all of which can be combined to provide redundancy and resiliency for both the source and destination servers of SIP trunks. These options can be categorized as follows:

- [Multiple Source Unified CM Servers for Originating SIP Trunk Calls, page 14-18](#)
- [Multiple Destination IP Addresses per SIP Trunk, page 14-19](#)
- [Multiple SIP Trunks Using Route Lists and Route Groups, page 14-19](#)
- [SIP OPTIONS Ping, page 14-19](#)

Multiple Source Unified CM Servers for Originating SIP Trunk Calls

Using Standard Unified CM Groups

The nodes defined in the Unified CM Group associated with an individual trunk make up the set of servers that can place or receive calls over that trunk. Up to three nodes can be defined in a Unified CM Group, thus ensuring high availability of the trunk itself.

Using Run on All Active Unified CM Nodes

The **Run on all Active Unified CM Nodes** feature creates and enables a SIP trunk instance on each call processing subscriber within the cluster, thus allowing these nodes to place or receive calls over the trunk.

The Unified CM Route Local Feature And Its Effect on Subscriber Selection for Outbound SIP Trunk Calls

The Route Local feature in Unified CM is designed to reduce intra-cluster traffic. The feature operates as illustrated by the following example:

When a device such as a phone is making an outbound call over SIP Trunk 1, if an instance of SIP Trunk 1 is active on the same node as the one to which the phone is registered, then always use this co-located SIP Trunk 1 instance rather than internally routing the call to another SIP Trunk 1 instance on another node within the cluster.

The effect of the Route Local feature on node selection depends on whether Unified CM Groups or **Run on all Active Unified CM Nodes** is configured on the trunk. For trunks with **Run on all Active Unified CM Nodes** configured, the node to which the calling device is registered is used to make the outbound SIP trunk call. When Unified CM Groups are used on the trunk, if the calling device is registered to one of the nodes in the trunk's Unified CM Group, then the Route Local rule applies. If the calling device is not registered to one of the nodes in the trunk's Unified CM Group, then Unified CM will randomly distribute the call over the nodes in the trunk's Unified CM Group.

Using **Run on all Active Unified CM Nodes** is the recommended approach for SIP trunks because it allows call distribution across nodes to be determined by the calling device and it minimizes intra-cluster traffic.

Multiple Destination IP Addresses per SIP Trunk

A single SIP trunk can be configured with up to 16 destination IP addresses. Unified CM uses random distribution to the configured destination IP addresses when placing calls over a SIP trunk. Using multiple IP addresses on a SIP trunk can help to reduce the need to deploy multiple trunks with route lists and route groups.

Design Considerations When Using Run on All Active Unified CM Nodes

When using **Run on All Active Unified CM Nodes** in conjunction with multiple destination addresses, be aware that to accept inbound calls, the inbound source IP address received on the SIP trunk must match with a configured destination IP address on the inbound trunk. For example, if **Run on all Active Unified CM Nodes** is configured on the SIP intercluster trunk in each cluster, then each trunk must be configured with the corresponding destination address of every active node in the destination cluster. Where clustering over the WAN designs are deployed and geographic call distribution and failover are required, use standard Unified CM Groups on multiple intercluster trunks (each with up to three destination IP addresses) in conjunction with route lists and route groups.

Multiple SIP Trunks Using Route Lists and Route Groups

Multiple prioritized SIP trunks are often required to address failure scenarios in Unified Communications designs. These trunks should be configured in route groups in a single route list and associated with a route pattern. If Unified CM is not able to place a call over the selected trunk in the list, it will try the next trunk in the list. As a general recommendation, enable **Run on all Active Unified CM Nodes** for all route lists.

SIP OPTIONS Ping

SIP OPTIONS Ping can be enabled on the SIP Profile associated with a SIP trunk to dynamically track the state of the trunk's destination(s). When this option is enabled, each node running the trunk's SIP daemon will periodically send an OPTIONS Request to each of the trunk's destination IP addresses to determine its reachability. Enabling SIP OPTIONS Ping is recommended for all SIP trunks that require high availability because it allows Unified CM to dynamically track trunk state rather than determining trunk state on a per-call and timeout basis.

Load Balancing for SIP Trunks

When designing load balancing for SIP trunks, consider both the node that sources the call and its destination. With Unified CM SIP trunks, the node used to originate the call is determined by the Route Local rule, the number of nodes on which the outbound trunk is active, and whether a route list is used in conjunction with multiple outbound trunks. These considerations are discussed in the following sections.

Outbound Calls over a Single SIP Trunk

A single SIP trunk can run on up to three Unified CM nodes in a Unified CM Group, or it can run on all active Unified CM nodes in the cluster. To select the source node for outbound calls, Unified CM applies the following decision processes:

- Where an instance of the trunk runs on all nodes, the Route Local rule applies and the node used for each outbound call is determined by the node on which the call arrives (for example, the node to which the calling phone is registered or the node on which the inbound trunk call arrives).
- Where Unified CM Groups are used, the Route Local rule still applies for those calling devices that are registered to the same node as the nodes in the trunk's Unified CM Group. For calling devices that are registered to other servers within the cluster, Unified CM will randomly distribute calls across the nodes in the trunk's Unified CM Group. Unified CM uses round-robin call distribution across the trunk's configured destination addresses. SIP trunks may be configured with up to 16 destination IP addresses.

Outbound Calls over Multiple SIP Trunks

Because SIP trunks can run on all active Unified CM nodes and have up to 16 destination addresses, multiple SIP trunks typically do not need to be used to provide even call distribution between two Unified Communications systems. Where multiple trunks are used with route lists and route groups, route lists should be enabled to run on all active Unified CM nodes. Multiple SIP trunks are often used in conjunction with route lists to provide failover to the PSTN or to a group of Unified CM servers in a different site as part of a cluster deployed over the WAN. The selection of the Unified CM node used to initiate an outbound SIP trunk call, and the distribution of calls over the trunk's configured destination IP addresses, are determined in the same way as described for single trunks. Where clustering over the WAN designs are deployed and geographic call distribution and failover are required, use multiple intercluster trunks (each with up to three destination IP addresses) with standard Unified CM Groups in conjunction with route lists and route groups.

SIP OPTIONS Ping

Use OPTIONS Ping to dynamically track the state of each destination IP address on each SIP trunk and the collective state of the trunk as a whole. If a destination address is unreachable, Unified CM will not extend calls to this device. When all destinations are unreachable, the SIP trunk is considered to be out-of-service.

SIP Delayed Offer and Early Offer

Cisco Unified CM uses the SIP Offer/Answer model for establishing SIP sessions, as defined in RFC 3264. In this context, an Offer is contained in the Session Description Protocol (SDP) fields sent in the body of a SIP message. The Offer typically defines the media characteristics supported by the device (media streams, codecs, directional attributes, IP address, and ports to use). The device receiving the Offer sends an Answer in the SDP fields of its SIP response, with its corresponding matching media streams and codec, whether accepted or not, and the IP address and port on which it wants to receive the media streams. Unified CM uses this Offer/Answer model to establish SIP sessions as defined in the key SIP standard, RFC 3261.

RFC 3261 defines two ways that SDP messages can be sent in the Offer and Answer. These methods are commonly known as Delayed Offer and Early Offer, and support for both methods by User Agent Client/Servers is a mandatory requirement of the specification. In the simplest terms, an initial SIP Invite sent with SDP in the message body defines an Early Offer, whereas an initial SIP Invite without SDP in the message body defines a Delayed Offer.

In an Early Offer, the session initiator (calling device) sends its capabilities (for example, codecs supported) in the SDP contained in the initial Invite (thus allowing the called device to choose its preferred codec for the session). In a Delayed Offer, the session initiator does not send its capabilities in the initial Invite but waits for the called device to send its capabilities first (for example, the list of codecs supported by the called device, thus allowing the calling device to choose the codec to be used for the session).

Delayed Offer and Early Offer are the two options available to all standards-based SIP switches for media capabilities exchange. Most vendors have a preference for either Delayed Offer or Early Offer, each of which has its own set of benefits and limitations. For Unified CM SIP trunks, SIP Delayed Offer is preferred over SIP Early Offer because MTPs are not required to establish a call over a Delayed Offer trunk.

**Note**

Unified CM can support Delayed Offer in one direction and Early Offer in the other direction over a SIP trunk. This capability can often be useful in situations where a SIP switch connected to Unified CM by a SIP trunk wishes to control the codecs offered and selected for inbound and outbound calls (that is, where using Delayed Offer outbound from Unified CM and Early Offer inbound to Unified CM allows the service provider to send the Offer in all cases and, in doing so, to decide which codecs are offered for all calls.)

Early Media

In certain circumstances, a SIP session might require that a media path be set up prior to the finalization of the media capabilities exchange between the two SIP endpoints. To this end, the SIP protocol allows the establishment of Early Media after the initial Offer has been received by an endpoint. Some reasons for using Early Media include:

- The called device might want to establish an Early Media RTP path to reduce the effects of audio cut-through delay (clipping) for calls experiencing long signaling delays or to provide a network-based voice message to the caller.
- The calling device might want to establish an Early Media RTP path to access a DTMF or voice-driven interactive voice response (IVR) system.

Unified CM supports Early Media for both Early Offer and Delayed Offer calls.

For a SIP trunk to support Early Media cut-through, you must enable PRACK through the **SIP Rel1XX Options** feature in the SIP Profile associate with the trunk.

**Note**

The terms Early Offer and Early Media are often confused, but they are not the same.

Media Termination Points

MTPs are used by Unified CM for the following purposes:

- To deliver a SIP Early Offer over SIP trunks
- To address DTMF transport mismatches

- To act as an RSVP agent
- To act as a Trusted Relay Point (TRP)
- To provide conversion between IPv4 and IPv6 for voice RTP streams

Either of the following methods can be used to enable Early Offer on SIP trunks:

- Check the **MTP Required** checkbox on the SIP trunk
In this case an MTP is used for every outbound call, and only voice calls using a single codec are supported.
- Check the **Early Offer support for voice and video calls (insert MTP if needed)** checkbox on the SIP Profile associated with the SIP trunk

With this method an MTP is inserted only if the calling device or trunk cannot send all of the information about its media capabilities in the initial SIP Invite (for example, an inbound call to Unified CM from a SIP Delayed Offer or H.323 Slow Start trunk). In this case, when an MTP is used, additional voice codecs can be supported in the initial call setup by using the MTP's pass-through codec. Once established, this audio call can be escalated to support video and encryption if the call's media is renegotiated (for example, after hold/resume). When an MTP is not needed, all calls support voice, video, and encrypted media.

Unified CM SIP Delayed Offer and Early Offer Recommendations

Cisco Unified CM SIP trunks support Delayed Offer (Invite without SDP) by default. Media termination points (MTPs) are generally not required for Delayed Offer calls from Unified CM SIP trunks and therefore voice, video, and encrypted calls are all supported. Cisco recommends the use of Delayed Offer for outbound calls over Unified CM SIP trunks.

In cases where SIP Early Offer is required on Unified CM SIP trunks, Cisco recommends **Early Offer support for voice and video calls (insert MTP if needed)** because fewer MTP resources are required in comparison with **MTP Required**. When MTPs are used with **Early Offer support for voice and video calls (insert MTP if needed)**, they can provide support for voice, video, and encrypted media.

For IP PSTN SIP trunk connections, SIP Early Offer is generally required by the Service Provider. For designs where the IP PSTN needs to support large numbers of concurrent calls, the Cisco Unified Border Element (SIP Delayed Offer to Early Offer feature) can be used as an alternative to using Early Offer on the Unified CM SIP trunk, thereby eliminating MTP usage.

For calls inbound and outbound from Unified CM, endpoints can negotiate the use of RFC 2833 or an out-of-band DTMF method (for example, KPML) end-to-end. If a common DTMF method cannot be negotiated between the endpoints, Unified CM will insert an MTP dynamically.

MTPs are available in three forms:

- Software MTPs in Cisco IOS gateways — Available with any Cisco IOS T-train software release and scaling up to 5,000 sessions (calls) on the Cisco ASR 1000 Series Aggregation Services Routers with Route Processor RP2.
- Hardware MTPs in Cisco IOS gateways — Available with any Cisco IOS T-train software release, hardware MTPs use on-board DSP resources and scale calls according to the number of DSPs supported on the Cisco router platform.
- Cisco Unified CM software MTPs using the Cisco IP Voice Media Streaming Application on a Cisco Media Convergence Server (MCS).

In general, Cisco IOS MTPs are recommended over Unified CM MTPs because Cisco IOS MTPs provide additional functionality such as support for additional codec types and the pass-through codec. (For details, see [Media Termination Point \(MTP\)](#), page 17-12.)

The following example configuration is for a Cisco IOS software-based MTP:

```
!  
sccp local Vlan5  
sccp ccm 10.10.5.1 identifier 5 version 5.0.1  
! Communications Manager IP address (10.10.5.1)  
sccp  
!  
sccp ccm group 5  
  bind interface Vlan5  
  associate ccm 5 priority 1  
  associate profile 5 register MTP000E83783C50  
! MTP name (MTP000E83783C50) ... must match the Unified CM MTP name.  
!  
dspfarm profile 5 mtp  
  description software MTP  
  codec g711ulaw  
  codec pass-through  
  maximum sessions software 500  
  associate application SCCP
```

DTMF Transport

There are several methods of transporting DTMF information between SIP endpoints. In general terms, these methods can be classified as out-of-band (OOB) and in-band signaling. In-band DTMF transport methods send either raw or signaled DTMF tones within the RTP stream, and they need to be handled and interpreted by the endpoints that generate and/or receive them. Out-of-band signaling methods transport DTMF tones outside of the RTP path, either directly to and from the endpoints or through a call agent such as Cisco Unified CM, which interprets and/or forwards these tones as required.

Out-of-band (OOB) SIP DTMF signaling methods include Unsolicited Notify (UN), Information (INFO), and Key Press Markup Language (KPML). While KPML (RFC 4730) is the OOB signaling method preferred by Cisco, KPML is not widely used in the market place at this time. Currently, the only known products supporting KPML are Cisco Unified CM, Cisco IOS Gateways (Release 12.4 and later), and some models of Cisco IP Phones. INFO is not supported by Unified CM.

In-band DTMF transport methods send DTMF tones as either raw tones in the RTP media stream or as signaled tones in the RTP payload using RFC 2833. Among SIP product vendors, RFC 2833 has become the predominant method of sending and receiving DTMF tones and is supported by the majority of Cisco voice products.

Because in-band signaling methods send DTMF tones in the RTP media stream, the SIP endpoints in a session must either support the transport method used (for example, RFC 2833) or provide a method of intercepting this in-band signaling and converting it. If the two endpoints are using a back-to-back user agent (B2BUA) server for the call control (for example, Cisco Unified CM) and the endpoints negotiate different DTMF methods between each device and call control box, then the call agent determines how to handle the DTMF differences, either through MTP insertion or by OOB methods. With Unified CM, a DTMF transport mismatch (for example, in-band to out-of-band DTMF) is resolved by inserting a media termination point (MTP), which terminates the RTP stream with in-band DTMF signaling (RFC 2833), extracts the DTMF tones from the RTP stream, and forwards these tones out-of-band to Unified CM, where they are then forwarded to the endpoint supporting out-of-band signaling. In this case, the MTP is always in the media path between the two endpoints because there is no MTP codec dependency for DTMF translation.

In-band DTMF tones can also be transported as raw (audible) tones in the RTP media stream. This transport method is not widely supported by Cisco products and, in general, is not recommended as an end-to-end DTMF transport mechanism. In-band audio DTMF tones can generally be reproduced

reliably only when using G.711 a-law or mu-law codecs, and they are not suitable for use with low-bandwidth codecs. In cases where in-band audio is the only available DTMF transport mechanism, the Cisco Unified Border Element can be used to translate the in-band audio DTMF signaling into RFC 2833 signaling.

Over Unified CM SIP trunks, Cisco recommends configuring the DTMF Signaling Method to **No Preference**. This setting allows Unified CM to make an optimal decision for DTMF and to minimize MTP allocation.

SIP Trunk Transport Protocols

SIP trunks can use either TCP or UDP as a message transport protocol. As a reliable, connection-orientated protocol that maintains the connection state, TCP is preferred. UDP is not connection-orientated and relies on the SIP Invite Retry count and SIP Trying timers to detect and respond to far-end device failures. Use SIP OPTIONS Ping to dynamically track the state of each destination IP address on each SIP trunk and the collective state of the trunk as a whole.

For more information on SIP trunk timer tuning, refer to the configuration example and technical notes at:

http://www.cisco.com/en/US/products/sw/voicesw/ps556/products_configuration_example09186a008082d76a.shtml

Secure SIP Trunks

Securing SIP trunks involves two processes:

- Configuring the trunk to encrypt media (see [Media Encryption, page 14-24](#))
- Configuring the trunk to encrypt signaling (see [Signaling Encryption, page 14-24](#))

Media Encryption

Media encryption can be configured on SIP trunks by checking the trunk's **SRTP allowed** check box. It is important to understand that enabling **SRTP allowed** causes the media for calls to be encrypted, but the trunk signaling will not be encrypted and therefore the session keys used to establish the secure media stream will be sent in the clear. It is therefore important that you ensure that signaling between Unified CM and its destination SIP trunk device is also encrypted so that keys and other security-related information do not get exposed during call negotiations.

Signaling Encryption

SIP trunks use TLS for signaling encryption. TLS is configured on the SIP Security Profile associated with the SIP trunk, and it uses X.509 certificate exchanges to authenticate trunk devices and to enable signaling encryption.

Certificates can be either of the following:

- Imported to each Unified CM node from every device that wishes to establish a TLS connection to that node's SIP trunk daemon
- Signed by a Certificate Authority (CA), in which case there is no need to import the certificates of the remote devices; only the CA certificate needs to be imported.

Unified CM provides a bulk certificate import and export facility. However, for SIP trunks using **Run on all Active Unified CM Nodes** and up to 16 destination addresses, using a Certificate Authority provides a centralized and less administratively burdensome approach to setting up signaling encryption on SIP trunks.

For more information on TLS for SIP trunks, refer to the latest version of the *Cisco Unified Communications Manager Security Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

For information on certificate authorities, refer to the Certificate Authority (CA) information in the latest version of the *Cisco Unified Communications Operating System Administration Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

If the system can establish a secure media or signaling path and if the end devices support SRTP, the system uses a SRTP connection. If the system cannot establish a secure media or signaling path or if at least one device does not support SRTP, the system uses an RTP connection. SRTP-to-RTP fallback (and vice versa) may occur for transfers from a secure device to a non-secure device or for conferencing, transcoding, music on hold, and so on.

For SRTP-configured devices, Unified CM classifies a call as encrypted if the **SRTP Allowed** check box is checked for the device and if the SRTP capabilities for the devices are successfully negotiated for the call. If these criteria are not met, Unified CM classifies the call as non-secure. If the device is connected to a phone that can display security icons, the phone displays the lock icon when the call is encrypted.

**Note**

MTPs that are statically assigned to a SIP trunk by means of the **MTP Required** checkbox do not support SRTP because they do not support the pass-through codec.

To ensure that SRTP is supported for all calls, configure the SIP trunk for Delayed Offer.

Where **Early Offer support for voice and video calls (insert MTP if needed)** is configured, for devices that support encryption, all calls that do not need to use MTPs can support SRTP. When an MTP is inserted into the call path, this dynamically inserted MTP supports the pass-through codec, and encrypted calls are supported in the following cases:

- If the calling device is an older SCCP-based phone (see [Endpoint Features Summary, page 18-55](#)) registered to Unified CM, SRTP can be negotiated in the initial call setup.
- If the call arrives inbound to Unified CM on a Delayed Offer SIP trunk or an H.323 Slow Start trunk, SRTP will not be negotiated in the initial call setup because no security keys are available, but the call can be escalated mid-call to support SRTP if the call media is renegotiated (for example, after hold/resume).

If Unified CM dynamically inserts an MTP for reasons other than Early Offer, such as for a Trusted Relay Point or as an RSVP agent, then SRTP will be supported with an MTP that supports the pass-through codec.

Note that **dtmf-relay** using an MTP (where the MTP needs to convert between in-band and out-of-band DTMF signals) will not function for SRTP because it will be unable to decrypt the DTMF packets in the media stream.

**Note**

SRTP is not supported over SAF-enabled SIP trunks.

Calling Party Number Transformation and SIP Trunks

Unified CM provides the capability to transform calling party numbers of calls inbound over gateways and trunks to a normalized format. Typically, you would want this format to be the globally routable international representation of the number according to E.164 specifications.

The process of normalization relies on receiving the number and the associated number-type of the incoming call. The number-type parameter can be used to select the appropriate digits to prefix to the calling number. Number-types can be one of four types: Unknown, Subscriber, National, or International. For more details and examples on how these number-types are used, refer to the chapter on [Dial Plan](#), page 9-1.

You can specify the prefix digits for each of the four number types in the H.323 trunk and H.323 gateway configuration pages in Unified CM. H.323 can transport these number types in its signaling. SIP, on the other hand, is unable to transport the number-type information in its signaling. Thus, a call coming in through a SIP gateway across a SIP trunk to Unified CM will not have any indication of whether the calling-party number is local, national, or international. Without the number-type information, Unified CM is unable to apply the correct prefix to the calling-party number.

The inability of the SIP trunk to transport the number type implies that the normalization of the calling number must be performed before the call is presented to Unified CM. One place where the transformation can be performed is on the ingress SIP gateway. The following example configuration shows the translation rules that can be defined on a Cisco IOS gateway to accomplish this transformation:

```
voice translation-rule 1
  rule 1 // /+4940/ type subscriber subscriber
  rule 2 // /+49/ type national national
  rule 3 // /+/ type international international
  ...
voice translation-profile 1
  translate calling 1
  ...
dial-peer voice 300 voip
  translation-profile outgoing 1
  destination-pattern .T
  session protocol sipv2
  session target ipv4:9.6.3.12
  ...
```

When configured as in the example above, a Cisco IOS gateway using SIP to communicate with Unified CM will send calling party information digits normalized to the E.164 format, including the + sign. The Unified CM configuration will receive all calls from this gateway with a numbering type of "unknown" and would not need to add any prefixes.

For more details on configuring translation rules, refer to the document *Voice Translation Rules*, available at

http://www.cisco.com/en/US/tech/tk652/tk90/technologies_tech_note09186a0080325e8e.shtml

Unified CM can set the calling party number of outgoing calls to the normalized global format. The number-type in outgoing calls from the SIP trunk will be "unknown," and the Cisco IOS gateway should change it to International if no stripping is done, or perform a combination of stripping and numbering type change if required by the connected service provider.

SIP Trunk Service Types

Most SIP trunks are general-purpose trunks capable of connecting to a wide variety of SIP servers such as other Cisco Unified CMs, Cisco Unified Border Elements, Cisco Unified Gateways, and so forth. In addition to these all-purpose trunks, Unified CM provides SIP trunks dedicated for specific services. These special-purpose trunks enable technologies such as the following:

- Cisco Intercompany Media Engine (IME)
See [Cisco Intercompany Media Engine](#), page 5-34.
- Cisco Unified Communications Call Control Discovery (CCD) through the Cisco IOS Service Advertisement Framework (SAF)
See [Service Advertisement Framework \(SAF\)](#), page 3-72.
- Cisco Extension Mobility Cross Cluster (EMCC)
See [Extension Mobility Cross Cluster \(EMCC\)](#), page 19-9.

Design Considerations for SIP Trunks

Considerations for SIP Intercluster Trunks

For intercluster trunk connections, the SIP trunk configured in each cluster may be using standard Unified CM Groups or the **Run on all Active Unified CM Nodes** feature. The reasons for using each type of feature will typically be determined by the Unified CM version used in the cluster, or if clustering over the WAN has been deployed and geographically based call distribution is required.

Using Standard Unified CM Groups with SIP Intercluster Trunks

In this type of deployment standard Unified CM Groups are used by SIP intercluster trunks in each cluster. When defining this type of trunk with standard Unified CM Groups, you should define a maximum of three remote Unified CM servers as destination IP addresses in the remote cluster. The trunk will automatically load-balance across all defined remote Unified CM servers. In the remote cluster, it is important to configure a corresponding SIP intercluster trunk that has the same Unified CM nodes in its Unified CM Group as those defined as remote destination Unified CM servers in the first cluster.

For example, if Cluster 1 has a SIP trunk to Cluster 2 and Cluster 2 has a SIP trunk to Cluster 1, the following configurations would be needed (see [Figure 14-10](#)):

- Cluster 1
 - Servers B, C, and D are configured as members of the Unified CM Group defined in the device pool associated with the SIP trunk to Cluster 2.
 - The SIP trunk has Cluster 2's remote servers G, H, and I configured as destinations.
- Cluster 2
 - Servers G, H, and I are configured as members of the Unified CM Group defined in the device pool associated with the SIP trunk to Cluster 1.
 - The SIP trunk has Cluster 1's remote servers B, C, and D configured as destinations.

Figure 14-10 SIP Intercluster Trunks with Unified CM Groups

Using Run on All Active Unified CM Nodes with SIP Intercluster Trunks

In this type of deployment, **Run on all Active Unified CM Nodes** is used by SIP intercluster trunks in each cluster. When defining this type of trunk you may define up to 16 remote Unified CM servers in the destination cluster. (The number of remote servers that you need to define will depend on the number of active Unified CM nodes in the destination cluster.) The trunk will automatically load-balance calls across all defined remote destination servers. In the remote cluster, it is important to configure a corresponding SIP intercluster trunk that has **Run on all Active Unified CM Nodes** configured, where these nodes are defined as the remote destination Unified CM servers in the first cluster.

For example, if Cluster 1 (with four active nodes) has a SIP trunk to Cluster 2, and Cluster 2 (with five active nodes) has a SIP trunk to Cluster 1, the following configurations would be needed (see Figure 14-11):

- Cluster 1 has four active Unified CM nodes (A, B, C, and D).
 - Enabling **Run on all Active Unified CM Nodes** causes servers A, B, C, and D to have active SIP trunk daemons associated with the SIP trunk to Cluster 2.
 - The SIP trunk has Cluster 2's remote servers E, F, G, H, and I configured as destinations.

- Cluster 2 has five active Unified CM nodes (E, F, G, H, and I).
 - Enabling **Run on all Active Unified CM Nodes** causes servers E, F, G, H, and I to have active SIP trunk daemons associated with the SIP trunk to Cluster 1.
 - The SIP trunk has Cluster 1's remote servers A, B, C, and D configured.

Figure 14-11 SIP Intercluster Trunks Running on All Active Unified CM Nodes

Using Standard Unified CM Groups and Run on All Active Unified CM Nodes with SIP Intercluster Trunks

In this type of deployment, **Run on all Active Unified CM Nodes** is used by the SIP intercluster trunk in one cluster and standard Unified CM Groups are used by the SIP intercluster trunk in the other cluster. When configuring these trunks, the number of remote Unified CM server destinations that you define should match the number of active Unified CM nodes associated with the corresponding trunk in the destination cluster. The trunk will automatically load-balance calls across all defined remote destination Unified CM servers. In the remote cluster, it is important to configure a corresponding SIP intercluster trunk that has Unified CM nodes with active SIP daemons where these nodes are defined as remote destination Unified CM servers in the first cluster.

For example, if Cluster 1 has a trunk to Cluster 2, and Cluster 2 has a trunk to Cluster 1, the following configurations would be needed (see Figure 14-12):

- Cluster 1 has five active Unified CM nodes (A, B, C, D, and E).
 - Enabling **Run on all Active Unified CM Nodes** causes servers A, B, C, D, and E to have active SIP trunk daemons associated with the SIP trunk to Cluster 2.
 - The SIP trunk has Cluster 2's remote servers G, H, and I configured as destinations.
- Cluster 2 has five active Unified CM nodes and uses an intercluster trunk with a Unified CM Group containing nodes G, H, and I.
 - Servers G, H, and I are configured as members of the Unified CM Group defined in the device pool associated with the SIP trunk to Cluster 1.
 - The SIP trunk has Cluster 1's remote servers A, B, C, D, and E configured as destinations.

Figure 14-12 SIP Intercluster Trunks Using Unified CM Groups and Run on All Active Unified CM Nodes

Trunk Type and Feature Recommendations for Multi-Cluster Deployments

Multiple Clusters All Running Unified CM 8.5 or Later Releases

Where all clusters are running Unified CM 8.5 or later releases, the following SIP trunk features should be used where applicable (see [Figure 14-13](#)):

- SIP OPTIONS Ping
- SIP Delayed Offer
- Early Offer support for Voice and Video (insert MTP if needed)
- Run on All Active Unified CM Nodes
- Multiple destination IP addresses
- QSIG over SIP
- SIP Normalization and Transparency

Deploying these features reduces MTP usage and provides high availability, even call distribution, and dynamic SIP trunk failure detection. In general, for outbound calls from Unified CM SIP trunks, Delayed Offer is preferred because MTPs are not required to establish a Delayed Offer call. For inbound calls to Unified CM SIP trunks, Early Offer or Delayed Offer (or a mixture of both Early Offer and Delayed Offer) can be used.

SIP intercluster trunks support voice, video, and encrypted media between Unified CM clusters, and all of the above features can be used. SIP Delayed Offer is preferred for intercluster trunks because MTPs are not required to establish a Delayed Offer call. If multiple trunks are used with route lists, enable the **Run on All Active Unified CM Nodes** feature on the route lists.

For SIP trunks to an IP PSTN, SIP Early Offer is typically required by the service provider, and most providers support voice calls only. However, if required, video calls and encrypted media are also supported. Where SIP Early Offer is required by the Service Provider, the Cisco Unified Border Element (SIP Delayed Offer to Early Offer feature) can be used as an alternative to configuring Early Offer on the Unified CM SIP trunk. For inbound calls to Unified CM SIP trunks, Early Offer or Delayed Offer (or a mixture of both Early Offer and Delayed Offer) can be used. When connecting to a service provider's IP PSTN network, Cisco strongly recommends the use of the Cisco Unified Border Element as an enterprise edge Session Border Controller to provide a controlled demarcation and security point between your enterprise and the service provider's network.

SIP trunks to third-party unified communications systems may support voice, video, and encrypted media. Check the capabilities of the end system to determine the SIP trunk features and media capabilities that it supports. For outbound calls from Unified CM SIP trunks, Delayed Offer is preferred because MTPs are not required to establish a Delayed Offer call. For inbound calls to Unified CM SIP trunks, Early Offer or Delayed Offer (or a mixture of both Early Offer and Delayed Offer) can be used.

**Note**

SIP trunks on Cisco IOS gateways always send Early Offer.

For SIP trunk connections to the IP PSTN and third-party unified communications systems, normalization and transparency scripts can be used to address SIP interoperability issues.

Figure 14-13 Multi-Cluster Deployments with Unified CM 8.5 and Later Releases

Multiple Clusters Running Unified CM 8.5 and Prior Releases

When the leaf clusters are running Unified CM 8.5 in combination with prior releases of Unified CM, the following trunk types and features should be used (see [Figure 14-14](#)):

When the leaf cluster is running an earlier version (pre-8.5) of Unified CM and voice, video, and encryption are required, use H.323 Slow Start intercluster trunks and Annex M1 (QSIG) if desired. Deploy one or more H.323 Slow Start intercluster trunks using standard Unified CM Groups and up to three destination IP addresses. If multiple trunks are used with route lists, to avoid the Route Local rule (described earlier) ensure that the primary server in the route list's Unified CM Group does not reside on the same node as an associated outbound H.323 trunk.

For leaf clusters running Unified CM 8.5, use a SIP Delayed Offer intercluster trunk, enable **Run on All Active Unified CM Nodes**, and use multiple destination IP addresses and SIP OPTIONS Ping for high availability and even call distribution. If multiple trunks are used with route lists, enable the **Run on All Active Unified CM Nodes** feature on the route lists.

Using SIP Delayed Offer intercluster trunks on Unified CM 8.5 leaf clusters and H.323 Slow Start intercluster trunks on leaf clusters using earlier versions of Unified CM, allows voice, video, and encrypted calls to be made between clusters and reduces the number MTPs required. (MTPs are inserted only when required for DTMF translation, transcoding, and so forth.)

For SIP trunks to an IP PSTN, SIP Early Offer is typically required by the service provider, and most providers support voice calls only. However, if required, video calls and encrypted media are also supported. Where SIP Early Offer is required by the service provider, the Cisco Unified Border Element (SIP Delayed Offer to Early Offer feature) can be used as an alternative to configuring Early Offer on the Unified CM SIP trunk. For inbound calls to Unified CM SIP trunks, Early Offer or Delayed Offer (or a mixture of both Early Offer and Delayed Offer) can be used. When connecting to a service provider's IP PSTN network, Cisco strongly recommends the use of the Cisco Unified Border Element as an enterprise edge Session Border Controller to provide a controlled demarcation and security point between your enterprise and the service provider's network.

SIP trunks to third-party unified communications systems may support voice, video, and encrypted media. Check the capabilities of the end system to determine the SIP trunk features and media capabilities that it supports. For outbound calls from Unified CM SIP trunks, Delayed Offer is preferred because MTPs are not required to establish a Delayed Offer call. For inbound calls to Unified CM SIP trunks, Early Offer or Delayed Offer (or a mixture of both Early Offer and Delayed Offer) can be used.

**Note**

SIP trunks on Cisco IOS gateways always send Early Offer.

For Unified CM SIP trunk connections to the IP PSTN and third-party unified communications systems, normalization and transparency scripts can be used to address SIP interoperability issues.

Figure 14-14 Multi-Cluster Deployments with Unified CM 8.5 and Prior Releases

Trunk Design Considerations for Clustering over the WAN

When deploying clustering over the WAN for spatial resilience and redundancy, SIP trunk features such as OPTIONS Ping and QSIG can be used as required and appropriate. SIP and H.323 trunk features such as **Run on all Unified CM Nodes** and multiple destination addresses should be used with consideration, primarily because of the mechanism that trunks use to identify and accept inbound calls. (A trunk will accept a call if the incoming source IP address matches one of the addresses defined as its destination IP address.)

For clustering over the WAN deployments where calls need to be routed to different groups of Unified CM nodes based on their geographic location, consideration should be given to the trunk configuration for both inbound and outbound calls. This is described in the following section, using a Unified CM Session Management Edition cluster that is clustered over the WAN as an example.

Design Guidance for Clustering over the WAN with Leaf Cluster Trunks

Create and prioritize multiple SIP trunks in route lists in each leaf cluster to distribute calls to each group of Unified CM Session Management Edition nodes in each data center, and run route lists on all nodes. (See Figure 14-15.)

Enable **Run on all Nodes** on each leaf cluster SIP trunk (each SIP trunk must use a unique incoming port number). Define destination IP addresses per trunk for geographic call distribution.

Figure 14-15 Calls from Leaf Clusters to Unified CM Session Management Edition

254793

Design Guidance for Clustering over the WAN with Unified CM Session Management Edition Cluster Trunks

For each leaf cluster, create a single SIP trunk on the Unified CM Session Management Edition cluster. Enable **Run on all Unified CM Nodes** on this SME trunk and configure destination IP addresses for each call processing node in the leaf cluster. (See [Figure 14-16](#).)

Figure 14-16 Calls from Unified CM Session Management Edition to Leaf Clusters

254794

Other SIP Trunk Deployment Considerations

For outbound calls from Unified CM SIP trunks with connections to third-party devices such as SIP-based PBXs or service-provider IP PSTN connections, Delayed Offer is preferred because MTPs are not required to establish a Delayed Offer call (except in cases where a mismatch in DTMF transport types exists between the called and calling endpoints, in which case Unified CM will insert an MTP dynamically). For inbound calls to Unified CM SIP Trunks, Early Offer or Delayed Offer (or a mixture of both Early Offer and Delayed Offer) can be used.

Voice clipping, if observed, can be minimized or eliminated by enabling PRACK on the trunk. This parameter can be enabled in the Service Parameters for the Cisco CallManager Service (SIP Rel1XX Enabled).

Other operating parameters for security settings and the types of messages accepted over a SIP trunk can be enabled in the SIP Trunk Security Profile. Here you can set parameters not only for TLS and Digest Authentication, but also for whether or not the trunk will accept Presence Subscription, an out-of-dialog REFER message, Replaces header, or an Unsolicited Notify message.

SIP trunks support topology-aware RSVP call admission control using SIP Preconditions and locations-based call admission control which is unaware of the underlying WAN topology.

For connection to service provider networks, Cisco recommends the use of the Cisco Unified Border Element. In addition to providing a demarcation point between the enterprise and service provider networks, the Cisco Unified Border Element can also be used for address hiding and enhancing SIP signaling interoperability between the two networks.

For more information on the Cisco Unified Border Element, refer to the documentation available at

<http://www.cisco.com/en/US/products/sw/voicesw/ps5640/index.html>

H.323 Trunks Overview

H.323 trunks provide connectivity to other H.323 devices such as gateways, Unified CM Session Management Edition, gatekeepers, Unified Communications applications, and other Unified CM clusters. Cisco Unified CM 8.5 and later releases provide the following call routing enhancement for all H.323 trunk types:

- Run route lists on all Unified CM nodes

In addition to this, H.323 non-gatekeeper controlled intercluster trunks also support the following features:

- Run on all Unified CM nodes
- Up to 16 destination IP addresses per trunk

These two features improve outbound call distribution from Unified CM clusters and reduce the number of H.323 non-gatekeeper controlled intercluster trunks required between clusters.

These features and their operation are discussed in detail later in this section.

For the complete list of new enhancements for H.323 trunks, refer to the latest Cisco Unified Communications Manager product release notes available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_release_notes_list.html

General H.323 Intercluster Trunk Deployment Considerations

Prior to Unified CM 8.5, H.323 Annex M1 trunks were the preferred choice for connections between Unified CM clusters. Unified CM SIP trunks now offer a greater set of features in comparison with H.323 intercluster trunks, thus making SIP the protocol of choice for intercluster trunk connections. However, the majority of Unified CM clusters using earlier software versions are likely to be deployed with H.323 Annex M1 intercluster trunks, and this may determine the intercluster trunk type that you use to these clusters.

Basic Operation of H.323 Trunks

H.323 trunks provide connectivity to other Unified CM clusters and other H.323 devices such as gateways. H.323 trunks support most of the audio and video codecs that Unified CM supports for intra-cluster communications, with the exception of wideband audio and wideband video.

H.323 trunks use the Empty Capabilities Set (ECS) to provide supplementary call services such as hold/resume and transfer. This method is a standard H.245 mechanism to stop or close a media stream (or channel) and start or open it to the same or a different endpoint address. This method allows Unified CM to keep a call active while still being able to control the source and destination of the media streams on the fly.

For example, consider a call between two clusters (A and B) using the H.323 trunk. When a user in cluster A places a user in cluster B on hold, the media streams between the two users are closed and the user in cluster B is connected to a music on hold (MoH) server in cluster A. The MoH server is instructed to send media (the music file) to the user. When the user in cluster A resumes the call, the MoH stream is closed and the two-way media streams are reopened between the two users. (Unified CM does not support H.450 for supplementary call services.) In this case, MoH is an example of an ECS operation. H.323 trunks support multicast MoH, therefore the media resource group list (MRGL) for the H.323 trunks can contain both unicast and multicast MoH sources. (For details, see [Music on Hold, page 17-21](#).)

The bandwidth used for calls on H.323 trunks can be controlled by the use of regions configured in Unified CM and assigned to each trunk. A region limits the amount of bandwidth allocated for calls by specifying the inter-region Max Audio Bit Rate for audio and the inter-region Max Video Call Bit Rate setting for video (that includes audio). Calls between one region and another region must be within the specified bandwidth limit. If the device making the call over the H.323 trunk is in a more restrictive region or does not support a particular codec such as video, then it is a subset of codecs that are allowed for that call.

H.323 Trunk Types

The following major types of H.323 trunks can be configured in a Unified CM:

- [Intercluster Trunk \(Non-Gatekeeper Controlled\)](#), page 14-38
- [Intercluster Trunk \(Gatekeeper Controlled\)](#), page 14-44
- [H.225 Trunk \(Gatekeeper Controlled\)](#), page 14-45

Each of these H.323 trunk types and their specific design considerations are discussed in the following sections.

Intercluster Trunk (Non-Gatekeeper Controlled)

This trunk is the simplest H.323 trunk type and is used for connecting to other Unified CM clusters in either a multi-cluster single campus or a distributed call processing deployment. This trunk does not use a gatekeeper for call admission control, although it may use locations configured in Unified CM if bandwidth control is required.

Cisco Unified CM 8.5 and later releases support the following trunk features and call routing enhancements for H.323 non-gatekeeper controlled intercluster trunks:

- Run on all active Unified CM nodes
- Up to 16 destination IP addresses per trunk
- Run route lists on all Unified CM nodes

These features are discussed in the following sections.

H.323 Non-Gatekeeper Intercluster Trunks Running on all Active Unified CM Nodes

When the **Run on all Active Unified CM Nodes** option is checked on a H.323 non-gatekeeper intercluster trunk, Unified CM creates an instance of the H.323 trunk daemon on every call processing Unified CM Group. This allows H.323 non-gatekeeper intercluster trunk calls to be made or received on any call processing subscriber. With **Run on all Active Unified CM Nodes** enabled, outbound H.323 non-gatekeeper intercluster trunk calls originate from the same server on which the inbound call (for example, from a phone or trunk) is received. As with all Unified CM H.323 non-gatekeeper intercluster trunks, the H.323 daemons associated with the trunk will accept only inbound calls from end systems with IP addresses that are defined in the trunk's destination address fields. Running the H.323 non-gatekeeper intercluster trunk on all nodes is recommended where the H.323 a non-gatekeeper intercluster trunk is required to process a large number of calls, so that outbound and inbound call distribution can be evenly spread across all call processing subscribers within a cluster. Bear in mind that (unlike SIP trunks) H.323 non-gatekeeper intercluster trunks use a fixed destination port and an ephemeral source, and therefore H. 323 non-gatekeeper intercluster trunks cannot be differentiated using port numbers. When configuring H.323 non-gatekeeper intercluster trunks, make sure that each trunk uses different destination IP addresses when **Run on all Active Unified CM Nodes** is enabled.

Up to 16 Destination IP Addresses per H.323 Non-Gatekeeper Intercluster Trunk

An H.323 non-gatekeeper intercluster trunk can be configured with up to 16 destination IP addresses. Support for additional destination IP addresses reduces the need to create multiple trunks associated with route lists and route groups for call distribution between two Unified Communications systems, thus simplifying Unified CM trunk design. This feature can be used in conjunction with the **Run on all Active Unified CM Nodes** feature. Bear in mind, however, that the H.323 daemons associated with a Unified CM H.323 non-gatekeeper intercluster trunk will accept only inbound calls from end systems with IP addresses that are defined in the trunk's destination address fields.

Route Lists Running on All Active Unified CM Nodes

Although this is not specifically an H.323 non-gatekeeper intercluster trunk feature, running route lists on all nodes provides benefits for trunks in route lists and route groups. Running route lists on all nodes improves outbound call distribution by using the Route Local rule to avoid unnecessary intra-cluster traffic.

For route lists, the Route Local rule operates as follows:

For outbound calls that use route lists and associated route groups and trunks, when a call from a registered phone or inbound trunk arrives at the node with the route list instance associated with the trunk selected for the outbound call, Unified CM checks to see if an instance of the selected outbound trunk exists on the same node as the route list. If so, Unified CM will use this node to establish the outbound trunk call.

If both the route list and the selected outbound trunk have **Run on all Active Unified CM Nodes** enabled, outbound call distribution will be determined by the node on which the inbound call arrives. When the selected outbound trunk uses Unified Groups instead of running on all nodes, Unified CM will apply the Route Local rule if an instance of the selected outbound trunk exists on the same node on which the inbound call arrived. If an instance of the trunk does not exist on this node, then Unified CM will forward the call (within the cluster) to a node where the trunk is active.

If the route list does not have **Run on all Active Unified CM Nodes** enabled, the route list will be active on one node within the cluster (the primary node in the route list's Unified Group) and the Route Local rule will be applied on this node.

As a general recommendation, **Run on all Active Unified CM Nodes** should be enabled for all route lists.

Design Considerations for H.323 Non-Gatekeeper Intercluster Trunks

For intercluster trunk connections, the H.323 non-gatekeeper intercluster trunk configured in each cluster may be using standard Unified CM Groups or the **Run on all Active Unified CM Nodes** feature. The reasons for using each type of feature will typically be determined by the Unified CM version used by a cluster, or if clustering over the WAN has been deployed and geographically based call distribution is required.

Using Standard Unified CM Groups with H.323 Non-Gatekeeper Intercluster Trunks

In this type of deployment, standard Unified CM Groups are used by H.323 non-gatekeeper intercluster trunks in each cluster. When defining this type of trunk with standard Unified CM Groups, you should define a maximum of three remote Unified CM servers in the destination cluster. The trunk will automatically load-balance calls across all servers defined as remote destination addresses. In the remote cluster, it is important to configure a corresponding intercluster trunk (non-gatekeeper controlled) that has the same Unified CM nodes in its Unified CM Group as those defined as remote destination Unified CM servers in the first cluster.

For example, if Cluster 1 has a trunk to Cluster 2, and Cluster 2 has a trunk to Cluster 1, the following configurations would be needed (see [Figure 14-17](#)):

- Cluster 1
 - Servers B, C, and D are configured as members of the Unified CM Group defined in the device pool associated with the non-gatekeeper controlled trunk to Cluster 2.
 - The non-gatekeeper controlled trunk has Cluster 2's remote servers G, H, and I configured as destinations.
- Cluster 2
 - Servers G, H, and I are configured as members of the Unified CM Group defined in the device pool associated with the non-gatekeeper controlled trunk to Cluster 1.
 - The non-gatekeeper controlled trunk has Cluster 1's remote servers B, C, and D configured as destinations.

Figure 14-17 H.323 Non-Gatekeeper Intercluster Trunks Using Standard Unified CM Groups

Using Run on All Active Unified Nodes with H.323 Non-Gatekeeper Intercluster Trunks

In this type of deployment, **Run on all Active Unified CM Nodes** is used by the H.323 non-gatekeeper intercluster trunks in each cluster. When defining this type of trunk, you may define up to 16 remote Unified CM servers in the destination cluster. (The number of remote servers that you need will depend on the number of active Unified CM nodes in the destination cluster.) The trunk will automatically load-balance calls across all defined remote destination Unified CM servers. In the remote cluster, it is important to configure a corresponding intercluster trunk (non-gatekeeper controlled) that has **Run on all Active Unified CM Nodes** configured, where these nodes are defined as the remote destination Unified CM servers in the first cluster.

For example, if Cluster 1 (four nodes) has a trunk to Cluster 2, and Cluster 2 (five nodes) has a trunk to Cluster 1, the following configurations would be needed (see Figure 14-18):

- Cluster 1 has four active Unified CM nodes (A, B, C, and D).
 - Enabling **Run on all active Unified CM Nodes** causes servers A, B, C, and D to have active H.323 trunk daemons associated with the non-gatekeeper controlled trunk to Cluster 2.
 - The non-gatekeeper controlled trunk has Cluster 2's remote servers E, F, G, H, and I configured as destinations.

- Cluster 2 has five active Unified CM nodes (E, F, G, H, and I).
 - Enabling Run on all active Unified CM Nodes causes servers E, F, G, H, and I to have active H.323 trunk daemons associated with the non-gatekeeper controlled trunk to Cluster 2.
 - The non-gatekeeper controlled trunk has Cluster 1's remote servers A, B, C, and D configured.

Figure 14-18 H.323 Non-Gatekeeper Intercluster Trunks Using Run on All Active Unified Nodes

Using Standard Unified CM Groups and Run on All Active Unified CM Nodes with H.323 Non-Gatekeeper Intercluster Trunks

In this type of deployment, **Run on all Active Unified CM Nodes** is used by the H.323 non-gatekeeper intercluster trunk in one cluster, and standard Unified CM Groups are used by the H.323 non-gatekeeper intercluster trunk in the other cluster. When configuring these trunks, the number of remote Unified CM server destinations that you define should match the number of active Unified CM nodes for the corresponding trunk in the destination cluster. The trunk will automatically load-balance calls across all defined remote destination Unified CM servers. In the remote cluster, it is important to configure a corresponding intercluster trunk (non-gatekeeper controlled) that has Unified CM nodes with active H.323 daemons where these nodes are defined as remote destination Unified CM servers in the first cluster.

For example, if Cluster 1 has a trunk to Cluster 2, and Cluster 2 has a trunk to Cluster 1, the following configurations would be needed (see Figure 14-19):

- Cluster 1 has five active Unified CM nodes (A, B, C, D, and E).
 - Enabling **Run on all Active Unified CM Nodes** causes servers A, B, C, D, and E to have active H.323 trunk daemons associated with the non-gatekeeper controlled trunk to Cluster 2.
 - The non-gatekeeper controlled trunk has Cluster 2's remote servers G, H, and I configured as destinations.
- Cluster 2 has five active Unified CM nodes and uses an intercluster trunk with a Unified CM Group containing nodes G, H, and I.
 - Servers G, H, and I are configured as members of the Unified CM Group defined in the device pool associated with the non-gatekeeper controlled trunk to Cluster 1.
 - The non-gatekeeper controlled trunk has Cluster 1's remote servers A, B, C, D, and E configured as destinations.

High Availability for Non-Gatekeeper Controlled Intercluster Trunks

High availability and redundancy for H.323 non-gatekeeper intercluster trunks can be provided by using multiple source Unified CM servers for originating calls and multiple destination IP addresses per trunk.

Multiple Source Unified CM Servers for Originating H.323 Non-Gatekeeper Intercluster Trunk Calls

- Using standard Unified CM Groups

The nodes defined in the Unified CM Group associated with an individual trunk make up the set of servers that can place or receive calls over that trunk. Up to three nodes can be defined in a Unified CM Group, thus ensuring high availability of the trunk itself.

- Using **Run on all Active Unified CM Nodes**

The **Run on all Active Unified CM Nodes** feature creates and enables an H.323 trunk instance on each call processing subscriber within the cluster, thus allowing these nodes to place or receive calls over that trunk.

- The Unified CM Route Local feature and its effect of subscriber selection for outbound H.323 non-gatekeeper intercluster trunk calls

The Route Local feature in Unified CM is designed to reduce intra-cluster traffic. The feature operates as follows: When a device such as a phone is making an outbound call over H.323 intercluster trunk ICT 1, if an instance of H.323 ICT 1 is active on the same node as the one to which the phone is registered, then always use this co-located H.323 ICT 1 instance rather than internally route the call to another H.323 ICT 1 instance on another node within the cluster.

The effect of the Route Local feature on node selection depends on whether Unified CM Groups or **Run on all Active Unified CM Nodes** is configured on the trunk. For trunks with **Run on all Active Unified CM Nodes** configured, the node to which the calling device is registered is used to make the outbound H.323 intercluster trunk call. When Unified CM Groups are used on the trunk, if the calling device is registered to one of the nodes in the trunk's Unified CM Group, then the Route Local rule applies. If the calling device is not registered to one of the nodes in the trunk's Unified CM Group, then Unified CM will randomly distribute the call over the nodes in the trunk's Unified CM Group.

In general, using **Run on all Active Unified CM Nodes** is recommended for H.323 intercluster trunks because call distribution across nodes is determined by the calling device and intra-cluster traffic is minimized.

Multiple Destination IP Addresses per H.323 Non-Gatekeeper Intercluster Trunks

A single H.323 non-gatekeeper intercluster trunk can be configured with up to 16 destination IP addresses. Unified CM uses round-robin distribution to the configured destination IP addresses when placing calls over an H.323 non-gatekeeper intercluster trunk.

Design Considerations When Using Run on All Active Unified CM Nodes

When using **Run on All Active Unified CM Nodes** in conjunction with multiple destination addresses, be aware that to accept inbound calls, the inbound source IP address received on the H.323 trunk must match with a configured destination IP address on the inbound trunk. Where clustering over the WAN designs are deployed and geographic call distribution and failover are required, use standard Unified CM Groups on multiple intercluster trunks (each with up to three destination IP addresses) in conjunction with route lists and route groups.

Load Balancing for H.323 Non-Gatekeeper Intercluster Trunks

When designing load balancing for H.323 non-gatekeeper intercluster trunks, consider both the node that sources the call and its destination. With H.323 non-gatekeeper intercluster trunks, the node that originates the call is determined by the Route Local rule, the number of nodes on which the outbound trunk is active, and whether a route list is used in conjunction with multiple outbound trunks. These considerations are discussed below.

Outbound Calls over a Single H.323 Non-Gatekeeper Intercluster Trunk

A single H.323 non-gatekeeper intercluster trunk can run on up to three Unified CM nodes in a Unified CM Group or on all active Unified CM nodes in the cluster. To select the source node for outbound calls, Unified CM applies the following decision processes:

Where an instance of the trunk runs on all nodes, the Route Local rule applies and the node used for each outbound call is determined by the node on which the call arrives (for example, the node to which the calling phone is registered or the node on which the inbound trunk call arrives). Where Unified CM Groups are used, the route local rule still applies for those calling devices that are registered to the same node as the nodes in the trunk's Unified CM Group. For calling devices that are registered to other servers within the cluster, Unified CM will randomly distribute calls across the nodes in the trunk's Unified CM Group. Unified CM uses round-robin call distribution across the trunk's configured destination addresses. H.323 non-gatekeeper intercluster trunks may be configured with up to 16 destination IP addresses.

Outbound Calls over Multiple H.323 Non-Gatekeeper Intercluster Trunks

Because H.323 non-gatekeeper intercluster trunks can run on all active Unified CM nodes and have up to 16 destination addresses, you typically do not have to use multiple H.323 non-gatekeeper intercluster trunks to provide even call distribution between two Unified Communications clusters. Where multiple trunks are used with route lists and route groups, route lists should be enabled to run on all active Unified CM nodes. Multiple H.323 trunks are often used in conjunction with route lists to provide failover to the PSTN or to a group of Unified CM servers in a different site as part of a clustering over the WAN deployment. The selection of the Unified CM node used to initiate an outbound trunk call and the distribution of calls over the trunk's configured destination IP addresses is determined in the same way as described for single trunks. Where clustering over the WAN designs are deployed and geographic call distribution and failover are required, use multiple intercluster trunks (each with up to three destination IP addresses) with standard Unified CM Groups in conjunction with route lists and route groups.

Intercluster Trunk (Gatekeeper Controlled)

The intercluster gatekeeper controlled trunk can be used instead of the non-gatekeeper controlled trunk to interconnect a large number of Unified CM clusters. The advantages of using the gatekeeper controlled trunk are mainly the overall administration of the cluster and failover times. With non-gatekeeper controlled trunks, if a subscriber server in a cluster becomes unreachable, there will be a 5-second (default) timeout while the call is attempted. If an entire cluster is unreachable, the number of attempts before either call failure or rerouting over the PSTN will depend on the number of remote servers defined for the trunk and on the number of trunks in the route list or route group (if any). If there are many remote servers and many non-gatekeeper controlled trunks, the call delay can become excessive.

With a H.323 gatekeeper controlled trunk, you configure only one trunk that can then communicate by means of the gatekeeper with all other clusters registered to the gatekeeper. If a cluster or subscriber becomes unreachable, the gatekeeper automatically directs the call to another subscriber in the cluster or rejects the call if no other possibilities exist, thus allowing the call to be rerouted over the PSTN (if

required) with little incurred delay. With a single Cisco gatekeeper, it is possible to have 100 clusters all registering a single trunk each, with all clusters being able to call each other. The gatekeeper controlled intercluster trunk should be used for communicating only with other Unified CMs because the use of this trunk with other H.323 devices might cause problems with supplementary services.

**Note**

Gatekeeper controlled trunks do not support the **Run on All Active Unified CM Nodes** feature, and only standard Unified CM Groups are supported. Destination addresses are returned to Unified CM by the gatekeeper. Where gatekeeper controlled trunks are used in route lists, Cisco recommends enabling the **Run on All Active Unified CM Nodes** feature on the route list.

H.225 Trunk (Gatekeeper Controlled)

The H.225 gatekeeper controlled trunk is essentially the same as the intercluster gatekeeper controlled trunk except that it has the capability of working with Unified CM clusters as well as other H.323 devices such as gateways, conferencing systems, and clients. This capability is achieved through a discovery mechanism on a call-by-call basis. (See [H.323 Operation in Unified CM, page 14-51](#), for details of this discovery process.)

**Note**

Gatekeeper controlled trunks do not support the **Run on All Active Unified CM Nodes** feature, and only standard Unified CM Groups are supported. Destination addresses are returned to Unified CM by the gatekeeper. Where gatekeeper controlled trunks are used in route lists, Cisco recommends enabling the **Run on All Active Unified CM Nodes** feature on the route list.

High Availability for Gatekeeper Controlled Trunks

Redundancy can be achieved in several ways, depending on the requirements of the design. The simplest method is to configure a gatekeeper controlled trunk and assign up to three subscribers in the Unified CM Group associated with the device pool assigned to that trunk. This configuration will cause all servers to register with the same gatekeeper in the same zone with the same technology prefix. However, the H.323 trunk name that is used for the h323_id will have a suffix of "_n" where *n* is the node number in the cluster. This ID is automatically generated and cannot be changed. You configure a single trunk, but the gatekeeper registers multiple trunks, one from each subscriber in the Unified CM Group.

If you have additional redundancy requirements, it is possible to configure another gatekeeper controlled trunk with a different name and different subscribers in the Unified CM Group, but with all the other parameters identical to the first trunk. This second trunk will cause additional subscribers to register with the gatekeeper.

Cisco recommends assigning device pools that contain a Unified CM Group consisting of the two servers that make up the standard subscriber pair. (See [Call Processing Subscriber Redundancy, page 8-19](#), for more information on subscriber redundancy.) For complete redundancy in each full cluster, four trunks would be needed, using four different device pools and resulting in eight subscribers registering with the gatekeeper. (The same result could be achieved with three trunks and larger Unified CM Groups.)

During registration, several parameters are passed between Unified CM and the gatekeeper. Unified CM uses an ephemeral User Datagram Protocol (UDP) port for gatekeeper Registration Admission Status (RAS) messages. This port would normally be UDP 1719. However, Unified CM must be able to identify precisely which H.323 daemon is the originator of a RAS message from a particular server; therefore it uses a range of UDP ports and assigns them dynamically.

During the registration process, a trunk registers the following information for the other subscribers in its Unified CM Group:

- H.225 call signaling port
- h323_id
- CanMapAlias support
- Technology prefix
- H.225 call signaling address

If the recommended clustered gatekeepers are used, the gatekeeper will return a list of alternate gatekeeper addresses that may be used if the primary gatekeeper fails or does not have sufficient available resources.

Figure 14-20 shows a cluster of gatekeepers that use Gatekeeper Update Protocol (GUP) to communicate. (See the chapter on Call Processing, page 8-1, for more information on gatekeepers.)

Figure 14-20 Gatekeeper Cluster

If an H.323 trunk has only a single subscriber in its Unified CM Group, there will be only one connection between the configured gatekeeper in Unified CM and the gatekeeper cluster, as illustrated in Figure 14-21.

Figure 14-21 H.323 Trunk with a Single Unified CM Subscriber

If there are multiple subscribers in the Unified CM Group associated with the trunk, additional connections will be established between the Unified CM cluster and the gatekeeper cluster, as illustrated in Figure 14-22.

Figure 14-22 H.323 Trunk with Multiple Unified CM Subscribers

This approach provides redundancy for subscriber failures as well as gatekeeper failures after registration because the alternate gatekeeper is communicated when the trunk registers. This approach does not, however, provide redundancy if the configured gatekeeper is unavailable at initial registration or following a reset because the list of alternate gatekeepers is dynamic and not stored in the database. To provide an additional level of redundancy as well as load balancing, an additional gatekeeper from the gatekeeper cluster is configured in Unified CM. For example, if the original trunk is registered with Element 2, the additional gatekeeper could be configured as Element 4, as illustrated in [Figure 14-23](#).

Figure 14-23 Additional Gatekeeper Configured for Load Balancing and Additional Redundancy

The Unified CM configuration for the example in [Figure 14-23](#) would contain the following components:

- Two gatekeepers for Element 2 and Element 4
- Two H.323 trunks defined with a Unified CM Group containing subscriber servers A and B

Using this approach, the Unified CM cluster will still be able to register when either Element 2 or Element 4 is not reachable during initial registration (that is, during power-up or trunk reset).

Load balancing of calls inbound to the Unified CM cluster is done automatic by default because the gatekeeper randomly selects one of the subscribers registered within the zone. If this is not the desired behavior, you can use the **gw-priority** configuration command in the gatekeeper to modify this default behavior, as illustrated in [Example 14-3](#).

Example 14-3 Using the gw-priority Command to Direct Calls to a Particular Trunk

```

gatekeeper
zone local SJC cisco.com 10.0.1.10
zone prefix SJC 1408..... gw-priority 10 sjc-trunk_2
zone prefix SJC 1408..... gw-priority 9 sjc-trunk_3
zone prefix SJC 1408..... gw-default-priority 0
gw-type-prefix 1#* default-technology
arq reject-unknown-prefix
no shutdown
endpoint ttl 60

```

In [Example 14-3](#), the H.323 trunk was configured as sjc-trunk in Unified CM, and the “_2” and “_3” suffixes are appended automatically by the Unified CM subscribers to indicate which node number they are in the cluster. Therefore, this example uses node 2 as the first choice, which should be the highest-priority Unified CM in the Unified CM Group for this trunk. Node 3 is the second choice in this case.

The use of **gw-default-priority 0** is optional. It was used in this example to disable the use of any other trunk that might accidentally be configured to register in this zone.

Load Balancing Outbound Calls over H.323 Gatekeeper Controlled Trunks

With Unified CM H.323 gatekeeper controlled trunks, the node from which the call originates is determined by the Route Local rule, the number of nodes on which the outbound trunk is active, and whether a route list is used in conjunction with multiple outbound trunks. These considerations are discussed below.

Outbound Call Load Balancing When Deploying a Single H.323 Gatekeeper Controlled Trunk

For the initiation of outbound calls over a single H.323 gatekeeper controlled trunk, the route local rule applies and the following factors within a Unified CM cluster determine which server is selected:

- Which Unified CM servers have an active H.323 daemon for the selected trunk
- Whether the phone originating the call is registered to a Unified CM server with an active H.323 daemon for the selected trunk

For a single H.323 gatekeeper controlled trunk, the Route Local process of server selection for outgoing calls operates as follows:

- If there is an active H.323 daemon for the selected trunk on the Unified CM server to which the phone or device originating the call is registered (that is, if the server is one of those listed in the trunk's Unified CM Group), then use this Unified CM server to originate the H.323 call.
- If there is no active H.323 daemon for the selected trunk on the Unified CM server to which the phone or device originating the call is registered, then select a server on a round-robin basis from the Unified CM Group of the selected trunk.

Outbound Call Load Balancing When Deploying Route Lists in Conjunction with H.323 Gatekeeper Controlled Trunks

In configurations where route lists are employed to select a trunk for outbound calls, enable **Run on all Active Unified CM Nodes** for all route lists. Running route lists on all nodes improves outbound call distribution by using the Route Local rule to avoid unnecessary intra-cluster traffic. For route lists, the Route Local rule operates as follows:

For outbound calls that use route lists (and associated route groups and trunks), when a call (from a registered phone or inbound trunk) arrives at the node with the route list instance associated with the outbound trunk call, Unified CM checks to see if an instance of the selected outbound trunk call exists on the same node as the route list. If so, Unified CM will use this node to establish the outbound trunk call.

If the route list has **Run on all Active Unified CM Nodes** enabled: For gatekeeper controlled trunks using Unified CM Groups, Unified CM will apply the route local rule if an instance of the selected outbound trunk exists on the same node on which the inbound call arrived. If an instance of the trunk does not exist on this node, then Unified CM will forward the call (within the cluster) to a node where the trunk is active.

If the route list does not have **Run on all Active Unified CM Nodes** enabled, the route list will be active on one node within the cluster (the primary node in the route list's Unified CM Group) and the Route Local rule will be applied on this node.

H.323 Outbound Fast Start Call Connections

Calls that are placed from IP phones over large WAN topologies with long delays can experience voice clipping when the called party goes off-hook to answer the call. When H.323 trunks or gateways are separated from the Unified CM server, significant delays can occur because of the many H.245 messages that are exchanged when a call is set up.

With the Fast Start feature, information that is required to complete a media connection between two parties gets exchanged during the H.225 portion of call setup, and this exchange eliminates the need for H.245 messages. The connection experiences one round-trip WAN delay during call setup, and the calling party does not experience voice clipping when the called party answers the call.

Unified CM uses media termination points (MTPs) for making an H.323 outbound Fast Start call. Unified CM starts an outbound Fast Start call by allocating an MTP and opening the receive channel. Next, the H.323 Fast Connect procedure sends the SETUP message with a Fast Start element to the called endpoint. The Fast Start element includes information about the receiving channel for the MTP.

By default, H.323 Fast Start is disabled. To enable H.323 Fast Start, check the **MTP Required** and **Enable Outbound FastStart** checkboxes on the H.323 trunk, and select the desired Codec For Outbound Fast Start. Also note that Inbound Fast Start is enabled separately with check box **Enable Inbound FastStart**. (Inbound Fast Start does not require an MTP or a codec selection.)

Note

When H.323 Fast Start is enabled, an MTP is assigned for every outbound H.323 trunk call. MTPs used for H.323 Fast Start support a single voice codec only, and therefore video and encrypted calls are not supported. H.323 Fast Start is disabled by default on H.323 trunks, and MTPs are not required for outbound or inbound calls. As a general rule, this default H.323 (Slow Start) trunk configuration is preferred so that voice, video, and encrypted calls are supported over H.323 trunk connections.

H.323 Trunks with Media Termination Points

Media termination points (MTPs) are generally not required for normal operation of the H.323 trunk. They are, however, required for communication with devices that are H.323 Version 1, that do not support the Empty Capabilities Set (ECS) for supplementary services, or that require H.323 Fast Start.

To test whether or not an MTP is required, use the following simple procedure:

1. Place a call from a phone through the H.323 trunk to the other device. This call should work normally.
2. Place the call on hold, then resume it. If the call drops, then it is highly likely that an MTP is required to ensure interoperability between Unified CM and the other device.

DTMF Transport

The H.323 trunk supports DTMF signaling for both out-of-band DTMF using H.245 and in-band DTMF using RTP Named Telephone Events (RFC 2833). There are no configuration options. An MTP may be allocated dynamically to convert between out-of-band DTMF relay to in-band DTMF relay, if required. For an explanation of when the H.323 trunk uses which method and when MTPs are required, refer to the chapter on [Media Resources](#), page 17-1.

H.323 Trunk Transport Protocols

H.323 trunks use TCP for H.225 call control and H.245 media control signaling, and UDP for gatekeeper H.225 Registration Admission Status (RAS) signaling.

Secure H.323 Trunks

Securing H.323 trunks involves two processes: configuring the trunk to encrypt media and configuring the trunk to encrypt signaling.

Media Encryption

Media encryption can be configured on H.323 trunks by checking the trunk's **SRTP allowed** check box. It is important to understand that checking the **SRTP allowed** checkbox will cause the media for calls to be encrypted but the trunk signaling will not be encrypted, therefore the session keys used to establish the secure media stream will be sent in the clear. It is therefore important to ensure that signaling between Unified CM and its destination H.323 trunk device is also encrypted so that keys and other security-related information do not get exposed during call negotiations.

Signaling Encryption

H.323 trunks use IPSec for signaling encryption. You may configure IPSec in the network infrastructure, or you may configure IPSec between Cisco Unified Communications Manager (Unified CM) and the remote gateway or trunk. If you implement one method to set up IPSec, you do not need to implement the other method. Using IPSec on Unified CM servers can incur a significant impact on server performance, therefore Cisco recommends that you provision IPSec in the network infrastructure rather than in Unified CM itself.

If the system can establish a secure media or signaling path and if the end devices support SRTP, the system uses an SRTP connection. If the system cannot establish a secure media or signaling path or if at least one device does not support SRTP, the system uses an RTP connection. SRTP-to-RTP fallback (and vice versa) may occur for transfers from a secure device to a non-secure device, conferencing, transcoding, music on hold, and so on.

For SRTP-configured devices, Unified CM classifies a call as encrypted if the **SRTP Allowed** check box is checked for the device and if the SRTP capabilities for the devices are successfully negotiated for the call. If the preceding criteria are not met, Unified CM classifies the call as non-secure. If the device is connected to a phone that can display security icons, the phone displays the lock icon when the call is encrypted.

MTPs that are statically assigned to an H.323 trunk using the **MTP Required** checkbox do not support SRTP because they do not support the pass-through codec. To ensure that SRTP is supported for all calls, do not configure the H.323 trunk for H.323 Outbound Fast Start (that is, do not select **MTP Required**). SRTP is supported for Inbound Fast Start. (Inbound Fast Start does not require an MTP or a codec selection.)

H.323 Operation in Unified CM

This section provides information on how the H.323 protocol is used and implemented in Unified CM, and it explains how and why certain features work the way they do.

The most important point to understand is which subscribers run the call signaling daemons. These daemons are pieces of code that make and receive H.323 calls. They are usually referred to as H.323 or H.225 daemons (H.323Ds or H.225Ds). H.225 is part of the H.323 protocol and is mainly responsible for call control. H.245 is the other major component of H.323 that is responsible for the media control of a call.

For the majority of H.323 devices, the subscribers listed in the Unified CM Group for a particular H.323 device determine which subscribers run the daemons and when. For H.323 non-gatekeeper controlled intercluster trunks, standard Unified CM Groups can be used or the **Run on All Active Unified CM Nodes** can be enabled, in which case the daemon will run on all active nodes.

For devices using Unified CM Groups, it is important to know which nodes will run H.225 daemons because calls sent to an incorrect subscriber might be rejected. For example, this situation would occur if a Cisco IOS H.323 gateway is configured with dial peers that send calls to subscriber C in a Unified CM cluster but the Unified CM Group for that gateway has only subscribers A and B in its list. In such a case, the call will fail or be handled by an H.323 trunk daemon if one happens to be configured on the subscriber.

The following scenarios describe where and when H.225Ds are created on subscribers:

- H.323 client

The H.225D is active on only the highest-priority subscriber available in the Unified CM Group associated with the H.323 client.

If the H.323 client is gatekeeper controlled, the RasAggregator device registers from only the highest-priority subscriber available in the Unified CM Group associated with the gatekeeper controlled H.323 client.

The RasAggregator is a special device that registers in gatekeeper zones for the purpose of providing two specific features:

- If H.323 clients use DHCP, they cannot be used with a Unified CM using DNS unless they support Dynamic DNS. With the RasAggregator, Unified CM can obtain the IP address of a specific H.323 client that is registered with the gatekeeper whenever a call is placed. The gatekeeper registration is done using standard RAS ARQ messages that contain the E.164 address of the H.323 client. The gatekeeper resolves the E.164 address and provides the IP address back to Unified CM in an ACF message.

- The RasAggregator also ensures that all calls by the H.323 clients are made through Unified CM and not directly between the clients themselves, thus ensuring that dialing rules and codec restrictions are enforced.
- H.323 gateway
The H.225D is active on all subscribers in the Unified CM Group associated with the H.323 gateway.
- H.323 gatekeeper controlled trunks
The H.225D is active on all subscribers in the Unified CM Group associated with the H.323 trunk. A RAS daemon registers the trunk with the gatekeeper from all subscribers in the associated Unified CM Group.
- H.323 non-gatekeeper controlled trunks using Unified CM Groups
The H.225D is active on all subscribers in the Unified CM Group associated with the H.323 trunk.
- H.323 non-gatekeeper controlled trunks using **Run on all Active Unified CM Nodes**
The H.225D is active on all active Unified CM subscribers in the cluster.

When an incoming H.323 call is made to a subscriber in a Unified CM cluster, various decisions are made to determine if the call is accepted or rejected and which H.225D will receive the call if it is accepted. [Figure 14-24](#) shows how this process works.

Figure 14-24 Process for Determining if an H.323 Call is Accepted or Rejected

Unified CM H.323 protocol includes the following additional features:

- Protocol Auto Detect

This feature provides the ability to determine, on a call-by-call basis, if the calling device is from Cisco Unified CM. Whenever a call is received, Unified CM looks for an H.225 User-to-User Information Element (UUIE) that indicates if the other end is another Unified CM. If it is, it will always use the Intercluster Trunk Protocol. If no UUIE is found, it will use the configured protocol for that device. This feature enables an H.225 gatekeeper controlled trunk to switch between Intercluster Trunk Protocol and H.225 on a call-by-call basis, allowing a mixture of Unified CM clusters and other H.323 devices to use the gatekeeper. Intercluster Trunk Protocol is the same as H.225 except for several differences that enable specific features to work correctly between Unified CM clusters.

- Tunneled QSIG or H.323 Annex M1 (ISO and ECMA variants supported per trunk)

This feature can be enabled on all H.323 trunks. It allows specific H.323 Annex M1 features to be implemented between Unified CM clusters and other verified systems that also support H.323 Annex M1. These features include:

- Path replacement
- Message waiting indication (MWI)
- Callback

- Alternate Endpoints

When registering with a gatekeeper that supports this feature, such as a Cisco Multimedia Conference Manager (MCM) Gatekeeper, Unified CM can inform the gatekeeper of alternate destinations for calls to the H.323 trunk. These alternate endpoints or destinations are sent to the calling device by the gatekeeper when this H.323 trunk is called. They are the other subscribers listed in the Unified CM Group associated with the H.323 trunk that registers with the gatekeeper.

- Alternate Gatekeeper

When an H.323 trunk registers with a gatekeeper that supports this feature (for example, a Cisco gatekeeper cluster), Unified CM is dynamically informed about other gatekeepers that can process registrations, call admission requests, and other RAS functions in the event that this gatekeeper fails or exhausts its own resources.

- CanMapAlias

When an H.323 trunk sends an admission request (ARQ) to the gatekeeper, it might receive a different E.164 number in the admission confirmation message (ACF), indicating that the original called number should be replaced with this new one. This feature requires a route server using Gatekeeper Transaction Message Protocol (GKTMP) to communicate with Cisco gatekeepers.

Note CanMapAlias is supported for the called number only.

- Bandwidth Requests

H.323 trunks can update the gatekeeper with bandwidth information to indicate a change in the requested bandwidth allocated to a specific call. This feature is disabled by default and is controlled by setting the Unified CM service parameter **BRQ Enabled** to **True**, under the H.323 section. This feature is especially important when video is used on an H.323 trunk because the original bandwidth request is for the maximum amount allowed. Enabling this feature ensures that call admission control uses the actual bandwidth negotiated during call setup.

Other Design Considerations for H.323 Trunks

Unified CM SIP trunks now offer a greater set of features in comparison with H.323 intercluster trunk, making SIP the protocol of choice for intercluster trunk connections, although H.323 Annex M1 may still be preferred for intercluster trunk connections to Unified CM clusters using earlier software versions. For more information on deploying intercluster trunks in multi-cluster and clustering over the WAN environments, see [Design Considerations for SIP Trunks, page 14-27](#).

General SIP and H.323 Trunk Design Considerations

This section covers the following general design considerations:

- [Deterministic Outbound Call Load Balancing over Unified CM Trunks, page 14-55](#)
- [Codec Selection Over IP Trunks, page 14-56](#)
- [Other MTP Uses, page 14-57](#)

Deterministic Outbound Call Load Balancing over Unified CM Trunks

In the majority of cases, using **Run on all Active Unified CM Nodes** or assigning Unified CM Groups to devices is sufficient to handle the call distribution of outbound calls over trunks from call processing subscribers. Due to the Route Local rule, trunk calls might appear to originate randomly from call processing subscribers, but the trade-off for this random call origination is reduced call processing and reduced Intra-Cluster Communication Signaling (ICCS) traffic within the cluster.

Deterministic load balancing of outbound IP trunk calls across call processing servers is possible but can be counter-productive because the advantages gained from predictable call origination within the cluster can be outweighed by the increase in ICCS traffic created by calls from phones registered to one subscriber extending their communication to another server within the cluster to originate the outgoing IP trunk call.

Predictable and deterministic subscriber-based load balancing of outgoing IP trunk calls can be achieved as follows:

- To deterministically load-balance outbound trunk calls across a subset of the call processing servers in the cluster, define multiple trunks and assign only a single subscriber to the Unified CM Group of each trunk. Place these trunks into a route group and use circular call distribution.

For example, to spread outbound trunk calls across four subscribers in the cluster, perform the following tasks:

- Configure four H.323 trunks or four SIP trunks with individual Unified CM Groups, all contained within a route group with circular call distribution.
- Define Unified CM Groups as follows:
 - Group A: Subscriber A
 - Group B: Subscriber B
 - Group C: Subscriber C
 - Group D: Subscriber D

With no backup subscribers defined, if the primary subscriber for the specified trunk fails, Unified CM will re-route outgoing calls to the next trunk in the route group.

- To spread outbound trunk calls across all eight subscribers in a cluster, perform the following tasks:
 - Configure eight H.323 trunks or eight SIP trunks with individual Unified CM Groups, each containing only one subscriber and all contained within a circular route group.
 - Define Unified CM Groups as follows:
 - Group A: Subscriber A
 - Group B: Subscriber B
 - Group C: Subscriber C
 - Group D: Subscriber D
 - Group E: Subscriber E
 - Group F: Subscriber F
 - Group G: Subscriber G
 - Group H: Subscriber H

Codec Selection Over IP Trunks

Before media between communicating entities can be established, both the entities must agree on the codec(s) that they want to use. This codec (or codecs if both audio and video are involved) is derived from the intersection of codecs supported by communicating entities involved and the configured policy in Unified CM. Policy in Unified CM is configured by region settings. The inter-region Max Audio Bit Rate for audio and the inter-region Max Video Call Bit Rate setting for video (that includes audio) determine the set of codecs that will be used between devices contained in the respective regions. Note that the bit rate settings determine only the maximum bandwidth that is allowed for devices communicating across those regions and does not specify the exact codec that will be used for every call. If the entities share several codecs in common and the inter-region bit rate setting allows the selection of more than one codec, Unified CM will select the codec with the best quality without consideration of the actual bit rate of the codec.

For example, if the inter-region audio bit rate setting between a trunk and an IP phone is set to 8 kbps (G.729) and both endpoints indicate support for G.729, then that codec will be selected. However, if the inter-region audio bit rate is set to 64 kbps (G.722 and G.711) and both endpoints indicate support for G.711, G.722, and G.729, then Unified CM will choose G.722 because this codec will deliver the best audio quality. The codec selection rules change somewhat when the **Link Loss Type** for the region is characterized as being **Lossy**. In this case the iSAC codec, if supported by the communicating sides and allowed by the inter-region bit rate setting, takes priority over others because it can deliver good audio quality at a lower bit rate.

For calls over SIP and H.323 trunks, the codec selected for use for calls over a trunk is determined by the capabilities of the remote endpoint as learned from the call setup messages, capabilities of the local endpoint, and the inter-region bit rate settings between the trunk and the local endpoint regions.

Note

For low-loss links between regions, a higher-quality codec such as G.722 or G.711 will be selected over a lower-quality codec such as G.729, if possible. An exception to this rule is if the link between the regions is marked as lossy. In this case the iSAC codec, if available, will be used.

**Note**

If **MTP Required** is checked for the trunk, then the codec specified for the MTP will be used regardless of other settings. In this case, the inter-region bit rate settings must be configured appropriately to allow this codec.

Other MTP Uses

MTPs are very useful for terminating media streams from other devices that make calls over trunks and for re-originating the media streams with the same voice payload; however, in such cases the IP address is changed to that of the MTP. With this fact in mind, you can utilize MTPs in the following scenarios:

- If the phones, gateways, and other devices within your enterprise all use RFC 1918 private addresses, you might still want to connect to other systems on a public network without using Network Address Translation (NAT) for all your voice and video devices. If the Unified CM subscriber that communicates to the public network is using a public IP address, the signaling will be routed. If all MTPs are also using public addresses, the media from the devices with RFC 1918 addresses will be terminated on the MTP and then originated again, but this time with a public address that is routable on the public network. This approach allows tens of thousands of devices with RFC 1918 addresses to communicate with the public network. This same method can be used to conceal the real IP addresses of devices in an enterprise network when communicating with other enterprises or service providers.
- Trust boundaries can be established to traverse firewalls or to allow access through an access control list (ACL). Normally, for media to traverse a firewall, you could either use an Application Layer Gateway (ALG) or fix-up to provide access dynamically for the media streams or you could allocate a wide range of addresses and ports for use by all voice devices that need to communicate across the firewall. All calls that use a trunk and traverse a firewall or ACL will have media that is sourced from the MTP(s), which may use either a single IP address or a small range of IP addresses.

With both of these methods, if the **MTP Required** box is checked, the default behavior is to allow calls on SIP and H.323 trunks even if MTP resources are unavailable or exhausted. This default behavior might result in no voice path for the call, but the behavior can be changed by setting the Unified CM service parameter **Fail Call if MTP allocation fails** under the SIP and H.323 sections to **True**.

Cisco Unified CM Trunks and Emergency Services

IP trunks might be unable to deliver emergency 911 calls or, like centralized PSTN trunks, might be unable to deliver such calls to the appropriate Public Safety Answering Point (PSAP) for the caller's location. Customers must investigate carefully the capabilities of the IP trunk service provider to deliver emergency 911 calls and caller locations to the appropriate PSAP. Cisco Emergency Responder may be used to provide the location-specific calling party number to the IP trunk service provider for emergency 911 calls.

Centralized IP or PSTN trunks might also temporarily become unavailable for emergency 911 calls from remote locations due to WAN congestion or failure. For this reason, remote locations should always have local gateways to the PSTN that are capable of delivering emergency 911 calls. For more information, see [Emergency Services, page 10-1](#).

Capacity Planning for Unified CM IP Trunks

Cisco 7800 Series Media Convergence Servers support the following trunk capacities:

- An MCS-7845 cluster or Cisco Unified Computing System (UCS) equivalent cluster can support up to 2100 trunks.
- An MCS-7835 cluster can support up to 1100 trunks.
- An MCS-7825 cluster can support up to 1100 trunks.
- An MCS-7816 cluster can support up to 200 trunks.

While the above values represent the nominal maximum capacities, actual trunk scalability and performance ultimately depend on several factors including all other applications and tasks that the individual subscribers are processing, the busy hour call attempts (BHCA) across the trunks, and so forth. To determine the overall system capacity, use the Cisco Unified Communications Sizing Tool (Unified CST), which is available to Cisco employees and partners with proper login authentication at

<http://tools.cisco.com/cucst>

To obtain the most trunk throughput from a cluster, ensure that the trunk load for both incoming and outgoing calls is distributed uniformly over all of the subscribers in the cluster as much as possible.

IP PSTN and IP Trunks to Service Provider Networks

Service providers are increasing their offerings of non-TDM PSTN connections to enterprise customers. Apart from the key benefit of the cost savings from deploying non-TDM interfaces, these IP-based PSTN connections might also offer additional voice features compared to traditional PSTN interfaces.

SIP-based services dominate the available offerings, and although earlier H.323 services were available in select geographies, they are being phased out. This is mainly due to the increasing popularity of SIP within the enterprise and the promise of additional capabilities such as Presence and support for many rich media applications (such as instant messaging). SIP will probably become the most widely deployed Unified Communications protocol in the long term.

When connecting to a service provider's IP PSTN network, Cisco strongly recommends the use of the Cisco Unified Border Element as an enterprise edge Session Border Controller to provide a controlled demarcation and security point between your enterprise and the service provider's network.

Cisco Unified Border Element

The Cisco Unified Border Element provides a wide range of signaling and media functionality between the enterprise and service-provider Cisco Unified Communications networks. Cisco Unified Border Element provides a Session Border Controller network-to-network interface point for:

- Address and port translations (privacy and Level 7 topology hiding)
- SIP Delayed Offer to Early Offer conversion
- Protocol interworking (H.323 and SIP) and normalization
- Media interworking (DTMF, fax, codec transcoding, and transrating volume and gain control)
- Call admission control (based on total calls, CPU, memory, call arrival spike detection, or maximum calls per destination)

- Security (including SIP malformed packet detection, non-dialog RTP packet drops, SIP listening port configuration, digest authentication, simultaneous call limits, call rate limits, toll fraud protection, and a number of signaling and media encryption options)
- PPI/PAI/Privacy and RPID Interworking with service providers
- QoS and bandwidth management (QoS marking using ToS, DSCP, and bandwidth enforcement using RSVP and codec filtering)
- Simultaneous connectivity to SIP trunks from multiple service providers

High availability with in-box or box-to-box failover options (depending on platform and release)

- Billing statistics and CDR collection

The Cisco Unified Border Element is a licensed Cisco IOS application available on the Cisco Integrated Service Routers Generation 2 (ISR G2), the Cisco AS5000XM Media Gateways, and the Cisco 1000 Series Aggregation Services Routers (ASR). Depending on your choice of hardware platform, the Cisco Unified Border Element can provide session scalability for up to 16,000 concurrent voice calls with in-box or box-to-box failover options.

For more information on the Cisco Unified Border Element, refer to the documentation at

<http://www.cisco.com/go/cube>

Trunk Aggregation Platforms

Large-scale IP PSTN deployments often involve the requirement to aggregate trunks from many Unified Communications systems prior to connecting them by means of the Cisco Unified Border Element to the service provider's IP PSTN. In most cases, the choice of aggregation platform depends on the protocol(s) the end systems are using. Cisco Unified CM Session Management Edition and Cisco Unified SIP Proxy are two commonly used aggregation platforms and are discussed in this section. Cisco's H.323 gatekeeper is also an option but tends to be less widely used today since SIP has become the preferred choice of protocol for IP PSTN connections. (Cisco H.323 gatekeeper options are discussed in the section on [H.323 Trunk Types, page 14-37](#).)

Unified CM Session Management Edition

Unified Communications deployments using Unified CM Session Management Edition are a variation on the multisite distributed call processing deployment model and are typically employed to interconnect large numbers of Unified Communications systems and also to provide connections to an IP PSTN.

Cisco Unified CM Session Management Edition is essentially a Unified CM cluster with trunk interfaces only and no IP endpoints. It enables aggregation of multiple unified communications systems, referred to as leaf systems. (See [Figure 14-25](#).)

Figure 14-25 Cisco Unified CM Session Management Edition

Unified CM Session Management Edition deployments can be used to migrate a deployment of multiple PBXs and associated phones to a Unified CM cluster with IP phones and relatively few trunks. The Unified CM Session Management Edition cluster may start with a large number of trunks interconnecting third-party PBXs and migrate over time to a Unified CM cluster deployment with thousands of IP phones. Unified CM Session Management Edition may also be used to connect to third-party unified communications systems such as IP PSTN connections and centralized unified communications applications.

With Cisco Unified CM 8.5 and later releases, Unified CM Session Management Edition supports the following features:

- SIP trunks (Delayed Offer preferred)
- H.323 trunks (Slow Start preferred)
- MGCP trunks
- Voice calls
- Video calls
- Encrypted calls
- Fax calls

Because Unified CM Session Management Edition uses the same software as Unified CM, all Unified CM features such as scalability, availability, load balancing, SIP message normalization, call routing, and number modification are available to the Unified CM Session Management Edition cluster.

For more information on Cisco Unified CM Session Management Edition, see the chapter on [Unified Communications Deployment Models](#), page 5-1.

Cisco Unified SIP Proxy

The Cisco Unified SIP Proxy provides SIP proxy functionality on a Cisco NME-522 network module that can be plugged into a network module slot on the Cisco 3800 Series Integrated Services Routers (ISRs). This ISR does not have to be dedicated to hosting the network module and running the proxy alone, but can be used simultaneously for other network functions such as to run the Cisco Unified Border Element described above.

The Cisco Unified SIP Proxy brings the following benefits to a network using Unified CM SIP trunks:

- Aggregation and routing

The Unified SIP Proxy is capable of connecting several SIP servers to each other without each of the servers connecting to every other one in a full-mesh configuration

- Scalability

The Unified SIP Proxy can be used to terminate calls to and from the enterprise and IP PSTN service providers. The proxy, in turn, distributes the calls across a pool of Unified Border Elements. More Unified Border Elements may be added to increase capacity.

- Availability and load balancing

The Unified SIP Proxy distributes calls over the pool of available Unified Border Elements and monitors the status of each Unified Border Element to ensure reliable call completion.

- Message normalization

The Unified SIP Proxy serves to hide differences in SIP protocol messaging by providing the means to manipulate headers and contents of the messages as they pass through the Unified SIP Proxy.

The following design considerations should be taken into account when deploying the Cisco Unified SIP Proxy with the Cisco Unified Border Element:

- Configure a load balancing scheme on the Unified SIP Proxy so that none of the attached Unified Border Elements is overloaded.
- Set up trunk monitoring in the Unified SIP Proxy so that it can detect and act on any failure of the Unified CM or Unified Border Element.

Figure 14-26 shows the call flow using the Cisco Unified SIP Proxy with Cisco Unified Border Element.

Figure 14-26 Call Flow for Cisco Unified SIP Proxy with Cisco Unified Border Element

To originate a call to the service provider, Unified CM sends the call to the Unified SIP Proxy. The Unified SIP Proxy determines that the request came from Unified CM and forwards the call to a Unified Border Element. The Unified Border Element terminates and re-originates the call, and sends it back to the Unified SIP Proxy. The Unified SIP Proxy determines that the call came from a Unified Border Element, and this time forwards it to the service provider. Media is then established directly from the originating phone to the service provider through the Unified Border Element.

Large-Scale Session Border Controller

Depending on hardware platform, Cisco Unified Border Element on a single hardware chassis can aggregate up to 16,000 simultaneous calls on SIP trunks from one or more providers, and if desired, also with stateful failover between redundant chassis.

Trunk IP-PSTN Connection Models

Trunks may be connected to IP PSTN service providers in several different ways, depending on the desired architecture. The two most common architectures for this connectivity are centralized trunks and distributed trunks.

Centralized trunks connect to the service provider (SP) through one logical connection (although there may be more than one physical connection for redundancy) with Session Border Controllers (SBCs) such as the Cisco Unified Border Element. (See [Figure 14-27](#).) All calls to and from the enterprise use this set of trunks. If the enterprise hosts a single central Unified CM cluster at its headquarters, with remote branches connected to the headquarters through a WAN, then media and signaling for PSTN calls to and from each of the sites traverse the WAN.

Figure 14-27 Centralized or Aggregated SIP Trunk Model

Distributed trunks connect to the service provider through several logical connections. (See [Figure 14-28](#).) Each branch of an enterprise may have its own local trunk to the service provider. Media from branches no longer needs to traverse the WAN but flows to the service provider interface through a local SBC.

Figure 14-28 Distributed SIP Trunk Model

Each connectivity model has its own advantages and disadvantages. Centralized trunks are generally easier to deploy in terms of both physical equipment and configuration complexity. Distributed trunks have the advantage of local hand-off of media and better number portability from local providers. As illustrated in Figure 14-29, a hybrid connectivity model that groups some of the branches together for connectivity, or that provides trunks from each Unified CM cluster of a multi-cluster deployment, captures the advantages of both forms of deployment.

Figure 14-29 Hybrid SIP Trunk Model with Regional Aggregation

PART 3

Unified Communications Call Control

CHAPTER 15

Overview of Cisco Unified Communications Call Control

Revised: February 29, 2012; OL-21733-18

After the network infrastructure and call routing have been properly designed and deployed for your Cisco Unified Communications System, the next phase involves deploying a group of core call control components. These call control components allow users to initiate calls more easily, enhance user capabilities, and enhance the experience of remote callers as well. The following aspects are essential to Unified Communications call control components:

- Integration with central Lightweight Directory Access Protocol (LDAP) directories
- Access to media resources such as audio conferencing or codec transcoding
- Capabilities for music on hold for callers into the Unified Communications System
- Capabilities and feature sets for Unified Communications endpoints
- Applications embedded in the call routing, such as click-to-call dialing, manager-assistant applications, and the ability for users to log in to any phone

This part of the SRND provides coverage for all the various call control components mentioned above. Each chapter provides an introduction to the call control components, followed by discussions surrounding architecture, high availability, capacity planning, and design considerations. The content of each chapter focuses on design-related information rather than product-specific support and configuration information.

This part of the SRND includes the following chapters:

- [LDAP Directory Integration, page 16-1](#)

This chapter covers aspects of Unified Communications integration with the LDAP directories, including the Cisco Unified Communications Manager directory architecture itself as well as design considerations for LDAP synchronization and authentication. Directory access from Unified Communications endpoints and security considerations are also explored.

- [Media Resources, page 17-1](#)

This chapter examines all components classified as Unified Communications media resources. Digital signal processors (DSPs) and their deployment for voice termination, conferencing and transcoding capabilities, and music on hold (MoH) are all discussed. Media termination points (MTPs), how they function, and design considerations with SIP and H.323 trunks are also covered. In addition, design considerations surrounding Trusted Relay Points, RSVP Agents, annunciator, MoH, and secure conferencing are included in the chapter.

- [Unified Communications Endpoints, page 18-1](#)

This chapter discusses all the Unified Communications endpoints available in the Cisco portfolio, and it lists their capabilities in table form for easy comparison. Software-based endpoints are discussed in addition to wireless and hard-wired phones. The chapter also covers video telephony endpoints and gateways that provide foreign exchange station (FXS) ports for analog connectivity.

- [Cisco Unified CM Applications, page 19-1](#)

This chapter covers the inherent applications built into Cisco Unified Communications Manager (Unified CM): IP Phone Services, WebDialer, Unified CM Assistant, and Extension Mobility (EM). In addition, this chapter covers Attendant Console applications and their integration through CTI to Unified CM. The chapter first explains the architecture behind the applications, followed by a discussion of design considerations. The chapter also explores variations in the applications such as Extension Mobility Cross Cluster (EMCC) and Unified CM Assistant proxy-line versus shared-line mode.

Architecture

As with other network and application technology systems, unified communications call control components build upon the underlying network and system infrastructures. [Figure 15-1](#) shows the logical location of unified communications call control components in the overall Cisco Unified Communications System architecture.

Figure 15-1 Cisco Unified Communications Call Control Architecture

253669

Unified communications call control components such as conferencing resources, music on hold, directory integration, and endpoints require the unified communications networking infrastructure and unified communications call routing architecture to be well designed and already deployed. These call control components build on the unified communications system and provide enhanced (and usually required) user features.

High Availability

As with the network and call routing, call control infrastructure should be made highly available to ensure that required features and functionality remain available during outages in the network or call processing entities. It is important to understand the various types of failures that can occur and the design considerations around these failures. In some cases, the failure of a single server or feature can impact multiple services because many unified communications components are dependent on others. For example, while the various service components of Cisco Unified Communications Manager (Unified CM) applications may be functioning properly, the loss of the Unified CM call processing

service will effectively render the Unified CM applications unusable because the deployment is dependent upon Unified CM to place or receive calls. In many cases, all or part of the functionality can be handled by a redundant resource, thus giving end users the ability to continue to leverage services in the event of certain failures.

For media resources and music on hold, high availability considerations include temporary loss of functionality due to network outages and server or DSP platform failures. This could lead to a poor user experience (for example, initiating a conference only to see a "Resources Not Available" or similar message on the phone) as well as a poor experience for callers into the system (for example, possibly hearing silence instead of a specific advertising message while on hold). Design details around configuration best practices and deployment of redundant resources are discussed in the respective chapters.

Unified CM applications are deployed by enabling specific services on Unified CM nodes in the cluster. If there is a service outage, it will result in a degraded or completely non-functional user experience. Users logging in to phones or accessing IP phone services will experience long delays and typically re-initiate the connection several times, further exacerbating the problem. The chapters in this part of the SRND explain the architecture of the applications and provide design considerations related to which nodes and/or how many nodes in the cluster to enable for application-specific features.

Similarly, for LDAP directory integrations, an LDAP directory server can go offline or the connection between LDAP and the call processing entity can become unavailable. There must be design considerations to allow for LDAP authentication or user directory lookups to continue to function with an alternate server or through an alternate path.

Capacity Planning

Network, call routing, and call control infrastructures must be designed and deployed with an understanding of the capacity and scalability of the individual components and the overall system. When deploying various unified communications call control components, it is important to consider not only the scalability of the components themselves, but also the underlying infrastructures. Certainly the network infrastructure must have available bandwidth and be capable of handling the additional traffic load these components create. Likewise, the call routing infrastructure must be capable of handling user and device configuration and registration as well as additional load surrounding protocols and connections associated with call control elements.

There are capacity planning considerations across all of the chapters of this part of the SRND. For LDAP directory integrations, the most common consideration is the number of users that can be synchronized in the unified communications database, along with polling updates and how they can affect system performance. DSP media resources have a finite number of conferencing or transcoding sessions they each can handle, so proper sizing and allocation of DSPs is critical to a good design. Each Unified CM application has its own set of upper limits, whether it is the supported Extension Mobility login rate or the number of IP Manager Assistants that can be configured in the system. Each call control chapter contains a capacity planning section that offers capacity design guidance and assists in architecting sound Unified Communications designs.

For a complete discussion of system sizing, capacity planning, and deployment considerations related to sizing, refer to the chapter on [Unified Communications Design and Deployment Sizing Considerations](#), page 29-1.

CHAPTER 16

LDAP Directory Integration

Revised: April 30, 2012; OL-21733-18

Directories are specialized databases that are optimized for a high number of reads and searches, and occasional writes and updates. Directories typically store data that does not change often, such as employee information, user policies, user privileges, and group membership on the corporate network.

Directories are extensible, meaning that the type of information stored can be modified and extended. The term *directory schema* defines the type of information stored, its container (or attribute), and its relationship to users and resources.

The Lightweight Directory Access Protocol (LDAP) provides applications with a standard method for accessing and potentially modifying the information stored in the directory. This capability enables companies to centralize all user information in a single repository available to several applications, with a remarkable reduction in maintenance costs through the ease of adds, moves, and changes.

This chapter covers the main design principles for integrating a Cisco Unified Communications system based on Cisco Unified Communications Manager (Unified CM) with a corporate LDAP directory. The main topics include:

- [What is Directory Integration?, page 16-2](#)

This section analyzes the various requirements for integration with a corporate LDAP directory in a typical enterprise IT organization.

- [Directory Access for Unified Communications Endpoints, page 16-3](#)

This section describes the technical solution to enable directory access for Cisco Unified Communications endpoints and provides design best-practices around it.

- [Directory Integration with Unified CM, page 16-5](#)

This section describes the technical solutions and provides design considerations for directory integration with Cisco Unified CM, including the LDAP synchronization and LDAP authentication functions.

The considerations presented in this chapter apply to Cisco Unified CM as well as the following applications bundled with it: Cisco Extension Mobility, Cisco Unified Communications Manager Assistant, WebDialer, Bulk Administration Tool, and Real-Time Monitoring Tool.

For Cisco Unity, refer to the *Cisco Unity Design Guide* and to the following white papers: *Cisco Unity Data and the Directory*, *Active Directory Capacity Planning*, and *Cisco Unity Data Architecture and How Cisco Unity Works*, also available at

<http://www.cisco.com>

What's New in This Chapter

Table 16-1 lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Table 16-1 *New or Changed Information Since the Previous Release of This Document*

| New or Revised Topic | Described in | Revision Date |
|--|---|-------------------|
| Capacity limits for LDAP directory synchronization | Capacity Planning for Unified CM Database Synchronization, page 16-27 | April 30, 2012 |
| LDAP directory types supported by Cisco Unified CM | Table 16-3 | April 30, 2012 |
| Multi-forest LDAP synchronization | Unified CM Multi-Forest LDAP Synchronization, page 16-18 | November 15, 2010 |
| Filtering | User Filtering for Directory Synchronization and Authentication, page 16-23 | April 2, 2010 |

What is Directory Integration?

Integrating voice applications with a corporate LDAP directory is a common task for many enterprise IT organizations. However, the exact scope of the integration varies from company to company, and can translate into one or more specific and independent requirements, as shown in Figure 16-1.

Figure 16-1 *Various Requirements for Directory Integration*

One common requirement is to enable user lookups (sometimes called the "white pages" service) from IP phones or other voice and/or video endpoints, so that users can dial contacts quickly after looking up their numbers in the directory.

Another requirement is to provision users automatically from the corporate directory into the user database for applications. This method avoids having to add, remove, or modify core user information manually each time a change occurs in the corporate directory.

Authentication of end-users and administrators of the voice and/or video applications using their corporate directory credentials is also a common requirement. Enabling directory authentication allows the IT department to deliver single log-on functionality while reducing the number of passwords each user needs to maintain across different corporate applications.

As shown in [Table 16-2](#), within the context of a Cisco Unified Communications system, the term *directory access* refers to mechanisms and solutions that satisfy the requirement of user lookups for Cisco Unified Communications endpoints, while the term *directory integration* refers to mechanisms and solutions that satisfy the requirements of user provisioning and authentication (for both end users and administrators).

Table 16-2 Directory Requirements and Cisco Solutions

| Requirement | Cisco Solution | Cisco Unified CM Feature |
|--|-----------------------|-------------------------------------|
| User lookup for endpoints | Directory access | Cisco Unified IP Phone Services SDK |
| User provisioning | Directory integration | LDAP Synchronization |
| Authentication for Unified Communications end users | Directory integration | LDAP Authentication |
| Authentication for Unified Communications application administrators | Directory integration | LDAP Authentication |

The remainder of this chapter describes how to address these requirements in a Cisco Unified Communications system based on Cisco Unified CM.

Note

Another interpretation of the term *directory integration* revolves around the ability to add application servers to a Microsoft Active Directory domain in order to centralize management and security policies. Cisco Unified CM is an appliance that runs on a customized embedded operating system, and it cannot be added to a Microsoft Active Directory domain. Server management for Unified CM is provided through the Cisco Real Time Monitoring Tool (RTMT). Strong security policies tailored to the application are already implemented within the embedded operating system.

Directory Access for Unified Communications Endpoints

This section describes how to configure corporate directory access to any LDAP-compliant directory server to perform user lookups from Cisco Unified Communications endpoints (such as Cisco Unified IP Phones). The guidelines contained in this section apply regardless of whether Unified CM or other Unified Communications applications have been integrated with a corporate directory for user provisioning and authentication.

Cisco Unified IP Phones equipped with a display screen can search a user directory when a user presses the Directories button on the phone. The IP Phones use Hyper-Text Transfer Protocol (HTTP) to send requests to a web server. The responses from the web server contain specific Extensible Markup Language (XML) objects that the phone interprets and displays.

By default, Cisco Unified IP Phones are configured to perform user lookups against Unified CM's embedded database. However, it is possible to change this configuration so that the lookup is performed on a corporate LDAP directory. In this case, the phones send an HTTP request to an external web server that operates as a proxy by translating the request into an LDAP query which is then processed by the corporate directory. The web server encapsulates the LDAP response into an XML object that is sent back to the phone using HTTP, to be rendered to the end user.

Figure 16-2 illustrates this mechanism in a deployment where Unified CM has not been integrated with the corporate directory. Note that, in this scenario, Unified CM is not involved in the message exchange. The authentication mechanism to Unified CM web pages, shown on the right half of Figure 16-2, is independent of how directory lookup is configured.

Figure 16-2 Directory Access for Cisco Unified IP Phones Using the Cisco Unified IP Phone Services SDK

In the example shown in Figure 16-2, the web server proxy function is provided by the Cisco LDAP Search Component Object Model (COM) server, which is included in the Cisco Unified IP Phone Services Software Development Kit (SDK). You can download the latest Cisco Unified IP Phone Services SDK from the Cisco Developer Community at

<http://developer.cisco.com/web/ipps/home>

The IP Phone Services SDK can be installed on a Microsoft Windows web server running IIS 4.0 or later, but it cannot be installed on a Unified CM server. The SDK includes some sample scripts to provide simple directory lookup functionality.

To set up a corporate directory lookup service using the IP Phone Services SDK, perform the following steps:

-
- Step 1** Modify one of the sample scripts to point to your corporate LDAP directory, or write your own script using the LDAP Search COM Programming Guide provided with the SDK.
- Step 2** In Unified CM, configure the URL Directories parameter (under **System > Enterprise Parameters**) to point to the URL of the script on the external web server.
- Step 3** Reset the phones to make the changes take effect.
-

**Note**

If you want to offer the service only to a subset of users, configure the URL Directories parameter directly within the Phone Configuration page instead of the Enterprise Parameters page.

In conclusion, the following design considerations apply to directory access with the Cisco Unified IP Phone Services SDK:

- User lookups are supported against any LDAP-compliant corporate directory.
- When querying Microsoft Active Directory, you can perform lookups against the Global Catalog by pointing the script to a Global Catalog server and specifying port 3268 in the script configuration. This method typically results in faster lookups. Note that a Global Catalog does not contain a complete set of attributes for users. Refer to Microsoft Active Directory documentation for details.
- There is no impact on Unified CM when this functionality is enabled, and only minimal impact on the LDAP directory server.
- The sample scripts provided with the SDK allow only a minimal amount of customization (for example, you can prefix a digit string to all returned numbers). For a higher degree of manipulation, you will have to develop custom scripts, and a programming guide is included with the SDK to aid in writing the scripts.
- This functionality does not entail provisioning or authentication of Unified CM users with the corporate directory.

Directory Integration with Unified CM

This section describes the mechanisms and best practices for directory integration with Cisco Unified CM to allow for user provisioning and authentication with a corporate LDAP directory. This section covers the following topics:

- [Cisco Unified Communications Directory Architecture, page 16-7](#)

This section provides an overview of the user-related architecture in Unified CM.

- [LDAP Synchronization, page 16-10](#)

This section describes the functionality of LDAP synchronization and provides design guidelines for its deployment, with additional considerations for Microsoft Active Directory.

- [LDAP Authentication, page 16-19](#)

This section describes the functionality of LDAP authentication and provides design guidelines for its deployment, with additional considerations for Microsoft Active Directory.

[Table 16-3](#) specifies the currently supported LDAP directories for both synchronization and authentication on Cisco Unified Communication Manager.

Table 16-3 LDAP Directory Support

| LDAP Directory Type | Cisco Unified CM 6.x | Cisco Unified CM 7.x | Cisco Unified CM 8.x |
|---|-------------------------------|---|----------------------------------|
| Microsoft Active Directory 2000 | Yes | Yes | No longer supported |
| Microsoft Active Directory 2003 R1/R2 | R1/R2 supported (32 bit only) | R1/R2 supported (32 bit only) | R1/R2 supported (32 bit only) |
| Microsoft Active Directory 2008 R1/R2 | R1 supported (32 bit only) | R1 supported (32 bit only) | R1 supported (32 bit only) |
| Microsoft ADAM 2003 R1/R2 | No | R1/R2 supported (32 bit only) | R1/R2 supported (32 bit only) |
| Microsoft Active Directory LDS 2008 R1/R2 | No | No | R1 supported |
| Netscape 4.x | Yes | No longer supported ¹ | No longer supported ¹ |
| iPlanet 5.0 | Yes | No longer supported ¹ | No longer supported ¹ |
| iPlanet 5.1 | Yes | Yes | Yes |
| SunOne 5.2 | Yes | Yes | Yes |
| SunOne 6.1.x and 6.2.x | Yes | Yes | Yes |
| Sun One 6.3.xm | No | Supported with Unified CM 7.1(4) and later releases | Yes |
| Sun DS 7.0 | No | Supported with Unified CM 7.1(4) and later releases | Yes |
| OpenLDAP 2.3.39 | No | Supported with Unified CM 7.1(2) and later releases | Yes |
| OpenLDAP 2.4 | No | Supported with Unified CM 7.1(2) and later releases | Yes |

1. The directory vendor indicates that this solution has reached End of Life.

Note

All Microsoft Directory products listed in [Table 16-3](#) have equivalent support by Cisco Unified CM. All references to AD in this document are applicable to all the Microsoft products listed in this table.

Cisco Unified Communications Directory Architecture

Figure 16-3 shows the basic architecture of a Unified CM cluster. The embedded database stores all configuration information, including device-related data, call routing, feature provisioning, and user profiles. The database is present on all servers within a Unified CM cluster and is replicated automatically from the publisher server to all subscriber servers.

Figure 16-3 Cisco Unified CM Architecture

By default, all users are provisioned manually in the publisher database through the Unified CM Administration web interface. Cisco Unified CM has two types of users:

- End users — All users associated with a physical person and an interactive login. This category includes all Unified Communications users as well as Unified CM administrators when using the User Groups and Roles configuration (equivalent to the Cisco Multilevel Administration feature in prior Unified CM versions).
- Application users — All users associated with other Cisco Unified Communications features or applications, such as Cisco Attendant Console, Cisco Unified Contact Center Express, or Cisco Unified Communications Manager Assistant. These applications need to authenticate with Unified CM, but these internal "users" do not have an interactive login and serve purely for internal communications between applications.

Table 16-4 lists the application users created by default in the Unified CM database, together with the feature or application that uses them. Additional application users can be created manually when integrating other Cisco Unified Communications applications (for example, the **ac** application user for Cisco Attendant Console, the **jtapi** application user for Cisco Unified Contact Center Express, and so forth).

Table 16-4 Default Application Users for Unified CM

| Application User | Used by: |
|---------------------|--|
| CCMAdministrator | Unified CM Administration (default "super user") |
| CCMQRTSecureSysUser | Cisco Quality Reporting Tool |
| CCMQRTSysUser | |
| CCMSysUser | Cisco Extension Mobility |
| IPMASecureSysUser | Cisco Unified Communications Manager Assistant |
| IPMASysUser | |
| WDSecureSysUser | Cisco WebDialer |
| WDSysUser | |

Based on these considerations, [Figure 16-4](#) illustrates the default behavior in Unified CM for user-related operations such as lookups, provisioning, and authentication.

Figure 16-4 Default Behavior for User-Related Operations for Unified CM

End users access the Unified CM User Options page via HTTPS and authenticate with a user name and password. If they have been configured as administrators by means of User Groups and Roles, they can also access the Unified CM Administration pages with the same credentials.

Similarly, other Cisco features and applications authenticate to Unified CM via HTTPS with the user name and password associated with their respective application users.

The authentication challenge carried by the HTTPS messages are relayed by the web service on Unified CM to an internal library called Identity Management System (IMS). In its default configuration, the IMS library authenticates both end users and application users against the embedded database. In this way, both "physical" users of the Unified Communications system and internal application accounts are authenticated using the credentials configured in Unified CM.

End users may also authenticate with their user name and a numeric password (or PIN) when logging into the Extension Mobility service from an IP phone. In this case, the authentication challenge is carried via HTTP to Unified CM but is still relayed by the web service to the IMS library, which authenticates the credentials against the embedded database.

In addition, user lookups performed by Unified Communications endpoints via the Directories button communicate with the web service on Unified CM via HTTP and access data on the embedded database.

The importance of the distinction between End Users and Application Users becomes apparent when integration with a corporate directory is required. As mentioned in the previous section, this integration is accomplished by means of the following two separate processes:

- LDAP synchronization

This process uses an internal tool called Cisco Directory Synchronization (DirSync) on Unified CM to synchronize a number of user attributes (either manually or periodically) from a corporate LDAP directory. When this feature is enabled, users are automatically provisioned from the corporate directory. This feature applies only to End Users, while Application Users are kept separate and are still provisioned via the Unified CM Administration interface. In summary, End Users are defined in the corporate directory and synchronized into the Unified CM database, while Application Users are stored only in the Unified CM database and do not need to be defined in the corporate directory.

- LDAP authentication

This process enables the IMS library to authenticate user credentials against a corporate LDAP directory using the LDAP standard Simple_Bind operation. When this feature is enabled, End User passwords are authenticated against the corporate directory, while Application User passwords are still authenticated locally against the Unified CM database. Cisco Extension Mobility PINs are also still authenticated locally.

Maintaining and authenticating the Application Users internally to the Unified CM database provides resilience for all the applications and features that use these accounts to communicate with Unified CM, independently of the availability of the corporate LDAP directory.

Cisco Extension Mobility PINs are also kept within the Unified CM database because they are an integral part of a real-time application, which should not have dependencies on the responsiveness of the corporate directory.

The next two sections describe in more detail LDAP synchronization and LDAP authentication, and they provide design best-practices for both functions.

**Note**

As illustrated in the section on [Directory Access for Unified Communications Endpoints, page 16-3](#), user lookups from endpoints can also be performed against a corporate directory by configuring the Cisco Unified IP Phone Services SDK on an external web server.

LDAP Synchronization

Synchronization of Unified CM with a corporate LDAP directory allows the administrator to provision users easily by mapping Unified CM data fields to directory attributes. Critical user data maintained in the LDAP store is copied into the appropriate corresponding fields in the Unified CM database on a scheduled or on-demand basis. The corporate LDAP directory retains its status as the central repository. Unified CM has an integrated database for storing user data and a web interface within Unified CM Administration for creating and managing user accounts and data. When LDAP synchronization is enabled, the local database is still used, but the Unified CM facility to create end-user accounts is disabled. Management of end-user accounts is then accomplished through the interface of the LDAP directory. (See [Figure 16-5](#).) Accounts for application users can still be created and managed using the Unified CM Administration web interface.

The user account information is imported from the LDAP directory into the database located on the Unified CM publisher server. Information that is imported from the LDAP directory may not be changed by Unified CM. Additional user information specific to Cisco Unified Communications is managed by Unified CM and stored only within its local database. For example, device-to-user associations, speed dials, call forward settings, and user PINs are all examples of data that is managed by Unified CM and does not exist in the corporate LDAP directory. The user data is then propagated from the Unified CM publisher server to the subscriber servers through the built-in database synchronization mechanism.

Figure 16-5 Enabling Synchronization of User Data

When LDAP synchronization is activated, only one type of LDAP directory may be chosen globally for the cluster at any one time. Also, one attribute of the LDAP directory user is chosen to map into the Unified CM User ID field. Unified CM uses standard LDAPv3 for accessing the data.

Cisco Unified CM imports data from standard attributes. Extending the directory schema is not required. [Table 16-5](#) lists the attributes that are available for mapping to Unified CM fields. The data of the directory attribute that is mapped to the Unified CM User ID must be unique within all entries for that cluster. The attribute mapped to the Cisco UserID field must be populated in the directory and the **sn** attribute must be populated with data, otherwise those records are skipped during this import action. If the primary attribute used during import of end-user accounts matches any application user in the Unified CM database, that end user is not imported from the LDAP directory.

[Table 16-5](#) lists the attributes that are imported from the LDAP directory into corresponding Unified CM user fields, and it describes the mapping between those fields. Some Unified CM user fields might be mapped from one of several LDAP attributes.

Table 16-5 Synchronized LDAP Attributes and Corresponding Unified CM Field Names

| Unified CM User Field | Microsoft Active Directory | Active Directory Application Mode (ADAM) or Active Directory Lightweight Directory Service (AD LDS) | Netscape, iPlanet, or Sun ONE | OpenLDAP |
|-----------------------|---|---|--|--|
| User ID | One of: sAMAccountName mail employeeNumber telephoneNumber userPrincipalName | One of: uid mail employeeNumber telephoneNumber userPrincipalName | One of: uid mail employeeNumber telephonePhone | One of: uid mail employeeNumber telephonePhone |
| First Name | givenName | givenName | givenname | givenname |
| Middle Name | One of: middleName initials | One of: middleName initials | initials | initials |
| Last Name | sn | sn | sn | sn |
| Manager ID | manager | manager | manager | manager |
| Department | department | department | departmentnumber | departmentnumber |
| Phone Number | One of: telephoneNumber ipPhone | One of: telephoneNumber ipPhone | telephonenumber | telephonenumber |
| Mail ID | One of: mail sAMAccountName | One of: mail uid | One of: mail uid | One of: mail uid |

[Table 16-6](#) contains a list of additional attributes that are imported by the Dirsync process and copied into the Unified CM database but are not displayed in the administrator user configuration web pages. The attribute msRTCSIP-PrimaryUserAddress is populated in AD when Microsoft OCS is used. This table is included for completeness.

Table 16-6 Synchronized LDAP Attributes that Are Not Displayed

| Unified CM User Field | Microsoft Active Directory | Netscape, iPlanet, or Sun ONE | OpenLDAP |
|-----------------------|-----------------------------|-------------------------------|-----------------------|
| objectGUID | objectGUID | Not applicable | Not applicable |
| OCSPrimaryUserAddress | msRTCSIP-PrimaryUserAddress | Not applicable | Not applicable |
| Title | title | Title | title |
| Home Phone Number | homePhone | Homephone | hometelephonenumber |
| Mobile Phone Number | mobile | Mobile | Mobiletelephonenumber |
| Pager Number | pager | Pager | pagertelephonenumber |

The synchronization is performed by a process called Cisco DirSync, which is enabled through the Serviceability web page. When enabled, it allows one to five synchronization agreements to be configured in the system. An agreement specifies a search base that is a position in the LDAP tree where Unified CM will begin its search for user accounts to import. Unified CM can import only users that exist in the domain specified by the search base for a particular synchronization agreement.

In Figure 16-6, two synchronization agreements are represented. One synchronization agreement specifies User Search Base 1 and imports users jsmith, jdoe and jblogs. The other synchronization agreement specifies User Search Base 2 and imports users jjones, bfoo, and tbrown. The CCMDirMgr account is not imported because it does not reside below the point specified by a user search base. When users are organized in a structure in the LDAP directory, you can use that structure to control which user groups are imported. In this example, a single synchronization agreement could have been used to specify the root of the domain, but that search base would also have imported the Service Accts. The search base does not have to specify the domain root; it may specify any point in the tree.

Figure 16-6 User Search Bases

153285

To import the data into the Unified CM database, the system performs a bind to the LDAP directory using the account specified in the configuration as the LDAP Manager Distinguished Name, and reading of the database is done with this account. The account must be available in the LDAP directory for

Unified CM to log in, and Cisco recommends that you create a specific account with permissions to allow it to read all user objects within the sub-tree that was specified by the user search base. The sync agreement specifies the full Distinguished Name of that account so that the account may reside anywhere within that domain. In the example in [Figure 16-6](#), CCMDirMgr is the account used for the synchronization.

It is possible to control the import of accounts through use of permissions of the LDAP Manager Distinguished Name account. In this example, if that account is restricted to have read access to ou=Eng but not to ou=Mktg, then only the accounts located under Eng will be imported.

Synchronization agreements have the ability to specify multiple directory servers to provide redundancy. You can specify an ordered list of up to three directory servers in the configuration that will be used when attempting to synchronize. The servers are tried in order until the list is exhausted. If none of the directory servers responds, then the synchronization fails, but it will be attempted again according to the configured synchronization schedule.

Synchronization Mechanism

The synchronization agreement specifies a time for synchronizing to begin and a period for re-synchronizing that can be specified in hours, days, weeks, or months (with a minimum value of 6 hours). A synchronization agreement can also be set up to run only once at a specific time.

When synchronization is enabled for the first time on a Unified CM publisher server, user accounts that exist in the corporate directory are imported into the Unified CM database. Then either existing Unified CM end-user accounts are activated and data is updated, or a new end-user account is created according to the following process:

1. If end-user accounts already exist in the Unified CM database and a synchronization agreement is configured, all pre-existing accounts are marked inactive in Unified CM. The configuration of the synchronization agreement specifies a mapping of an LDAP database attribute to the Unified CM UserID. During the synchronization, accounts from the LDAP database that match an existing Unified CM account cause that Unified CM account to be marked active again.
2. After the synchronization is completed, any accounts that were not set to active are permanently deleted from Unified CM when the garbage collection process runs. Garbage collection is a process that runs automatically at the fixed time of 3:15 AM, and it is not configurable. The deletion of Unified CM accounts that do not match LDAP directory accounts is necessary because Unified CM cannot manage accounts while synchronization is configured.
3. Subsequently when changes are made in the corporate directory, the synchronization from Microsoft Active Directory occurs as a full re-synchronization at the next scheduled synchronization period. On the other hand, the iPlanet and Sun ONE directory products perform an incremental synchronization triggered by a change in the directory. The following sections present examples of each of these two scenarios.

Note

Once users are synchronized from LDAP into the Unified CM database, deletion of a synchronization configuration will cause users that were imported by that configuration to be marked inactive in the database. Garbage collection will subsequently remove those users.

Account Synchronization with Active Directory

Figure 16-7 shows an example timeline of events for a Unified CM deployment where LDAP Synchronization and LDAP Authentication have both been enabled. The re-synchronization is set for 11:00 PM daily.

Figure 16-7 Change Propagation with Active Directory

After the initial synchronization, the creation, deletion, or disablement of an account will propagate to Unified CM according to the timeline shown in Figure 16-7 and as described in the following steps:

1. At 8:00 AM on January 1, an account is disabled or deleted in AD. From this time and during the whole period A, password authentication (for example, Unified CM User Options page) will fail for this user because Unified CM redirects authentication to AD. However, PIN authentication (for example, Extension Mobility login) will still succeed because the PIN is stored in the Unified CM database.
2. The periodic re-synchronization is scheduled for 11:00 PM on January 1. During that process, Unified CM will verify all accounts. Any accounts that have been disabled or deleted from AD will at that time be tagged in the Unified CM database as inactive. After 11:00 PM on January 1, when the account is marked inactive, both the PIN and password authentication by Unified CM will fail.
3. Garbage collection of accounts occurs daily at the fixed time of 3:15 AM. This process permanently deletes user information from the Unified CM database for any record that has been marked inactive for over 24 hours. In this example, the garbage collection that runs at 3:15 AM on January 2 does not delete the account because it has not been inactive for 24 hours yet, so the account is deleted at 3:15 AM on January 3. At that point, the user data is permanently deleted from Unified CM.

If an account has been created in AD at the beginning of period A, it will be imported to Unified CM at the periodic re-synchronization that occurs at the beginning of period B and will immediately be active on Unified CM.

Account Synchronization with iPlanet or Sun ONE

The iPlanet and Sun ONE products support incremental synchronization agreements and use a different synchronization timeline than Microsoft Active Directory. The synchronization makes use of the Persistent Search mechanism defined by an IETF Draft and supported by many LDAP implementations. Figure 16-8 shows an example of this synchronization timeline for a Unified CM deployment with LDAP Synchronization and LDAP Authentication both enabled.

Figure 16-8 Change Propagation with iPlanet and Sun ONE

The example in Figure 16-8 involves the following steps:

1. An account is deleted from the corporate directory at 8:00 AM on January 1, which causes an incremental update to be sent from the LDAP server to Unified CM. Unified CM sets its corresponding copy of the data to inactive. Because LDAP authentication is configured, the user will be unable to log in via password as soon as the LDAP server has deleted the record. Also, the PIN may not be used for login at the moment the Unified CM record is marked inactive.
2. During period B, the user's record is still present in Unified CM, albeit inactive.
3. When the garbage collection runs at 3:15 AM on January 2, the record has not yet been inactive for 24 hours. The data remains in the Unified CM database until the beginning of period C on January 3, when the garbage collection process runs again at 3:15 AM and determines that the record has been inactive for 24 hours or more. The record is then permanently deleted from the database.

Accounts that are newly created in the directory are synchronized to Unified CM via incremental updates as well, and they may be used as soon as the incremental update is received.

Security Considerations

During the import of accounts, no passwords or PINs are copied from the LDAP directory to the Unified CM database. If LDAP synchronization is not enabled in Unified CM, the password for the end user is managed by using Unified CM Administration. The password and PIN are stored in an encrypted format in the Unified CM database. The PIN is always managed on Unified CM. If you want to use the LDAP directory password to authenticate an end user, see the section on [LDAP Authentication](#), page 16-19.

The connection between the Unified CM publisher server and the directory server can be secured by enabling Secure LDAP (SLDAP) on Unified CM and the LDAP server. Secure LDAP enables LDAP to be sent over a Secure Socket Layer (SSL) connection and can be enabled by uploading the SSL certificate from within the Unified CM Platform Administration. For detailed procedure steps, refer to the Unified CM product documentation available at <http://www.cisco.com>. Refer to the documentation of the LDAP directory vendor to determine how to enable SLDAP.

Design Considerations for LDAP Synchronization

Observe the following design and implementation best practices when deploying LDAP synchronization with Cisco Unified CM:

- Use a specific account within the corporate directory to allow the Unified CM synchronization agreement to connect and authenticate to it. Cisco recommends that you use an account dedicated to Unified CM, with minimum permissions set to "read" all user objects within the desired search base and with a password set never to expire. The password for this account in the directory must be kept in synchronization with the password configuration of the account in Unified CM. If the service account password changes in the directory, be sure to update the account configuration in Unified CM.
- All synchronization agreements on a given cluster must integrate with the same family of LDAP servers.
- Stagger the scheduling of synchronization agreements so that multiple agreements are not querying the same LDAP servers simultaneously. Choose synchronization times that occur during quiet periods (off-peak hours).
- If security of user data is required, enable Secure LDAP (SLDAP) by checking the **Use SSL** field on the LDAP Directory configuration page in Unified CM Administration.
- Ensure that the LDAP directory attribute chosen to map into the Unified CM UserID field is unique within all synchronization agreements for that cluster.
- The attribute chosen as UserID must not be the same as that for any of the Application Users defined in Unified CM.
- The LDAP attribute sn(lastname) is a mandatory attribute for LDAP Synchronization of users.
- An existing account in the Unified CM database before synchronization is maintained only if an account imported from the LDAP directory has a matching attribute. The attribute that is matched to the Unified CM UserID is determined by the synchronization agreement.
- Administer end-user accounts through the LDAP directory's management tools, and manage the Cisco-specific data for those accounts through the Unified CM Administration web page.
- LDAP Synchronization is supported only with Microsoft NT LAN Manager (NTLM). Kerberos and NTLMv2 are not supported.
- For AD deployments, the ObjectGUID is used internally in Unified CM as the key attribute of a user. The attribute in AD that corresponds to the Unified CM User ID may be changed in AD. For example, if sAMAccountname is being used, a user may change their sAMAccountname in AD, and the corresponding user record in Unified CM would be updated.

With all other LDAP platforms, the attribute that is mapped to User ID is the key for that account in Unified CM. Changing that attribute in LDAP will result in a new user being created in Unified CM, and the original user will be marked inactive.

Additional Considerations for Microsoft Active Directory

A synchronization agreement for a domain will not synchronize users outside of that domain nor within a child domain because Unified CM does not follow AD referrals during the synchronization process. The example in [Figure 16-9](#) requires three synchronization agreements to import all of the users. Although Search Base 1 specifies the root of the tree, it will not import users that exist in either of the child domains. Its scope is only VSE.LAB, and separate agreements are configured for the other two domains to import those users.

Figure 16-9 Synchronization with Multiple Active Directory Domains

In Figure 16-9, each of the domains and sub-domains contains at least one domain controller (DC) associated to them, and the three synchronization agreements each specify the appropriate domain controller. The DCs have information only on users within the domain where they reside, therefore three synchronization agreements are required to import all of the users.

When synchronization is enabled with an AD forest containing multiple trees, as shown in Figure 16-10, multiple synchronization agreements are still needed for the same reasons listed above. Additionally, the UserPrincipalName (UPN) attribute is guaranteed by Active Directory to be unique across the forest and must be chosen as the attribute that is mapped to the Unified CM UserID. For additional considerations on the use of the UPN attribute in a multi-tree AD scenario, see the section on [Additional Considerations for Microsoft Active Directory](#), page 16-21.

Figure 16-10 Synchronization with Multiple AD Trees (Discontiguous Namespaces)

Unified CM sends a default LDAP search filter string to AD when performing the synchronization of accounts. One of the clauses is to not return accounts that have been marked as disabled in AD. An account marked disabled by AD, such as when failed login attempts are exceeded, will be marked inactive if synchronization runs while the account is disabled.

Unified CM Multi-Forest LDAP Synchronization

A Unified CM deployment using a multi-forest LDAP infrastructure can be supported by using Active Directory Lightweight Directory Services (AD LDS) as a single forest view integrating with the multiple disparate forests. The integration also requires the use of LDAP filtering (see [User Filtering for Directory Synchronization and Authentication, page 16-23](#)). For full details, refer to the document on *How to Configure Unified Communication Manager Directory Integration in a Multi-Forest Environment*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/products_configuration_example09186a0080b2b103.shtml

LDAP Authentication

The LDAP authentication feature enables Unified CM to authenticate end user passwords against a corporate LDAP directory instead of using the embedded database. This authentication is accomplished with an LDAPv3 connection established between the IMS module within Unified CM and a corporate directory server, as shown in Figure 16-11.

Figure 16-11 Enabling LDAP Authentication

To enable authentication, a single authentication agreement may be defined for the entire cluster. The authentication agreement supports configuration of up to three LDAP servers for redundancy and also supports secure connections LDAP over SSL (SLDAP) if desired. Authentication can be enabled only when LDAP synchronization is properly configured and used.

The following statements describe Unified CM's behavior when authentication is enabled:

- End user passwords are authenticated against the corporate directory by a simple bind operation.
- Application user passwords are authenticated against the Unified CM database.
- End user PINs are authenticated against the Unified CM database.

This behavior is in line with the guiding principle of providing single logon functionality for end users while making the operation of the real-time Unified Communications system independent of the availability of the corporate directory, and is shown graphically in Figure 16-12.

Figure 16-12 Authenticating End User Passwords, Application User Passwords, and End User PINs

Figure 16-13 illustrates the following process, adopted by Unified CM to authenticate an end user against a corporate LDAP directory:

1. A user connects to the Unified CM User Options page via HTTPS and attempts to authenticate with a user name and password. In this example, the user name is jsmith.
2. Unified CM issues an LDAP query for the user name jsmith, using the value specified in the LDAP Search Base on the LDAP Authentication configuration page as the scope for this query. If SLDAP is enabled, this query travels over an SSL connection.
3. The corporate directory server replies via LDAP with the full Distinguished Name (DN) of user jsmith (for example, "cn=jsmith, ou=Users, dc=vse, dc=lab").
4. Unified CM then attempts to validate the user's credentials by using an LDAP bind operation to pass the full DN and password provided by the user.
5. If the LDAP bind is successful, Unified CM allows the user to proceed to the configuration page requested.

Figure 16-13 Authentication Process

Design Considerations for LDAP Authentication

Observe the following design and implementation best-practices when deploying LDAP authentication with Cisco Unified CM:

- Create a specific account within the corporate directory to allow Unified CM to connect and authenticate to it. Cisco recommends that you use an account dedicated to Unified CM, with minimum permissions set to "read" all user objects within the desired search base and with a password set to never expire. The password for this account in the directory must be kept in synchronization with the password configuration of the account in Unified CM. If the account password changes in the directory, be sure to update the account configuration in Unified CM. If LDAP synchronization is also enabled, you can use the same account for both functions.
- Enable LDAP authentication on Unified CM by specifying the credentials of the aforementioned account under LDAP Manager Distinguished Name and LDAP Password, and by specifying the directory subtree where all the users reside under LDAP User Search Base.
- This method provides single logon functionality to all end users: when they log in to the Unified CM User Options page, they can now use their corporate directory credentials.
- Manage end-user passwords from within the corporate directory interface. Note that the password field is no longer displayed in the Unified CM Administration pages when authentication is enabled.
- Manage end-user PINs from the Unified CM Administration web pages or from the Unified CM User Options page.
- Manage Application User passwords from the Unified CM Administration web pages. Remember that these application users facilitate communication and remote call control with other Cisco Unified Communications applications and are not associated with real people.
- Enable single logon for Unified CM administrators by adding their corresponding end user to the Unified CM Super Users user group from the Unified CM Administration web pages. Multiple levels of administrator rights can be defined by creating customized user groups and roles.

Additional Considerations for Microsoft Active Directory

In environments that employ a distributed AD topology with multiple domain controllers geographically distributed, authentication speed might be unacceptable. When the Domain Controller for the authentication agreement does not contain a user account, a search must occur for that user across other domain controllers. If this configuration applies, and login speed is unacceptable, it is possible to set the authentication configuration to use a Global Catalog Server.

An important restriction exists, however. Because a Global Catalog does not carry the Employee ID attribute, this method cannot be used if the Employee ID is used as the login. Only Domain Controllers may be used with this attribute.

To enable queries against the Global Catalog, simply configure the LDAP Server Information in the LDAP Authentication page to point to the IP address or host name of a Domain Controller that has the Global Catalog role enabled, and configure the LDAP port as 3268.

The use of Global Catalog for authentication becomes even more efficient if the users synchronized from Microsoft AD belong to multiple domains, because it allows Unified CM to authenticate users immediately without having to follow referrals. For these cases, point Unified CM to a Global Catalog server and set the LDAP User Search Base to the top of the root domain.

In the case of a Microsoft AD forest that encompasses multiple trees, some additional considerations apply. Because a single LDAP search base cannot cover multiple namespaces, Unified CM must use a different mechanism to authenticate users across these discontinuous namespaces.

As mentioned in the section on [LDAP Synchronization](#), page 16-10, in order to support synchronization with an AD forest that has multiple trees, the UserPrincipalName (UPN) attribute must be used as the user ID within Unified CM. When the user ID is the UPN, the LDAP authentication configuration page within Unified CM Administration does not allow you to enter the LDAP Search Base field, but instead it displays the note, "LDAP user search base is formed using userid information."

In fact, the user search base is derived from the UPN suffix for each user, as shown in [Figure 16-14](#). In this example, a Microsoft Active Directory forest consists of two trees, `avvid.info` and `vse.lab`. Because the same user name may appear in both trees, Unified CM has been configured to use the UPN to uniquely identify users in its database during the synchronization and authentication processes.

Figure 16-14 Authentication with Microsoft AD Forests with Multiple Trees

As shown in [Figure 16-14](#), a user named John Doe exists in both the avvid.info tree and the vse.lab tree. The following steps illustrate the authentication process for the first user, whose UPN is jdoe@avvid.info:

1. The user authenticates to Unified CM via HTTPS with its user name (which corresponds to the UPN) and password.
2. Unified CM performs an LDAP query against a Microsoft Active Directory Global Catalog server, using the user name specified in the UPN (anything before the @ sign) and deriving the LDAP search base from the UPN suffix (anything after the @ sign). In this case, the user name is jdoe and the LDAP search base is "dc=avvid, dc=info".
3. Microsoft Active Directory identifies the correct Distinguished Name corresponding to the user name in the tree specified by the LDAP query. In this case, "cn=jdoe, ou=Users, dc=avvid, dc=info".
4. Microsoft Active Directory responds via LDAP to Unified CM with the full Distinguished Name for this user.
5. Unified CM attempts an LDAP bind with the Distinguished Name provided and the password initially entered by the user, and the authentication process then continues as in the standard case shown in [Figure 16-13](#).

**Note**

Support for LDAP authentication with Microsoft AD forests containing multiple trees relies exclusively on the approach described above. Therefore, support is limited to deployments where the UPN suffix of a user corresponds to the root domain of the tree where the user resides. AD allows the use of aliases, which allows a different UPN suffix. If the UPN suffix is disjointed from the actual namespace of the tree, it is not possible to authenticate Unified CM users against the entire Microsoft Active Directory forest. (It is, however, still possible to use a different attribute as user ID and limit the integration to a single tree within the forest.)

User Filtering for Directory Synchronization and Authentication

Unified CM provides an LDAP Query Filter to optimize directory synchronization performance. Cisco recommends importing only those directory user accounts that will be assigned to Unified Communications resources in each individual cluster. When the number of directory user accounts exceeds the number supported for an individual cluster, filtering must be used to select the subset of users that will be associated on that cluster. The Unified CM synchronization feature is not meant to replace a large-scale corporate directory.

In many cases, a unique search base is all that is needed to control which accounts are synchronized. When a unique search base is not available, a custom LDAP filter might be required. The information in the following sections addresses both methods that can be used to optimize directory synchronization. When any mechanism is used to limit the accounts imported into Unified CM, the default directory lookup configuration will list only those directory entries that exist in the Unified CM database. For directory lookup to access the entire directory, you must configure Unified CM to utilize an external web server. Details of this configuration are not discussed here but are discussed in the Unified CM product documentation available at

http://www.cisco.com/en/US/partner/products/sw/voicesw/ps556/tsd_products_support_series_home.html

Optimizing Unified CM Database Synchronization

The Unified CM Database Synchronization feature provides a mechanism for importing a subset of the user configuration data (attributes) from the LDAP directory store into the Unified CM publisher database. Once synchronization of a user account has occurred, the copy of each user's LDAP account information may then be associated to additional data required to enable specific Unified Communications features for that user. When authentication is also enabled, the user's credentials are used to bind to the LDAP store for password verification. The end user's password is never stored in the Unified CM database when enabled for synchronization and/or authentication.

User account information is cluster-specific. Each Unified CM publisher server maintains a unique list of those users receiving Unified Communications services from that cluster. Synchronization agreements are cluster-specific, and each publisher has its own unique copy of user account information. Only those users who will be assigned Unified Communications resources should be synchronized with Unified CM. The following is a partial list of common reasons why the entire set of users defined in the LDAP directory should not be imported into the Unified CM cluster:

- Importing users who will not be assigned Unified Communications resources can increase directory synchronization time.
- Importing users who will not be assigned Unified Communications resources can slow Unified CM searches and overall database performance.
- In many cases, the number of user accounts in the LDAP directory store far exceeds the total user capacity of the Unified CM database.

Unified CM has no enforced limit on the number of accounts that may be added to the system. Cisco recommends limiting the number of users to the same quantity as the supported number of endpoints. For example, a full-sized cluster of Cisco MCS-7845 servers can support up to 30,000 endpoints, and the system should be administered to limit the number of users to roughly 30,000. There might be cases where accounts are needed for applications, and some designs might require additional accounts.

Cisco recommends using the control mechanisms described here to minimize the number of user accounts imported, regardless of the LDAP database size. This will improve the speed of the first and subsequent periodic synchronizations and will also improve manageability of the user accounts.

Using the LDAP Structure to Control Synchronization

Many deployments of LDAP directories use the Organizational Unit Name (OU) to group users into a logical order and sometimes hierarchical order. If the LDAP directory has a structure that organizes users into multiple OUs, then it often is possible to use that structure to control the groups of users imported. Each individual Unified CM synchronization agreement specifies a single OU. All active accounts under the specified OU, even within sub-OUs, are imported. Only those users in the OU are synchronized. When multiple OUs containing users are required in a cluster, multiple synchronization agreements are required. When an OU contains users that will not be assigned Unified Communications resources, Cisco recommends omitting those OUs from the directory synchronization.

The same technique may be used with AD, which defines containers. A synchronization agreement may specify a particular container in the directory tree and thereby limit the extent of the import.

Because there are only five synchronization agreements available, LDAP deployments with many OUs or containers can quickly exhaust this technique. One possible method to synchronize users in a multi-OU environment is to control the permissions assigned to the synchronization service account. Configure the synchronization agreement to a tree node that contains a mix of users, and then restrict the system account from read access to selected parts of the subtree. Refer to your LDAP vendor documentation on how to restrict this access.

LDAP Query

Additional control over filtering might be required for any of the following reasons:

- The LDAP directory has a flat structure that does not enable adequate control by configuration of the synchronization agreements. When the aggregate number of users that are imported by all the synchronization agreements is greater than the maximum number of users supported by the Unified CM cluster, then it is necessary to control the number of users imported through filters.
- You want to import a subset of user accounts into the Unified CM cluster, for administrative segmentation of users, to control a subset of users that have access and authentication to the cluster. Any account that is imported into a cluster has some level of access to the web pages and authentication mechanisms, which might not be desirable in some cases.
- The LDAP directory structure does not have an accurate representation of how users are going to be mapped into the Unified CM clusters. For instance, if OUs are set up according to an organizational hierarchy but users are mapped to Unified CM by geography, there might be little overlap between the two.

In these cases, the LDAP Query filter may be used to provide additional control over the synchronization agreements.

LDAP Query Filter Syntax and Server-Side Filtering

Unified CM uses standard LDAP mechanisms for synchronizing data from an LDAP directory store. It utilizes the Search mechanism, as defined by RFC 2251—Lightweight Directory Access Protocol (v3), to send a request to retrieve data from the LDAP server. Also defined by that mechanism is the ability to specify a filter string inside the Search message that is used by the LDAP server to select entries in the database for which to return data. The syntax of the filter string is defined by RFC 2254, The String Representation of LDAP Search Filters. This RFC may be used as a reference for constructing more complex filter strings.

The filter string is embedded within a Search message that is sent by Unified CM to the LDAP server and is executed by the server to select which user accounts will be provided in the response.

Simple Filter Syntax

You can configure a filter by specifying standard attribute names and values that are desired for those attributes. The attributes may also be specified by DN element instead of name. The filter string that is used by Unified CM in LDAP queries is stored internally in the `ldapfilter` table and is the string inserted into the Search message.

A filter is a UTF-8 formatted string that has the following syntax:

(attribute operator value)

or

(operator(filter1)(filter2))

Where *filter1* and *filter2* have the syntax shown in first line, and the *operator* is one of those listed in [Table 16-7](#). The *attribute* corresponds to an LDAP attribute that exists in the directory, *operator* is one of the operators listed in [Table 16-7](#), and *value* corresponds to the actual data value that is requested for the attribute.

Table 16-7 Basic Filter String Operators

| Operator | Meaning of Function |
|----------|--|
| ! | Logical NOT |
| & | Logical AND |
| | Logical OR |
| * | Wildcard |
| = | Equal to |
| >= | Lexicographically greater than or equal to |
| <= | Lexicographically less than or equal to |

An attribute specified in the filter can be any attribute that exists in the LDAP directory store, and it does not have to be one of the attributes that is understood and imported by Unified CM. The attribute is used only on the LDAP server to select data, and the corresponding entries will have a subset of their data imported into Unified CM.

Example 16-1 A Single Condition

```
(givenName=Jack)
```

The filter in [Example 16-1](#) selects any user with a given name of Jack.

Example 16-2 Multiple Conditions May Be Joined with Logical Characters

```
(&(objectclass=user)(department=Engineering))
```

The filter in [Example 16-2](#) selects all users in the engineering department.

Default Filter Strings

The filter string has a default value in the `ldapfilter` table, `typeldapserver`, and that default value depends on the LDAP directory store being used, as indicated by the following cases:

- Default Active Directory (AD) filter string

```
(&(objectclass=user)(!(objectclass=Computer))(!(UserAccountControl:1.2.840.113556.1.4.803:=2)))
```

This default filter selects entries for which the object class is a user but not a computer, and for which the account is not flagged as disabled.

- Default SunOne or Netscape filter string

```
(objectclass=inetOrgPerson)
```

This default filter selects all users for which the object class is `inetOrgPerson`.

- Default OpenLDAP filter string

```
(objectclass=inetOrgPerson)
```

- Default Active Directory Application Mode (ADAM) or Active Directory Lightweight Directory Services (AD LDS) filter string

```
(&(objectclass=user)((objectclass=Computer))(!(msDS-UserAccountDisabled=TRUE)))
```

Extending the Default Filter

Cisco recommends that you use the default filter string and append additional conditions to it. For example:

```
(&(objectclass=user)(!(objectclass=Computer))(!(UserAccountControl:1.2.840.1.13556.1.4.803:=2)))(telephonenumber=919*)
```

This filter selects only users that have a prefix of 919 in their telephonenumber field. The synchronization agreement will import only users with an area code of 919. This example assumes all entries begin with an area code.

For the search filter, you may use any existing attribute or even a custom attribute that is defined in the LDAP directory store. The filter string controls which records are selected by the LDAP server to be returned to Unified CM, but the attributes that are imported are not affected by the filter string. The filter string that is used by Unified CM for LDAP queries is stored internally in the `ldapfilter` database table, and that string can be up to 1024 characters long. Unified CM can support a custom filter for each LDAP Directory Synchronization agreement.

High Availability

Unified CM LDAP Synchronization allows for the configuration of up to three redundant LDAP servers for each directory synchronization agreement. Unified CM LDAP Authentication allows for the configuration of up to three redundant LDAP servers for a single authentication agreement. You should configure a minimum of two LDAP servers for redundancy. The LDAP servers can be configured with IP addresses instead of host names to eliminate dependencies on Domain Name System (DNS) availability.

Capacity Planning for Unified CM Database Synchronization

The Unified CM Database Synchronization feature provides a mechanism for importing a subset of the user configuration data (attributes) from the LDAP store into the Unified CM publisher database. Once synchronization of a user account has occurred, the copy of each user's LDAP account information may then be associated to additional data required to enable specific Unified Communications features for that user. When authentication is also enabled, the user's credentials are used to bind to the LDAP store for password verification. The end user's password is never stored in the Unified CM database when enabled for synchronization and/or authentication.

User account information is cluster-specific. Each Unified CM publisher server maintains a unique list of those users receiving Unified Communications services from that cluster. Synchronization agreements are cluster-specific, and each publisher has its own unique copy of user account information.

The maximum number of users that a Unified CM cluster can handle is limited by the maximum size of the internal configuration database that gets replicated between the cluster members. Starting with Unified CM release 8.6(1), the maximum number of users that can be configured or synchronized was increased from 60,000 to 80,000. To optimize directory synchronization performance, Cisco recommends considering the following points:

- Directory lookup from phones and web pages may use the Unified CM database or the IP Phone Service SDK. When directory lookup functionality uses the Unified CM database, only users who were configured or synchronized from the LDAP store are shown in the directory. If a subset of users are synchronized, then only that subset of users are seen on directory lookup.
- When the IP Phone Services SDK is used for directory lookup, but authentication of Unified CM users to LDAP is needed, the synchronization can be limited to the subset of users who would log in to the Unified CM cluster.

- If only one cluster exists, and the LDAP store contains fewer than the maximum number of users supported by the Unified CM cluster, and directory lookup is implemented to the Unified CM database, then it is possible to import the entire LDAP directory.
- When multiple clusters exist and the number of users in LDAP is less than the maximum number of users supported by the Unified CM cluster, it is possible to import all users into every cluster to ensure directory lookup has all entries.
- If the number of user accounts in LDAP exceeds the maximum number of users supported by the Unified CM cluster and the entire user set should be visible to all users, it will be necessary to use the Unified IP Phone Services SDK to off-load the directory lookup from Unified CM.
- If both synchronization and authentication are enabled, user accounts that have either been configured or synchronized into the Unified CM database will be able to log in to that cluster. The decision about which users to synchronize will impact the decision on directory lookup support.

**Note**

Cisco supports the synchronization of user accounts up to the limit mentioned above, but it does not enforce this limit. Synchronizing more user accounts can lead to starvation of disk space, slower database performance, and longer upgrade times.

CHAPTER 17

Media Resources

Revised: April 30, 2012; OL-21733-18

A media resource is a software-based or hardware-based entity that performs media processing functions on the data streams to which it is connected. Media processing functions include mixing multiple streams to create one output stream (conferencing), passing the stream from one connection to another (media termination point), converting the data stream from one compression type to another (transcoding), streaming music to callers on hold (music on hold), echo cancellation, signaling, voice termination from a TDM circuit (coding/decoding), packetization of a stream, streaming audio (annunciation), and so forth. The software-based resources are provided by the Unified CM IP Voice Media Streaming Service (IP VMS). Digital signal processor (DSP) cards provide both software and hardware based resources.

This chapter explains the overall Media Resources Architecture and Cisco IP Voice Media Streaming Application service, and it focuses on the following media resources:

- [Voice Termination, page 17-4](#)
- [Conferencing, page 17-6](#)
- [Transcoding, page 17-9](#)
- [Media Termination Point \(MTP\), page 17-12](#)
- [Trusted Relay Point, page 17-19](#)
- [Annunciator, page 17-20](#)
- [Cisco RSVP Agent, page 17-21](#)
- [Music on Hold, page 17-21](#)

Use this chapter to gain an understanding of the function and capabilities of each media resource type and to determine which resource would be required for your deployment.

For proper DSP sizing of Cisco Integrated Service Router (ISR) gateways, you can use the Cisco Unified Communications Sizing Tool (Unified CST), available to Cisco employees and partners at <http://tools.cisco.com/cucst>. If you are not a Cisco partner or employee, you can use the DSP Calculator at <http://www.cisco.com/go/dspcalculator>. For other Cisco non-ISR gateway platforms (such as the Cisco 1700, 2600, 3700, and AS5000 Series) and/or Cisco IOS releases preceding and up to 12.4 mainline, you can access the legacy DSP calculator at http://www.cisco.com/cgi-bin/Support/DSP/cisco_dsp_calc.pl.

What's New in This Chapter

Table 17-1 lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Table 17-1 *New or Changed Information Since the Previous Release of This Document*

| New or Revised Topic | Described in: | Revision Date |
|---|--|-------------------|
| Numerous updates and general reorganization of the chapter | All sections of this chapter | April 30, 2012 |
| Minor corrections and changes | Various sections throughout this chapter | June 30, 2011 |
| Cisco Business Edition capability | Various sections throughout this chapter | February 28, 2011 |
| DSP calculator tools for DSP sizing for Cisco ISR gateways and legacy platforms | Various sections throughout this chapter | February 28, 2011 |
| Updates to DSP hardware and Cisco IOS release versions | Various sections throughout this chapter | February 28, 2011 |
| Music on Hold (MoH) information has been integrated into this chapter, and the separate MoH chapter has been eliminated from this document. | Various sections throughout this chapter | November 15, 2010 |
| Cisco Integrated Services Routers Generation 2 (ISR G2) platforms | Various sections throughout this chapter | April 2, 2010 |
| PVDM3 DSPs | Various sections throughout this chapter | April 2, 2010 |

Media Resources Architecture

To properly design the media resource allocation strategy for an enterprise, it is critical to understand the Cisco Unified CM architecture for the various media resource components. The following sections highlight the important characteristics of media resource design with Unified CM.

Media Resource Manager

The Media Resource Manager (MRM), a software component in the Unified CM, determines whether a media resource needs to be allocated and inserted in the media path. This media resource may be provided by the Unified CM IP Voice Media Streaming Application service or by digital signal processor (DSP) cards. When the MRM decides and identifies the type of the media resource, it searches through the available resources according to the configuration settings of the media resource group list (MRGL) and media resource groups (MRGs) associated with the devices in question. MRGLs and MRGs are constructs that hold related groups of media resources together for allocation purposes and are described in detail in the section on [Media Resource Groups and Lists](#), page 17-39.

Figure 17-1 shows how a media resource such as a transcoder may be placed in the media path between an IP phone and a Cisco Unified Border Element when a common codec between the two is not available.

Figure 17-1 Use of a Transcoder Where a Common Codec Is Not Available

Unified CM communicates with media resources using Skinny Client Control Protocol (SCCP). This messaging is independent of the protocol that might be in use between Unified CM and the communicating entities. Figure 17-2 shows an example of the message flow, but it does not show all of the SCCP or SIP messages exchanged between the entities.

Figure 17-2 Message Flow Between Components

Cisco IP Voice Media Streaming Application

The Cisco IP Voice Media Streaming Application provides the following software-based media resources:

- Conference bridge
- Music on Hold (MoH)
- Annunciator
- Media termination point (MTP)

The details of these resources are covered in the respective sections below.

When the IP Voice Media Streaming Application is activated, one of each of the above resources is automatically configured. Conferencing, annunciator, and MTP services can be disabled if required. If these resources are not needed, Cisco recommends that you disable them by modifying the appropriate service parameter in the Unified CM configuration. The service parameters have default settings for the maximum number of connections that each service can handle. For details on how to modify the service parameters, refer to the appropriate version of the *Cisco Unified Communications Manager Administration Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

Give careful consideration to situations that require multiple resources and to the load they place on the IP Voice Media Streaming Application. The media resources can reside on the same server as Unified CM or on a dedicated server not running the Unified CM call processing service. If your deployment requires more than the default number of any resource, Cisco recommends that you configure that resource to run on its own dedicated server. If heavy use of media resources is expected within a deployment, Cisco recommends deploying dedicated Unified CM media resource nodes (non-publisher nodes that do not perform call processing within the cluster) or relying on hardware-based media resources. Software-based media resources on Unified CM nodes are intended for small deployments or deployments where need for media resources is limited.

**Note**

Cisco Business Edition 3000 provides only MoH and annunciator software-based media resources. No software-based media resources are available for conferencing and MTP. Hardware-based conferencing and MTP resources are provided by the DSP cards on board the Cisco MCS 7890 C2 platform.

Voice Termination

Voice termination applies to a call that has two call legs, one leg on a time-division multiplexing (TDM) interface and the second leg on a Voice over IP (VoIP) connection. The TDM leg must be terminated by hardware that performs encoding/decoding and packetization of the stream. This termination function is performed by a digital signal processor (DSP) resource residing in the same hardware module, blade, or platform.

All DSP hardware on Cisco TDM gateways is capable of terminating voice streams, and certain hardware is also capable of performing other media resource functions such as conferencing or transcoding (see [Conferencing, page 17-6](#) and [Transcoding, page 17-9](#)). The DSP hardware has either fixed DSP resources that cannot be upgraded or changed, or modular DSP resources that can be upgraded.

The number of supported calls per DSP depends on the computational complexity of the codec used for a call and also on the complexity mode configured on the DSP. Cisco IOS enables you to configure a complexity mode on the hardware module. Hardware platforms such as the PVDM2 and PVDM3 DSPs support three complexity modes: medium, high and flex mode. Some of the other hardware platforms support only medium and high complexity modes.

Medium and High Complexity Mode

You can configure each DSP separately as either medium complexity, high complexity, or flex mode (PVDM3 DSPs and those based on C5510). The DSP treats all calls according to its configured complexity, regardless of the actual complexity of the codec of the call. A resource with configured complexity equal or higher than the actual complexity of the incoming call must be available, or the call will fail. For example, if a call requires a high-complexity codec but the DSP resource is configured for medium complexity mode, the call will fail. However, if a medium-complexity call is attempted on a DSP configured for high complexity mode, then the call will succeed and Cisco IOS will allocate a high-complexity mode resource.

Flex Mode

Flex mode, available on hardware platforms that use the C5510 chipset and on PVDM3 DSPs, eliminates the requirement to specify the codec complexity at configuration time. A DSP in flex mode accepts a call of any supported codec type, as long as it has available processing power.

For C5510-based DSPs, the overhead of each call is tracked dynamically via a calculation of processing power in millions of instructions per second (MIPS). Cisco IOS performs a MIPS calculation for each call received and subtracts MIPS credits from its budget whenever a new call is initiated. The number of MIPS consumed by a call depends on the codec of the call. The DSP will allow a new call as long as it has remaining MIPS credits greater than or equal to the MIPS required for the incoming call.

Similarly, PVDM3 DSP modules use a credit-based system. Each module is assigned a fixed number of "credits" that represent a measure of its capacity to process media streams. Each media operation, such as voice termination, transcoding, and so forth, is assigned a cost in terms of credits. As DSP resources are allocated for a media processing function, its cost value is subtracted from the available credits. A DSP module runs out of capacity when the available credits run out and are no longer sufficient for the requested operation. The credit allocation rules for PVDM3 DSPs are rather complex.

For proper DSP sizing of Cisco ISR gateways, you can use the Cisco Unified Communications Sizing Tool (Unified CST), available to Cisco employees and partners at <http://tools.cisco.com/cucst>. If you are not a Cisco partner, you can use the DSP Calculator at <http://www.cisco.com/go/dspcalculator>. For other Cisco non-ISR gateway platforms (such as the Cisco 1700, 2600, 3700, and AS5000 Series) and/or Cisco IOS releases preceding and up to 12.4 mainline, you can access the legacy DSP calculator at http://www.cisco.com/cgi-bin/Support/DSP/cisco_dsp_calc.pl.

Flex mode has an advantage when calls of multiple codecs must be supported on the same hardware because flex mode can support more calls than when the DSPs are configured as medium or high complexity. However, flex mode does allow oversubscription of the resources, which introduces the risk of call failure if all resources are used. With flex mode it is possible to have fewer DSP resources than with physical TDM interfaces.

Compared to medium or high complexity mode, flex mode has the advantage of supporting the most G.711 calls per DSP. For example, a PVDM2-16 DSP can support 8 G.711 calls in medium complexity mode or 16 G.711 calls in flex mode.

Conferencing

A conference bridge is a resource that joins multiple participants into a single call (audio or video). It can accept any number of connections for a given conference, up to the maximum number of streams allowed for a single conference on that device. There is a one-to-one correspondence between media streams connected to a conference and participants connected to the conference. The conference bridge mixes the streams together and creates a unique output stream for each connected party. The output stream for a given party is the composite of the streams from all connected parties minus their own input stream. Some conference bridges mix only the three loudest talkers on the conference and distribute that composite stream to each participant (minus their own input stream if they are one of the talkers).

Audio Conferencing

Audio conferencing can be performed by both software-based and hardware-based conferencing resources. A hardware conference bridge has all the capabilities of a software conference bridge. In addition, some hardware conference bridges can support multiple low bit-rate (LBR) stream types such as G.729 or G.723. This capability enables some hardware conference bridges to handle mixed-mode conferences. In a mixed-mode conference, the hardware conference bridge transcodes G.729 and G.723 streams into G.711 streams, mixes them, and then encodes the resulting stream into the appropriate stream type for transmission back to the user. Some hardware conference bridges support only G.711 conferences.

All conference bridges that are under the control of Cisco Unified Communications Manager (Unified CM) use Skinny Client Control Protocol (SCCP) to communicate with Unified CM.

Unified CM allocates a conference bridge from a conferencing resource that is registered with the Unified CM cluster. Both hardware and software conferencing resources can register with Unified CM at the same time, and Unified CM can allocate and use conference bridges from either resource. Unified CM does not distinguish between these types of conference bridges when it processes a conference allocation request.

The number of individual conferences that may be supported by the resource varies, and the maximum number of participants in a single conference varies, depending on the resource.

The following types of conference bridge resources may be used on a Unified CM system:

- [Software Audio Conference Bridge \(Cisco IP Voice Media Streaming Application\)](#), page 17-6
- [Hardware Audio Conference Bridge \(Cisco NM-HDV2, NM-HD-1V/2V/2VE, PVDM2, and PVDM3 DSPs\)](#), page 17-7
- [Hardware Audio Conference Bridge \(Cisco WS-SVC-CMM-ACT\)](#), page 17-7
- [Hardware Audio Conference Bridge \(Cisco NM-HDV and 1700 Series Routers\)](#), page 17-7

Software Audio Conference Bridge (Cisco IP Voice Media Streaming Application)

A software unicast conference bridge is a standard conference mixer that is capable of mixing G.711 audio streams and Cisco Wideband audio streams. Any combination of Wideband or G.711 a-law and mu-law streams may be connected to the same conference. The number of conferences that can be supported on a given configuration depends on the server where the conference bridge software is running and on what other functionality has been enabled for the application. The Cisco IP Voice Media Streaming Application is a resource that can also be used for several functions, and the design must consider all functions together (see [Cisco IP Voice Media Streaming Application](#), page 17-4).

Hardware Audio Conference Bridge (Cisco NM-HDV2, NM-HD-1V/2V/2VE, PVDM2, and PVDM3 DSPs)

DSPs that are configured through Cisco IOS as conference resources will load firmware into the DSPs that are specific to conferencing functionality only, and these DSPs cannot be used for any other media feature. Any PVDM2 or PVDM3 based hardware, such as the NM-HDV2, may be used simultaneously in a single chassis for voice termination but may not be used simultaneously for other media resource functionality. The DSPs based on PVDM-256K and PVDM2 have different DSP farm configurations, and only one may be configured in a router at a time. DSPs on PVDM2 hardware are configured individually as voice termination, conferencing, media termination, or transcoding, so that DSPs on a single PVDM may be used as different resource types. Allocate DSPs to voice termination first, then to other functionality as needed.

Starting with Cisco IOS Release 12.4(15)T, the limit on the maximum number of participants has been increased to 32. A conference based on these DSPs can be configured to have a maximum of 8, 16, or 32 participants. The DSP resources for a conference are reserved during configuration, based on the profile attributes and irrespective of how many participants actually join. Refer to the following module data sheets for accurate information on module capacity and capabilities:

- For capacity information on PVDM2 modules, refer to the *High-Density Packet Voice Digital Signal Processor Module for Cisco Unified Communications Solutions* data sheet, available at http://www.cisco.com/en/US/prod/collateral/routers/ps5854/product_data_sheet0900aecd8016e845_ps3115_Products_Data_Sheet.html
- For capacity information on PVDM3 modules, refer to the *High-Density Packet Voice Video Digital Signal Processor Module for Cisco Unified Communications Solutions* data sheet, available at http://www.cisco.com/en/US/prod/collateral/modules/ps3115/data_sheet_c78-553971.html

**Note**

The integrated gateway on the Cisco MCS 7890 C2 platform for Cisco Business Edition 3000 supports up to 24 conference streams.

Hardware Audio Conference Bridge (Cisco WS-SVC-CMM-ACT)

The following guidelines and considerations apply to this DSP resource:

- DSPs on this hardware are configured individually as voice termination, conferencing, media termination, or transcoding, so that DSPs on a single module may be used as different resource types. Allocate DSPs to voice termination first.
- Each ACT Port Adaptor contains 4 DSPs that are individually configurable. Each DSP can support 32 conference participants. You can configure up to 4 ACT Port Adaptors per CMM Module.
- This Cisco Catalyst-based hardware provides DSP resources that can provide conference bridges of up to 128 participants per bridge. A conference bridge may span multiple DSPs on a single ACT Port Adaptor; but conference bridges cannot span across multiple ACT Port Adaptors.
- The G.711 and G.729 codecs are supported on these conference bridges without extra transcoder resources. However, transcoder resources would be necessary if other codecs are used.

Hardware Audio Conference Bridge (Cisco NM-HDV and 1700 Series Routers)

The following guidelines and considerations apply to these DSP resources:

- This hardware utilizes the PVDM-256K type modules that are based on the C549 DSP chipset.
- Conferences using this hardware provide bridges that allow up to 6 participants in a single bridge.
- The resources are configured on a per-DSP basis as conference bridges.

- The NM-HDV may have up to 5 PVDM-256K modules, while the Cisco 1700 Series Routers may have 1 or 2 PVDM-256K modules.
- Each DSP provides a single conference bridge that can accept G.711 or G.729 calls.
- The Cisco 1751 is limited to 5 conference calls per chassis, and the Cisco 1760 can support 20 conference calls per chassis.

**Note**

Any PVDM2-based hardware, such as the NM-HDV2, may be used simultaneously in a single chassis for voice termination but may not be used simultaneously for other media resource functionality. The DSPs based on PVDM-256K and PVDM2 have different DSP farm configurations, and only one may be configured in a router at a time.

Video Conferencing

Video-capable endpoints provide the capability to conduct video conferences that function similar to audio conferences. Video conferences can be invoked as ad-hoc conferences from a Skinny Client Control Protocol (SCCP) device through the use of Conf, Join, or cBarge softkeys.

The video portion of the conference can operate in either of two modes:

- Voice activation

In this mode, the video endpoints display the dominant participant (the one speaking most recently or speaking the loudest). In this way, the video portion follows or tracks the audio portion. This mode is optimal when one participant speaks most of the time, as with an instructor teaching or training a group.

- Continuous presence

In this mode, input from all (or selected) video endpoints is displayed simultaneously and continuously. The audio portion of the conference follows or tracks the dominant speaker. Continuous presence is more popular, and it is optimal for conferences or discussions between speakers at various sites.

Videoconferencing resources are of two types:

- Software videoconferencing bridges

Software videoconferencing bridges process video and audio for the conference using just software. Cisco Unified MeetingPlace Express Media Server is a software videoconferencing bridge that can support ad-hoc video conferences. Cisco Unified MeetingPlace Express Media Server supports only voice activation mode for video conferences.

- Hardware videoconferencing bridges

Hardware videoconferencing bridges have hardware DSPs that are used for the video conferences. The Cisco 3500 Series Multipoint Control Units (MCUs) and, starting with Cisco IOS Release 15.1.4M, the PVDM3 DSPs provide this type of videoconferencing bridge. Most hardware videoconferencing bridges can also be used as audio-only conference bridges. Hardware videoconferencing bridges provide the advantages of video transrating, higher video resolution, and scalability.

Videoconferencing bridges can be configured in a manner similar to audio conferencing resources, with similar characteristics for media resource groups (MRGs) and media resource group lists (MRGLs) for the device pools or endpoints.

Cisco Unified CM includes the Intelligent Bridge Selection feature, which provides a method for selecting conference resources based on the capabilities of the endpoints in the conference. For additional details on this functionality, see [Intelligent Bridge Selection, page 12-20](#).

Secure Conferencing

Secure conferencing is a way to use regular conferencing to ensure that the media for the conference is secure and cannot be compromised. There are various security levels that a conference can have, such as authenticated or encrypted. With secure conferencing, the devices and conferencing resource can be authenticated to be trusted devices, and the conference media can then be encrypted so that every authenticated participant sends and received encrypted media for that conference. In most cases the security level of the conference will depend on the lowest security level of the participants in the conference. For example, if there is one participant who is not using a secure endpoint, then the entire conference will be non-secure. As another example, if one of the endpoints is authenticated but does not do encryption, then the conference will be in authenticated mode.

Secure conferencing provides conferencing functionality at an enhanced security level and prevents unauthorized capture and decryption of conference calls.

Consider the following factors when designing secure conferencing:

- Security levels of devices (phones and conferencing resources)
- Security overhead for call signaling and secure (SRTP) media
- Bandwidth utilization impact if secure participants are across the WAN
- Any intermediate devices such as NAT and firewalls that might not support secure calls across them

Secure conferencing is subject to the following restrictions and limitations:

- Secure conferencing is supported only for audio conferencing; video conferencing is not supported.
- With secure conferencing, Cisco IOS DSPs support a maximum of 8 participants in a conference.
- Secure conferencing may also use more DSP resources than non-secure conferencing, so DSPs must be provisioned according to the DSP Calculator.
- Some protocols may rely on IPSec to secure the call signaling.
- Secure conferencing cannot be cascaded between Unified CM and Unified CM Express.
- MTPs and transcoders do not support secure calls. Therefore, a conference might no longer be secure if any call into that conference invokes an MTP or a transcoder.
- An elaborate security policy might be needed.
- Secure conferencing might not be available for all codecs.

Transcoding

A transcoder is a device that converts an input stream from one codec into an output stream that uses a different codec. Starting with Cisco IOS Release 15.0.1M, a transcoder also supports transrating, whereby it connects two streams that utilize the same codec but with a different packet size.

Transcoding from G.711 to any other codec is referred to as traditional transcoding. Transcoding between any two non-G.711 codecs is called universal transcoding and requires Universal Cisco IOS transcoders. Universal transcoding is supported starting with Cisco IOS Release 12.4.20T. Universal transcoding has a lower DSP density than traditional transcoding.

In a Unified CM system, the typical use of a transcoder is to convert between a G.711 voice stream and the low bit-rate compressed voice stream G729a. The following cases determine when transcoder resources are needed:

- Single codec for the entire system

A single codec is generally used in a single-site deployment that usually has no need for conserving bandwidth. When a single codec is configured for all calls in the system, then no transcoder resources are required. In this scenario, G.711 is the most common choice that is supported by all vendors.

- Multiple codecs in use in the system, with all endpoints capable of all codec types

The most common reason for multiple codecs is to use G.711 for LAN calls to maximize the call quality and to use a low-bandwidth codec to maximize bandwidth efficiency for calls that traverse a WAN with limited bandwidth. Cisco recommends using G.729a as the low-bandwidth codec because it is supported on all Cisco Unified IP Phone models as well as most other Cisco Unified Communications devices, therefore it can eliminate the need for transcoding. Although Unified CM allows configuration of other low-bandwidth codecs between regions, some phone models do not support those codecs and therefore would require transcoders. They would require one transcoder for a call to a gateway and two transcoders if the call is to another IP phone. The use of transcoders is avoided if all devices support and are configured for both G.711 and G.729 because the devices will use the appropriate codec on a call-by-call basis.

- Multiple codecs in use in the system, and some endpoints support or are configured for G.711 only

This condition exists when G.729a is used in the system but there are devices that do not support this codec, or a device with G.729a support may be configured to not use it. In this case, a transcoder is also required. Devices from some third-party vendors may not support G.729.

Note

Cisco Unified MeetingPlace Express prior to release 2.0 supported G.711 only. In an environment where G.729 is configured for a call into earlier versions of Cisco Unified MeetingPlace Express, transcoder resources are required.

A transcoder is also capable of performing the same functionality as a media termination point (MTP). In cases where transcoder functionality and MTP functionality are both needed, a transcoder is allocated by the system. If MTP functionality is required, Unified CM will allocate either a transcoder or an MTP from the resource pool, and the choice of resource will be determined by the media resource groups, as described in the section on [Media Resource Groups and Lists, page 17-39](#).

To finalize the design, it is necessary to know how many transcoders are needed and where they will be placed. For a multi-site deployment, Cisco recommends placing a transcoder local at each site where it might be required. If multiple codecs are needed, it is necessary to know how many endpoints do not support all codecs, where those endpoints are located, what other groups will be accessing those resources, how many maximum simultaneous calls these device must support, and where those resources are located in the network.

Transcoding Resources

DSP resources are required to perform transcoding. Those DSP resources can be located in the voice modules and the hardware platforms for transcoding that are listed in the following sections.

Hardware Transcoder (Cisco NM-HDV2, NM-HD-1V/2V/2VE, and PVDM2 DSPs)

The number of sessions supported on each DSP is determined by the codecs used in universal transcoding mode. The following guidelines and considerations apply to these DSP resources:

- Transcoding is available between G.711 mu-law or a-law and G.729a, G.729ab, G.722, and iLBC. A single PVDM2-16 can support 8 sessions for transcoding between low and medium complexity codecs (such as G.711 and G.729a or G.722) or 6 sessions for transcoding between low and high complexity codecs (such as G.711 and G.729 or iLBC).

**Note**

If transcoding is not required between G.711 and G.722, Cisco recommends that you do not include G.722 in the Cisco IOS configuration of the dspfarm profile. This is to preclude Unified CM from selecting G.722 as the codec for a call in which transcoding is required. DSP resources configured as Universal Transcoders are required for transcoding between G.722 and other codecs.

- Cisco Unified IP Phones use only the G.729a variants of the G.729 codecs. The default for a new DSP farm profile is G.729a/G.729ab/G.711u/G.711a. Because a single DSP can provide only one function at a time, the maximum sessions configured on the profile should be specified in multiples of 8 to prevent wasted resources.

For capacity information on PVDM2 modules, refer to the *High-Density Packet Voice Digital Signal Processor Module for Cisco Unified Communications Solutions* data sheet, available at

http://www.cisco.com/en/US/prod/collateral/routers/ps5854/product_data_sheet0900aecd8016e845_ps3115_Products_Data_Sheet.html

Hardware Transcoder (Cisco WS-SVC-CMM-ACT)

The following guidelines and considerations apply to this DSP resource:

- Transcoding is available between G.711 mu-law or a-law and G.729, G.729b, or G.723.
- There are 4 DSPs per ACT that may be allocated individually to DSP pools.
- The CCM-ACT can have 16 transcoded calls per DSP or 64 per ACT. The ACT reports resources as streams rather than calls, and a single transcoded call consists of two streams.

Hardware Transcoder (Cisco NM-HDV and 1700 Series Routers)

The following guidelines and considerations apply to these DSP resources:

This hardware utilizes the PVDM-256K type modules, and each DSP provides 2 transcoding sessions.

- The NM-HDV may have up to 4 PVDM-256K modules, and the Cisco 1700 Series Routers may have 1 or 2 PVDM-256K modules. The Cisco 1751 Router has a chassis limit of 16 sessions, and the Cisco 1760 Router has a chassis limit of 20 sessions.
- NM-HDV and NM-HDV2 modules may be used simultaneously in a single chassis for voice termination but may not be used simultaneously for other media resource functionality. Only one type of DSP farm configuration may be active at one time (either the NM-HDV or the NM-HDV2) for conferencing, MTP, or transcoding.

- Transcoding is supported from G.711 mu-law or a-law to any of G.729, G.729a, G.729b, or G.729ab codecs.

Hardware Transcoder (PVDM3 DSP)

PVDM3 DSPs are hosted by Cisco 2900 Series and 3900 Series Integrated Services Routers, and they support both secure and non-secure transcoding from any and to any codec. As with voice termination and conferencing, each transcoding session debits the available credits for each type of PVDM3 DSPs. The available credits determine the total capacity of the DSP.

For example, a PVDM3-16 can support 12 sessions for transcoding between low and medium complexity codecs (such as G.711 and G.729a or G.722) or 10 sessions for transcoding between low and high complexity codecs (such as G.711 and G.729 or iLBC).

Note

For Cisco Business Edition 3000, the default gateway configuration will support only 10 transcoding sessions per Cisco MCS 7890 appliance.

For capacity information on PVDM3 modules, refer to the *High-Density Packet Voice Video Digital Signal Processor Module for Cisco Unified Communications Solutions* data sheet, available at

http://www.cisco.com/en/US/prod/collateral/modules/ps3115/data_sheet_c78-553971.html

Media Termination Point (MTP)

A media termination point (MTP) is an entity that accepts two full-duplex media streams. It bridges the streams together and allows them to be set up and torn down independently. The streaming data received from the input stream on one connection is passed to the output stream on the other connection, and vice versa. MTPs have many possible uses, such as:

- [Re-Packetization of a Stream, page 17-12](#)
- [DTMF Conversion, page 17-12](#)
- Protocol-specific usage
 - [DTMF Relay over SIP Trunks, page 17-14](#)
 - [H.323 Supplementary Services, page 17-17](#)
 - [H.323 Outbound Fast Connect, page 17-17](#)

Re-Packetization of a Stream

An MTP can be used to transcode G.711 a-law audio packets to G.711 mu-law packets and vice versa, or it can be used to bridge two connections that utilize different packetization periods (different sample sizes). Note that re-packetization requires DSP resources in a Cisco IOS MTP.

DTMF Conversion

DTMF tones are used during a call to signal to a far-end device for purposes of navigating a menu system, entering data, or other manipulation. They are processed differently than DTMF tones sent during a call setup as part of the call control. There are several methods for sending DTMF over IP, and two communicating endpoints might not support a common procedure. In these cases, Unified CM may

dynamically insert an MTP in the media path to convert DTMF signals from one endpoint to the other. Unfortunately, this method does not scale because one MTP resource is required for each such call. The following sections help determine the optimum amount of MTP resources required, based on the combination of endpoints, trunks, and gateways in the system.

If Unified CM determines that an MTP needs to be inserted but no MTP resources are available, it uses the setting of the service parameter **Fail call if MTP allocation fails** to decide whether or not to allow the call to proceed.

DTMF Relay Between Endpoints

The following methods are used to relay DTMF from one endpoint to another.

Named Telephony Events (RFC 2833)

Named Telephony Events (NTEs) defined by RFC 2833 are a method of sending DTMF from one endpoint to another after the call media has been established. The tones are sent as packet data using the already established RTP stream and are distinguished from the audio by the RTP payload type field. For example, the audio of a call can be sent on a session with an RTP payload type that identifies it as G.711 data, and the DTMF packets are sent with an RTP payload type that identifies them as NTEs. The consumer of the stream utilizes the G.711 packets and the NTE packets separately.

Key Press Markup Language (RFC 4730)

The Key Press Markup Language (KPML) is defined in RFC 4730. Unlike NTEs, which is an in-band method of sending DTMF, KPML uses the signaling channel (out-of-band, or OOB) to send SIP messages containing the DTMF digits.

KPML procedures use a SIP SUBSCRIBE message to register for DTMF digits. The digits themselves are delivered in NOTIFY messages containing an XML encoded body.

Unsolicited Notify (UN)

Unsolicited Notify procedures are used primarily by Cisco IOS SIP Gateways to transport DTMF digits using SIP NOTIFY messages. Unlike KPML, these NOTIFY messages are unsolicited, and there is no prior registration to receive these messages using a SIP SUBSCRIBE message. But like KPML, Unsolicited Notify messages are out-of-band.

Also unlike KPML, which has an XML encoded body, the message body in these NOTIFY messages is a 10-character encoded digit, volume, and duration, describing the DTMF event.

H.245 Signal, H.245 Alphanumeric

H.245 is the media control protocol used in H.323 networks. In addition to its use in negotiating media characteristics, H.245 also provides a channel for DTMF transport. H.245 utilizes the signaling channel and, hence, provides an out-of-band (OOB) way to send DTMF digits. The Signal method carries more information about the DTMF event (such as its actual duration) than does Alphanumeric.

Cisco Proprietary RTP

This method sends DTMF digits in-band, that is, in the same stream as RTP packets. However, the DTMF packets are encoded differently than the media packets and use a different payload type. This method is not supported by Unified CM but is supported on Cisco IOS Gateways.

Skinny Client Control Protocol (SCCP)

The Skinny Client Control Protocol is used by Unified CM for controlling the various SCCP-based devices registered to it. SCCP defines out-of-band messages that transport DTMF digits between Unified CM and the controlled device.

DTMF Relay Between Endpoints in the Same Unified CM Cluster

The following rules apply to endpoints registered to Unified CM servers in the same cluster:

- Calls between two non-SIP endpoints do not require MTPs.

All Cisco Unified Communications endpoints other than SIP send DTMF to Unified CM via various signaling paths, and Unified CM forwards the DTMF between dissimilar endpoints. For example, an IP phone may use SCCP messages to Unified CM to send DTMF, which then gets sent to an H.323 gateway via H.245 signaling events. Unified CM provides the DTMF forwarding between different signaling types.

- Calls between two Cisco SIP endpoints do not require MTPs.

All Cisco SIP endpoints support NTE, so DTMF is sent directly between endpoints and no conversion is required.

- A combination of a SIP endpoint and a non-SIP endpoint might require MTPs.

To determine the support for NTE in your devices, refer to the product documentation for those devices. Support of NTE is not limited to SIP and can be supported in devices with other call control protocols. Unified CM has the ability to allocate MTPs dynamically on a call-by-call basis, based on the capabilities of the pair of endpoints.

DTMF Relay over SIP Trunks

A SIP trunk configuration is used to set up communication with a SIP User Agent such as another Cisco Unified CM cluster or a SIP gateway.

SIP negotiates media exchange via Session Description Protocol (SDP), where one side offers a set of capabilities to which the other side answers, thus converging on a set of media characteristics. SIP allows the initial offer to be sent either by the caller in the initial INVITE message (Early Offer) or, if the caller chooses not to, the called party can send the initial offer in the first reliable response (Delayed Offer).

By default, Unified CM SIP trunks send the INVITE without an initial offer (Delayed Offer).

Unified CM has two configurable options to enable a SIP trunk to send the offer in the INVITE (Early Offer):

- Media Termination Point Required

Checking this option on the SIP trunk assigns an MTP for every outbound call. This statically assigned MTP supports only the G.711 codec or the G.729 codec, thus limiting media to voice calls only.

- Early Offer support for voice and video calls (insert MTP if needed)

Checking this option on the SIP Profile associated with the SIP Trunk inserts an MTP only if the calling device cannot provide Unified CM with the media characteristics required to create the Early Offer (for example, where an inbound call to Unified CM is received on a Delayed Offer SIP trunk or a Slow Start H.323 trunk). This option is available only with Unified CM 8.5 and later releases.

In general, Cisco recommends **Early Offer support for voice and video calls (insert MTP if needed)** because this configuration option reduces MTP usage. Calls from older SCCP phones registered to Unified CM over SIP Early Offer trunks use an MTP to create the Offer SDP. These calls support voice, video, and encryption. Inbound calls to Unified CM from SIP Early Offer trunks or H.323 Slow Start

trunks that are extended over a SIP Early Offer trunk use an MTP to create the Offer SDP. However, these calls support audio only in the initial call setup, but they can be escalated to support video mid-call if the called or calling device invokes it.

Also note that MTP resources are not required for incoming INVITE messages, whether or not they contain an initial offer.

Whether or not an MTP will be allocated by Unified CM depends on the capabilities of the communicating endpoints and the configuration on the intermediary device, if any. For example, the SIP trunk may be configured to handle DTMF exchange in one of several ways: a SIP trunk can carry DTMF using KPML or it can instruct the communicating endpoints to use NTE.

**Note**

As described in this section, SIP Early Offer can also be enabled by checking the **Media Termination Point Required** option on the SIP trunk. However, this option increases MTP usage because an MTP is assigned for every outbound call rather than on an as-needed basis.

SIP Trunk MTP Requirements

By default, the SIP trunk parameter **Media Termination Point Required** and the SIP Profile parameter **Early Offer support for voice and video calls (insert MTP if needed)** are not selected.

Use the following steps to determine whether MTP resources are required for your SIP trunks.

1. Is the far-end SIP device defined by this SIP trunk capable of accepting an inbound call without a SIP Early Offer?

If not, then on the SIP Profile associated with this trunk, check the box to enable **Early Offer support for voice and video calls (insert MTP if needed)**. For outbound SIP trunk calls, an MTP will be inserted only if the calling device cannot provide Unified CM with the media characteristics required to create the Early Offer, or if DTMF conversion is needed.

If yes, then do not check the **Early Offer support for voice and video calls (insert MTP if needed)** box, and use Step 2. to determine whether an MTP is inserted dynamically for DTMF conversion. Note that DTMF conversion can be performed by the MTP regardless of the codec in use.

Note The option for **Early Offer support for voice and video calls (insert MTP if needed)** is available only with Unified CM 8.5 and later releases.

2. Select a Trunk DTMF Signaling Method, which controls the behavior of DTMF selection on that trunk. Available MTPs will be allocated based on the requirements for matching DTMF methods for all calls.

- a. DTMF Signaling Method: No Preference

In this mode, Unified CM attempts to minimize the usage of MTP by selecting the most appropriate DTMF signaling method.

If both endpoints support NTE, then no MTP is required.

If both devices support any out-of-band DTMF mechanism, then Unified CM will use KPML or Unsolicited Notify over the SIP trunk. For example, this is the case if a Cisco Unified IP Phone 7936 using SCCP (which supports DTMF using only SCCP messaging) communicates with a Cisco Unified IP Phone 7970 using SIP (which supports DTMF using NTE and KPML) over a SIP trunk configured as described above. The only case where MTP is required is when

one of the endpoints supports out-of-band only and the other supports NTE only (for example, an SCCP Cisco Unified IP Phone 7936 communicating with a SIP Cisco Unified IP Phone 7970).

b. DTMF Signaling Method: RFC 2833

By placing a restriction on the DTMF signaling method across the trunk, Unified CM is forced to allocate an MTP if any one or both the endpoints do not support NTE. In this configuration, the only time an MTP will not be allocated is when both endpoints support NTE.

c. DTMF Signaling Method: OOB and RFC 2833

In this mode, the SIP trunk signals both KPML (or Unsolicited Notify) and NTE-based DTMF across the trunk, and it is the most intensive MTP usage mode. The only cases where MTP resources will not be required is when both endpoints support both NTE and any OOB DTMF method (KPML or SCCP).

Note

Cisco Unified IP Phones play DTMF to the end user when DTMF is received via SCCP, but they do not play tones received by NTE. However, there is no requirement to send DTMF to another end user. It is necessary only to consider the endpoints that originate calls combined with endpoints that might need DTMF, such as PSTN gateways, application servers, and so forth.

DTMF Relay on SIP Gateways and Cisco Unified Border Element

Cisco SIP Gateways support KPML, NTE, or Unsolicited Notify as the DTMF mechanism, depending on the configuration. Because there may be a mix of endpoints in the system, multiple methods may be configured on the gateway simultaneously in order to minimize MTP requirements.

On Cisco SIP Gateways, configure both **sip-kpml** and **rtp-nte** as DTMF relay methods under SIP dial peers. This configuration will enable DTMF exchange with all types of endpoints, including those that support only NTE and those that support only OOB methods, without the need for MTP resources. With this configuration, the gateway will negotiate both NTE and KPML with Unified CM. If NTE is not supported by the Unified CM endpoint, then KPML will be used for DTMF exchange. If both methods are negotiated successfully, the gateway will rely on NTE to receive digits and will not subscribe to KPML.

Cisco SIP gateways also have the ability to use proprietary Unsolicited Notify (UN) method for DTMF. The UN method sends a SIP Notify message with a body that contains text describing the DTMF tone. This method is also supported on Unified CM and may be used if **sip-kpml** is not available. Configure **sip-notify** as the DTMF relay method. Note that this method is Cisco proprietary.

SIP gateways that support only NTE require MTP resources to be allocated when communicating with endpoints that do not support NTE.

H.323 Trunks and Gateways

For the H.323 gateways and trunks there are three reasons for invoking an MTP:

- [H.323 Supplementary Services, page 17-17](#)
- [H.323 Outbound Fast Connect, page 17-17](#)
- [DTMF Conversion, page 17-17](#)

H.323 Supplementary Services

MTPs can be used to extend supplementary services to H.323 endpoints that do not support the H.323v2 OpenLogicalChannel and CloseLogicalChannel request features of the Empty Capabilities Set (ECS). This requirement occurs infrequently. All Cisco H.323 endpoints support ECS, and most third-party endpoints have support as well. When needed, an MTP is allocated and connected into a call on behalf of an H.323 endpoint. When an MTP is required on an H.323 call and none is available, the call will proceed but will not be able to invoke supplementary services.

H.323 Outbound Fast Connect

H.323 defines a procedure called Fast Connect, which reduces the number of packets exchanged during a call setup, thereby reducing the amount of time for media to be established. This procedure uses Fast Start elements for control channel signaling, and it is useful when two devices that are utilizing H.323 have high network latency between them because the time to establish media depends on that latency. Unified CM distinguishes between inbound and outbound Fast Start based on the direction of the call setup, and the distinction is important because the MTP requirements are not equal. For inbound Fast Start, no MTP is required. Outbound calls on an H.323 trunk do require an MTP when Fast Start is enabled. Frequently, it is only inbound calls that are problematic, and it is possible to use inbound Fast Start to solve the issue without also enabling outbound Fast Start.

DTMF Conversion

An H.323 trunk supports the signaling of DTMF by means of H.245 out-of-band methods. H.323 intercluster trunks also support DTMF by means of NTE. There are no DTMF configuration options for H.323 trunks; Unified CM dynamically chooses the DTMF transport method.

The following scenarios can occur when two endpoints on different clusters are connected with an H.323 trunk:

- When both endpoints are SIP, then NTE is used. No MTP is required for DTMF.
- When one endpoint is SIP and supports both KPML and NTE, but the other endpoint is not SIP, then DTMF is sent as KPML from the SIP endpoint to Unified CM, and H.245 is used on the trunk. No MTP is required for DTMF.
- If one endpoint is SIP and supports only NTE but the other is not SIP, then H.245 is used on the trunk. An available MTP is allocated for the call. The MTP will be allocated on the Unified CM cluster where the SIP endpoint is located.

For example: A Cisco Unified IP Phone 7970 using SIP to communicate with a Cisco Unified IP Phone 7970 running SCCP, will use NTE when connected via a SIP trunk but will use OOB methods when communicating over an H.323 trunk (with the trunk using the H.245 method).

When a call is inbound from one H.323 trunk and is routed to another H.323 trunk, NTE will be used for DTMF when both endpoints are SIP. H.245 will be used if either endpoint is not SIP. An MTP will be allocated if one side is a SIP endpoint that supports only NTE and the other side is non-SIP.

DTMF Relay on H.323 Gateways and Cisco Unified Border Element

H.323 gateways support DTMF relay via H.245 Alphanumeric, H.245 Signal, NTE, and audio in the media stream. The NTE option must not be used because it is not supported on Unified CM for H.323 gateways at this time. The preferred option is H.245 Signal. MTPs are required for establishing calls to an H.323 gateway if the other endpoint does not have signaling capability in common with Unified CM. For example, a Cisco Unified IP Phone 7960 running the SIP stack supports only NTEs, so an MTP is needed with an H.323 gateway.

CTI Route Points

A CTI Route Point uses CTI events to communicate with CTI applications. For DTMF purposes, the CTI Route Point can be considered as an endpoint that supports all OOB methods and does not support RFC 2833. For such endpoints, the only instance where an MTP will be required for DTMF conversion would be when it is communicating with another endpoint that supports only RFC 2833.

CTI Route Points that have first-party control of a phone call will participate in the media stream of the call and require an MTP to be inserted. When the CTI has third-party control of a call so that the media passes through a device that is controlled by the CTI, then the requirement for an MTP is dependent on the capabilities of the controlled device.

Example 17-1 Call Flow that Requires an MTP for NTE Conversion

Assume the example system has CTI route points with first-party control (the CTI port terminates the media), which integrate to a system that uses DTMF to navigate an IVR menu. If all phones in the system are running SCCP, then no MTP is required. In this case Unified CM controls the CTI port and receives DTMF from the IP phones via SCCP. Unified CM provides DTMF conversion.

However, if there are phones running a SIP stack (that support only NTE and not KPML), an MTP is required. NTEs are part of the media stream; therefore Unified CM does not receive them. An MTP is invoked into the media stream and has one call leg that uses SCCP, and the second call leg uses NTEs. The MTP is under SCCP control by Unified CM and performs the NTE-to-SCCP conversion. Note that the newer phones that do support KPML will not need an MTP.

MTP Usage with a Conference Bridge

MTPs are utilized in a conference call when one or more participant devices in the conference use RFC 2833. When the conference feature is invoked, Unified CM allocates MTP resources for every conference participant device in the call that supports only RFC 2833. This is regardless of the DTMF capabilities of the conference bridge used.

MTP Resources

The following types of devices are available for use as an MTP:

Software MTP (Cisco IP Voice Media Streaming Application)

A software MTP is a device that is implemented by enabling the Cisco IP Voice Media Streaming Application on a Unified CM server. When the installed application is configured as an MTP application, it registers with a Unified CM node and informs Unified CM of how many MTP resources it supports. A software MTP device supports only G.711 streams. The IP Voice Media Streaming Application is a resource that may also be used for several functions, and the design guidance must consider all functions together (see [Cisco IP Voice Media Streaming Application, page 17-4](#)).

Software MTP (Based on Cisco IOS)

- The capability to provide a software-based MTP on the router is available beginning with Cisco IOS Release 12.3(11)T for the Cisco 3800 Series Routers; Release 15.0(1)M for the Cisco 2900 Series and 3900 Series Routers; Release IOS-XE for ASR1002, 1004, and 1006 Routers; Release IOS-XE 3.2 for ASR1001 Routers; and Release 12.3(8)T4 for other router models.
- This MTP allows configuration of any of the following codecs, but only one may be configured at a given time: G.711 mu-law and a-law, G.729a, G.729, G.729ab, G.729b, and passthrough. Some of these are not pertinent to a Unified CM implementation.
- Router configurations permit up to 1,000 individual streams, which support 500 transcoded sessions. This number of G.711 streams generates 10 Mbytes of traffic. The Cisco ISR G2s and ASR routers can support significantly higher numbers than this.

Hardware MTP (PVDM2, Cisco NM-HDV2 and NM-HD-1V/2V/2VE)

- This hardware uses the PVDM-2 modules for providing DSPs.
- Each DSP can provide 16 G.711 mu-law or a-law, 8 G.729a or G.722, or 6 G.729 or G.729b MTP sessions.

Hardware MTP (Cisco 2900 and 3900 Series Routers with PVDM3)

- These routers use the PVDM3 DSPs natively on the motherboards or PVDM2 with an adaptor on the motherboard or on service modules.
- The capacity of each of the DSP type varies from 16 G.711 a-law or mu-law sessions for the PVDM3-16 to 256 G.711 sessions for the PVDM3-256.

**Note**

You cannot configure G.729 or G.729b codecs when configuring hardware MTP resources in Cisco IOS. However, Unified CM can use hardware transcoding resources as MTPs if all other MTP resources are exhausted or otherwise unavailable.

Trusted Relay Point

A Trusted Relay Point (TRP) is a device that can be inserted into a media stream to act as a control point for that stream. It may be used to provide further processing on that stream or as a method to ensure that the stream follows a specific desired path. There are two components to the TRP functionality, the logic utilized by Unified CM to invoke the TRP and the actual device that is invoked as the anchor point of the call. The TRP functionality can invoke an MTP device to act as that anchor point.

Unified CM provides a new configuration parameter for individual phone devices, which invokes a TRP for any call to or from that phone. The system utilizes the media resource pool mechanisms to manage the TRP resources. The media resource pool of that device must have an available device that will be invoked as a TRP.

See the chapter on [Network Infrastructure, page 3-1](#), for an example of a use case for the TRP as a QoS enforcement mechanism, and see the chapter on [Unified Communications Security, page 4-1](#), for an example of utilizing the TRP as an anchor point for media streams in a redundant data center with firewall redundancy.

Annunciator

An annunciator is a software function of the Cisco IP Voice Media Streaming Application that provides the ability to stream spoken messages or various call progress tones from the system to a user. It uses SCCP messages to establish RTP streams, and it can send multiple one-way RTP streams to devices such as Cisco IP phones or gateways. The device must be capable of SCCP to utilize this feature. SIP phones and devices are still able to receive all the various messages provided by the annunciator. For SIP devices, all these messages and tones are downloaded (pushed) to the device at registration so that they can be invoked as needed by SIP signaling messages from Unified CM.

Tones and announcements are predefined by the system. The announcements support localization and may also be customized by replacing the appropriate .wav file. The annunciator is capable of supporting G.711 a-law and mu-law, G.729, and Wideband codecs without any transcoding resources.

The following features require an annunciator resource:

- Cisco Multilevel Precedence Preemption (MLPP)

This feature has streaming messages that it plays in response to the following call failure conditions.

- Unable to preempt due to an existing higher-precedence call.
- A precedence access limitation was reached.
- The attempted precedence level was unauthorized.
- The called number is not equipped for preemption or call waiting.

- Integration via SIP trunk

SIP endpoints have the ability to generate and send tones in-band in the RTP stream. Because SCCP devices do not have this ability, an annunciator is used in conjunction with an MTP to generate or accept DTMF tones when integrating with a SIP endpoint. The following types of tones are supported:

- Call progress tones (busy, alerting, and ringback)
- DTMF tones

- Cisco IOS gateways and intercluster trunks

These devices require support for call progress tone (ringback tone).

- System messages

During the following call failure conditions, the system plays a streaming message to the end user:

- A dialed number that the system cannot recognize
- A call that is not routed due to a service disruption
- A number that is busy and not configured for preemption or call waiting

- Conferencing

During a conference call, the system plays a barge-in tone to announce that a participant has joined or left the bridge.

An annunciator is automatically created in the system when the Cisco IP Voice Media Streaming Application is activated on a server. If the Media Streaming Application is deactivated, then the annunciator is also deleted. A single annunciator instance can service the entire Unified CM cluster if it meets the performance requirements (see [Annunciator Performance, page 17-21](#)); otherwise, you must configure additional annunciators for the cluster. Additional annunciators can be added by activating the Cisco IP Voice Media Streaming Application on other servers within the cluster.

The annunciator registers with a single Unified CM at a time, as defined by its device pool. It will automatically fail over to a secondary Unified CM if a secondary is configured for the device pool. Any announcement that is playing at the time of an outage will not be maintained.

An annunciator is considered a media device, and it can be included in media resource groups (MRGs) to control which annunciator is selected for use by phones and gateways.

Annunciator Performance

By default, the annunciator is configured to support 48 simultaneous streams, which is the maximum recommended for an annunciator running on the same server (co-resident) with the Unified CM service. If the server has only 10 Mbps connectivity, lower the setting to 24 simultaneous streams.

A standalone server without the Cisco CallManager Service can support up to 255 simultaneous announcement streams, and a high-performance server with dual CPUs and a high-performance disk system can support up to 400 streams. You can add multiple standalone servers to support the required number of streams.

Cisco RSVP Agent

In order to provide topology-aware call admission control, Unified CM invokes one or two RSVP Agents during the call setup to perform an RSVP reservation across the IP WAN. These agents are MTP or transcoder resources that have been configured to provide RSVP functionality. RSVP resources are treated the same way as regular MTPs or transcoders from the perspective of allocation of an MTP or transcoder resource by Unified CM.

The Cisco RSVP Agent feature was first introduced in Cisco IOS Release 12.4(6)T. For details on RSVP and Cisco RSVP Agents, refer to the chapter on [Call Admission Control, page 11-1](#).

Music on Hold

The Music on Hold (MoH) feature requires that each MoH server must be part of a Unified CM cluster and participate in the data replication schema. Specifically, the MoH server must share the following information with the Unified CM cluster through the database replication process:

- Audio sources - The number and identity of all configured MoH audio sources
- Multicast or unicast - The transport nature (multicast or unicast) configured for each of these sources
- Multicast address - The multicast base IP address of those sources configured to stream as multicast

To configure a MoH server, enable the Cisco IP Voice Media Streaming Application Service on one or more Unified CM nodes. An MoH server can be deployed along with Unified CM on the same server or in standalone mode.

Unicast and Multicast MoH

Unified CM supports unicast and multicast MoH transport mechanisms.

A unicast MoH stream is a point-to-point, one-way audio Real-Time Transport Protocol (RTP) stream from the MoH server to the endpoint requesting MoH. It uses a separate source stream for each user or connection. Thus, if twenty devices are on hold, then twenty streams are generated over the network between the server and these endpoint devices. Unicast MoH can be extremely useful in those networks where multicast is not enabled or where devices are not capable of multicast, thereby still allowing an administrator to take advantage of the MoH feature. However, these additional MoH streams can potentially have a negative effect on network throughput and bandwidth.

A multicast MoH stream is a point-to-multipoint, one-way audio RTP stream between the MoH server and the multicast group IP address. The endpoints requesting an MoH audio stream can join the multicast group as needed. This mode of MoH conserves system resources and bandwidth because it enables multiple users to use the same audio source stream to provide music on hold. For this reason, multicast is an extremely attractive transport mechanism for the deployment of a service such as MoH because it greatly reduces the CPU impact on the source device and also greatly reduces the bandwidth consumption for delivery over common paths. However, multicast MoH can be problematic in situations where a network is not enabled for multicast or where the endpoint devices are not capable of handling multicast.

There are distinct differences between unicast and multicast MoH in terms of call flow behavior. A unicast MoH call flow is initiated by a message from Unified CM to the MoH server. This message tells the MoH server to send an audio stream to the holdee device's IP address. On the other hand, a multicast MoH call flow is initiated by a message from Unified CM to the holdee device. This message instructs the endpoint device to join the multicast group address of the configured multicast MoH audio stream.

For a detailed look at MoH call flows, see the section on [MoH Call Flows, page 17-27](#).

Supported Unicast and Multicast Gateways

The following gateways support both unicast and multicast MoH:

- Cisco 2900 Series and Cisco 3900/3900E Series ISR G2 Routers with Cisco IOS 15.0.1M or later release
- Cisco 2800 Series and 3800 Series Routers with MGCP or H.323 and Cisco IOS 12.3.14T or later release
- Cisco 2800 Series and 3800 Series Routers with SIP and Cisco IOS 12.4(24)T or later release
- Cisco VG224 Analog Voice Gateways with MGCP and Cisco IOS 12.3.14T or later release
- Cisco VG204 and VG202 Analog Voice Gateways with MGCP or SCCP and Cisco IOS 12.4(22)T or later release
- Cisco VG248 Analog Phone Gateways
- Cisco ASR 1000 Series Aggregation Services Routers

**Note**

Cisco 2800 Series, 3800 Series, and VG248 gateways are End of Sale (EoS). There are other legacy gateways that also support unicast and multicast MoH.

**Note**

The Cisco Unified Border Element on Cisco ASR 1000 Series Aggregation Services Routers might not support one-way streaming of music or announcements by the Cisco Unified Communications Manager Music on Hold (MoH) feature. For more information, refer to the release notes for your version of Cisco Unified Communications Manager, available at http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_release_notes_list.html.

MoH Selection Process

This section describes the MoH selection process as implemented in Unified CM.

The basic operation of MoH in a Cisco Unified Communications environment consists of a holder and a holdee. The *holder* is the endpoint user or network application placing a call on hold, and the *holdee* is the endpoint user or device placed on hold.

The MoH stream that an endpoint receives is determined by a combination of the User Hold MoH Audio Source of the device placing the endpoint on hold (holder) and the configured media resource group list (MRGL) of the endpoint placed on hold (holdee). The User Hold MoH Audio Source configured for the holder determines the audio file that will be streamed when the holder puts a call on hold, and the holdee's configured MRGL indicates the resource or server from which the holdee will receive the MoH stream.

As illustrated by the example in Figure 17-3, if phones A and B are on a call and phone B (holder) places phone A (holdee) on hold, phone A will hear the MoH audio source configured for phone B (Audio-source2). However, phone A will receive this MoH audio stream from the MRGL (resource or server) configured for phone A (MRGL A).

Figure 17-3 User Hold Audio Source and Media Resource Group List (MRGL)

Because the configured MRGL determines the server from which a unicast-only device will receive the MoH stream, you must configure unicast-only devices with an MRGL that points to a unicast MoH resource or media resource group (MRG). Likewise, a device capable of multicast should be configured with an MRGL that points to a multicast MRG containing a MoH server configured for multicast.

User and Network Hold

User hold includes the following types:

- User on hold at an IP phone or other endpoint device
- User on hold at the PSTN, where MoH is streamed to the gateway

Figure 17-4 shows these two types of call flows. If phone A is in a call with phone B and phone A (holder) pushes the Hold softkey, then a music stream is sent from the MoH server to phone B (holdee). The music stream can be sent to holdees within the IP network or holdees on the PSTN, as is the case if phone A places phone C on hold. In the case of phone C, the MoH stream is sent to the voice gateway interface and converted to the appropriate format for the PSTN phone. When phone A presses the Resume softkey, the holdee (phone B or C) disconnects from the music stream and reconnects to phone A.

Figure 17-4 Basic User Hold Example

Network hold can occur in following scenarios:

- Call transfer
- Call Park
- Conference setup
- Application-based hold

Figure 17-5 illustrates an example of network hold during a call transfer. The call flow involves the following steps:

1. Phone A receives a call from PSTN phone C.
2. Phone A answers the call and then transfers it to phone B. During the transfer process, phone C is put on network hold.
3. Phone C receives an MoH stream from the MoH server via the gateway. After phone A completes the transfer action, phone C disconnects from the music stream and gets redirected to phone B.

This process is the same for other network hold operations such as call park and conference setup.

Figure 17-5 Basic Network Hold Example for Call Transfer

MoH Sources

A Unified CM MoH server can generate a MoH stream from two types of sources, audio file and fixed source, either of which can be transmitted as unicast or multicast. You can configure a maximum of 51 MoH audio sources per Unified CM cluster, of which up to 50 can be audio files but only one can be a fixed source.

Audio File

Audio files (.wav format) can be uploaded to Unified CM, which then automatically generates MoH audio files for the specified codecs. Unified CM supports G711 (a-law and mu-law), G.729 Annex A, and Wideband codecs for MoH streams.

**Note**

Before configuring a MoH audio source, you must upload the .wav formatted audio source file to every MoH server within the cluster using the upload file function in the Unified CM Administration interface. Cisco recommends that you first upload the audio source file onto each MoH server in the cluster, then upload it onto the publisher (even if not an MoH server), and finally assign an MoH Audio Stream Number and configure the MoH audio source in the Unified CM Administration interface on the publisher.

Fixed Source

If recorded or live audio is needed, MoH can be generated from a fixed source connected to the audio input of the local sound card. The Cisco MoH USB audio sound card (MOH-USB-AUDIO=) must be used for connecting a fixed or live audio source to the MoH server. This USB sound card is compatible with all Cisco MCS platforms that support Cisco Unified CM.

This mechanism enables you to use radios, CD players, or any other compatible sound source to stream MoH. The stream from the fixed audio source is transcoded in real-time to support the codec that was configured through Unified CM Administration. The fixed audio source can be transcoded into G.711 (A-law or mu-law), G.729 Annex A, and Wideband, and it is the only audio source that is transcoded in real-time.

**Note**

Prior to using a fixed audio source to transmit music on hold, you should consider the legalities and the ramifications of re-broadcasting copyrighted audio materials. Consult your legal department for potential issues.

MoH Selection

To determine which User and Network Audio Source configuration setting to apply in a particular case, Unified CM interprets these settings for the *holder* device in the following priority order:

1. Directory or line setting (Devices with no line definition, such as gateways, do not have this level.)
2. Device setting
3. Common Device Configuration setting
4. Cluster-wide default setting

Unified CM also interprets the MRGL configuration settings of the *holdee* device in the following priority order:

1. Device setting
2. Device pool setting
3. System default MoH resources

Note that system default MoH resources are resources that are not assigned to any MRG and they are always unicast.

MoH Call Flows

The following sections provide detailed illustrations and explanations of unicast and multicast MoH call flows for both SCCP and SIP endpoints.

SCCP Call Flows

This section describes the multicast and unicast call flows for music on hold with Skinny Client Control Protocol (SCCP) endpoints.

SCCP Multicast Call Flow

[Figure 17-6](#) illustrates a typical SCCP multicast call flow. As shown in the diagram, when the Hold softkey is pressed at phone A, Unified CM instructs both phone A and phone B to Close Receive Channel and Stop Media Transmission. This action effectively stops the RTP two-way audio stream. Next, Unified CM tells phone B (the holdee) to Start Multicast Media Reception from multicast group address 239.192.240.1. The phone then issues an Internet Group Management Protocol (IGMP) V2 Membership Report message indicating that it is joining this group.

Figure 17-6 Detailed SCCP Multicast MoH Call Flow

Meanwhile, the MoH server has been sourcing RTP audio to this multicast group address and, upon joining the multicast group, phone B begins receiving the MoH stream. Once phone A presses the Resume softkey, Unified CM instructs phone B to Stop Multicast Media Reception. Phone B then sends an IGMP V2 Leave Group message to 224.0.0.2 to indicate that the multicast stream is no longer needed. This effectively ends the MoH session. Next, Unified CM sends a series of Open Receive Channel messages to phones A and B, just as would be sent at the beginning of a phone call between the two phones. Soon afterwards, Unified CM instructs both phones to Start Media Transmission to each other's IP addresses. The phones are once again connected by means of an RTP two-way audio stream.

**Note**

The call flow diagrams in [Figure 17-6](#) and [Figure 17-7](#) assume that an initial call exists between phones A and B, with a two-way RTP audio stream. These diagrams are representative of call flows and therefore include only the pertinent traffic required for proper MoH operation. Thus, keep-alives, acknowledgements, and other miscellaneous traffic have been eliminated to better illustrate the interaction. The initial event in each diagram is the Hold softkey action performed by phone A.

SCCP Unicast Call Flow

Figure 17-7 depicts an SCCP unicast MoH call flow. In this call flow diagram, when the Hold softkey is pressed at phone A, Unified CM instructs both phone A and phone B to Close Receive Channel and Stop Media Transmission. This action effectively stops the RTP two-way audio stream. Up to this point, unicast and multicast MoH call flows behave exactly the same way.

Figure 17-7 Detailed SCCP Unicast MoH Call Flow

Next, Unified CM tells phone B (the holdee) to Open Receive Channel. (This is quite different from the multicast case, where Unified CM tells the holdee to Start Multicast Media Reception.) Then Unified CM tells the MoH server to Start Media Transmission to the IP address of phone B. (This too is quite different behavior from the multicast MoH call flow, where the phone is prompted to join a multicast group address.) At this point, the MoH server is sending a one-way unicast RTP music stream to phone B. When phone A presses the Resume softkey, Unified CM instructs the MoH server to Stop Media Transmission and instructs phone B to Close Receive Channel, effectively ending the MoH session. As with the multicast scenario, Unified CM sends a series of Open Receive Channel messages and Start Media Transmissions messages to phones A and B with each other's IP addresses. The phones are once again connected by means of an RTP two-way audio stream.

SIP Call Flows

This section describes the multicast and unicast call flows for music on hold with Session Initiation Protocol (SIP) endpoints.

SIP Multicast Call Flow

[Figure 17-8](#) illustrates a typical SIP multicast call flow. As shown in the diagram, when the Hold softkey is pressed at phone A, phone A sends a SIP INVITE with a Session Description Protocol (SDP) connection information indication of phone A's IP address and a media attribute indication of sendonly. Unified CM then instructs phone A to disconnect the RTP stream by means of a SIP 200 OK Response with an SDP connection information indication of 0.0.0.0 and a media attribute indication of recvonly. Phone B is then told to disconnect the RTP stream by means of a SIP INVITE from Unified CM with an SDP connection information indication of 0.0.0.0 and a media attribute of inactive. After a SIP 200 OK Response is sent back from phone B to Unified CM indicating an SDP media attribute of inactive, Unified CM then sends a SIP INVITE to phone B with an SDP connection information indication of the MoH multicast group address (in this case 239.23.1.1) and a media attribute of recvonly.

Figure 17-8 Detailed SIP Multicast MoH Call Flow

Next, phone B in Figure 17-8 issues an IGMP V2 Membership Report message indicating that it is joining this multicast group. In addition, phone B sends a SIP 200 OK Response back to Unified CM indicating an SDP media attribute of recvonly in response to the previous SIP INVITE. Meanwhile, the MoH server has been sourcing RTP audio to this MoH multicast group address and, upon joining the multicast group, phone B begins receiving the one-way MoH stream.

When the user at phone A presses the Resume softkey, phone A sends a SIP INVITE with an SDP connection information indication of phone A's IP address and media attribute indications of phone A's receiving RTP port and sendrecv. Unified CM then instructs phone B to disconnect from the multicast MoH stream by means of a SIP INVITE with an SDP connection information indication of 0.0.0.0 and a media attribute indication of inactive. A SIP 200 OK Response is sent back from phone B to Unified CM, indicating an SDP media attribute of inactive.

Next Unified CM sends a SIP INVITE to phone B, and phone B responds with a SIP 200 OK Response with an SDP connection information indication of phone B's IP address and media attribute indications of phone B's receiving RTP port and sendrecv. Unified CM responds by sending a SIP ACK to phone B with an SDP connection information indication of phone A's IP address and a media attribute of phone A's receiving RTP port number. Likewise, Unified CM forwards a SIP 200 OK Response to phone A's original resuming SIP INVITE, with an SDP connection information indication of phone B's IP address and a media attribute of phone B's receiving RTP port number. Phone B then sends an IGMP V2 Leave Group message to 224.0.0.2 to indicate that the multicast stream is no longer needed. Finally, the RTP two-way audio stream between phones A and B is reestablished.

Note

The call flow diagrams in [Figure 17-8](#) and [Figure 17-9](#) assume that an initial call exists between phones A and B, with a two-way RTP audio stream. These diagrams are representative of call flows and therefore include only the pertinent traffic required for proper MoH operation. Thus, keep-alives, some acknowledgements, progression indications, and other miscellaneous traffic have been eliminated to better illustrate the interaction. The initial event in each diagram is the Hold softkey action performed by phone A.

SIP Unicast Call Flow

[Figure 17-9](#) depicts a SIP unicast MoH call flow. As shown in the diagram, when the Hold softkey is pressed at phone A, phone A sends a SIP INVITE with an SDP connection information indication of phone A's IP address and a media attribute indication of sendonly. Unified CM then instructs phone A to disconnect the RTP stream by means of a SIP 200 OK Response with an SDP connection information indication of 0.0.0.0 and a media attribute indication of recvonly. Phone B is then told to disconnect the RTP stream by means of a SIP INVITE from Unified CM, with an SDP connection information indication of 0.0.0.0 and a media attribute of inactive. Next a SIP 200 OK Response is sent back from phone B to Unified CM, indicating an SDP media attribute of inactive. Up to this point, unicast and multicast MoH call flows are exactly the same.

Figure 17-9 Detailed SIP Unicast MoH Call Flow

Unified CM then sends a SIP INVITE to phone B, and phone B responds back with a SIP 200 OK Response indicating SDP connection information with phone B's IP address and media attribute indications of phone B's receiving RTP port number and sendrecv. Unified CM then sends a SCCP StartMediaTransmission message to the MoH server, with phone B's address and receiving RTP port

number. This is followed by a SIP ACK from Unified CM to phone B indicating SDP connection information of the Unified CM IP address and a media attribute of `sendonly`. Meanwhile, the MoH server begins sourcing RTP audio to phone B, and phone B begins receiving the one-way MoH stream.

When the user at phone A presses the Resume softkey, phone A sends a SIP INVITE with an SDP connection information indication of phone A's IP address and media attribute indications of phone A's receiving RTP port and `sendrecv`. Unified CM then instructs phone B to disconnect from the multicast MoH stream by means of a SIP INVITE with an SDP connection information indication of `0.0.0.0` and a media attribute indication of `inactive`. A SIP 200 OK Response is sent back from phone B to Unified CM, indicating an SDP media attribute of `inactive`. Then Unified CM sends an SCCP `StopMediaTransmission` message to the MoH server, causing the MoH server to stop forwarding the MoH stream to phone B.

Next Unified CM sends a SIP INVITE to phone B, and phone B responds with a SIP 200 OK Response with an SDP connection information indication of phone B's IP address and media attribute indications of phone B's receiving RTP port and `sendrecv`. Unified CM responds by sending a SIP ACK to phone B, with an SDP connection information indication of phone A's IP address and a media attribute of phone A's receiving RTP port number. Likewise, Unified CM forwards a SIP 200 OK Response to phone A's original resuming SIP INVITE with an SDP connection information indication of phone B's IP address and a media attribute of phone B's receiving RTP port. Finally, the RTP two-way audio stream between phones A and B is reestablished.

Capacity Planning for Media Resources

This section provides information on the capacities of various network modules and chassis that carry DSPs, the capacities of the chassis to carry network modules, and software dependencies of the hardware.

For all Cisco ISR G1 and G2 capacity planning, use the DSP Calculator available at <http://www.cisco.com/go/dspcalculator>. For other platforms (such as the Cisco 1700, 2600, and 3700 Series Routers), use the legacy DSP calculator at http://www.cisco.com/cgi-bin/Support/DSP/cisco_dsp_calc.pl.

The DSP resources for Unified Communications solutions are provided by NM-HD, NM-HDV, and PVDM modules. NM-HD and NM-HDV2 modules are supported on Cisco ISR G1 and G2 Series platforms. Refer to the respective product data sheets for capacity information for these modules.

PVDM modules are available in three models: PVDM-256K, PVDM2, and the newer PVDM3. Each of the models has several modules with different density support. For example, a PVDM-256K-4 and a PVDM2-16 are single DSP modules in their respective category. PVDM2 modules are supported on Cisco ISR G1 and ISR G2 platforms (minimum of Cisco IOS Release 15.0(1)M is required for the Cisco ISR G2 Series). The PVDM3 DSP modules are supported on the Cisco 2900 Series and 3900 Series platforms and require a minimum Cisco IOS Release of 15.0(1) M. PVDM3 modules provide DSP resources for both voice and video. The PVDM3 modules are newer than the PVDM2 and PVDM-256K modules, and the three types are not interchangeable.

Some things to consider when doing capacity planning for hardware-based media resources include the density of the module, the underlying platform (Cisco ISR G1 or G2), and the minimum Cisco IOS version required.

For capacity information on PVDM2 modules, refer to the *High-Density Packet Voice Digital Signal Processor Module for Cisco Unified Communications Solutions* data sheet, available at

http://www.cisco.com/en/US/prod/collateral/routers/ps5854/product_data_sheet0900aecd8016e845_ps3115_Products_Data_Sheet.html

For capacity information on PVDM3 modules, refer to the *High-Density Packet Voice Video Digital Signal Processor Module for Cisco Unified Communications Solutions* data sheet, available at

http://www.cisco.com/en/US/prod/collateral/modules/ps3115/data_sheet_c78-553971.html

Considerations for Cisco 2900 and 3900 Series Platforms

The following guidelines and considerations apply to the DSP resources hosted by these platforms:

- The Cisco 2900 and 3900 Series Routers support only the PVDM3 DSPs in the on-board (motherboard) DSP slots. PVDM2 DSPs may be used in those slots by using an adaptor card. NM-HD and NM-HDV2 cards can be used in Service Module slots with an adaptor card.
- PVDM2 and PVDM3 modules cannot be used at the same time on the same motherboard.
- DSP sharing can be done only between the same DSP types. For example, if the motherboard is populated with PVDM3 DSPs and the Service Modules are populated with PVDM2 DSPs, then the DSPs in the Service Modules may be shared with each other but DSPs on the motherboard may not be shared with those in the Service Modules.
- PVDM3 DSPs support all the functions that the PVDM2 DSPs support except for Cisco Fax Relay.

Unlike the PVDM2, the PVDM3 DSPs have a single software image for all media functions.

Cisco 2800 and 3800 Series Platforms

The following guidelines and considerations apply to the DSP resources hosted by these platforms:

- Although the Cisco 2800 and 3800 Series Routers all have two AIM slots, they do not support the AIM-VOICE-30 or AIM-ATM-VOICE-30 cards because PVDM2 modules that are installed on the motherboard provide that functionality.

You can install the NM-HDV2, NM-HD-xx, and NM-HDV modules in the Cisco IOS platforms as indicated in the product data sheets.

All three families of modules may be installed in a single chassis. However, the conferencing and transcoding features cannot be used simultaneously on both the NM-HDV family and either of the other two families (NM-HD-xx or NM-HDV2). In addition, the NM-HDV (TI-549), NM-HD-xx, and NM-HDV2 (TI-5510) cannot be used simultaneously for conferencing and transcoding within a single chassis.

You can mix NM-HDV and NM-HDV-FARM modules in the same chassis, but not all chassis can be completely populated by these modules.

Capacity Planning for Music On Hold

It is important to be aware of the hardware capacity for MoH resources and to consider the implications of multicast and unicast MoH in relation to this capacity when doing capacity planning for MoH resources. The capacity of the MoH server depends on several factors such as deployment model (co-resident or standalone), underlying server platform, and so forth.

Co-resident and Standalone MoH

The MoH feature requires the use of a server that is part of a Unified CM cluster. You can configure the MoH server in either of the following ways:

- Co-resident deployment

The term *co-resident* refers to two or more services or applications running on the same server. In a co-resident deployment, the MoH feature runs on any server (either publisher or subscriber) in the cluster that is also running the Unified CM software.

- Standalone deployment

A standalone deployment, places the MoH feature on a dedicated media resource server node within the Unified CM cluster. This server acts as neither a publisher or a subscriber. That is, the Cisco IP Voice Media Streaming Application service is the only service enabled on the server. The only function of this dedicated server is to send MoH streams to devices within the network

Server Platform Limits

Table 17-2 lists the server platforms and the maximum number of simultaneous MoH sessions each can support. Ensure that network call volumes do not exceed these limits because, once MoH sessions have reached these limits, additional load could result in poor MoH quality, erratic MoH operation, or even loss of MoH functionality.

Table 17-2 Maximum Number of MoH Sessions per Server Platform or OVA Template

| Server Platform | Codecs Supported | MoH Sessions Supported |
|--|--|--|
| MCS 7816 MCS 7825 (or OVA equivalent) MCS 7828 | G.711 (A-law and mu-law) G.729a Wideband audio | Co-resident or standalone server: 250 MoH sessions ¹ |
| MCS 7835 (or OVA equivalent) MCS 7845 (or OVA equivalent) | G.711 (A-law and mu-law) G.729a Wideband audio | Co-resident or standalone server: 500 MoH sessions |

1. You can configure a maximum of 51 unique audio sources per Unified CM cluster.

The following two MoH Server Configuration parameters affect MoH server capacity:

- **Maximum Half Duplex Streams**

This parameter determines the number of devices that can be placed on unicast MoH. By default this value is set to 250.

The Maximum Half Duplex Streams parameter should be set to the value derived from the following formula:

$$(\text{Server and deployment capacity}) - ((\text{Number of multicast MoH sources}) * (\text{Number of MoH codecs enabled}))$$

For example:

| MCS-7835 standalone MoH server (or OVA equivalent) | Multicast MoH audio sources | MoH codecs enabled (G.711 mu-law and G.729) | Maximum half-duplex streams |
|--|-----------------------------|---|------------------------------------|
| 500 | - (12 | * 2) | = 476 |

Therefore, in this example, the Maximum Half Duplex Streams parameter would be configured with a value of no more than 476.

The value of this parameter should never be set higher than the capacities indicated in [Table 17-2](#), based on the platform and deployment type (co-resident or standalone).

- **Maximum Multicast Connections**

This parameter determines the number of devices that can be placed on multicast MoH.

The Maximum Multicast Connections parameter should be set to a number that ensures that all devices can be placed on multicast MoH if necessary. Although the MoH server can generate only a finite number of multicast streams, a large number of held devices can join each multicast stream. This parameter should be set to a number that is greater than or equal to the number of devices that might be placed on multicast MoH at any given time. Typically multicast traffic is accounted for based on the number of streams being generated; however, Unified CM maintains a count of the actual number of devices placed on multicast MoH or joined to each multicast MoH stream. Although this method is different than the way multicast traffic is normally tracked, it is important to configure this parameter appropriately.

Note Because you can configure only 51 unique audio sources per Unified CM cluster and because there are only four possible codecs for MoH streams, the maximum number of multicast streams per MoH server is 204.

Failure to configure these parameters properly could lead to under-utilization of MoH server resources or failure of the server to handle the network load. For details on how to configure the service parameters, refer to the *Cisco Unified Communications Manager Administration Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

Note

The maximum session limits listed in [Table 17-2](#) apply to unicast, multicast, or simultaneous unicast and multicast sessions. The limits represent the recommended maximum sessions a platform can support, irrespective of the transport mechanism.

Resource Provisioning

When provisioning for co-resident or standalone MoH server configurations, network administrators should consider the type of transport mechanism used for the MoH audio streams. If using unicast MoH, each device on hold requires a separate MoH stream. However, if using multicast MoH and only a single audio source, then only a single MoH stream is required for each configured codec type, no matter how many devices of that type are on hold.

For example, given a cluster with 30,000 phones and a 2% hold rate (only 2% of all endpoint devices are on hold at any given time), 600 MoH streams or sessions would be required. Given a unicast-only MoH environment, two co-resident (or standalone) MoH servers would be required to handle this load, as shown by the following calculation:

$$[(500 \text{ sessions per MCS 7835 or 7845 co-resident server}) * (1 \text{ co-resident server})] + [(250 \text{ sessions per MCS 7816, 7825, or 7878 co-resident server}) * (1 \text{ co-resident server})] > 600 \text{ sessions}$$

By comparison, a multicast-only MoH environment with 36 unique MoH audio streams, for example, would require only one co-resident MoH server (MCS 7816, 7825, or 7878), as shown by the following calculation:

$$(250 \text{ sessions per MCS 7816, 7825, or 7878 co-resident server}) * (1 \text{ co-resident server}) > 36 \text{ sessions}$$

These 36 unique multicast streams could be provisioned in any one of the following ways:

- 36 unique audio sources streamed using a single codec
- 18 unique audio sources streamed using only 2 codecs
- 12 unique audio sources streamed using only 3 codecs
- 9 unique audio source streamed using all 4 codecs

As these examples show, multicast MoH can provide a considerable savings in server resources over unicast MoH.

In the preceding examples, the 2% hold rate is based on 30,000 phones and does not take into account gateways or other endpoint devices in the network that are also capable of being placed on hold. You should consider these other devices when calculating a hold rate because they could potentially be placed on hold just as the phones can.

The preceding calculations also do not provide for MoH server redundancy. If an MoH server fails or if more than 2% of the users go on hold at the same time, there are no other MoH resources in this scenario to handle the overflow or additional load. Your MoH resource calculations should include enough extra capacity to provide for redundancy.

High Availability for Media Resources

The Unified CM constructs of media resource groups (MRGs) and media resource group lists (MRGLs) are used to control how the resources described in this chapter are organized and accessed. This section discusses considerations for how to utilize these constructs effectively.

Media Resource Groups and Lists

Media resource groups (MRGs) and media resource lists (MRGLs) provide a method to control how resources are allocated that could include rights to resources, location of resources, or resource type for specific applications. This section assumes you have an understanding of media resource groups and lists, and it highlights the following design considerations:

- The system defines a default media resource group that is not visible in the user interface. All resources are members of this default MRG when they are created. When using MRGs to control access to resources, it is necessary to move the resources out of the default MRG by explicitly configuring them in some other MRG. If the desired effect is for resources to be available only as a last resort for all calls, then the resources may remain in the default group. Also, if no control over resources is necessary, they may remain in the default group.
- Consumers of media resources use resources first from any media resource group (MRG) or media resource group list (MRGL) that their configuration specifies. If the required resource is not available, the default MRG is searched for the resource. For simple deployments, the default MRG alone may be used.
- Use media resource groups (MRGs) and media resource group lists (MRGLs) to provide sharing of resources across multiple Unified CMs. If you do not use MRGs and MRGLs, the resources are available to a single Unified CM only.
- MRGLs will use MRGs in the order that they are listed in the configuration. If one MRG does not have the needed resource, the next MRG is searched. If all MRGs are searched and no resource is found, the search terminates.
- Within an MRG, resources are allocated based on their order in their configuration even though Unified CM Administration displays the devices in an MRG in alphabetical order. If you want media resources to be allocated in a specific order, Cisco recommends that you create a separate MRG for each individual resource and use MRGLs to specify the order of allocation.
- When there are multiple devices providing the same type of resource within an MRG, the algorithm for allocating that resource load-balances across all those devices. The load balancing depends on the capacity of each device providing similar resources, so it frequently might not be a round-robin behavior. For example, if an MRG has more than one device providing MTP resources, the system will load-balance across each device for MTP requirements. When a resource has been used, a pointer for that MRG is incremented to the next device. A device may be present in more than one MRG, which will affect the pointers of all groups of which the device is a member.
- An MRG may contain multiple types of resources, and the appropriate resource will be allocated from the group based on the feature needed. MTPs and transcoders are a special case because a transcoder may also be used as an MTP. For example, when both MTPs and transcoders exist in the same MRG and an MTP is required, the allocation is done based on the order in which the resources appear in the MRG. If transcoder devices appear earlier than MTPs in the MRG, transcoder resources will be allocated for the MTP requirement until the transcoder resources are exhausted and then the system will start allocating MTPs. For this reason, it is important to consider the order of resources when creating MRGs and MRGLs.

- MRGs can also be used to group resources of similar types. As explained in the example above, because a transcoder is a more expensive resource, Cisco recommend grouping transcoders and MTPs into separate MRGs and invoking the right resource by assigning MRGs appropriately. Another example involves conference bridges. Conference bridge resources vary in the number of participants they support, and different MRGs could be used to group the conference resources by conference bridge size.
- You can also use MRGs and MRGLs to separate resources based on geographical location, thereby conserving WAN bandwidth whenever possible.
- Ensure that the media resources themselves have configurations that prevent further invocation of other media resources. For example, if an MTP is inserted into a call and the codec configured on that MTP does not match the one needed by Unified CM for the call, then a transcoder may also be invoked. A frequent mistake is to configure an MTP for G.729 or G.729b when Unified CM needs G.729a.

Redundancy and Failover Considerations for Cisco IOS-Based Media Resources

A high availability design with media resources must include redundant media resources. When these resources are Cisco IOS-based, they can be distributed on more than one Cisco IOS platform to guard against failure of a single platform and they can be registered to different primary Unified CM servers.

Cisco IOS supports two modes of failover capability: graceful and immediate. The default failover method is graceful, in which the resources register to a backup Unified CM server only after all media activity has ceased. The immediate method, on the other hand, makes the resources register to the backup Unified CM server as soon as failure of the primary is detected. In situations where there is only one set of media resources with no redundancy, Cisco recommends use of the immediate failover method.

High Availability for Music On Hold

Cisco recommends that you configure and deploy multiple MoH servers for completely redundant MoH operation. If the first MoH server fails or becomes unavailable because it no longer has the resources required to service requests, the second server can provide continued MoH functionality. For proper redundant configuration, assign resources from at least two MoH servers to each MRG in the cluster.

In environments where both multicast and unicast MoH are required, be sure to provide redundancy for both transport types to ensure MoH redundancy for all endpoints in the network.

Design Considerations for Media Resources

This section discusses specific considerations for deploying media resources for use with the various Unified CM deployment models. It also highlights the configuration considerations and best practices to help you design a robust solution for media resource allocation in your Unified CM implementation.

Deployment Models

This section examines where and when the MTP and transcoding resources are used within the following three enterprise IP Telephony deployment models:

- [Single-Site Deployments, page 17-41](#)
- [Multisite Deployments with Centralized Call Processing, page 17-41](#)
- [Multisite Deployments with Distributed Call Processing, page 17-42](#)

Single-Site Deployments

In a single-site deployment, there is no need for transcoding because there are no low-speed links to justify the use of a low bit-rate (LBR) codec. Some MTP resources might be required in the presence of a significant number of devices that are not compliant with H.323v2, such as older versions of Microsoft NetMeeting or certain video devices. MTP resources may be required for DTMF conversion if SIP endpoints are present (see [Named Telephony Events \(RFC 2833\), page 17-13.](#))

Multisite Deployments with Centralized Call Processing

In a centralized call processing deployment, the Unified CM cluster and the applications (such as voice mail and IVR) are located at the central site, while several remote sites are connected through an IP WAN. The remote sites rely on the centralized Unified CMs to handle their call processing.

Because WAN bandwidth is typically limited, calls are configured to use a low bit-rate codec such as G.729 when traversing the WAN. (See [Figure 17-10.](#))

Voice compression between IP phones is easily configured through the use of *regions* and *locations* in Unified CM. A region defines the type of compression (for example, G.711 or G.729) used by the devices in that region, and a location specifies the total amount of bandwidth available for calls to and from devices at that location.

Figure 17-10 Transcoding for the WAN with Centralized Call Processing

77304

Unified CM uses media resource groups (MRGs) to enable sharing of MTP and transcoding resources among the Unified CM servers within a cluster. In addition, when using an LBR codec (for example, G.729a) for calls that traverse different regions, the transcoding resources are used only if one (or both) of the endpoints is unable to use the LBR codec.

In [Figure 17-10](#), Unified CM knows that a transcoder is required and allocates one based on the MRGL and/or MRG of the device that is using the higher-bandwidth codec. In this case it is the VM/UM server that determines which transcoder device is used. This behavior of Unified CM is based on the assumption that the transcoder resources are actually located close to the higher-bandwidth device. If this system was designed so that the transcoder for the VM/UM server was located at the remote site, then G.711 would be sent across the WAN, which would defeat the intended design. As a result, if there are multiple sites with G.711-only devices, then each of these sites would need transcoder resources when an LBR is run on the WAN.

The placement of other resources is also important. For example, if a conference occurs with three phones at a remote site and the conference resource is located in the central (call processing) site, then three media streams are carried over the WAN. If the conference resource were local, then the calls would not traverse the WAN. It is necessary to consider this factor when designing the bandwidth and call admission control for your WAN.

Multisite Deployments with Distributed Call Processing

In distributed call processing deployments, several sites are connected through an IP WAN. Each site contains a Unified CM cluster that can, in turn, follow the single-site model or the centralized call processing model. A gatekeeper may be used for call admission control between sites.

Because WAN bandwidth is typically limited, calls between sites may be configured to use an LBR codec (such as G.729a) when traversing the WAN. H.323v2 intercluster trunks are used to connect Unified CM clusters. Unified CM also supports compressed voice call connections through the MTP service if a hardware MTP is used. (See [Figure 17-11](#).)

A distributed call processing deployment might need transcoding and MTP services in the following situations:

- With current versions of Cisco applications, it is possible and recommended to avoid the use of transcoding resources. There might be specific instances where G.711 on a specific device cannot be avoided.
- Some endpoints (for example, video endpoints) do not support the H.323v2 features.

Figure 17-11 Intercluster Call Flow with Transcoding

Unified CM uses media resource groups (MRGs) to enable sharing of MTP and transcoding resources among the Unified CM servers within a cluster. In addition, for calls across intercluster trunks, MTP and transcoding resources are used only when needed, thus eliminating the need to configure the MTP service for applications that do not support LBR codecs.

The following characteristics apply to distributed call processing deployments:

- Only the intercluster calls that require transcoding will use the MTP service. For example, if both endpoints of a call are capable of using a G.729 codec, no transcoding resources will be used.
- Sharing MTP resources among servers within a cluster provides more efficient resource utilization.

Media Functions and Voice Quality

Any process that manipulates media can degrade the quality of the media. For example, encoding a voice stream for transmission across any network (IP or TDM) and decoding it at the other end will result in a loss of information, and the resulting voice stream will not be an exact reproduction of the original. If there are media traversal paths through the network that involve multiple encoding and decoding steps of the same voice stream, then each successive encoding/decoding operation will further degrade the voice quality. In general, such paths should be avoided. This is especially true for low-bandwidth codecs (LBC) such as G.729.

If such paths cannot be avoided, voice quality can generally be improved by using a higher bandwidth, low-compression codec, such as the G.711 or G.722 codecs, which are recommended wherever such paths are anticipated. Use of lower bandwidth, higher compression codecs in such scenarios is not recommended.

Music on Hold Design Considerations

This section highlights some MoH configuration considerations and best practice to help you design a robust MoH solution.

Codec Selection

If you need multiple codecs for MoH deployment, configure them in the IP Voice Media Streaming Application service parameter **Supported MoH Codecs** under the Clusterwide Unified CM Service Parameters Configuration. From the Supported MoH Codecs list under the Clusterwide Parameters, select all the desired codec types that should be allowed for MoH streams. By default, only G.711 mu-law is selected. To select another codec type, click on it in the scrollable list. For multiple selections, hold down the CTRL key and use the mouse to select multiple codecs from the scrollable list. The actual codec used for a MoH event is determined by the Region settings of the MoH server and the device being put on hold (IP phone, gateway, and so forth). Therefore, assign the proper Region setting to your MoH servers and configure the desired Region Relationships to control the codec selection of MoH interactions.

Note

If you are using the G.729 codec for MoH audio streams, be aware that this codec is optimized for speech and it provides only marginal audio fidelity for music.

Multicast Addressing

Proper IP addressing is important for configuring multicast MoH. Addresses for IP multicast range from 224.0.1.0 to 239.255.255.255. The Internet Assigned Numbers Authority (IANA), however, assigns addresses in the range 224.0.1.0 to 238.255.255.255 for public multicast applications. Cisco strongly discourages using public multicast addresses for music on hold. Instead, Cisco recommends that you configure multicast MoH audio sources to use IP addresses in the range 239.1.1.1 to 239.255.255.255, which is reserved for administratively controlled applications on private networks.

Furthermore, you should configure multicast audio sources to increment on the IP address and not the port number, for the following reasons:

- IP phones placed on hold join multicast IP addresses, not port numbers.
Cisco IP phones have no concept of multicast port numbers. Therefore, if all the configured codecs for a particular audio stream transmit to the same multicast IP address (even on different port numbers), all streams will be sent to the IP phone even though only one stream is needed. This has the potential of saturating the network with unnecessary traffic because the IP phone is capable of receiving only a single MoH stream.
- IP network routers route multicast based on IP addresses, not port numbers.
Routers have no concept of multicast port numbers. Thus, when it encounters multiple streams sent to the same multicast group address (even on different port numbers), the router forwards all streams of the multicast group. Because only one stream is needed, network bandwidth is over-utilized and network congestion can eventually result.

MoH Audio Sources

Configured audio sources are shared among *all* MoH servers in the Unified CM cluster, requiring each audio source file to be uploaded to every MoH server within the cluster. You can configure up to 51 unique audio sources per cluster (50 audio file sources and one fixed/live source via a sound card). For methods of providing additional sources, refer to the sections on [Using Multiple Fixed \(Live\) Audio Sources, page 17-45](#), and [Multicast MoH from Branch Routers, page 17-50](#).

For those audio sources that will be used for multicast streaming, ensure that **Allow Multicasting** and **Play continuously (repeat)** are enabled. If continuous play of an audio source is not specified, only the first party placed on hold, not additional parties, will receive the MoH audio source.

Using Multiple Fixed (Live) Audio Sources

It is important to remember that only a single fixed audio source can be configured within Unified CM. However, each MoH server in the Unified CM cluster is capable of streaming a single fixed audio source by means of a Cisco MoH USB audio sound card (MOH-USB-AUDIO). When multiple fixed audio sources are needed, additional MoH servers can be added to provide these multiple sources. The audio supplied to each MoH server sound card can be the same or different, and the administrator can determine which MoH server is selected based on MRG and MRGL selections. When multiple audio sources are done in this manner, the holder's **User/Network Hold MoH Audio Source** should be configured for the fixed audio source (the single fixed audio source that is configured in Unified CM), and the MoH server to stream that fixed audio source to the device is then determined by the MRGL of the holdee.

In the case where the audio source is the same, this method also allows for redundancy of the fixed audio source. For example, in [Figure 17-12](#) there are two MoH servers, each with an MOH-USB-AUDIO sound card connected to an audio source streaming audio derived from a live radio station feed. Phone B's MRGL contains first an MRG that contains the MOH1 server and second an MRG that contains the MOH2 server. Assuming the User/Network Hold Audio Source at Phone A has been set to the fixed audio source, after a call is established between Phone A and Phone B, and Phone B is placed on hold by Phone A, Phone B will receive the live feed audio source from the MOH1 server. In the case where the MOH1 server is down (or has no available capacity) when Phone A puts Phone B on hold, Phone B will receive the live feed audio source from the MOH2 server.

Figure 17-12 Fixed Audio Source Redundancy Example

**Note**

Using live radio broadcasts as multicast audio sources can have legal ramifications. Consult your legal department for potential issues.

Unicast and Multicast in the Same Unified CM Cluster

In some cases, administrators might want to configure a single Unified CM cluster to handle both unicast and multicast MoH streams. This configuration might be necessary because the telephony network contains devices or endpoint that do not support multicast or because some portions of the network are not enabled for multicast.

Use one of the following methods to enable a cluster to support both unicast and multicast MoH audio streams:

- Deploy separate MoH servers, with one server configured as a unicast MoH server and the second server configured as a multicast MoH server.
- Deploy a single MoH server with two media resource groups (MRGs), each containing the same MoH server, with one MRG configured to use multicast for audio streams and the second MRG configured to use unicast.

In either case, you must configure at least two MRGs and at least two media resource group lists (MRGLs). Configure one unicast MRG and one unicast MRGL for those endpoints requiring unicast MoH. Likewise, configure one multicast MRG and one multicast MRGL for those endpoints requiring multicast MoH.

When deploying separate MoH servers, configure one server without multicast enabled (unicast-only) and configure a second MoH server with multicast enabled. Assign the unicast-only MoH media resource and the multicast-enabled MoH media resource to the unicast and multicast MRGs, respectively. Ensure that the **Use Multicast for MoH Audio** box is checked for the multicast MRG but not for the unicast MRG. Also assign these unicast and multicast MRGs to their respective MRGLs. In this case, an MoH stream is unicast or multicast based on whether the MRG is configured to use multicast and then on the server from which it is served.

When deploying a single MoH server for both unicast and multicast MoH, configure the server for multicast. Assign this same MoH media resource to both the unicast MRG and the multicast MRG, and check the **Use Multicast for MoH Audio** box for the multicast MRG. In this case, an MoH stream is unicast or multicast based solely on whether the MRG is configured to use multicast.

**Note**

When configuring the unicast MRG, do not be confused by the fact that the MoH media resource you are adding to this MRG has [Multicast] appended to the end of the resource name even though you are adding it to the unicast MRG. This label is simply an indication that the resource is capable of being multicast, but the **Use Multicast for MoH Audio** box determines whether the resource will use unicast or multicast.

In addition, you must configure individual devices or device pools to use the appropriate MRGL. You can place all unicast devices in a device pool or pools and configure those device pools to use the unicast MRGL. Likewise, you can place all multicast devices in a device pool or pools and configure those device pools to use the multicast MRGL. Optionally, you can configure individual devices to use the appropriate unicast or multicast MRGL. Lastly, configure a User Hold Audio Source and Network Hold Audio Source for each individual device or (in the case of phone devices) individual lines or directory numbers to assign the appropriate audio source to stream.

When choosing a method for deploying both multicast and unicast MoH in the same cluster, an important factor to consider is the number of servers required. When using a single MoH server for both unicast and multicast, fewer MoH servers are required throughout the cluster. Deploying separate multicast and unicast MoH servers will obviously require more servers within the cluster.

Quality of Service (QoS)

Convergence of data and voice on a single network requires adequate QoS to ensure that time-sensitive and critical real-time applications such as voice are not delayed or dropped. To ensure proper QoS for voice traffic, the streams must be marked, classified, and queued as they enter and traverse the network to give the voice streams preferential treatment over less critical traffic. MoH servers automatically mark audio stream traffic the same as voice bearer traffic, with a Differentiated Services Code Point (DSCP) value of 46 or a Per Hop Behavior (PHB) value of EF (ToS of 0xB8). Therefore, as long as QoS is properly configured on the network, MoH streams will receive the same classification and priority queuing treatment as voice RTP media traffic.

Call signaling traffic between MoH servers and Unified CM servers is automatically marked with a DSCP value of 24 or a PHB value of CS3 (ToS of 0x60) by default. Therefore, as long as QoS is properly configured on the network, this call signalling traffic will be properly classified and queued within the network along with all other call signalling traffic.

Call Admission Control and MoH

Call admission control (CAC) is required when IP telephony traffic is traveling across WAN links. Due to the limited bandwidth available on these links, it is highly probable that voice media traffic might get delayed or dropped without appropriate call admission control. For additional information, see [Call Admission Control, page 11-1](#).

Call admission control for Unified CM (based on either static locations or RSVP-enabled locations) is capable of tracking unicast MoH streams traversing the WAN but not multicast MoH streams. Thus, even if WAN bandwidth has been fully subscribed, a multicast MoH stream will not be denied access to the WAN by call admission control. Instead, the stream will be sent across the WAN, likely resulting in poor audio stream quality and poor quality on all other calls traversing the WAN. To ensure that multicast MoH streams do not cause this over-subscription situation, you should over-provision the QoS

configuration on all downstream WAN interfaces by configuring the low-latency queuing (LLQ) voice priority queue with additional bandwidth. Because MoH streams are uni-directional, only the voice priority queues of the downstream interfaces (from the central site to remote sites) must be over-provisioned. Add enough bandwidth for every unique multicast MoH stream that might traverse the WAN link. For example, if there are four unique multicast audio streams that could potentially traverse the WAN, then add 96 kbps to the voice priority queue ($4 * 24 \text{ kbps per G.729 audio stream} = 96 \text{ kbps}$).

Figure 17-13 shows an example of call admission control and MoH in a centralized multisite deployment. For this example, assume that IP phone C is in a call with a PSTN phone (phone B). At this point, no bandwidth has been consumed on the WAN. When phone C pushes the Hold softkey (step 1), phone B receives an MoH stream from the central-site MoH server by way of the WAN, thereby consuming bandwidth on the link. Whether or not this bandwidth is taken into consideration by call admission control depends on the type of MoH stream. If multicast MoH is streamed, then call admission control will not consider the 24 kbps being consumed (therefore, QoS on the downstream WAN interfaces should be provisioned accordingly). However, if unicast MoH is streamed, call admission control will subtract 24 kbps from the available WAN bandwidth (step 2).

**Note**

The preceding example might seem to imply that unicast MoH should be streamed across the WAN. However, this is merely an example used to illustrate locations-based call admission control with MoH and is not intended as a recommendation or endorsement of this configuration. As stated earlier, multicast MoH is the recommended transport mechanism for sending MoH audio streams across the WAN.

Figure 17-13 Locations-Based Call Admission Control and MoH

Deployment Models for Music on Hold

The various Unified Communications call processing deployment models introduce additional considerations for MoH configuration design. Which deployment model you choose can also affect your decisions about MoH transport mechanisms (unicast or multicast), resource provisioning, and codecs. This section discusses these issues in relation to the various deployment models.

For more detailed information about the deployment models, see the chapter on [Unified Communications Deployment Models](#), page 5-1.

Single-Site Campus (Relevant to All Deployments)

Single-site campus deployments are typically based on a LAN infrastructure and provide sufficient bandwidth for large amounts of traffic. Because bandwidth is typically not limited in a LAN infrastructure, Cisco recommends the use of the G.711 (A-law or mu-law) codec for all MoH audio streams in a single-site deployment. G.711 provides the optimal voice and music streaming quality in an IP Telephony environment.

MoH server redundancy should also be considered. In the event that an MoH server becomes overloaded or is unavailable, configuring multiple MoH servers and assigning them in preferred order to MRGs ensures that another server can take over and provide the MoH streams.

With the increasing diversity of network technologies, in a large single-site campus it is likely that some endpoint devices or areas of the network will be unable to support multicast. For this reason, you might have to deploy both unicast and multicast MoH resources. For more information, see the section on [Unicast and Multicast in the Same Unified CM Cluster](#), page 17-46.

To ensure that off-net calls and application-handled calls receive expected MoH streams when placed on hold, configure all gateways and other devices with the appropriate MRGLs and audio sources, or assign them to appropriate device pools.

Centralized Multisite Deployments

Multisite IP telephony deployments with centralized call processing typically contain WAN connections to multiple non-central sites. These WAN links usually cause bandwidth and throughput bottlenecks. To minimize bandwidth consumption on these links, Cisco recommends the use of the G.729 codec for all MoH audio streams traversing the WAN. Because the G.729 codec is optimized for voice and not music applications, you should use G.729 only across the WAN, where the bandwidth savings far outweighs the lower quality afforded by G.729 for MoH transport. Likewise, because multicast traffic provides significant bandwidth savings, you should always use multicast MoH when streaming audio to endpoints across the WAN.

If the sound quality of an MoH stream becomes an issue when using the G.729 codec across the WAN, you can use the G.711 codec for MoH audio streams across the WAN while still using G.729 for voice calls. In order to send MoH streams across the WAN with the G.711 codec but voice calls across the WAN with the G.729 codec, place all MoH servers in a Unified CM region by themselves, and configure that region to use G.711 between itself and all other regions. Thus, when a call is placed between two phones on either side of a WAN, the G.729 codec is used between their respective regions. However, when the call is placed on hold by either party, the MoH audio stream is encoded using G.711 because G.711 is the configured codec to use between the MoH server's region and the region of the phone placed on hold.

Multicast MoH from Branch Routers

Branch routers deployed with the Cisco Unified Survivable Remote Site Telephony (SRST) feature can provide multicast MoH in a remote or branch site, with the MoH streaming from the branch SRST router's flash or from a live feed connected to an analog port. Multicast MoH from a branch router via these two methods enhances the Cisco Unified Communications MoH feature in both of the following scenarios:

- **Non-Fallback Mode**

When the WAN is up and the phones are controlled by Unified CM, this configuration can eliminate the need to forward MoH across the WAN to remote branch sites by providing locally sourced MoH.

- **Fallback Mode**

When SRST is active and the branch devices have lost connectivity to the central-site Unified CM, the branch router can continue to provide multicast MoH.

When using the live feed option in either scenario, the SRST router provides redundancy by monitoring the live feed input, and it will revert to streaming MoH from a file in flash if the live feed is disconnected. You can use only a single multicast address and port number per SRST router to provide multicast MoH; therefore, the SRST router does not support streaming from both the live feed and the flash file at the same time. In addition, the SRST router can stream only a single audio file from flash.

Note

An SRST license is required regardless of whether the SRST functionality will actually be used. The license is required because the configuration for streaming MoH from branch router flash is done under the SRST configuration mode and, even if SRST functionality will not be used, at least one **max-ephones** and one **max-dn** must be configured.

Non-Fallback Mode

During non-fallback mode (when the WAN is up and SRST is not active), the branch SRST router can provide multicast MoH to all local Cisco Unified Communications devices. To accomplish this, you must configure a Unified CM MoH server with an audio source that has the same multicast IP address and port number as configured on the branch router. In this scenario, because the multicast MoH audio stream is always coming from the SRST router, it is not necessary for the central-site MoH server audio source to traverse the WAN.

To prevent the central-site audio stream(s) from traversing the WAN, use one of the following methods:

- **Configure a maximum hop count**

Configure the central-site MoH audio source with a maximum hop count (or TTL) low enough to ensure that it will not stream further than the central-site LAN.

- **Configure an access control list (ACL) on the WAN interface**

Configure an ACL on the central-site WAN interface to disallow packets destined to the multicast group address(es) from being sent out the interface.

- **Disable multicast routing on the WAN interface**

Do not configure multicast routing on the WAN interface, thus ensuring that multicast streams are not forwarded into the WAN.

Figure 17-14 illustrates streaming multicast MoH from a branch router when it is not in fallback mode. After phone A places phone C on hold, phone C receives multicast MoH from the local SRST router. In this example, the MoH server is streaming a multicast audio source to 239.192.240.1 (on RTP port 16384); however, this stream has been limited to a maximum hop of one (1) to ensure that it will not travel off the local MoH server's subnet and across the WAN. At the same time, the branch office SRST

router/gateway is multicasting an audio stream from either flash or a live feed. This stream is also using 239.192.240.1 as its multicast address and 16384 as the RTP port number. When phone A presses the Hold softkey, phone C receives the MoH audio stream sourced by the SRST router.

Figure 17-14 Multicast MoH from Branch Router

When using this method for delivering multicast MoH, configure all devices within the Unified CM cluster to use the same user hold and network hold audio source and configure all branch routers with the same multicast group address and port number. Because the user or network hold audio source of the holder is used to determine the audio source, if you configure more than one user or network hold audio source within the cluster, there is no way to guarantee that a remote holdees will always receive the local MoH stream. For example, suppose a central-site phone is configured with an audio source that uses group address 239.192.254.1 as its user and network hold audio source. If this phone places a remote device on hold, the remote device will attempt to join 239.192.254.1 even if the local router flash MoH stream is sending to multicast group address 239.192.240.1. If instead all devices in the network are configured to use the user/network hold audio source with multicast group address 239.192.240.1 and all branch routers are configured to multicast from flash on 239.192.240.1, then every remote device will receive the MoH from its local router.

In networks with multiple branch routers configured to stream multicast MoH, this allows for more than 51 unique MoH audio sources within the Unified CM cluster. Each branch site router can multicast a unique audio stream, although all routers must multicast this audio on the same multicast group address. In addition, the central-site MoH server can multicast a MoH stream on this same multicast group address. Thus, if there are 100 branch sites each multicasting audio, then the cluster actually contains 101 unique MoH audio sources (100 branch streams and one central-site stream). If you want more than 51 unique audio streams in the central site, see the methods described in [Using Multiple Fixed \(Live\) Audio Sources](#), page 17-45.

Fallback Mode

During fallback mode (when the WAN is down and SRST is active), the branch SRST router can stream multicast MoH to all analog and digital ports within the chassis, thereby providing MoH to analog phones and PSTN callers.

The branch router's configuration for fallback mode multicast MoH is the same as the normal operation configuration. However, which multicast address you configure on the router depends on the intended operation. If you want the branch router to provide multicast MoH to devices only in fallback mode (for example, if MoH received by remote devices is to be sourced from the central-site MoH server during non-fallback mode), then the multicast address and port number configured on the SRST router should not overlap with any of the central-site MoH server audio sources. Otherwise, remote devices might continue to receive MoH from the local router flash, depending on the configured user/network hold audio sources.

Note that, once the branch SRST/gateway router is configured to provide multicast MoH, the router will continue to multicast the MoH stream even when not in fallback mode.

It is also possible to configure the fallback mode to use Cisco Unified Communications Manager Express (Unified CME) in SRST mode. Fallback mode behavior is still the same, but the configuration commands are slightly different. SRST commands are entered under the Cisco IOS **call-manager-fallback** construct, while the commands for Unified CME in SRST mode are entered under **telephony-service**.

There are four methods of providing multicast MoH via SRST:

- SRST multicast MoH from branch router flash
- SRST multicast MoH from a live feed
- Unified CME in SRST mode with multicast MoH from branch router flash
- Unified CME in SRST mode with multicast MoH from a live feed

For more details on configuration of Cisco Unified SRST and Unified CME, refer to the following documentation:

- *Cisco Unified SRST System Administrator Guide*, available at http://www.cisco.com/en/US/products/sw/voicesw/ps2169/products_installation_and_configuration_guides_list.html
- *Cisco Unified Communications Manager Express System Administrator Guide*, available at http://www.cisco.com/en/US/products/sw/voicesw/ps4625/products_installation_and_configuration_guides_list.html

Distributed Multisite Deployments

Multisite IP telephony deployments with distributed call processing typically contain WAN or MAN connections between the sites. These lower-speed links usually cause bandwidth and throughput bottlenecks. To minimize bandwidth consumption on these links, Cisco recommends use of the G.729 codec for all MoH audio streams traversing them. Because the G.729 codec is optimized for voice and not music applications, you should use G.729 only across the WAN/MAN links, where the bandwidth savings far outweighs the lower quality afforded by G.729 for MoH transport.

Unlike with centralized multisite deployments, in situations where G.711 might be required for MoH audio streams traveling across a WAN, MoH audio streams cannot be forced to G.711 in a distributed multisite deployment. Even when MoH servers are placed in a separate Unified CM region and the G.711 codec is configured between this region and the intercluster or SIP trunk's region, the codec of

the original voice call is maintained when a call between the two clusters is placed on hold by either phone. Because these intercluster calls are typically encoded using G.729 for bandwidth savings, a MoH stream from either cluster will also be encoded using G.729.

Another option is to provision multicast MoH for intercluster calls across an intercluster trunk (ICT) or SIP trunk. This allows endpoints in one Unified CM cluster to hear multicast MoH streamed from another Unified CM cluster, while making more efficient use of intercluster bandwidth. A properly designed IP Multicast environment is required to take advantage of this feature. For more information on IP Multicast, refer to the documentation available at

http://www.cisco.com/en/US/products/ps6552/products_ios_technology_home.html

Proper multicast address management is another important design consideration in the distributed intercluster environment. All MoH audio source multicast addresses must be unique across all Unified CM clusters in the deployment to prevent possible overlap of streaming resources throughout the distributed network.

Clustering Over the WAN

As its name suggests, clustering-over-the-WAN deployments also contain the same type of lower-speed WAN links as other multisite deployments and therefore are subject to the same requirements for G.729 codec, multicast transport mechanism, and solid QoS for MoH traffic traversing these links.

In addition, you should deploy MoH server resources at each side of the WAN in this type of configuration. In the event of a WAN failure, devices on each side of the WAN will be able to continue to receive MoH audio streams from their locally deployed MoH server. Furthermore, proper MoH redundancy configuration is extremely important. The devices on each side of the WAN should point to an MRGL whose MRG has a priority list of MoH resources with at least one local resource as the highest priority. Additional MoH resources should be configured for this MRG in the event that the primary server becomes unavailable or is unable to process requests. At least one other MoH resource in the list should point to an MoH resource on the remote side of the WAN in the event that resources at the local side of the WAN are unavailable.

CHAPTER 18

Unified Communications Endpoints

Revised: July 31, 2012; OL-21733-18

A variety of endpoints can be used in a Cisco Unified Communications deployment. These endpoints range from gateways that support ordinary analog phones in an IP environment to an extensive set of native IP phones offering a range of capabilities.

When deploying endpoints, you need to consider several factors, include configuration, authentication, upgrades, signaling protocol, QoS, and so forth. The Unified Communications system must be designed appropriately to accommodate these factors.

This chapter summarizes various types of Unified Communications endpoints along with their features and QoS recommendations. The endpoints can be categorized into the following major types:

- [Analog Gateways, page 18-3](#)
- [Cisco Unified IP Phones, page 18-8](#)
- [Software-Based Endpoints, page 18-21](#)
- [Wireless Endpoints, page 18-23](#)
- [Cisco Unified IP Conference Station, page 18-29](#)
- [Video Endpoints, page 18-30](#)
- [Cisco Virtualization Experience Clients, page 18-37](#)
- [Third-Party SIP IP Phones, page 18-38](#)

The sections listed above provide detailed information about each endpoint type. In addition, the section on [QoS Recommendations, page 18-39](#), lists generic QoS configurations, and the [Endpoint Features Summary, page 18-55](#), lists all the endpoint features.

Use this chapter to understand the range of available endpoint options and the design considerations that go along with their deployment.

What's New in This Chapter

Table 18-1 lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Unified Communications Endpoints Architecture

Call signaling in Cisco Unified Communications Manager (Unified CM) distinguishes between line-side signaling and trunk-side signaling. Whereas trunk-side signaling is used for connecting the entire Unified CM cluster to other servers and gateways, the line side is used for connecting end-user devices to the cluster. The two interfaces are distinct in the services they offer, with the line side offering a rich set of user-oriented features.

Session Initiation Protocol (SIP) and Skinny Client Control Protocol (SCCP) are the two main line-side signaling protocols supported by Unified CM. All Cisco endpoints support either or both of these protocols. The set of features supported in both protocols is roughly equivalent, and the choice of which protocol to use is essentially a personal preference in a deployment. [Table 18-7](#) through [Table 18-15](#) present a comparison of protocols and features supported by various endpoints.

Cisco endpoints must be configured with several operating parameters before they can be used to make or receive calls or to run applications. This configuration must be performed in advance in the Unified CM. Once configured, Unified CM generates a configuration file for the endpoint to use, and it places stores that file in a Trivial File Transfer Protocol (TFTP) server. The endpoints themselves go through a boot-up sequence when powered on. They retrieve this configuration file before they register with the appropriate server, and then they are ready to be used. The endpoints execute the following steps as part of the boot-up sequence:

1. When connected to the access switch, if the endpoint is not plugged in to a power source, it attempts to obtain power from the switch (Power over Ethernet).
2. Once power is obtained, if device security is enabled, the endpoint presents its credentials to the security server.
3. If it is allowed to use the network, the endpoint obtains its network parameters such as IP address, Domain Name Service (DNS) servers, gateway address, and so forth., either through static provisioning in the endpoint or through Dynamic Host Control Protocol (DHCP).
4. The endpoint also obtains a TFTP server address either through static provisioning or through DHCP options.
5. The endpoint then uses the TFTP server address to obtain its configuration files that, among other parameters, detail the server(s) in the Unified CM cluster that the endpoint may associate with, the directory numbers that the endpoint must support, and so forth.
6. The endpoint registers with the server and is available for use.

Analog Gateways

Analog gateways include router-based analog interface modules, Cisco Communication Media Module (CMM) with 24-FXS port adapter, Catalyst 6500 24-FXS analog interface module, Cisco VG202, Cisco VG204, Cisco VG224, Cisco VG248, and Cisco Analog Telephone Adaptor (ATA) 186 and 188. An analog gateway is usually used to connect analog devices, such as fax machines, modems, telecommunications devices for the deaf (TDD), teletypewriters (TTY), and analog phones, to the VoIP network so that the analog signal can be packetized and transmitted over the IP network.

Analog Interface Module

Cisco router-based analog interface modules include low-density interface modules (NM-1V, NM-2V, NM-HD-1V, NM-HD-2V, NM-HD-2VE, NM-HDV2, NM-HDV2-1T1/E1, and NM-HDV2-2T1/E1) and high-density interface modules (NM-HDA-4FXS and EVM-HD-8FXS/DID). Cisco analog interface modules connect the PSTN and other legacy telephony equipment, including PBXs, analog telephones, fax machines, and key systems, to Cisco multiservice access routers. Cisco analog interface modules are best suited for connecting low- to high-density analog devices to the IP network with limited call features.

Low-Density Analog Interface Module

The low-density analog interface modules include the NM-1V, NM-2V, NM-HD-1V, NM-HD-2V, NM-HD-2VE, NM-HDV2, NM-HDV2-1T1/E1, and NM-HDV2-2T1/E1. The NM-1V and NM-2V contain one or two interface cards (VIC). The interface cards include: two-port FXS VIC (VIC-2FXS); two-port FXO VIC (VIC-2FXO, VIC-2FXO-M1/M2/M3, and VIC-2FXO-EU); two-port Direct Inward Dial VIC (VIC-2DID); two-port E&M VIC (VIC-2E/M); two-port Centralized Automated Message Accounting VIC (VIC-2CAMA); and two-port BRI VIC (VIC-2BRI-S/T-TE and VIC-2BRI-NT/TE). The NM-1V and NM-2V can serve up to two and four FXS connections, respectively.

Note

The NM-1V and NM-2V are not supported on the Cisco 2800 and 3800 Series platforms. On the Cisco 2800 and 3800 Series platforms, the voice interface cards are supported in the on-board High-Speed WIC slots, including the VIC-2DID, VIC4-FXS/DID, VIC2-2FXO, VIC-2-4FXO, VIC2-2FXS, VIC2-2E/M, and VIC2-2BRI-NT/TE.

The NM-HD-1V and NM-HD-2V contain one and two VICs, respectively. The NM-HD-2VE contains two VICs or two voice/WAN interface cards (VWIC), or a combination of one VIC and one VWIC. The NM-HD-1V, NM-HD-2V, and NM-HD-2VE can serve up to 4, 8, and 8 FXS or FXO connections, respectively. The NM-HDV2, NM-HDV2-1T1/E1, and NM-HDV2-2T1/E1 can be fitted with either digital T1/E1 or analog/BRI voice interface cards, with up to 4 FXS or FXO connections. The difference among these three interface modules is that the NM-HDV2-1T1/E1 has one built-in T1/E1 port while the NM-HDV2-2T1/E1 has two built-in T1/E1 ports.

The voice interface cards include: 2-port and 4-port FXS VICs (VIC2-2FXS and VIC-4FXS/DID); 2-port and 4-port FXO VICs (VIC2-2FXO and VIC2-4FXO); 2-port Direct Inward Dial VIC (VIC-2DID); 2-port E&M VIC (VIC2-2E/M); and 2-port BRI VIC (VIC2-2BRI-NT/TE). The voice/WAN interface cards include: 1-port and 2-port RJ-48 multiflex trunk (MFT) T1/E1 VWICs for both voice and WAN connections (VWIC-1MFT-T1, VWIC-2MFT-T1, VWIC-2MFT-T1-DI, VWIC-1MFT-E1, VWIC-2MFT-E1, VWIC-2MFT-E1-DI, VWIC-1MFT-G703, VWIC-2MFT-G703, VWIC2-1MFT-T1/E1, VWIC2-2MFT-T1/E1, VWIC2-1MFT-G703, and VWIC2-2MFT-G703). The G.703 interface cards are primarily for data connectivity but can in some cases be configured to support voice applications.

High-Density Analog Interface Module

The high-density analog interface module includes the NM-HDA-4FXS and EVM-HD-8FXS/DID. The NM-HDA-4FXS has four on-board FXS ports and room for two expansion modules from the following options:

- EM-HDA-8FXS: An 8-port FXS interface card
- EM-HDA-4FXO/EM2-HDA-4FXO: A 4-port FXO interface card

The NM-HDA-4FXS provides up to 12 analog ports (4 FXS and 8 FXO) with four built-in FXS ports and two EM-HDA-4FXO or EM2-HDA-4FXO extension modules, or 16 analog ports (12 FXS and 4 FXO) with four built-in FXS ports and one EM-HDA-8FXS, and one EM-HDA-4FXO or EM2-HDA-4FXO extension module. A configuration using two 8-port FXS extension modules is not supported. The NM-HDA also has a connector for a daughter module (DSP-HDA-16) that provides additional DSP resources to serve an additional 8 high-complexity calls or 16 medium-complexity calls.

**Note**

The EM2-HDA-4FXO supports the same density and features as the EM-HDA-FXO, but it provides enhanced features including longer loop length support of up to 15,000 feet and improved performance under poor line conditions when used in ground-start signaling mode.

The EVM-HD-8FXS/DID provides eight individual ports on the baseboard module and can be configured for FXS or DID signaling. In addition, the EVM-HD-8FXS/DID has room for two expansion modules from the following options:

- EM-HDA-8FXS: An 8-port FXS interface card
- EM-HDA-6FXO: A 6-port FXO interface card
- EM-HDA-3FXS/4FXO: A 3-port FXS and 4-port FXO interface card
- EM-4BRI-NT/TE: A 4-port BRI interface card

These extension modules can be used in any combination and provide for configurations of up to 24 FXS ports per EVM-HD-8FXS/DID.

Supported Platforms and Cisco IOS Requirements for Analog Interface Modules

The supported platforms for Cisco analog interface modules are the Cisco 2600, 2800, 3600, 3700, and 3800 Series. [Table 18-2](#) lists the maximum number of interface modules supported per platform, and [Table 18-3](#) lists the minimum Cisco IOS software version required.

Table 18-2 Maximum Number of Analog Interface Modules Supported per Platform

| Platform | Maximum Number of Interface Modules Supported | | | | |
|--------------|---|-------------|--------|---------------------|---------------------------|
| | NM-1V, -2V | NM-HDA-4FXS | EVM-HD | NM-HD-1V, -2V, -2VE | NM-HDV2, -1T1/E1, -2T1/E1 |
| Cisco 2600XM | 1 | 1 | No | 1 | 1 |
| Cisco 2691 | 1 | 1 | No | 1 | 1 |
| Cisco 3640 | 3 | 3 | No | 3 | No |

Cisco Communication Media Module (CMM)

The Cisco CMM is a line card that provides high-density analog, T1, and E1 gateway connections for Catalyst 6000 and Cisco 7600 Series switches. The Cisco CMM can serve up to 72 FXS connections. The CMM operates as either an MGCP or H.323 gateway, and it provides Survivable Remote Site Telephony (SRST) service for up to 480 IP phones.

Cisco CMM can contain the following interface port adapters: 24-port FXS analog port adapter (WS-SVC-CMM-24FXS), 6-port T1 interface port adapter (WS-SVC-CMM-6T1), 6-port E1 interface port adapter (WS-SVC-CMM-6E1), and conference/transcoding port adapter (WS-SVC-CMM-ACT).

[Table 18-4](#) lists the minimum software requirements for the compatible port adapters.

Table 18-4 Software Requirements for CMM Port Adapters

| | WS-SVC-CMM-24FXS | WS-SVC-CMM-6T1 | WS-SVC-CMM-6E1 | WS-SVC-CMM-ACT |
|---|------------------|----------------|----------------|----------------|
| Cisco IOS Release | 12.3(8)XY | 12.3(8)XY | 12.3(8)XY | 12.3(8)XY |
| CatOS Release | 7.3(1) | 7.3(1) | 7.3(1) | 7.6.8 |
| Native IOS Release | 12.1(15)E | 12.1(14)E | 12.1(13)E | 12.1(13)E |
| Maximum number of port adapters per CMM | 3 | 3 | 3 | 4 |

WS-X6624-FXS Analog Interface Module

The Cisco WS-X6624-FXS analog interface module is an MGCP-based device for connecting high-density analog devices to the IP telephony network, and it provides 24 analog ports.

Note

The WS-X6624 FXS analog interface module is no longer available for sale.

Cisco VG202 and VG204 Gateways

The Cisco VG202 and VG204 analog gateways are Cisco IOS-based low density 2-port and 4-port gateways, respectively, that can connect analog phones, fax machines, modems, and other analog devices to the enterprise voice system. These gateways can be integrated directly into Unified CM as either Skinny Client Control Protocol (SCCP) or Media Gateway Control Protocol (MGCP) gateways. Both of these gateways, if operated in MGCP mode, provide H.323 failover to Survivable Remote Site Telephony (SRST) in case of loss of connectivity with the Unified CM cluster.

These gateways also support the SIP protocol and can be connected over a SIP trunk to Unified CM. In this mode, however, several features available in SCCP or MGCP integration with Unified CM are not available.

Cisco VG224 Gateway

The Cisco VG224 analog gateway is a Cisco IOS high-density 24-port gateway for connecting analog devices to the IP Telephony network. In Cisco IOS Release 12.4(2)T and later, the Cisco VG224 can act as an Skinny Client Control Protocol (SCCP) or Media Gateway Control Protocol (MGCP) endpoint with Cisco Unified Communications Manager (Unified CM) and can re-home to a Survivable Remote Site Telephone (SRST) router in failover scenarios. The Cisco VG224 also supports modem pass-through, modem relay, fax pass-through, and fax relay. In addition, the Cisco VG224 can be used to connect analog phones for SCCP support on Cisco Unified Communications Manager Express (Unified CME) and Cisco Unified Survivable Remote Site Telephone (SRST).

Cisco VG248 Gateway

The Cisco VG248 is a high-density, 48 port, Skinny Client Control Protocol (SCCP) gateway for connecting analog devices such as analog phones, fax machines, modems and speakerphones to an enterprise Cisco Unified CM and voice network. The Cisco VG248 also supports Unified CM integration with legacy voicemail systems and PBXs compatible with Simplified Message Desk Interface (SMDI), NEC Message Center Interface (MCI), or Ericsson voicemail protocols. The Cisco VG248 supports failover to Survivable Remote Site Telephone (SRST).

Cisco ATA 186 and 188

The Cisco Analog Telephone Adaptor (ATA) 186 or 188 can connect two analog devices to the IP telephony network, and it is the best suited for low-density analog devices connecting to the IP network.

The difference between the Cisco ATA 186 and 188 is that the former has only one 10 Base-T Ethernet connection while the later has an integrated Ethernet switch providing two 10/100 Base-T Ethernet connections for itself and a co-located PC or other Ethernet-based device. The Cisco ATA 186 and 188 can be configured in any of the following ways:

- Cisco ATA web configuration page
- Cisco ATA voice configuration menu
- Configuration file downloaded from the TFTP server

The SCCP-based ATA behaves like an SCCP IP phone. The Cisco ATA 186 or 188 can be configured as a SIP client that registers with the SIP proxy server to make phone calls with another endpoint. The Cisco ATA 186 or 188 can act as either a user agent client (UAC) when it initiates SIP requests or as a user agent server (UAS) when it responds to requests.

Additional Information on Analog Gateways

For more information, including details regarding the latest hardware and software version support for analog gateways, refer to the appropriate data sheets and documentation for:

- Cisco VG 200 Series Gateways:
http://www.cisco.com/en/US/products/hw/gatecont/ps2250/prod_literature.html

Cisco Unified IP Phones

The Cisco IP phone portfolio includes basic IP phones, business IP phones, manager IP Phones, and executive IP phones.

Cisco Basic IP Phones

The Cisco basic IP phone is best suited for low-traffic users with limited call features and budget requirements. The basic IP phones include the Cisco Unified SIP Phone 3900 Series and the Cisco Unified IP Phones 6901, 6911, 7902G, 7905G, 7906G, 7910G, 7910G+SW, 7911G, and 7912G.

Cisco Unified SIP Phone 3900 Series

The Cisco Unified SIP Phone 3900 Series supports a single line and has a single 10/100 Base-T Ethernet port on the back of the phone. The Cisco Unified SIP Phone 3900 Series has a two-line liquid crystal display (LCD) screen and a half-duplex or full-duplex speakerphone. These phones support SIP only.

Cisco Unified IP Phone 6901

The Cisco Unified IP Phone 6901 shares its hardware characteristics and industrial design with the other models in the Cisco Unified IP Phone 6900 Series.

The Cisco Unified IP Phone 6901 is a basic single-line phone with one 10/100 Base-T Ethernet connection, and is ideal for use in lobbies, hallways, elevators, and other areas with occasional need for voice communications. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

Cisco Unified IP Phone 6911

The Cisco Unified IP Phone 6911 shares its hardware characteristics and industrial design with the other models in the Cisco Unified IP Phone 6900 Series.

The Cisco Unified IP Phone 6911 supports a single directory number, has two 10/100 Base-T Ethernet connections, and has a full-duplex speakerphone. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

Cisco Unified IP Phone 7902G

The Cisco Unified IP Phone 7902G supports a single line and it has a single 10-Base-T Ethernet port on the back of the phone. The Cisco Unified IP Phone 7902G does not have any liquid crystal display (LCD) screen. The Cisco Unified IP Phone 7902G supports SCCP but has no support for SIP.

Cisco Unified IP Phone 7905G

The Cisco Unified IP Phone 7905G supports a single line and it has a single 10-Base-T Ethernet port on the back of the phone. The speaker operates in one-way listen mode only. The Cisco Unified IP Phone 7905G supports SCCP and SIP; however, the features and user interface (UI) are not consistent across the two call signaling protocols.

Cisco Unified IP Phone 7906G

The Cisco Unified IP Phone 7906G supports a single line and it has a single 10/100 Base-T Ethernet port on the back of the phone. The speaker operates in one-way listen mode only. Power is supplied via IEEE 802.3af, Cisco inline power, or local power through a power adaptor (CP-PWR-CUBE-3). The Cisco Unified IP Phone 7906G supports SCCP and SIP and is one of the phones included in the enhanced architecture of Cisco Desktop IP Phones. This architecture provides for feature and UI consistency across the Cisco Desktop IP Phones regardless of call signaling protocol. The end-user experience for a supported feature will behave consistently whether using SCCP or SIP call control signaling.

Cisco Unified IP Phone 7910G and 7910G+SW

The Cisco Unified IP Phone 7910G supports only a single line, and the speaker operates in one-way listen mode only. The Cisco Unified IP Phone 7910G also has six feature access keys that can be configured in the customized phone button template by the administrator to provide the end-user with various call features. Because there are only six feature access keys on this phone model, one phone button template cannot provide the end-user with all the call features. Both the Cisco Unified IP Phone 7910G and 7910+SW support SCCP but have no support for SIP. The only difference between the Cisco Unified IP Phone 7910G and 7910G+SW is that the former has a 10 Base-T Ethernet port and the latter has two 10/100 Base-T Ethernet ports.

Cisco Unified IP Phone 7911G

The Cisco Unified IP Phone 7911G supports only a single line and it has two 10/100 Base-T Ethernet connections. The speaker operates in one-way listen mode only. The Cisco Unified IP Phone 7911G supports SCCP and SIP and is one of the phones included in the enhanced architecture of Cisco Desktop IP Phones. This architecture provides for feature and UI consistency across the Cisco Desktop IP Phones regardless of call signaling protocol. The end-user experience for a supported feature will behave consistently whether using SCCP or SIP call control signaling.

Cisco Unified IP Phone 7912G

The Cisco Unified IP Phone 7912G supports only a single line and it has two 10/100 Base-T Ethernet connections. The speaker operates in one-way listen mode only. The Cisco Unified IP Phone 7912G supports SCCP and SIP; however, the features and user interface (UI) are not consistent across the two call signaling protocols.

**Note**

The Cisco Unified IP Phones 7902G, 7905G, 7910G, 7910G+SW, and 7912G are no longer available for sale, but they are still supported by Cisco Unified Communications Manager.

Cisco Business IP Phones

The Cisco business IP phone is best suited for the transaction-type worker with medium telephony traffic use and extensive call features, such as speakers, headset, and so forth. The business IP phones include Cisco Unified IP Phones 6921, 6961, 7931G, 7940G, 7941G, 7941G-GE, 7942G, and 7945G.

Cisco Unified IP Phone 6921

The Cisco Unified IP Phone 6921 shares its hardware characteristics and industrial design with the other models in the Cisco Unified IP Phone 6900 Series.

The Cisco Unified IP Phone 6921 supports up to two directory numbers, has two 10/100 Base-T Ethernet connections, and has a full-duplex speakerphone. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

Cisco Unified IP Phone 6961

The Cisco Unified IP Phone 6961 shares its hardware characteristics and industrial design with the other models in the Cisco Unified IP Phone 6900 Series.

The Cisco Unified IP Phone 6961 supports up to 12 directory numbers and includes two 10/100 Base-T Ethernet connections. It also has a full-duplex speakerphone. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

Cisco Unified IP Phone 7931G

The Cisco Unified IP Phone 7931G supports up to 24 directory numbers that can be assigned to 24 illuminated line keys, and it is most suitable for retail, commercial, and manufacturing users. The Cisco Unified IP Phone 7931G has two 10/100 Base-T Ethernet connections, and it supports both SIP and SCCP. In addition to the programmable softkey support available on other Cisco Unified IP Phones, the Cisco Unified IP Phone 7931G also has three dedicated keys for Hold, Redial, and Transfer features. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

Cisco Unified IP Phone 7940G

The Cisco Unified IP Phone 7940G can have up to two directory numbers and includes two 10/100 Base-T Ethernet connections. The Cisco Unified IP Phone 7940G supports SCCP and SIP; however, the features and user interface (UI) are not consistent across the two call signaling protocols. For example, the Cisco Unified IP Phone 7940G using SCCP has full security capability, whereas SIP does not have any previously implemented security features. The Cisco Unified IP Phone 7940G using SCCP is compatible with the Cisco Unified Video Advantage video-enabled endpoint to make video calls, whereas the Cisco Unified IP Phone 7940G using SIP has no video support. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

Cisco Unified IP Phone 7941G

The Cisco Unified IP Phone 7941G can have up to two directory numbers and includes two 10/100 Base-T Ethernet connections. The Cisco Unified IP Phone 7941G supports SCCP and SIP and is included in the enhanced architecture of Cisco Unified IP Phones. This architecture provides for feature and UI consistency across the Cisco IP phones regardless of call signaling protocol. The end-user experience for a supported feature will behave consistently whether using SCCP or SIP call control signaling.

There are a few features that are not supported with SIP that are supported with SCCP. For example, the Cisco Unified IP Phone 7941G using SCCP is compatible with the Cisco Unified Video Advantage video-enabled endpoint to make video calls, whereas SIP has no video support. The Cisco Unified IP Phone 7941G using SCCP supports Tone on Hold, whereas SIP has no Tone on Hold support. This phone includes a higher-resolution, 4-bit grayscale display for enhancing feature usage and Extensible Markup Language (XML) applications, as well as for enabling support for double-byte languages. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

Cisco Unified IP Phone 7941G-GE

The Cisco Unified IP Phone 7941G-GE can have up to two directory numbers and is the equivalent of the Cisco Unified IP Phone 7941G with the exception that it includes two 10/100/1000 Base-T Ethernet connections. The addition of gigabit throughput capability allows for high bit-rate and bandwidth-intensive applications on a co-located PC.

Cisco Unified IP Phone 7942G

The Cisco Unified IP Phone 7942G, like the 7941G, can have up to two directory numbers and includes two 10/100 Base-T Ethernet connections. In addition to the 7941G's other features and support for protocols, the 7942G adds support for the G.722 wideband codec and updates the speaker, microphone, and handset for high-fidelity voice communications. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

Cisco Unified IP Phone 7945G

The Cisco Unified IP Phone 7945G extends the features of the 7942G. Like the 7942G, the 7945G can have up to two directory numbers; but unlike the 7942G, the 7945G also includes two 10/100/1000 Base-T Ethernet connections and a five-way navigation button set. In addition to the support for G.722 wideband codec and high-fidelity speaker, microphone, and handset, the 7945G adds a backlit TFT color display for easy access to communications information, timesaving applications, and feature usage. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

Cisco Manager IP Phones

The Cisco manager IP phone is best suited for managers and administrative assistants with medium to heavy telephony traffic use and extensive call features such as speakers, headset, and so forth. The business IP phones include Cisco Unified IP Phone 6941, 7960G, 7961G, 7961G-GE, 7962G, 7965G, 8941, 8945, and 8961.

Cisco Unified IP Phone 6941 and 6945

The Unified IP Phones 6941 and 6945 share hardware characteristics and industrial design with the other models in the Cisco Unified IP Phone 6900 Series.

The Cisco Unified IP Phones 6941 and 6945 support up to four directory numbers and have two 10/100 or 10/100/1000 Base-T Ethernet ports, respectively. These phone models also include a full-duplex speakerphone. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

Cisco Unified IP Phone 7960G

The Cisco Unified IP Phone 7960G can have up to six directory numbers and includes two 10/100 Base-T Ethernet connections. The Cisco Unified IP Phone 7960G supports SCCP and SIP; however, the features and user interface (UI) are not consistent across the two call signaling protocols. For example, the Cisco Unified IP Phone 7960G using SCCP has full security capability, whereas SIP does not have any previously implemented security features. The Cisco Unified IP Phone 7960G using SCCP is compatible with the Cisco Unified Video Advantage video-enabled endpoint to make video calls, whereas the Cisco Unified IP Phone 7960G using SIP has no video support. The Cisco Unified IP Phone 7960G using SCCP supports the Cisco Unified IP Phone Expansion Module 7914, whereas SIP has no support for the expansion module. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

Cisco Unified IP Phone 7961G

The Cisco Unified IP Phone 7961G can have up to six directory numbers and includes two 10/100 Base-T Ethernet connections. The Cisco Unified IP Phone 7961G supports SCCP and SIP and is included in the enhanced architecture of the Cisco Unified IP Phones. This architecture provides for feature and UI consistency across the Cisco IP phones regardless of call signaling protocol. The end-user experience for a supported feature will behave consistently whether using SCCP or SIP call control signaling.

There are a few features that are not supported with SIP that are supported with SCCP. For example, the Cisco Unified IP Phone 7961G using SCCP is compatible with the Cisco Unified Video Advantage video-enabled endpoint to make video calls, whereas SIP has no video support. The Cisco Unified IP Phone 7961G using SCCP supports Tone on Hold, whereas SIP has no Tone on Hold support. The Cisco Unified IP Phone 7961G using SCCP supports the Cisco Unified IP Phone Expansion Module 7914, whereas SIP has no support for the expansion module. This phone includes a higher-resolution, 4-bit grayscale display for enhancing feature usage and Extensible Markup Language (XML) applications, as well as for enabling support for double-byte languages. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

Cisco Unified IP Phone 7961G-GE

The Cisco Unified IP Phone 7961G-GE can have up to six directory numbers and is the equivalent of the Cisco Unified IP Phone 7961G with the exception that it includes two 10/100/1000 Base-T Ethernet connections. The addition of gigabit throughput capability allows for high bit-rate and bandwidth-intensive applications on a co-located PC.

Cisco Unified IP Phone 7962G

The Cisco Unified IP Phone 7962G, like the 7961G, can have up to six directory numbers and includes two 10/100 Base-T Ethernet connections. In addition to the 7961G's other features and support for protocols, the 7962G adds support for the G.722 wideband codec and updates the speaker, microphone, and handset for high-fidelity voice communications. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

Cisco Unified IP Phone 7965G

The Cisco Unified IP Phone 7965G extends the features of the 7962G. Like the 7962G, the 7965G can have up to six directory numbers; but unlike the 7962G, the 7965G also includes two 10/100/1000 Base-T Ethernet connections and a five-way navigation button set. In addition to the support for G.722 wideband codec and high-fidelity speaker, microphone, and handset, the 7965G adds a backlit TFT color display for easy access to communications information, timesaving applications, and feature usage. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

Cisco Unified IP Phone 8900 Series

The Cisco Unified IP Phone 8900 Series offers advanced capabilities within the Cisco IP phone portfolio. The Cisco Unified IP Phone 8961 supports up to five directory numbers, while the Cisco Unified IP Phones 8941 and 8945 each support four directory numbers. All 8900 Series endpoints support two Ethernet connections, with the Cisco Unified IP Phones 8945 and 8961 supporting 10/100/1000 Base-T and the Cisco Unified IP Phone 8941 supporting only 10/100 Base-T. The Cisco Unified IP Phone 8900 Series includes the most commonly used call features (hold, transfer, and

conference) on fixed hard buttons and incorporates a wideband audio headset, speaker, and handset. The Cisco Unified IP Phone 8961 also provides support for MIDlet and XML applications. For a list of supported features for the Cisco Unified IP Phone 8961, see the [Endpoint Features Summary, page 18-55](#).

Cisco Executive IP Phones

The Cisco executive IP phone is best suited for the executive high-traffic user with extensive call features. The executive IP phones include the Cisco Unified IP Phone 7970G, 7971G-GE, 7975G, 9951, and 9971.

Cisco Unified IP Phone 7970G

The Cisco Unified IP Phone 7970G can have up to eight directory numbers, has a high-resolution color touch screen, and has more access keys on the phone compared to other Cisco Unified IP Phones. The Cisco Unified IP Phone 7970G supports both SCCP and SIP and is included in the enhanced architecture of Cisco Desktop IP Phones. This architecture provides for feature and UI consistency across the Cisco Desktop IP Phones regardless of call signaling protocol. The end-user experience for a supported feature will behave consistently whether using SCCP or SIP call control signaling.

There are a few features that are not supported with SIP that are supported with SCCP. For example, the Cisco Unified IP Phone 7970G using SCCP is compatible with the Cisco Unified Video Advantage video-enabled endpoint to make video calls, whereas SIP has no video support. The Cisco Unified IP Phone 7970G using SCCP supports Tone on Hold, whereas SIP has no Tone on Hold support. The Cisco Unified IP Phone 7970G using SCCP supports the Cisco Unified IP Phone Expansion Module 7914, whereas SIP has no support for the expansion module. This phone includes a higher-resolution, 4-bit grayscale display for enhancing feature usage and Extensible Markup Language (XML) applications, as well as for enabling support for double-byte languages. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

Cisco Unified IP Phone 7971G-GE

The Cisco Unified IP Phone 7971G-GE can have up to eight directory numbers and is the equivalent of the Cisco Unified IP Phone 7970G with the exception that it includes two 10/100/1000 Base-T Ethernet connections. The addition of gigabit throughput capability allows for high bit-rate and bandwidth-intensive applications on a co-located PC.

Note

In addition to using the inline power from the access switch or local wall power, a Cisco Unified IP Phone can also be supplied power by a Cisco Unified IP Phone power injector. The Cisco Unified IP Phone power injector connects Cisco Unified IP Phones to Cisco switches that do not support online power or to non-Cisco switches. The Cisco Unified IP Phone power injector is compatible with all Cisco Unified IP Phones, and it supports both Cisco PoE and IEEE 802.3af PoE. It has two 10/100/1000 Base-T Ethernet ports. One Ethernet port connects to the switch access port and the other connects to the Cisco Unified IP Phone.

Cisco Unified IP Phone 7975G

The Cisco Unified IP Phone 7975G, like the 7971G-GE, can have up to eight directory numbers and two 10/100/1000 Base-T Ethernet connections. Unlike the 7971G-GE, however, the 7975G adds the G.722 wideband codec and high-fidelity speaker, microphone, and handset. The 7975G also has a touchscreen color display. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

Cisco Unified IP Phone 9951

The Cisco Unified IP Phone 9951 offers advanced capabilities within the Cisco IP phone portfolio. The 9951 supports up to five directory numbers, two 10/100/1000 Base-T Ethernet connections, and a five-way navigation button set. The 9951 also includes five session keys, a USB port, support for a Bluetooth headset, and the most commonly used call features on fixed hard buttons (hold, transfer, and conference) for a rich user experience. The 9951 also incorporates a wideband audio headset, speaker, and handset, and support for MIDlet and XML applications. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

The 9951 includes the capability to receive a video media stream. To make point-to-point video calls, a specially designed optional USB camera may be attached to the 9951. For video related design considerations, see the section on [Video Endpoints, page 18-30](#).

Cisco Unified IP Phone 9971

The Cisco Unified IP Phone 9971 offers advanced capabilities within the Cisco IP phone portfolio. The 9971 supports up to six directory numbers, two 10/100/1000 Base-T Ethernet connections, and a five-way navigation button set. The 9971 also includes six session keys, two USB ports, support for a Bluetooth headset, touch screen, an 802.11a/b/g wireless interface, and the most commonly used call features on fixed hard buttons (hold, transfer, and conference) for a rich user experience. The 9971 also incorporates a wideband audio headset, speaker, and handset, and support for MIDlet and XML applications. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

The 9971 includes the capability to receive a video media stream. To make point-to-point video calls, a specially designed optional USB camera may be attached to the 9971. For video related design considerations, see the section on [Video Endpoints, page 18-30](#).

Cisco Unified IP Phone Expansion Modules 7914, 7915, and 7916

The Cisco Unified IP Phone Expansion Modules 7914, 7915, and 7916 are for administrative assistants and others who need to determine the status of a number of lines beyond the current line capability of the phone.

The Cisco Unified IP Phone Expansion Modules 7914, 7915, and 7916 extend the capability of the Cisco Unified IP Phones 7960G, 7961G, 7961G-GE, 7962G, 7965G, 7970G, 7971G-GE, or 7975G with additional buttons and an LCD. The Cisco Unified IP Phone Expansion Module 7914 provides 14 buttons per module, and the Cisco Unified IP Phone Expansion Modules 7915 and 7916 provide up to 24 buttons per module. Cisco Unified IP Phones 796xG and 797xG can support up to two Cisco Unified IP Phone Expansion Modules. If the IP phone uses Cisco inline power or IEEE802.3af PoE, then the Cisco Unified IP Phone Expansion Modules 7914, 7915, and 7916 require the use of an external power adaptor (CP-PWR-CUBE-3).

**Note**

When two Expansion Modules are used with a single phone, the second module must be the same model as the first one.

Deployment Considerations for Cisco Unified IP Phones 6921, 6941, 6945, and 6961

These IP phones share common characteristics such as: a uniform industrial design; a single call per line; and hard keys for most commonly used user functions such as hold, transfer, and conference.

All these phone models support a single call per line. An incoming call on a line that already has an active call will be given the busy treatment; that is, depending on the configuration, it will be forwarded either to voicemail or to another directory number, or (if forwarding is not configured) the call will not complete and a busy tone will be returned to the caller. To have the second call presented to the phone instead of being forwarded, it is necessary to configure a second line with the same directory number as the primary. Note that this second line must be in a different partition than the primary, and the primary line must be configured to forward calls to the second line. For more information on setting up partitions, refer to the chapter on [Dial Plan, page 9-1](#).

The Cisco Unified IP Phones 6921, 6941, 6945, and 6961 introduce call features such as Direct Transfer and Direct Transfer Across Lines, and also provide the Join and Join Across Lines features. These features can operate over calls spanning multiple lines, and their operation can be opaque to CTI applications that monitor only the primary line on the phone. Therefore, in order for these applications to work properly and maintain control over the phone functions, it might be necessary to disable the call features. These features may be disabled, in decreasing priority order, in either the specific phone configuration, the Common Device Profile configuration applicable to a group of phones that share the profile, or the enterprise-wide phone configuration.

Deployment Considerations for Cisco Unified IP Phones 8900 and 9900 Series

The Cisco Unified IP Phones 8941, 8945, 8961, 9951, and 9971 are a family of IP Phones that share common hardware and software platforms, increased support for accessories, and a unique user experience. The user experience includes dedicated hard keys for common call functions such as hold, transfer, and conference; a set of session buttons separate from the line buttons, which facilitate more intuitive handling of several concurrent calls; and wideband acoustics-capable handset, microphone, and speaker. Depending on the model, this family of phones supports various user accessories and hardware features such as touch-sensitive screen, USB and Bluetooth headsets, SDIO, IEEE 802.11a/b/g wireless interfaces, and more.

These phones run the SIP signaling protocol exclusively and support XSI, Java MIDlet applications.

The Cisco Unified IP Phones 8900 and 9900 Series have advanced capabilities that set them apart from the Cisco Unified IP Phones 3900, 6900, and the 7900 Series. Deploying these phones requires considerations in several areas discussed in the following sections.

Firmware Upgrades

Most commonly, and by default, IP phones upgrade their images using the Trivial File Transfer Protocol (TFTP), which is a UDP-based protocol, from TFTP servers integrated into one or more of the Unified CM subscriber servers. With this arrangement, all the phones obtain their images directly from

these TFTP servers. This method works well for a relatively small number of phones or if all of the phones are located in a single campus region that has a LAN environment with essentially unlimited bandwidth.

For larger deployments that use centralized call processing, upgrading phones in branch offices that are connected to the central data center by low-speed WAN links, can require a large amount of data traffic over the WAN. The same set of files will have to traverse the WAN multiple times, once for each phone. Transferring this amount of data is not only wasteful of the WAN bandwidth but can also take a long time as each data transfer competes with the others for bandwidth. Moreover, due to the nature of TFTP protocol, some phones might be forced to abort their upgrades and fall back to the existing version of the code.

**Note**

During the upgrade, the Cisco Unified IP Phones 9900 and 8900 Series stay in service, unlike the 7900 Series phones. The 9900 and 8900 Series phones download and store the new firmware in their memory while still maintaining their active status, and they reboot with the new firmware only after a successful download.

Two methods are available to alleviate problems created by the need to upgrade phones over the WAN. One method is to use a local TFTP server just for the upgrades. The administrator can place a TFTP server in branch offices (particularly in branches that have a larger number of phones, or whose WAN link is not speedy or robust), and can configure the phones in those offices to use that particular TFTP server just for new firmware. With this change, phones will retrieve new firmware locally. This upgrade method would require the administrator to pre-load the phone firmware on the TFTP server in the branch and manually configure the TFTP server address in the "load server" parameter in the affected phone configurations. Note that the branch router may be used as a TFTP server.

The second method to upgrade phones without using the WAN resources excessively is to use the Peer File Sharing (PFS) feature. In this feature, only one phone of each model in the branch downloads each new firmware file from the central TFTP server. Once the phone downloads the firmware file, it distributes that file to all the other phones in the branch. If there is only one phone type in the branch, then the firmware is transferred across the WAN only once. This method avoids the manual loading and configuration required for the load server method.

The PFS feature works when the phones in the same branch subnet arrange themselves in a hierarchy (chain) when asked to upgrade. They do this by exchanging messages between themselves and selecting the "root" phone that will actually perform the download. The root phone sends the firmware file to the second phone in the chain using a TCP connection, the second phone sends the firmware file to the third phone in the chain, and so on until all of the phones in the chain are upgraded. Note that the root phone may be different for different files that make up the complete phone firmware.

Once an upgrade process completes, the system administrator can check whether or not all of the phones have successfully upgraded by going to the Unified CM Administration page (**Device -> Device Settings -> Firmware Load Information**). All phones that are not at the default image level are flagged here.

Network Connectivity Through a Wireless Interface

The Cisco Unified IP Phone 9971 is equipped with an IEEE 802.11a/b/g wireless interface. This capability provides flexibility in placement of the phone. However, consider the following before deploying these phones with wireless access:

- Users will not be able to connect a PC to the PC port of the phone for network access.
- The network port on the back of the phone should be left unconnected for the wireless interface to function. If the phone detects that a wired connection is available, it will disconnect from the wireless interface and start using the wired connection

- The phone will have to be powered by an external power source.
- There are known issues of interference between 2.4 GHz wireless and Bluetooth. Coexistence of both Bluetooth headsets and 802.11b/g is possible, but call capacity might be reduced. Note also that multicast music on hold is not supported in this coexistence mode. If this coexistence mode is used with 2.4 GHz IEEE 802.11g, then Cisco recommends using the wireless interface at data rates greater than 12 Mbps. To avoid any interference issues when Bluetooth is active, Cisco recommends using 5.0 GHz IEEE 802.11a wireless connectivity.
- The wireless access density needs to be considered.
- Firmware downloads might be slower than in the wired mode.
- The phone does not have to be configured with two different MAC addresses. The MAC address shown in the settings menu should be used for both wireless and wired configurations.
- Cisco Emergency Responder tracks wireless IP phones by IP addresses only, not by the switch port as it does for wired IP phones. Hence, the location information for wireless connected phones is not as precise as for wired phones.

Power Over Ethernet

The Cisco Unified IP Phones 9971 and 9951 support both the older IEEE 802.3af and the newly ratified 802.3at standard of power over ethernet. The new standard allows for up to 30 W of power. These phones by themselves consume less than this value (12.95 W) and therefore can work with the 802.3af power standard. But when they are equipped with Key Extension Modules (5 W each) and other power consuming attachments such as USB devices, they might require more power than even what the IEEE 802.3at standard can offer. In those cases the phones should be powered using a wall outlet. The phones do have power management capabilities that would alert the user if the required power is not available.

Because the IEEE 802.3at standard is fairly new, existing switches that supply power to the phones might have to be upgraded to this new standard.

Applications

The Cisco Unified IP Phones 8900 and 9900 Series introduce call capabilities that generate JTAPI events that must be handled by applications that monitor the phone through CTI. These call features allow the user to cancel an in-progress transfer or conference, or to perform a join or direct transfer of calls across the same or different lines. If the monitoring applications have not been upgraded to versions that properly handle these events, unexpected application behavior could result, including applications that no longer have their view of the phone or call state in sync with the phone itself. Therefore, by default, all applications are restricted from monitoring or controlling these phones.

For applications that have been upgraded to properly handle these new events or for applications that have verified that they are not impacted by these events, the administrator may enable the newly defined role of **Standard CTI Allow Control of Phones supporting Connected Xfer and conf** in the application or end-user configuration associated with the application. Only after this role has been enabled can the application monitor or control these phones.

Support on SRST, Unified CME, and Unified CME as SRST

The Cisco Unified IP Phones 8900 and 9900 Series may fail-over to Survivable Remote Site Telephony (SRST) if WAN connectivity with the Unified CM cluster is lost. However, the set of available features is much smaller in SRST mode than when the phone is registered to Unified CM.

There currently is no support for these phones in Cisco Unified Communications Manager Express (Unified CME) or in Unified CME as SRST.

Support for Video

The Cisco Unified IP Phones 8941, 8945, 9951, and 9971 have video capability and are able to receive and transmit video. The Cisco Unified IP Phone 9900 Series requires the addition of a USB mounted camera, while the Cisco Unified IP Phones 8941 and 8945 have a built-in camera. The video capabilities of these phones can be enabled and disabled or tuned as desired from the Unified CM configuration pages. The Cisco Unified IP Phone 8900 and 9900 Series configuration pages contain the controls for enabling or disabling USB ports, video, and Cisco Camera. While the phone provides control for video mute, full screen, picture-in-picture, brightness, contrast, and so forth, the resolution and the frame rate depend on the inter-region settings for the device pools associated with the two phones. Use the bit-rate values in the following table to achieve the desired resolution and frame rate.

Table 18-5 Resolution and Frame Rate Settings for Cisco Unified IP Phones 8900 and 9900 Series

| Resolution | Frame Rate | Video Bit Rate for Inter-Region Setting |
|------------|------------|---|
| QCIF | 10 fps | 60 to 79.9 kbps |
| QCIF | 15 fps | 80 to 99.9 kbps |
| QCIF | 30 fps | 100 to 249.9 kbps |
| CIF | 15 fps | 250 to 299.9 kbps |
| CIF | 30 fps | 300 to 499.9 kbps |
| VGA | 15 fps | 500 to 799.9 kbps |
| VGA | 24 fps | 800 to 999.9 kbps |

By default, the video bit-rate setting is for Common Intermediate Format (CIF) at 30 fps (384 kbps). For video calls in higher resolution, adjust the inter-region bandwidth accordingly.

Similarly, any locations-based call admission control in effect should reflect the possibly higher bandwidth needs for video calls. Note also that a video call made to a Cisco Unified IP Phones 8900 or 9900 Series not equipped with a camera, resulting in one-way video transmission only, will still count as a two-way video call for call admission control purposes.

General QoS Deployment Considerations for Cisco Unified IP Phones

Cisco Unified IP Phones mark Layer 3 DSCP and Layer 2 CoS as dictated by Unified CM configuration or by signaling in the case of SCCP. These markings should conform to the following Cisco recommended QoS voice, video, and signaling marking value.

- For voice media the appropriate QoS values are: DSCP 0x46, PHB EF, CoS 5.
- For video media the appropriate QoS values are: DSCP 0x34, PHB AF41, CoS 4.
- For voice and video signaling (SIP or SCCP) the appropriate QoS values are: DSCP 0x24, PHB CS3, CoS 3.

**Note**

While many Cisco Unified IP Phones may support Link Layer Discovery Protocol for Media Endpoint Devices (LLDP-MED), they do so only for VLAN and Power over Ethernet negotiation. Cisco Unified IP Phones do not honor DSCP and CoS markings provided by LLDP-MED.

Additional Information on Cisco Unified IP Phones

Software-Based Endpoints

Software-based endpoints include Cisco Unified Personal Communicator and Cisco IP Communicator. A software-based endpoint is an application installed on a client PC, and it registers with (and is controlled by) Unified CM.

Cisco Unified Personal Communicator

Cisco Unified Personal Communicator is a software application based on Microsoft Windows or Macintosh. Cisco Unified Personal Communicator integrates a wide variety of communications applications and services into a single desktop application to help people communicate effectively. It allows users to access a variety of powerful communications tools, including voice, video, call management, presence, and web conferencing. The integrated applications include Cisco Unified Communications Manager (Unified CM), Cisco Unified Presence, Cisco Unity, Cisco Unity Connection, Cisco Unified MeetingPlace, Cisco Unified MeetingPlace Express, Cisco Unified Videoconferencing and MeetingPlace Express VT, and the Lightweight Directory Access Protocol (LDAP) version 3 (v3) server. For more information on Cisco Unified Personal Communicator, see the chapter on [Cisco Unified Presence](#), page 23-1.

Regardless of the device limits allowed per server, there are maximum limits on the number CTI devices you can configure in Unified CM. The CTI device limits as they apply to Cisco Unified Personal Communicator are as follows:

- Maximum of 800 Cisco Unified Personal Communicators per Cisco Media Convergence Server (MCS) 7825 or 7835; maximum of 3,200 Cisco Unified Personal Communicators per cluster of MCS 7825 or 7835 servers.
- Maximum of 2,500 Cisco Unified Personal Communicators per Cisco Media Convergence Server (MCS) 7845; maximum of 10,000 Cisco Unified Personal Communicators per cluster of MCS 7845 servers.

The following assumptions apply to the preceding maximum Cisco Unified Personal Communicator limits:

- Each Cisco Unified Personal Communicator is processing an estimated six or fewer busy hour call attempts (BHCA).
- No other CTI applications requiring CTI devices are configured in the Unified CM cluster.

Cisco IP Communicator

Cisco IP Communicator is a Microsoft Windows-based application that endows computers with the functionality of IP phones. This application enables high-quality voice calls on the road, in the office, or from wherever users can access the corporate network. It is an ideal solution for remote users and telecommuters. Cisco IP Communicator is easy to deploy and features some of the latest technology and advancements available with IP communications today.

Because Cisco IP Communicator is a standalone device that supports both SCCP and SIP, the design guidelines for IP phones in the various IP Telephony deployment models still hold true for the Cisco IP Communicator. Refer to the chapter on [Unified Communications Deployment Models](#), page 5-1, for details.

The end-user experience for a supported feature is the same whether using SCCP or SIP call control signaling. There are a few features that are not supported with SIP that are supported with SCCP. For example, Cisco IP Communicator using SCCP is compatible with the Cisco Unified Video Advantage

video-enabled endpoint for making video calls, whereas SIP has no video support. In addition, Cisco IP Communicator using SCCP supports Tone on Hold, whereas SIP has no Tone on Hold support. For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

Cisco IP Communicator 2.1 supports image and signaling authentication. Cisco IP Communicator 2.1 also supports Transport Layer Security (TLS) mutual authentication using certificates, which prevents Cisco IP Communicator from impersonating another Cisco Unified IP Phone. The security is implemented with two-way authentication with the Certificate Authority Proxy Function (CAPF) and a Locally Significant Certificate (LSC). Cisco IP Communicator 2.1 also supports Certificate Trust List (CTL) for device authentication.

Cisco Unified Client Services Framework

Cisco Unified Client Services Framework (CSF) is a software application based on Microsoft Windows that provides an underlying framework for integration of Unified Communications services including audio, video, web collaboration, visual voicemail, and so forth, into a presence and instant messaging application. The Cisco Unified Client Services Framework allows users to access a variety of communications services that interface into Cisco Unified Communications Manager (Unified CM), Cisco Unity, Cisco Unity Connection, Cisco Unified MeetingPlace, and a Lightweight Directory Access Protocol (LDAP) version 3 (v3) server. For more information on Cisco Unified Communications integrations that use the Cisco Unified Client Services Framework, see the chapter on [Cisco Unified Presence, page 23-1](#).

The Cisco Unified Client Services Framework is a new device in Cisco Unified CM, and it operates in either softphone mode or deskphone mode to control a Cisco Unified IP Phone.

Softphone Mode of Operation

When the Cisco Unified Client Services Framework operates in softphone mode, a new device must be configured in Cisco Unified CM. The Cisco Unified Client Services Framework will then operate as a SIP-based single line Cisco Unified IP Phone and will support the full registration and redundancy mechanisms of a Cisco Unified IP Phone.

Deskphone Control Mode of Operation

When the Cisco Unified Client Services Framework operates in deskphone control mode, the application will use CTI/JTAPI to control an associated Cisco Unified IP Phone. The Unified Client Services Framework uses the Cisco CallManager Cisco IP Phone Services (CCMCIP) service from Unified CM to provide a listing of valid Cisco Unified IP Phones to control.

The following design considerations should be taken into account when deploying the Cisco Unified Client Services Framework:

- The administrator must determine how to install, deploy, and configure the Unified Client Services Framework in their organization. Cisco recommends using a well known installation package such as Altris to install the application, and use Group Policies to configure the user registry settings for the required components of TFTP Server, CTI Manager, CCMCIP Server, Voicemail Pilot, LDAP Server, LDAP Domain Name, and LDAP search contexts.
- The userid and password configuration of the Cisco Unified Client Services Framework user must match the userid and password of the user stored in the LDAP server to allow for seamless integration of the Unified Communications and backend directory components.

- The directory number configuration on Cisco Unified CM and the telephoneNumber attribute in LDAP should be configured with a full E.164 number. A private enterprise dial plan can be used, but it might involve the need to use application dial rules and directory lookup rules.
- The use of deskphone mode for control of a Cisco Unified IP Phone uses CTI; therefore, when sizing a Unified CM deployment, you must also account for other applications that require CTI usage.

Video Design Considerations

High definition video calls of up to 720p (1280x720) resolution are supported by the Cisco Unified Client Services Framework (CSF). Ensure that the inter-region video bit rate has been set appropriately to allow for high definition video. In addition, ensure that bandwidth settings for locations-based call admission control are also revised, if necessary, for the higher usage.

When used for video in deskphone control mode, the Cisco Unified Client Services Framework uses the CAST protocol to establish the association with the deskphone. SIP-based phones currently do not support CAST protocol and thus cannot be used in this manner.

The Cisco Unified Client Services Framework processes video on the computer on which it is running. The quality of the decoding and encoding depends on the availability of CPU and memory resources on the computer.

Additional Information on Software-Based Endpoints

For more information, including details regarding the latest hardware and software version support for software-based endpoints, refer to the appropriate data sheets and documentation for:

- Cisco Unified Personal Communicator:
<http://www.cisco.com/en/US/products/ps6844/index.html>
- Cisco IP Communicator:
<http://www.cisco.com/en/US/products/sw/voicesw/ps5475/index.html>
- Cisco Jabber for Windows (based on Cisco Unified Client Services Framework):
<http://www.cisco.com/en/US/products/ps12511/index.html>
- Cisco Jabber for Mac (based on Cisco Unified Client Services Framework):
<http://www.cisco.com/en/US/products/ps11764/index.html>

Wireless Endpoints

Cisco wireless endpoints use a wireless LAN (WLAN) infrastructure via wireless access points (APs) to provide telephony functionality and features. This type of endpoint is ideal for environments with the need for mobile users within an area where traditional wired phones are undesirable or problematic. (Refer to [Wireless LAN Infrastructure, page 3-57](#), for more information about wireless network design.)

Cisco offers the following Voice over WLAN (VoWLAN) IP phones:

- Cisco Unified Wireless IP Phone 7921G
- Cisco Unified Wireless IP Phone 7925G and 7925G-EX
- Cisco Unified Wireless IP Phone 7926G
- Cisco Unified IP Phone 9971

All are hardware-based phones with built-in radio antenna. The Cisco Unified Wireless IP Phones 7921G, 7925G, 7925G-EX, and 7926G as well as the wirelessly attached Cisco Unified IP Phone 9971 enable 802.11b, 802.11g, or 802.11a connectivity to the network. The Cisco Unified Wireless IP Phones register with Unified CM using Skinny Client Control Protocol (SCCP), while the Cisco Unified IP Phone 9971 registers using Session Initiation Protocol (SIP). For more information about these phones, refer to the appropriate phone documentation available at

<http://www.cisco.com>

Site Survey

Before deploying the Cisco Unified Wireless IP Phones, you must perform a complete site survey to determine the appropriate number and location of APs required to provide radio frequency (RF) coverage. Your site survey should take into consideration which types of antennas will provide the best coverage, as well as where sources of RF interference might exist. A site survey requires the use of the Site Survey tool on the Cisco Unified Wireless IP Phones (accessed by selecting **Settings > Status > Site Survey** on the 7921G, 7925G, 7925G-EX, and 7926G, or by selecting and **Applications Button > Administrator Settings > Network Setup > WLAN Setup** on the 9971). Additional third-party tools can also be used for site surveys; however, Cisco highly recommends that you conduct a final site survey using the Cisco Unified Wireless IP Phones 7921G, 7925G, 7925G-EX, and 7926G, and the Cisco Unified IP Phone 9971, because each endpoint or client radio can behave differently depending on antenna sensitivity and survey application limitations.

Authentication

To connect to the wireless network, wireless Cisco Unified IP Phones must first use one of the following authentication methods to associate and communicate with the AP:

- **Extensible Authentication Protocol-Flexible Authentication via Secure Tunneling (EAP-FAST)**

This method allows the wirelessly attached Cisco Unified IP Phone to be authenticated to the AP via 802.1X with a user name and password once a secure authenticated tunnel is established between the client and an EAP-compliant Remote Authentication, Authorization, and Accounting server via Protected Access Credential (PAC). Upon authentication, traffic to and from the wireless device is encrypted using TKIP or WEP. Using the 802.1X authentication method and the PAC authenticated tunnel exchange requires an EAP-compliant Remote Authentication Dial-In User Service (RADIUS) authentication server such as the Cisco Secure Access Control Server (ACS), which provides access to a user database.
- **Extensible Authentication Protocol-Transport Layer Security (EAP-TLS)**

This method allows the wirelessly attached Cisco Unified IP Phone to be authenticated to the AP via 802.1X with a user name and password once a secure authenticated tunnel is established between the client and the authentication server using the TLS protocol with a public key infrastructure (PKI). Upon authentication, traffic to and from the wireless device is encrypted using TKIP or WEP. TLS provides the ability to use certificates for both user and server authentication and for dynamic session key generation. The certificate used for authentication can be either the Manufacturing Installed Certificate (MIC) or a user installed certificate. EAP-TLS is not supported on the Cisco Unified IP Phone 9971.
- **Protected Extensible Authentication Protocol (PEAP)**

This method allows the wirelessly attached Cisco Unified IP Phone to be authenticated to the AP via 802.1X with a user name and password over an encrypted SSL/TLS tunnel between the client and the authentication server. The encrypted SSL/TLS tunnel is created using server-side public key

certificates, ensuring that exchange of authentication information is encrypted using Version 2 of Microsoft's Challenge Handshake Authentication Protocol (MS-CHAP) and that user credentials are safe from eavesdropping. Upon authentication, traffic to and from the wireless device is encrypted using TKIP or WEP. PEAP is not supported on the Cisco Unified IP Phone 9971.

- **Wi-Fi Protected Access (WPA)**

This method allows the wirelessly attached Cisco Unified IP Phone to be authenticated to the AP via 802.1X with a user name and password. Upon authentication, traffic to and from the wireless device is encrypted using Temporal Key Integrity Protocol (TKIP). Using the 802.1X authentication method requires an EAP-compliant Remote Authentication Dial-In User Service (RADIUS) authentication server such as the Cisco Secure Access Control Server (ACS), which provides access to a user database.

- **Wi-Fi Protected Access 2 (WPA2)**

This method is the 802.11i enhanced version of WPA, which uses Advanced Encryption Standards (AES) rather than TKIP for encrypting traffic to and from the wireless device.

- **Wi-Fi Protected Access Pre-Shared Key (WPA-PSK)**

This method allows the wirelessly attached Cisco Unified IP Phone to be authenticated to the AP via the configuration of a shared key on the Cisco Unified Wireless IP Phone and the AP. Upon authentication, traffic to and from the wireless device is encrypted using TKIP. This method of authentication is not recommended for enterprise deployments.

- **Wi-Fi Protected Access 2 Pre-Shared Key (WPA2-PSK)**

This method is the 802.11i enhanced version of WPA-PSK, which uses AES rather than TKIP for encrypting traffic to and from the wireless device.

- **Cisco Centralized Key Management (Cisco CKM)**

This method allows the wirelessly attached Cisco Unified IP Phone to be authenticated to the AP via 802.1x with a user name and password. Upon authentication, traffic to and from the wireless device is encrypted using either WEP 128 or TKIP. The 802.1X authentication method requires an EAP-compliant RADIUS authentication server such as the Cisco ACS, which provides access to a user database for the initial authentication request. Subsequent authentication requests are validated via the wireless domain service (WDS) at the AP, which shortens re-authentication times and ensures fast, secure roaming.

- **Cisco LEAP**

This method allows the wirelessly attached Cisco Unified IP Phone and AP to be authenticated mutually based on a user name and password. Upon authentication, the dynamic key is generated and used for encrypting traffic between the Cisco Unified Wireless IP Phone and the AP. A LEAP-compliant Radius authentication server, such as the Cisco Secure Access Control Server (ACS), is required to provide access to the user database.

- **Shared Key**

This method involves the configuration of static 10 (40-bit) or 26 (128-bit) character keys on the wirelessly attached Cisco Unified IP Phone and the AP. This method is AP-based authentication in which access to the network is gained if the device has a matching key.

- **Open Authentication**

This method requires no exchange of identifying information between the wireless IP phone and the AP. Cisco does *not* recommend this method because it provides no secure exchange of voice or signaling, and it allows any rogue device to associate to the AP.

Capacity

The capacity of each AP depends on a number of factors including the AP radio types, associated client radio types, enabled data rates, and channel utilization.

Given an 802.11b-only AP with 802.11b clients and a data rate of 11 Mbps, the AP can support a maximum of seven active G.711 voice streams or eight G.729 streams. If these numbers are exceeded, poor quality can result due to dropped or delayed voice packets or dropped calls. AP rates set lower than 11 Mbps will result in lower call capacity per AP.

When using 802.11a at a data rate of 54 Mbps, the maximum number of active voice streams increases to between 14 and 18 per AP.

For 802.11g environments with a data rate of 54 Mbps, in theory the maximum number of active voice streams also increases to between 14 and 18 per AP. However, because most 802.11g environments are mixed and include 802.11b clients (and therefore 11 Mbps data rates) as well as 802.11g clients, capacity is typically significantly lower with a maximum of 8 to 12 active voice streams per AP.

Regardless of 802.11 radio type, call capacity can be diminished significantly if there is heavy channel utilization due to data traffic.

For additional information about call capacity, radio types, and data rates, refer to the VoWLAN design recommendations in the latest version of the *Voice over Wireless LAN Design Guide*, available at

<http://www.cisco.com/go/designzone>

Note

A call between two phones associated to the same AP counts as two active voice streams.

Based on these active call capacity limits, and using Erlang ratios, you can calculate the number of Cisco Unified Wireless IP Phones that each AP can support. For example, given an 802.11b AP with 802.11b clients and a typical user-to-call capacity ratio of 3:1, a single AP can support 21 to 24 Cisco Unified Wireless IP Phones, depending on whether the codec used is G.711 or G.729. As another example, given an 802.11a AP with an 802.11a client at a data rate of 54 Mbps and user-to-call capacity ratio of 3:1, a single AP can support 42 to 54 Cisco Unified Wireless IP Phone 7921Gs. However, these numbers do not take into consideration the possibility that other Cisco Unified Wireless IP Phones could roam to the AP, so a lower number of phones per AP might be more realistic.

These capacities are based on voice activity detection (VAD) being disabled and a packetization sample size of 20 milliseconds (ms). VAD is a mechanism for conserving bandwidth by not sending RTP packets while no speech is occurring during the call. However, enabling or disabling VAD is a global cluster-wide configuration parameter on Unified CM. (It is referred to as Silence Suppression in Unified CM.) Thus, if VAD is enabled for wirelessly attached Cisco Unified IP Phones, then it will be enabled for all devices in the Unified CM cluster. Cisco recommends leaving VAD (Silence Suppression) *disabled* to provide better overall voice quality.

At a sampling rate of 20 ms, a voice call will generate 50 packets per second (pps) in either direction. Cisco recommends setting the sample rate to 20 ms for almost all cases. By using a larger sample size (for example, 30 or 40 ms), you can increase the number of simultaneous calls per AP, but a larger end-to-end delay will result. In addition, the percentage of acceptable voice packet loss within a wireless environment decreases dramatically with a larger sample size because more of the conversation is missing when a packet is lost. For more information about voice sampling size, see [Bandwidth Provisioning, page 3-47](#).

Phone Configuration

For information on configuring the Cisco Unified Wireless IP Phones, refer to the administration guides for the Cisco Unified Wireless IP Phones 7921G, 7925G, 7925G-EX, and 7926G, all available at

http://www.cisco.com/en/US/products/hw/phones/ps379/prod_maintenance_guides_list.html

For information on configuring and deploying the Cisco Unified IP Phone 9971 on a Cisco Unified Wireless Network, refer to the *Cisco Unified IP Phone 9971 Wireless LAN Deployment Guide*, available at

http://www.cisco.com/en/US/products/ps10453/tsd_products_support_series_home.html

Roaming

Cisco Unified Wireless IP Phones are able to roam at Layer 2 (within the same VLAN or subnet) and still maintain an active call. Layer 2 roaming occurs in the following situations:

- During the initial boot-up of the wirelessly attached Cisco Unified IP Phones, the phone roams to a new AP for the first time.
- If the wirelessly attached Cisco Unified IP Phone receives no beacons or responses from the AP to which it is currently associated, the phone assumes that the current AP is unavailable and it attempts to roam and associate with a new AP.
- The Cisco Unified Wireless IP Phone and wirelessly attached Cisco Unified IP Phone 9971 maintain a list of eligible AP roam targets. If conditions change on the current AP, the phone consults the list of available AP roam targets. If one of the roam targets is determined to be a better choice, then the phone attempts to roam to the new AP.
- If the configured SSID or authentication type on the wirelessly attached Cisco Unified IP Phone is changed, the phone must roam to re-associate with an AP.

In trying to determine eligible AP roam targets for roaming, the wireless IP phone uses the following variables to determine the best AP to associate with:

- **Relative Signal Strength Indicator (RSSI)**
Used by the wirelessly attached IP phone to determine the signal strength and quality of available APs within an RF coverage area. The phone will attempt to associate with the AP that has the highest RSSI value and matching authentication/encryption type.
- **QoS Basic Service Set (QBSS)**
Enables the AP to communicate channel utilization information to the wireless phone. The phone will use the QBSS value to determine if it should attempt to roam to another AP, because APs with high channel utilization might not be able to handle VoIP traffic effectively.
- **Wi-Fi Multimedia Traffic Specification (WMM TSPEC)**
WMM TSPEC is an 802.11e QoS mechanism that assists wireless IP phone roaming by enabling the phone to request bandwidth and priority treatment via a TSPEC indication while roaming to determine if the new AP can handle the phones bandwidth needs based on current utilization.

When devices roam at Layer 3, they move from one AP to another AP across native VLAN boundaries. When the WLAN network infrastructure consists of autonomous APs, the Cisco Catalyst 6500 Series Wireless Services Module (WiSM) allows wirelessly attached Cisco Unified Wireless IP Phones to keep

their IP addresses and roam at Layer 3 while still maintaining an active call. Seamless Layer 3 roaming occurs only when the client is roaming within the same mobility group. For details about the Cisco WiSM and Layer 3 roaming, refer to the Cisco WiSM product documentation available at

<http://www.cisco.com>

Seamless Layer 3 roaming for clients across a lightweight access point infrastructure is accomplished by WLAN controllers that use dynamic interface tunneling. Cisco Unified Wireless IP Phones that roam across WLAN controllers and VLANS can keep their IP address when using the same SSID and therefore can maintain an active call.

With stronger authentication methods such as WPA and EAP, the number of information exchanges increases and causes more delay during roaming. To avoid additional delays, use Cisco Centralized Key Management (Cisco CKM) to manage authentication. With Cisco CKM, whether at Layer 2 or Layer 3, roaming can occur without any perceptible delay. Cisco CKM also takes some of the load off the Access Control Server (ACS) by reducing the number of authentication requests that must be sent to the ACS.

Note

In dual-band WLANs (those with both 2.4 GHz and 5 GHz bands), it is possible to roam between 802.11b/g and 802.11a with the same SSID, provided the client is capable of supporting both bands. However, this can cause gaps in the voice path. In order to avoid these gaps, use only one band for voice communications.

AP Call Admission Control

Call admission control mechanisms in Unified CM or in a gatekeeper can control WAN bandwidth utilization and provide QoS for existing calls, but both mechanisms are applied at the beginning of a call. For calls between static devices, this type of call admission control is sufficient. However, for a call between two mobile wireless devices, there must also be a call admission control mechanism at the AP level because these wireless devices may roam from one AP to another.

Cisco APs and wireless voice clients have two mechanisms that are used for call admission control:

- QoS Basic Service Set (QBSS)

QBSS is the beacon information element that enables the AP to communicate channel utilization information to the wireless IP phone. As previously mentioned, this QBSS value helps the phone determine whether it should roam to another AP. A lower QBSS value indicates that the AP is a good candidate to roam to, while a higher QBSS value indicates that the phone should not roam to this AP.

While this QBSS information is useful, it is not a true call admission control mechanism because it does not guarantee that calls will retain proper QoS or that there is enough bandwidth to handle the call. When a wirelessly attached Cisco Unified IP Phone is associated to an AP with a high QBSS, the AP will prevent a call from being initiated or received by rejecting the call setup and sending a Network Busy message to the initiating phone. However, once a call is set up between a wireless IP phone and another endpoint, the phone may roam and associate with an AP with a high QBSS, thus resulting in oversubscription of the available bandwidth on that AP.

- Wi-Fi Multimedia Traffic Specification (WMM TSPEC)

WMM TSPEC is the QoS mechanism that enables WLAN clients to provide an indication of their bandwidth and QoS requirements so that APs can react to those requirements. When a client is preparing to make a call, it sends an Add Traffic Stream (ADDTTS) message to the AP with which it is associated, indicating TSPEC. The AP can then accept or reject the ADDTTS request based on whether bandwidth and priority treatment are available. If the call is rejected, the phone will receive a Network Busy message. When roaming, mid-call clients supporting TSPEC will send a ADDTTS

message to the new AP as part of the association process to ensure that there is available bandwidth for priority treatment. If there is not enough bandwidth, the roam can be load-balanced to a neighboring AP if one is available.

Bluetooth Support

The Cisco Unified Wireless IP Phones 7925G, 7925G-EX, and 7926G, and the Cisco Unified IP Phone 9971 are Bluetooth-enabled devices. The Bluetooth radio or module within these wireless Cisco Unified IP Phones provides the ability to support Bluetooth headsets with the phones. Because Bluetooth devices use the same 2.4 GHz radio band as 802.11 b and g devices, it is possible that Bluetooth and 802.11 b or g devices can interfere with each other, thus resulting in connectivity issues.

While the Bluetooth and 802.11 WLAN modules co-exist in the Cisco Unified Wireless IP Phones 7925G, 7925G-EX, and 7926G, and Cisco Unified IP Phone 9971, greatly reducing and avoiding radio interference between the Bluetooth and 802.11b/g radio, the Bluetooth radio in these wirelessly attached phones can cause interference for other 802.11 b or g devices deployed in close proximity. Due to the potential for interference and disruption of 802.11 b and g WLAN voice devices (which can result in poor voice quality, deregistration, and/or call setup delays), Cisco recommends deploying all WLAN voice devices on 802.11a, which uses the 5 GHz radio band. By deploying wireless phones on the 802.11a radio band, you can avoid interference caused by Bluetooth devices.

Note

Using Bluetooth wireless headsets with the Cisco Unified Wireless IP Phones 7925G, 7925G-EX, and 7926G will increase battery power consumption on your phone and will result in reduced battery life.

Additional Information on Wireless Endpoints

For more information, including details regarding the latest hardware and software version support for wireless endpoints, refer to the appropriate data sheets and documentation for:

- Cisco Unified Wireless IP Phones:
<http://www.cisco.com/en/US/products/hw/phones/ps379/index.html>
- Cisco Unified IP Phone 9971:
<http://www.cisco.com/en/US/products/ps10453/index.html>

Cisco Unified IP Conference Station

The Cisco Unified IP Conference Station combines conference room speaker-phone technology with Cisco Unified Communications technology. The Cisco Unified IP Conference Station is best suited for use in conferencing environments providing 360-degree room coverage.

Cisco offers the following IP conference phones:

- Cisco Unified IP Conference Station 7936
- Cisco Unified IP Conference Station 7937G

Both of these IP conference phones use SCCP as the call signaling protocol.

The Cisco Unified IP Conference Station 7936 has an external speaker and three built-in microphones. The Cisco Unified IP Conference Station 7936 also features a pixel-based LCD display with backlighting, and optional extension microphones can be connected to it for extended microphone coverage in larger rooms.

The Cisco Unified IP Conference Station 7937G adds wideband acoustics, expanded room coverage, a larger backlit LCD, and an extra softkey. The Cisco Unified IP Conference Station 7937G also supports IEEE 802.3af Power over Ethernet, or it can also use an external power adaptor (Cisco part number CP-PWR-CUBE-3).

For more information, including details regarding the latest hardware models and feature sets, refer to the appropriate Cisco Unified IP Conference Station data sheets and documentation at

<http://www.cisco.com/en/US/partner/products/ps8759/index.html>

Video Endpoints

Cisco Unified CM supports the following types of video-enabled endpoints:

- Cisco Unified Video Advantage associated with a Cisco Unified IP Phone 7911, 7940, 7941, 7942, 7945, 7960, 7961, 7962, 7965, 7970, 7971, or 7975, or with Cisco IP Communicator, running Skinny Client Control Protocol (SCCP)
- Cisco Unified IP Phones 9971 and 9951 with the optional USB camera attachment. Without the camera, these phones can only receive video.
- Cisco Unified IP Phones 8941 and 8945 with built-in camera
- Cisco IP Video Phone 7985
- Cisco E20 Video Phone
- Tandberg 2000 MXP, 1500 MXP, 1000 MXP, 770 MXP, 550 MXP, T-1000, and T-550 models running SCCP
- Sony PCS-1, PCS-TL30, and PCS-TL50 models running SCCP
- H.323 and SIP clients (Polycom, Sony, PictureTel, EyeBeam, Tandberg, VCON, VTEL, Microsoft NetMeeting, and others)
- Cisco Unified Personal Communicator (running in softphone mode)
- Cisco Unified Client Services Framework (CSF) clients
- Cisco Unified Personal Communicator and Cisco Unified Client Services Framework (CSF) clients (running in deskphone mode) associated with a Cisco Unified IP Phone 7941, 7942, 7945, 7961, 7962, 7965, 7971, or 7975 running Skinny Client Control Protocol (SCCP)

Cisco Unified Video Advantage

Cisco Unified Video Advantage is a Windows-based application and USB camera that you can install on a personal computer running Windows 2000, Windows XP, or Windows Vista. When the PC is physically connected to the PC port on a Cisco Unified IP Phone 7911, 7940, 7941, 7942, 7945, 7960, 7961, 7962, 7965, 7970, 7971, or 7975 running the Skinny Client Control Protocol, the Cisco Unified Video Advantage application "associates" with the phone, thus enabling users to operate their phones as they always have but now with the added benefit of video. In Cisco Unified Video Advantage Release 2.0, this association can also be to Cisco IP Communicator running SCCP on the same PC.

The system administrator can control which IP Phones allow this association to take place by toggling the **Video Capabilities: Enabled/Disabled** setting on the IP Phone configuration page in Unified CM Administration. When this feature is enabled, an icon representing a camera appears in the bottom right-hand corner of the IP Phone display. By default, Cisco Unified Video Advantage is disabled. You can also use the Bulk Administration Tool to modify this setting on many phones at once. Note that the **PC Port: Enabled/Disabled** setting must also be enabled for Cisco Unified Video Advantage to work with a hardware IP Phone; however, the **PC Access to Voice VLAN** setting does not have to be enabled.

To achieve the association with a hardware IP Phone, Cisco Unified Video Advantage installs a Cisco Discovery Protocol (CDP) driver onto the Ethernet interface of the PC. CDP enables the PC and the hardware IP Phone to discover each other automatically, which means that the user does not have to configure anything on the PC or the hardware IP Phone in order for Cisco Unified Video Advantage to work. The user can, therefore, plug the PC into any hardware IP Phone that is video-enabled and automatically associate with it. (See [Figure 18-1](#).)

Cisco Unified Video Advantage 2.0 does not rely on CDP to discover the presence of Cisco IP Communicator running SCCP on the same PC. Instead, it listens for a private Windows message sent from the Cisco IP Communicator process. If Cisco IP Communicator is discovered, the association process works exactly as it does for a hardware IP phone. (See [Figure 18-2](#).)

**Note**

When you install Cisco Unified Video Advantage, the CDP packet drivers install on all Ethernet interfaces of the PC. If you add a new network interface card (NIC) or replace an old NIC with a new one, you must reinstall Cisco Unified Video Advantage so that the CDP drivers also install on the new NIC.

Figure 18-1 Cisco Unified Video Advantage Operational Overview

[Figure 18-1](#) illustrates the following events:

1. The IP Phone and PC exchange Cisco Discovery Protocol (CDP) messages. The phone begins listening for PC association packets on TCP port 4224 from the IP address of its CDP neighbor.
2. The PC initiates association messages to the phone over TCP/IP. Association packets are routed up to the Layer-3 boundary between VLANs. Firewalls and/or access control lists (ACLs) must permit TCP port 4224.

- The phone acts as an SCCP proxy between Cisco Unified Video Advantage and Unified CM. Unified CM tells the phone to open video channels for the call, and the phone proxies those messages to the PC.
- The phone sends/receives audio, and the PC sends/receives video. Both audio and video traffic are marked DSCP AF41. Video traffic uses UDP port 5445.

Figure 18-2 Cisco IP Communicator Associating with Cisco Unified Video Advantage

Figure 18-2 illustrates the following events:

- Cisco IP Communicator sends a private Windows message to Cisco Unified Video Advantage. The message includes the IP address of Cisco IP Communicator and the port number for CAST messages.
- Cisco Unified Video Advantage initiates CAST messages to Cisco IP Communicator over TCP/IP. CAST messages do not leave the PC because it is a connected address.
- Cisco IP Communicator acts as an SCCP proxy between Cisco Unified Video Advantage and Unified CM. Unified CM tells IP Communicator to open video channels for the call, and IP Communicator proxies those messages to Cisco Unified Video Advantage via CAST protocol.
- Cisco IP Communicator sends/receives audio, and Cisco Unified Video Advantage sends/receives video. Both audio and video traffic are marked DSCP AF41. Video traffic uses UDP port 5445.

When a call is made using Cisco Unified Video Advantage, the audio is handled by the IP Phone while the video is handled by the PC. There is no synchronization mechanism between the two devices, so QoS is essential to minimize jitter, latency, fragmented packets, and out-of-order packets.

When using a hardware IP Phone, the phone resides in the voice VLAN while the PC resides in the data VLAN, which means that there must be a Layer-3 routing path between the voice and data VLANs in order for the association to occur. If there are access control lists (ACLs) or firewalls between these VLANs, they must be configured to permit the association protocol (which uses TCP port 4224 in both directions) to pass. When using Cisco IP Communicator, this communication happens internal to the PC, and there are no Layer-3 boundaries to cross.

Cisco Unified Video Advantage supports Differentiated Services Code Point (DSCP) traffic classifications. Unified CM specifies the DSCP value in the SCCP messages it sends to the phone. When the IP Phone makes an audio-only call, it marks its SCCP control traffic as DSCP CS3 and its audio RTP media traffic as DSCP EF. However, when the IP Phone makes a video call, it marks its SCCP control

traffic as DSCP CS3 and its audio RTP media traffic as DSCP AF41, and the Cisco Unified Video Advantage application marks its video RTP media traffic as DSCP AF41 as well. Both the IP Phone and the Cisco Unified Video Advantage application mark their "association" protocol messages as DSCP CS3 because it is considered to be signaling traffic and is grouped with all other signaling traffic such as SCCP.

**Note**

The Cisco Unified IP Phone 7970 and 7971 are able to use Transport Layer Security (TLS) and Secure RTP (SRTP) to authenticate and encrypt signaling and audio media traffic. The association protocol does not use this authentication or encryption, nor are the video RTP media streams encrypted. However, the SCCP signaling and the audio RTP media streams are encrypted if they are so configured.

**Note**

Do not set the voice VLAN equal to the data VLAN because doing so can cause issues with connectivity.

Cisco Unified Video Advantage, like any other application that runs on a PC, does have an impact on system performance, which you should take into consideration. Cisco Unified Video Advantage 1.0 supports two types of video codecs: H.263 and the Cisco VT Camera Wideband Video Codec. Cisco Unified Video Advantage 2.0 also supports two types of codecs: H.263 and H.264. The Cisco VT Camera Wideband Video Codec places the least demand on the PC but the most demand on the network. H.263 places a lower demand on the network but a higher demand on the PC. Finally, H.264 places the least demand on the network but the highest demand on the PC. Therefore, if your network has plenty of available bandwidth, you can use the Cisco VT Camera Wideband Video Codec and save on PC CPU and memory resources.

The H.263 and H.264 codec supports a range of speeds up to 1.5 Mbps. In summary, customers must balance PC performance with network utilization when deploying Cisco Unified Video Advantage.

System Requirements

For detailed PC requirements, refer to the *Cisco Unified Video Advantage Data Sheet*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps5662/products_data_sheet0900aecd8044de04.html

Cisco IP Video Phone 7985G

The Cisco IP Video Phone 7985G is a personal desktop video phone. Unlike Cisco Unified Video Advantage, which is an application that runs on a PC, the Cisco IP Video Phone 7985G is a standalone phone with integrated video features. The phone has an 8.4 inch color LCD screen and an embedded video camera for making video calls. The phone supports up to eight line appearances, has two 10/100 Base-T Ethernet connections, and has buttons for Directories, Messages, Settings, and Services. Like other Cisco Unified IP Phones, the Cisco IP Video Phone 7985G uses CDP to learn VLAN and CoS information from the attached switch to use in 802.1p/q markings.

Cisco Unified IP Phones 8900 and 9900 Series

The Cisco Unified IP Phones 8900 and 9900 Series are capable of receiving and displaying video natively on their screens. With the built-in camera (8941 and 8945) or optional, specially designed USB camera attachment (9900 Series), they can also transmit video. The screens on these phones can display

a variety of video resolutions and frame rates, from QCIF (176x144) at 10 fps to VGA (640x480) at 24 fps. While the base phone decodes and displays the incoming video stream, the camera encodes video for transmission to the remote end.

Due to the increased power requirements of the camera attachment, these phones need to be powered through either an 802.3AF PoE interface or an AC adaptor.

Cisco E20 Video Phone

The Cisco E20 Video Phone is a personal standalone desktop phone with integrated video features. The phone has an 10.6 inch LCD screen and an embedded video camera for making video calls. The phone supports a single line appearance and has two 10/100/1000 Base-T Ethernet connections. The device incorporates a wideband audio headset, speaker, and handset, and provides support for XML applications.

For a complete list of supported features, see the [Endpoint Features Summary, page 18-55](#).

The Cisco E20 Video Phone is most commonly deployed with the Tandberg VCS call control. However, with the latest firmware release and Unified CM 8.5, the Cisco E20 Video Phone is capable of registering directly to Cisco Unified CM as a Cisco SIP video phone. With Unified CM 8.0, the Cisco E20 Video Phone is only capable of registering directly to Unified CM as a third-party SIP endpoint.

Product documentation for the Cisco E20 Video Phone can be found at <http://www.tandberg.com>.

Codecs Supported by Cisco Unified Video Advantage, Cisco IP Video Phone 7985G, Cisco Unified IP Phones 8900 and 9900 Series, and Cisco E20 Video Phone

[Table 18-6](#) lists the codecs supported by Cisco Unified Video Advantage, Cisco IP Video Phone 7985G, Cisco Unified IP Phones 8900 and 9900 Series, and Cisco E20 Video Phone.

Table 18-6 *Codecs Supported by Cisco Unified Video Advantage, Cisco IP Video Phone 7985G, Cisco Unified IP Phones 8900 and 9900 Series, and Cisco E20 Video Phone*

| Codec or Feature | Cisco Unified Video Advantage | Cisco IP Video Phone 7985G | Cisco Unified IP Phone 9951 and 9971 | Cisco Unified IP Phone 8941 and 8945 | Cisco E20 Video Phone |
|------------------|-------------------------------|----------------------------|--------------------------------------|--------------------------------------|-----------------------|
| H.264 | Yes in Release 2.0 | Yes | Yes | Yes | Yes |
| H.263 | Yes | Yes | No | No | Yes |
| H.261 | No | Yes | No | No | No |
| G.711 | Yes | Yes | Yes | Yes | Yes |
| G.722 | No | Yes | Yes | Yes | Yes |
| G.722.1 | No | No | No | No | Yes |
| G.723.1 | No | No | No | No | No |
| G.728 | No | No | No | No | No |
| G.729 | Yes | Yes | Yes | Yes | Yes |

Table 18-6 Codecs Supported by Cisco Unified Video Advantage, Cisco IP Video Phone 7985G, Cisco Unified IP Phones 8900 and 9900 Series, and Cisco E20 Video Phone (continued)

| Codec or Feature | Cisco Unified Video Advantage | Cisco IP Video Phone 7985G | Cisco Unified IP Phone 9951 and 9971 | Cisco Unified IP Phone 8941 and 8945 | Cisco E20 Video Phone |
|-------------------|---|---|--------------------------------------|--------------------------------------|---|
| Maximum Bandwidth | 7 Mbps for Release 1.0 and 1.5 Mbps for Release 2.0 | 768 kbps | 1 Mbps | 1 Mbps | 1.152 Mbps |
| Video Resolution | CIF, QCIF | NTSC: 4SIF, SIF PAL: 4CIF, QCIF, SQCIF | QCIF, CIF, VGA | QCIF, CIF, VGA | Transmit and receive: 768x448@30fps (w448p) 576x448@30fps (448p) 512x288@30fps (w288p) 352x288@30fps (CIF) 176x144@30fps (QCIF) Receive only: 1024x768@7.5fps (XGA) 1024x576@7.5fps (w576) 800x600@7.5fps (SVGA) 704x480@15fps (4SIF) 704x576@15fps (4CIF) 640x480@15fps (VGA) 352x240@30fps (SIF) |

Third-Party SCCP Video Endpoints

Two manufacturers of video endpoints, Sony and Tandberg, currently have products that support the Cisco Skinny Client Control Protocol (SCCP). SCCP on both the Sony and Tandberg endpoints is modeled after SCCP on the Cisco Unified IP Phone 7940. Most features found on the Cisco Unified IP Phone 7940 user interface are also supported on the Sony endpoints as well as the Tandberg endpoints, including multiple line appearances, softkeys, and buttons for Directories, Messages, Settings, Services, and so forth. The Sony and Tandberg endpoints also support the Option 150 field in DHCP to discover the IP address of the TFTP server, and they download their configurations from the TFTP server. However, software upgrades of the Sony and Tandberg endpoints are not done via TFTP. Instead, the customer must manually upgrade each endpoint using tools provided

by the vendor. (Tandberg uses an FTP method, while Sony uses FTP or a physical memory stick.) The Sony and Tandberg endpoints register with up to three Unified CM servers and will fail-over to its secondary or tertiary servers if its primary server becomes unreachable.

While the Sony and Tandberg endpoints support softkey functionality similar to that of the Cisco Unified IP Phone 7940 and 7960, the exact feature support differs between vendor and model. Check the manufacturers' documentation for supported features. Features that are currently known to be missing on some platforms include:

- Messages button
- Directories (placed calls, received calls, missed calls, and corporate directory)
- Settings and Services buttons
- Some XML services (such as Extension Mobility and Berbee's InformaCast)

Because the Sony and Tandberg endpoints use SCCP, dialing a video call from an endpoint is similar to dialing an audio call from a Cisco Unified IP Phone. If users are familiar with Cisco Unified IP Phones, they should also find the Sony and Tandberg endpoints very intuitive to use. The main difference in the user interface is that the Sony and Tandberg endpoints do not have a button keypad or a handset like those on a phone. Instead, the remote control is used to access features and to dial numbers on the Sony and Tandberg endpoints.

**Note**

Sony and Tandberg endpoints do not support the Cisco Discovery Protocol (CDP) or IEEE 802.Q/p. Therefore, you must manually configure the VLAN ID and Quality of Service trust boundary on the ethernet switch to which they are attached. (For more details, see [Network Infrastructure, page 3-1.](#))

Codecs Supported by Sony and Tandberg SCCP Endpoints

Codec support for the third-party SCCP endpoints varies by vendor, model, and software version. Check the vendors' product documentation for the supported codecs.

General QoS Deployment Considerations for Cisco Video Endpoints

Cisco hardware video endpoints mark Layer 3 DSCP and Layer 2 CoS as dictated by Unified CM configuration or by signaling in the case of SCCP. These markings should conform to the following Cisco recommended QoS voice, video, and signaling marking values.

- For voice media the appropriate QoS values are: DSCP 0x46, PHB EF, CoS 5.
- For video media the appropriate QoS values are: DSCP 0x34, PHB AF41, CoS 4.
- For video signaling (SIP or SCCP) the appropriate QoS values are: DSCP 0x24, PHB CS3, CoS 3.

Cisco video endpoints, in combination with Cisco call control, are capable of dynamically marking QoS values up or down based on the escalation or de-escalation of a call from voice-only to video, and vice versa.

**Note**

While many Cisco endpoints may support Link Layer Discovery Protocol for Media Endpoint Devices (LLDP-MED), they do so only for VLAN and Power over Ethernet negotiation. Cisco endpoints do not honor DSCP and CoS markings provided by LLDP-MED.

Additional Information on Video Endpoints

For more information, including details regarding the latest hardware and software version support for video endpoints, refer to the appropriate data sheets and documentation for:

- Cisco Unified Video Advantage:
<http://www.cisco.com/en/US/products/sw/voicesw/ps5662/index.html>
- Cisco Unified IP Phone 7985G:
<http://www.cisco.com/en/US/products/ps6564/index.html>
- Cisco Unified IP Phone 8900 and 9900 Series video capabilities:
<http://www.cisco.com/en/US/products/ps10453/index.html>
- Cisco IP Video Phone E20:
<http://www.cisco.com/en/US/products/ps11329/index.html>

Cisco Virtualization Experience Clients

The Cisco Virtualization Experience Clients (VXC) are the integral collaboration components of the Cisco Virtualization Experience Infrastructure (VXI). The VXCs provide user access to data, applications, and services across various network environments, as well as user preferences and device form factors for a fully integrated voice, video, and virtual desktop environment.

Cisco Virtualization Experience Client 2111, 2112, 2211, and 2212

Cisco Virtualization Experience Clients (VXC) 2111, 2112, 2211, and 2212 provide simple devices with a small firmware footprint (also known as a “zero client”) for virtual desktop access to a Citrix or VMware environment. The VXC 2112 and 2212 are specifically designed to work in a Citrix environment, while the VXC 2111 and 2211 work in a VMware environment. The VXC 2111 and 2112 integrated form factor devices are designed to replace the footstand on the Cisco Unified IP Phones 8961, 9951, or 9971 to provide a fully integrated voice, video, and virtual desktop environment. The VXC 2211 and 2212 standalone form factor devices are designed to operate as a simple virtual desktop environment, or they can be paired with any third-generation Cisco Unified IP Phone to provide a full voice, video, and virtual desktop environment.

Cisco Virtualization Experience Client 4000

Cisco Virtualization Experience Client (VXC) 4000 is a software appliance that, when used in conjunction with a repurposed PC, allows for secure access to a remote hosted virtual desktop while supporting rich media locally. Windows 7 and Windows XP are the only operating systems supported for the repurposed PC. The hosted virtual desktop is supported, using Citrix XenDesktop or VMware View, through a locally installed thick-client Citrix Receiver 3.0 and VMware View Client 5.0, respectively.

Cisco Virtualization Experience Client 6215

Cisco Virtualization Experience Client (VXC) 6215 thin client provides a fully integrated voice, video, and virtual desktop solution in a single device. The VXC 6215 is a Linux platform that can be used in Virtual Desktop Infrastructure (VDI) mode to support Citrix XenDesktop or VMware View, or it can be enabled for Unified Communications with a software appliance add-on that allows for full voice, video, and virtual desktop support of Citrix XenDesktop 5.5.

Additional Information on Cisco Virtualization Experience Clients

For more information, including details regarding the latest hardware and software version support for virtualization clients, refer to the appropriate data sheets and documentation for:

- Cisco Virtualization Experience Client 2000 Series:
<http://www.cisco.com/en/US/products/ps11499/index.html>
- Cisco Virtualization Experience Client 4000 Series:
<http://www.cisco.com/en/US/products/ps11498/index.html>
- Cisco Virtualization Experience Client 6000 Series:
<http://www.cisco.com/en/US/products/ps11976/index.html>

Third-Party SIP IP Phones

Third-party phones have specific local features that are independent of the call control signaling protocol, such as features access buttons (fixed or variable). Basic SIP RFC support allows for certain desktop features to be the same as Cisco Unified IP Phones and also allows for interoperability of certain features. However, these third-party SIP phones do not provide the full feature functionality of Cisco Unified IP Phones.

Cisco is working with key third-party vendors who are part of the Cisco Technology Development Partner Program and who are developing solutions that leverage the new Unified CM and Cisco Unified Communications Manager Express (Unified CME) SIP capabilities. Vendors include IPCelerate (unified client for education space), RIM (Blackberry 7270 wireless LAN handsets) and IP blue (Softphone). Cisco has also worked with third-party vendor Grandstream to test their Grandstream GXP 2000 to ensure interoperability.

Cisco is also participating in an independent third party testing and interoperability verification process being offered by tekVizion. This independent service provided by tekVizion has been established to enable third-party vendors to test and verify the interoperability of their endpoints with Unified CM and Unified CME.

For more information on Cisco's line-side SIP interoperability and third-party verification, visit <http://www.cisco.com>.

QoS Recommendations

This section provides the basic QoS guidelines and configurations for the Cisco Catalyst switches most commonly deployed with IP Telephony endpoints. For more details, refer to the *Quality of Service* design guide at

<http://www.cisco.com/go/designzone>

Cisco VG224 and VG248

Analog gateways are trusted endpoints. For Cisco VG224 and VG248 gateways, configure the switch to trust the DSCP value of the VG248 packets. The following sections list the commands to configure the most common Cisco Catalyst switches for the Cisco VG224 and VG248 analog gateways.

Note

In the following sections, *vvlan_id* is the voice VLAN ID and *dvlan_id* is the data VLAN ID.

Cisco 2950

```
CAT2950 (config)#interface interface-id
CAT2950 (config-if)#mls qos trust dscp
CAT2950 (config-if)#switchport mode access
CAT2950 (config-if)#switchport access vlan vvlan_id
```

Note

The `mls qos trust dscp` command is available only with Enhanced Image (EI).

Cisco 2970 or 3750

```
CAT2970 (config)#mls qos
CAT2970 (config)#interface interface-id
CAT2970 (config-if)#mls qos trust dscp
CAT2970 (config-if)#switchport mode access
CAT2970 (config-if)#switchport access vlan vvlan_id
```

Cisco 3550

```
CAT3550 (config)#mls qos
CAT3550 (config)#interface interface-id
CAT3550 (config-if)#mls qos trust dscp
CAT3550 (config-if)#switchport mode access
Cat3550 (config-if)#switchport access vlan vvlan_id
```

Cisco 4500 with SUP3, IV, or V

```
CAT4500 (config)#qos
CAT4500 (config)#interface interface-id
CAT4500 (config-if)#qos trust dscp
CAT4500 (config-if)#switchport mode access
CAT4500 (config-if)#switchport access vlan vvlan_id
```

Cisco 6500

```
CAT6500> (enable) set qos enable
CAT6500> (enable) set port qos 2/1 vlan-based
CAT6500> (enable) set vlan vvlan_id mod/port
```

```
CAT6500>(enable)set port qos mod/port trust trust-dscp
```

Cisco ATA 186 and IP Conference Station

Because the Cisco Analog Telephone Adaptor (ATA) 186 and IP Conference Station are trusted endpoints, their QoS configurations are identical to those described in the section on [Cisco VG224 and VG248, page 18-39](#).

Cisco ATA 188 and IP Phones

For the Cisco Analog Telephone Adaptor (ATA) 188 and IP Phones, Cisco recommends segregating the voice VLAN from the data VLAN. For the Cisco ATA 186, 7902, 7905, 7906, 7910, and IP Conference Station, Cisco still recommends configuring voice and data VLAN segregation and an auxiliary voice VLAN. In this way, the same access-layer configurations can be used with different IP phone models and ATAs, and end-users can plug their IP phones or ATAs into different access ports on the switch and get the same treatment. For the Cisco ATA 186, 7902, 7905, 7906, 7910, and IP Conference Stations, the command to override the CoS value of the frames from the attached PC has no effects because these devices do not have a PC connected to them.

The following sections list the configuration commands for IP phones on the most commonly deployed Cisco Catalyst switches.

Cisco 2950

```
CAT2950(config)#
CAT2950(config)#class-map VVLAN
CAT2950(config-cmap)# match access-group name VVLAN
CAT2950(config-cmap)#class-map DVLAN
CAT2950(config-cmap)# match access-group name DVLAN
CAT2950(config-cmap)#exit
CAT2950(config)#
CAT2950(config)#policy-map IPPHONE-PC
CAT2950(config-pmap)# class VVLAN
CAT2950(config-pmap-c0# set ip dscp 46
CAT2950(config-pmap-c)# police 1000000 8192 exceed-action-drop
CAT2950(config-pmap)# class DVLAN
CAT2950(config-pmap-c0# set ip dscp 0
CAT2950(config-pmap-c)# police 5000000 8192 exceed-action-drop
CAT2950(config-pmap-c)#exit
CAT2950(config-pmap)#exit
CAT2950(config)#
CAT2950(config)#interface interface-id
CAT2950(config-if)#mls qos trust device cisco-phone
CAT2950(config-if)#mls qos trust cos
CAT2950(config-if)#switchport mode access
CAT2950(config-if)#switchport voice vlan vvlan_id
CAT2950(config-if)#switchport access vlan dvlan_id
CAT2950(config-if)#service-policy input IPPHONE-PC
CAT2950(config-if)#exit
CAT2950(config)#
CAT2950(config)#ip access-list standard VVLAN
CAT2950(config-std-nacl)# permit voice_IP_subnet wild_card_mask
CAT2950(config-std-nacl)#exit
CAT2950(config)#ip access-list standard DVLAN
CAT2950(config-std-nacl)# permit data_IP_subnet wild_card_mask
CAT2950(config-std-nacl)#end
```

**Note**

The `mls qos map cos-dscp` command is available only with Enhanced Image (EI). With Standard Image (SI), this command is not available and the default CoS-to-DSCP mapping is as follows:

| | | | | | | | | |
|------------|---|---|----|----|----|----|----|----|
| CoS Value | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| DSCP Value | 0 | 8 | 16 | 24 | 32 | 40 | 48 | 56 |

Cisco 2970, 3560, or 3750

```

CAT2970 (config)# mls qos map cos-dscp 0 8 16 24 34 46 48 56

**Note**

The DSCP re-marking must be done by a Layer-3 capable switch. If the access layer switch (such as the Cisco Catalyst 2950 with Standard Image or the Cisco 3524XL) does not have this capability, then the DSCP re-marking must be done at the distribution layer switch.

Software-Based Endpoints

Cisco Unified Personal Communicator and Cisco IP Communicator with Cisco Unified Video Advantage are both voice and video capable, which presents two challenges when using the ACL and policy map for packet classification and DSCP re-marking. First, Cisco Unified Personal Communicator uses the same IP address and UDP port range to source voice and video streams. The ACL that is based on IP address and port number is not granular enough to differentiate a voice call from a video call in order to apply appropriate DSCP re-marking. Second, Cisco IP Communicator uses the same IP address and UDP port range to source its voice packets. Similarly, the ACL is not granular enough to differentiate the voice stream of an audio-only call from the voice stream of a video call. Therefore, using the ACL and policy-map for packet classification and DSCP re-marking is not a feasible QoS solution for software-based endpoints.

Because both Cisco Unified Personal Communicator and Cisco IP Communicator with Cisco Unified Video Advantage mark their signaling and media packets correctly as they ingress the network, Cisco recommends configuring the policy map to trust the DSCP marking of incoming traffic and apply traffic policing and rate limiting. The following sections list the configuration commands for Cisco Unified Personal Communicator and Cisco IP Communicator on the most commonly deployed Cisco Catalyst switches.

**Note**

The Cisco Catalyst 2950 Series switches are not recommended for software-based endpoint QoS implementations because the Cisco 2950 supports only 1-Mbps increments on FastEthernet ports, which can create a fairly large hole to admit onto the network unauthorized traffic that might be mimicking call signaling or media.

Cisco Unified Wireless IP Phones

By default, the Cisco Unified Wireless IP Phones and wirelessly attached Cisco Unified IP Phones 9971 mark their SCCP signaling messages using a Per-Hop Behavior (PHB) value of CS3 or a Differentiated Services Code Point (DSCP) value of 24 (this corresponds to a ToS value of 0x60), and it marks RTP voice packets using a PHB value of EF or a DSCP value of 46 (ToS of 0xB8). With proper queueing on the AP and configuration on the upstream first-hop switch to trust the AP's port, the wireless IP phone traffic will receive the same treatment as wired IP phone traffic. This practice allows the QoS settings to be consistent from LAN to WLAN environments.

In addition, the Cisco Unified Wireless IP Phones and the Cisco Unified IP Phone 9971, when wirelessly attached, automatically announce their presence to the AP using the Cisco Discovery Protocol (CDP). The CDP packets are sent from the wireless IP phone to the AP, and they identify the phone so that the AP can place all traffic to the phone in the high-priority queue.

As indicated in the configuration examples, packets coming from the AP should be trusted and, based on the VLAN tag of each packet, the DSCP marking should either be maintained or marked down. Thus, packets sourced from the Cisco Unified Wireless IP Phones on the voice VLAN should maintain the appropriate DSCP marking, and packets source from data devices on the data VLAN should be remarked to a DSCP value of 0.

Video Telephony Endpoints

This section discusses how the following types of endpoint devices classify traffic:

- [Cisco Unified Video Advantage with a Cisco Unified IP Phone, page 18-48](#)
- [Cisco IP Video Phone 7985G, page 18-50](#)
- [Sony and Tandberg SCCP Endpoints, page 18-51](#)
- [H.323 and SIP Video Endpoints, page 18-52](#)

Cisco Unified Video Advantage with a Cisco Unified IP Phone

The Cisco Unified Video Advantage application residing on the user's PC supports the classification of video packets using DSCP and, therefore, only at Layer 3. The current best practices for Cisco Unified Communications design recommend that the upstream Ethernet switch to which the phone is attached should be configured to trust the 802.1p CoS from the phone. Because the PC packets are unlikely to have an 802.1Q tag, they are unable to support 802.1p CoS bits. This lack of 802.1p support from the PC leaves the following possible options for providing QoS for Cisco Unified Video Advantage.

Option 1

If your current QoS model extends trust to the IP Phone, then the voice and signaling packets will be correctly marked as they ingress the network. With an additional ACL on the port to match UDP port 5445, the video media channel will also be classified to PHB AF41. Without this ACL, the video media would be classified Best Effort and would incur poor image quality and lip-sync issues. The same ACL could also be used to match the CAST connection between the Cisco Unified Video Advantage PC and the IP Phone, which uses TCP port 4224 (classifying it as CS3), although the benefit of doing so is minimal. The signaling packets from the PC, which is on the data VLAN, are returned over the same high-speed port onto the voice VLAN, therefore they are highly unlikely to encounter any congestion.

The following example illustrates the configuration for this option:

```

3550(config)#class-map match-all SOFTWARE-BASED-ENDPOINT-VOICE
3550(config-cmap)#match access-group name SOFTWARE-BASED-ENDPOINT-VOICE
3550(config-cmap)#class-map match-all SOFTWARE-BASED-ENDPOINT-VIDEO
3550(config-cmap)# match access-group name SOFTWARE-BASED-ENDPOINT-VIDEO
3550(config-cmap)#class-map match-all SOFTWARE-BASED-ENDPOINT-SIGNALING
3550(config-cmap)# match access-group name SOFTWARE-BASED-ENDPOINT-SIGNALING
3550(config-cmap)#exit
3550(config)#
3550(config)#policy-map SOFTWARE-BASED-ENDPOINT
3550(config-pmap)#class SOFTWARE-BASED-ENDPOINT-VOICE
3550(config-pmap)# police 128000 8000 exceed-action drop
3550(config-pmap)#class SOFTWARE-BASED-ENDPOINT-VIDEO
3550(config-pmap)#set ip dscp 34
3550(config-pmap)# police 50000000 8000 exceed-action policed-dscp-transmit
3550(config-pmap)#class SOFTWARE-BASED-ENDPOINT-SIGNALING
3550(config-pmap)#set ip dscp 24
3550(config-pmap)# police 32000 8000 exceed-action policed-dscp-transmit

```

```

3550(config-pmap)#class class-default
3550(config-pmap)# set ip dscp 0
3550(config-pmap)# police 5000000 8000 exceed-action policed-dscp-transmit
3550(config-pmap)# exit
3550(config)#exit
3550(config)#
3550(config)#interface FastEthernet interface_id

3550(config-ext-nacl)#permit tcp PC_Subnet_Source wildcard_bits eq 4224 any
3550(config-ext-nacl)#exit
3550(config-if)# ip access-list extended SOFTWARE-BASED-ENDPOINT-VIDEO
3550(config-ext-nacl)#permit ip PC_Subnet_Source wildcard_bits any dscp 34
3550(config-ext-nacl)#permit udp PC_Subnet_Source wildcard_bits eq 5445 any
3550(config-ext-nacl)#exit
3550(config-if)# ip access-list extended SOFTWARE-BASED-ENDPOINT-VOICE
3550(config-ext-nacl)# permit ip PC_Subnet_Source wildcard_bits any dscp 46
3550(config-ext-nacl)#exit
3550(config)#exit

```

Option 2

The *Enterprise QoS Solution Reference Network Design Guide, Version 3.1* (available at <http://www.cisco.com/go/designzone>) presents another method. This alternative method recommends changing the port to trust the DSCP of incoming traffic instead of trusting CoS, and then running the incoming packets through a series of Per-Port/Per-VLAN Access Control Lists that match packets based on their TCP/UDP ports (along with other criteria) and police them to appropriate levels. For instance, Cisco Unified Video Advantage will mark its video packets with DSCP AF41, with the switch port set to trust DSCP. The packet will run through an ACL that matches it based on the fact that it is using UDP port 5445, is marked with DSCP AF41, and is coming in on the data VLAN. This ACL will then be used in a class map or policy map to trust the DSCP and police the traffic to N kbps (where N is the amount of video bandwidth you want to allow per port). Similar ACLs and policers will be present for the voice and signaling packets from the IP Phone in the voice VLAN.

The following example illustrates the configuration for this option:

```

3550(config)#class-map match-all SOFTWARE-BASED-ENDPOINT-VOICE
3550(config-cmap)#match access-group name SOFTWARE-BASED-ENDPOINT-VOICE
3550(config-cmap)#class-map match-all SOFTWARE-BASED-ENDPOINT-VIDEO
3550(config-cmap)# match access-group name SOFTWARE-BASED-ENDPOINT-VIDEO
3550(config-cmap)#class-map match-all SOFTWARE-BASED-ENDPOINT-SIGNALING
3550(config-cmap)# match access-group name SOFTWARE-BASED-ENDPOINT-SIGNALING
3550(config-cmap)#exit
3550(config)#
3550(config)#policy-map SOFTWARE-BASED-ENDPOINT
3550(config-pmap)#class SOFTWARE-BASED-ENDPOINT-VOICE
3550(config-pmap)# police 128000 8000 exceed-action drop
3550(config-pmap)#class SOFTWARE-BASED-ENDPOINT-VIDEO
3550(config-pmap)#set ip dscp 34
3550(config-pmap)# police 5000000 8000 exceed-action policed-dscp-transmit
3550(config-pmap)#class SOFTWARE-BASED-ENDPOINT-SIGNALING
3550(config-pmap)#set ip dscp 24
3550(config-pmap)# police 32000 8000 exceed-action policed-dscp-transmit
3550(config-pmap)#class class-default
3550(config-pmap)# set ip dscp 0
3550(config-pmap)# police 5000000 8000 exceed-action policed-dscp-transmit
3550(config-pmap)# exit

```

```

3550(config)#exit
3550(config)#
3550(config)#interface FastEthernet interface_id
3550(config-if)# switchport access vlan dvlan_id
3550(config-if)# switchport mode access
3550(config-if)# service-policy input SOFTWARE-BASED-ENDPOINT
3550(config-if)# exit
3550(config)#ip access-list extended SOFTWARE-BASED-ENDPOINT-SIGNALING
3550(config-ext-nacl)#permit tcp PC_Subnet_Source wildcard_bits eq 4224 any dscp 24
3550(config-ext-nacl)#exit
3550(config-if)# ip access-list extended SOFTWARE-BASED-ENDPOINT-VIDEO
3550(config-ext-nacl)#permit udp PC_Subnet_Source wildcard_bits eq 5445 any dscp 34
3550(config-ext-nacl)#exit
3550(config-if)# ip access-list extended SOFTWARE-BASED-ENDPOINT-VOICE
3550(config-ext-nacl)# permit ip PC_Subnet_Source wildcard_bits any dscp 46
3550(config-ext-nacl)#exit
3550(config)#exit

```

Cisco IP Video Phone 7985G

Like many other Cisco Unified IP Phones, the Cisco IP Video Phone 7985G supports 802.1p/Q tagging for traffic originating from the phone and, because the Cisco IP Video Phone 7985G has a second Ethernet interface for PC access, traffic originating from attached devices as well. The current best practices for Cisco Unified Communications design recommend that the upstream Ethernet switch to which the phone is attached should be configured to trust the 802.1p CoS from the phone. Cisco recommends that trust not be extended to the PC port of the phone and, if the switch supports it, that you configure policers to limit the maximum amount of voice, video, and signaling traffic.

The following example illustrates this type of configuration:

```

3550(config)#class-map match-all C7985-ENDPOINT-VOICE
3550(config-cmap)#match access-group name C7985-ENDPOINT-VOICE
3550(config-cmap)#class-map match-all C7985-ENDPOINT-VIDEO
3550(config-cmap)# match access-group name C7985-ENDPOINT-VIDEO
3550(config-cmap)#class-map match-all C7985-ENDPOINT-SIGNALING
3550(config-cmap)# match access-group name C7985-ENDPOINT-SIGNALING
3550(config-cmap)#exit
3550(config)#
3550(config)#policy-map C7985-ENDPOINT
3550(config-pmap)#class C7985-ENDPOINT-VOICE
3550(config-pmap)# police 128000 8000 exceed-action drop
3550(config-pmap)#class C7985-ENDPOINT-VIDEO
3550(config-pmap)#set ip dscp 34
3550(config-pmap)# police 50000000 8000 exceed-action policed-dscp-transmit
3550(config-pmap)#class C7985-ENDPOINT-SIGNALING
3550(config-pmap)#set ip dscp 24
3550(config-pmap)# police 32000 8000 exceed-action policed-dscp-transmit
3550(config-pmap)#class class-default
3550(config-pmap)# set ip dscp 0
3550(config-pmap)# police 5000000 8000 exceed-action policed-dscp-transmit
3550(config-pmap)# exit
3550(config)#exit
3550(config)#
3550(config)#interface FastEthernet interface_id
3550(config-if)# switchport access vlan dvlan_id
3550(config-if)# switchport mode access
3550(config-if)# service-policy input C7985-ENDPOINT

```

3550(config-if)# ip access-list extended C7985-ENDPOINT-VIDEO
3550(config-ext-nacl)#permit ip Voice_IP_Subnet Subnet_Mask any dscp 34
3550(config-ext-nacl)#exit
3550(config-if)# ip access-list extended C7985-ENDPOINT-VOICE
3550(config-ext-nacl)# permit ip Voice_IP_Subnet Subnet_Mask any dscp 46
3550(config-ext-nacl)#exit
3550(config)#exit

```

Sony and Tandberg SCCP Endpoints

Sony and Tandberg SCCP endpoints correctly mark their media and signaling packets at Layer 3 using DSCP. They do not, however, support 802.1Q and are therefore unable to classify using 802.1p CoS. If you use the UDP and TCP port-matching option, you would be able to classify the SCCP signaling correctly as CS3 and the video media as AF41; however, you would be unable to tell when a UDP port is being used in a voice-only call and should therefore be classified as EF. In such a case, the call admission control mechanisms would not be able to account for the bandwidth correctly. To avoid this situation, there is only one viable option for how to classify and trust traffic from a Sony or Tandberg endpoint:

Option 1

Trust DSCP on the port used by the Sony or Tandberg endpoint. If the switch allows it, configure policers to limit the maximum amount of EF, AF41, and CS3 traffic that can be received on that port. Any other device plugged into that port should not necessarily be trusted, even if its packets are classified using DSCP. This option may be acceptable if the Sony or Tandberg system is a permanent installation in an office or small conference room.

Because the Sony or Tandberg device does not support CDP, the VLAN placement of this endpoint requires manual modification if the requirement is to place it in the voice VLAN. The advantage of placing the endpoint directly in the voice VLAN is that it can be treated like any other IP Telephony endpoint in the system. The disadvantage is that the port might pose a security risk because it provides direct access to the voice VLAN. Alternatively, you can leave the Sony or Tandberg endpoint in the data VLAN, but you will have to provision access between the data and voice VLANs to permit SCCP signaling to Unified CM and to allow the UDP media streams to pass between the data and voice VLANs during voice or video calls.

The following example illustrates the configuration for this option:

```

CAT2970(config)# mls qos map cos-dscp 0 8 16 24 34 46 48 56

```

H.323 and SIP Video Endpoints

This type of endpoint is potentially the most challenging from a QoS perspective due to the wide range of H.323 and SIP video endpoints, the variation in implementations, and the feature sets. There are two main QoS options for these endpoints; the first relies on the H.323 or SIP video endpoint to correctly mark all the traffic, and the second relies on detailed knowledge of the TCP and UDP ports used.

Option 1

If the endpoint correctly marks the media and signaling traffic (signaling should include SIP, H.225, H.245, and RAS), you could trust the classifications. Because it is unlikely that the endpoint supports 802.1Q (and therefore 802.1p CoS), you will probably have to use IP Precedence or DSCP in this case. The choice of classification type depends on the specific vendor, model, and software version.

Note

It is highly unlikely that an H.323 or SIP endpoint will mark its packets correctly.

Note

Prior to Unified CM 8.5 and the latest device firmware, the Cisco E20 does not mark traffic and does not support Cisco Discovery Protocol (CDP). In addition, Tandberg video endpoints do not mark traffic or support CDP. For this reason, ACLs for matching and classify traffic correctly as described in [Option 2, page 18-53](#), below should be used. Likewise, given the lack of support for CDP, the VLAN placement of this endpoint requires manual modification to place the device in the voice VLAN. As previously stated, the advantage of placing the endpoint directly in the voice VLAN is that it can be treated like any other IP Telephony endpoint in the system. But this can pose a security risk because it provides direct

access to the voice VLAN. Alternatively, endpoints can be left in the data VLAN, but access must be granted between the data and voice VLANs to permit SIP signaling to Unified CM and to allow the UDP media streams to pass between the data and voice VLANs during voice or video calls.

Option 2

Using a combination of source, destination, or both TCP and UDP port numbers (possibly including IP addresses as well), you could define an ACL that matches and classifies the traffic correctly. In addition, Cisco recommends that you also apply policers to limit the amount of each class of traffic that is admitted to the network. This option has the same potential as Option 1 for classifying voice-only calls incorrectly.

The following example illustrates the configuration for this option:

```
CAT2970(config)# mls qos map cos-dscp 0 8 16 24 34 46 48 56
CAT2970(config)# mls qos map policed-dscp 0 24 to 8
CAT2970(config)#
CAT2970(config)#class-map match-all VVLAN-VIDEO
CAT2970(config-cmap)# match access-group name VVLAN-VIDEO
CAT2970(config-cmap)#
CAT2970(config-cmap)#class-map match-all VVLAN-CALL-SIGNALING
CAT2970(config-cmap)# match access-group name VVLAN-CALL-SIGNALING
CAT2970(config-cmap)#
CAT2970(config-cmap)#class-map match-all VVLAN-ANY
CAT2970(config-cmap)# match access-group name VVLAN-ANY
CAT2970(config-cmap)#
CAT2970(config-cmap)# policy-map SCCP-VIDEO-ENDPOINT
CAT2970(config-pmap)#class VVLAN-VIDEO
CAT2970(config-pmap-c)# set ip dscp 34
CAT2970(config-pmap-c)# police 1500000 8000 exceed-action policed-dscp-transmit
CAT2970(config-pmap-c)# class VVLAN-CALL-SIGNALING
CAT2970(config-pmap-c)# set ip dscp 24
CAT2970(config-pmap-c)# police 32000 8000 exceed-action policed-dscp-transmit
CAT2970(config-pmap-c)# class VVLAN-ANY
CAT2970(config-pmap-c)# set ip dscp 0
CAT2970(config-pmap-c)# police 32000 8000 exceed-action policed-dscp-transmit
CAT2970(config-pmap-c)# class class-default
CAT2970(config-pmap-c)# set ip dscp 0
CAT2970(config-pmap-c)# police 5000000 8000 exceed-action policed-dscp-transmit
CAT2970(config-pmap-c)# exit
CAT2970(config-pmap)# exit
CAT2970(config)#interface interface-id
CAT2970(config-if)# switchport voice vlan vvlan_id
CAT2970(config-if)# mls qos trust device cisco-phone
CAT2970(config-if)# service-policy input SCCP-VIDEO-ENDPOINT
CAT2970(config-if)# exit
CAT2970(config)#
CAT2970(config)#ip access list extended VVLAN-VIDEO
CAT2970(config-ext-nacl)# permit udp Voice_IP_Subnet Subnet_Mask any range 16384 32767
CAT2970(config-ext-nacl)# exit
CAT2970(config)#ip access list extended VVLAN-CALL-SIGNALING
CAT2970(config-ext-nacl)# permit udp Voice_IP_Subnet Subnet_Mask any eq 1719 dscp cs3
CAT2970(config-ext-nacl)# permit tcp Voice_IP_Subnet Subnet_Mask any eq 1720 dscp cs3
CAT2970(config-ext-nacl)# permit tcp Voice_IP_Subnet Subnet_Mask any range 11000 65535
dscp cs3
CAT2970(config-ext-nacl)# permit udp Voice_IP_Subnet Subnet_Mask any eq 5060 dscp cs3
CAT2970(config-ext-nacl)# permit tcp Voice_IP_Subnet Subnet_Mask any range 5060 5061 dscp
cs3
CAT2970(config-ext-nacl)# exit
CAT2970(config)#ip access list extended VVLAN-ANY
CAT2970(config-ext-nacl)# permit ip Voice_IP_Subnet Subnet_Mask any
CAT2970(config-ext-nacl)# end
```

**Note**

The above configuration will cause voice traffic to be marked similar to video traffic, even for audio-only calls. The signaling and RTP port usage can vary from vendor to vendor, so you must use the appropriate port range if it differs from what is used in the above example.

High Availability for Unified Communications Endpoints

To stay in service even during failure of the Unified CM subscriber or other servers, Cisco Unified Communications endpoints are capable of being configured with multiple servers. For example, either through direct configuration or through DHCP during the boot-up phase, the endpoints can accept and process more than one TFTP server address. In case the primary TFTP server is down when the endpoint is booting up, the endpoint can get its configuration files from the secondary TFTP server.

Each of the endpoints is also associated with a device pool. The device pool contains a Unified CM Group that has one or more Unified CM subscribers. A list of these subscribers is sent to the endpoints in their configuration files. The endpoints attempt to register with the first (the primary) subscriber in the list. If that Unified CM subscriber is unavailable, the endpoint attempts to register with the second subscriber in the list (the secondary), and so on. Once registered to a subscriber, an endpoint can fail-over to another subscriber in the priority list in the Unified CM Group if the current subscriber fails. When a higher-priority subscriber comes back up, the endpoint will re-register to it.

To protect against network failure for endpoints located across a WAN from the Unified CM cluster, a locally available Cisco Integrated Services Router (ISR) equipped with Survivable Remote Site Telephony (SRST) or Unified CME acting as SRST may also be configured in the list of servers with which the endpoint may register. In case of a WAN failure, the endpoints register to the SRST router and provide uninterrupted telephony services (although the set of features they support in SRST mode might be smaller). Note that some endpoints might not support SRST.

Endpoints should be distributed uniformly across servers in the cluster to avoid overloading of any single server. For more information on redundancy methods between cluster subscribers, see the chapter on [Call Processing, page 8-1](#).

Capacity Planning for Unified Communications Endpoints

Cisco call control platforms support the following high-level endpoint capacities:

- A Cisco Unified CM cluster supports a maximum of 40,000 SCCP or SIP endpoints.
- Cisco Business Edition supports a maximum of between 400 and 1,200 SCCP or SIP endpoints, depending on the version.
- Cisco Unified CM Express supports a maximum of 450 SCCP or SIP endpoints.

The above numbers are nominal maximum capacities. The maximum number of endpoints that the call control platform will actually support depends on all of the other functions that the platform is performing, the Busy Hour Call Attempts (BHCA) of the users, and so forth, and the actual capacity could be less than the nominal maximum capacity.

For more information on endpoint capacity with Cisco call control, including platform-specific endpoint capacities per node, see the chapter on [Unified Communications Design and Deployment Sizing Considerations, page 29-1](#).

Design Considerations for Unified Communications Endpoints

The following list summarizes high-level recommendations for selecting the right endpoint from the set of Cisco Unified Communications endpoints:

- For low-density analog connections, use the Cisco Analog Telephone Adapter (ATA) or low-density analog interface module.
- For medium to high-density analog connections, use the high-density analog interface module, Cisco Communication Media Module (CMM) with 24-FXS port adapter, Catalyst 6500 24-FXS analog interface module, Cisco VG224, or Cisco VG248.
- For voice-centric users with little or no usage of XML and other phone-based services, use the Cisco Unified IP Phones 6921, 6941, 6945, and 6961.
- For telephony users with limited call features who generate small amounts of traffic, use the Cisco Unified SIP Phone 3905 or 3911 or the Cisco Unified IP Phones 7902G, 7905G, 7906G, 7910G, 7910G+SW, 7911G, 7912G, or 7912G-A.
- For transaction-type telephony users who generate a medium amount of traffic, use Cisco Unified IP Phones 7931G, 7940G, 7941G, 7941G-GE, 7942G, or 7945G.
- For managers and administrative assistants who generate medium to heavy telephony traffic, use Cisco Unified IP Phones 7960G, 7961G, 7961G-GE, 7962G, 7965G, or 8941, 8945, 8961.
- For executives with extensive call features who generate high amounts of telephony traffic, use Cisco Unified IP Phones 7970G, 7971G-GE, 7975G, 9951, or 9971.
- For mobile workers and telecommuters, use Cisco IP Communicator.
- For users who need a mobile IP phone, use the Cisco Unified Wireless IP Phones 7921G, 7925G, 7925G-EX, or 7926G.
- For making video calls, use the following software-based clients: Cisco Unified Video Advantage associated with a Cisco Unified IP Phone or Cisco IP Communicator, Cisco Unified Personal Communicator, and Cisco Unified Client Services Framework (CSF). Or use the following integrated video hardware devices: Cisco IP Video Phone 7985G; Cisco Unified IP Phone 8941 or 8945 with built-in camera; Cisco Unified IP Phone 9951 or 9971 with optional USB camera; Tandberg video endpoints, including the Cisco E20 Video Phone; and Sony or other third-party video endpoint devices.
- For accessing voice, video, document sharing, and presence information from a single integrated interface, use Cisco Unified Personal Communicator.
- For formal conferencing environments, use the Cisco Unified IP Conference Station 7936 or 7937G.

Endpoint Features Summary

The tables in this section might not contain the most up-to-date information regarding endpoint models or specific features and capabilities support. Consult the current product documentation listed below for the latest information regarding hardware models, feature support, and call control compatibility.

- Two 10/100 Base-T.
- One 10/100 Base-T.
- Two 10/100 Base-T for ATA 188; one 10 Base-T for ATA 186.
- The EVM-HD-8FXS/DID provides eight ports on the baseboard and can be configured for FXS or DID signaling. In addition, it has room for two EM-HDA-8FXS as extension modules.
- H.323 and SIP call control.
- Call Forward All.
- Last Number Redial.
- Only on SCCP and SIP version.
- Supported on VG248 version 1.2 or later.
- It marks MGCP signaling on UDP port 2427, but it marks the MGCP keep-alive packets as best-effort on TCP port 2428.
- Fax pass-through and fax relay.
- Fax pass-through.
- Unified CM does not support MGCP with the ATA.

- One 10/100 Base-T.
- One 10 Base-T.
- Two 10/100 Base-T.
- The Cisco Unified IP Phone 7912G-A has an enhanced version of Ethernet switch.
- For the Cisco Unified IP Phone 7905G and 7912G with SIP, if CFWDALL is configured on the phone, the phone must be in service to make CFWDALL work because Unified CM has no knowledge of the configuration on the phone. This behavior is different from an SCCP phone, which can be out of service and CFWDALL will still work. If CFWDALL is enabled on the Unified CM User page, Unified CM will handle this change but there will be no status line on the phone to indicate that the call is forwarded. CFWDALL configuration on the Unified CM User page overrides the configuration on the phone.
- The Cisco Unified SIP Phone 3911 has a half-duplex speaker phone, whereas the Cisco Unified IP Phones 7905G, 7906G, 7911G, and 7912G/GA support one-way audio monitor mode.
- Last Number Redial.
- Speed dial can be configured only on the phone for these models.
- The Cisco Unified IP Phone 6911 supports a single programmable feature key.
- These IP phone models do not support G.729b or G.729ab.

- Two 10/100 Base-T Ethernet connections.
- The Cisco Unified IP Phones 7941G and 7942G have two 10/100 Mbps Ethernet connections, and the Cisco Unified IP Phones 7941G-GE and 7945G have two 10/100/1000 Mbps Ethernet connections.
- The Cisco Unified IP Phone 7941G supports both Cisco Prestandard Power over Ethernet (PoE) and IEEE 802.3af PoE, and the Cisco Unified IP Phone 7941G-GE supports only IEEE 802.3af PoE.
- To implement Call Waiting on Cisco Unified IP Phones 6921 and 6961, configure the same DN on both lines (in different partitions) and then forward the first line to the second one on busy.
- For the Cisco Unified IP Phone 7905, 7912, 7940, or 7960 with SIP, if CFWDALL is configured on the phone, the phone must be in service to make CFWDALL work because Unified CM has no knowledge of the configuration on the phone. This behavior is different from an SCCP phone, which can be out of service and CFWDALL will still work. If CFWDALL is enabled on the Unified CM User page, Unified CM will handle this change but there will be no status line on the phone to indicate that the call is forwarded. CFWDALL configuration on the Unified CM User page overrides the configuration on the phone.
- This feature can be configured locally on the phone.
- One-way audio monitor mode.
- The Cisco Unified IP Phone 7940 with IP supports only local mixing for ad hoc conferences and up to three parties in the conference.
- Last Number Redial.
- Speed dial can be configured only on the phone.
- Only on speed dials and not on call history entries.
- With limited support.
- These IP phone models do not support G.729b or G.729ab.

- Two 10/100 Base-T Ethernet connections.
- The Cisco Unified IP Phones 7961G and 7962G have two 10/100 Mbps Ethernet connections, and the Cisco Unified IP Phones 7961G-GE and 7965G have two 10/100/1000 Mbps Ethernet connections.
- Two 10/100/100 Mbps Ethernet connections.
- The Cisco Unified IP Phone 7961G supports both Cisco Prestandard PoE and IEEE 802.3af PoE, and the Cisco Unified IP Phone 7961G-GE supports only IEEE 802.3af PoE.
- To implement Call Waiting on the Cisco Unified IP Phone 6941, configure the same DN (in different partitions) on two of its lines and then forward the first line to the second one on busy.
- For the Cisco Unified IP Phone 7905, 7912, 7940, or 7960 with SIP, if CFWDALL is configured on the phone, the phone must be in service to make CFWDALL work because Unified CM has no knowledge of the configuration on the phone. This behavior is different from an SCCP phone, which can be out of service and CFWDALL will still work. If CFWDALL is enabled on the Unified CM User page, Unified CM will handle this change but there will be no status line on the phone to indicate that the call is forwarded. CFWDALL configuration on the Unified CM User page overrides the configuration on the phone.
- This feature can be configured locally on the phone.
- The Cisco Unified IP Phone 7960G with IP supports only local mixing for ad hoc conferences and up to three parties in the conference.
- Last Number Redial.

10. Only on speed dials and not on call history entries.
 11. With limited support.
 12. These IP phone models do not support G.729b or G.729ab.

1. Cisco Unified Personal Communicator does not have an explicit transfer feature. Calls can be transferred by the Cisco Unified Personal Communicator user by merging two calls and then disconnecting to obtain the effect of a transfer.
2. Cisco Unified Personal Communicator does not support the “consult, then merge” feature (equivalent to conference on IP phones), but it does support **merge** (equivalent to **join** on IP phones) to conference calls.
3. Cisco Unified Personal Communicator cannot create a meet-me conference, but the user can join one by dialing the correct number.
4. Last number redial.
5. Cisco Unified Personal Communicator does not support the Unified CM speed dials page, however it does support click-to-call from the Contacts (buddy) list, including personal contacts, in a similar fashion.
6. This feature is not supported with Cisco IP Communicator Release 2.1.
7. In combination with Cisco Unified Video Advantage, Cisco IP Communicator operating in SCCP mode supports video calls.
8. Cisco IP Communicator 2.1 does not support wideband audio.

CHAPTER 19

Cisco Unified CM Applications

Revised: June 2, 2011; OL-21733-18

Cisco Unified Communications Manager (Unified CM) applications provide numerous operational and functional enhancements to basic IP telephony. External eXtensible Markup Language (XML) productivity applications or IP Phone Services can be run on the web server and/or client on most Cisco Unified IP Phones. For example, the IP phone on a user's desk can be used to get stock quotes, weather information, flight information, and other types of web-based information. In addition, custom IP phone service applications can be written that allow users to track inventory, bill customers for time, or control conference room environments (lights, video screen, temperature, and so forth). Unified CM also has a number of integrated applications that provide additional functionality, including:

- Cisco Extension Mobility (EM)

The Extension Mobility feature enables mobile users to configure a Cisco Unified IP Phone as their own, on a temporary basis, by logging in to that phone.

- Cisco Unified Communications Manager Assistant (Unified CM Assistant)

Unified CM Assistant is a Unified CM integrated application that enables assistants to handle one or more managers' incoming phone calls.

- Cisco WebDialer

WebDialer is a click-to-call application for Unified CM that enables users to place calls easily from their PCs using any supported phone device.

In some cases these integrated applications also invoke IP Phone Services to provide additional functionality.

This chapter examines the following Unified CM applications:

- [IP Phone Services, page 19-2](#)
- [Extension Mobility, page 19-7](#)
- [Unified CM Assistant, page 19-19](#)
- [WebDialer, page 19-32](#)
- [Attendant Consoles, page 19-42](#)

What's New in This Chapter

Table 19-1 lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Table 19-1 New or Changed Information Since the Previous Release of This Document

| New or Revised Topic | Described in | Revision Date |
|---|---|---------------|
| Cisco Extension Mobility Application service and Cisco Extension Mobility service | Extension Mobility, page 19-7 | June 2, 2011 |
| Attendant console capacity planning | Capacity Planning for Attendant Consoles, page 19-45 | April 2, 2010 |
| Extension Mobility Cross Cluster (EMCC) | Extension Mobility Cross Cluster (EMCC), page 19-9 Design Considerations for Extension Mobility Cross Cluster (EMCC), page 19-17 | April 2, 2010 |
| Secure IP Phone Services URL | IP Phone Services Architecture, page 19-2 | April 2, 2010 |

IP Phone Services

Cisco Unified IP Phone Services are applications that utilize the web client and/or server and XML capabilities of the Cisco Unified IP Phone. The Cisco Unified IP Phone firmware contains a micro-browser that enables limited web browsing capability. These phone service applications provide the potential for value-added services and productivity enhancement by running directly on the user's desktop phone. For purposes of this chapter, the term *phone service* refers to an application that transmits and receives content to and from the Cisco Unified IP Phone.

This section examines the following design aspects of the IP Phone Services feature:

- [IP Phone Services Architecture, page 19-2](#)
- [High Availability for IP Phone Services, page 19-5](#)
- [Capacity Planning for IP Phone Services, page 19-7](#)
- [Design Considerations for IP Phone Services, page 19-7](#)

IP Phone Services Architecture

An IP Phone service can be initiated in several ways:

- User-initiated (pull)

An IP Phone user presses the Services button, which sends an HTTP GET message to Unified CM for displaying a list of user-subscribed phone services. [Figure 19-1](#) illustrates this functionality.

- Phone-initiated (pull)

An idle time value can be set within the IP Phone firmware, as indicated by the URL Idle Time parameter. When this timeout value is exceeded, the IP Phone firmware itself initiates an HTTP GET to the idle URL location specified by the URL Idle parameter.

- Phone service-initiated (push)

A phone service application can push content to the IP Phone by sending an HTTP POST message to the phone.

Note

Unlike with the user-initiated and phone-initiated pull functionality, whereby the phone's web client is used to invoke phone services, the phone service-initiated push functionality invokes action on the phone by posting content (via an HTTP POST) to the phone's web server (not to its client).

Figure 19-1 shows a detailed illustration of the user-initiated IP Phone service operation. With Services Provisioning set to External URL when a user presses the Services button, an HTTP GET message is sent from the IP Phone to the Unified CM getservicesmenu.jsp script by default (step 1). You can specify a different script by changing the Phone URL enterprise parameter. The getservicesmenu.jsp script returns the list of phone service URL locations to which the individual user has subscribed (step 2). The HTTP response returns this list to the IP Phone (step 3). Any further phone service menu options chosen by the user continue the HTTP messaging between the user and the web server containing the selected phone service application (step 4).

Note

If the Service Provisioning enterprise parameter is set to Internal, steps 1 through 3 are bypassed and the operation of phone services begins with step 4.

Figure 19-1 User-Initiated IP Phone Service Architecture

153263

Figure 19-2 shows examples of both phone-initiated and phone service-initiated push functionality. In the phone-initiated example, the phone automatically sends an HTTP GET to the location specified under the URL Idle parameter when the URL Idle Time is reached. The HTTP GET is forwarded via Unified CM to the external web server. The web server sends back an HTTP Response, which is relayed by Unified CM back to the phone, and the phone displays the text and/or image on the screen.

In the phone service-initiated push example, the phone service on the external web server sends an HTTP POST with a Common Gateway Interface (CGI) or Execute call to the phone's web server. Before performing the CGI or Execute call, the phone authenticates the request using the proxy authentication service specified by the URL Authentication parameter. This proxy authentication service provides an interface between the phone and the Unified CM directory in order to validate requests made directly to the phone. If the request is authenticated, Unified CM forwards an HTTP Response to the phone. The phone's web server then performs the requested action, and the phone returns an HTTP response back to the external web server. If authentication fails, Unified CM forwards a negative HTTP Response, and the phone does not perform the requested CGI or Execute action but in turn forwards a negative HTTP Response to the external web server.

Figure 19-2 Phone-Initiated and Phone Service-Initiated IP Phone Service Architecture

In addition to XML Services, a new service can be created with a Service Category of Java MIDlet. When a Java MIDlet-type service is invoked, the configured Service URL contains the URL from which the MIDlet JAD file can be retrieved. When the application server receives the JAD file request, the server should return the appropriate JAR file for that device, which the phone's MIDlet-installer will download and process.

For more information on Java MIDlet support on Cisco IP Phones, refer to the Cisco IP Phone data sheets at <http://www.cisco.com>.

**Note**

After a phone has downloaded its configuration file via TFTP, the phone parses the services configuration to determine whether or not the list of services has changed, and if so, it updates its local (persisted) services configuration. If any of the changed services were Java MIDlets (which are explicitly provisioned and stored on the phone), then the phone sequentially walks through the necessary install, upgrade, downgrade, and uninstall operations to comply with what was provisioned in the configuration file. If a MIDlet install fails, it will re-attempt the install the next time the phone checks its configuration file (during boot, reset, or restart).

The administrator has the added ability to specify the Service Type of configured services to be one of the following: IP Phone Services, Directories, or Messages. This gives the administrator the flexibility to control which button users must press on the IP phone to access new services. New services can optionally be configured as Enterprise Subscriptions, which forces them to appear automatically on all IP phones without the need to update subscriptions for each individual phone. In addition, services can be enabled or disabled without the need to delete the service from the Unified CM database.

**Note**

Default services such as Missed Calls, Placed Calls, and Corporate Directory can also be disabled. This allows the administrator to create a custom service with a Service URL matching that of the corresponding default service, thus allowing phones to subscribe to these default services on an as-needed basis.

Unified CM 8.x provides the ability to configure a secure IP Phone Services URL using HTTPS in addition to a non-secure URL. Phones that support HTTPS will automatically use the secure URL. For more information about Trust Verification Services and security certificate handling for IP phones, along with a complete list of phones that support HTTPS, refer to the HTTPS information in the latest version of the *Cisco Unified Communications Manager Security Guide*, available at

http://cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

High Availability for IP Phone Services

To ensure reliable services for phone users, you must maintain a high level of system availability, with a seamless transition to redundant systems during a system failure.

With Services Provisioning set to Internal, the phone will receive its subscribed phone services from the phone's configuration file and store these (and their corresponding service URLs) in flash. This allows the phone to access the service URLs directly on a web server without first querying the Cisco CallManager IP Phone Service. With Services Provisioning set to Internal, the Corporate and Personal Directories default services also have an extra level of redundancy built into the phones. When these services are selected, the phone will attempt to send an HTTP message with the proper URL string to the Unified CM with which it is currently registered. Therefore, the Unified CM Group configuration of the phone's device pool provides redundancy for these services.

If Services Provisioning is set to External URL or both, while most of the back-end processing of a phone service occurs on a web server, the phones still depend upon Unified CM to inform them of the service URLs for their subscribed phone services. Given the architecture of IP phone service functionality and the message flows shown in [Figure 19-1](#) and [Figure 19-2](#), the following two main failure scenarios should be considered.

Failure Scenario 1: Server with Cisco CallManager Cisco IP Phone Services Fails

Redundancy in this case depends upon some type of server load balancing (SLB), as illustrated in [Figure 19-3](#), where a virtual IP address (or DNS-resolvable hostname) is used to point to one or more Unified CM servers. This virtual IP address (or DNS-resolvable hostname) is used when configuring the URL Services parameter. The SLB device is configured with the real IP addresses of the Unified CM subscriber nodes. Thus, a Unified CM server failure does not prevent the IP Phone Services subscription list from being returned to the phone when the phone's Services button is pushed. In addition, phone services such as Extension Mobility and Unified CM Assistant that run on a Unified CM server are also potentially made redundant by this method. (See [High Availability for Extension Mobility, page 19-14](#), and [High Availability for Unified CM Assistant, page 19-23](#).)

Most SLB devices, such as the Cisco Application Control Engine (ACE), can be configured to monitor the status of multiple servers and automatically redirect requests during failure events. For more information on the Cisco Application Control Engine (ACE), refer to the documentation available at

http://www.cisco.com/en/US/products/ps6906/tsd_products_support_model_home.html

Figure 19-3 Method for Providing Redundancy for Phone Services

Failure Scenario 2: External Web Server Hosting a Particular IP Phone Service Fails

In this scenario, the connection to the Unified CM server is preserved, but the link fails to the web server hosting the user-subscribed phone service. This is an easier scenario to provision for redundancy because the IP phone is still able to access the Unified CM server when the Services button is pressed. In this case, the IP phone is similar to any other HTTP client accessing a web server. As a result, you can again use some type of SLB functionality (similar to the one indicated in [Figure 19-3](#)) to redirect the HTTP request from the phone to one or more redundant web servers hosting the user-subscribed phone service.

Capacity Planning for IP Phone Services

Cisco Unified IP Phone Services act, for the most part, as an HTTP client. In most cases it uses Unified CM only as a redirect server to the location of the subscribed service. Because Unified CM acts as a redirect server to the phone service, there is minimal performance impact on Unified CM when a user initiates a phone service request by pressing the Services key.

**Note**

In the case of Extension Mobility and Unified CM Assistant phone service, Unified CM acts as more than a redirect server, and performance impacts should be considered. See the sections on [Extension Mobility, page 19-7](#), and [Unified CM Assistant, page 19-19](#), for specific performance and scalability considerations for these applications.

Because the IP Phone is either an HTTP client or server, estimating the required bandwidth used by an IP Phone service is similar to estimating the bandwidth of an HTTP browser accessing the same text as HTTP content residing on a web hosting server.

Design Considerations for IP Phone Services

With the exception of the integrated Extension Mobility and Unified CM Assistant applications' Phone Services, IP Phone services must reside on a separate off-cluster non-Unified CM web server. Running phone services other than Extension Mobility and Unified CM Assistant on the Unified CM server node is not supported.

Most Cisco IP phones support content with text and graphics. Some phones such as the Cisco Unified IP Phone 7911G support only text-based XML applications.

Extension Mobility

The Cisco Extension Mobility (EM) feature enables users to configure a Cisco Unified IP Phone as their own, on a temporary basis, by logging in to that phone. After a user logs in, the phone adopts the user's individual device profile information, including line numbers, speed dials, services links, and other user-specific properties of a phone. For example, when user X occupies a desk and logs in to the phone, that user's directory number(s), speed dials, and other properties appear on that phone; but when user Y uses the same desk at a different time, user Y's information appears. The EM feature dynamically configures a phone according to the authenticated user's device profile. The benefit of this application is that it allows users to be reached at their own extension on any phone within the Unified CM cluster, regardless of physical location, provided the phone supports EM.

This section examines the following design aspects of the Extension Mobility feature:

- [Unified CM Services for Extension Mobility, page 19-8](#)
- [Extension Mobility Architecture, page 19-8](#)
- [Extension Mobility Security, page 19-13](#)
- [Extension Mobility Cross Cluster \(EMCC\), page 19-9](#)
- [High Availability for Extension Mobility, page 19-14](#)
- [Capacity Planning for Extension Mobility, page 19-16](#)
- [Design Considerations for Extension Mobility, page 19-17](#)

Unified CM Services for Extension Mobility

The EM application relies on the Cisco Extension Mobility service, which is a feature service and which you must activate manually from the Serviceability page.

EM also relies on the following network services, which are activated automatically on all Unified CM nodes during installation:

- Cisco Extension Mobility Application
- Cisco CallManager Cisco IP Phone Services

The Cisco Extension Mobility Application service is a network service that provides an interface between the EM user phone and the Cisco Extension Mobility service. In addition, the Cisco Extension Mobility Application service subscribes to the change notification indications within the cluster and maintains a list of nodes in the cluster that have an active Cisco Extension Mobility service.

Extension Mobility Architecture

Figure 19-4 depicts the message flows and architecture of the EM application. When a phone user wants to access the EM application, the following sequence of events occurs:

1. When the user presses the Services button on the phone, this action generates a call to the URL specified under the URL Services parameter on the Enterprise Parameter configuration page (see step 1 in Figure 19-4).
2. An HTTP/XML call is generated to the IP Phone Services, which returns a list of all services to which the user's phone is subscribed (see step 2 in Figure 19-4).

Note

With the Services Provisioning enterprise parameter set to Internal, steps 1 and 2 are bypassed. Alternatively, with Services Provisioning set to External URL or Both, a Service URL button can be configured for EM on a user's phone so that the user can press a line or speed-dial button to generate a direct call to the Cisco Extension Mobility Application service, also bypassing steps 1 and 2.

3. Next the user selects the Extension Mobility phone service listing. This selection in turn generates an HTTP call to the Cisco Extension Mobility Application service, which serves as the interface between the phone and the Cisco Extension Mobility service (see step 3 in Figure 19-4).
4. The Cisco Extension Mobility Application service then forwards an XML response back to the phone requesting user login credentials (userID and PIN) or, if the user is already logged in, a response asking if the user wants to log off the phone (see step 4 in Figure 19-4).
5. Assuming the user is attempting to log in, the user must use the phone's keypad to enter a valid userID and PIN. After the user presses the Submit softkey, a response containing the userID and PIN just entered is forwarded back to the Cisco Extension Mobility Application service (see step 5 in Figure 19-4).
6. The Cisco Extension Mobility Application service next forwards this login information to the Cisco Extension Mobility service, which interacts with the Unified CM database to verify the user's credentials (see step 6 in Figure 19-4). The Cisco Extension Mobility Application service subscribes to cluster change notification, and it maintains a list of all nodes in the cluster with the Cisco Extension Mobility service activated. Therefore, in case the Cisco Extension Mobility service is not running on the same Unified CM node, the Cisco Extension Mobility Application service forwards the login information to other Unified CM nodes that are running the Cisco Extension Mobility service.

7. Upon successful verification of the user's credentials, the Cisco Extension Mobility service also interacts with the Unified CM database to read and select the appropriate user device profile and to write needed changes to the phone configuration based on this device profile (see step 7 in Figure 19-4).
8. Once these changes have been made, the Cisco Extension Mobility service sends back a successful response to the Cisco Extension Mobility Application service (see step 8 in Figure 19-4).
9. The Cisco Extension Mobility Application service, in turn, sends a reset message to the phone, and the phone resets and accepts the new phone configuration (see step 9 in Figure 19-4).

Figure 19-4 EM Application Architecture and Message Flow

Extension Mobility Cross Cluster (EMCC)

Unified CM 8.x provides the ability to perform Extension Mobility logins between clusters within an enterprise with a new feature called Extension Mobility Cross Cluster (EMCC). It is important to understand the high-level architecture of EMCC. The EMCC feature employs the concepts of a home cluster and a visiting cluster, and these terms are defined from the perspective of the user performing the login. When a user travels to an office and attempts to log in to a phone, if the cluster to which this phone

is registered does not contain the user's information in its database, then this cluster is considered a visiting cluster and the phone is hereinafter referred to as the visiting phone. Figure 19-5 illustrates the concept of home and visiting clusters.

Figure 19-5 EMCC Home Cluster and Visiting Cluster

The EM service in the visiting cluster attempts to locate the home cluster of the user by sending out queries to each of the EMCC remote clusters that have been configured in Unified CM. When the user's home cluster responds positively, this initiates communications between the EM services of both clusters to exchange information that essentially brings the device information into the home cluster database and allows the home cluster to build a configuration file for this visiting phone. This configuration file incorporates some device configuration from the visiting cluster, configuration parameters from the home cluster, and the user's device profile in the home cluster. Once the home cluster TFTP server has a configuration file for this visiting phone, a reset issued by the visiting cluster forces the visiting phone to download a small configuration from the visiting cluster, which further instructs it to download a full configuration from the home cluster. Ultimately, the visiting phone cross-registers with the home cluster. This means that all call control signaling occurs between a home cluster Unified CM subscriber and the visiting phone, and the user's home cluster dialing habits are maintained.

For a step-by-step description of the EMCC login process, refer to the Extension Mobility Cross Cluster information in the latest version of the *Cisco Unified Communications Manager Features and Services Guide*, available at

http://cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

Call Processing

EMCC call processing behavior is also critical to understand because it impacts dial plan design. When a user has logged into a phone in a visiting cluster, any digits dialed by the user are analyzed by the home cluster according to the visiting phone's assembled call search space (CSS), which is a concatenation of the Adjunct CSS in the home cluster's device pool for the visiting phone (referred to as the EMCC

roaming device pool), the Line CSS configured on the directory number associated with the user's device profile, and the EMCC CSS configured on the user's device profile. Figure 19-6 illustrates the resulting CSS for an EMCC phone.

Figure 19-6 Resulting CSS for an EMCC Phone

The Adjunct Calling Search Space is a new call routing configuration parameter that is used by EMCC to intercept and route emergency numbers for users from a visiting cluster. The Adjunct CSS contains a partition with directory numbers such as 911, 112, or 999, that route the calls to the visiting cluster and allow the call to reach emergency services local to the physical phone's location. For more information on Adjunct Calling Search Spaces and the EMCC roaming device pool and how it is associated with a visiting phone, refer to the Extension Mobility Cross Cluster information in the latest version of the *Cisco Unified Communications Manager Features and Services Guide*, available at

http://cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

Note

The EMCC roaming device pool associated with the EMCC feature is not related to the roaming device pool associated with the Device Mobility feature.

EMCC users must be aware that, when placing calls, they will be leveraging their home Unified CM routes and numbering plan. For example, if a user from Cluster A logs into a phone from Cluster B and wants to place a call to the directory number of a Cluster B phone located right next to it, the user would have to dial the appropriate pattern as if the user was placing the call from Cluster A to the phone in Cluster B. This implies that the home cluster may initiate an intercluster trunk call from Cluster A to Cluster B, but the media will flow locally between the visiting phone and the remote phone.

If the EMCC clusters have been deployed using +E.164 numbering, then the users should already be accustomed to dialing the full number of the target number and will not need to alter their dialing habits.

With PSTN routed calls, there are two different configurations that affect call processing behavior:

- Route patterns that do not use the Local Route Group (LRG) feature
- Route patterns that use the LRG feature

When an EMCC logged-in user dials a PSTN call, if the digit analysis matches a route pattern that ultimately leads to a voice gateway (either via the route list and route group construct or configured directly to a voice gateway), the call is offered out the gateway. If the Standard Local Route Group

(Standard LRG) feature is not in use, and the call involves a voice gateway associated with the home cluster; therefore media will flow between the visiting phone (typically across a WAN) back to the voice gateway. When the route pattern leads to a route list configured to use Standard LRG, the behavior changes. (For more information about LRG, see [Local Route Group, page 9-97](#).) When Unified CM logic must invoke a Standard LRG for an EMCC logged-in device, it recognizes the endpoint as an EMCC device and sends the PSTN call across a designated EMCC-specific SIP trunk to the visiting cluster to which this visiting phone is normally registered.

**Note**

Only one SIP trunk with an EMCC trunk service type is required per cluster. There is no destination information configured on this trunk; that information is gathered dynamically when adding and updating an EMCC remote cluster.

When a call invite is received on the EMCC SIP trunk in the visiting cluster, the visiting cluster again performs digit analysis on the called number according to the CSS of the trunk (or alternatively, according to the CSS of the visiting phone's original device configuration), and routes the call accordingly. There is additional information included in a SIP invite across an EMCC SIP trunk, namely the device name of the visiting phone. This enables the visiting cluster to determine the configured device CSS of the visiting phone in the database (if required); and if the digit analysis results in matching a route pattern that ultimately points to the Standard LRG, the visiting cluster is able to determine the configured Standard LRG for this visiting phone. The Standard LRG in the visiting cluster will typically contain voice gateways associated with the visiting cluster, therefore the PSTN call is offered out a voice gateway local to the visiting phone.

The difference between LRG and non-LRG call processing behavior is critical when considering calls to emergency numbers. While the use of Local Route Groups (LRGs) is not required cluster-wide for an EMCC deployment, the EMCC logged-in phones must have access to an LRG in order to route emergency calls correctly. An LRG is required to correctly route an emergency call to a visiting cluster so that the call can be placed through an appropriate voice gateway local to the visiting phone. The Adjunct Calling Search Space in the roaming device pool configuration for an EMCC device enables an administrator to add emergency route patterns that will use an LRG for EMCC logged-in devices, but it will not affect emergency dialing for other devices in the home cluster. As discussed earlier, an EMCC logged-in phone will be associated with a device pool (by means of geolocations) that represents all phone devices from another cluster. The device pool's Adjunct Calling Search Space allows for the visiting cluster's emergency route pattern to be configured so that only emergency calls for an EMCC logged-in phone will be sent through an LRG. So even if the home and visiting clusters use the same emergency route pattern, the EMCC logged-in phone's emergency call will route through the LRG to the visiting cluster. Once the call is received at the visiting cluster through the EMCC SIP trunk, the visiting cluster dial plan will be responsible for further processing of the call.

**Note**

If any cluster supporting EMCC is also using Cisco Emergency Responder for emergency call processing, refer to the *Cisco Emergency Responder Administration Guide* for information on how to configure the dial plan to support the deployment, available at http://www.cisco.com/en/US/products/sw/voicesw/ps842/prod_maintenance_guides_list.html.

**Note**

If Standard LRGs are already deployed for the emergency route pattern, and if the home and visiting clusters use the same emergency dial string, use of the Adjunct CSS is not required.

For detailed EMCC call processing examples and configuration, refer to the Extension Mobility Cross Cluster information in the latest version of the *Cisco Unified Communications Manager Features and Services Guide*, available at

http://cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

Media Resources

All media resources except for RSVP agents are allocated from the home cluster according to the media resource group list of the device pool assigned to the visiting phone. Conferencing, transcoding, and music on hold all function as normal, with the difference being that media is streaming between the visiting phone and media resources across (typically) a WAN separating the home and visiting clusters. When an EMCC logged-in user makes a call that requires use of an RSVP agent, the Unified CM EMCC logic is able to determine it is a visiting phone, and it sends a resource request across the EMCC SIP trunk to the remote cluster to which the visiting phone belongs. The device name of the visiting phone is included in this request, which enables the visiting cluster to verify the RSVP agent media resources that are normally assigned to this visiting phone and to allocate its use for the call. For more information on RSVP-based call admission control for EMCC, see [Architecture and Considerations for Extension Mobility Cross Cluster](#), page 11-59.

Extension Mobility Security

Unified CM 8.x provides the ability to create an Extension Mobility secure service URL using HTTPS. This encrypts the entire EM login/logout exchange. Cisco recommends configuring a secure service URL for Extension Mobility. If there are phones deployed for EM that do not support HTTPS, a non-secure service URL must also be configured. When secure and non-secure service URLs exist for the service, phones that support HTTPS use the secure service URL by default. For a complete list of phones that support HTTPS, refer to the HTTPS information in the latest version of the *Cisco Unified Communications Manager Security Guide*, available at

http://cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

The EM feature provides an optional level of security for EM login and logout requests by validating the source IP address of the request. By default, EM does not perform this request validation; therefore, to enable EM security, the administrator must set the cluster-wide service parameter Validate IP Address to true.

For organizations that implement a web proxy to handle EM login and logout HTTP requests, the Allow Proxy service parameter must be set to true. A proxy server, while forwarding the HTTP request, will set the via-field of the HTTP header with its hostname. If there are multiple proxy servers between the device and Unified CM, and if the request is forwarded by all the servers, then the via-field in the HTTP header will have a comma-separated list of hostnames for each of the proxy servers in the forwarding path. The Allow Proxy service parameter, if set to true, will allow EM login and logouts received via a web proxy. In addition, if the proxied EM requests use the source IP address of the proxy server, this IP address must also be configured in the Trusted List of IPs service parameter.

With the introduction of HTTPS support and Security By Default in Unified CM 8.x, the intercluster interactions of EMCC require some extra steps to ensure that clusters can communicate with each other in a secure manner. In particular, all clusters that participate in EMCC must export their Tomcat (web) and TFTP security certificates to a central sFTP server, the certificates will all be combined, and then each cluster must import the combined certificate into its cluster. It is important to remember that any time a new node that may participate in EMCC is added to the cluster, or if a certificate on any existing node is updated, the process of exporting, combining, and importing must be repeated. All of these steps

have been streamlined via Unified CM Serviceability administration. For details on EMCC configuration, refer to the Extension Mobility Cross Cluster information in the latest version of the *Cisco Unified Communications Manager Features and Services Guide*, available at

http://cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

High Availability for Extension Mobility

According to the EM architecture illustrated in [Figure 19-4](#), reads and writes to the Unified CM database are required. EM is a user-facing feature, and database writes pertaining to EM can be performed by subscriber nodes. Therefore, if the Unified CM publisher is unavailable, EM logins and logouts are still possible.

From a redundancy perspective, the following component levels of redundancy must be considered for full EM resiliency:

- Cisco CallManager Cisco IP Phone Services

High availability for the CallManager Cisco IP Phone Services is obtained by using the Services Provisioning service parameter or by using an SLB device pointing to multiple Unified CM nodes running the Cisco CallManager Cisco IP Phone Services. For more details, see [High Availability for IP Phone Services, page 19-5](#).

- Cisco Extension Mobility service

High availability for the Cisco Extension Mobility service is obtained by activating the Cisco Extension Mobility service on multiple Unified CM nodes.

Note While the Cisco Extension Mobility service can be activated on more than two nodes, a maximum of two nodes can actively handle login/logout requests at any given time. The other nodes running the Cisco Extension Mobility service should start handling login/logout requests only in case of failure.

Cisco recommends deploying a server load balancer device such as the Cisco Application Control Engine (ACE) to load-balance the requests across two Unified CM nodes and to provide redundancy. Without a server load balancer, load balancing would be uneven and the redundancy would be manual. For example, two EM IP Phone services could be configured on each phone. If one Unified CM node is not reachable, the end user would have to manually select the other EM IP Phone service to reach the other node.

Note

While it is possible to provide redundancy for the EM IP Phone service by relying on end users to manually select an EM IP Phone service from a list of EM IP Phone services, achieving high availability in this manner can be problematic. Because there is no control over which EM IP Phone service a user might select from the phone services menu (or assigned feature keys), there is no way to ensure that the EM login/logout load is balanced between Unified CM nodes handling EM login/logout requests. Further, end user behavior when encountering delay in response of the EM service, which is typical in a failure scenario, will usually exacerbate the situation as users cancel EM service calls and select alternate EM IP Phone service. This can lead to added congestion and load on the network as well as on the remaining Unified CM node handling EM login/logout requests.

A deployment with two Unified CM nodes running the Cisco Extension Mobility service provides the highest capacity in terms of number of login/logout requests per minute. (See [Capacity Planning for Extension Mobility, page 19-16](#), for details.) It also provides redundancy. However, in case of failure,

the login/logout request capacity is reduced because there is only one node left. Therefore, to achieve the highest login/logout capacity and maintain this capacity in case of failure, the Cisco Extension Mobility service should be activated on additional Unified CM nodes. To load balance evenly across the active nodes and to ensure that only two nodes are handling login/logout requests at any given time, a server load balancer device such as the Cisco Application Control Engine (ACE) should be deployed. The Cisco Application Control Engine has the capability to detect if a primary server is down and to start sending requests to backup servers in case of failure. For details on the Cisco Application Control Engine (ACE) configuration, refer to the documentation available at

http://www.cisco.com/en/US/products/ps6906/tsd_products_support_model_home.html

**Note**

Cisco does not recommend a redundancy design using DNS A or SRV records with multiple IP listings. With multiple IP addresses returned to a DNS request, the phones must wait for a timeout period before trying the next IP address in the list, and in most cases this results in unacceptable delays to the end user. In addition, this can result in more than two subscriber nodes with the Cisco Extension Mobility Application service enabled to handle login/logout requests, which is not supported.

With EMCC, remote clusters are administratively added via Unified CM web administration by specifying a single FQDN or IP address of a Unified CM subscriber node running the EM service in the remote cluster. The EM services between the two clusters provide information about the Unified CM version, an ordered list of EM Service nodes for EMCC EM Service communications, which EMCC SIP trunk services are enabled (PSTN Access and/or RSVP Agent) in the remote cluster, and an ordered list of up to three remote Unified CM nodes that handle EMCC SIP trunk operations for each EMCC service. EMCC EM service communications over HTTPS include locating users' home clusters, exchanging information during EMCC logins, and remote cluster updates. Upon an initial update, a remote cluster's Extension Mobility Application service is queried, which will return the first three EM Service nodes in its list. This ordered list determines which remote cluster EM Service nodes will be used for EMCC communications.

The remote cluster obtains the information regarding primary, secondary, and tertiary options for EMCC PSTN Access and RSVP Agent services from the Unified CM Group that is associated with the device pool of the assigned EMCC SIP trunk for those services. This ensures that, if the primary Unified CM subscriber handling the EMCC SIP trunk is offline, then the EMCC SIP trunk call will be handled by the secondary Unified CM subscriber, and so on.

Once a phone is logged in through EMCC, redundancy is provided for the phone in the form of the Unified CM Group configured in its assigned EMCC device pool. If the visiting phone is located in a remote site and there is a WAN outage in which both the visiting and home cluster are unreachable, then the SRST reference from the visiting cluster is maintained by the EMCC phone. Therefore, an EMCC logged-in phone will still be able to register with the appropriate SRST router in the site where it is located. The EMCC logged-in user's DID most likely will not be associated with the local gateway(s) at the SRST site, so incoming calls will still be routed based on the call forwarding rules on the user's home cluster. While in SRST mode, the user will also have to adapt to the visiting SRST site's configured dial habits during SRST failover registration. For additional examples of an EMCC logged-in phone's behavior during a networking failure, refer to the Cisco Extension Mobility Cross Cluster section in the *Cisco Unified Communications Manager Features and Services Guide*, available at

http://cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

Cisco also recommends configuring a default and backup Unified CM TFTP server to be used for visiting phones to download EMCC configuration files that will allow them to register with the home cluster. This is configured under EMCC Feature Configuration.

Capacity Planning for Extension Mobility

The Cisco EM application supports the following cluster-wide login and logout capacities:

- Maximum of 250 sequential logins and/or logouts per minute with the Cisco MCS 7845-H2/I2 server.
- Maximum of 235 sequential logins and/or logouts per minute with the Cisco MCS 7835-H2/I2 server.
- Maximum of 200 sequential logins and/or logouts per minute with the Cisco MCS 7825-H2/I2 server.

Note

Deploying earlier server models will result in diminished capacity.

Cisco Extension Mobility login and logout functionality can be distributed across a pair of subscriber nodes to increase login/logout cluster capacity. An SLB device can be used, or to manually distribute the EM load evenly between the two subscriber nodes, the phones should be divided into two groups, with one group of phones subscribed to an EM phone service pointing to one of the subscriber nodes and the other group of phones subscribed to a second EM phone service that is pointing to a second subscriber node. When the EM load is distributed in this way, evenly between two MCS 7845-H2/I2 servers, the maximum cluster-wide capacity is 375 sequential logins and/or logouts per minute.

Note

The Cisco Extension Mobility service can be activated on more than two nodes for redundancy purposes, but Cisco supports a maximum of two subscriber nodes actively handling logins/logouts at any given time.

Note

Enabling EM Security does not diminish performance.

The EMCC login/logout process requires more processing resources than intracluster EM login/logout, therefore the maximum supported login/logout rates are lower. In the absence of any intracluster EM logins/logouts, Unified CM 8.x supports a maximum rate of 75 EMCC logins/logouts per minute with Cisco MCS 7845-H2/I2 and MCS 7845-I3 servers. Most deployments will have a combination of intracluster and intercluster logins/logouts occurring. For this more common scenario, the mix of EMCC logins/logouts (whether acting as home cluster or visiting cluster) should be modeled for 40 per minute while the intracluster EM logins should be modeled for 185 logins/logouts when using a single EM login server. The intracluster EM login rate can be increased to 280 login/logouts per minute when using MCS 7845-H2/I2 or MCS 7845-I3 servers in dual EM service configuration. (See [Table 19-2](#).)

Table 19-2 Maximum Number of Intracluster and Intercluster Logins/Logouts

| Type of Login/Logout | Single EM Login Server (I2/H2) | Dual EM Login Servers (I2/H2) |
|-------------------------------|--------------------------------|-------------------------------|
| Intracluster only | 250 | 375 |
| Intercluster only | 75 | 90 |
| Intercluster and intracluster | 225 (40 EMCC and 185 EM) | 320 (40 EMCC and 280 EM) |

EMCC logged-in devices (visiting phones) consume twice as many resources as any other endpoint in a cluster. The maximum supported number of EMCC logged-in devices is 2,500 per cluster, but this also decreases the theoretical maximum number of other devices per cluster from 30,000 to 25,000. Even if the number of other registered devices in the cluster is reduced, the maximum supported number of EMCC logged-in devices is still 2,500.

There is no technical limit to the number of EMCC remote clusters that can be added to a cluster; however, the full-mesh requirement will increase the load on the EM service as the number of remote clusters increases. For a high number of sites (more than 10), the EM CPU should be monitored by means of the Cisco Real-Time Monitoring Tool (RTMT).

Design Considerations for Extension Mobility

The following guidelines and restrictions apply with regard to the deployment and operation of EM within the Unified CM telephony environment:

- EM users should not move between locations or sites within a cluster when Automated Alternate Routing (AAR) and/or the Voice over PSTN (VoPSTN) deployment model are in use.

EM functionality relies on the use of the IP network for routing calls. Call routing via the PSTN is more problematic because E.164 PSTN numbers are static and the PSTN is unable to account for movement of EM user directory numbers (DNs) from their home sites. AAR relies on the PSTN for call routing, as does the VoPSTN deployment model. In both cases, EM user movement between locations and sites is supported only if all sites the user is traversing are in the same AAR group. For additional information, see [Extension Mobility, page 9-114](#).

- Restarting the Cisco Extension Mobility service or the node on which the service is running will affect auto-logout settings.

If the Cisco Extension Mobility service is stopped or restarted, the system does not auto-logout users who are already logged in after the expiration of the maximum login interval. These phones will either have to be logged out manually or wait until the daily database clean-up process runs (typically at midnight).

WebDialer supports the use of phones logged in using Extension Mobility. For more information, please see [WebDialer, page 19-32](#).

Design Considerations for Extension Mobility Cross Cluster (EMCC)

The following design considerations apply when deploying EMCC.

General Design Considerations

- EMCC requires that all users must be unique across all clusters in the enterprise. If LDAP synchronization is maintaining common users for multiple clusters, some type of filtering must be applied.
- Consider the network delay between clusters in combination with the features you plan to use. As the visiting phone is registered with the home cluster, features will work. However, depending on the network delay for a given deployment, all applications and features might not meet user requirements. Testing might be required to determine the usability of features for a given network.

For example, EMCC supports dynamic CTI control of a visiting phone. But if an offhook is issued via an application and it takes 1 second before the phone goes offhook, this might be acceptable for an office worker but might not be acceptable for a call center agent.

- Phone load firmware is not enforced during the login process. Instead, the visiting cluster phone load information is maintained so that cross-registration does not result in new phone firmware downloads.
- If the home cluster locale is different than that of the visiting cluster, the phone will download the new locale from the visiting cluster TFTP server. If it is not available, then the phone will not change locales and instead will maintain the visiting cluster locale.
- DLUs are not consumed in the home cluster for the registered visiting phones.
- The total number of EMCC logins is controlled by the total number of EMCC inserted devices in the Bulk Administration Tool (BAT).
- EMCC supports non-secure clusters and mixed-mode clusters. However, all participating EMCC clusters must be of the same mode, and only non-secure phones are supported for EMCC registration.
- EMCC supports only RSVP-based call admission control. Unified CM locations-based call admission control is not supported.
- Except for RSVP agents, all other media resources are allocated from the home cluster according to the media resource group list associated with the EMCC roaming device pool.
- Audio and video codecs are determined by the EMCC region settings. These settings override normal region configuration for EMCC registered phones. All EMCC region parameters must be configured with the same values in all clusters. If they are different, RSVP Agent for that cluster will be disabled by the remote cluster update operation.
- For the EMCC roaming device pool to be assigned correctly, EMCC-capable phones must have a geo-location configured via device configuration or a device pool.

Call Processing Design Considerations

- Incoming calls for a user's directory number will always be received on a home cluster voice gateway, therefore RTP media will flow between the visiting phone and the home gateway for incoming calls.
- Calls sent across the EMCC SIP trunk will have gone through digit manipulation in the home cluster. The called number may require manipulation to match visiting cluster route patterns.
- Verify configured codec capabilities of H.323 and SIP gateways in the home cluster. For example, if home cluster gateways are configured to accept only G.711 calls and the EMCC region bandwidth is set to 8 kbps (G.729), a transcoder is required to complete the call. Alternatively, the H.323 or SIP gateway dial peers may be configured to allow for G.729 in addition to G.711.
- Design considerations must be made regarding the calling party for EMCC emergency calls. Depending on dial plan configurations, the calling party number leaving the visiting cluster gateway may be the user's DID that is normally associated with the home cluster. This would require transforming the calling number incoming on the EMCC SIP trunk, on route patterns, or egressing on the visiting gateways.
- When EMCC is deployed with Cisco Emergency Responder, Emergency Responder should be deployed in all clusters handled by a single Emergency Responder cluster. If the visiting cluster is deployed with Emergency Responder and the home cluster is not, Emergency Responder will not be able to identify the visiting phone when the call arrives back to the visiting cluster.

Unified CM Assistant

Cisco Unified Communications Manager Assistant (Unified CM Assistant) is a Unified CM integrated application that enables assistants to handle incoming calls on behalf of one or more managers. With the use of the Unified CM Assistant Console desktop application or the Unified CM Assistant Console phone service on the assistant phone, assistants can quickly determine a manager's status and determine what to do with a call. Assistants can manipulate calls using their phone's softkeys and service menus or via the PC interface with either keyboard shortcuts, drop-down menus, or by dragging and dropping calls to the managers' proxy lines.

This section examines the following design aspects of the Unified CM Assistant feature:

- [Unified CM Assistant Architecture, page 19-19](#)
- [High Availability for Unified CM Assistant, page 19-23](#)
- [Capacity Planning for Unified CM Assistant, page 19-25](#)
- [Design Considerations for Unified CM Assistant, page 19-27](#)
- [Unified CM Assistant Console, page 19-31](#)

Unified CM Assistant Architecture

The Unified CM Assistant application can operate in two modes: proxy line mode and shared line mode. The operation and functionality of each mode is different, and each has specific advantages and disadvantages. Both modes can be configured within a single cluster. However, mixing modes on the same assistant is not allowed. A single assistant providing support for one or more managers can support those managers in either shared line mode or proxy line mode.

Unified CM Assistant Proxy Line Mode

[Figure 19-7](#) illustrates a simple call flow with Unified CM Assistant in proxy line mode. In this example, Phone A calls the Manager phone with directory number (DN) 60001 (step 1). The CTI/Unified CM Assistant Route Point (RP) intercepts this call based on a configured DN of 6XXXX. Next, based on the Manager DN, the call is redirected by the route point to the Manager's proxy line (DN: 39001) on the Assistant's phone (step 2). The Assistant can then answer or handle the call and, if appropriate, redirect the call to the Manager's phone (step 3). In the event of Unified CM Assistant application failure or if the Unified CM Assistant RP fails, a fall-through mechanism exists via the Call Forward No Answer (CFNA) 6XXXX configuration of the RP, so that calls to the Manager's DN will fall-through directly to the Manager's phone (step 4).

Figure 19-7 Unified CM Assistant Proxy Line Mode

**Note**

The CFNA fall-through mechanism illustrated in [Figure 19-7](#) requires configuration of the same summarized digit-string as the Unified CM Assistant RP directory number in both the Forward No Answer Internal and Forward No Answer External fields under the Unified CM Assistant RP directory number configuration page. In addition, the calling search space (CSS) field for each of these call forward parameters should be configured with the calling search space containing the partition with which the Manager phone DNs are configured, so that the Manager phone DNs can be reached if the Unified CM Assistant RP or Unified CM Assistant application fails.

Unified CM Assistant Share Lined Mode

[Figure 19-8](#) illustrates a simple call flow with Unified CM Assistant in shared line mode. In this example, Phone A calls the Manager phone with directory number (DN) 60001, which is a shared line on the Assistant phone (step 1). The call will ring at both the Assistant and Manager phones unless the Manager has invoked the Do Not Disturb (DND) feature, in which case the Assistant's phone will be the only phone that rings audibly (step 2).

Figure 19-8 Unified CM Assistant Shared Line Mode

In Unified CM Assistant shared line mode, the Unified CM Assistant RP is not needed or required for intercepting calls to the Manager phone. However, the Do Not Disturb (DND) feature on the Manager phone and the Unified CM Assistant Console desktop application still depend on the Cisco IP Manager Assistant and Cisco CTIManager services. Furthermore, in Unified CM Assistant shared line mode, features such as call filtering, call intercept, assistant selection, and Assistant Watch are not available.

Unified CM Assistant Architecture

The architecture of the Unified CM Assistant application is as important to understand as its functionality. [Figure 19-9](#) depicts the message flows and architecture of Unified CM Assistant. When Unified CM Assistant has been configured for Unified CM Assistant Manager and Assistant users, the following sequence of interactions and events can occur:

1. Manager and Assistant phones register with the Cisco CallManager Service, and the phone's keypad and softkeys are used to handle call flows (see step 1 in [Figure 19-9](#)).
2. Both the Unified CM Assistant Console desktop application and the Manager Configuration web-based application communicate and interface with the Cisco IP Manager Assistant service (see step 2 in [Figure 19-9](#)).
3. The Cisco IP Manager Assistant service in turn interacts with the CTIManager service for exchanging line monitoring and phone control information (see step 3 in [Figure 19-9](#)).
4. The CTIManager service passes Unified CM Assistant phone control information to the Cisco CallManager service and also controls the Unified CM Assistant RP (see step 4 in [Figure 19-9](#)).
5. In parallel, the Cisco IP Manager Assistant service reads and writes Unified CM Assistant application information to and from the Unified CM database (see step 5 in [Figure 19-9](#)).
6. The Manager may choose to invoke the Unified CM Assistant phone service by pushing the Services button, thus generating a call to the IP Phone Services service that will return a list of all services (including the Unified CM Assistant phone service) to which the phone is subscribed (see step 6 in [Figure 19-9](#)).

The Unified CM Assistant phone service is controlled by the Cisco IP Manager Assistant service, and configuration changes made by the Manager using the phone are handled and propagated via the Cisco IP Manager Assistant service.

**Note**

With the Services Provisioning enterprise parameter set to Internal, steps 1 and 2 are bypassed. Alternatively, with Services Provisioning set to External URL or Both, a Service URL button can be configured for the Unified CM Assistant phone service on a user's phone so that the user can press a line or speed-dial button to generate a direct call to the Cisco IP Manager Assistant service, also bypassing steps 1 and 2.

Figure 19-9 Unified CM Assistant Architecture

**Note**

While [Figure 19-9](#) shows the IP Phone Services, Cisco CallManager, CTIManager, and Cisco IP Manager Assistant services all running on the same node, this configuration is not a requirement. These services can be distributed between multiple nodes in the cluster but have been shown on the same node here for ease of explanation.

High Availability for Unified CM Assistant

Unified CM Assistant application redundancy can be provided at two levels:

- Redundancy at the component and service level

At this level, redundancy must be considered with regard to Unified CM Assistant service or server redundancy and CTIManager service redundancy. Likewise, the lack of publisher redundancy and the impact of this component failing should also be considered.

- Redundancy at the device and reachability level

At this level, redundancy should be considered as it relates to Assistant and Manager phones, the Unified CM Assistant route point, and the Unified CM Assistant Console desktop application and phone service, as well as redundancy in terms of Assistant and Manager reachability.

Service and Component Redundancy

As shown in [Figure 19-9](#), Unified CM Assistant functionality is primarily dependent on the Cisco IP Manager Assistant service and the Cisco CTIManager service. In both cases, redundancy is automatically built-in using a primary and backup mechanism. Up to three pairs of active and backup Unified CM Assistant servers (nodes running the Cisco IP Manager service) can be defined, for a total of six Unified CM Assistant servers within a single cluster. Active and backup Unified CM Assistant server pairs are configured using the Cisco IPMA Server IP Address, Pool 2 Cisco IPMA Server IP Address, and Pool 3 Cisco IPMA Server IP Address service parameters. With the configuration of these parameters, the required Cisco IP Manager service is made redundant. Given a failure of any of the primary Unified CM Assistant servers, the backup or standby Unified CM Assistant servers are able to handle Unified CM Assistant service requests. For each pair of Unified CM Assistant servers, only one Unified CM Assistant server can be active and handling request at a given time, while the other Unified CM Assistant server will be in a standby state and will not handle requests unless the active server fails.

In addition, two CTIManager servers or services can be defined for each Unified CM Assistant server using the CTIManager (Primary) IP Address and CTIManager (Backup) IP Address service parameters. By configuring these parameters, you can make the CTIManager service redundant. Thus, given a failure of a primary CTIManager, CTIManager services can still be provided by the backup CTIManager. If all Cisco IP Manager Assistant and CTIManager services on cluster nodes fail, the Unified CM Assistant route point, Unified CM Assistant Console desktop application and phone service, and in turn the Unified CM Assistant application as a whole will fail. However as noted previously, given a failure of the Unified CM Assistant application, the CFNA fall-through mechanism will continue to work, allowing calls to a Manager to be routed directly to the Manager's phone.

Note

If configured in Unified CM Assistant shared-line mode, a complete failure of Cisco IP Manager Assistant and CTIManager service will not keep the Assistant from continuing to handle calls on behalf of the Manager because the phones will continue to share a line. However, the Unified CM Assistant Console desktop application and phone service and the DND feature will not be available.

[Figure 19-10](#) shows an example redundancy configuration for Unified CM Assistant and CTIManager primary and backup servers in a two-site deployment with clustering over the WAN. In order to provide maximum redundancy, a node at Site 1 is configured as the primary Unified CM Assistant server and a node at Site 2 is configured as the backup Unified CM Assistant server. In the event of a WAN failure, the backup Unified CM Assistant server at Site 2 will become a primary Unified CM Assistant server because the existing primary Unified CM Assistant server will be unreachable from Site 2. In this way, Unified CM Assistant servers can be made redundant in the clustering-over-the-WAN environment

given a WAN failure. Furthermore, with a primary and backup CTIManager configured at both Site 1 and Site 2, CTIManager is made redundant given a WAN failure, and additional redundancy is provided for a CTIManager failure at each site.

Note

The redundancy scenario depicted in Figure 19-10 shows a special circumstance. During normal operation it is not possible to have any pair of Unified CM Assistant servers active at the same time. If an active and backup pair of Unified CM Assistant servers can communicate over the network, then one server will be in backup mode and cannot handle requests.

Figure 19-10 Unified CM Assistant Redundancy with Two-Site Clustering over the WAN

As previously mentioned, the publisher is a single point of failure when it comes to writing Unified CM Assistant information to the Unified CM database. Given a publisher failure, all aspects of the Unified CM Assistant application will continue to work; however, no changes to the Unified CM Assistant application configuration can be made. Configuration changes via the Unified CM Assistant Console desktop application, the Manager configuration web-based application, the phone softkeys, or the Unified CM Assistant phone service, will not be possible until the publisher is restored. This condition includes enabling or disabling features such as Do Not Disturb, DivertAll, Assistant Watch, and call filtering, as well as changing call filter and assistant selection configuration.

Device and Reachability Redundancy

Redundancy for Unified CM Assistant at the devices level relies on a number of mechanisms. First and foremost, manager and assistant phones as well as the Unified CM Assistant RP rely on the built-in redundancy provided by a combination of the device pool and Unified CM group configuration for device registration.

In addition, some devices rely on component services for additional redundancy and functionality. For example, the Unified CM Assistant RP also relies on CTIManager for call control functionality and therefore must rely on the primary and back CTIManager mechanism described in the previous section. The Unified CM Assistant Console desktop application also relies on the component services for redundancy and functionality. The Assistant Console desktop application supports automatic failover from the primary to the backup Unified CM Assistant server (and vice versa) in order to continue to handle incoming calls for managers. The amount of time this automatic failover will take can be controlled using the Cisco IPMA Assistant Console Heartbeat Interval and the Cisco IPMA Assistant Console Request Timeout service parameters. Although the heartbeat or keep-alive frequency can be configured so that failures of the Unified CM Assistant server are detected by the desktop application more quickly, be careful not to affect the network adversely by sending keep-alives too frequently. This consideration is especially important if there are a large number of Assistant Console desktop applications in use.

The Unified CM Assistant Console phone service, unlike the Unified CM Assistant Console desktop application, requires manual intervention for redundancy given the failure of the primary Unified CM Assistant server. If the primary Unified CM Assistant server goes down, assistants using the phone console will not see an indication of this condition. However, the assistant phone will receive a "Host not found Exception" message upon trying to use a softkey. In order to continue using the phone console with the backup Unified CM Assistant server, the user must manually select the secondary Unified CM Assistant phone service from the IP Services menu and log in again.

There are several other failover mechanisms which ensure that Manager and Assistant reachability are redundant. First, calls sent to a Manager's Assistant via the Unified CM Assistant application (in proxy line mode) can be forwarded to the Manager's next available Assistant if the call is not answered after a configured amount of time. If the next Assistant does not answer the call after the configured amount of time, the call can again be forwarded to the Manager's next available Assistant, and so on. The mechanism is configured using the Cisco IPMA RNA Forward Calls and Cisco IPMA RNA Timeout service parameters. Second, as mentioned previously, if all Cisco IP Manager Assistant and CTI services on cluster nodes fail, the Unified CM Assistant RP will become unavailable. However, based on the CFNA configuration of the Unified CM Assistant RP, calls to all Manager DNs will fall-through directly to the Manager phones so that Manager reachability is sufficiently redundant.

Capacity Planning for Unified CM Assistant

The Cisco Unified CM Assistant application supports the following capacities:

- A maximum of 10 Assistants can be configured per Manager.
- A maximum of 33 Managers can be configured for a single Assistant (if each Manager has one Unified CM Assistant-controlled line).
- A maximum of 3500 Assistants and 3500 Managers (7000 total users) can be configured per cluster using the Cisco MCS 7845 server.
- A maximum of three pairs of primary and backup Unified CM Assistant servers can be deployed per cluster if the Enable Multiple Active Mode advanced service parameter is set to True and a second and third pool of Unified CM Assistant servers are configured.

In order to achieve the maximum Unified CM Assistant user capacity of 3500 Managers and 3500 Assistants (7000 users total), multiple Unified CM Assistant server pools must be defined. As illustrated in [Figure 19-11](#), up to three pools can be configured. Each pool consists of a primary and backup Unified CM Assistant server and a group of Managers and Assistants. Pool 1's Unified CM Assistant servers are configured with the Cisco IPMA Server (Primary/Backup) IP Address service parameters,

Pool 2's servers are configured with the Pool2: Cisco IPMA Server (Primary/Backup) IP Address advanced service parameters, and Pool 3's servers are configured with the Pool3: Cisco IPMA Server (Primary/Backup) IP Address advanced service parameters.

Figure 19-11 Multiple Active Mode with Unified CM Assistant Server Pools

The Cisco Unified CM Assistant application interacts with the CTIManager for line monitoring and phone control. Each line (including Intercom lines) on a Unified CM Assistant or Manager phone requires a CTI line from the CTIManager. In addition, each Unified CM Assistant route point requires a

CTI line instance from the CTIManager. When you configure Unified CM Assistant, the number of required CTI lines or connections must be considered with regard to the overall cluster limit for CTI lines or connections. (For more information on CTI connection limits per cluster, see [Capacity Planning for CTI, page 8-34](#).) If additional CTI lines are required for other applications, they can limit the capacity of Unified CM Assistant.

Design Considerations for Unified CM Assistant

Unified CM Assistant has the following limitations with regard to overlapping and shared extensions, which you should keep in mind when planning directory number provisioning:

- With Unified CM Assistant in proxy line mode, the proxy line number(s) on the assistant phone should be unique, even across different partitions.
- With Unified CM Assistant in proxy line mode, two Managers cannot have the same Unified CM Assistant controlled line number (DN), even across different partitions.

When enabling Multiple Active Mode and using more than one Unified CM Assistant server pool, ensure that the appropriate server pool (1 to 3) is selected in the Assistant Pool field under the end user Manager Configuration page so that Managers and Assistants are evenly distributed between the Unified CM Assistant server pools. A Manager's associated Assistant will automatically be assigned to the pool where their Manager is configured.

Unified CM Assistant supports a non-secure or secure connection (Transport Layer Security) to the CTI Manager.

Unified CM Assistant Extension Mobility Considerations

Unified CM Assistant Managers can use Extension Mobility (EM) to log in to their phones in both proxy-line and shared-lined modes. However, the Manager must be configured as a Mobile Manager under the Cisco Unified CM Assistant Manager configuration page of the End-user Directory. When using EM in conjunction with Unified CM Assistant, users should not be able to log in to more than one phone using EM. This behavior can be enabled/disabled via the EM service parameter Multiple Login Behavior. If multiple EM logins by the same user are required within the cluster, Unified CM Assistant Managers who use EM should be instructed not to log in to multiple phones. Allowing a manager to log in to two different phones with EM violates the previously stated restriction that, in proxy line mode, two Managers cannot have the same Unified CM Assistant controlled line number (DN), even across different partitions.

**Note**

Unified CM Assistants cannot use EM to log in to their phones because there is no concept of a Mobile Assistant.

Unified CM Assistant Dial Plan Considerations

Dial plan configuration is extremely important for Unified CM Assistant configured in proxy line mode. To ensure that calls to Manager DNs are intercepted by the Unified CM Assistant RP and redirected to the Assistant phone, calling search spaces and partitions must be configured in such a way that Manager DNs are unreachable from all devices except the Unified CM Assistant RP and the Manager's proxy line on the Assistant phone.

Figure 19-12 shows an example of a proxy line mode Unified CM Assistant dial plan with the minimum requirements for calling search spaces, partitions, and the configuration of various types of devices within these dial plan components. Three partitions are required for proxy line mode, and for the example in Figure 19-12 they are as follows:

- Assistant_Route_Point partition, containing all the Unified CM Assistant RP DNs
- Assistant_Everyone partition, containing all the Assistant and other user phone DNs
- Assistant_Manager partition, containing all the Manager phone DNs

In addition, two calling search spaces are required, and for the example in Figure 19-12 they are as follows:

- ASSISTANT_EVERYONE_CSS calling search space, containing both the Assistant_Route_Point and Assistant_Everyone partitions.
- MANAGER_EVERYONE_CSS calling search space, containing both the Assistant_Manager and Assistant_Everyone partitions.

That is the extent of the dial plan for this example. However, it is also important to properly configure the various phone and Unified CM Assistant RP DNs or lines with the appropriate calling search spaces so that call routing works as required. In this case all user, Assistant primary (or personal), and Manager phone lines would be configured with the ASSISTANT_EVERYONE_CSS calling search space so that all of these lines can reach all the DNs in the Assistant_Everyone and Assistant_Route_Point partitions. Intercom lines and any other lines configured on devices within the telephony network would be configured with this same calling search space. All Manager proxy lines and all Assistant_RP lines are configured with the MANAGER_EVERYONE_CSS calling search space so that all of these lines can reach the Manager DNs in the Assistant_Manager partition as well as all the DNs belonging to the Assistant_Everyone partition. In this way, the dial plan ensures that only the Assistant_RP lines and the Manager proxy lines on the Assistant phones are capable of reaching the Manager phone DNs directly.

Figure 19-12 Unified CM Assistant Proxy Line Mode Dial Plan Example

153270

The example in Figure 19-12 shows the minimum dial plan requirements for Unified CM Assistant in proxy line mode. However, most real-world telephony networks will have additional or existing dial plan requirements that must be integrated with the Unified CM Assistant calling search spaces and partitions. Figure 19-13 illustrates such an integration dial plan. In this example, the previously discussed dial plan must now handle two additional partitions and an additional calling search space. The On Cluster partition has been added in Figure 19-13, and it contains some additional phone DNs. The On Cluster partition has been added to both of the existing Unified CM Assistant calling search spaces (ASSISTANT_EVERYONE_CSS and MANAGER_EVERYONE_CSS) so that existing devices can reach these added DNs. The UNRESTRICTED_CSS calling search space has also been added to the existing dial plan. This calling search space is configured with the Assistant_Route_Point, Assistant_Everyone, and the recently added On Cluster partitions. In addition, a second new partition called PSTN has been added, and it contains a set of route patterns used for routing calls to the PSTN via the common route list (RL), route group (RG), and voice gateway mechanism. This PSTN partition is configured as part of the UNRESTRICTED_CSS calling search space.

Phone and device line calling search space configurations may be adjusted to incorporate the newly added partitions and calling search spaces, provided the Assistant_RP and Assistant phone Manager proxy lines remain assigned to the MANAGER_EVERYONE_CSS calling search space. In this example, the Manager phone line has been moved from the originally configured ASSISTANT_EVERYONE_CSS calling search space to the new UNRESTRICTED_CSS because it is likely that a Manager would be given unrestricted access to the PSTN.

Figure 19-13 Unified CM Assistant Proxy Line Mode Dial Plan Integration Example

As [Figure 19-13](#) illustrates, integrating additional partitions and calling search spaces into a new or existing Unified CM Assistant dial plan is feasible, but care must be taken to ensure that the underlying proxy line mode mechanism remains intact.

For Unified CM Assistant shared line mode, no special dial plan provisioning is required. Manager and Assistant phones can be configured with calling search spaces and partitions like any other phones in the network because there are no Unified CM Assistant RPs or proxy lines to be concerned about. The only requirement with regard to shared line mode is that the Manager and Assistant DNs must be in the same partition so that shared line functionality is possible.

Unified CM Assistant Console

The Unified CM Assistant Console desktop application or the Unified CM Assistant Console phone service is required in order for assistants to handle calls on a manager's behalf. The desktop application provides assistants with a graphical interface for handling calls, while the phone service provides a menu-driven interface for handling calls. Both the desktop application and the IP phone service allow the assistant to configure the Manager phone and environment and monitor line status and availability. In addition, the desktop application provides other functions such as click-to-call speed dialing and directory entries, which can also be performed on the assistant phone using the traditional softkey and menu approach.

Unified CM Assistant Console Installation

The Unified CM Assistant Console desktop application can be installed from the following URL:

```
https://<Server_IP-Address>:8443/plugins/CiscoUnifiedCallManagerAssistantConsole.exe
```

(where <Server_IP-Address> is the IP address of any node in the cluster)

The Unified CM Assistant Console phone service does not require any installation. To enable the Assistant's phone as a console, subscribe the phone to the Unified CM Assistant phone service. (This is the same service to which Manager phones must also be subscribed.)

Unified CM Assistant Desktop Console QoS

After installation, and in order to handle calls on a Manager's behalf, the Assistant must log on to the application by providing userID and password (as configured in the End-user directory on Unified CM) and will have to toggle status to "online" by clicking the Go Online icon or menu item. Once the user is logged in and online, the desktop application communicates with the Unified CM Assistant server at TCP port 2912. The application chooses an ephemeral TCP port when sourcing traffic. Because the Unified CM Assistant server on Unified CM interfaces with the desktop application for call control (generation and handling of call flows), traffic sourced from Unified CM on TCP port 2912 is QoS-marked by Unified CM as Differentiated Services Code Point (DSCP) of 24 or Per Hop Behavior (PHB) of CS3. In this way, Unified CM Assistant phone control traffic can be queued throughout the network like all other call signaling traffic.

In order to ensure symmetrical marking and queuing, the Unified CM Assistant Console application traffic destined for Unified CM TCP port 2912 should also be marked as DSCP 24 (PHB CS3) to ensure this traffic is placed in the appropriate call signaling queues along the network path toward Unified CM and the Unified CM Assistant server. The Unified CM Assistant Console application marks all traffic as best-effort. This means that you will have to apply an access control list (ACL) at the switch port level (or somewhere along the network path, preferably as close to the console PC as possible) to remark traffic sent by the application PC destined for Unified CM on TCP port 2912 from DSCP 0 (PHB Best Effort) to DSCP 24 (PHB CS3).

Unified CM Assistant Console Directory Window

The directory window within the Assistant Console desktop application enables an assistant to search for end-users in the Unified CM Directory. Search strings entered into the Name field of the directory window are sent to the Unified CM Assistant server, and searches are generated directly against the Unified CM database. Responses to search queries are then sent back to the desktop application by the Unified CM Assistant server.

While the additional traffic generated by directory searches within the desktop application is nominal, this traffic can be problematic in centralized call processing deployments when one or more Unified CM Assistant console applications are running at remote sites. A directory search resulting in a single entry generates approximately one (1) kilobit of traffic from the Unified CM Assistant server to the desktop application. Fortunately, a maximum of 25 entries can be retrieved per search, meaning that a maximum of approximately 25 kilobits of traffic can be generated for each search made by the desktop application. However, if directory searches are made by multiple Unified CM Assistant Console desktop applications across low-speed WAN links from the Unified CM Assistant server, the potential for congestion, delay, and queuing is increased. In addition, directory retrieval traffic is sourced from Unified CM on TCP port 2912, like all other Unified CM Assistant traffic to the desktop. This means that directory retrieval traffic is also marked with DSCP 24 (PHB CS3) and therefore is queued like call signaling traffic. As a result, directory retrieval could potentially congest, overrun, or delay call control traffic.

**Note**

If a directory search generates more than 25 entries, the assistant is warned via a dialog box with the message: “Your search returned more than 25 entries. Please refine your search.”

Given the potential for network congestion, Cisco recommends that administrators encourage Unified CM Assistant Console users to do the following:

- Limit their use of the directory window search function.
- To reduce the number of entries returned, enter as much information as possible in the Name field and avoid wild-card or blank searches when using the feature.

These recommendations are especially important if either of the following conditions is true:

- There are many Unified CM Assistant Assistants within the cluster.
- There are many assistants separated from the Unified CM and/or Unified CM Assistant servers by low-speed WAN links.

Unified CM Assistant Phone Console QoS

In order to handle calls on a Manager's behalf using the Unified CM Assistant Phone Console phone service, the Assistant must log on to the service by providing a userID and PIN (as configured in the End-user directory on Unified CM). Once the user is logged in, the phone console service communicates with Unified CM using HTTPS and SCCP. Call control traffic for Unified CM Assistant call generation and call handling is sent between the phone and Unified CM using SCCP. By default this traffic is marked as Differentiated Services Code Point (DSCP) of 24 or Per Hop Behavior (PHB) of CS3, thus ensuring it is queued throughout the network as call signaling traffic, therefore no additional QoS configuration or marking is required.

WebDialer

WebDialer is a click-to-call application for Unified CM that enables users to place calls easily from their PCs using any supported phone device. There is no requirement for administrators to manage CTI links or build JTAPI or TAPI applications because Cisco WebDialer provides a simplified web application and HTTP or Simple Objects Access Protocol (SOAP) interface for those who want to provide their own user

interface and authentication mechanisms. Alternatively, the **Click to Call** Cisco Unified Communications Widget makes use of the SOAP interface and is currently available for download (login authentication required) at

<http://tools.cisco.com/support/downloads/go/Redirect.x?mdfid=278875240>

This section examines the following design aspects of the WebDialer feature:

- [WebDialer Architecture, page 19-33](#)
- [High Availability for WebDialer, page 19-39](#)
- [Capacity Planning for WebDialer, page 19-40](#)
- [Design Considerations for WebDialer, page 19-41](#)

WebDialer Architecture

The WebDialer application contains two servlets: the WebDialer servlet and the Redirector servlet. Both servlets are enabled when the Cisco WebDialer Web service is activated on a subscriber server. While related, they each serve different functions and can be configured to run simultaneously.

WebDialer Servlet

[Figure 19-14](#) illustrates a simple WebDialer example. In this example, user John Smith launches WebDialer from a web-based or desktop application such as the Click to Call Cisco Unified Communications Widget (step 1). WebDialer responds with a request for login credentials. The user must respond with a valid userID and password as configured in the Unified CM end-user directory. In this case, John Smith submits userID = jsmith and password = cisco (step 2). Next, based on this login, WebDialer responds with the Cisco WebDialer Preferences configuration page, and the user must indicate either “User preferred device” or “Use Extension Mobility” (assuming the user has an EM device profile). In this case, user John Smith selects “User preferred device” and selects the appropriate MAC address (SEP00036BC7B973) and directory number (10001) for his phone from drop-down menus on the configuration page (step 3). Finally, the user is presented with a screen requesting the phone number to be called (this value may already be indicated) and must click Dial. In this case, John Smith enters 10002 and, after clicking Dial, a call is automatically generated from his phone to Phone B at number 10002 (step 4).

Note

If the user has previously logged in to the WebDialer application and a web browser and server cookie are still active, the user will not be prompted to log in again during subsequent requests. The user will be prompted to log in again when the cookie has been cleared at the browser or by a restart of the WebDialer server. Alternatively, the user web browser cookie can be set to expire automatically after a certain number of hours as configured by the User Session Expiry WebDialer service parameter.

Figure 19-14 WebDialer Servlet Operation

Redirector Servlet

The Redirector servlet provides WebDialer functionality in a multi-cluster or distributed call processing environment. This functionality allows the use of a single enterprise-wide web-based WebDialer application between all Unified CM clusters. Figure 19-15 illustrates the basic operation of the Redirector servlet as part of the WebDialer application. In this example, the enterprise has three Unified CM clusters: New York, Chicago, and San Francisco. All three clusters have been configured with a single WebDialer application. The San Francisco cluster has been designated as the Redirector. In order to designate the San Francisco WebDialer as the enterprise-wide Redirector, each cluster WebDialer server must have the service parameter List of WebDialers configured with its own IP address and the San Francisco WebDialer IP address.

Note

In Cisco Unified CM 7.1(2) and later releases, the List of WebDialers can also be configured through the Application Server menu. For more information, refer to the *Cisco Unified Communications Manager Administration Guide*, available at http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html.

The San Francisco WebDialer server will be configured with its own IP address and the addresses of all other WebDialer servers in the enterprise. Based on this example, the List of WebDialers service parameter field for each WebDialer server would be configured as follows:

- New York WebDialer — List of WebDialers: 10.1.1.10:8443 10.3.1.10:8443
- Chicago WebDialer — List of WebDialers: 10.1.1.10:8443 10.2.1.10:8443
- San Francisco WebDialer — List of WebDialers: 10.1.1.10:8443 10.2.1.10:8443 10.3.1.10:8443

The enterprise-wide web-based application points to the San Francisco Redirector and is launched by the New York user (see step 1 in [Figure 19-15](#)). Next the Redirector requests user login, and the New York user responds back with their userID and password (see step 2 in [Figure 19-15](#)).

**Note**

If the user has previously logged in to the WebDialer application and a web browser and server cookie are still active, the user will not be prompted to log in again during subsequent requests. Alternatively, the user web browser cookie can be set to expire automatically after a certain number of hours as configured by the User Session Expiry WebDialer service parameter.

The Redirector then broadcasts an isClusterUser HTTPS request to every WebDialer in the enterprise simultaneously (as configured in the List of WebDialers service parameter). In this example, the requests go to the Chicago and New York WebDialer servers (see step 3 in [Figure 19-15](#)). Because the New York user is local to the New York cluster, the New York WebDialer responds with a positive response (see step 4 in [Figure 19-15](#)). Finally, the New York user is redirected to their local WebDialer server, which will handle the application request (see step 5 in [Figure 19-15](#)). The user is not notified of the redirect; however, the URL in the browser address bar will be changed as the user is redirected from the Redirector to the local WebDialer server).

Figure 19-15 Redirector Servlet Operation

**Note**

Because the Redirector application is an enterprise-wide application that requires user authentication against the Unified CM Database, Cisco highly recommends that all end-user userIDs be unique across all Unified CM clusters. If they are not, then it is possible that more than one positive response to the `isClusterUser` request could be received by the Redirector application. If this happens, the user will be asked by the Redirector application to select their local WebDialer server manually. The user will then have to know which server is their local server. If the wrong server is chosen, the WebDialer request will fail.

WebDialer Architecture

The architecture of the WebDialer application is as important to understand as its functionality. [Figure 19-16](#) depicts the message flows and architecture of WebDialer. The following sequence of interactions and events can occur:

1. WebDialer user phones register and make and receive calls via the Cisco CallManager service (see step 1 in [Figure 19-16](#)).
2. The WebDialer application on the user's PC communicates with the Cisco WebDialer Web Service (see step 2 in [Figure 19-16](#)) via one of the following interfaces:
 - HTML over HTTPS
This interface is used by web-based applications based on the HTTPS protocol. This is the only interface that provides access to the WebDialer and Redirector servlets.
 - Simple Object Access Protocol (SOAP) over HTTPS
This interface is used by desktop applications based on the SOAP interface.
3. The WebDialer Web service reads user and phone information from the Unified CM Database (see step 3 in [Figure 19-16](#)).
4. The WebDialer Web service in turn interacts with the CTIManager service for exchanging line and phone control information (see step 4 in [Figure 19-16](#)).
5. The CTIManager service passes WebDialer phone control information to the Cisco CallManager service (see step 5 in [Figure 19-16](#)).

Figure 19-16 WebDialer Architecture

**Note**

Although [Figure 19-16](#) shows the Cisco CallManager, CTIManager, and WebDialer Web Service services all running on the same node, this configuration is not a requirement. These services can be distributed among multiple nodes in the cluster, but they are shown on the same node here for ease of explanation.

WebDialer URLs

The WebDialer application can be accessed from web-based applications via the HTML-over-HTTPS interface using the following URLs:

- WebDialer servlet

`https://<Server-IP_Addr>:8443/webdialer/Webdialer?destination=<Number_to_dial>`

(where *<Server_IP-Address>* is the IP address of any node in the cluster running the Cisco WebDialer Web Service service, and where *<Number_to_dial>* is the number that the WebDialer user wishes to dial)

- Redirector servlet

`https://<Server-IP_Addr>:8443/webdialer/Redirector?destination=<Number_to_dial>`

(where *<Server_IP-Address>* is the IP address of any node in the enterprise running the Cisco WebDialer Web Service service, and where *<Number_to_dial>* is the number that the WebDialer user wishes to dial)

[Figure 19-17](#) gives an example of HTML source code used in a click-to-call web-based application calling the Cisco WebDialer application. In this example, the URL `https://10.1.1.1:8443/webdialer/Webdialer?destination=30271` in the HTML source view corresponds to the "Phone: 30721" link for user Steve Smith within the web browser view. A user clicking on this link would launch the WebDialer application and, after logging in and clicking Dial, would generate a call from the user's phone to Steve Smith's phone. The same code could be used for a click-to-call application using the Redirector function by changing the URL to `https://10.1.1.1:8443/webdialer/Redirector?destination=30271`.

For information and examples of SOAP-over-HTTPS source code to be used in click-to-call desktop applications, refer to the WebDialer API Programming information in the *Cisco Unified Communications Manager Developers Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/products_programming_reference_guides_list.html

High Availability for WebDialer

WebDialer application redundancy can be provided at two levels:

- Redundancy at the component and service level

At this level, redundancy must be considered with regard to WebDialer and CTIManager service redundancy. Likewise, the lack of publisher redundancy and the impact of this component failing should also be considered.

- Redundancy at the device and reachability level

At this level, redundancy should be considered as it relates to user phones and the WebDialer user interface.

Service and Component Redundancy

As shown in [Figure 19-16](#), WebDialer functionality is primarily dependent on the Cisco WebDialer Web Service and the Cisco CTIManager services. In the case of the WebDialer service, redundancy is provided by listing multiple WebDialer server IP addresses in the List of WebDialers service parameter and enabling the service on multiple nodes within the cluster. In the case of CTIManager, redundancy is automatically built-in using a primary and backup mechanism. Two CTIManager servers or services can be defined within the cluster using the Primary Cisco CTIManager and the Backup Cisco CTIManager service parameters. By configuring these parameters, you can make the CTIManager service redundant. Thus, if the primary CTIManager fails, CTIManager services can still be provided by the backup CTIManager. If the WebDialer server to which the web-based (or desktop) application is pointing fails and the primary and backup CTIManager services on cluster nodes also fail, the WebDialer application will fail. The WebDialer service is not dependant upon the Unified CM publisher

Device and Reachability Redundancy

Redundancy for WebDialer at the device level relies on a number of mechanisms. First and foremost, user phones rely on the built-in redundancy provided by a combination of the device pool and Unified CM group configuration for device registration.

The WebDialer service can run on multiple Unified CM subscribers to provide redundancy, however many applications might not be equipped to handle more than one IP address. Cisco recommends using a Server Load Balancer (SLB) to mask the presence of multiple WebDialer servers in the enterprise. SLB functionality provides a virtual IP address or DNS-resolvable hostname that front-ends the real IP addresses of the WebDialer and/or Redirector servers. Most SLB devices, such as the Cisco Application Control Engine (ACE) or the Cisco IOS SLB feature, can be configured to monitor the status of multiple WebDialer servers and automatically redirect requests during failure events. The SLB feature can also be configured to load-balance WebDialer requests when additional click-to-call capacity is required. As an alternative, DNS Service (SRV) records can also be used to provide redundancy.

In enterprise deployments, link cost might also be an important consideration. The Cisco ACE Global Site Selector (GSS) appliance builds upon the capabilities of the SLB feature by adding link cost and location to the load-balancing algorithm, among other features. For more information on ACE and GSS, refer to the product documentation available at <http://www.cisco.com>.

Capacity Planning for WebDialer

The WebDialer and Redirector services can run on one or more subscriber nodes within a Unified CM cluster, and they support the following capacities:

- Each WebDialer service can handle up to 2 call requests per second (7,200 calls per hour) per node.
- Each Redirector service can handle up to 8 call requests per second.

The following general formula can be used to determine the number of WebDialer calls per second (cps):

$$(\text{Number of WebDialer users}) * ((\text{Average BHCA}) / (3600 \text{ seconds/hour}))$$

When performing this calculation, it is important to estimate properly the number of BHCA per user that will be initiated specifically from using the WebDialer service. The following example illustrates the use of these WebDialer design calculations for a sample organization.

Example 19-1 Calculating WebDialer Calls per Second

Company XYZ wishes to enable click-to-call applications using the WebDialer service, and their preliminary traffic analysis resulted in the following information:

- 10,000 users will be enabled for click-to-call functionality.
- Each user averages 6 BHCA.
- 50% of all calls are dialed outbound, and 50% are received inbound.
- Projections estimate 30% of all outbound calls will be initiated using the WebDialer service.

**Note**

These values are just examples used to illustrate a WebDialer deployment sizing exercise. User dialing characteristics vary widely from organization to organization.

10,000 users each with 6 BHCA equates to a total of 60,000 BHCA. However, WebDialer deployment sizing calculations must account for placed calls only. Given the initial information for this sizing example, we know that 50% of the total BHCA are placed or outbound calls. This results in a total of 30,000 placed BHCA for all the users enabled for click-to-call using WebDialer.

Of these placed calls, the percentage that will be initiated using the WebDialer service will vary from organization to organization. For the organization in this example, several click-to-call applications are made available to the users, and it is projected that 30% of all placed calls will be initiated using WebDialer.

$$(30,000 \text{ placed BHCA}) * 0.30 = 9,000 \text{ placed BHCA using WebDialer}$$

To determine the number of WebDialer servers required to support a load of 9,000 BHCA, we convert this value to the average call attempts per second required to sustain this busy hour:

$$(9,000 \text{ call attempts / hour}) * (\text{hour}/3600 \text{ seconds}) = 2.5 \text{ cps}$$

Each WebDialer service can support up to 2 cps, therefore 2 nodes should be configured to run the WebDialer service in this example. This would allow for future growth of WebDialer usage. In order to maintain WebDialer capacity during a server failure, additional backup WebDialer servers should be deployed to provide redundancy.

Keep in mind that the Cisco WebDialer application interacts with the CTIManager for phone control. When enabled, each WebDialer service opens a single persistent CTI connection to the CTIManager. In addition, each WebDialer individual MakeCall (or EndCall) request generates a temporary CTI connection. The number of CTI connections required to handle WebDialer call rates also applies against the CTI connection limits per cluster. (For more information on CTI connection limits per cluster, see [Capacity Planning for CTI, page 8-34.](#))

Design Considerations for WebDialer

The following guidelines and restrictions apply with regard to deployment and operation of WebDialer within the Unified CM telephony environment:

- The administrator should ensure that all WebDialer users are associated with a phone or device profile in the Unified CM end-user directory.
 - If the user selects "Use permanent device" under the Cisco WebDialer Preferences screen with no phone association, then the following message is received when the Dial button is pressed:

“No supported device configured for user”

- If the user selects Use Extension Mobility under the Cisco WebDialer Preferences screen with no device profile association (or the user is not logged in using a profile), then the following message is received when the Dial button is pressed:

“Call to <dialed_number> failed: User not logged in on any device”

- When configuring the List of WebDialers service parameter, port number 8443 must be specified along with WebDialer IP address.
- If using Client Matter Codes (CMC) or Forced Authorization Codes (FAC), WebDialer users must enter the proper code at the tone by using the phone's keypad. Failure to enter the appropriate code at the tone will result in call failure signaled by a reorder tone.
- Cisco WebDialer supports Cisco IP Phones that run Skinning Client Control Protocol (SCCP) and Session Initiation Protocol (SIP), both of which are supported by Cisco Computer Telephony Integration (CTI).
- Cisco Unified Personal Communicator supports WebDialer only when running in deskphone mode. With Cisco Unified Personal Communicator in deskphone mode, WebDialer can be used to provide click-to-call functionality for the desk phone as long as it is a phone model supported by WebDialer. Cisco Unified Personal Communicator in softphone mode does not support WebDialer.

Attendant Consoles

Attendant console integrations enable a receptionist to answer and transfer or dispatch calls within an organization from a desktop application designed specifically for this purpose. Attendant consoles allow for access to the corporate directory and, in some cases, monitoring of line state for specific users. The Cisco Unified Communications portfolio provides three types of Cisco Unified Attendant Console:

- Cisco Unified Department Attendant Console
- Cisco Unified Business Attendant Console
- Cisco Unified Enterprise Attendant Console

The Cisco Unified Department, Business, and Enterprise Attendant Consoles have a client attendant console application that installs on an attendant's Windows PC. It also requires an attendant console server application installed on a separate physical server than Unified CM. The attendant console application communicates with the attendant console server application, and the attendant console server application communicates with Unified CM securely through CTI and AXL over Secure Socket Layer (SSL). Multiple attendant consoles can connect to a single attendant console server. The Department, Business, and Enterprise versions of the attendant console differ in their limits to various capabilities such as the number of supported operator clients and the number of supported directory entries.

This section examines the following design aspects of the attendant consoles:

- [Attendant Console Architecture, page 19-43](#)
- [High Availability for Attendant Consoles, page 19-45](#)
- [Capacity Planning for Attendant Consoles, page 19-45](#)
- [Design Considerations for Attendant Consoles, page 19-46](#)

Attendant Console Architecture

Figure 19-18 illustrates the high-level architecture of a Cisco Unified Department, Business, or Enterprise Attendant Console integration. Understanding the functionality and operation of the solution enhances the understanding of the architecture itself. The following steps (denoted in Figure 19-18) detail the events involved for a typical call into an attendant console.

1. A call comes into Unified CM, and the called number matches the directory number configured on a CTI route point.
2. The CTI route point is CTI-controlled by the attendant console server application and is associated with a Queue Direct Dial In (DDI) configured on the server.
3. The attendant console server application immediately redirects the call internally to one of its Computer Telephony (CT) Gateway Devices. As part of this process, the attendant console server application sends a CTI redirect message to the CTI Manager service to redirect the call to a CTI port.

Note A CTI redirect message does not result in a connected call; the call is not answered and there is no media connection.

4. The attendant console server application now associates the call with the CT Gateway Device and controls the call on the CTI port.
5. At this point, the call is presented to the attendant console client applications in the system that are associated with the Queue DDI.
6. Once an attendant chooses to answer the call through the attendant console client application, another CTI redirect message is sent to the CTI Manager service, which moves the call from the CTI port to the answering attendant's physical phone. The call is automatically connected on the attendant's phone, either to the handset or the headset, depending on the phone configuration. The region and location settings of the attendant's phone and the initiating gateway or phone dictate the codec used for media.
7. When a transfer to another extension is required, the attendant initiates the transfer through the attendant console client application, which communicates the transfer to the attendant console server application.
8. The attendant console server application internally associates the call with a Service Queue and sends a CTI redirect message to the CTI Manager service. This redirects the call from the attendant's phone to a CTI port controlled by the attendant console server application.

Note A call transfer may also be initiated from the attendant's phone; however, this would remove the attendant console server application from the call flow, and enhanced functionality (such as the transfer recall feature) would no longer be possible.

9. At this stage, the Service Queue actually answers the call (there is a short connect) before issuing the transfer, therefore the Cisco TAPI Wave driver installed on the attendant console server application is invoked. The region and location settings of this CTI port and the call-initiating gateway or phone dictate the codec used for media. The configured Music on Hold (MoH) audio sources of the CTI port also affect the MoH heard by the caller. Transfers are performed in this manner so that the attendant console client application still maintains control of the call if there is no answer. Once the call is received by the final party, the attendant console server application is removed from the call flow.

**Note**

The Cisco TAPI Wave Driver installed on the attendant console server application supports only the G.711 codec. When configuring the CTI ports correlating with Service Queues and Call Park Devices, design the system so that these CTI ports have a region setting with other devices that dictates the use of G.711, or else provide transcoding media resources.

**Note**

Cisco TAPI Wave Driver support for the G.711 a-law codec was introduced in Cisco Unified CM 7.1(2) and in Cisco TSP 7.1(3.3) and later releases.

Figure 19-18 Architecture for Cisco Unified Department, Business, and Enterprise Attendant Consoles

The attendant console server application's call park function does not use the inherent call park feature of Unified CM. Instead, it uses its own call park facility using Call Park Devices. Call Park Devices work very much like the Service Queues as outlined in steps 7 to 9 of [Figure 19-18](#). Similar to transfers, Call Park Devices allow the attendant console server application to maintain control of the call for the duration of the parked call. The Cisco TAPI Wave Driver codec limitation (support of G.711 only) also affects calls involving Call Park Devices.

High Availability for Attendant Consoles

You should consider providing redundancy on both sides of the integration for both CTI and AXL communication.

Regarding CTI, the attendant console server application uses the Cisco Telephony Service Provider (TSP) plug-in (downloaded from Unified CM) to communicate with the CTI Manager service. Cisco TSP allows for the configuration of a primary and backup CTI Manager service. Cisco recommends enabling the CTI Manager service on at least two Unified CM subscriber nodes in the cluster to gain resilience in case the primary CTI Manager service goes offline. Currently there are no resiliency capabilities for the attendant console server application. Therefore, in the event of an attendant console server failure, resilience can be achieved by configuring a Call Forward No Answer (CFNA) destination on all of the CTI route points associated with Queue DDIs. If the attendant console server application is offline, calls will automatically follow the CFNA setting. For example, the destination could be a Hunt Pilot number or a Directory Number (DN) associated with a single IP phone.

AXL communication is enabled by activating the Cisco AXL Web Service on a Unified CM node. Multiple Unified CM nodes can have the Cisco AXL Web Service enabled, but the attendant console server application has only a single entry for Unified CM connectivity. In the event of a failure, an administrator could update this entry to a backup Unified CM node running the Cisco AXL Web Service.

The Unified CM also has a series of CTI route points and CTI ports configured for integration with the Unified Department, Business, and Enterprise Attendant Console solutions. These devices have a device pool and therefore are assigned a Unified CM group, which specifies a prioritized list of the Unified CM call processing nodes responsible for maintaining registration. When the primary Unified CM in the Unified CM group is offline, the CTI route points and CTI ports have the ability to register with a secondary Unified CM node, thus allowing for high availability of the CTI route points and ports themselves.

Capacity Planning for Attendant Consoles

For a comparison of the various Cisco Unified Department, Business, and Enterprise Attendant Console models and their respective capacities, please see the *Cisco Unified Business/Department/Enterprise Attendant Console Design Guide*, available at

http://www.cisco.com/en/US/products/ps7282/products_implementation_design_guides_list.html

To size a Unified CM cluster properly, your Cisco Partner or Cisco Systems Engineer should use the Cisco Unified Communications Sizing Tool (<http://tools.cisco.com/cucst>) to validate all designs that incorporate a large number of CTI resources and high call volumes, because there are many interdependent variables that can affect Unified CM cluster scalability. The Sizing Tool can accurately determine the number of servers or clusters required to meet your Attendant Console design criteria.

For performance and capacity information about the various Unified Department, Business, and Enterprise Attendant Consoles, refer to the product documentation available at

http://www.cisco.com/en/US/products/ps7282/tsd_products_support_series_home.html

Design Considerations for Attendant Consoles

The following design guidelines and restrictions apply with regard to the deployment and operation of Cisco Unified Department, Business, and Enterprise Attendant Consoles within the Unified CM telephony environment.

- The following general design guidance applies to the attendant console server application components:
 - Queue DDI

One unique Queue DDI is required for each unique incoming directory number in the system that should be routed specifically to the attendant consoles.
 - CT Gateway Device

Every incoming call into a Queue DDI is immediately redirected to a CT Gateway Device. Design the system so that the number of CT Gateway Devices can handle the maximum expected number of incoming calls at any given time.
 - Service Queue

Each time an attendant transfers a call or places a call on hold, a Service Queue is required. The system should be designed so that there are enough Service Queues to sustain the maximum number of calls that all attendants in the system are in the process of transferring or putting on hold at any given time. A general guideline is to provide 3 or 4 Service Queues per attendant, but some scenarios might require more.
 - Call Park Device

Each time an attendant invokes the Call Park feature through the attendant console client application, a Call Park Device is required. This feature does not use the inherent Call Park capability of Unified CM. Design the system so that there are sufficient Call Park Devices to handle the maximum number of calls parked by all attendants in the system at any given time.
- Every Queue DDI, CT Gateway Device, Service Queue, and Call Park Device configured in the attendant console server application creates a CTI route point or CTI port in Unified CM. The number of CTI connections required to handle the Unified Department, Business, or Enterprise Attendant Console integration also counts toward the CTI connection limits per cluster. (For more information on CTI connection limits per cluster, see [Capacity Planning for CTI, page 8-34.](#))
- The attendant console server application provides busy lamp field (BLF) monitoring of end-user devices, but it is important to note that this does not use the same facility in Unified CM that provides BLF speed dial capability. Instead, the attendant console server application communicates through CTI with Unified CM to obtain line state information on monitored devices. Once the attendant console server application monitors an end-user device, it continues monitoring this device through CTI until the number of devices monitored for BLF reaches a certain level (2,000 by default). Once this limit is reached, the BLF plug-in begins to drop devices from the list of monitored devices in order to add newly requested devices to the list, thus ensuring that the number of devices monitored by the attendant console server through CTI does not exceed the limit (2,000 by default). These devices monitored through CTI also count toward the CTI limits in Unified CM.
- The Cisco TAPI Wave Driver installed on the attendant console server application supports only the G.711 codec. When configuring the CTI ports correlating with Service Queues and Call Park Devices, design the system so that these CTI ports have a region setting with other devices that dictates the use of G.711, or else provide transcoding media resources.

- The attendant console server application provides Busy Lamp Field (BLF) monitoring of end-user devices, but it is important to note that this does not use the same facility in Unified CM that provides BLF speed dial capability. Instead, the attendant console server application communicates through CTI with Unified CM to obtain line state information on monitored devices.
- With respect to Quality of Service (QoS), the attendant console server application, the attendant console client application, and the Cisco TSP all send their traffic marked as Best Effort (DSCP=0). If this traffic traverses a WAN or a link that is typically congested, packets must be marked to receive preferential treatment through the network. For a complete list of the TCP port numbers associated with these applications, refer to the Unified Department, Business, or Enterprise Attendant Console design guide, available with appropriate login authentication at
<http://www.cisco.com/go/ac>
- The attendant console server application is not aware of partitions. Therefore, if the same directory number (DN) exists in multiple partitions, the monitored device might not be the correct DN.
- The Cisco Unified Department, Business, and Enterprise Attendant Consoles can also integrate with a Cisco Unified Presence Server. For more information about this type of integration, refer to the appropriate Unified Department, Business, or Enterprise Attendant Console administration guide, available at
http://www.cisco.com/en/US/products/ps7282/prod_maintenance_guides_list.html
- For design guidance on the Cisco Unified Department, Business, and Enterprise Attendant Consoles, refer to the documentation available at
http://www.cisco.com/en/US/products/ps7282/products_implementation_design_guides_list.html

PART 4

Unified Communications Applications and Services

CHAPTER 20

Overview of Cisco Unified Communications Applications and Services

Revised: February 29, 2012; OL-21733-18

Once the network, call routing, and call control infrastructure has been put in place for your Cisco Unified Communications System, additional applications and services can be added or layered on top of that infrastructure. There are numerous applications and services that can be deployed on an existing Cisco Unified Communications infrastructure, and the following applications and services are typically deployed:

- Voice messaging — Provides voicemail services and message waiting indication.
- Rich media conferencing — Provides audio and video conferencing as well as web-based application and document sharing.
- Presence services — Provide user availability tracking across user devices and clients.
- Mobility services — Provide enterprise-level unified communications features and functionality to users outside the enterprise.
- Contact center — Provides call handling, queuing, and monitoring for large call volumes.
- Collaboration client services — Provide integration to unified communications services and leveraging of various applications.

The chapters in this part of the SRND cover the applications and services mentioned above. Each chapter provides an introduction to the application or service, followed by discussions surrounding architecture, high availability, capacity planning, and design considerations. The chapters focus on design-related aspects of the applications and services rather than product-specific support and configuration information, which is covered in the related product documentation.

This part of the SRND includes the following chapters:

- [Cisco Voice Messaging, page 21-1](#)

This chapter examines voice messaging, a common and prevalent application within most unified communications deployments, which allows callers to send messages and subscribers of the system to retrieve messages. The chapter examines messaging deployment models, voice messaging features and functionality, voicemail networking, and design and deployment best practices for voice messaging applications.

- [Cisco Collaborative Conferencing, page 22-1](#)

This chapter explores rich media conferencing, which allows users of the unified communications system to schedule, manage, and attend audio, video, and/or web collaboration conferences. The chapter considers various aspects of rich media conferencing, including components, deployment models, video capabilities, H.323 and SIP call control integrations, capacity and redundancy, and various solution recommendations and design best practices.

- [Cisco Unified Presence, page 23-1](#)

This chapter discusses presence services, an increasingly critical piece of most unified communications deployments due to the productivity improvements that can be realized from user availability-based applications. This chapter defines presence and explores the various presence components and features, protocols, deployment models, redundancy, capacity, and general design guidelines.

- [Cisco Collaboration Clients and Applications, page 24-1](#)

This chapter covers collaboration clients and applications, which are quickly closing the gap between traditional hardware-based phones and feature-rich PC-based clients. This chapter explores the various collaboration clients, their features, and the various integration methods, as well as integrations with various third-party collaboration applications.

- [Mobile Unified Communications, page 25-1](#)

This chapter looks at mobility applications, which are becoming extremely important given the growth of mobile work forces and the blurring of enterprise boundaries for unified communications features and services, resulting in an increased demand for mobility applications and services. This chapter discusses mobility solution architectures, functionality, and design and deployment implications.

- [Cisco Unified Contact Center, page 26-1](#)

This chapter covers contact center solutions, an important and integral part of large unified communications deployments requiring high-volume call center applications. This chapter examines call center solution architectures, functionality, and design and deployment implications.

Architecture

As with other network and application technology systems, unified communications applications and services must be layered on top of the underlying network and system infrastructures. Figure 20-1 shows the logical location of unified communications applications and services in the overall Cisco Unified Communications System architecture.

Figure 20-1 Cisco Unified Communications Applications and Services Architecture

253670

Unified communications applications and services such as voice messaging, rich media conferencing, presence, mobility, contact center, and collaboration clients rely on the underlying unified communications call routing and call control infrastructure and network infrastructure for everything from network connectivity to basic unified communications functions such as call control, supplementary services, dial plan, call admission control, and gateway services. For example, voice messaging and rich media conferencing applications leverage the network infrastructure for reaching users in campus sites, in branch sites, and on the Internet. Further, these same applications depend on the unified communications voice and video endpoints, call routing, PSTN connectivity, and media

resources provided by the call routing and control infrastructure. In addition to relying on these infrastructure layers and basic unified communications services, applications and services are also often dependent upon each other for full functionality.

High Availability

As with network, call routing, and call control infrastructures, critical unified communications applications and services should be made highly available to ensure that required features and functionality remain available if failures occur in the network or applications. It is important to understand the various types of failures that can occur and the design considerations around those failures. In some cases, the failure of a single server or feature can impact multiple services because many unified communications applications are dependent on other applications or services. For example, while the various application service components of a contact center deployment might be functioning properly, the loss of all call control servers would effectively render the contact center unusable because the deployment is dependent upon the call control servers to route calls to the call center applications.

For applications and services such as voice messaging and rich media conferencing, high availability considerations include temporary loss of functionality due to network connectivity or application server failures resulting in the inability of callers to leave messages, of users to retrieve messages, and of users to schedule or attend conferences. In addition, failover considerations for callers and users of voice messaging and rich media conferencing applications include scenarios in which portions of the functionality can be handled by a redundant resource that allows end users to continue to access services in the event of certain failures.

High availability considerations are also a concern for services such as presence and mobility. Interrupted network connectivity or server failures will typically result in reduced functionality or, in some case, complete loss of functionality. For presence services, this can mean that some or all devices and clients will be unable to send or receive presence or availability updates. For mobility services, high availability considerations include the potential for loss of specific functionality such as two-stage dialing or dial-via-office, or reduced functionality for features such as single number reach (resulting in situations where only the enterprise phone rings or only the mobile phone rings). Further, in some failure scenarios, enterprise phones and mobile clients might have to reregister, reconnect and/or re-authenticate before full functionality is available again.

For contact center deployments, there are numerous servers and components for which high availability must be considered. Typically, an isolated single-server or single-component failure can be handled without loss of features or functionality as long as the server or component has been made redundant. In other situations, loss of multiple servers or components will typically result in loss of some features or functionality. However, in scenarios where there is complete loss of a particular component such as all call control servers, more catastrophic loss of features or functionality is possible.

When considering collaboration clients and applications, high availability is certainly important. Not only can specific collaboration features or functions become unavailable in failure scenarios, but in some cases presence-capable clients might be unable to connect to the network for even basic functionality such as registration and making or receiving calls. In other cases, clients or devices might have to reconnect and re-authenticate in order to return to service.

Capacity Planning

Network, call routing, and call control infrastructures must be designed and deployed with an understanding of the capacity and scalability of the individual components and the overall system. Similarly, deployments of unified communications applications and services must also be designed with attention to capacity and scalability considerations. When deploying various unified communications applications, not only is it important to consider the scalability of the applications themselves, but you must also consider the scalability of the underlying infrastructures. Certainly the network infrastructure must have available bandwidth and be capable of handling the additional traffic load the applications will create. Likewise, the call routing and control infrastructure must be capable of handling user and device configuration and registration as well as application integration loads surrounding protocols and connections. For example, with applications and services such as mobility, presence, and contact center, there are capacity implications for each of these individual applications in terms of users, devices, and features, but just as important is the scalability of the underlying infrastructure to handle connections and protocols such as Computer Telephony Integration (CTI). While a mobility, presence, or contact center application may be able to support many CTI connections, the underlying call control and routing infrastructure might not have available capacity to handle the added CTI load of these application and services.

For applications and services such as voice messaging and rich media conferencing, capacity planning considerations include things like number of mailboxes or users, mailbox size, audio and video ports, and MCU sessions. In most cases additional capacity can be added by increasing the number of application servers and MCUs or by upgrading server or MCU hardware with higher-scale models, assuming the underlying network and call routing and control infrastructures are capable of handling the additional load.

Capacity planning considerations are also a concern for services such as presence and mobility. Scalability must be contemplated not only for things like numbers of configured and supported users and devices, but also for the number of integrations and connections between those applications and others. The volume of two-stage dialing and dial-via-office calls is of particular concern for mobility applications from the perspective of both the call control capacity and the PSTN gateway capacity. With presence services, on the other hand, critical scalability concerns include frequency of presence status changes and the propagation of these changes to the network, as well as text or instant message volumes. Typically, additional application servers or hardware upgrades will result in increased capacity for these applications and services, but the underlying call routing and control infrastructures must be capable of handling any increases in load.

Contact center deployments are no different than other applications and services in terms of scalability concerns. Certainly the number of agents and agent devices handling calls is important in terms of user and device configuration and registration. However, the major concerns in terms capacity for contact center deployments are the high number of busy hour call attempts (BHCA) common in contact centers and the number of CTI integrations to the call control and routing infrastructure.

When considering collaboration clients and application capacity planning, device registration and configuration are the most important scalability concerns. However, certainly there are other scalability implications in terms of the back-end applications and services such as presence and messaging. Further, when deploying or integrating various clients with third-party applications and infrastructures, you must also consider the supported capacities for those third-party deployments.

For a complete discussion of system sizing, capacity planning, and deployment considerations related to sizing, refer to the chapter on [Unified Communications Design and Deployment Sizing Considerations](#), page 29-1.

CHAPTER 21

Cisco Voice Messaging

Revised: July 31, 2012; OL-21733-18

This chapter describes the voice messaging solutions available in the Cisco Unified Communications System. It includes the Cisco voice messaging products Cisco Unity, Cisco Unity Connection, and Cisco Unity Express, and it covers the design guidelines and best practices for deploying these products together with Cisco Unified Communications Manager (Unified CM). This chapter also covers aspects of integration with third-party voicemail systems using industry standard protocols.

Although this guide focuses on the messaging deployment scenarios with regard to Unified CM, Cisco Unified Communications Manager Express (Unified CME) is also noted where applicable, especially when used with Survivable Remote Site Telephony (SRST) fallback support in a centralized Unified CM deployment.

This chapter covers the following topics:

- [Voice Messaging Portfolio, page 21-3](#)
- [Messaging Deployment Models, page 21-5](#)
- [Messaging and Unified CM Deployment Model Combinations, page 21-7](#)
- [Voicemail Networking, page 21-30](#)
- [Best Practices for Voice Messaging, page 21-34](#)
- [Third-Party Voicemail Design, page 21-47](#)

The chapter begins with a short description of each of the products in the Cisco messaging solutions portfolio and provides a simple overview of where each product fits in an enterprise Unified Communications solution. Next, messaging deployment models form the basis of discussion for voicemail integrations, which start with a definition of the various messaging deployment models and then explain how each of the messaging deployment models fits into the various Unified CM call processing deployment models. Furthermore, design aspects for various redundancy options along with Survivable Remote Site Voicemail are covered. Cisco Unity and Unity Connection are discussed together in this section, while Cisco Unity Express has a dedicated section for its supported deployment models. Key design guidelines are covered for interoperability available within the Cisco Voice Messaging product portfolio. Virtualization, a new concept, is covered along with the important design factors to be considered while designing the virtual system. Many system-level design considerations and best practices, including transcoding and various integrations with Cisco Unified Communications Manager, are explained in this section. In addition, this chapter provides details on third-party voicemail integration for supported industry-standard protocols.

This chapter presents a high-level design discussion and is focused on how the voice messaging products fit into the Unified Communications System with Unified CM. For detailed design guidelines for each product as well as interoperability information for third-party messaging and telephony systems, refer to the following product-specific design guides:

- Cisco Unity Connection design guides
http://www.cisco.com/en/US/products/ps6509/products_implementation_design_guides_list.html
- Cisco Unity design guides
http://www.cisco.com/en/US/products/sw/voicew/ps2237/products_implementation_design_guides_list.html

What's New in This Chapter

Table 21-1 lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Table 21-1 New or Changed Information Since the Previous Release of This Document

| New or Revised Topic | Described in: | Revision Date |
|--|---|-------------------|
| End-of-Sale and End-of-Life for Cisco Unity | Voice Messaging Portfolio, page 21-3 | July 31, 2012 |
| End-of-Sale and End-of-Life for Survivable Remote Site Voicemail (SRSV) | Survivable Remote Site Voicemail, page 21-9 | April 30, 2012 |
| End-of-Sale and End-of-Life for Voice Profile for Internet Mail (VPIM) feature | Voicemail Networking with Cisco Unified Messaging Gateway, page 21-30 | April 30, 2012 |
| Virtualization | Cisco Unity and Unity Connection Virtualization, page 21-33 | July 29, 2011 |
| E.164 support in Cisco Unity Connection | E.164 Number Support with Cisco Unity Connection, page 21-39 | June 2, 2011 |
| IPv6 support in Cisco Unity Connection | IPv6 Support with Cisco Unity Connection, page 21-44 | November 15, 2010 |

| Virtualization | Cisco Unity and Unity Connection Virtualization, page 21-33 | April 2, 2010 |
| Voicemail interoperability | Voicemail Interoperability, page 21-31 | April 2, 2010 |

Voice Messaging Portfolio

The Cisco Unified Communications messaging portfolio consists of three main messaging products: Cisco Unity, Cisco Unity Connection, and Cisco Unity Express. Each product fits different requirements yet each one contains overlapping features and scalability with regard to the others. They also have the ability to interwork with one another using Voice Mail Networking and can also leverage the Cisco Unified Messaging Gateway to achieve this in a highly scalable fashion, as discussed later in this chapter.

When considering these products, it helps to think of the messaging types that the products apply to in order to understand the messaging options they include and to determine which options could fit your deployment requirements. The following definitions help describe these messaging types:

- *Voicemail-only* refers to a telephony voicemail integration where there is no access to the voicemail via any messaging client.
- *Integrated messaging* refers to voicemail with telephony access as well as voicemail-only access via a messaging client.
- *Unified messaging* refers to voicemail with telephony access as well as voicemail, email, and fax access via a messaging client.

Table 21-2 shows which Cisco products support these types of messaging.

Table 21-2 Supported Messaging Environments per Product

| Messaging Type | Cisco Unity | Cisco Unity Connection | Cisco Unity Express |
|----------------------|-------------|------------------------|---------------------|
| Voicemail-only | Yes | Yes | Yes |
| Integrated messaging | Yes | Yes | Yes |
| Unified messaging | Yes | Yes | No |

Note

For further details on Unified Messaging with Cisco Unity Connection, see [Single Inbox with Cisco Unity Connection, page 21-44](#).

Based on the above messaging types and definitions, the three messaging product options are:

- Cisco Unity

This solution option scales to meet the needs of large enterprise organizations and delivers powerful voice, integrated, and unified messaging options that integrate with Microsoft Exchange (including Exchange 2007/2010).
- Cisco Unity Connection

This option combines unified/integrated messaging, voice recognition, and call transfer rules into an easy-to-manage system for medium-sized businesses with up to 20,000 users, or it can network up to 10 nodes in a digital network system. (Additionally, if required, a maximum of two digital networks can be joined to support a maximum of 20 nodes.) Cisco Unity Connection can support up to 100,000 users or contacts in a digital network. For organizations with up to 500 users, Cisco Unity Connection is available as a single-server solution with Cisco Business Edition 3000 and 5000. For more information on Cisco Business Edition, see [Design Considerations for Call Processing, page 8-29](#).

- Cisco Unity Express

This option provides cost-effective voice and integrated messaging, automated attendant, and interactive voice response (IVR) capabilities in certain Cisco Integrated Services Routers for small and medium-sized businesses and enterprise branch offices with up to 500 users.

**Note**

Cisco Unity has reached End-of-Sale (EoS) and End-of-Life (EoL). There is no replacement available for Cisco Unity at this time. For more information on this, refer to the End-of-Sale and End-of-Life Announcement available at http://www.cisco.com/en/US/prod/collateral/voicesw/ps6789/ps5745/ps6509/end_of_life_notice_c51-681593.html.

For a complete comparison of product feature, refer to the *Cisco Messaging Products: Feature Comparison*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps2237/products_data_sheets_list.html.

Table 21-3 gives a brief product comparison with regard to scalability.

Table 21-3 Scalability of Voice Messaging Solutions

| Solutions | Users supported on a single server (or failover or clustered deployment) | | | Maximum number of users supported in a digital networking solution ¹ | |
|--|--|--------|--------|---|---------|
| | 500 | 15,000 | 20,000 | 100,000 | 250,000 |
| Cisco Unity Express | Y | N | N | Y | Y |
| Cisco Business Edition | Y | N | N | N | N |
| Cisco Unity Connection (Unified/Integrated Messaging) | Y | Y | Y | Y | N |
| Cisco Unity (Unified Messaging and Voice Messaging) | Y | Y | N | Y | Y |

1. If you use the Cisco Unified Messaging Gateway to network the various products, the number of supported users increases significantly and is directly related to the number of networked nodes and maximum number of users supported by the Unified Messaging Gateway. For further details on Cisco Unified Messaging Gateway scalability, refer to the Cisco Unified Messaging Gateway data sheet, available at http://www.cisco.com/en/US/products/ps8605/products_data_sheets_list.html.

**Note**

Although both the Voice Profile for Internet Mail (VPIM) protocol and Digital Networking provide a significant increase in the maximum number of supported users, Digital Networking also provides additional server discovery and directory synchronization functionality.

See [Voicemail Networking with Cisco Unified Messaging Gateway, page 21-4](#), for more details on scalability.

Voicemail Networking with Cisco Unified Messaging Gateway

Cisco Unified Messaging Gateway (UMG) enables Cisco's end-to-end networked voice messaging solution by providing intelligent voice message routing, management of system directories, messaging format, and delivery of a scalable voice messaging framework. Cisco UMG supports Cisco Unity, Cisco Unity Express, Cisco Unity Connection, and Avaya Interchange.

This chapter focuses on the design aspects of integrating Cisco Unity, Cisco Unity Connection, and Cisco Unity Express with Cisco Unified Communications Manager (Unified CM). Cisco Unified CM provides functionality for Session Initiation Protocol (SIP) trunks, which support integration directly to Cisco Unity and Unity Connection without the need for a SIP proxy server.

For information on earlier releases of Cisco Unity, Unity Connection, Unity Express, and Unified CM or Unified CM Express, refer to the appropriate online product documentation available at <http://www.cisco.com>.

As mentioned, the design topics covered in this chapter apply to voicemail-only, unified messaging, and integrated messaging configurations. Additionally, this chapter discusses design aspects of deploying Cisco Unity or Cisco Unity Connection with Microsoft Exchange (2003, 2007, or 2010) and Microsoft Windows (2003). Also, support for Microsoft Active Directory (AD) 2008 has been added to Cisco Unity 7.x and later releases. This chapter does not cover design aspects of deployments or upgrades from Microsoft NT 4.0 and/or Exchange 5.5. Cisco Unity Connection and Unity Express have no dependencies on an external message store. Although Cisco Unity Connection 8.x supports Exchange integration, it is not dependent upon Exchange integration as is Cisco Unity.

**Note**

For exact versions of Cisco Unity that support Microsoft Exchange 2010 and Active Directory 2008 R2, refer to the release notes for Cisco Unity available at http://www.cisco.com/en/US/products/sw/voicesw/ps2237/prod_release_notes_list.html.

For additional design information about Cisco Unity or Cisco Unity Connection, including integrations with other non-Cisco messaging systems, refer to the *Design Guide for Cisco Unity* or the *Design Guide for Cisco Unity Connection*, respectively, available at <http://www.cisco.com>.

For additional design information about Cisco Unity Express, including integrations with other non-Cisco messaging systems, refer to the applicable product documentation, available at <http://www.cisco.com>.

For additional design information about Cisco Unified Messaging Gateway, including integrations with other non-Cisco messaging systems, refer to the Cisco Unified Messaging Gateway product documentation, available at <http://www.cisco.com>.

Messaging Deployment Models

This section summarizes the various messaging deployment models for Cisco Unity, Cisco Unity Connection, and Cisco Unity Express. For a complete discussion of the deployment models and design considerations specific to Cisco Unity, Unity Connection, and the various messaging components, refer to the *Design Guide for Cisco Unity* or the *Design Guide for Cisco Unity Connection*, respectively, available at <http://www.cisco.com>. For Cisco Unity Express, refer to the applicable product documentation available at <http://www.cisco.com>.

Cisco Unity and Unity Connection support three primary messaging deployment models:

- Single-site messaging
- Multisite deployment with centralized messaging
- Multisite deployment with distributed messaging

Cisco Unity Express also supports three primary messaging deployment models:

- Single-site messaging
- Multisite deployment with distributed messaging

- Multisite deployment with distributed messaging with Cisco Unified CME

**Note**

The Cisco Unity Express supports centralized voice messaging for up to 10 Unified CMEs. For more information, refer to the Cisco Unified Communications Manager Express documentation on <http://www.cisco.com>.

Although the call processing deployment models for Cisco Unified CM and Unified CME are independent of the messaging deployment models for Cisco Unity, Unity Connection, and Unity Express, each has implications toward the other that must be considered.

In addition to the three messaging deployment models, Cisco Unity also supports messaging redundancy. (See [Messaging Redundancy, page 21-18](#).) Cisco Unity Connection messaging redundancy is also available in an active/active configuration. For more information, refer to the *Design Guide for Cisco Unity Connection* available on <http://www.cisco.com>.

All messaging deployment models support voicemail, integrated messaging, and unified messaging installations.

Single-Site Messaging

In this model, the messaging systems and messaging infrastructure components are all located at the same site, on the same highly available LAN. The site can be either a single site or a campus site interconnected via high-speed metropolitan area networks (MANs). All clients of the messaging system are also located at the single (or campus) site. The key distinguishing feature of this model is that there are no remote clients.

Centralized Messaging

In this model, similar to the single-site model, all the messaging system and messaging infrastructure components are located at the same site. The site can be one physical site or a campus site interconnected via high-speed MANs. However, unlike the single-site model, centralized messaging clients can be located both locally and remotely.

Because messaging clients may be either local or remote from the messaging system, special design considerations apply to the following graphical user interface (GUI) clients: ViewMail for Outlook (VMO) and the use of the telephone record and playback (TRaP) and message streaming features when used in Cisco Unity. Remote clients should not use TRaP and should be configured to download messages before playback. Because different features and operations for local and remote clients can cause user confusion, TRaP should be disabled on the voice ports and GUI clients should be configured to download messages and not use TRaP, regardless of whether the client is local or remote. This applies to ViewMail for Outlook (VMO) for Cisco Unity IMAP clients. These design considerations are specific to Cisco Unity only.

The Cisco Unity telephone user interface (TUI) operates the same way for both local and remote clients.

Distributed Messaging

A distributed messaging model consists of multiple single-site messaging systems distributed with a common messaging backbone. There can be multiple locations, each with its own messaging system and messaging infrastructure components. All client access is local to each messaging system, and the

messaging systems share a messaging backbone that spans all locations. Message delivery from the distributed messaging systems occurs via the messaging backbone through a full-mesh or hub-and-spoke type of message routing infrastructure. No messaging infrastructure components should be separated by a WAN from the messaging system they service.

Distributed messaging is essentially multiple, single-site messaging models with a common messaging backbone. The exception to this rule is the PBX-IP Media Gateway (PIMG) and T1-IP Media Gateway (TIMG) integrations. PIMG and TIMG integrations are not discussed in this design document. For further information regarding PIMG or TIMG, refer to the Cisco Unity integration guides available on <http://www.cisco.com>.

The distributed messaging model has the same design criteria as centralized messaging with regard to local and remote GUI clients, TRaP, and message downloads.

Messaging and Unified CM Deployment Model Combinations

This section discusses the design considerations for integrating the various messaging deployment models with the Unified CM call processing deployment models. Table 21-4 lists the various combinations of messaging and call processing deployment models supported by Cisco Unity, Unity Connection, and Unity Express.

Table 21-4 Supported Combinations of Messaging and Unified CM Call Processing Deployment Models

| Model Type | Cisco Unity | Cisco Unity Connection | Cisco Unity Express |
|---|-------------|------------------------|---------------------|
| Single-site messaging and single-site call processing | Yes | Yes | Yes |
| Centralized messaging and centralized call processing | Yes | Yes | No ¹ |
| Distributed messaging and centralized call processing | Yes | Yes | Yes |
| Centralized messaging and distributed call processing | Yes | Yes | No ¹ |
| Distributed messaging and distributed call processing | Yes | Yes | Yes |
| Centralized messaging with cluster over the WAN | Yes | Yes | No |
| Distributed messaging with cluster over the WAN | Yes | Yes | Yes |

1. Support for centralized voicemail messaging with Unified CME is available starting with Cisco Unity Express 3.2; however, this is not applicable to Unified CM call processing deployment models.

This section covers the following topics:

- Cisco Unity and Unity Connection messaging and Unified CM deployment models
- Cisco Unity Express deployment models

Each topic defines a messaging and Unified CM deployment model combination and then highlights each Cisco voicemail messaging product applicable to that model as well as the design considerations for that model combination. Not all combinations are discussed for each product. Some examples are provided, with best practices and design considerations for each product. The intention is to provide an understanding of the base messaging deployment models and the interaction with Unified CM without detailing all possibilities.

Refer to the *Design Guide for Cisco Unity* and the *Design Guide for Cisco Unity Connection*, available at <http://www.cisco.com>, for further details on site classification and a detailed analysis of supported combinations of messaging and call processing deployment models.

Cisco Unity and Unity Connection Messaging and Unified CM Deployment Models

This section discusses some of the various combinations of messaging and call processing deployment models for Cisco Unity and Unity Connection.

Centralized Messaging and Centralized Call Processing

In centralized messaging, the voice messaging server is located in the same site as the Unified CM cluster. With centralized call processing, subscribers may be located either remotely and/or locally to the cluster and messaging server(s). (See [Figure 21-1](#).) When remote users access resources at the central site (such as voice ports, IP phones, or PSTN gateways, as in Tail-End Hop-Off (TEHO)), these calls are transparent to gatekeeper call admission control. Therefore, regions and locations must be configured in Unified CM for call admission control. (See [Managing Bandwidth, page 21-34](#).) When making inter-region calls to IP phones or MGCP gateways, IP phones automatically select the inter-region codec that has been configured. With Cisco Unity messaging deployments, native transcoding should be disabled so that the voice ports use Unified CM transcoding resources for calls that transverse the WAN (inter-region). See the section on [Native Transcoding Operation, page 21-35](#), for information on disabling this feature in Cisco Unity.

Figure 21-1 Centralized Messaging with Centralized Call Processing

In [Figure 21-1](#), regions 1 and 2 are configured to use G.711 for intra-region calls and G.729 for inter-region calls. Native transcoding has been disabled on the Cisco Unity server.

As [Figure 21-1](#) shows, when a call is made from extension 200 to the voicemail ports in Region 1, the inter-region G.729 codec is used at the endpoint but the RTP stream is transcoded to use G.711 on the voice ports. Native transcoding on the Cisco Unity server has been disabled in this example. Unified CM transcoding resources must be located at the same site as the voicemail system.

Impact of Non-Delivery of RDNIS on Voicemail Calls Routed by AAR

In centralized messaging environments, automated alternate routing (AAR), a Unified CM feature, can route calls over the PSTN to the messaging store at the central site when the WAN is oversubscribed. However, when calls are rerouted over the PSTN, Redirected Dialed Number Information Service (RDNIS) can be affected. Incorrect RDNIS information can impact voicemail calls that are rerouted over the PSTN by AAR when Cisco Unity or Unity Connection is remote from its messaging clients. If the RDNIS information is not correct, the call will not reach the voicemail box of the dialed user but will instead receive the auto-attendant prompt, and the caller might be asked to re-enter the extension number of the party they wish to reach. This behavior is primarily an issue when the telephone carrier is unable to ensure RDNIS across the network. There are numerous reasons why the carrier might not be able to ensure that RDNIS is properly sent. Check with your carrier to determine if they provide guaranteed RDNIS deliver end-to-end for your circuits. The alternative to using AAR for oversubscribed WANs is simply to let callers hear reorder tone in an oversubscribed condition.

Survivable Remote Site Voicemail

Survivable Remote Site Voicemail (SRSV) provides backup voicemail service in the centralized messaging and centralized call processing deployment. SRSV utilizes Cisco Unity Express in the branch location to provide backup voicemail service for Cisco Unity Connection located in the headquarters when the connection between sites is unavailable. (See [Figure 21-2](#).) During normal operation, Cisco Unified Messaging Gateway in the headquarters retrieves the configurations (for example, SRST phones, user, and mailbox information) from Cisco Unified CM and Cisco Unity Connection to provision and update the mailboxes in Cisco Unity Express SRSV based on a configured schedule. Cisco Unity Express SRSV is active when only SRST is activated, and it remains idle otherwise. When the network connection between sites is restored, Cisco Unity Express SRSV uploads all messages (new, saved, deleted, and so forth) to Cisco Unity Connection.

Figure 21-2 Typical Survivable Remote Site Voicemail Deployment

**Note**

Survivable Remote Site Telephony (SRST) and Cisco Unity Express SRSV are one logical unit, with Cisco Unity Express SRSV installed in the SRST router.

**Note**

The Cisco Unified Messaging Gateway SRSV feature has reached End-of-Sale (EoS) and End-of-Life (EoL). There is no replacement available for the SRSV feature at this time. For more information on this, refer to the End-of-Sale and End-of-Life Announcement at http://www.cisco.com/en/US/prod/collateral/voicesw/ps6789/ps5745/ps8605/end_of_life_notice_c51-695653.pdf.

SRSV uses bandwidth from the WAN link during the following activities:

- Configuration uploads from Unified CM and Cisco Unity Connection to Cisco Unity Express SRSV
- Voice message uploads from Cisco Unity Express SRSV to Cisco Unity Connection when the WAN link is restored

To minimize the impact of SRSV traffic on the existing voice network, classify the SRSV traffic (configuration and voice message uploads) as best-effort. The SRSV software does not mark any network packets. Cisco recommends marking the SRSV traffic with IP Precedence 0 (DSCP 0 or PHB BE) in the network edge router in order to yield to voice and other high-priority traffic. To further reduce the impact, Cisco recommends scheduling the configuration uploads to take place during non-peak hours (for example, in the evening hours or during the weekend). The schedule can be configured from the Unified Messaging Gateway SRSV web interface.

When you deploy SRSV, the following rules apply:

- Unified Messaging Gateway SRSV supports up to 1,000 Cisco Unity Express SRSV nodes.
- SRSV does not support Cisco Unified CM Business Edition.
- Install Cisco Unity Express SRSV on the SRST router or on Unified CME running in SRST mode.

- Multiple SRST routers are supported in the branch, but each router must have its own Cisco Unity Express SRSV and allows only one Cisco Unity Express SRSV.
- Deploy redundant Unified Messaging Gateway SRSV to provide high availability for voice message uploads. Unified Messaging Gateway SRSV does not support high availability for configuration uploads.
- Use Secure Socket Layer (SSL) protocol to secure the connection between Unified Messaging Gateway SRSV and Cisco Unity Express SRSV.
- SRSV does not support Cisco Unity.

For more information on SRSV, refer to the documentation available at <http://www.cisco.com/go/srsv>.

Distributed Messaging with Centralized Call Processing

Distributed messaging means that there are multiple messaging systems distributed within the telephony environment, and each messaging system services only local messaging clients. This model differs from centralized messaging, where clients are both local and remote from the messaging system.

[Figure 21-3](#) illustrates the distributed messaging model with centralized call processing. As with other multisite call processing models, the use of regions and locations is required to manage WAN bandwidth. For this model, you should also disable native transcoding in Cisco Unity.

Note that Cisco Unified Communications Manager Express (Unified CME) in SRST mode is used for call processing backup of both IP phones and Cisco Unity or Unity Connection voicemail ports. Deployed at the remote site (for example, Region 2 in [Figure 21-3](#)), this fallback support provides backup call processing in the event that the phones lose connectivity with Unified CM, such as during a WAN failure, while simultaneously providing users at the remote site with access to the local Cisco Unity or Unity Connection server as well as MWI support during WAN failure. For further details on Unified CME in SRST mode, refer to the Unified CME product documentation on <http://www.cisco.com>.

maximum of 20 nodes. This provides support for up to 100,000 entities in the directory. Cisco Unity Connection can integrate with a corporate directory such as Microsoft Active Directory to synchronize users and use digital networking simultaneously. In this configuration, each Cisco Unity Connection server or server pair will be able to synchronize up to 20,000 users from the corporate directory. Refer to the *Design Guide for Cisco Unity Connection*, available at <http://www.cisco.com>, for further information regarding digital networking or directory integration in Cisco Unity Connection.

Cisco Unity and Unity Connection with Unified CME in SRST Mode

Unified CME in SRST mode offers the possibility for both Cisco Unity and Unity Connection servers located in remote sites and registered with a Unified CM at the central site to fall-back to Unified CME in the remote location. When the WAN link is down and the phones fail-over to Unified CME in SRST mode, Cisco Unity and Unity Connection voicemail ports can also fail-over to Unified CME in SRST mode to provide the remote site users with access to their voicemail with MWI during the WAN outage.

This scenario requires the following:

- Cisco Unified CME 4.0 or later
- Cisco Unity 4.0(5) or later with TSP version 8.1(3) or later
- Cisco Unity Connection 2.x or later

Note

MWI has to be resynchronized from the Cisco Unity or Unity Connection server whenever a failover happens from Unified CM to Unified CME in SRST mode, or vice versa.

Combined Messaging Deployment Models

It is possible to combine messaging models in the same deployment, provided that the deployment adheres to all the guidelines listed in the preceding sections. [Figure 21-4](#) shows a user environment in which both centralized and distributed messaging are employed simultaneously.

Figure 21-4 Combined Deployment Models

[Figure 21-4](#) shows the combination of two messaging models. Regions 1 and 3 use centralized messaging with centralized call processing, while Region 2 uses distributed messaging with centralized call processing. All regions are configured to use G.711 for intra-region calls and G.729 for inter-region calls.

In [Figure 21-4](#), centralized messaging and centralized call signaling are used between the Central Site and Site3. The messaging system at the Central Site provides messaging services for clients at both the Central Site and Site3. Site2 uses the distributed messaging model with centralized call processing. The messaging system (Unity2) located at Site2 provides messaging services for only those users located within Site2. In this deployment, both models adhere to their respective design guidelines as presented

in this chapter. Transcoding resources are located locally to each messaging system site, and they support clients who access messaging services from a remote site (relative to the messaging system), as in the case of a Site2 user leaving a message for a Central Site user.

In addition, Cisco Unified Communications Manager Express (Unified CME) in SRST mode is used for call processing backup of both IP phones and Cisco Unity or Unity Connection voicemail ports. Deployed at the remote site (for example, Region 2 in [Figure 21-4](#)), this fallback support provides backup call processing in the event that the phones lose connectivity with Unified CM, such as during a WAN failure, while simultaneously providing users at the remote site with access to the local Cisco Unity or Unity Connection server as well as MWI support during WAN failure. For further details on Unified CME in SRST mode, refer to the product documentation on <http://www.cisco.com>.

Centralized Messaging with Clustering Over the WAN

This section addresses Cisco Unity design issues for deploying centralized messaging with Unified CM clustering over the WAN with local failover. In the case of a WAN failure with this model, all remote messaging sites will lose voicemail capability until the WAN is restored. (See [Figure 21-5](#).)

Clustering over the WAN supports local failover. With local failover, each site has a backup subscriber server physically located at the site. This section focuses on deploying Cisco Unity centralized messaging with local failover for clustering over the WAN.

For additional information, refer to the section on [Clustering Over the IP WAN](#), page 5-45.

Figure 21-5 Cisco Unity Centralized Messaging and Clustering Over the WAN with Local Failover

For minimum bandwidth requirements between clustered servers see the section on [Local Failover Deployment Model](#), page 5-49.

Clustering over the WAN with Unified CM supports up to eight sites, as does Cisco Unity. The voicemail ports are configured only at the site where the Cisco Unity messaging system is located (see [Figure 21-5](#)). Voicemail ports do not register over the WAN to the remote site(s). Messaging clients at the other site(s) access all voicemail resources from the primary site. There is no benefit to configuring voice ports over the WAN to any of the remote sites because, in the event of a WAN failure, remote sites would lose access to the centralized messaging system. Because of bandwidth consideration, the voicemail ports should have TRaP disabled and all messaging clients should download voicemail messages to their local PCs (unified messaging only).

Distributed Messaging with Clustering Over the WAN

Local failover sites that also have Cisco Unity messaging server(s) deployed would have voice ports registered to the local Unified CM subscriber server(s), similar to the centralized messaging model. For information about configuring the voice ports, see [Voice Port Integration with a Unified CM Cluster](#), page 21-41, and [Voice Port Integration with Dedicated Unified CM Backup Servers](#), page 21-43.

Figure 21-6 Cisco Unity Distributed Messaging and Clustering over the WAN with Local Failover

In a purely distributed messaging implementation with clustering over the WAN, each site in the cluster would have its own Cisco Unity messaging server with messaging infrastructure components. If not all of the sites have local Cisco Unity messaging systems but some sites have local messaging clients using a remote messaging server(s), this deployment would be a combination model with both distributed messaging and centralized messaging. (See [Combined Messaging Deployment Models](#), page 21-14.) In the event of a WAN failure in this model, all remote sites that use centralized messaging will lose voicemail capability until the WAN is restored.

Each site that does not have a local messaging server must use a single messaging server for all of its messaging clients, but all such sites do not have to use the same messaging server. For example, suppose Site1 and Site2 each have a local messaging server. Site3 can then have all of its clients use (register with) the messaging server at Site2, while Site4 can have all of its clients use the messaging server at Site1. Transcoder resources are required at sites that have local Cisco Unity messaging server(s).

As with other distributed call processing deployments, calls going between these sites are transparent to gatekeeper call admission control, therefore you must configure regions and locations in Unified CM to provide call admission control. (See [Managing Bandwidth](#), page 21-34.)

The distributed Cisco Unity servers may also be networked digitally. For more information on this topic, refer to the *Cisco Unity Networking Guide*, available at <http://www.cisco.com>. The networking guides are specific to the particular messaging store deployed.

Messaging Redundancy

Messaging redundancy is discussed in this section as it refers to Cisco Unity and Cisco Unity Connection. Cisco Unity Express does not support messaging redundancy.

Cisco Unity

Cisco Unity supports two categories of redundancy. The first one is referred to simply as Unity Failover (local messaging failover), and it provides system malfunction failover. The second category is referred to as Standby Redundancy, and it provides disaster-recovery across geographic locations. See the *Cisco Unity Design Guide* for a comparison of Cisco Unity Failover and Standby Redundancy.

Cisco Unity failover consists of two servers, a primary and a secondary, configured as an active/passive redundant pair of servers, where the primary server is active and taking calls while the secondary is inactive and not taking calls. Any changes to subscriber or configuration data on the primary server are automatically replicated to the secondary server. If the primary server stops functioning for some reason, the secondary server automatically becomes the active server and starts taking calls while the primary server temporarily becomes inactive.

You can implement local messaging failover as illustrated in [Figure 21-7](#). With local failover, both the primary and secondary Cisco Unity servers are located at the same site on the same highly available LAN.

Figure 21-7 Local Failover of Cisco Unity Messaging

Cisco Unity Standby Redundancy also provides disaster recovery across geographic locations. There are still two servers, a primary and a secondary, but they are installed in separate data centers, commonly in separate cities. If the data center in which the primary server is installed is affected by a natural disaster or other catastrophe, someone in (or with remote access to) the disaster-recovery facility manually activates the secondary server, and the secondary server begins taking calls. For further information on the requirements for Standby Redundancy or Failover (local messaging failover), refer to the appropriate version of the *System Requirements for Cisco Unity*, available on <http://www.cisco.com>.

Cisco Unity Connection

Cisco Unity Connection supports messaging redundancy and load balancing in an active-active redundancy model consisting of two servers, a primary and a secondary, configured as an active/active redundant pair of servers, where both the primary and secondary servers actively accept calls as well as HTTP and IMAP requests. For more information, refer to the *Design Guide for Cisco Unity Connection*, available at <http://www.cisco.com>.

Figure 21-8 illustrates Cisco Unity Connection active/active messaging redundancy.

Figure 21-8 Redundancy of Cisco Unity Connection Messaging

Both Cisco Unity and Cisco Unity Connection SIP trunk implementation requires call forking for messaging redundancy functionality. Currently, Unified CM does not support call forking on SIP trunks; therefore, Cisco Unity failover is not available when SIP trunks are used with Unified CM. However, when using SIP trunks with a Cisco Unity Connection server pair in active/active redundancy, Cisco recommends that you configure two separate SIP trunks, one to each server in the server pair, and add them to the same route group associated to the same route list. The route group should be configured in top-down order so that calls are sent first to the primary Unity Connection server and then overflow to the secondary Unity Connection server.

Cisco Unity Failover and Clustering Over the WAN

When deploying Cisco Unity local failover with clustering over the WAN, apply the same design practices described in [Centralized Messaging with Clustering Over the WAN, page 21-15](#), and [Distributed Messaging with Clustering Over the WAN, page 21-17](#). The voice ports from the primary Cisco Unity server should not cross the WAN during normal operation.

Figure 21-9 depicts Cisco Unity local failover. Note that the primary and secondary Cisco Unity servers are both physically located at the same site. Cisco Unity failover supports up to the maximum number of remote sites available with clustering over the WAN for Unified CM.

Figure 21-9 Cisco Unity Local Failover and Clustering Over the WAN

For information on configuring Cisco Unity failover, refer to the *Cisco Unity Failover Configuration and Administration Guide*, available at <http://www.cisco.com>.

Cisco Unity Failover Deployed Over a Split Data Center

As mentioned earlier, Cisco Unity failover can be configured to operate for high availability over a WAN; however, there are a number of requirements for deploying this. For example, if full redundancy at geographically separated data centers is important, there are certain requirements that must be met in order to ensure the successful operation of an installation in this configuration. Figure 21-10 depicts Cisco Unity failover for geographically separated data centers.

Figure 21-10 Cisco Unity Failover for Geographically Separated Data Centers

The following requirements apply to the configuration shown in Figure 21-10:

- Maximum of 10 ms round trip time (RTT) between primary and secondary Cisco Unity servers
- Minimum of 1 Gigabit of bandwidth
- Maximum of 10 ms RTT between the Cisco Unity server and respective messaging server
- The Cisco Unity server and domain controller or global catalog server should be co-located

For a complete set of requirements, refer to the latest version of the *System Requirements for Cisco Unity*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps2237/prod_installation_guides_list.html

253869

Cisco Unity Connection Redundancy and Clustering Over the WAN

Cisco Unity Connection supports active/active clustering for redundancy and can be deployed over the WAN. The active/active or "high availability" configuration provides both high availability and redundancy. Both servers in the active/active pair run the Cisco Unity Connection application to accept calls as well as HTTP and IMAP requests from clients. Each of the servers from the cluster can be deployed over the WAN at different sites following required design consideration. Figure 21-11 depicts a Cisco Unity Connection active/active deployment for geographically separated data centers

Figure 21-11 Cisco Unity Connection with High Availability Between Two Sites

The following requirements apply to deployments of Cisco Unity Connection servers over different sites:

- Maximum of 150 ms RTT between an active/active pair at different sites.
- Minimum of 7 Mbps bandwidth is required for every 50 ports. (For example, 250 ports require 35 Mbps.)

Note

Bandwidth and latency requirements may differ for different versions of Cisco Unity Connection.

253870

For a complete set of requirements, refer to the latest version of the *System Requirements for Cisco Unity Connection*, available at

http://www.cisco.com/en/US/products/ps6509/prod_installation_guides_list.html

Note

The Cisco Unity Connection cluster feature is not supported for use with Cisco Business Edition 3000 and 5000.

Centralized Messaging with Distributed Unified CM Clusters

Cisco Unity and Unity Connection can also be deployed in a centralized messaging configuration with multiple Unified CM clusters (see Figure 21-12). See the section on [Telephony Integrations](#), page 21-38, for details on multiple integrations and MWI considerations with multiple Unified CM clusters.

Figure 21-12 Integrating Cisco Unity or Unity Connection with Multiple Unified CM Clusters

For the configuration in Figure 21-12, messaging clients at both Cluster 1 and Cluster 2 sites use the Cisco Unity or Unity Connection messaging infrastructure physically located at Cluster 1.

Cisco Unity Express Deployment Models

This section begins with a quick overview of Cisco Unity Express, covering product related information. Next the deployment models section presents three supported deployment models with Cisco Unity Express, focusing on distributed voice messaging with both centralized and distributed call processing followed by some deployment characteristics and design guidelines. Lastly, this section discusses the signaling call flows and the various protocols used between Cisco Unity Express and Unified CM as well as between Cisco Unity Express and Unified SRST or Unified CME in SRST mode.

Overview of Cisco Unity Express

Cisco Unity Express is Linux-based software running on a Cisco Network Module in Cisco Integrated Services Routers (ISRs). It is an entry-level auto-attendant (AA) and voicemail solution that can be deployed with Cisco Unified Communications Manager (Unified CM), Cisco Unified SRST, or Cisco Unified Communications Manager Express (Unified CME). In prior releases, Cisco Unity Express was limited to a co-resident deployment with Unified CME or a Survivable Remote Site Telephony (SRST) router. However, with the H.323-to-SIP call routing capability introduced in Cisco IOS Release 12.3(11)T, Cisco Unity Express and SRST or Unified CME can reside on two separate routers when deployed with Unified CM or Unified CME, respectively. Cisco Unity Express uses SIP to communicate with Cisco Unified Communications Manager Express (Unified CME) while Cisco Unity Express uses JTAPI to connect to Cisco Unified Communications Manager (Unified CM).

For more information on supported hardware platforms and capacity with Cisco Unity Express, refer to the product release note available at http://www.cisco.com/en/US/products/sw/voicesw/ps5520/prod_release_notes_list.html.

For details on interoperability of Unified CM and Unified CME, see [Interoperability of Unified CM and Unified CM Express, page 8-44](#).

For additional information on supported deployment models with Unified CME, refer to the appropriate Cisco Unified Communications Manager Express design documentation available at <http://www.cisco.com>.

Deployment Models

Cisco Unity Express can be deployed as a single site or distributed voicemail and automated attendant (AA) solution for Cisco Unified Communications Manager (Unified CM) or Unified Communications Manager Express (Unified CME). However, Cisco Unity Express is supported with all of the Cisco Unified CM deployment models, including:

- Single-site deployments
- Multisite deployments with centralized call processing
- Multisite deployments with distributed call processing

[Figure 21-13](#) shows a centralized call processing deployment incorporating Cisco Unity Express, and [Figure 21-14](#) shows a distributed call processing deployment.

Cisco Unity Express sites controlled by Unified CME, as well as other sites controlled by Unified CM, can be interconnected with each other using H.323 or SIP trunking protocol. Although Cisco Unity Express can integrate with either Unified CM or Unified CME, it cannot integrate with both simultaneously.

**Note**

Cisco Unity Express supports a centralized deployment model with up to 10 Unified CMEs.

Figure 21-13 Cisco Unity Express in a Centralized Call Processing Deployment

Figure 21-14 Cisco Unity Express in a Distributed Call Processing Deployment

The most likely deployment model to use Cisco Unity Express is the multisite WAN model with centralized call processing, where Cisco Unity Express provides distributed voicemail at the smaller remote offices and a central Cisco Unity system provides voicemail to the main campus and larger remote sites.

Use Cisco Unity Express as a distributed voicemail solution if any of the following conditions apply to your Unified CM network deployment:

- Survivability of voicemail and AA access must be ensured regardless of WAN availability.
- Available WAN bandwidth is insufficient to support voicemail calls traversing the WAN to a central voicemail server.
- There is limited geographic coverage of the AA or branch site PSTN phone numbers published to the local community, and these numbers cannot be dialed to reach a central AA server without incurring toll charges.
- The likelihood is high that a PSTN call into a branch office will be transferred from the branch AA to a local extension in the same office.
- Management philosophy allows remote locations to select their own voicemail and AA technology.

The following characteristics and guidelines apply to Cisco Unity Express in either a centralized or distributed Unified CM deployment:

- A single Cisco Unity Express can be integrated with a single Unified CM cluster.
- Cisco Unity Express integrates with Unified CM using a JTAPI application and Computer Telephony Integration (CTI) Quick Buffer Encoding (QBE) protocol. CTI ports and CTI route points control the Cisco Unity Express voicemail and automated attendant (AA) applications.

- Cisco Unity Express provides voicemail functionality to Cisco Unified IP Phones running Skinny Client Control Protocol (SCCP). Cisco Unity Express 2.3 and later releases also provide support for Session Initiation Protocol (SIP) IP phones with Unified CM.
- The following CTI route points are defined on Unified CM for Cisco Unity Express:
 - Automated attendant entry point (Cisco Unity Express can contain up to five distinct AAs and may therefore require up to five different route points.)
 - Voicemail pilot number
 - Greeting management system (GMS) pilot number (Optional; if the GMS is not used, then this route point need not be defined.)
- The number of CTI ports and mailboxes supported for Cisco Unity Express on Unified CM depends on the hardware platform. For details, refer to the Cisco Unity Express data sheet available at:
http://www.cisco.com/en/US/products/sw/voicesw/ps5520/products_data_sheets_list.html
- For Cisco Unity Express deployments that require more than the maximum number of supported mailboxes, consider using Cisco Unity or other voicemail solutions.
- Each Cisco Unity Express mailbox can be associated with a maximum of two different extensions, if needed.
- The automated attendant function for any office deployed with Cisco Unity Express can be local to the office (using the AA application in Cisco Unity Express) or centralized (using Cisco Unity Express for voicemail only).
- Cisco Unity Express can be networked with other Cisco Unity Expresses or with Cisco Unity via Voice Profile for Internet Mail (VPIM) version 2. Thus, a Cisco Unity Express subscriber can send, receive, or forward messages to or from another remote Cisco Unity Express or Cisco Unity subscriber.
- Cisco Unity Express allows you to specify up to three Unified CMs for failover. If IP connectivity to all three Unified CMs is lost, Cisco Unity Express switches to Survivable Remote Site Telephony (SRST) call signaling, thus providing AA call answering service as well as mailbox access to IP phones and PSTN calls coming into the branch office.
- Cisco Unity Express automated attendant supports dial-by-extension and dial-by-name functions. The dial-by-extension operation enables a caller to transfer a call to any user endpoint in the network. The dial-by-name operation uses the directory database internal to Cisco Unity Express and does not interact with external LDAP or Active Directory databases.
- Centralized Cisco Unity Express with Unified CM is not supported.
- Cisco Unity Express is not supported in pure SIP networks that do not have either Cisco Unified CM or Unified CME controlling the SIP phones.
- Cisco Unity Express can be deployed on a separate Unified CME or SRST router or a separate PSTN gateway.
- When Cisco Unity Express is deployed on a router separate from Unified CME or SRST, configure the command **allow-connections h323 to sip** for H.323-to-SIP routing.

Figure 21-15 shows the protocols involved in the call flow between Unified CM and Cisco Unity Express.

Figure 21-15 Protocols Used Between Cisco Unity Express and Unified CM

Figure 21-15 illustrates the following signaling and media flows:

- Phones are controlled via SCCP or SIP from Unified CM.
- Cisco Unity Express is controlled via JTAPI (CTI-QBE) from Unified CM.
- The Message Waiting Indicator (MWI) on the phone is affected by Cisco Unity Express communicating a change of mailbox content to Unified CM via CTI-QBE, and by Unified CM in turn sending a MWI message to the phone to change the state of the lamp.
- The voice gateway communicates via H.323, SIP, or MGCP to Unified CM.
- Real-Time Transport Protocol (RTP) stream flows carry the voice traffic between endpoints.

Figure 21-16 shows the protocols involved in the call flow between the router for SRST or Unified CME in SRST mode and Cisco Unity Express when the WAN link is down.

Figure 21-16 Protocols Used Between Cisco Unity Express and the Router for SRST or Unified CME in SRST Mode

Figure 21-16 illustrates the following signaling and media flows:

- Phones are controlled via SCCP or SIP from the router for SRST or Unified CME in SRST mode.
- Cisco Unity Express communicates with the SRST router via an internal SIP interface.
- Although MWI changes are not supported in SRST mode with previous releases of Cisco Unity Express, voice messages can be sent and retrieved as during normal operation, but the MWI lamp state on the phone remains unchanged until the phone registers again with Unified CM. At that time, all MWI lamp states are automatically resynchronized with the current state of the users' Cisco Unity Express voicemail boxes. Cisco Unity Express 3.0 and later releases support MWI for SRST mode.
- Cisco Unity Express supports SIP Subscriber/Notify and Unsolicited Notify to generate MWI notifications, in both Unified CME and SRST modes.
- RTP stream flows carry the voice traffic between endpoints.
- SRST subscribes to Cisco Unity Express for MWI for each of the ephone-dns registered to receive MWI notifications.

Note

Unified CM MWI (JTAPI) is independent of the SIP MWI methods.

Voicemail Networking

This section covers specific considerations for voicemail networking, including Cisco Unity, Cisco Unity Connection, and Cisco Unity Express. Also included is a high-level overview of voicemail networking with the Cisco Unified Messaging Gateway. For information specific to voicemail networking in Cisco Unity and Unity Connection, refer to the *Design Guide for Cisco Unity* or the *Design Guide for Cisco Unity Connection*, respectively, available at <http://www.cisco.com>.

Voicemail networking is the ability to allow subscribers (voicemail users) to send, receive, reply to, and forward voicemail messages between systems such as Cisco Unity, Cisco Unity Connection, and Cisco Unity Express using an embedded Simple Mail Transfer Protocol (SMTP) server and a subset of the Voice Profile for Internet Mail (VPIM) version 2 protocol. All three voicemail messaging products support interoperability between one another using VPIM messaging.

Cisco Unity Express Voicemail Networking

Cisco Unity Express communicates with Cisco Unity and Cisco Unity Connection by means of VPIM for message routing and SMTP for message delivery. Cisco Unity Express voicemail networking provides the following capabilities:

- Subscribers can receive, send, and forward messages to or from another remote Cisco Unity Express or Cisco Unity for locations configured on the originating system.
- Subscribers can also reply to a remote message received from a remote system.
- Subscribers can be recipients of a distribution list or individual message originating from Cisco Unity.

For more information on voicemail networking with a specific product, refer to the corresponding voicemail product documentation available at <http://www.cisco.com>.

Voicemail Networking with Cisco Unified Messaging Gateway

The Cisco Unified Messaging Gateway is Linux-based software running on a Cisco Network Module in Cisco Integrated Services Routers (ISRs). The Unified Messaging Gateway can act as the central hub for Cisco Unity, Cisco Unity Connection, and Cisco Unity Express to network VPIM v2 voicemail systems in a hub-and-spoke or hierarchical structure. This approach dramatically reduces the VPIM connections between voicemail systems and simplifies the configuration effort on each system. Each voicemail system (Cisco Unity, Cisco Unity Connection, Cisco Unity Express, or Avaya Interchange and Message Networking Server) needs to configure only the connection between itself and the Cisco Unified Messaging Gateway. The Unified Messaging Gateway then handles message routing and delivery between the systems. This end-to-end message networking functionality is required by medium to larger distributed enterprises in order to migrate to the Cisco Unified Communications solution.

The Cisco Unified Messaging Gateway provides the following benefits:

- It enables intelligent routing for multiple autonomous voicemail networks with VPIM.
- It provides scalable voicemail networks and interoperability with third-party voicemail systems (such as Avaya Interchange) over VPIM networks.
- It simplifies voicemail VPIM network additions and expansion.

Cisco Unified Messaging can support up to 1000 nodes and 50,000 subscribers. The number of subscribers is calculated based on 50 subscribers on any single Cisco Unity Express node that is registered with the Unified Messaging Gateway. The capacity of the Unified Messaging Gateway is tied

to both the maximum number of nodes supported and the maximum number of subscribers supported, and increasing one quantity will cause a decrease in the other quantity. For example, if the network has Cisco Unity and/or Avaya endpoints with a large number of subscribers, the number of nodes that can register with the Unified Messaging Gateway will be significantly less.

Observe the following guidelines when deploying the Cisco Unified Messaging Gateway:

- Plan in advance for possible upgrades to the network if you anticipate the deployment will exceed the maximum capacity of one network module, because the network module with less capacity cannot be upgraded to the network module with higher capacity.
- Cisco Unity Express 3.1 and later releases register automatically and exchange directory information with the Cisco Unified Messaging Gateway, whereas Cisco Unity, Cisco Unity Connection, and Avaya Interchange or Message Networking Server must be provisioned manually on the Unified Messaging Gateway.
- Deploy a pair of Unified Messaging Gateways (primary and backup) for redundancy.
- Deploy up to 20 Unified Messaging Gateways (10 primary and 10 backup) for large deployments of up to 10,000 nodes.

**Note**

Voicemail networking with the Cisco Unified Messaging Gateway does not apply to deployments of Cisco Unified Communications 500 Series for Small Businesses because the Cisco Unified Communications 500 Series supports a maximum of only 5 sites in a distributed environment.

**Note**

The Cisco Unified Messaging Gateway VPIM feature has reached End-of-Sale (EoS) and End-of-Life (EoL). There is no replacement available for the VPIM feature at this time. For more information on this, refer to the End-of-Sale and End-of-Life Announcement at http://www.cisco.com/en/US/prod/collateral/voicesw/ps6789/ps5745/ps8605/end_of_life_notice_c51-695654.pdf.

For information on the Cisco Unified Communications 500 Series for Small Business deployments, refer to the product documentation on <http://www.cisco.com>.

For a complete discussion of VPIM as a distributed messaging solution and for design guidelines on the Cisco Unified Messaging Gateway, refer to the Cisco Unified Messaging Gateway product documentation available on <http://www.cisco.com>.

Voicemail Interoperability

Both Cisco Unity and Cisco Unity Connection offer good scalability options and interoperability support. Many deployments with Cisco Unity (standalone or cluster) can be expanded or migrated to include the following capabilities:

- Cisco Unity interoperability with Cisco Unity Connection
- Cisco Unity Connection interoperability with Cisco Unity Connection

For more information on these interoperability options, refer to the latest version of the *Networking Guide for Cisco Unity Connection*, available at

http://www.cisco.com/en/US/products/ps6509/prod_maintenance_guides_list.html

The following guidelines apply to both types of interoperability mentioned above:

- A Cisco Unity Connection standalone server, cluster, or digital network can interoperate with a Cisco Unity server or digital network.
- One Cisco Unity Connection digital network can be joined to only one Cisco Unity or Unity Connection digital network.
- Maximum number of users and/or contacts can be 100,000 only in any interoperate system post that system will only allow to delete and change.
- Cisco Business Edition 3000 and 5000 are not supported.
- Designate one server each from the two Cisco Unity Connection and Cisco Unity digital networks as the bridgehead or site gateway.
- The Cisco Unity Connection server designated as the site gateway should be version 8.0 or higher.
- All Cisco Unity Connection servers digitally networked to Cisco Unity must be version 8.0 or higher.
- The Cisco Unity server designated as the site gateway should be version 8.0 or higher.

Cisco Unity and Cisco Unity Connection Interoperability

Cisco Unity and Cisco Unity Connection (digital networks) can join digitally to interoperate, thus enabling users to achieve directory sharing, easy administration, and other features. The following considerations apply to designing a Cisco Unity and Cisco Unity Connection network:

- All node of the Cisco Unity Connection network should be version 8.0 or higher.
- The Cisco Unity digital network can have servers other than the site gateway on version 5.0 or higher.
- Interoperability Gateway for Microsoft Exchange should be installed on a Microsoft Exchange server.
- The Microsoft Exchange server can be 2010, 2007, 2003, or Microsoft Business Productivity Online Services (BPOS) dedicated cloud solution (Exchange 2010 at the back end only for Cisco Unity Connection 8.6 and later releases). For further details on exact versions for Microsoft Exchange, refer to the Cisco Unity Connection design guides available at
http://www.cisco.com/en/US/products/ps6509/tsd_products_support_design.html
- There is no support for IBM Domino.
- The Cisco Unity Connection network can have a maximum of 10 nodes. In a Cisco Unity Connection cluster, only the publisher server is joined to the network, so a cluster counts as a single node toward the limit of 10 in each site.

Cisco Unity Connection and Cisco Unity Connection Interoperability

Cisco Unity Connection (digital network, standalone servers, or cluster) can interoperate with another Cisco Unity Connection (digital network), thus enabling users to achieve directory sharing, easy administration, and other features, as well as expanding the total number of nodes (cluster or standalone server) up to 20. Consider the following points when deploying Cisco Unity Connection for interoperability with another Cisco Unity Connection network:

- If any of the Cisco Unity Connection nodes in the digital network system is running Cisco Unity Connection 7.0, then the maximum number of users supported is 50,000.
- There is no support for IBM Domino.
- Each Cisco Unity Connection digital network can support a maximum of 10 servers.

Cisco Unity and Unity Connection Virtualization

The Cisco Unified Computing System (UCS) is a next-generation data center platform that unites computing, networking, storage access, and virtualization into a cohesive system designed to reduce total cost of ownership (TCO) and increase business agility. Cisco Unity and Cisco Unity Connection both support virtualization over VMware with the Cisco Unified Computing system.

The following key design considerations apply to Cisco Unity Connection virtualization:

- Supports up to 20,000 users
- The Tested Reference Configurations include selected Cisco Unified Computing System (UCS) platforms. Other platforms may be supported with the specifications-based hardware support policy.
- VMware ESXi is required for virtualization.
- Servers in an active/active cluster should be on separate blades, preferably on different chassis.

**Note**

One CPU core per physical server must be left idle and reserved for the ESXi scheduler.

For more information on deploying Cisco Unified Communications, Cisco Unity, and Cisco Unity Connection in a virtualized system, refer to the documentation available at

<http://www.cisco.com/go/uc-virtualized>

General information about deploying Unified Communications on virtualized servers is also available in the section on [Deploying Unified Communications on Virtualized Servers](#), page 5-58.

For Cisco Unity Connection virtualization, also refer to the latest version of the *Design Guide for Cisco Unity Connection* available at

http://www.cisco.com/en/US/products/ps6509/products_implementation_design_guides_list.html

For Cisco Unity virtualization, also refer to the latest version of the *Design Guide for Cisco Unity Virtualization* available at

http://www.cisco.com/en/US/products/sw/voicesw/ps2237/products_implementation_design_guides_list.html

Best Practices for Voice Messaging

This section discusses some general best practices and guidelines that were not mentioned previously yet are important aspects of the products and should be considered in the solution. They are separated into two groupings, Cisco Unity and Cisco Unity Connection in one grouping and Cisco Unity Express in another.

Best Practices for Deploying Cisco Unity and Cisco Unity Connection with Unified CM

This section applies to Cisco Unity and Unity Connection. For Cisco Unity Express, see [Best Practices for Deploying Cisco Unity Express](#), page 21-45.

Managing Bandwidth

Unified CM provides a variety of features for managing bandwidth. Through the use of regions, locations, and even gatekeepers, Unified CM can ensure that the number of voice calls going over a WAN link does not oversubscribe the existing bandwidth and cause poor voice quality. Cisco Unity and Unity Connection rely on Unified CM to manage bandwidth and to route calls. If you deploy Cisco Unity or Unity Connection in an environment where calls or voice ports might cross WAN links, these calls will be transparent to gatekeeper-based call admission control. This situation occurs any time the Cisco Unity or Unity Connection server is servicing either distributed clients (distributed messaging or distributed call processing) or when Unified CM is remotely located (distributed messaging or centralized call processing). Unified CM provides regions and locations for call admission control.

[Figure 21-17](#) uses a small centralized messaging and centralized call processing site to illustrate how regions and locations work together to manage available bandwidth. For a more detailed discussion of regions and locations, refer to the chapter on Call Admission Control, page 9-1.

Figure 21-17 Locations and Regions

In Figure 21-17, regions 1 and 2 are configured to use G.711 for intra-region calls and G.729 for inter-region calls. Locations 1 and 2 are both set to 24 kbps. Location bandwidth is budgeted only in the case of inter-location calls.

An intra-region (G.711) call would not be budgeted against the available bandwidth for the location. For example, when extension 100 calls extension 101, this call is not budgeted against the 24 kbps of available bandwidth for Location 1. However, an inter-region call using G.729 is budgeted against both bandwidth allocations of 24 kbps for Location 1 and Location 2. For example, when extension 100 calls extension 200, this call would be connected but any additional (simultaneous) inter-region calls would receive reorder (busy) tone.

Native Transcoding Operation

In Cisco Unity and Unity Connection, native transcoding occurs when a call is negotiated between an IP endpoint and the Cisco Unity or Unity Connection server in one codec and is recorded or played out in another codec format. If a call is negotiated in G.729 and the system-wide recording format is done in G.711, then the server has to transcode that call natively. Cisco Unity and Unity Connection native transcoding does not use external hardware transcoders but instead uses the server's main CPU. This is what is meant by native transcoding.

Cisco Unity Operation

By default, Cisco Unity servers support G.711 and G.729 in the telephony integration via Skinny Client Control Protocol (SCCP) and/or SIP. Cisco Unity also has a default system-wide message recording format set to G.711. In order to disable native transcoding, Cisco recommends configuring the system recording format and the SCCP or SIP integration codec advertisement to coincide. For example, if you have a Cisco Unity implementation with Unified CM using SCCP Ports or a SIP trunk, you would configure the ports or trunk to advertise G.711 only by removing G.729 as one of the advertised codecs. Also, by leaving the default system-wide recording format set to G.711, any call that was negotiated with this system would effectively be in G.711 and the recording would also occur in that format, thus removing any need to transcode natively on the messaging server.

Disabling Native Transcoding in Cisco Unity

For SCCP integrations only in Cisco Unity, the native transcoding must be disabled (turned off) on the Cisco Unity server via a registry setting in order for Unified CM to assign hardware transcoders to voice port calls. The registry setting is called **Audio - Enable G.729a codec support**, and the tool for setting it is the Advanced Settings Tool available at <http://www.CiscoUnityTools.com>. (For information on disabling native transcoding on Cisco Unity when integrated via SIP, refer to the *Cisco Unified Communications Manager SIP Trunk Integration Guide for Cisco Unity* for your specific release of Cisco Unity, available at <http://www.cisco.com>.)

By default, there is no codec registry key, therefore native transcoding is enabled (on). The Advanced Settings Tool adds a new registry key that enables you to select either one of the two available codecs. Cisco Unity will then "advertise" to Unified CM that it supports only one codec. If a call terminating or originating on the voice ports is using a different codec than the type configured for the Cisco Unity server, Unified CM will assign an external transcoding resource for the call. For detailed information on how to configure transcoding resources on Unified CM, refer to the chapter on [Media Resources](#), page 17-1.

Note

Currently, the Cisco Unity TAPI Service Provider (TSP) for Unified CM supports only G.729 and G.711 mu-law (a-law is not supported) for the Skinny Client Control Protocol (SCCP) voice ports. A software Media Termination Point (MTP), such as Unified CM itself or an Integrated Services Router (ISR), is required for mu-law to a-law conversion.

When the Advanced Settings Tool is used to advertise only one codec, the Cisco Unity server system prompts must be the same as the codec used. By default, the system prompts are G.711. If the codec is set to G.711, the system prompts will work correctly. However, if G.729 is selected, you will have to change the system prompts. Refer to the *Cisco Unity System Administration Guide* on <http://www.cisco.com> for details on how to change the system prompts. If the system prompts are not the same as the codec selected by the registry, then the end users will hear unintelligible system prompts.

Cisco Unity Connection Operation

Cisco Unity Connection handles transcoding operations differently than Cisco Unity. In Cisco Unity Connection, a call in any codec format supported by Cisco Unity Connection SCCP or SIP signaling (G.711 mu-law, G.711 a-law, G.729, iLBC, and G.722) will always be transcoded to Linear PCM. From Linear PCM, the recording is encoded in the system-level recording format (Linear PCM, G.711 mu-law/a-law, G.729a, or G.726), which is set system-wide in the general configuration settings (G.711 mu-law is the default). As such the overall impact of transcoding in Cisco Unity Connection is quite

different from Cisco Unity. In the rest of this chapter, we refer to the codec negotiated between the calling device and Unity Connection as the "line codec," and we refer to the codec set in the system-level recording format as the "recording codec."

Because transcoding is inherent in every connection, there is little difference in system impact when the line codec differs from the recording codec. The exception to this is when using iLBC or G.722. G.722 and iLBC require more computation to transcode, therefore they have a higher system impact. G.722 and iLBC use approximately twice the amount of resources as G.711 mu-law. The subsequent impact this has is that a system can support only half as many G.722 or iLBC connections as it can G.711 mu-law connections.

As a general rule, Cisco recommends leaving the default codec as G.711. If the configuration is constrained by disk space, then a lower bit rate codec such as G.729a or G.726 can be configured as the recording format; however, keep in mind that the audio quality will not have the fidelity of G.711 audio. Also, if G.722 is used by devices on the line, then linear pulse code modulation (PCM) is an option to improve the audio quality of the recording. This will, however, increase the disk usage and impact disk space.

There are also a few reasons to change the recording codec or to choose to advertise only specific line codecs. Consider the following factors when deciding on the system-level recording format and the advertised codecs on the SCCP or SIP integration:

- Which codecs will be negotiated between the majority of the endpoints and Cisco Unity Connection? This will help you decide on which codecs need to be advertised by Cisco Unity Connection and which do not. You can then decide on when you need Unified CM to provide hardware transcoding resources in lieu of doing computationally significant native transcoding in Cisco Unity Connection, such as when requiring a large number of clients connected to Cisco Unity Connection using G.722 or iLBC.
- Which types of graphical user interface (GUI) clients (web browsers, email clients, media players, and so forth) will be fetching the recordings, and which codecs do the GUI clients support?
- What quality of the sound is produced by the selected codec? Some codecs are higher quality than others. For example, G.711 has a higher quality than G.729a, and it is a better choice if higher audio quality is necessary.
- How much disk space does the codec use per second of recording time?

Table 21-5 summarizes the characteristics of the codec formats supported by Cisco Unity Connection.

Table 21-5 **Codec Characteristics**

| Recording Format (Codec) | Audio Quality | Supportability | Disk Space (Bandwidth) |
|--------------------------|---------------|----------------------|------------------------|
| Linear PCM | Highest | Widely supported | 16 kbps |
| G.711 mu-law and a-law | Moderate | Widely supported | 8 kbps |
| G.729a | Lowest | Poorly supported | 1 kbps |
| G.726 | Moderate | Moderately supported | 3 kbps |
| GSM 6.10 | Moderate | Moderately supported | 1.6 kbps |

To change how Cisco Unity Connection advertises the codecs that it supports on the SIP or SCCP ports, the configuration is done differently than for Cisco Unity. Refer to the *System Administration Guide for Cisco Unity Connection* for details on changing the codec advertised by Cisco Unity Connection. The choices for advertised codecs are G.711 mu-law, G.711 a-law, G.729, iLBC and G.722. There is also a

list of preferences according to how they are ordered in the list (top-down). For SCCP integrations, the order of the codecs has no bearing because codecs are advertised and Unified CM negotiates the codec based on the location of the port and device in the negotiated call. For SIP integrations, however, the order list is significant. If the codec is preferred, then Cisco Unity Connection will advertise that it supports both protocols but will prefer to use the one specified over the other.

For information on how to change the system-level recording format in Cisco Unity Connection Administration, refer to the *System Administration Guide for Cisco Unity Connection*.

Integration with Unified CM

Cisco Unified CM can integrate with both Cisco Unity and Unity Connection via SCCP or SIP. This section discusses some specifics of that integration regarding phones, SIP trunks, and voice ports.

Telephony Integrations

Cisco Unity supports multiple separate telephony integrations, which allow users to be associated with a particular telephony integration. The message waiting indication (MWI) ports are also associated with a particular integration; thus, MWI requests are made through the ports that are associated with that specific integration.

In Cisco Unity Connection this functionality is similar. Users are associated to a phone system that contains one or more port groups. The port groups are associated with MWI ports; thus, the MWI requests are made through the ports associated to that specific port group.

Cisco Unity telephony integrations are configured with the Cisco Unity Telephony Integration Manager (UTIM), while Cisco Unity Connection phone systems and port groups are configured with the System Administrator.

Cisco Unity and Unity Connection now support an unlimited number of telephony integrations and are limited only by the number of ports per system. These features function the same way for both SCCP and SIP integrations. For details, refer to the appropriate Cisco Unity or Cisco Unity Connection administration guides available at <http://www.cisco.com>.

In addition to the option of adding multiple clusters by adding additional integrations for each new Unified CM cluster in Cisco Unity, Unified CM supports Annex M.1, Message Tunneling for QSIG, which gives administrators the ability to enable QSIG on intercluster trunks (ICTs) between Unified CM clusters. When QSIG is enabled on ICTs, Cisco Unity needs to integrate with only one Unified CM cluster and designate ports only in this one cluster for turning MWIs on and off, even when supporting multiple clusters. The Annex M.1 feature in Unified CM allows for propagation of the MWI requests across the ICTs to the proper Unified CM cluster and phone within that cluster. All calls originating in other clusters can be forwarded to the Cisco Unity server integrated to that one cluster. There is no need to designate MWI ports on the other clusters when Annex M.1 is enabled on the ICT.

For more information on Annex M.1, refer to the protocol descriptions in the *Cisco Unified Communications Manager System Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

E.164 Number Support with Cisco Unity Connection

Cisco Unity Connection 8.6 and later releases support the E.164 number format for the following fields only:

- Transfer rule extensions for the end users
- Notification device phone numbers for the end users
- Personal contact phone numbers for the end users
- System contact phone numbers for the Cisco Unity Connection System
- Personal call transfer rule (PCTR) phone numbers for the Cisco Unity Connection System
- Alternate extensions for the end users
- Restriction patterns for the Cisco Unity Connection System
- Message waiting indicator (MWI) extensions for the Cisco Unity Connection System

For the Alternate Extension learning feature to work with the E.164 formatted numbers, the following restriction tables must be updated:

- User-Defined and Automatically-Added Alternate Extensions
- Default Outdial

Also consider the following points when using E.164 phone numbers:

- The extension of an end user account (user with a voicemail box) cannot be in the E.164 format. The "+" character is not supported for this field.
- When importing users from LDAP with E.164 formatted primary phone numbers, use the regular expressions supported to set up a translation pattern.

For converting phone numbers into extensions (Cisco Unity Connection 8.5 and later releases only), refer to the latest version of the *System Administration Guide for Cisco Unity Connection*, available at

http://www.cisco.com/en/US/products/ps6509/prod_maintenance_guides_list.html

If you want to import users from Cisco Unified Communications Manager (Unified CM) with E.164 formatted extensions through AXL integration, you will have to export the E.164 extensions from Unified CM into a comma-separated values (CSV) file and perform the necessary translations on the alternate extensions (in Excel, for example) prior to using the Bulk Administration Tool (BAT) to import them into Unity Connection. For more details on using the Cisco Unity Connection Bulk Administration Tool, refer to the latest version of the *User Moves, Adds, and Changes Guide for Cisco Unity Connection*, available at

http://www.cisco.com/en/US/products/ps6509/prod_maintenance_guides_list.html

Enhanced Message Waiting Indicator (eMWI)

Enhanced Message Waiting Indicator (eMWI) is an enhancement to traditional MWI, and it provides a visual indication of the number of voice messages. Traditional MWI works in a binary format by either enabling or disabling the message lamp on the phone whenever a new voice message arrives in or is deleted from a user's voicemail box. EMWI works with both Cisco Unity and Cisco Unity Connection and is supported on the Cisco Unified IP Phones 8900 and 9900 Series SIP phones.

eMWI is a visual indication of unplayed messages in the user's voicemail box, with a colored indication depicting the status of the message. An unplayed message displays a red indication on the screen of the phone. eMWI is supported on Unified CM for both Cisco Unity and Cisco Unity Connection through SIP and SCCP integrations. eMWI does not function when the system is running in SRST or SRSV

mode. In an integration with Cisco Unity Connection, only the messages stored on the Cisco Unity Connection servers will be indicated with eMWI, and any messages stored on an external IMAP server will not be indicated.

eMWI works in distributed call processing environments with Unified CM. In a system with distributed call processing and centralized voice messaging integration, where one cluster provides the connectivity to the voice messaging server through an intercluster trunk (H.323 or SIP), eMWI updates over the intercluster trunk are supported and are displayed on the end device. (See [Figure 21-18](#).)

**Note**

eMWI also works in a distributed call processing environment with centralized messaging over an intercluster trunk (H.323 or SIP).

Figure 21-18 Enhanced Message Waiting Indicator (eMWI)

[Figure 21-19](#) illustrates eMWI over an intercluster trunk (H.323 or SIP) in a distributed call processing environment with centralized voice messaging.

Figure 21-19 eMWI with Distributed Call Processing and Centralized Voice Messaging

As shown in [Figure 21-19](#), Cluster 2 and its voice messaging solution support eMWI, but Cluster 1 does not. If an eMWI update with a voice message count is sent from the voice messaging solution intended for the Cluster 2 phone, Cluster 1 will forward only a standard MWI to Cluster 2 without the voice message count.

The following guidelines apply to eMWI:

- All clusters should support eMWI. If an intermediate cluster does not support eMWI, then the terminating cluster will receive a standard MWI only without voicemail counts.
- Standard MWI does not generate much traffic because it sends only a change of lamp state (ON or OFF). However, enabling eMWI can increase the amount of traffic because it also sends message counts from the messaging system. The amount of traffic depends on the number of messages and change notifications.

Voice Port Integration with a Unified CM Cluster

When deploying Cisco Unity in a single-site messaging environment, integration with the Unified CM cluster occurs through the SCCP voice ports or SIP trunks. Design considerations must include proper deployment of the voice ports among the Unified CM subscribers so that, in the event of a subscriber failure (Unified CM failover), users and outside calls can continue to access voice messaging. (See [Figure 21-20](#).)

Figure 21-20 Cisco Unity Server(s) Integrated with a Unified CM Cluster (No Dedicated Backup Servers)

The Unified CM cluster in [Figure 21-20](#) employs 1:1 server redundancy and 50/50 load balancing. During normal operations, each subscriber server is active and handles up to 50% of the total server call processing load. In the event of a subscriber server failure, the remaining subscriber server takes up the load of the failed server.

This configuration uses two groups of voicemail ports, with each group containing one-half of the total number of licensed voice ports. One group is configured so that its primary server is Sub1 and its secondary (backup) server is Sub2. The second group is configured so that Sub2 is the primary server and Sub1 is the backup.

Make sure that MWI-only ports or any other special ports are equally distributed between the two groups. During the configuration of the voice ports, pay special attention to the naming convention. When configuring the two groups of ports in the Cisco Unity Telephony Integration Manager (UTIM) utility, make sure that the device name prefix is unique for each group and that you use the same device name when configuring the voicemail ports in Unified CM Administration. The device name prefix is unique for each group of ports in this example, with group Sub1 using CiscoUM1 as the device name prefix and Sub2 using CiscoUM2 in this example.

For additional design information on the ratio of inbound to outbound voicemail ports (for MWI, message notification, and TRaP), refer to the *Cisco Unity System Administration Guide* available at <http://www.cisco.com>.

**Note**

The device name prefix is unique for each group of ports and must match the same naming convention for the voicemail ports configured in Unified CM Administration.

In Unified CM Administration, half of the ports in this example are configured to register using the unique device name prefix of CiscoUM1, and the other half are configured to register using the unique device prefix CiscoUM2. (See [Table 21-6](#).) When the ports register with Unified CM, half will be registered with subscriber server Sub1, and the other half will be registered with Sub2, as shown in [Table 21-6](#).

Table 21-6 Voicemail Port Configuration in Unified CM Administration

| Device Name | Description | Device Pool | SCCP Security Profile | Status | IP Address |
|--------------|-------------|-------------|-----------------------|----------------------|------------|
| CiscoUM1-VI1 | Unity1 | Default | Standard Profile | Registered with sub1 | 1.1.2.9 |
| CiscoUM1-VI2 | Unity1 | Default | Standard Profile | Registered with sub1 | 1.1.2.9 |
| CiscoUM1-VI3 | Unity1 | Default | Standard Profile | Registered with sub1 | 1.1.2.9 |
| CiscoUM1-VI4 | Unity1 | Default | Standard Profile | Registered with sub1 | 1.1.2.9 |
| CiscoUM2-VI1 | Unity1 | Default | Standard Profile | Registered with sub2 | 1.1.2.9 |
| CiscoUM2-VI2 | Unity1 | Default | Standard Profile | Registered with sub2 | 1.1.2.9 |
| CiscoUM2-VI3 | Unity1 | Default | Standard Profile | Registered with sub2 | 1.1.2.9 |
| CiscoUM2-VI4 | Unity1 | Default | Standard Profile | Registered with sub2 | 1.1.2.9 |

**Note**

The naming convention used for the voicemail ports in Unified CM Administration must match the device name prefix used in Cisco UTIM, otherwise the ports will fail to register.

Voice Port Integration with Dedicated Unified CM Backup Servers

This Unified CM cluster configuration allows each subscriber server to operate at a call processing load higher than 50%. Each primary subscriber server has either a dedicated or shared backup server. (See Figure 21-21.) During normal operation, the backup server processes no calls; but in the event of failure or maintenance of a Subscriber server, the backup server will then take the full load of that server.

Figure 21-21 Cisco Unity Server(s) Integrated with a Single Unified CM Cluster with Backup Subscriber Server(s)

Configuration of the voicemail ports in this case is similar to the 50/50 load-balanced cluster. However, instead of configuring the voice ports to use the opposite subscriber server as the secondary server, the individual shared or dedicated backup server is used. In the Unified CM cluster with a shared backup server, both of the secondary ports for the subscriber servers are configured to use the single backup server.

The voice port names (device name prefix) must be unique for each Cisco UTIM group and must be the same as the device names used on the Unified CM server.

To configure the voicemail ports on Cisco Unity, use the UTIM tool. For Cisco Unity Connection, use the Telephony Integration section of the Unity Connection Administration console. For details, refer to the Cisco Unity or Cisco Unity Connection administration guides available at <http://www.cisco.com>.

IPv6 Support with Cisco Unity Connection

The current requirements for IP addressing are surpassing the available set of IP address with IPv4, the current version of IP addressing. Therefore, most IP-based solutions are moving toward incorporating support for IPv6, which provides many more available IP addresses than IPv4. Cisco Unity Connection supports IPv6 addressing with Cisco Unified Communications Manager system integrations through SCCP or SIP. At a component level, dual-stack addressing (both IPv4 and IPv6) is supported over call control and media only.

**Note**

Voice messages are stored as .wav files and are independent of IPv6 or IPv4.

IPv6 support is disabled by default, but system administrators can enable IPv6 and configure IPv6 address settings either in Cisco Unified Operating System Administration or in the command line interface (CLI). Cisco Unity Connection can obtain an IPv6 address either through router advertisement, through DHCP, or from addresses configured manually either in Cisco Unified Operating System Administration or through the CLI.

Both IPv4 and IPv6 are implemented, but they are not operational at the same time. Cisco Unity Connection does not support "IPv6 ONLY" server configuration. Cisco Unity Connection supports Unicast only for IPv6.

**Note**

Cisco Unity Connection does not provide support for dual-stack addressing mode (both IPv4 and IPv6) in Cisco Business Edition 3000 and 5000.

Single Inbox with Cisco Unity Connection

Cisco Unified Communications Manager 8.5 and later releases support the Single Inbox feature with Cisco Unity Connection and Microsoft Exchange 2003, 2007, and 2010 (clustered or non-clustered), thereby providing Unified Messaging for voicemail. Cisco Unity Connection can support all three of these Microsoft Exchange versions simultaneously or any one of them separately. All voice messages, including those sent from Cisco Unity Connection ViewMail for Microsoft Outlook, are first stored in Cisco Unity Connection and are immediately replicated to the Exchange mailbox for the recipient; however, replication is optional. Also, this feature can be configured per individual user.

Cisco Unity Connection support of Unified Messaging for voicemail involves several design considerations. The user's email becomes a single container for all messages, including email and voicemail. If a message is moved to any other folder under the user's Inbox, it will continue to show up in Cisco Unity Connection. However, if the user moves voice messages into Outlook folders that are not under the Inbox folder, the messages are deleted from Cisco Unity Connection but they can still be played by using ViewMail for Outlook because a copy still exists in the Outlook folder. If the user moves the messages back into the Inbox folder or into a folder under the Inbox folder, the message is synchronized back into the Cisco Unity Connection mailbox for that user. In addition, when a user deletes a voice message from Cisco Unity Connection or when Cisco Unity Connection automatically deletes a voice message because of message aging, the message is also deleted from Microsoft Exchange. Likewise, when a voice message is deleted from Microsoft Exchange, it is also deleted from Cisco Unity Connection.

If a message is marked as secured and private, the actual message is not replicated in Microsoft Exchange; instead, a placeholder with a brief description is created for the message. The only copy of actual message stays on Cisco Unity Connection and the user retrieves the message, it is played back from Cisco Unity Connection directly instead of from a local source, unlike in the case of a normal message.

This also means that there is no local access to the audio file if it is accessed through voicemail from Outlook. Movement of the secure and private message to any folder other than Inbox and folders below Inbox would result in deletion of the message permanently, thereby leaving no opportunity for retrieval.

**Note**

All voice messages remain on the Cisco Unity Connection Server regardless of the type of messaging deployment. Cisco Unity Connection is the authoritative source of voice messaging traffic, notifications, and synchronizations.

The amount of space a single voicemail message can acquire is configured on the Cisco Unity Connection server and is similar to message aging. The maximum size for a voicemail message is also configured on the Microsoft Exchange Server. Typically, the Microsoft Exchange Server maintains a larger size than Cisco Unity Connection that is synchronized to the mailbox. Hence, the minimum size of the message in Microsoft Exchange should be bigger than the maximum size in Cisco Unity Connection.

From a security aspect for communications between Cisco Unity Connection and Microsoft Exchange, HTTPS is chosen as the default option. HTTP is also supported but not recommended because it reduces security and might also need further configuration on Microsoft Exchange. At the same time, there is an option to validate the Microsoft Exchange certificate, provided that access to the certificate server is available.

Best Practices for Deploying Cisco Unity Express

When deploying Cisco Unity Express, use the following guidelines and best practices:

- Ensure that the IP phones having Cisco Unity Express as their voicemail destination are located on the same LAN segment as the router hosting Cisco Unity Express.
- If uninterrupted automated attendant (AA) and voicemail access is required for a site deployed with Cisco Unity Express, ensure that Cisco Unity Express, SRST, and the PSTN voice gateway are all located at the same physical site. Hot Standby Router Protocol (HSRP) or other redundant router configurations are not currently supported with Cisco Unity Express.
- Each mailbox can be associated with a primary extension number and a primary E.164 number. Typically, this number is the direct-inward-dial (DID) number that PSTN callers use. If the primary E.164 number is configured to any other number, use Cisco IOS translation patterns to match either the primary extension number or primary E.164 number so that the correct mailbox can be reached during SRST mode.

Voicemail Integration with Unified CM

- Each Cisco Unity Express site must be associated with a CTI route point for voicemail and one for AA (if licensed and purchased), and you must configure the same number of CTI ports as Cisco Unity Express ports licensed. Ensure that the number of sites with Cisco Unity Express does not exceed the CTI scalability guidelines presented in the chapter on [Call Processing, page 8-1](#).
- Cisco Unity Express is associated with a JTAPI user on Unified CM. Although a single JTAPI user can be associated with multiple instances of Cisco Unity Express in a system, Cisco recommends associating each dedicated JTAPI user in Unified CM with a single Cisco Unity Express.
- If Unified CM is upgraded from a previous version, the password of the JTAPI user automatically gets reset on Unified CM. Therefore, after the upgrade, the administrator must make sure that the JTAPI password is synchronized between Cisco Unity Express and Unified CM so that Cisco Unity Express can register with Unified CM.

- The CTI ports and CTI route points can be defined in specific locations. Cisco recommends using locations-based call admission control between Unified CM and Cisco Unity Express. RSVP may also be used.
- Ensure proper Quality of Service (QoS) and bandwidth for signaling traffic that traverses the WAN between Cisco Unity Express and Unified CM. Provision 20 kbps of bandwidth for CTI-QBE signaling for each Cisco Unity Express site. See the chapter on [Network Infrastructure, page 3-1](#), for more details.
- The CTI-QBE signaling packets from Unified CM to Cisco Unity Express are marked with a DSCP value of AF31 (0x68). Unified CM uses TCP port 2748 for CTI-QBE signaling.
- The Unified CM JTAPI library sets the proper IP Precedence bits in all outgoing QBE signaling packets. As a result, all signaling between Cisco Unity Express and Unified CM will have the proper QoS bits set.

Cisco Unity Express Codec and DTMF Support

Calls into Cisco Unity Express use G.711 only. Cisco recommends using a local transcoder to convert the G.729 calls traversing the WAN into G.711 calls. You can configure Unified CM regions with the G.711 voice codec for intra-region calls and the G.729 voice codec for inter-region calls.

If transcoding facilities are not available at the Cisco Unity Express site, provision enough bandwidth for the required number of G.711 voicemail calls over the WAN. Configure the Unified CM regions with the G.711 voice codec for calls between the IP phones and Cisco Unity Express devices (CTI ports and CTI route points).

Cisco Unity Express does not support in-band DTMF tones; it supports only DTMF relay. With Cisco Unity Express, DTMF is carried out-of-band via either the SIP or JTAPI call control channels. Cisco Unity Express 2.3 supports G.711 SIP calls with RFC 2833 into Cisco Unity Express.

JTAPI, SIP Trunk and SIP Phone Support

Cisco Unified CM supports SIP trunking protocol; however, Cisco Unity Express uses JTAPI to communicate with Unified CM. Cisco Unity Express supports both SCCP and SIP phones.

- Configure a SIP trunk for SRST and Unified CM for support of SIP phones (through JTAPI).
- Cisco Unity Express supports G.729 SIP calls via a transcoder, with the ability added in Cisco IOS Release 12.3(11)XW for RFC 2833 to pass through a transcoder.
- Cisco Unity Express supports delayed media (no SDP in the INVITE message) for call setup in case of a slow-start call from Unified CM.
- Cisco Unity Express supports both blind and consultative transfer, but the default transfer mode is consultative transfer (semi-attended) using REFER in SIP calls. Use the Cisco Unity Express command line interface to explicitly change the transfer mode to consultative transfer using REFER or blind transfer using BYE/ALSO. If REFER is not supported by the remote end, BYE/ALSO will be used.
- Cisco Unity Express supports outcall for voice message notifications. It also supports consultative transfers. During both of these call setups, Cisco Unity Express can receive 3xx responses to the INVITE. Cisco Unity Express processes only 301 (Moved Permanently) and 302 (Moved Temporarily) responses to the INVITE. This requires the URL from the Contact header from the 3xx response to be used to send a new INVITE. 305 (Use Proxy) responses are not supported.

**Note**

For compatibility between Cisco Unified CM and Cisco Unity Express, refer to the *Cisco Unity Express Compatibility Matrix*, available at http://www.cisco.com/en/US/docs/voice_ip_comm/unity_exp/compatibility/cuecomp.htm.

For more information about Cisco Unity Express, refer to the product documentation available at <http://www.cisco.com>.

Third-Party Voicemail Design

This section discusses various options for deploying third-party voicemail systems with Cisco Unified Communications, and it covers both integration and messaging.

**Note**

This section does not discuss how to size a third-party voicemail system for ports and/or storage. For this type of information, contact your voicemail vendor, who should be better able to discuss the individual requirements of their own system, based upon specific traffic patterns.

Integration

Integration is defined as the physical connection between a voicemail system and its associated PBX or call processing agent, and it also provides for the feature set between the two.

There are many voicemail vendors, and it is not uncommon for customers to want to continue to use an existing voicemail system when deploying Cisco Unified CM. With this requirement in mind, Cisco provides support for the industry standard voicemail protocol known as Simplified Message Desk Interface (SMDI). SMDI is a serial protocol that provides all the necessary call information required for a voicemail system to answer calls appropriately and is probably the most common method deployed for voicemail integration between dissimilar systems from various vendors.

**Note**

Cisco does not test or certify any third-party voicemail systems. Within the industry, it is generally considered to be the responsibility of the voicemail vendor to test and/or certify their products with various PBX systems. Cisco does, of course, test its interfaces to such equipment and will support these interfaces regardless of which third-party voicemail system is connected.

An alternative to SMDI for voicemail integration is QSIG, which also allows a third-party PBX to connect to Unified CM through a Primary Rate Interface (PRI) T1/E1 trunk. Each method has its own advantages and disadvantages, and the method you employ will largely depend on how your voicemail system is integrated to your current PBX.

There are other methods for connecting voicemail systems to Unified CM (such as PRI ISDN trunks in conjunction with SMDI), but these methods are uncommon.

Today there are other potential methods of voicemail integration, such as H.323 or SIP. However, due to the varying methods of vendor implementation, features supported, and other factors, these third-party voicemail integrations will have to be evaluated on a per-customer basis. Customers are advised to contact their Cisco Account Team and/or Cisco Partner to discuss these options further.

Messaging

Messaging is defined as the exchange of messages between voicemail systems, and there are several open standards for this purpose.

The most common protocol deployed to allow messaging between dissimilar systems is Voice Profile for Internet Mail (VPIM). VPIM has seen several updates to its specification, and although Version 2 is not the latest, it still appears to be the most widely adopted. The messaging protocol prior to VPIM is Audio Messaging Interchange Specification - Analog (AMIS-A), and it is fairly rare in its adoption due mainly to its cumbersome user interface as well as the analog technology it employs and its lack of features.

CHAPTER 22

Cisco Collaborative Conferencing

Revised: July 31, 2012; OL-21733-18

Cisco offers a wide range of collaboration technologies that have the ultimate goal of allowing users to work in virtual collaborative environments that result in faster, more efficient decision-making processes and increased productivity. There are many technologies that fall under the large collaboration umbrella, but this chapter focuses on design guidance surrounding the Cisco offerings that allow for simultaneous communications through audio, video, and rich content sharing capabilities. This chapter also explores the differences in the various solutions and provides suggestions on when one solution may be a better fit than another.

Certain aspects are common to all the Cisco collaborative conferencing solutions. For instance, the capability to integrate with scheduling or calendaring systems so that the creation of a meeting is familiar and intuitive to users. Ties into LDAP directories for inviting attendees in the organization and a consistent authentication method are also critical. Users have the ability to host and attend virtual meetings, whether in the office or outside of the enterprise, to ensure continued productivity for users even when they are traveling outside the organization.

The Cisco collaborative conferencing solutions discussed in this chapter are available as on-premises, off-premises, or mixed deployments. This allows an organization to integrate with a Unified Communications solution in which they have already invested or, alternatively, to implement a service that is hosted “in the cloud.” This is one of the more important distinctions between the various solutions, and it is the first decision point when determining which solution is the best fit for an organization. This chapter contains sections on the following topics:

- Cisco WebEx Software as a Service (SaaS)
- Cisco Unified MeetingPlace
- Cisco Unified Videoconferencing

Each section defines the high-level architecture of the solution, followed by design guidance for high availability, capacity planning and other design considerations pertinent to the solution.

For more detail on the various Cisco collaborative client offerings and how they fit into collaborative conferencing solutions, see the chapter on [Cisco Collaboration Clients and Applications, page 24-1](#).

What's New in This Chapter

This chapter combines information from several chapters in previous versions of this document, and it incorporates new material to bring together design discussions surrounding Cisco's collaborative conferencing offerings. If you are reading this chapter for the first time, Cisco recommends reading the entire chapter.

[Table 22-1](#) lists the topics that are new in this chapter or that have changed significantly from the previous release of this document.

Table 22-1 *New or Changed Information Since the Previous Release of This Document*

| New or Revised Topic | Described in: | Revision Date |
|---|---|--------------------|
| Capacity planning information for Cisco Unified MeetingPlace has been moved to the chapter on Unified Communications Design and Deployment Sizing Considerations, page 29-1 . | Unified Communications Design and Deployment Sizing Considerations, page 29-1 | July 31, 2012 |
| Other miscellaneous corrections and changes | Various sections throughout this chapter | July 31, 2012 |

| Other miscellaneous corrections and changes | Various sections throughout this chapter | June 2, 2011 |
| High Quality Video | Architecture, page 22-5 Table 22-4 | November 15, 2010 |

Collaborative Conferencing Architecture

At a high level, collaborative conferencing involves receiving audio, video, and content from some or all of the attendees in a meeting, mixing those streams, and then sending the mixed audio, video, and content back to the attendees. [Figure 22-1](#) illustrates a logical conference involving both internal and external participants, mobile and remote workers, or even attendees from other organizations.

Figure 22-1 Logical View of Collaborative Conferencing

These three aspects of a collaborative conference – audio, video and content sharing – are not exclusive. Cisco collaborative conferencing solutions integrate the three to create an enhanced user experience. Features such as the ability to determine active speakers, muting users from the content share interface, or choosing the video layout displayed in the content share, all imply that these three elements are integrated by the solution. All the collaborative conferencing solutions discussed in this chapter use the Cisco WebEx interface for content sharing. This provides a very consistent user experience across all the solutions.

When considering which solution is best for a given organization, many factors should be evaluated. Characteristics of an organization's users (number of remote workers, access capabilities, and video usage) as well as the range of available endpoints and their capabilities are important to consider. Video requirements such as high definition or interworking with an existing video infrastructure can also dictate a solution. The nature of the meetings themselves (for example, training scenarios, collaborative meetings, or how many meeting participants are external to the organization) is a critical characteristic to identify. Of course, initial cost, maintenance costs, and return on investment (ROI) all play a role as well.

One of the first delineations between the solutions is whether the resources performing each type of conferencing (or mixing) are located on-premises or off-premises. Access to cloud services, the size of the mobile workforce, and support staff levels are all considerations. Cisco WebEx software as a service (SaaS) offers a completely off-premises solution with an option to extend the cloud on-premises, while

Cisco Unified MeetingPlace and Cisco Unified Videoconferencing are a hybrids (mix of on-premises and off-premises) with the option to pull the majority of resources on-premises. Organizations that have deployed Cisco Unified Communications will benefit most from leveraging an on-premises solution. The later sections in this chapter provide more detailed deployment options for each solution.

This document describes two approaches to providing a high-performance collaboration solution. The two solutions can be broadly categorized as either:

- Cloud-based (SaaS) service with on-premises acceleration
- On-premises solution with cloud-based augmentation

Table 22-2 summarizes available solutions from an on-premises cloud perspective.

Table 22-2 On-Premises, Cloud, and Hybrid Capabilities of Cisco Collaborative Solutions

| Solution | Audio | | Video | | Content Sharing | |
|--|-------------|-------|-------------|------------------|------------------|-------|
| | On-premises | Cloud | On-premises | Cloud | On-premises | Cloud |
| Cisco WebEx SaaS | No | Yes | No | Yes ¹ | No | Yes |
| Cisco WebEx SaaS with Cisco WebEx Node for Aggregation Services Router (ASR) | Yes (VoIP) | Yes | Yes | Yes ¹ | Yes ² | Yes |
| Cisco Unified MeetingPlace with WebEx SaaS ³ | Yes | No | Yes | No | No | Yes |
| Cisco Unified MeetingPlace with Cisco WebEx Node for Cisco MCS ³ | Yes | No | Yes | Yes | Yes ² | Yes |
| Cisco Unified MeetingPlace with Cisco WebEx Node for Cisco ASR ³ | Yes | Yes | Yes | Yes ¹ | Yes ² | Yes |
| Cisco Unified MeetingPlace (audio/video only deployment) | Yes | No | Yes | No | No | No |
| Cisco Unified Videoconferencing (audio/video only deployment) | Yes | No | Yes | No | No | No |

1. Cisco WebEx webcam video.
2. Cisco WebEx Node for ASR and MCS requires a connection to the Cisco WebEx network.
3. Cisco Unified MeetingPlace and Unified Videoconferencing solutions may alternatively use the WebEx webcam video streaming capabilities of the cloud. However, Cisco does not recommend using both because there is no interoperability.

Cisco WebEx Software as a Service

Cisco WebEx is a collaboration solution that does not require any hardware to be deployed on-site. All services (audio, video, and content sharing) are hosted in the Internet or the cloud. This is often referred to as software-as-a-service (SaaS). Meetings can be initiated and attended from anywhere, anytime, and do not require connectivity back into the enterprise. This section describes solution characteristics and provides design guidance for deploying WebEx SaaS.

With respect to scheduling and initiating meetings, WebEx provides cloud-based web scheduling capability, but most organizations prefer to schedule from their corporate email system (Exchange, Lotus Notes, and so forth) or other enterprise applications. The WebEx Productivity Tools is a bundle of integrations with well known desktop tools incorporated into a single application. A WebEx administrator can control the specific integrations that are provided through the tool to their organization's user population. It can be installed automatically when accessing the WebEx sitename, or it can be pushed out locally using standard desktop management tools. For more information on WebEx Productivity Tool, refer to the WebEx *Productivity Tools FAQs*, available at

https://vnc.WebEx.com/docs/T26L/pt/mc08001/en_US/support/productivitytools_faq.htm

There are three methods of creating WebEx user profiles for an organization in the cloud. Security considerations for the actual usernames and passwords, as well as for handling a large number of user accounts, should be considered. A WebEx administrator can create user profiles manually by bulk import of a CSV template or by a programmatic approach. A programmatic approach uses one or a combination of the WebEx APIs, URL, and XML, or a Federated SSO solution. The programmatic approach can be used by a customer portal, which is an application such as a CRM tool or a Learning Management System that integrates directly into WebEx. For more information regarding WebEx directory integration and authentication, refer to the WebEx *Approaches to Single Sign-On Developer Technical Note*, available at

http://developer.WebEx.com/c/document_library/get_file?folderId=11421&name=DLFE-213.pdf

For integrating directly with an organization's LDAP directory, Federated SSO with Security Assertion Markup Language (SAML) is the preferred approach. For more information regarding Federated SSO, refer to the WebEx *Federated SSO Authentication Service Technical Overview*, available at

http://developer.WebEx.com/c/document_library/get_file?folderId=11421&name=DLFE-201.pdf

Architecture

An organization's IT department needs to understand the architecture of the Cisco Collaboration cloud-based solution. In the traditional WebEx deployment model shown in [Figure 22-2](#), all the content, voice, and video traffic from every client traverses the internet and is mixed and managed in the cloud at the WebEx data center. The WebEx data center is logically divided into the Meeting Zone and the Web Zone. The Web Zone is responsible for things that happen before and after a web meeting. It incorporates tasks such as scheduling, user management, billing, reporting, and streaming recordings. The Meeting Zone is responsible for switching the actual meeting once it is in progress between the endpoints.

Figure 22-2 Traditional WebEx Deployment

The Meeting Zone consists of two subsystems. Within the Meeting Zone there are collaboration bridges that switch meeting content. The multimedia platform is responsible for mixing all of the VoIP and video streams within a meeting. To join a WebEx session, an attendee first connects to the Web Zone. The Web Zone traffic flows only before or after the meeting, is relatively low bandwidth, and is mainly non-real time. The real-time meeting content share flows to and from the Meeting Zone and can be bandwidth intensive. Its real-time nature can place a heavy burden on enterprise access infrastructure. For further details regarding network traffic planning, see [Capacity Planning, page 22-9](#).

By default, all WebEx meeting data is encrypted using 128-bit SSL encryption between the client and Cisco's Collaboration Cloud. SSL accelerators within the cloud decrypt the content sharing information and send it to a WebEx conference bridge that processes the content and sends it back through an SSL accelerator, where it is re-encrypted and sent back to the attendees. All Web Zone and Meeting Zone traffic is encrypted using 128-bit SSL where SSL accelerators are used to off-load the SSL function from the Web and Meeting Zone servers.

After the meeting ends, no session data is retained in the WebEx cloud or an attendee's computer. Only two types of data are retained on a long-term basis: billing and reporting information and optionally network based recordings, both of which are accessible only to authorized enterprise users.

Some limited caching of meeting data is carried out within the Meeting Zone, and this is done to ensure that users with connectivity issues or who may be joining the meeting after the start time receive a current fully synchronized version of the meeting content.

Independent third parties are used to conduct external audits covering both commercial and governmental security requirements, to ensure the WebEx cloud maintains its adherence to documented security best practices. WebEx performs an annual SAS-70 Type II audit in accordance with standards established by the AICPA, conducted by Pricewaterhouse Cooper. The controls audited against WebEx are based on ISO-17799 standards. This highly respected and recognized audit validates that WebEx services have been audited in-depth against control objectives and control activities (that often include controls over information technology and security related processes) with respect to handling and processing customer data.

For customers that require enhanced security, there is also an option to perform end-to-end 256 bit AES encryption for collaboration bridge and multimedia content so that traffic is never decrypted in the cloud. In addition, PKI identity validation support is optionally available to further enhance the end-to-end AES encryption. End-to-end encryption results in some lost features such as NBRs. For more information on enhanced WebEx security options, refer to the *Security Overview of Cisco WebEx Solutions* available at

http://static.WebEx.com/fileadmin/WebEx09/files_en_us/pdf/whitepapers/cwe_securityoverview.pdf

**Note**

Enhanced WebEx security options are available only for Meeting Center meetings. The WebEx security options come at no additional cost.

Starting with Cisco WebEx release WBS27, an organization can optionally accelerate WebEx meeting traffic using the WebEx Node for Aggregation Services Router (ASR) 1000 Series. Using a WebEx Node for ASR (a blade installed in the router), key components from the cloud can be extended onto a platform that resides on-premises within the enterprise, as shown in [Figure 22-3](#). This moves an instance of the collaboration bridge and the multimedia platform onto the ASR, which provides performance and bandwidth improvements over a pure cloud-based solution. This is a fully cascaded solution that allows attendees within the enterprise to connect to the Node and external attendees to connect to the cloud. Failover and overflow from the Node(s) to the cloud are fully supported and transparent in operation. The WebEx Node's operation is unapparent to both the user and the WebEx site administrator. The WebEx Node for ASR works with standalone WebEx SaaS accounts and with MeetingPlace 8.5 Audio on-premises.

Figure 22-3 WebEx Deployment with WebEx Node for ASR

When an attendee joins a WebEx meeting, the Web Zone in the WebEx cloud serves the client entry page and tells the WebEx client where to connect. The clients always get passed the list of cloud-based Meeting Zones available for the meeting, represented as URLs. If WebEx Nodes for ASR have been provisioned for the organization's WebEx site, the node hostnames are also included in the list of Meeting Zones. The clients then ping all of the cloud and on-premises resources to determine which Meeting Zone instance is closest in terms of latency. Because the on-premises nodes are available through the corporate network, they should respond first, and the on-premises client connect to these resources. Clients also connect to the node using 128 bit SSL encryption. The nodes provide support for Meeting Center, Event Center, Training Center, and Support Center.

**Note**

When deployed in multimedia mode, the WebEx Node for ASR is capable of mixing VoIP (from the WebEx client itself) and webcam video. Mixed Mode Audio involves PSTN callers and is always mixed in the cloud.

Comparing [Figure 22-3](#) with the traditional WebEx deployment model depicted in [Figure 22-2](#) indicates that session initiation still takes place in the Web Zone within the cloud, but the enterprise WebEx clients are using a conference bridge or multimedia platform in the WebEx Node in an ASR on the enterprise network, which saves internet bandwidth and improves performance. The WebEx Node for ASR cascades control traffic and meeting content or VoIP and video content back to the cloud over an SSL

tunnel. This allows external participants to access the meeting and to support network based recording (NBR). The SSL tunnel is built when the WebEx node is started and all the connections are made outbound from the enterprise to the WebEx cloud.

**Note**

A WebEx Node for ASR can be configured to act as either a content bridge or a multimedia node, but it does not support both functions simultaneously. To support both data and multimedia acceleration, a minimum of two WebEx Node blades are required. These can be deployed in the same ASR chassis or different chassis. There is no limit on the number of Nodes that may be deployed within an enterprise network.

For further details regarding network traffic optimization using WebEx Node for ASR, see [Capacity Planning, page 22-9](#).

There is also the potential to deploy the WebEx Node for ASR in a multi-tenant capacity, in which two businesses working closely together with staff working on each other's premises could have the other's WebEx site defined on their ASR Nodes. This means that, when staff for Enterprise B access their company's WebEx site through Enterprise A, they can use the local ASR Node to accelerate their meeting while saving bandwidth for Enterprise A. This feature can also benefit organizations that have multiple WebEx sites.

Starting with Cisco WebEx release WBS27-FR20, Meeting Center uses the H.264 AVC/SVC codec to provide High Quality Video for the conference. Higher network bandwidth is needed for those deployments. For further details regarding network traffic optimization for High Quality Video, see [Capacity Planning, page 22-9](#).

**Note**

Cisco TelePresence integrates with WebEx using OneTouch. For details on Cisco TelePresence WebEx OneTouch, refer to the documentation at http://www.cisco.com/en/US/solutions/ns669/webex_engage.html.

High Availability

The WebEx cloud itself has a very high level of redundancy and is managed by Cisco. With respect to a WebEx Node for ASR, if a Node fails or becomes congested, then user meetings re-connect to the cloud. When clients ping the Meeting Zone URLs, they do not get a response back from the ASR node, therefore they connect to another Meeting Zone. If there are active meetings on a node and the node goes offline, there is a copy of the content cached in the cloud even if all attendees are internal. The WebEx clients reconnect to an alternate Meeting Zone, and the meeting continues with no intervention by the users.

Capacity Planning

For a given customer, the actual number of concurrent meetings is essentially unlimited. Different WebEx conferencing types have different capacities with respect to number of attendees. For a detailed product comparison table, refer to the *Cisco WebEx Web Conferencing Product Comparison*, available at

http://www.cisco.com/en/US/prod/ps10352/product_comparison.html

The capacity of the WebEx Node for ASR depends on the function for which it is implemented. When deployed as a collaboration bridge (web conferencing), the Node supports up to 500 attendees. If a node reaches its maximum attendee limit, a WebEx client either uses an alternative on-premises node or overflows directly to the cloud. There is no limit to the number of ASR nodes deployed, and web conferencing can be cascaded across multiple nodes for redundancy and capacity.

The sizing for the WebEx Node for ASR when used to switch VoIP and video locally is slightly more complex because there are different video and VoIP traffic types that impact the performance of the node to a lesser or greater extent. To help with sizing the node for multimedia conferencing, there is a points system that starts with 11,600 points, and points are decremented from this total according to the type and number of streams that flow through the node. [Table 22-3](#) lists the different types of VoIP and video, and the points they consume. As is the case with the web conferencing version of the node, if a multimedia node runs out of capacity, a WebEx client simply connects to another available ASR node or to the cloud. This alleviates capacity concerns during unexpected random busy periods that over-utilize a given node's capacity.

Table 22-3 WebEx Node for ASR Points Consumed Per Video or VoIP Type

| Integrated VoIP or Video Type | Points per Use | Maximum Capacity If Using a Single Service |
|-------------------------------|----------------|--|
| Active Video 360p + 5x90p | 97 | 120 |
| Active Video 180p | 18 | 640 |
| Active Video 180p + 6x90p | 60 | 192 |
| VoIP | 19 | 600 |
| Audio broadcast | 6 | 1,933 |

Active Video means that the active speaker will appear in the main video window, and other attendees will be shown as thumbnail images, with the following resolutions:

- 360p: 640x360 resolution
- 180p: 320x180 resolution
- 90p: 160x90 resolution

Note

Multi-point video points are deducted per attendee watching the video panel during a meeting. A maximum of 6 webcam video sessions can be displayed per WebEx client, but each attendee has control over which are shown.

[Table 22-3](#) provides conservative estimates; however, it is difficult to predict usage precisely and to control user behavior. Cisco recommends provisioning enough resources to deal with the average load on the system, allowing for periods of peak usage to overflow to the cloud.

Network Traffic Planning

With the increased traffic out to the internet, it is important to consider network traffic planning. By evolving the WebEx architecture to include on-premises ASR nodes, performance can be optimized and significant savings in Internet access bandwidth can be achieved. [Table 22-4](#) itemizes different traffic types that could load the enterprise network during a WebEx meeting. The only traffic type that is not native to WebEx is IP telephony, which might be used with either an on-premises or off-premises conferencing service integrated with WebEx.

Table 22-4 Bandwidth Estimates for WebEx Meeting Traffic

| Traffic (Test Scenario) | Average (kbps) | Maximum (kbps) |
|--|---|--|
| Idle meeting: iPad (16G), iPhone (3G), and Blackberry Bold9700) use a WiFi network for data connectivity. | 0.8 for PC, 8.9 for iPad, 0.17 for iPhone, 0.42 for Blackberry devices | 3.7 for PC, 9 for iPad, 0.4 for iPhone, 0.45 for Blackberry devices |
| Desktop share (Slide presentation with 30 second transitions) | 43 for PC, 95 for iPad, 67 for iPhone, 24.8 for Blackberry devices | 598 for PC, 241 for iPad, 232 for iPhone, 29.9 for Blackberry devices |
| Presentation share (Slide presentation with 5 second transitions) | 6.5 for PC, 30 for iPad, 23 for iPhone, 54.56 for Blackberry devices | 7.5 for PC, 62 for iPad, 41 for iPhone, 55.28 for Blackberry devices |
| Video (Webcam with 352x288 resolution at 15 fps) | 172 | 298 |
| Video Standard Quality (6 thumbnail videos, each 160x90 resolution up to 10 fps) | 350 | 500 |
| Video High Quality Medium View (Webcam with 320x180 resolution up to 12 fps) | 300 | 500 |
| Video High Quality Large View (Webcam with 640x360 resolution up to 30 fps) | 900 | 1,500 |
| Video High Definition (Webcam with 1280x720 resolution up to 30 fps) | 1,500 | 2,000 |

How users actually use WebEx will make quite a bit of difference in the amount of traffic generated by the meeting. For example, if attendees use native presentation sharing (where the document is loaded to the WebEx site prior to sharing), it generates far less data than if they share their desktops. For a large enterprise, this can be important to understand to ensure correct traffic engineering, especially at the choke points in the network, such as the Internet access points. A preliminary estimate should be made around the average number of meetings to be hosted during the busy hour, along with the average number of attendees. Then, depending on the type and characteristics of these meetings, some projections on bandwidth requirements can be made. For more information regarding network traffic planning, please see the *WebEx Network Bandwidth White Paper*, available at

http://www.WebEx.com/pdf/wp_bandwidth.pdf

As discussed, the WebEx Node for ASR can be implemented to pull the collaboration bridge and the multimedia platform engine on-premises. To help quantify the impact of an ASR Node, [Table 22-5](#) and [Table 22-6](#) show some examples of theoretical bandwidth savings. In the examples, fairly large customer deployments have been assumed, each having 1,000 concurrent peak meeting attendees distributed across a number of separate meetings with two different average numbers of attendees for each example. Example 1 uses desktop sharing, while example 2 uses presentation sharing. Both examples result in large reductions in the WebEx traffic bandwidth across the organization's internet access pipes.

Table 22-5 Parameters for Example Bandwidth Calculations

| Parameters | Example 1 | Example 2 |
|---|-----------|-----------|
| Peak number of attendees | 1,000 | 1,000 |
| Average attendees per meeting | 6 | 10 |
| Percentage of internal attendees | 80% | 50% |
| Percentage of internal presenters | 90% | 90% |
| Average attendees receiving VoIP | 10% | 30% |
| Average attendees receiving video | 30% | 40% |
| Average meeting traffic bandwidth | 43 kbps | 6.5 kbps |
| Average video traffic bandwidth using 320x180 resolution High Quality Video | 300 kbps | 300 kbps |
| Average VoIP bandwidth | 35 kbps | 35 kbps |

Table 22-6 Example Bandwidth Estimate Calculations

| Traffic Types | Example 1 | | Example 2 | |
|--|------------------------|---------------------|------------------------|---------------------|
| | Bandwidth without Node | Bandwidth with Node | Bandwidth without Node | Bandwidth with Node |
| Average meeting traffic bandwidth | 34 Mbps | 1 Mbps | 22 Mbps | 1 Mbps |
| Average single-point video traffic bandwidth | 72 Mbps | 15 Mbps | 60 Mbps | 12 Mbps |
| Average VoIP bandwidth | 3 Mbps | 1 Mbps | 5 Mbps | 1 Mbps |

**Note**

The example in [Table 22-5](#) and [Table 22-6](#) assumes that two WebEx Nodes for ASRs are deployed, one in collaboration bridge mode and one in multimedia mode.

Design Considerations

Observe the following design considerations when implementing a Cisco WebEx SaaS solution:

- Collaborative meeting systems typically result in increased top-of-the-hour call processing loads. Cisco partners and employees have access to capacity planning tools with parameters specific to collaborative meetings to help calculate the capacity of the Cisco Unified Communications System for large configurations. Contact your Cisco partner or Cisco Systems Engineer (SE) for assistance with sizing of your system. For Cisco partners and employees, the Cisco Unified Communications Sizing Tool is available at <http://tools.cisco.com/cucst>.
- The WebEx Node for ASR is typically located in a DMZ because it serves as an extension of the WebEx cloud and is therefore managed from the cloud. However, there is no requirement for a DMZ, and the Node could be placed anywhere in the network. The WebEx cloud never makes any inbound connections to the Node; rather, secure connections are always initiated from the Node to the cloud on port 443.

- All connections from WebEx clients and WebEx Nodes are initiated out to the cloud. Typically, opening pinholes in network firewalls is not required as long as the firewalls allow intranet devices to initiate TCP connections to the Internet.
- If WebEx High Quality Video is integrated with a third-party audio bridge, video of the presenter will be displayed in the active speaker window rather than video of the active speaker on voice.
- For more details on the various Cisco collaborative client offerings and how they fit into collaborative conferencing solutions, see [Cisco Collaboration Clients and Applications, page 24-1](#).

Cisco Unified MeetingPlace

Cisco Unified MeetingPlace combines the benefits and capabilities of Cisco WebEx content sharing with the ability to host the audio and standards-based video portions of the collaboration meetings on-premises. Customers that have invested in Unified Communications solutions are able to leverage and extend their existing deployments to include audio and video conferencing using an all-SIP architecture. Unified MeetingPlace deployments vary depending on several options such as scalability, scheduling interface options, media resource options, and degree of high availability required. These options are discussed in more detail in this section.

There are two different deployment models available with Unified MeetingPlace architecture:

- Multinode Unified MeetingPlace Audio with WebEx Scheduling model for large, global enterprises:
 - Provides scalability to 14,400 G.711 audio ports using multiple Conferencing Nodes
 - Provides active/active resiliency for audio conferences
 - Provides virtualization support on the Cisco UCS platform
 - Provides enhanced WebEx integration features
 - Provides optional support for WebEx Node for MCS or ASR 1000 for on-premises mixing of Web conferences for internal network users
 - Provides user-based licensing for Active Users and hardware-based server capacity for ports

Note Multinode deployment support is available with Cisco Unified MeetingPlace 8.5 and later releases.

- Unified MeetingPlace Scheduling model:
 - Available to installed base of Unified MeetingPlace customers only
 - Available as audio/video only with no Web conferencing (no WebEx) to new or installed-base customers
 - Provides continuous meetings with blast outdial
 - Provides Cisco Unified Communications Manager Video Telephony ad-hoc support
 - Provides scalability to a maximum of 1,200 audio ports with Cisco Unified MeetingPlace Express Media Server (EMS) or 2,000 audio ports with Hardware Media Server (HMS) using G.711
 - Provides active/warm-standby resilience with manual failover

**Note**

This chapter focuses on audio, video, and Web sharing solutions. However, Unified MeetingPlace also supports deployments utilizing audio only, or audio and video only.

This section covers system-level design guidance of a Cisco Unified MeetingPlace system in the Cisco Unified Communications environment. This chapter does not cover any hardware requirements or software component configurations of Unified MeetingPlace that are not related to system design. For information on these topics, refer to the Unified MeetingPlace product documentation available at

http://www.cisco.com/en/US/products/sw/ps5664/ps5669/tsd_products_support_series_home.html

**Note**

The implementation of any Cisco Unified MeetingPlace 8.x web conferencing solution requires the purchase of a WebEx site. The WebEx services are independent of Cisco Unified MeetingPlace licensing.

Unified MeetingPlace Architecture

This section provides a high-level overview of each Unified MeetingPlace component and its function in the solution.

Unified MeetingPlace Meeting Director Server

The Meeting Director node supports several functions for multinode deployments with a WebEx scheduling front end. This is a required component used to support multinode configurations only. The Meeting Director module includes a WebEx Telephony Service Provider (TSP) connection to the WebEx collaboration cloud for integration using outbound TCP 443 only for a two-way communication path for the audio commands. The Meeting Broker Director is responsible for distributing audio meetings between different conferencing nodes in an equal load sharing methodology. The Events Aggregator monitors conferencing node capacity and events happening in real time. UserSync is used to synchronize all profiles from WebEx Site if it is enabled.

A multinode system has one Primary Meeting Director node and one Secondary Meeting Director node for redundancy, which can be located in any customer data center behind a corporate firewall. If the Primary Meeting Director fails, the Secondary Meeting Director becomes active. Cisco recommends that you configure your Meeting Directors as regional masters and that you locate your Meeting Directors in different data centers to provide greater system resiliency.

A "combined node" provides both Meeting Director and conferencing functionality, and it is supported when there are fewer than four Conferencing Nodes in a system. With more than four Conferencing Nodes, both Meeting Directors must reside on a dedicated hardware server (Cisco MCS or UCS).

Unified MeetingPlace Application Server (Conferencing Node)

The Unified MeetingPlace solution centers around the Unified MeetingPlace Application Server, also referred to as a Conferencing node in a multinode configuration, which provides audio and video mixing functionality through SIP trunking from a Unified CM or Session Management Edition call control system. At least one conferencing node is required in order to host conferences. Additional conferencing nodes provide greater capacity and resiliency.

The Unified MeetingPlace Application server is installed on a Cisco Media Convergence Server (MCS) or Unified Computing System (UCS) platform running the Linux operating system and the IBM Informix Dynamic Server (IDS) database, and it acts as the audio/video conference node component that mixes audio and standards-based video conferences in an enterprise network. The Unified MeetingPlace Application server controls the media servers of the solution, and it communicates with the Unified MeetingPlace Meeting Director component in a multinode configuration. The Unified MeetingPlace Application server supports SIP back-to-back user agent (B2BUA) and sends/receives calls through a SIP trunk connection with Cisco Unified CM or Session Management Edition (SME) for call delivery for inbound and outbound callbacks. The Cisco Unified MeetingPlace Express Media Server is also an optional software component that can be installed co-resident on the Unified MeetingPlace Application server and it is the preferred media mixer for most customer scenarios. Optionally, the Hardware Media Server scales higher per node (maximum of 2,000 G.711 audio port per audio node).

Media Server

The Cisco Unified MeetingPlace Media Servers provide the audio and video conferencing functionality for the solution, and they come in two distinct options:

- Cisco Unified MeetingPlace Express Media Server (EMS)
- Hardware Media Server (HMS)

The Express Media Server is the preferred cost-effective option with Cisco Unified MeetingPlace, and it performs audio mixing and standards-based video switching in software that is co-resident on the Unified MeetingPlace Application Server. The EMS allows for a single-box software-only solution for a Cisco Unified MeetingPlace audio/video-only deployment, or it can be deployed in a multinode configuration. Media cannot be cascaded across EMS instances; therefore, the capacity of a Unified MeetingPlace EMS solution depends on the MCS or UCS platform on which it is installed, or whether you install multiple Unified MeetingPlace Application and Express Media servers for scalability in a multinode deployment. Scalability in a multinode deployment can provide a maximum of 14,400 G.711 ports and requires the use of a WebEx Scheduling model. There is no cascading capability across EMSs. Higher capacities per node are available from the HMS option and with the EMS multinode deployment option.

For ultimate capacity on Express Media Servers, G.711 audio-only provides the highest number of simultaneous ports for audio conferencing. If G.729 or G.722 audio codecs are needed, then capacity is much less. Also, if standards-based video mixing is used, again this lowers capacity depending on the type mixing and maximum bandwidth settings. For instance, a Cisco UCS B-Series Blade Server using G.711 audio-only can support a maximum of 1,200 ports. To enable maximum capacity, Cisco highly recommends providing network layer audio codec transcoding to G.711 in Cisco Integrated Services Routers (ISRs) for calls that transverse a WAN in G.729 or G.722 and terminate in a Unified MeetingPlace conferencing node or single system. For more information, see [Capacity Planning, page 22-36](#).

A Hardware Media Server is a Cisco Unified MeetingPlace 3515 or 3545 outfitted with blades that are specific to the Unified MeetingPlace solution. There are audio blades and optionally standards-based video blades, both of which have on-board DSP resources to provide voice and video conferencing, respectively. The HMS is controlled by the Unified MeetingPlace Application server through SIP API and Unified MeetingPlace Media Control protocols. The HMS supports cascading of audio and video streams, therefore multiple HMS 3545 chassis can be deployed in a single location to achieve the capacity and high availability required. HMSs cannot be distributed throughout a network and must be located in the same data center as the Unified MeetingPlace Application server. HMS standards-based video provides "continuous presence," which is composed video with support for standard format up to

2 MB per video stream. HMS video also fully supports transcoding and transrating, important features in standards-based video to provide advanced video MCU functions. High definition formats are not currently supported, but HD video devices can join standard format meetings.

The Unified MeetingPlace Application server can be configured to use either the EMS or HMS, but the two cannot be used together in the same conferencing node. It is relatively easy to switch from one to the other, however. Use of either is transparent to the user except for differences in supported video formats and features such as active speaker or continuous presence, transrating, transcoding, video recording, video mute, or HD video capabilities. There are some major differences in features and capabilities between an EMS and HMS; therefore it is critical to review these differences before choosing between them. For more information, refer to the latest version of the *Planning Guide for Cisco Unified MeetingPlace*, available at

http://www.cisco.com/en/US/products/sw/ps5664/ps5669/products_implementation_design_guides_list.html

WebEx Node for MCS or ASR (Optional Component)

The design of a Unified MeetingPlace solution is affected by the nature of the meetings to be hosted on the system. For example, is there a requirement for meetings to include only internal participants, or are external attendees also allowed? All web conferencing for the Unified MeetingPlace solution is provided by WebEx; however, the WebEx Node for MCS or WebEx Node for ASR 1000 optionally allows an organization to pull content sharing resources on-premises if required. If all meetings involve external participants or if the customer would prefer to use the WebEx Collaboration cloud only, then the WebEx Node for MCS or ASR 1000 is not required. However, if there is a requirement to have internal meetings where all the audio, video, and content sharing remains on-premises, the WebEx node for MCS should be deployed. The WebEx Node for ASR provides on-premises mixing for both internal web conference attendees and/or WebEx webcam high quality video (HQ Video). The node essentially extends the WebEx cloud's collaboration bridge technology into a customer's organization by using dedicated MCS or ASR 1000 hardware and WebEx software. It does have direct communication with the Unified MeetingPlace Application server; however, it is still operated and managed through the WebEx site administration, thus it requires connectivity to the internet so that the node can initiate outbound TCP port 443 SSL connections to the organization's WebEx site.

The WebEx client finds the WebEx Node for MCS in the same way it does for the WebEx Node for ASR. The WebEx node names are provisioned in the cloud, and after initial connection to the WebEx site, a list of Meeting Zone URLs is passed to the client from the meeting entry page. For internal-only meetings, only WebEx Node for MCS hostnames are passed to the client. This ensures that all users will be connected to WebEx Node for MCSs internally and no meeting information is cascaded to the Collaboration Cloud for that meeting. For external meetings on WebEx Node for ASR or MCS, there are cloud-based URLs and WebEx Node for MCS hostnames for profiled users, and only cloud-based URLs for external users (guests). The client then pings all the Meeting Zones and connects to the URL with the least amount of latency. This means that all WebEx Nodes for MCS load-share, and you cannot specify certain users to use certain servers. Most likely, users will be connected to the closest node, but that might not be the case depending on network situation and congestion. External meeting guest users are always connected to the Collaboration Cloud, and internal users are on the closest WebEx Node for MCS or ASR 1000. The WebEx Nodes for MCS or ASR 1000 and cloud users can see content shared by anyone with Sharing assignment during a meeting.

**Note**

The WebEx Node for MCS and WebEx Node for ASR are different products. WebEx Node for MCS provides only collaboration bridge functionality (no multi-media) and is specific to the Unified MeetingPlace 8.x solution. It cannot be used for a WebEx SaaS implementation. For more information on WebEx Node for ASR, which provides on-premises mixing for both web meetings and HQ Video, see [Cisco WebEx Software as a Service, page 22-5](#).

**Note**

Internal meetings hosted on the WebEx Node for MCS support only Meeting Center meetings. Event Center and Training Center meeting traffic can be aggregated on the WebEx Node for MCS, but it can be designated only as an external meeting. Internal meetings do not support WebEx HQ Video nor Network Based Recordings (NBR) since both of these services are provided in the cloud. Only meetings scheduled as "external" provide both WebEx HQ Video and NBR recordings. NBR with WebEx Node for MCS is not supported for WebEx scheduling deployments but it is supported for MeetingPlace scheduling deployments.

Also, remember that the WebEx Node for MCS does not support HQ Video (webcam only) and WebEx VoIP switching. So unless WebEx webcam video is disabled for the site, it will propagate to the cloud and be switched there. Meetings scheduled as "internal" do not have a data connection to the WebEx collaboration cloud to get the webcam video, so users must schedule meetings as "external" to use both the bandwidth aggregation of the web conference and the webcam video mixed in the cloud. Customers should choose between using either Unified MeetingPlace standards-based video or WebEx HQ Video in the cloud. Additionally, WebEx Node for ASR can be deployed to provide bandwidth aggregation of both webex web conferencing meetings and WebEx HQ Video with webcam mixing on the ASR.

Customers can also choose to disable HQ Video for the WebEx site and instead use no video or Unified MeetingPlace standards-based video (H.323, SIP, and SCCP devices only) on native webcams.

WebEx Site

All Unified MeetingPlace 8.x web conferencing solutions require a WebEx site. A WebEx site for a given organization will have the format *companyXYZ.WebEx.com*. Enterprise customers may use Meeting Center only or a combination of all the WebEx centers, which is called Enterprise Edition and which supports Meeting Center (MC), Event Center (EC), Training Center (TC), and Support Center (SC). WebEx packages for Active Host, Named Host, Ports, or minutes are all supported with Cisco Unified MeetingPlace 8.5 and later releases, with or without WebEx Node.

Event Center and Training Center offer additional integration features. Event Center Audio Broadcast allows for efficient use of Unified MeetingPlace Audio. Only presenters in an event meeting are connected to the Unified MeetingPlace Audio system, and all participants (up to 3,000) join by means of a browser URL and can listen to the audio broadcast in streaming mode (not multicast). Unified MeetingPlace audio can support a maximum of 500 audio ports in a single large meeting with auto-mute

if desired, but Cisco highly recommends using the Event Center Audio broadcast feature for large meetings for one-to-many functions. Training Center offers the use of audio/web breakout rooms and mute participants upon entry.

A single WebEx Site is tied to only one Unified MeetingPlace system. A Unified MeetingPlace system in the multinode deployment model requires using the WebEx Scheduling model only. Multiple WebEx Sites cannot be supported on one Unified MeetingPlace system, and multiple Unified MeetingPlace systems cannot be supported on one WebEx Site.

Cisco Unified MeetingPlace 8.5 and later releases with WebEx WBS27 FR 26 and above allow Unified MeetingPlace to be integrated without any need for provisioning. Existing WebEx customers that have this release can easily add Unified MeetingPlace Audio to their existing site without any provisioning requests or changes. In addition, this WebEx release also supports Dual Audio vendor, which will allow for either WebEx Audio and Unified MeetingPlace Audio on the same site or Unified MeetingPlace Audio and TSP Audio on the same site. There is an administrative portal to the WebEx site that is used to configure key parameters that tie the site to the Unified MeetingPlace deployment. For more information regarding the WebEx site configuration, refer to the *Administration Documentation for Cisco Unified MeetingPlace*, available at

http://www.cisco.com/en/US/products/sw/ps5664/ps5669/prod_installation_guides_list.html

Note

For Unified MeetingPlace audio/video-only deployments, a WebEx site is not required.

WebEx Site Dual Audio Support

A WebEx site using Release 27 FR26 or above supports a new feature called Dual Audio Vendor support. This feature allows for the following configurations and integrations:

- WebEx Audio/VoIP + Unified MeetingPlace audio
- TSP audio + Unified MeetingPlace audio

The Dual Audio Vendor feature enables existing WebEx sites with TSP Audio or WebEx Audio to configure Unified MeetingPlace Audio as well, and do a phased migration from one type to the other, which allows future meetings already scheduled with the first audio provider to still be used while all new future meetings start using Unified MeetingPlace Audio. This also allows different regions of the world to use different audio systems based on profile default settings. For example, Singapore can use WebEx Audio while all North America users are set to use Unified MeetingPlace Audio only.

In addition, profiles can be configured to offer both audio providers, and users must know how to schedule using each provider per meeting. Specific WebEx session types can also be configured to use one type of audio provider based on the meeting type scheduled.

Dual Audio Vendor support does not provide automatic overflow from one to the other or combining of both audio systems together.

Unified MeetingPlace Audio currently does not support "mixed" audio conferencing with the WebEx VoIP feature. So if customers want to use WebEx Audio with VoIP, this dual vendor audio support would have to be configured, and users would have to know to choose the WebEx Audio/VoIP option to use this function.

User Based Licensing

Starting with Cisco Unified MeetingPlace 8.5, a user-based licensing model is used. In previous versions of Unified MeetingPlace, ports-based licensing was used. A user-based licensing model allows customers to purchase systems based on the "active" users on the Unified MeetingPlace system. Active users are defined as a profiled account that schedules meetings or hosts meetings on Unified

MeetingPlace. System reports are available for monitoring active usage to see if the system has exceeded the purchased user count. Also, a minor SNMP alarm is sent if the active user count is above licensed user count. In no way will Unified MeetingPlace block a conference call or profiled host from having a meeting. Customers may provision as many users as they need without any issues by using the various provisioning options available through WebEx or native to Unified MeetingPlace. The Unified MeetingPlace database will support a maximum of 400,000 profiles.

**Note**

A user license (audio, web, or video) is not granted to any particular user but, rather, is a system-wide resource shared by all users in the Unified MeetingPlace system.

System capacity for the total number of audio callers connected simultaneously is dependant entirely on the hardware server model and number deployed. Peak usage and future growth both must be factored in when designing a Unified MeetingPlace on-premises solution. If you deploy two Cisco UCS B-Series Blade Servers or C210 Series Rack-Mount Servers with Unified MeetingPlace Application and EMS software, you will have 1,200 G.711 ports per server or 2,400 total ports or 1,200 redundant ports that all profiled users and guests can utilize. Conferencing nodes have active/active load sharing of all meetings. If one server is down, the calls on that server are dropped and users can immediately dial back in or use Callback from the WebEx meeting room user interface, and that meeting will be reestablished automatically on the other server (or the least busy server in the region). Unified MeetingPlace supports up to 14 conferencing nodes with a total of 14,400 G.711 ports. If G.729, G.722, and/or standards-based video is used, it will reduce these capacity numbers.

Unified MeetingPlace supports both scheduled and reservationless meetings. Reservationless meetings are audio only (or audio/video only if video is enabled).

Scheduling Interface

The Cisco Unified MeetingPlace solution offers two scheduling interface options:

- WebEx Scheduling Model using Productivity Tools, One Click, and WebEx scheduling interfaces
- Unified MeetingPlace Scheduling Model using Outlook, Lotus Notes, Conference Manager, or Web scheduling interfaces

In many cases, user familiarity with a particular interface will influence the decision of which option to choose. If users are currently using a WebEx SaaS deployment and simply want to pull audio/video resources on-premises, or if this is a new Unified MeetingPlace installation, Cisco recommends the WebEx scheduling deployment model. The WebEx Scheduling model is required for multinode deployments of Unified MeetingPlace 8.5 or later releases. However, if Unified MeetingPlace is currently deployed, it might be beneficial to maintain the same scheduling interface. While there are certainly differences, both have a web-based user scheduling portal and both have their own integrations with common calendaring systems (Outlook or Lotus Notes). Also, WebEx scheduling supports Enterprise Edition meetings (Meeting Center, Event Center, and Training Center sessions), while Unified MeetingPlace scheduling supports Meeting Center sessions only. The Unified MeetingPlace scheduling model is not available for new customers deploying Unified MeetingPlace 8.5.

WebEx Scheduling Deployment

WebEx supports two deployment models:

- [Single-Site WebEx Scheduling Deployments, page 22-20](#)
- [Multisite WebEx Scheduling Deployment, page 22-21](#)

The WebEx Scheduling deployment model supports Meeting Center only or WebEx Enterprise Edition (EE), which includes Meeting Center, Event Center, and Training Center session types, all of which can integrate to Unified MeetingPlace Audio. Only Meeting Center meetings are mixed both on WebEx Node for MCS and in the cloud (for guest users). Event Center and Training Center are always considered external meeting types, and internal users join the WebEx node for MCS or ASR or cloud for those session types.

WebEx Scheduling utilizes all the current WebEx Productivity Tools (see [Cisco WebEx Software as a Service, page 22-5](#)), and all audio and WebEx recordings for external meetings are stored in the WebEx Collaboration cloud under the Network Based Recording site per host account.

Single-Site WebEx Scheduling Deployments

With WebEx scheduling, there are no Unified MeetingPlace Web servers required, and the click-to-attend URL in a meeting invitation takes users directly to the WebEx site. [Figure 22-4](#) illustrates a high-level view of a sample Unified MeetingPlace solution with WebEx scheduling, dual Express Media Servers with active/active redundancy, and a WebEx Node for MCS. The WebEx Node for MCS is optional (required for internal-only meeting, or ASR can also provide both Web and HQ Video bandwidth aggregation), and alternatively an HMS could be used in place of an EMS.

Figure 22-4 Unified MeetingPlace Single-Site Solution with WebEx Scheduling, EMS, and WebEx Node for MCS

253835

**Note**

If WebEx Node for MCS is deployed, then only external meetings can support Network Based Recordings and HQ Video webcams with WebEx scheduling.

WebEx Node for MCS or WebEx Node for ASR 1000 are optional, based on whether customer requirements detail bandwidth aggregation and/or use of "internal" meetings only is available. Because the audio conferencing is occurring on-premises while the web conferencing is occurring both in the cloud and on the WebEx Node, all meeting-related service requests are exchanged and processed via telephony service provider (TSP) application programming interface (API) communications with Unified MeetingPlace or the WebEx Node API to the cloud. This effectively ties the systems together and allows for in-meeting controls such as the ability to mute attendees or to see active speakers. This TSP link is established by the Meeting Director outbound to the cloud via a TLS encrypted dedicated socket connection on TCP port 443 to the customer WebEx site.

Network Requirements

This hybrid architecture does not require any "inbound" ports to be opened through the firewall. The Meeting Director TSP supports only SOCKS proxy servers (not HTTP or HTTPS proxy). The WebEx Node for MCS or ASR does not support any type of web proxy systems and must be allow TCP 443 outbound to the cloud if deployed. Users joining WebEx meetings also use TCP 443 outbound only through firewalls to the WebEx Collaboration Cloud. WebEx publishes the IP ranges required if firewall settings to limit internet access are necessary.

Cisco recommends a maximum latency between all components of 300 ms round-trip time (RTT), wherever components may be deployed in the enterprise network. Standard VoIP network best practices also apply to deploying Unified MeetingPlace on-premises conferencing resources. SIP trunking latency between Unified MeetingPlace conferencing nodes from/to Unified CM must adhere to this same standard for optimal conferencing performance.

For all network requirements, refer to the latest version of the *System Requirements for Cisco Unified MeetingPlace*, available at

http://www.cisco.com/en/US/products/sw/ps5664/ps5669/products_device_support_tables_list.html

Multisite WebEx Scheduling Deployment

Multisite deployments consist of sites and regions. Conferencing nodes, Meeting Director nodes, and optionally WebEx nodes are installed in data centers based on customer requirements for both capacity resiliency.

Sites are logical groups of nodes that have similar functions and capabilities. For example, a site might contain nodes with high-definition video capabilities. Sites are identified by a unique name in the system and can belong to only one region. A site contains one to all of the nodes in a region. You can configure a preferred site to host all meetings for specific user profiles.

Regions are groups of one or more sites. Regions are identified by a unique name in your system. You can have up to four regions in your system, and regions are also used to assign time zones.

A multinode Unified MeetingPlace Audio system has the following capacities:

- 14,400 G.711 audio ports
- 16 Cisco Unified MeetingPlace application server nodes consisting of two Meeting Director nodes and 14 conferencing nodes (12 with 1,200 G.711 ports = 14,400 ports, and 2 extra conferencing nodes for resiliency is supported)
- 1,200 ports per conferencing node (G.711) until the 14,400 limit is reached
- Maximum of four nodes per site

- Maximum of two sites per region (two sites with up to two nodes each, or one site with up to four nodes)
- Maximum of four regions

Note Capacities will be lower depending on G.729 or G.722 codec use, video use type, and bandwidth allowed.

WebEx Web Conferencing (required for scheduling and web conferencing) has the following capacities:

- 14,400 Web sessions (cloud and/or nodes)
- 2,000 internal Web sessions (using Cisco WebEx Node for MCS), consisting of up to 4 Cisco WebEx nodes with up to 500 sessions each
- Cisco WebEx Node for ASR supports:
 - Web conferencing per Shared Port Adapter (SPA), with up to 500 sessions each
 - HQ Video and VoIP per SPA (capacity based on usage)

Meetings are distributed evenly by configuring inbound SIP trunks to all Conferencing Nodes in a circular method in Unified CM or Session Management Edition. Callbacks initiated from within a WebEx meeting room are distributed by the Meeting Director who is monitoring all conferencing node traffic. The Meeting Director will start a new meeting on the least busy node in the region and based on the timezone of the host who scheduled that meeting. For inbound calls, the first person who joins the meeting will dictate which conferencing node they land on based on the SIP circular hunt mode. If that meeting ID is started on a different node within the same region or in a different region, a SIP Refer command will be initiated automatically to redirect that caller to the conferencing node where the host is assigned. All callers into the same meeting ID will be routed to one node in the system based on either timezone or the node on which the meeting was started by the first attendee. Thus, all users in the system will always dial their local Unified MeetingPlace dial-in numbers (or use callback) to join any meeting anywhere in the world. The SIP Refer will automatically redirect them to the proper node for that particular meeting, depending on the timezone of the host who scheduled that meeting. If a reservationless meeting ID is used, callbacks are distributed based again on the timezone where that host resides, but load sharing among multiple node is used for maximum capacity and resiliency.

Centralized Deployment Model with Multinode WebEx Scheduling

The example in [Figure 22-5](#) consists of one region with active/active resiliency in a single site. This system requires two Cisco MCS or UCS servers to provide for two Meeting Director and/or EMS servers deployed in one sites and one region, which is a centralized deployment model. Scalability is 1,200 G.711 ports with active/active redundancy, and both servers equally share the meeting load from all timezones. Unified CM SIP trunk sizing needs to take into account only simultaneous peak SIP traffic, not 2,400 ports of SIP traffic. The Meeting Director is co-located with two different conferencing nodes. The 1,200 ports generally can support a ratio of 20 users to 1 port with typical conferencing usage patterns, so this configuration should be able to support a total of 24,000 users.

Figure 22-5 Unified MeetingPlace Multinode Deployment with WebEx Scheduling for One Region

Two-Region Multinode Unified MeetingPlace Deployment Model with Webex Scheduling

The example in [Figure 22-6](#) consists of two regions in a globally distributed design with active/active resilience in each region. Also, data center sites are configured based on customer data center design. All conferencing nodes in a region are load-balanced, and nodes in different sites or regions can fail-over to other regions by means of administration settings.

This system requires four Cisco MCS or UCS servers to provide for two Meeting Director and/or EMS servers and two Conferencing Nodes in two sites and two regions. Scalability is 1,200 G.711 ports per region with active/active redundancy. Unified CM SIP trunk sizing needs to take into account only simultaneous peak SIP traffic, not 2,400 ports of SIP traffic. The Meeting Director is co-located with two different conferencing nodes and can be located in either data center depending on customer requirements.

Figure 22-7 Unified MeetingPlace Multisite Solution with WebEx Scheduling for Three Regions

Video

There are two difference types of video available to customers:

- Unified MeetingPlace standards-based third-party room/desktop or Unified Communications Video (H.323, SIP, or SCCP)
- WebEx HQ Video for Meeting Center and Training Center using webcams only

Customers must choose between these two options because there is no interoperability available today between them. Do not enable both because doing so will cause confusion for end users.

With respect to standards-based Unified MeetingPlace video, when video is mixed by the Unified MeetingPlace components on-premises, the video is displayed on the standard room and desktop endpoints themselves. It is not seen in the WebEx video pod inside the web meeting, and Cisco recommends disabling the webcam HQ Video feature on the WebEx site, otherwise there could be a mix of video conferencing with endpoints and webcam video shown in the WebEx application with no tie between them. User-based licensing supports both audio and video usage on any Unified MeetingPlace system. Enabling video on Conferencing Nodes will affect capacity based on the video type and bandwidth used.

For information about standards-based video devices supported with Unified MeetingPlace, refer to the latest version of the *Compatibility Matrix for Cisco Unified MeetingPlace*, available at

http://www.cisco.com/en/US/products/sw/ps5664/ps5669/products_device_support_tables_list.html

Alternatively, if no Unified MeetingPlace video conferencing is deployed, users could take advantage of the WebEx HQ/HD Video capabilities using pure webcams-only mixed in the cloud, or if WebEx Node for ASR with video Shared Port Adapter (SPA) is deployed, then bandwidth aggregation can occur on-premises. WebEx HQ/HD Video cannot be used if WebEx Node for MCS is deployed and users have scheduled meeting as "internal," where there is no data sharing connection to the cloud. If meetings are scheduled as "external," then users can see the webcam video and still be connected to the WebEx Node for MCS for web meeting bandwidth aggregation.

Unified Communications Client Services Framework (CSF) devices and Cisco Unified Video Advantage are both webcam-only or SCCP/SIP video standards-based devices. How the client joins a meeting and which video option is enabled will determine the video experience for the end user. (See [Table 22-7](#).)

Table 22-7 Supported Video Options

| Video Type | WebEx HQ Video | MeetingPlace Video |
|--|----------------|--------------------|
| Standards-based support for H.323, SIP, and SCCP | No | Yes |
| Webcam support | Yes | No |
| Webex Node for ASR | Yes | No |
| Internal premises-based | No | Yes |
| Global Access guest/users | Yes | No |

WebEx Owned Profile Management

There are two ways to configure profile management: WebEx Owned Profiles or Unified MeetingPlace Owned Profiles.

WebEx owned profile management allows for profiles to be provisioned in the following ways:

- Account sign-up (automatically approved or with system administrator approval required)
- Manual account creation
- Import periodically from Excel spreadsheet file
- Federated single sign-on (SSO) option (accounts automatically created upon login)
- WebEx XML API (custom account management)

With WebEx Owned Profile enabled, Unified MeetingPlace automatically synchronizes all user profiles from the cloud through the X.509 encrypted link and creates users on Unified MeetingPlace Conferencing nodes. Users can then use the Profile Number and PIN code to access the reservationless audio-only meetings.

**Note**

The Profile Number is eight digits in length and is assigned randomly when the user profile is created. The PIN code can be created by the user upon first logging in to the WebEx site. Optionally, the Profile Number can also be customized by retrieving it from the LDAP directory through the WebEx XML API by using a custom code for mapping LDAP fields to WebEx Profile fields.

Unified MeetingPlace then accesses profiled user information through an XML API User Synch module to automatically configure all users on Unified MeetingPlace Conferencing Nodes. When installing the Meeting Director primary server (the first one in the installation cycle), you choose the **WebEx Owned Profile** setting and the system then operates automatically to synchronize user profiles from the cloud through an X.509 encrypted link.

When WebEx Owned Profiles is enabled, the Unified MeetingPlace system uses a Profile Number and PIN code, which users enter only for reservationless audio-only meetings. When the user profile is newly created, WebEx Site with Unified MeetingPlace will atomically assign a random Profile Number to that user. Upon first logging in to the WebEx Site, that user is prompted to configure a PIN code. If customers want a specific number to be assigned to the users based on an LDAP field, then the WebEx XML API must be used for provisioning a custom code that uses LDAP fields to map to WebEx profile fields. The Profile Number and PIN length requirements are set in the Unified MeetingPlace System Administration parameters. Profile Numbers can be 4 to 8 digits in length, and PIN codes can be 5 to 24 digits in length.

**Note**

WebEx Owned Profile is mandatory in order to enable the optional WebEx Federated Authentication Service (FAS) LDAP capability. For more information on FAS, refer to the *WebEx Federated SSO Authentication Service Technical Overview*, available at http://developer.webex.com/c/document_library/get_file?groupId=10465&folderId=11421&name=DLFE-201.pdf.

WebEx XML API

If you want to control the creation of the MeetingPlace Profile ID with a field that exists in the LDAP profile, then you must write a script to call the WebEx XML APIs for User Service and Create Users functions. One of the parameters for this XML API is the Unified MeetingPlace profile number (mpProfileNumber) assignment. Unified MeetingPlace profile numbers must be between 4 digits and 8 digits in length. Unified MeetingPlace profile numbers are used only with audio-only meetings or reservationless meetings that are audio-only, where the host must log into meetings with this profile number that is the meeting ID and PIN code to start the meeting. All other callers are in a waiting room on Unified MeetingPlace until the host logs in and starts the meeting. Normal scheduled WebEx and Unified MeetingPlace combined meetings do not require the use of this profile number and PIN code to start them.

For more information on the XML API, refer to the Cisco WebEx Collaboration Cloud documentation available at

<http://developer.webex.com/web/meetingservices/xmlapi>

Unified MeetingPlace Owned Profile Management

Unified MeetingPlace Owned profile management is available only for existing customers that wish to retain the use of current profiles for use with WebEx. New customers will not be able to provision the WebEx site using the Unified MeetingPlace-to-WebEx SSO integration, which is supported only on installed systems already provisioned in this manner.

If there is no SSO enabled between Unified MeetingPlace and WebEx, all WebEx host accounts must be provisioned by manual export from Unified MeetingPlace to the WebEx site by an administrator (to be updated periodically), and all end-user authentication is provided by the local WebEx host account

passwords. WebEx host accounts may also be requested via the WebEx Site and then exported into the Unified MeetingPlace system for profile management. The SSO option must be chosen when ordering the WebEx Site for integration with Unified MeetingPlace on-premises, and it is available only for existing customers who already have Unified MeetingPlace and WebEx installed.

Unified MeetingPlace Scheduling Deployment

The Unified MeetingPlace scheduling deployment option requires the use of two Unified MeetingPlace Web Servers, solely for scheduling and attending meetings. They do not provide any web conferencing functionality. Figure 22-8 illustrates a high-level view of a sample Unified MeetingPlace solution with Unified MeetingPlace scheduling and HMS. Alternatively, an EMS could be used in place of the HMS, and a WebEx Node for MCS is not depicted but could optionally be added as well.

Figure 22-8 Unified MeetingPlace Solution with Unified MeetingPlace Scheduling and HMS

253834

With Unified MeetingPlace scheduling, when users select the click-to-attend URL in an invitation, they first connect with a Unified MeetingPlace Web server customer-configured URL (HTTPS option recommended). The Unified MeetingPlace Web servers immediately initiate a connection to the organization's WebEx site and create a meeting, and the WebEx site returns a join URL which the MeetingPlace Web servers pass onto the clients in the form of a redirect to the WebEx Media Tone Network via secure HTTPS. This redirect behavior is completely transparent to the user, and user authentication is performed solely by the on-premises Unified MeetingPlace system, which is required to enable the SSO capability. The use of the on-premises WebEx Node for MCS is also available for internal users.

When a Unified MeetingPlace profiled user schedules a WebEx meeting or accesses the My WebEx link from the Unified MeetingPlace web user interface, WebEx automatically creates the user account based on the Unified MeetingPlace user profile with the SSO option enabled. The Unified MeetingPlace

profile could be either from the local Unified MeetingPlace userID and password or from LDAP integration with Unified CM, which is the most commonly used. Several Unified MeetingPlace user profile attributes are inherited by WebEx, including username, password, first name, last name, telephone number, and email address. Because a WebEx Site is dedicated to a specific customer and the WebEx user profile is based on the Unified MeetingPlace user profile, there should not be any user profile conflicts. No WebEx host accounts are created manually because the Unified MeetingPlace SSO integration provides this function via the WebEx TSP link. Passwords are not sent over the TSP Link to WebEx. WebEx will trust all internal user traffic redirected by the Unified MeetingPlace Web servers. Guest users do not use any passwords or authentication to join WebEx meetings (except the WebEx Meeting Password if configured).

**Note**

Internal WebEx meetings can be recorded with Unified MeetingPlace scheduling, but this requires a WebEx Node for MCS to be deployed on-premises.

Cisco Unified Communications Manager

Cisco Unified Communications Manager (Unified CM) is also a central piece of the architecture, and it provides inbound and callback by means of SIP trunks. A SIP trunk is configured in Unified CM with a destination address of the Unified MeetingPlace Application server(s), and then a route pattern(s) must be used to route calls via the SIP trunk to Unified MeetingPlace. Typically there are three phone numbers that are sent in email notifications for use for dial-in capabilities: Toll free (optional), toll number, and internal Unified CM DN for abbreviated dialing for internal callers. In Unified MeetingPlace there is a separate configuration for callback or outdial feature support by means of SIP trunks to a primary Unified CM subscriber, and subsequent subscribers are used if the primary is not accepting calls due to various conditions. The IP addresses or hostnames of multiple Unified CM call processing subscribers are listed for outbound call delivery in a hunt mode.

It is imperative that the Unified CM servers be able to resolve all dial strings received from a callback request within a WebEx Meeting room after joining. Callbacks may also be disabled system-wide on the WebEx Site by means of Site Administration settings. Unified CM is also in control of all toll restrictions to various countries or other numbers most enterprises will block, because Unified MeetingPlace does not have any toll restriction blocking itself.

In a multinode deployment the Unified CM or Session Management Edition systems are a critical component supporting Unified MeetingPlace in geographically disbursed enterprises. Unified CM clusters with intercluster trunks (ICTs) are required to accommodate Unified MeetingPlace conferencing servers with their unique assigned dial-in numbers and to resolve all calls based on dial plans between sites and to the PSTN for guest or outside mobile users. Guest users can either dial in or use the WebEx callback feature within a meeting room after joining. Multinode Unified MeetingPlace conferencing nodes in a region are configured in a route group in a circular method, where all inbound calls are distributed evenly between all nodes. Callbacks are initiated by the Meeting Director, which chooses the least busy conference node per region based on the timezone of the host of that meeting. The SIP Refer command is used to send dial-in callers to the conferencing node chosen to host that meeting ID.

Additional guidelines for redundancy are described in the section on [High Availability, page 22-9](#). Third-party PBXs can be integrated with Unified MeetingPlace through Unified CM only. For further details on PBX interoperability with Unified CM, refer to the documentation available at

http://www.cisco.com/en/US/solutions/ns340/ns414/ns728/networking_solutions_products_genericontent0900aec805b561d.html

Unified MeetingPlace supports receiving both Early Offer (EO) and Delayed Offer (DO) SIP Invite messages. Unified MeetingPlace initiates EO SIP Invites for outbound calls, and Unified CM sends calls to Unified MeetingPlace by using DO SIP invites. Unified CM can be configured to use EO, but this might require the use of a media termination point (MTP) resource. For more information, see [SIP Delayed Offer and Early Offer, page 14-20](#).

**Note**

For Unified MeetingPlace audio/video deployments involving the Express Media Server (EMS), Unified MeetingPlace also supports call delivery by means of a Cisco IOS SIP gateway or Cisco Unified Border Element. LDAP synchronization capabilities are lost with this deployment. For more information, refer to the latest version of the *Planning Guide for Cisco Unified MeetingPlace*, available at http://www.cisco.com/en/US/products/sw/ps5664/ps5669/products_implementation_design_guides_lists.html.

Recording

Another criterion for choosing a deployment model is where customers prefer meeting recordings to be stored and accessed. Meeting participants can start audio-only recording via a voice user interface such as a telephone, or they can start audio and web recording from a WebEx meeting room. Audio recording invokes a call event from the WebEx Collaboration cloud to the Unified MeetingPlace Media server via the PSTN voice gateways. For the Unified MeetingPlace scheduling deployment model, the recorded meetings are available from the Unified MeetingPlace Web user interface to download and play back with a WebEx recording playback program. The internal Unified MeetingPlace web server (with optional SAN/NAS) stores recordings that are scheduled as internal meetings. All internal meeting recordings (WebEx audio recordings, audio-only, or audio/video recordings) are stored on-premises. Video recordings are available only with the Hardware Media Server option and the Unified MeetingPlace Scheduling option.

Unified MeetingPlace Scheduling uses the WebEx Network Based Recording (NBR) storage for all meetings that are scheduled as external meetings. However, users access these external recordings via the same method as internal recordings, but the files are simply stored in a different location.

All Unified MeetingPlace and WebEx recordings are played back via the standard NBR recording playback program provided by download to the local users' PCs. All files are editable as well by WebEx editing tools for NBR recordings.

Other Architectural Considerations

Some integration options available with a Unified MeetingPlace Scheduling deployment model may require additional integration servers. Outlook and Exchange calendaring integration is inherently built into the Unified MeetingPlace Application server. However, Lotus Notes integration requires additional software that is co-resident on the Internal Unified MeetingPlace Web server, but other integrations do not require the deployment of the Internal Unified Meeting Web server.

For more information on available Unified MeetingPlace integrations, refer to the latest version of the *Planning Guide for Cisco Unified MeetingPlace*, available at

http://www.cisco.com/en/US/products/sw/ps5664/ps5669/products_implementation_design_guides_lists.html

Deployment Options

The majority of Unified MeetingPlace deployments follow a single-site model. This section provides high-level details of each deployment option.

Single-Site Unified MeetingPlace Scheduling Deployment

This deployment model is for current customers who already have the Unified MeetingPlace Web components deployed. The other requirement for deploying this model include using the following features:

- Audio-only or audio/video-only deployments with no WebEx integration
 - Primary/warm standby redundancy is available with this deployment.
- Continuous meetings with blast outdial for audio-only meetings
 - Primary/warm standby redundancy is available with this deployment.
- Unified CM Video Telephony ad-hoc audio/video mixing for conference bridge resources
 - Multiple instances of Unified MeetingPlace in ad-hoc mode can be used per Unified CM cluster. Each Unified CM cluster requires its own Unified MeetingPlace audio-only server(s).
 - Multiple Unified MeetingPlace servers can be configured in hunt fashion on the conference bridge resource group configuration per cluster.
 - Standards-based video will affect overall capacity, depending on the type and bandwidth of video setting on Unified MeetingPlace.

Most deployments use the single-site deployment model, with all server components and users located at a single site interconnected by a single LAN. Solution components vary as discussed in the section on [Architecture, page 22-5](#). Single-site deployments have the following common characteristics:

- The Express Media Server is automatically co-located with the Application server. The optional Unified MeetingPlace Hardware Media Server(s) must be located in the same data center with the active Unified MeetingPlace Application server.
- Network Time Protocol (NTP) must be implemented to allow Unified MeetingPlace components to synchronize their clocks to a network time server or network-capable clock. NTP is a critical network service for Unified MeetingPlace because it ensures accurate time for scheduling meetings. The external NTP source can be specified during Unified MeetingPlace Application server installation, and other Unified MeetingPlace components will synchronize with the application server automatically.
- For existing customer installations only, Unified MeetingPlace Scheduling audio, video, and web recordings and meeting attachments can optionally be stored on an external customer-provided SAN/NAS storage server.
- For deployments with Unified MeetingPlace Scheduling, you must deploy a single Unified MeetingPlace Web server for internal users and a single Unified MeetingPlace Web server located in the DMZ for external participants.
- For deployments with Unified MeetingPlace Scheduling, the round-trip delay between the active Unified MeetingPlace Application server and any Unified MeetingPlace Web server(s) in the solution must not be greater than 150 ms.

- For deployments of WebEx Node for MCS, Cisco recommended placing it on the internal network closest to participants involved in meetings. WebEx Node for MCS does not support HTTPS Proxy servers, therefore it must route directly outbound using TCP port 443 to have access to the WebEx Site.

For a detailed list of incoming and outgoing ports by component, refer to the latest version of the *System Requirements for Cisco Unified MeetingPlace*, available at

http://www.cisco.com/en/US/products/sw/ps5664/ps5669/products_device_support_tables_list.html

High Availability

This section describes redundancy considerations for the following Unified MeetingPlace components:

- Unified MeetingPlace Application Server
- Unified MeetingPlace Media Server (optional)
- Unified MeetingPlace Web Server
- WebEx Node for MCS
- Call Control

Unified MeetingPlace Application Server

Unified MeetingPlace in a multinode deployment with WebEx Scheduling automatically provides active/active resiliency, and customers can choose the level of redundancy per region and site. Regions can be configured to overflow to other regions if desired.

Unified MeetingPlace with the MeetingPlace Scheduling model allows for an active (primary) and a single warm standby Unified MeetingPlace Application server for failover. Each Unified MeetingPlace Application server in a failover deployment is configured with the same IP address associated to its physical network interface controller (NIC) and a unique IP address associated to a virtual network interface. The requirement for both Unified MeetingPlace Application servers to share the same IP address mandates both Application servers to be connected to the same virtual LAN (VLAN) or IP subnet. This is not an issue when both servers are placed in a single data center; however, a dual data center design is supported only if the same VLAN (IP subnet) spans both data centers. All Unified MeetingPlace components as well as Unified CM communicate with this shared IP address. The physical NIC (with the shared IP address) of the standby server remains disabled until the primary server fails and the manual failover process is initiated by IT personnel.

For network requirements in deploying either multinode or a standby server, refer to the failover information in the latest version of the *Planning Guide for Cisco Unified MeetingPlace*, available at

http://www.cisco.com/en/US/products/sw/ps5664/ps5669/products_implementation_design_guides_list.html

The virtual network interface is used for Informix database replication between the primary and standby servers. The database replication ensures that database tables related to users, groups, and meetings are synchronized between primary and standby servers. Cisco recommends placing the virtual network interfaces of the active and standby servers in the same VLAN. For further information regarding Unified MeetingPlace Application server redundancy, refer to the latest version of the *Planning Guide for Cisco Unified MeetingPlace*, available at

http://www.cisco.com/en/US/products/sw/ps5664/ps5669/products_implementation_design_guides_list.html

Another key requirement for a Unified MeetingPlace solution is that the active Unified MeetingPlace Application server must be co-located with the active Unified MeetingPlace Media server(s). Since the Express Media Server runs in software on the Unified MeetingPlace Application server itself, failover to the standby Unified MeetingPlace Application server results in using EMS capabilities on the standby. In the case of Hardware Media Servers, there are some considerations when looking at single data center designs compared to dual data center designs.

Single Data Center Design

In a single data center design, multinode resiliency is automatically available in an active/active mode, and meetings are evenly distributed by the Meeting Director component between both nodes. If failure occurs on one conferencing node, calls will be dropped, and when users dial back into that same meeting ID or use the WebEx Callback feature in the meeting room GUI, then those meetings are automatically established on another node in that region or they overflow to another region if configured. Up to four conferencing nodes per site may be deployed.

With the Unified MeetingPlace Scheduling model, failover of the Unified MeetingPlace Application server occurs within the same geographic location. For this type of deployment, there would typically be one set of Unified MeetingPlace Hardware Media servers shared by the primary and standby Unified MeetingPlace Application servers. If the primary Unified MeetingPlace Application server fails, the Unified MeetingPlace Media server(s) must be synchronized with the standby (now primary) server. Unified MeetingPlace Web server(s) would also be shared for a Unified MeetingPlace scheduling deployment. [Figure 22-9](#) illustrates the failover process for the Unified MP Application server in a single data center deployment.

Note

For highly redundant solutions, it is also possible to have a set of standby Unified MeetingPlace Media servers and Web Collaboration servers in a single data center. Unified MeetingPlace Web servers cannot be made redundant with Unified MeetingPlace 8.x systems. The WebEx Scheduling Deployment model offers a more reliable redundant deployment model.

Figure 22-9 Failover of a Unified MeetingPlace Application Server in a Single Data Center Deployment

Dual Data Center Design

In a dual data center design, the WebEx Scheduling model with multinode conferencing nodes provides active/active failover per region, or overflow to other regions can be configured as well. Four regions with two sites per region is supported with a maximum of 14 conferencing nodes deployed for active/active load sharing in multiple data centers, based on customer requirements. If a conferencing node fails, audio calls are dropped, and when users call back in or use the WebEx Callback GUI feature

from within the meeting room, the meetings are automatically started on an active node with capacity. All conferencing nodes within a region can be used to distribute calls, and overflow to another region is based on optional system administration settings.

With the Unified MeetingPlace Scheduling model, failover of the Unified MeetingPlace Application server occurs between different geographic locations across an IP WAN. Again, although both servers are separated geographically, both the active and standby Application servers must be connected to the same VLAN to ensure proper failover operation. For this type of deployment, the standby Application server must be co-located with a redundant Unified MeetingPlace Hardware Media server(s) with which it is synchronized. If the identical number of Unified MeetingPlace Media server audio and video blades is not maintained in the standby data center, system capacity will be reduced during failover scenarios where the standby Application server is promoted to active.

Unified MeetingPlace Media Server

Since the Express Media Server runs in software on the Unified MeetingPlace Application server itself, in a multinode deployment model, any conferencing node in a region can be used for taking those additional meetings. A maximum of four servers per site, two sites per region, and four regions may be deployed for a globally distributed architecture.

Since the Express Media Server runs in software on the Unified MeetingPlace Application server itself, failover to the standby Application server will result in using EMS capabilities on the standby. EMSs do not support cascading or clustering to other EMS instances. A maximum of one primary and one failover Unified MeetingPlace Application and EMS server is supported with Unified MeetingPlace solutions with either Unified MeetingPlace Scheduling or WebEx Scheduling deployment models. Active RSNA failover is not supported with any WebEx integrations (only standalone audio/video deployments).

The Unified MeetingPlace Application Server automatically performs failover to alternate HMSs (audio or video blades) in the system. For example, if the Application Server detects a loss of connectivity with an audio blade, it removes it from the list of active audio blades so that subsequent audio sessions will connect to an active audio blade. To avoid reduction in Unified MeetingPlace Media Server capacity during an audio or video blade outage, one option is to add additional HMS audio and video blades to the solution. The Application Server will not exceed the number of sessions for which it is licensed. Another option is to revert to the standby Unified MeetingPlace Application Server with its own set of HMSs (as in a dual data center design). These two options are not mutually exclusive; a standby Unified MeetingPlace Application Server with its own set of HMSs can gain further redundancy by adding more audio or video blades.

For further information regarding Hardware Media Server failover, refer to the latest version of the *Planning Guide for Cisco Unified MeetingPlace*, available at

http://www.cisco.com/en/US/products/sw/ps5664/ps5669/products_implementation_design_guides_list.html

Unified MeetingPlace Web Server

The Unified MeetingPlace Scheduling model uses only one Web server with audio-only configuration for recordings and/or the Web scheduling interface. For existing customers using WebEx Integration to migrate to Unified MeetingPlace 8.5 (or later release) and still using the Unified MeetingPlace Scheduling model, then use an additional Web server deployed in a DMZ. Each Cisco Unified MeetingPlace system can have a maximum of one internal Web server and one Web server in the DMZ if using WebEx Integration only. There are no redundancy options for these servers. Unified MeetingPlace Web servers are implemented only for solutions incorporating the Unified MeetingPlace scheduling interface. The Unified MeetingPlace Lotus Notes or Jabber integration also cannot be made redundant.

WebEx Node for MCS or ASR

A Unified MeetingPlace solution supports unlimited nodes if WebEx Node for ASR is used, but the maximum number of supported WebEx Nodes for MCS depends on the deployment options. For a single Unified MeetingPlace Application server deployment, the solution supports a maximum of three WebEx Nodes for MCS. For a multi-node deployment with WebEx scheduling, the solution supports a maximum of four WebEx Nodes for MCS. Cascading meetings are supported across the WebEx Nodes for MCS and out to the WebEx Collaboration cloud. WebEx Nodes for MCS or ASR will each automatically provide a level of redundancy in case of a single node outage. After receiving a list of Meeting Zone URLs, the client then pings all the Meeting Zones URLs to determine the closest node. If a node does not respond, no clients will connect to this node. All internal users (even those that use VPN from remote locations) can connect to any of the WebEx Node for MCS servers.

If the WebEx Node for MCS or ASR that is hosting a meeting becomes unavailable, the next available WebEx Node for MCS or ASR automatically takes over. Any sharing and recordings will be stopped, and users will have to restart sharing and recording the meetings. When a customer has multiple WebEx Nodes for MCS or ASR active within a meeting with a subset of users on each node, content is cascaded between the WebEx Nodes for MCS or ASR. When there are three or more WebEx Nodes for MCS active in the same meeting, the cascade appears as a star with the WebEx Node for MCS that the host is on at its center. If a node fails, the clients automatically rejoin other nodes using the list presented to the client from WebEx within the client entry meeting window, with little or no effect to the end user. External scheduled meetings also allow for internal users to connect to the WebEx cloud as well, while internal scheduled meetings always stay internal on other redundant WebEx nodes (which can be distributed or co-located, depending on customer network design requirements). Audio calls remain intact on the Unified MeetingPlace system on-premises.

For more information on redundancy within the WebEx cloud, see [High Availability, page 22-9](#).

Call Control

Unified MeetingPlace allows you to define multiple SIP outdial connections that point to Cisco Unified CM call processing subscribers. For redundancy, multiple SIP proxy servers should be configured to direct calls to call processing subscribers in the Unified CM cluster. These call processing subscribers should correlate with the Unified CM Group of the configured SIP trunk for Unified MeetingPlace calls in Unified CM. Note that the Unified MeetingPlace Application server will send outbound calls to SIP proxy server 1 only and will not send calls to SIP proxy server 2 unless communication with SIP proxy server 1 is lost. Only then will Unified MeetingPlace send a SIP INVITE message to the next available call processing agent in the list. Failure of the call processing agent should not affect existing calls. The existing media connection is torn down after the user disconnects.

Note

The term SIP Proxy Server is simply the terminology seen on the Unified MeetingPlace Application Server configuration pages, and it does not imply that integration with any SIP Proxy server is supported.

For inbound calls, a single configured SIP trunk in Unified CM can be handled by up to three call processing subscribers found in its configured Unified CM Group. If the primary Unified CM call processing subscriber in the Unified CM Group is offline, the second one will take over initiating calls into the Unified MeetingPlace system. For more information, see [Cisco Unified CM Trunks, page 14-1](#). For Unified MeetingPlace scheduling deployments with EMS, multiple Cisco IOS SIP gateways are required to provide redundancy for call delivery.

Capacity Planning

The capacity of a given Unified MeetingPlace solution depends on the design of the Cisco Unified Communications system (for example, audio codecs or video format used in conferencing) and the platform selected to run the Unified MeetingPlace solution components. For details, see the sizing information in the section on [Collaborative Conferencing, page 29-39](#).

Network Traffic Planning

Network traffic planning for Unified MeetingPlace collaboration consists of the following elements:

- **Call Control Bandwidth**
Call control bandwidth is extremely small but critical. Co-locating the Unified MeetingPlace Application server with Unified CM helps protect against issues with call control. Remote locations need proper QoS provisioning to ensure reliable operation.
- **Real-Time Transport Protocol (RTP) Traffic Bandwidth**
RTP traffic consists of voice and video traffic. The Unified MeetingPlace Media servers supports G.711, G.729, G.722, and iLBC as audio codecs, and it supports a wide range of video codecs and bandwidths. For further information regarding bandwidth calculations per codec type, refer to the chapters on [Network Infrastructure, page 3-1](#), and [IP Video Telephony, page 12-1](#).
- **Web Collaboration Bandwidth**
Web collaboration bandwidth for a Unified MeetingPlace solution can be estimated the same way as for a WebEx SaaS solution. See [Network Traffic Planning, page 22-10](#).

Design Considerations

The following design considerations apply to Unified MeetingPlace deployments:

- Only a single Unified MeetingPlace system is supported per WebEx site.
- For scenarios where any Unified MeetingPlace solution components are separated by network firewalls, it is imperative to ensure the correct pinholes are opened for all required traffic. For a detailed ports list, refer to the network requirements information in the latest version of the *System Requirements for Cisco Unified MeetingPlace*, available at http://www.cisco.com/en/US/products/sw/ps5664/ps5669/products_device_support_tables_list.html
- Collaborative meeting systems typically result in increased top-of-the-hour call processing load. Capacity planning tools with specific parameters for Unified MeetingPlace are available to Cisco partners and employees to help calculate the capacity of the Cisco Unified Communications System for large configurations. Contact your Cisco partner or Cisco Systems Engineer (SE) for assistance with sizing of your system. For Cisco partners and employees, the Cisco Unified Communications Sizing Tool is available at <http://tools.cisco.com/cucst>.
- For more detail on the various Cisco collaborative client offerings and how they fit into collaborative conferencing solutions, see [Cisco Collaboration Clients and Applications, page 24-1](#).
- Call admission control with Unified MeetingPlace is performed by Unified CM. With locations-based call admission control, Unified CM can control bandwidth to the Unified MeetingPlace system by placing the SIP trunk specific to Unified MeetingPlace in a location with a set amount audio and/or video bandwidth allowed. Alternatively, Unified CM supports the use of

Resource Reservation Protocol (RSVP), which can also provide call admission control. For further information regarding call admission control strategies, see the chapter on [Call Admission Control](#), page 11-1.

- Unified MeetingPlace supports the following standard dual-tone multi-frequency (DTMF) transmission methods: RFC 2833 and KPML DTMF. Unified CM supports RFC 2833, and it is the recommended method for DTMF Relay.
- SIP signaling traffic from the Unified MeetingPlace Application server is marked CS3 (DSCP 0x18). However other traffic from the Unified MeetingPlace Application server, such as communications with Unified MeetingPlace Web servers, Media Servers, or the WebEx Site, are marked best-effort (DSCP 0x00). If any of this traffic is traversing low-speed or congested links, QoS considerations should be taken into account.
- The audio streams from the Unified MeetingPlace Media servers are marked EF (DSCP 0x2E), and the video streams are marked AF41 (DSCP 0x22) by default. These values are configurable from Unified MeetingPlace Administration.
- Web conferencing traffic is encrypted in SSL and is always marked best-effort (DSCP 0x00).
- The Unified MeetingPlace Meeting Director TSP component initiates dual outbound TCP port 443 connections to the WebEx Site and also provides SOCKS proxy server support.
- The Unified MeetingPlace WebEx Node for MCS or ASR initiates an outbound TCP port 443 connection to the WebEx Site but does not support any HTTPS proxy server. The WebEx Node for MCS or ASR must be allowed to connect directly to the WebEx Site without a proxy.

Cisco Unified Videoconferencing

As video is more widely deployed, meetings with video for the conference become more common. Cisco Multipoint Control Units (MCUs) are used for videoconferencing. Cisco Unified CM can enable IP phones and endpoints registered to it to use MCUs for videoconferencing. However, conferencing can also mean that users not only want to use voice and video conferencing but also want to have the ability to share desktop screens or applications on their desktops so as to enable collaboration.

Various solutions provide this functionality, and a Cisco Unified Videoconferencing solution provides the following key features:

- Audio conferences
- High resolution for video conferences
- Sharing of user desktops and applications using H.239 protocol
- Sharing of user desktops and applications with Web-based lightweight clients
- Conference control as moderator
- External participants from untrusted networks across firewalls and NAT

The Cisco Unified Videoconferencing collaboration solution consists of the following elements:

- Multipoint Control Unit (MCU)

The MCU is the conferencing device that receives the audio and video streams from IP phones or endpoints and mixes them to form the conference. The MCU uses its DSPs to perform this function. MCUs support various call signaling protocols such as Skinny Client Control Protocol (SCCP), H.323, or SIP. IP phones and endpoints use various signaling protocols to terminate calls at the MCU with the help of call control servers such as Unified CM.

- Cisco Unified Videoconferencing Manager

The Cisco Unified Videoconferencing Manager is a server that helps to manage the various video resources and MCUs in the enterprise. It provides the H.323 gatekeeper functionality. The Cisco Unified Videoconferencing Manager consists of two parts:

- Resource Manager

The Resource Manager manages resources such as Cisco MCUs, Cisco gatekeepers, H.320 gateways, terminals, and Cisco Unified Videoconferencing Desktop server connections. It also manages the meeting defaults on the MCU. The Cisco Unified Videoconferencing Manager provides the virtual MCU functionality that externally appears as a single MCU and internally uses cascading of the MCUs based on optimization criteria such as location, bandwidth, or delay to automatically manage the MCU ports and conferences. This provides optimum use of MCU ports that otherwise might be under-utilized by the organization. The Resource Manager also provides the scheduling intelligence so that resources like MCU ports can be reserved.

- Network Manager

The Network Manager manages the configuration of the various devices such as Cisco gatekeepers and endpoint terminals. It provides administrators with a tool to monitor device alarms and the status of calls or conferences.

- Cisco Unified Videoconferencing Desktop Server

The Cisco Unified Videoconferencing Desktop Server provides the functionality for Web-based users to participate in an H.323 video conference. The desktop clients communicate with the Desktop Server, and the Desktop Server communicates with the Cisco Unified Videoconferencing Manager for call signaling and with the MCU for the call and conference media. The Desktop Server provides interworking from the desktop client to H.239, and vice-versa. The Desktop Server also can stream conferences that can be viewed through Quicktime.

- Cisco Unified Videoconferencing Recording Server

The Cisco Unified Videoconferencing Recording Server records the meetings. It provides a mechanism for the enterprise to store and access recorded meetings. In a single screen view, the recordings capture the audio, video, and desktop or application sharing done during the meetings.

- H.239-based data sharing

H.323 endpoints support H.239 for data sharing. With this mechanism, endpoints use H.323 calls to add a media channel in addition to audio and video. This additional channel then is used by the endpoint to send data. Laptop or desktop screens connected to the endpoint then encode a VGA screen resolution, for example, into a video codec and send it over this data channel to be displayed at the far-end endpoint display. Unlike most conference collaboration methods, the desktop or application shared data is sent in a media channel that forms part of the video call.

Architecture

The central element in a videoconferencing design is the MCU, and it performs the actual conferencing. The MCU consists of a conference control block that interacts with a multipoint controller for signaling and a multipoint processor for audio and video mixing, as shown in [Figure 22-10](#).

Figure 22-10 Functional Components of an MCU

Conferences can be cascaded between MCUs. When participants are added to a conference but one MCU does not have the capacity for all of them, another MCU can be used to expand the conference. The two MCUs have a cascade link that enables the conference to be on both the MCUs, as shown in [Figure 22-11](#).

Figure 22-11 Cascaded MCU Conference

With H.323 endpoints, a separate gatekeeper device such as a Cisco IOS gatekeeper is needed so that H.323 endpoints can register to it. The Unified CM trunks can then provide the call routing based on the dial plan. Unified CM H.323 trunks can send conference calls to the gatekeeper, which in turn can route the calls to the Cisco Unified Videoconferencing Manager.

**Note**

SIP-based desktop sharing, similar to H.239, is supported by Binary Flow Control Protocol (BFCP). However, Cisco Unified Videoconferencing Manager and Unified Videoconferencing MCUs do not support BFCP, therefore Cisco does not recommend using Unified CM SIP trunks for integrating with Unified Videoconferencing Manager if data sharing capabilities are desired for conference collaboration.

The Unified Videoconferencing Manager is used to manage the MCUs and to provide call connectivity to desktop clients that use the Cisco Unified Videoconferencing Desktop server. [Figure 22-12](#) shows various components of a videoconferencing solution and how they connect with each other.

Figure 22-12 Cisco Unified Videoconferencing Solution

The MCU handles the media for the conference. With H.239, the endpoints send an additional media channel over which desktop or screen sharing can be sent into the conference and can be viewed by all participants on their endpoint screens. The Cisco Unified Videoconferencing Manager controls the MCU and the calls that are conferenced by the MCU. The MCUs can register to the internal gatekeeper in the Cisco Unified Videoconferencing Manager; this enables the Cisco Unified Videoconferencing Manager to closely control the MCU and the meetings on it.

The Cisco Unified Videoconferencing Manager has the enterprise user database. The users can be configured in the Cisco Unified Videoconferencing Manager or can be imported from the enterprise LDAP directory through LDAP integration. Users can then schedule their meetings through the scheduling functionality available in the Cisco Unified Videoconferencing Manager. Scheduling a meeting also reserves the MCU ports for the conference.

The Cisco Unified Videoconferencing Desktop server registers to the Cisco Unified Videoconferencing Manager gatekeeper as an H.323 endpoint. This enables the Desktop server to participate in the conferences on the MCU. When a desktop joins with the conference client, the desktop initiates a call to the MCU as a conference participant, thus enabling the desktop to participate in the call with desktop audio, video, and presentation sharing. While the desktop simulates an H.323 client to the MCU and the Cisco Unified Videoconferencing Manager, the desktop communicates over HTTP/HTTPS with the Desktop server. Every additional desktop adds another call into the MCU, thus using its port resources. The Desktop server in this case converts the HTTP/HTTPS connection from the desktop into an H.323 call to the MCU, with H.239 for the additional data channel.

Users can also use streaming with Real Time Streaming Protocol (RTSP) to participate in the conferences. Unlike the desktop, where users can participate with audio and video and can share their desktops, streaming provides users with the ability only to view the conference; they cannot participate in the conference or speak on the conference bridge. Streaming can be done through a common media player on the user's PC. Streaming of a conference causes the Desktop server to join the conference on the MCU, and it uses only a single MCU port regardless of the number of users listening into the streaming conference.

Integrating Unified Communications provides the enterprise with a way to bring together the videoconferencing network and the IP video telephony network. The Cisco Unified Videoconferencing Manager is an H.323 gatekeeper that can connect to Unified CM or other systems using H.323 trunks.

The gatekeeper supports Empty Capabilities Set (ECS) to service the supplementary services invoked by the Unified Communications endpoints. Connectivity to external networks can be done using Cisco Unified Border Element as the topology-hiding gateway between the two.

The Desktop server can also be the Recording server. Recording of the conference uses the conference moderator's desktop to record the desktop or application sharing as well as the audio and video for the conference.

Integrating Cisco Unified Videoconferencing with WebEx is also possible. Deployments that want to use standards-based video through the enterprise room conferencing systems or devices that can make H.323, SIP, or ISDN-based video calls will find this integration useful. Also, enterprises that wish to keep the audio and video conferencing within the enterprise network for WebEx conferences can use this integration.

The WebEx conference uses the cloud to provide the desktop and the data sharing capabilities, while the audio and video are handled by the MCU and the Cisco Unified Videoconferencing Desktop server, which provides the desktop client as the video panel in the WebEx conference.

For key design considerations and additional details on how to integrate the solution, refer to the latest version of the *Integration Note for Enabling Cisco Unified Videoconferencing Manager and Cisco WebEx*, available at

http://www.cisco.com/en/US/products/ps7088/prod_installation_guides_list.html

High Availability

Enterprise systems must be highly available, and in a videoconferencing solution, all components should be highly available.

For high availability of the Cisco IOS gatekeeper, you can use HSRP or gatekeeper clustering. The gatekeeper is a Cisco IOS router that runs the gatekeeper functionality, and endpoints register to this device.

Hot Standby Router Protocol (HSRP)

Cisco IOS routers support Hot Standby Router Protocol (HSRP), which provides a single virtual address for redundant devices. If the active device becomes unavailable, the standby device can take over the function. The two devices must have identical configurations. Endpoints reregister to the available gatekeeper and process calls.

For additional information on HSRP for gatekeepers, refer to *H.323 VoIP Gatekeeper for Cisco Access Platforms*, available at

<http://www.cisco.com/en/US/docs/routers/access/as5300/software/notes/0042gk.html>

Gatekeeper Update Protocol (GUP)

Multiple Cisco IOS gatekeepers can be clustered together into a large single cluster. Elements in the cluster then exchange information on the endpoint registrations and calls. This provides failover for registrations as well as for active calls. However, endpoints and trunks that register to the gatekeeper cluster must support alternate gatekeeper functionality.

Cisco Unified Videoconferencing Manager

The Cisco Unified Videoconferencing Manager supports high availability with the help of an additional identical server. The primary server's IP address is used by the standby device but remains inactive. The Cisco Unified Videoconferencing Manager uses a second network connection to synchronize the

databases with configuration and scheduling updates. If the primary server fails, the secondary server can be made active manually by enabling the services on it. The synchronization of the databases reduces the loss of scheduling and the overhead for restoring configurations.

Figure 22-13 shows the server with two networks: one for database replication that synchronizes the server database, and the other for enterprise connectivity.

Figure 22-13 Cisco Unified Videoconferencing Manager Redundancy

For additional details on high availability and redundancy, refer to the latest version of the *Configuration Guide for Cisco Unified Videoconferencing Manager*, available at

http://www.cisco.com/en/US/products/ps7088/products_installation_and_configuration_guides_list.html

MCU

To provide high availability for MCU devices, identical MCU ports must be made available. However, just providing for the MCU ports might not provide high availability for conference resources. The Virtual MCU provides the needed high availability because the Virtual MCU is managed by Cisco Unified Videoconferencing Manager. It automatically provides the needed ports for the conference, based on the available MCU capacities. If the MCUs have the service prefixes configured (service prefixes are used by the MCUs to convey the conference capabilities of the MCUs to Cisco Unified Videoconferencing Manager), then Cisco Unified Videoconferencing Manager extends the conference to the available MCUs in the event of MCU failures. Users on the failed MCU have to reconnect to join and participate in the conference again.

Cisco Unified Videoconferencing Desktop Server

The desktop server redundancy is provided by having separate servers. The servers are registered with the Cisco Unified Videoconferencing Manager running its gatekeeper. If a desktop server fails, users can be redirected to the next available desktop server. Because the conference is managed by the Cisco Unified Videoconferencing Manager and is on the MCU, existing users in the conference will have to

join again to continue the conference. Desktop sharing will have to be restarted because the desktop server does not support high availability for data sharing. Endpoints that were sharing their desktops using H.239 will experience no impact due to Cisco Unified Videoconferencing Desktop failures. Streaming conferences will have the same experience as desktop clients because they use the same server for both functions.

Cisco Unified Videoconferencing Recording Server

Support for high availability is not available with the recording server. If the desktop server is not available, recording cannot happen. If a secondary desktop server is used, recording can be done through this server if that functionality is enabled. However, to provide high availability for recorded conferences, Cisco recommends storing the recording on a highly available network storage device, accessible by the recording servers.

Capacity Planning

The gatekeeper supports a large number of endpoint registrations and calls. The Cisco Unified Communications Sizing Tool calculates gatekeeper capacity based on the gatekeeper platform. The sizing tool is available to Cisco partners and employees (with valid login authentication) at <http://tools.cisco.com/cust>.

For MCU capacities, refer to the product data sheets available at the following locations:

- http://www.cisco.com/en/US/products/ps10463/products_data_sheets_list.html
- http://www.cisco.com/en/US/products/hw/video/ps1870/products_data_sheets_list.html

Note

MCU cascading takes up one port per blade or device, as applicable.

For Cisco Unified Videoconferencing Manager capacities with regard to the number of MCU ports and other server capacities, refer to Cisco Unified Videoconferencing Manager data sheet available at

http://www.cisco.com/en/US/products/ps7088/products_data_sheets_list.html

Design Considerations

The following design considerations can help to build a good Cisco Unified Videoconferencing solution:

- The MCU is a key element, and the physical location of the MCU is a key design consideration. The MCUs should be at the locations with the most conferencing traffic. This optimizes the conference by keeping most of the media traffic within the same location, with only a few additional participants joining over the WAN from other locations. Central locations should have a pool of MCUs that can cascade conferences.
- Cisco Unified Videoconferencing Manager should be deployed with server redundancy. The server redundancy should have database synchronization enabled to minimize the time to switch over in the event of a failure.
- Use redundancy for Cisco IOS gatekeepers. HSRP should be used where endpoints need to reach a single IP address. Gatekeeper clustering should be used when endpoints support alternate gatekeeper with RAS, when load balancing between different gatekeeper devices is desired, and where the gatekeeper needs to maintain reservation and call information in spite of device failures.

- Use the virtual MCU capability of the Cisco Unified Videoconferencing Manager so that dynamic cascading can provide efficiency in WAN streams for conferences.
- The Desktop Server should be deployed close to the MCU to minimize delay of the conference media streams.
- Cisco Unified Videoconferencing Manager provides integrations with LDAP. Enterprises should use LDAP integration to maintain a single user list. However, any existing users in Cisco Unified Videoconferencing Manager prior to LDAP synchronization will have to be migrated to the LDAP directory to prevent any loss of user information. Cisco Unified Videoconferencing Manager has another list of application users and administrators that is maintained in addition to the enterprise LDAP users.
- Cisco Unified Videoconferencing Desktop supports H.235 for sessions with the MCU. The Cisco Unified Videoconferencing Desktop server should be enabled to support HTTPS sessions from the client to the server so that the session between the client and Desktop server is secure.
- Security devices such as firewalls should provide the needed pinholes if external users need access to the Desktop server or a Recording server
- Scheduling integrations, such as Outlook plug-ins or Lotus Notes integrations, should be leveraged to provide users with an integrated scheduling mechanism.
- Cisco Unified Border Element should be used when connecting external H.323 endpoints so they can call the enterprise video systems and join conferences.
- Consider the scalability of servers when multiple functionality, such as Cisco Unified Videoconferencing Manager, Desktop Server, and Recording Server, is provided by a single server.

CHAPTER 23

Cisco Unified Presence

Revised: July 31, 2012; OL-21733-18

Cisco Unified Presence consists of many components that enhance the value of a Cisco Unified Communications system. The main presence component of the solution is the Cisco Unified Presence server, which incorporates the Jabber Extensible Communications Platform and supports SIP/SIMPLE and Extensible Messaging and Presence Protocol (XMPP) for collecting information regarding a user's availability status and communications capabilities. The user's availability status indicates whether or not the user is actively using a particular communications device such as a phone. The user's communications capabilities indicate the types of communications that user is capable of using, such as video conferencing, web collaboration, instant messaging, or basic audio.

The aggregated user information captured by the Cisco Unified Presence server enables Cisco Unified Personal Communicator, Cisco Unified Communications Manager applications, and third-party applications to increase user productivity. These applications help connect colleagues more efficiently by determining the most effective form of communication.

This chapter explains the basic concepts of presence and instant messaging within the Cisco Unified Communications System and provides guidelines for how best to deploy the various components of the presence and instant messaging solution. Cisco Unified Presence must be deployed with Cisco Unified Communications Manager (Unified CM) 5.x or later releases; Cisco Unified CM 4.x and earlier releases do not support Cisco Unified Presence.

This chapter covers the following topics:

- [Presence, page 23-3](#)
- [Unified CM Presence, page 23-5](#)
- [Cisco Unified Presence Architecture, page 23-9](#)
- [Cisco Unified Presence Enterprise Instant Messaging, page 23-29](#)
- [Third-Party Presence Server Integration, page 23-41](#)

What's New in This Chapter

Table 23-1 lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Presence

Presence refers to the ability and willingness of a user to communicate across a set of devices. It involves the following phases or activities:

- Publish user status
User status changes can be published automatically by recognizing user keyboard activity, phone use, or device connectivity to the network.
- Collect this status
The published information is gathered from all the available sources, privacy policies are applied, and then current status is aggregated, synchronized, and stored for consumption.
- Consume the information
Desktop applications, calendar applications, and devices can use the user status information to provide real-time updates for the end users to make better communication decisions.

Status combines the capabilities of what the device or user can do (voice, video, instant messaging, web collaboration, and so forth) and the attributes showing the state of the device or user (available, busy, on a call, and so forth). Presence status can be derived from automatic events such as client login and telephone off-hook, or it can be derived from explicit notification events for changing status such as the user selecting Do Not Disturb from a change-status pick list.

Terminology surrounding presence refers to a watcher, presence entity (*presentity*), and presence server. The presence entity publishes its current status to the presence server by using a PUBLISH or REGISTER message for SIP/SIMPLE clients, or by using an XML Presence Stanza for XMPP clients. It can be a directory number (DN) or a SIP uniform resource identifier (URI) that resides within or outside the communications cluster. A *watcher* (device or user) requests presence status about a presence entity by sending a message to the presence server. The presence server responds to the watcher with a message containing the current status of the presence entity.

Cisco Unified Presence Components

Cisco Unified Presence encompasses the following components, illustrated in [Figure 23-1](#):

- Cisco Unified Presence server
- Cisco Unified Communications Manager (Unified CM)
- Cisco Unified Personal Communicator
- Cisco Unified MeetingPlace or MeetingPlace Express
- Cisco Unity or Unity Connection
- Cisco Unified Videoconferencing or Cisco Unified MeetingPlace Express VT
- Lightweight Directory Access Protocol (LDAP) Server v3.0
- Cisco Unified IP Phones
- Third-party presence server
- Third-party XMPP clients
- Third-party applications

Figure 23-1 Cisco Unified Presence Components

Cisco Unified Presence User

For presence, typically a user is described in terms of the user's presence status, the number of users on the system, or the user's presence capabilities.

As defined by Cisco Unified Presence, a user is specified in Cisco Unified CM by default as an *end user* and must be configured with a primary extension. The user is effectively tied to a directory number, and the presence status is reflected for the user's primary extension rather than for the device to which the user is associated. (See [Figure 23-2](#).)

A user, specified in Unified CM as an *end user*, can be configured with a primary extension or associated with a line appearance. When using the CUP PUBLISH Trunk service parameter on Unified CM, you must associate the user with a line appearance rather than just a primary extension. With the line appearance, the user is effectively tied to a line appearance (directory number associated with a particular device), which allows for a more detailed level of granularity for aggregation of presence information. The user can be mapped to multiple line appearances, and each line appearance can have multiple users (up to 5). Cisco recommends associating the end user with a line appearance. (See [Figure 23-2](#).)

Figure 23-2 Associating an End User with a Primary Extension or Line Appearance

The concept of a *presence user* appears throughout this chapter; therefore, keep in mind the meaning of a user as defined for Cisco Unified Presence.

Unified CM Presence

All telephony presence requests for users, whether inside or outside the cluster, are processed and handled by Cisco Unified CM.

A Unified CM watcher that sends a presence request will receive a direct response, including the presence status, if the watcher and presence entity are co-located within the Unified CM cluster.

If the presence entity exists outside the cluster, Unified CM will query the external presence entity through the SIP trunk. If the watcher has permission to monitor the external presence entity based on the SUBSCRIBE calling search space and presence group (both described in the section on [Unified CM Presence Policy, page 23-8](#)), the SIP trunk will forward the presence request to the external presence entity, await the presence response from the external presence entity, and return the current presence status to the watcher.

A watcher that is not in a Unified CM cluster can send a presence request to a SIP trunk. If Unified CM supports the presence entity, it will respond with the current presence status. If Unified CM does not support the presence entity, it will reject the presence request with a SIP error response.

Unified CM Presence with SIP

Unified CM uses the term *SIP line* to represent endpoints supporting SIP that are directly connected and registered to Unified CM and the term *SIP trunk* to represent trunks supporting SIP. SIP line-side endpoints acting as presence watchers can send a SIP SUBSCRIBE message to Unified CM requesting the presence status of the indicated presence entity.

If the presence entity resides within the Unified CM cluster, Unified CM responds to a SIP line-side presence request by sending a SIP NOTIFY message to the presence watcher, indicating the current status of the presence entity. (See Figure 23-3.)

Figure 23-3 SIP Line SUBSCRIBE/NOTIFY Exchange

If the presence entity resides outside the Unified CM cluster, Unified CM routes a SUBSCRIBE request out the appropriate SIP trunk, based on the SUBSCRIBE calling search space, presence group, and SIP route pattern. When Unified CM receives a SIP NOTIFY response on the trunk, indicating the presence entity status, it responds to the SIP line-side presence request by sending a SIP NOTIFY message to the presence watcher, indicating the current status of the presence entity. (See Figure 23-4.)

Figure 23-4 SIP Trunk SUBSCRIBE/NOTIFY Exchange

SUBSCRIBE messages for any directory number or SIP URI residing outside the Unified CM cluster are sent or received on a SIP trunk in Unified CM. The SIP trunk could be an interface to another Unified CM or it could be an interface to the Cisco Unified Presence server.

Unified CM Presence with SCCP

Unified CM supports Skinny Client Control Protocol (SCCP) line-side endpoints acting as presence watchers. There are no SCCP trunks. SCCP endpoints can request presence status of the indicated presence entity by sending SCCP messages to Unified CM.

If the presence entity resides within the Unified CM cluster, Unified CM responds to the SCCP line-side presence request by sending SCCP messages to the presence watcher, indicating the current status of the presence entity.

If the presence entity resides outside the Unified CM cluster, Unified CM routes a SUBSCRIBE request out the appropriate SIP trunk, based on the SUBSCRIBE calling search space, presence group, and SIP route pattern. When Unified CM receives a SIP NOTIFY response on the trunk, indicating the presence entity status, it responds to the SCCP line-side presence request by sending SCCP messages to the presence watcher, indicating the current status of the presence entity.

Unified CM Speed Dial Presence

Unified CM supports the ability for a speed dial to have presence capabilities by means of a busy lamp field (BLF) speed dial. BLF speed dials work as both a speed dial and a presence indicator. However, only the system administrator can configure a BLF speed dial; a system user is not allowed to configure a BLF speed dial.

The administrator must configure the BLF speed dial with a target directory number that is resolvable to a directory number within the Unified CM cluster or a SIP trunk destination. BLF SIP line-side endpoints can also be configured with a SIP URI for the BLF speed dial, but SCCP line-side endpoints cannot be configured with a SIP URI for BLF speed dial. The BLF speed dial indication is a line-level indication and not a device-level indication.

For a listing of the phone models that support BLF speed dials, consult the Cisco Unified IP Phone administration guides available on <http://www.cisco.com/>.

Figure 23-5 lists the various types of BLF speed dial indications from the phones.

Figure 23-5 Indicators for Speed Dial Presence

| State | Icon | LED |
|---------|---|--|
| Idle |  |  |
| Busy |  |  |
| Unknown |  |  |

190465

Unified CM Call History Presence

Unified CM supports presence capabilities for call history lists (the Directories button on the phone). Call history list presence capabilities are controlled via the **BLF for Call Lists** Enterprise Parameter within Unified CM Administration. The **BLF for Call Lists** Enterprise Parameter impacts all pages using the phone Directories button (Missed, Received, and Placed Calls, Personal Directory, or Corporate Directory), and it is set on a global basis.

For a listing of the phone models that support presence capabilities for call history lists, consult the Cisco Unified IP Phone administration guides available on <http://www.cisco.com/>.

The presence indicators for call history lists are the same as those listed in the Icon column in [Figure 23-5](#); however, no LED indications are available.

Unified CM Presence Policy

Unified CM provides the capability to set policy for users who request presence status. You can set this policy by configuring a calling search space specifically to route SIP SUBSCRIBE messages for presence status and by configuring presence groups with which users can be associated to specify rules for viewing the presence status of users associated with another group.

Unified CM Subscribe Calling Search Space

The first aspect of presence policy for Unified CM is the SUBSCRIBE calling search space. Unified CM uses the SUBSCRIBE calling search space to determine how to route presence requests (SUBSCRIBE messages with the Event field set to Presence) that come from the watcher, which could be a phone or a trunk. The SUBSCRIBE calling search space is associated with the watcher and lists the partitions that the watcher is allowed to "see." This mechanism provides an additional level of granularity for the presence SUBSCRIBE requests to be routed independently from the normal call-processing calling search space.

The SUBSCRIBE calling search space can be assigned on a device basis or on a user basis. The user setting applies for originating subscriptions when the user is logged in to the device through Extension Mobility or when the user is administratively assigned to the device.

With the SUBSCRIBE calling search space set to <None>, BLF speed dial and call history list presence status does not work and the subscription messages is rejected as "user unknown." When a valid SUBSCRIBE calling search space is specified, the indicators work and the SUBSCRIBE messages are accepted and routed properly.

**Note**

Cisco strongly recommends that you do not leave any calling search space defined as <None>. Leaving a calling search space set to <None> can introduce presence status or dialing plan behavior that is difficult to predict.

Unified CM Presence Groups

The second aspect of the presence policy for Unified CM is presence groups. Devices, directory numbers, and users can be assigned to a presence group, and by default all users are assigned to the Standard Presence Group. A presence group controls the destinations that a watcher can monitor, based on the user's association with their defined presence group (for example, Contractors watching

Executives is disallowed, but Executives watching Contractors is allowed). The presence group user setting applies for originating subscriptions when the user is logged in to the device via Extension Mobility or when the user is administratively assigned to the device.

When multiple presence groups are defined, the Inter-Presence Group Subscribe Policy service parameter is used. If one group has a relationship to another group via the Use System Default setting rather than being allowed or disallowed, this service parameter's value will take effect. If the Inter-Presence Group Subscribe Policy service parameter is set to **Disallowed**, Unified CM will block the request even if the SUBSCRIBE calling search space allows it. The Inter-Presence Group Subscribe Policy service parameter applies only for presence status with call history lists and is not used for BLF speed dials.

Presence groups can list all associated directory numbers, users, and devices if you enable dependency records. Dependency records allow the administrator to find specific information about group-level settings. However, use caution when enabling the Dependency Record Enterprise parameter because it could lead to high CPU usage.

Unified CM Presence Guidelines

Unified CM enables the system administrator to configure and control user phone state presence capabilities from within Unified CM Administration. Observe the following guidelines when configuring presence within Unified CM:

- Select the appropriate model of Cisco Unified IP Phones that have the ability to display user phone state presence status.
- Define a presence policy for presence users.
 - Use SUBSCRIBE calling search spaces to control the routing of a watcher presence-based SIP SUBSCRIBE message to the correct destinations.
 - Use presence groups to define sets of similar users and to define whether presence status updates of other user groups are allowed or disallowed.
- Call history list presence capabilities are enabled on a global basis; however, user status can be secured by using a presence policy.
- BLF speed dials are administratively controlled and are not impacted by the presence policy configuration.

Note

Cisco Business Edition can be used in ways similar to Unified CM to configure and control user presence capabilities. For more information, refer to the chapter on [Call Processing, page 8-1](#).

Cisco Unified Presence Architecture

The Cisco Unified Presence server uses standards-based SIP, SIP for Instant Messaging and Presence Leveraging Extensions (SIMPLE), and Extensible Messaging and Presence Protocol (XMPP) to provide a common demarcation point for integrating clients and applications into the Cisco Unified Communications System. Cisco Unified Presence also provides an HTTP interface that has a configuration interface through Simple Object Access Protocol (SOAP), a presence interface through Representational State Transfer (REST), and a presence, instant messaging, and roster interface through JabberWerx AJAX. The JabberWerx AJAX interface communicates to the Bidirectional-streams Over

Synchronous HTTP (BOSH) interface on the Extensible Communications Platform within Cisco Unified Presence. The Cisco Unified Presence server collects, aggregates, and distributes user capabilities and attributes using these standards-based SIP, SIMPLE, XMPP, and HTTP interfaces.

Cisco or third-party applications can integrate with presence and provide services that improve the end-user experience and efficiency. The core components of the Cisco Unified Presence server consist of: the Jabber Extensible Communications Platform (XCP), which handles presence, instant messaging, roster, routing, policy, and federation management; the Rich Presence Service, which handles presence state gathering, network-based rich presence composition, and presence-enabled routing functionality; and support for ad-hoc group chat storage with persistent chat and message archiving handled to an external database. If persistent chat is enabled, ad-hoc rooms are stored to the external PostgreSQL database for the duration of the ad-hoc chat. This allows a room owner to escalate an ad-hoc chat to a persistent chat; otherwise, these ad-hoc chats are purged from PostgreSQL at the end of the chat. If persistent chat is disabled, ad-hoc chats are stored in volatile memory for the duration of the chat.

Applications (either Cisco or third-party) can integrate presence and provide services that improve the end user experience and efficiency. By default, the Cisco Unified Presence server contains the IP Phone Messenger application to allow for instant messaging and presence status using Cisco Unified IP Phones. In addition, Cisco Unified Personal Communicator is a supported client of the Cisco Unified Presence server that also integrates instant messaging and presence status.

The Cisco Unified Presence server also contains support for interoperability with Microsoft Live Communications Server 2005, Microsoft Office Communications Server 2007, and the Microsoft Office Communicator client for any Cisco Unified IP Phone connected to a Unified CM. The Microsoft Office Communicator client interoperability includes click-to-dial functionality, phone control capability, and presence status of Cisco Unified IP Phones.

Cisco Unified Presence Cluster

The Cisco Unified Presence server uses the same underlying appliance model and hardware used by Unified CM as well as Unified CM on the Cisco Unified Computing System (UCS) platform, including a similar administration interface. For details on the supported platforms, refer to the *Cisco Unified Presence Server Administration Guide*, available at

http://www.cisco.com/en/US/products/ps6837/prod_maintenance_guides_list.html

A Cisco Unified Presence cluster consists of up to six servers, including one designated as a publisher, which utilize the same architectural concepts as the Unified CM publisher and subscriber. Within a Cisco Unified Presence cluster, individual servers can be grouped to form a subcluster, and the subcluster can have at most two servers associated with it. [Figure 23-6](#) shows the basic topology for a Cisco Unified Presence cluster, while [Figure 23-7](#) shows a highly available topology. The Cisco Unified Presence cluster can also have mixed subclusters, where one subcluster is configured with two servers while other subclusters contain a single server, as shown in [Figure 23-8](#). The Cisco Unified Presence servers form their own cluster and are not formally integrated as part of the Unified CM cluster.

Figure 23-6 Basic Deployment of Cisco Unified Presence

Figure 23-7 High Availability Deployment of Cisco Unified Presence

Figure 23-8 Mixed Deployment of Cisco Unified Presence

The Cisco Unified Presence publisher utilizes and builds upon the database used by the Unified CM publisher by sharing the user and device information. A Cisco Unified Presence cluster supports only a single Unified CM cluster; therefore, all users of Cisco Unified Presence must be defined within the same Unified CM cluster.

Intracluster traffic participates at a very low level between Cisco Unified Presence and Unified CM and between the Cisco Unified Presence publisher and subscriber servers. Both clusters share a common hosts file and have a strong trust relationship using IPTables. At the level of the database and services, the clusters are separate and distinct, and each Cisco Unified Presence server and Unified CM cluster requires separate administration. There is currently no Transport Layer Security (TLS) or IPsec utilization for intracluster traffic.

The Cisco Unified Presence server interface with external systems sends SIP and XMPP traffic over UDP, TCP, or TLS. TLS mutual authentication requires the import and export of certificates between Cisco Unified Presence server and the external system. TLS server authentication (Cisco Unified Presence server presenting its TLS certificate to the client device for verification) validates the end user via digest authentication.

The Cisco Unified Presence publisher communicates directly with the Unified CM publisher via the AVVID XML Layer Application Program Interface (AXL API) using the Simple Object Access Protocol (SOAP) interface. When first configured, the Cisco Unified Presence publisher performs an initial synchronization of the entire Unified CM user and device database. All Cisco Unified Presence users are configured in the Unified CM End User configuration. During the synchronization, Cisco Unified Presence populates these users in its database from the Unified CM database and does not provide end-user configuration from its administration interface.

The initial Cisco Unified Presence database synchronization from Unified CM might take a while, depending on the amount of information in the database as well as the load that is currently on the system. Subsequent database synchronizations from Unified CM to Cisco Unified Presence are performed in real time when any new user or device information is added to Unified CM. For planning purposes, use the values in [Table 23-2](#) as guidelines when executing the initial database synchronization with Unified CM using a single Cisco Unified Presence publisher.

**Note**

Cisco Unified Presence supports synchronization of up to 160,000 users, equivalent to Unified CM. However, the maximum number of licensed presence users for a Cisco Unified Presence cluster is 45,000 in full Unified Communications mode and 75,000 in IM-only mode.

Table 23-2 Synchronization Times for a Cisco Unified Presence Publisher

| Server Platform | Number of Users | Synchronization Time |
|-----------------|-----------------|----------------------|
| Cisco MCS 7816 | 500 | 5 minutes |
| Cisco MCS 7825 | 1,000 | 5 minutes |
| Cisco MCS 7835 | 1,000 | 5 minutes |
| | 10,000 | 25 minutes |
| Cisco MCS 7845 | 1,000 | 5 minutes |
| | 10,000 | 20 minutes |
| | 30,000 | 70 minutes |

**Note**

The numbers for the Cisco Unified Computing System (UCS) platform are equivalent to those for the MCS 7835 (2 vCPU, 4 GB RAM, 80 GB drive, 1 vNIC) and MCS 7845 (4 vCPU, 4 GB RAM, two 80 GB drives, 1 vNIC).

For planning purposes, use the values in [Table 23-3](#) as guidelines when executing the initial database synchronization with Unified CM using a Cisco Unified Presence publisher and subscriber servers:

Table 23-3 Synchronization Times for a Cisco Unified Presence Publisher and Subscriber Servers

| Server Platform | Number of Users | Synchronization Time |
|-----------------|-----------------|----------------------|
| Cisco MCS 7816 | 500 | 5 minutes |
| Cisco MCS 7825 | 1,000 | 10 minutes |
| Cisco MCS 7835 | 1,000 | 10 minutes |
| | 10,000 | 50 minutes |
| Cisco MCS 7845 | 1,000 | 10 minutes |
| | 10,000 | 40 minutes |
| | 30,000 | 140 minutes |

**Note**

When the Cisco Unified Presence server is performing the initial database synchronization from Unified CM, do not perform any administrative activities on Unified CM while the synchronization agent is active.

If the database entries are not updating or if the Sync Agent service is stopped, you can check for broken connections with the synchronization agent by using the Real-Time Monitoring Tool (RTMT) to monitor the Critical Alarm **Cisco Unified Presence ServerSyncAgentAXLConnectionFailed**.

Cisco Unified Presence Server High Availability

Unified CM provides a choice of the following optional redundancy configurations:

- Two to one (2:1) — For every two primary subscribers, there is one shared backup subscriber.
- One to one (1:1) — For every primary subscriber, there is a backup subscriber.

For more information on Unified CM redundancy, see the chapter on [Call Processing, page 8-1](#).

The Cisco Unified Presence cluster consists of up to six servers, which can be configured into multiple subclusters, with a maximum of three subclusters for high availability. A subcluster contains a maximum of two servers and allows for users associated with one server of the subcluster to use the other server in the subcluster automatically if a failover event occurs. Cisco Unified Presence does not provide failover between subclusters.

When deploying a Cisco Unified Presence cluster for high availability, you must take into consideration the maximum number of users per server to avoid oversubscribing any one server within the subcluster in the event of a failover. When deploying a Cisco Unified Presence cluster, use equivalent hardware for all servers within the cluster.

Cisco Unified Presence Deployment Models

Unified CM provides a choice of the following deployment models:

- Single site
- Multisite WAN with centralized call processing
- Multisite WAN with distributed call processing
- Clustering over the WAN

Cisco Unified Presence is supported with all the Unified CM deployment models. However, Cisco recommends co-locating the Cisco Unified Presence publisher with the Unified CM publisher due to the initial user database synchronization. All Cisco Unified Presence servers should be co-located within the Cisco Unified Presence cluster, with the following exceptions:

- Geographic datacenter redundancy and clustering over the WAN

For details, see [Clustering Over the WAN, page 23-22](#).

- Cisco Unified Customer Voice Portal (Unified CVP)

A Cisco Unified Presence cluster can be deployed with a maximum of two servers forming a single subcluster between two sites (one server in each site) for SIP Proxy functionality only (no presence functionality), as required by the Cisco Unified Customer Voice Portal deployment. This deployment must have a minimum bandwidth of 5 Mbps (primarily for installation and configuration) and a maximum latency of 80 ms round-trip time (RTT). For more information on Unified CVP, refer to the *Cisco Unified Customer Voice Portal SRND*, available at <http://www.cisco.com/go/ucsrnd>.

For more information on Unified CM deployment models, see the chapter on [Unified Communications Deployment Models, page 5-1](#).

Cisco Unified Presence deployment depends on high-availability requirements, the total number of users, and the server hardware being used. Cisco recommends using similar hardware for each server in the Cisco Unified Presence cluster. Detailed configuration and deployment steps can be found in the *Deployment Guide for Cisco Unified Presence*, available at

http://www.cisco.com/en/US/products/ps6837/products_installation_and_configuration_guides_list.html

A highly available Cisco Unified Presence cluster requires two servers per subcluster. This allows for users to fail-over between the servers within the subcluster; however, the total number of users supported and the time to failover vary based on which features are enabled, the average size of contact lists, and the rate of traffic placed on the servers. Once a Cisco Unified Presence subcluster is configured for two servers, it always operates as highly available. High availability can be deployed using an Active/Standby model or an Active/Active model, and these modes are controlled by the Sync Agent service parameter User Assignment Mode. By default all users are balanced across all servers in the cluster, and Cisco recommends leaving this parameter set to its default value.

Cisco Unified Presence Active/Standby mode (setting User Assignment Mode to **None**) is attained by manually assigning users to the first server in the subcluster, leaving the second server with no users assigned but all processes synchronized and ready for a failover if the first server in the subcluster fails. For example, in [Figure 23-7](#) the first user would be assigned to server 1A, the second user to server 2A, the third user to server 3A, the fourth user to server 1A, the fifth user to server 2A, the sixth user to server 3A, and so forth. The users should be assigned equally across all the 'A' servers in the cluster.

Cisco Unified Presence Active/Active mode (setting User Assignment Mode to **balanced**) will automatically assign users equally across all servers in the subclusters. Each server is synchronized and ready for a failover if the other server in the subcluster fails. For example, in [Figure 23-7](#) the first user

would be assigned to server 1A, the second user to server 2A, the third user to server 3A, the fourth user to server 1B, the fifth user to server 2B, the sixth user to server 3B, and so forth. The users are assigned equally across all the servers in the cluster.

Cisco Unified Presence Active/Active deployments with a balanced User Assignment Mode allows for redundancy flexibility based on the features being used, the size of user contact lists, and the traffic (user data profiles) being generated. A Cisco Unified Presence Active/Active deployment with a fully redundant mode, regardless of features, requires the total number of supported users to be reduced in half (for example, Cisco MCS 7845 servers in a balanced high-availability redundant deployment support up to 5,000 users per subcluster). A Cisco Unified Presence Active/Active deployment with a non-redundant mode requires a more detailed look at the Cisco Unified Presence features being utilized, the average size of the users contact lists, as well as the traffic being generated. For example, for a deployment with presence and instant messaging enabled and calendaring and mobility integration disabled, with an average contact list of 30 users and a user data profile of a few presence and instant message updates, it is possible to support more than 5,000 users per subcluster (if using Cisco MCS 7845 servers).

A Cisco Unified Presence cluster deployment that is not highly available allows for each server in the subcluster to support up to the maximum number of users. Once a second server is added in a subcluster, the subcluster will still act as if in a high-available deployment; however, if a server failure occurs, an attempt to fail-over might not result in success if the online server reaches its capacity limit based on the Cisco Unified Presence features enabled, the average user contact list size, and the traffic being generated by the users.

Cisco Unified Presence Deployment Examples

Example 23-1 Single Unified CM Cluster with Cisco Unified Presence

Deployment requirements:

- 4,000 users that could scale to 13,000 users
- Single Cisco Unified Communications Manager cluster
- Instant message logging and compliance are not needed
- High availability is not needed

Hardware:

- Cisco MCS 7845 servers

Deployment:

- One single-server subcluster using User Assignment Mode = balanced

Example 23-2 Two Unified CM Clusters with Cisco Unified Presence

Deployment requirements:

- 11,000 users that could scale to 24,000 users
- Two Cisco Unified Communications Manager clusters
- Instant message logging and compliance are not needed
- High availability is not needed

Hardware:

- Cisco MCS 7845 servers

Deployment:

- Two Cisco Unified Presence clusters (one per Cisco Unified Communications Manager cluster), each with one server using User Assignment Mode = balanced

Example 23-3 Single Unified CM Cluster with Cisco Unified Presence

Deployment requirements:

- 500 users that could scale to 2500 users
- Single Cisco Unified Communications Manager cluster
- Instant message archiving is required
- High availability is required

Hardware:

- Cisco MCS 7835 servers

Deployment:

- One two-server subcluster using User Assignment Mode set to **balanced**, with a PostgreSQL database instance for the cluster

Example 23-4 Single Cisco Business Edition Cluster with Cisco Unified Presence

Deployment requirements:

- 100 users that could scale to 500 users
- Single Cisco Business Edition
- Instant message archiving and persistent chat are required
- High availability is required

Hardware:

- Cisco MCS 7825 servers

Deployment:

- One two-server subcluster using User Assignment Mode set to **balanced**, with a unique PostgreSQL database instance per server in the cluster for persistent chat functionality

Example 23-5 Multiple Unified CM Clusters with Cisco Unified Presence

Deployment requirements:

- 5,000 users that could scale to 40,000 users
- Multiple Cisco Unified Communications Manager clusters
- Instant message compliance is required
- High availability is required

Hardware:

- Cisco MCS 7845 servers

Deployment:

- Multiple Cisco Unified Presence clusters must be set up with intercluster peers between each. Start with a single two-server subcluster, with up to 15,000 users for each Cisco Unified Presence cluster, before adding more subclusters within existing Cisco Unified Presence clusters. With a large

number of users within a single Cisco Unified Presence cluster, set the User Assignment Mode service parameter to **balanced**. Set up a third-party compliance server for instant messaging compliance for each server in each Cisco Unified Presence cluster.

Cisco Unified Presence Deployment for Instant Messaging Only

A Cisco Unified Presence cluster (or clusters) can be deployed to provide enterprise-class presence and instant messaging in an environment where Unified CM is not deployed for call control for specific users. Unified CM is still required to establish user accounts entered either manually or through LDAP synchronization. A Cisco Unified Presence instant messaging only deployment synchronizes user information from Unified CM in the same way as is done with a full Unified Communications deployment. If Unified CM is not deployed or if the existing deployed Unified CM will not be used for instant messaging only, a Cisco MCS 7816 Media Convergence Server with preloaded Unified CM software is provided as an option.

For existing Cisco Unified Presence deployments where a Unified CM cluster is already deployed, users can also be added for use with the instant messaging only mode. This allows for a mix of full Unified Communications users in addition to instant messaging only users, in accordance with the end-user license agreement.

Cisco Unified Presence Server Performance

Cisco Unified Presence server clusters support single-server as well as multi-server configurations. However, if multiple servers are used, each server must be on the same type of server platform as the publisher server.

Table 23-4 lists the hardware platform requirements for the Cisco Unified Presence server as well as the maximum number of users supported per platform. The maximum number of users supported for a Cisco Unified Presence cluster is based on the hardware being used in the deployment. For example, if a Cisco Unified Presence cluster is deployed with three Cisco MCS 7825 servers, each forming their own subcluster, a total of 3,000 users would be supported. The maximum number supported for a Cisco Unified Presence cluster is 15,000 users.

Table 23-4 Cisco Unified Presence Server Platforms and Number of Users Supported

| Server Platform | Users Supported Per Platform in Full Unified Communications Mode | Users Supported Per Platform in Instant Messaging Only Mode |
|----------------------------------|--|---|
| Cisco MCS 7816 | 3,000 | 7,500 |
| Cisco MCS 7825 | 6,000 | 15,000 |
| Cisco MCS 7835 or OVA equivalent | 15,000 | 37,500 |
| Cisco MCS 7845 or OVA equivalent | 45,000 | 75,000 |

For additional hardware specifications, refer to the Media Convergence Server documentation available at

http://www.cisco.com/en/US/products/hw/voiceapp/ps378/prod_models_home.html

Cisco Unified Presence Licensing

User presence capabilities are assigned from Unified CM Administration under the licensing capabilities assignment. Users are licensed for presence capabilities from Unified CM, therefore Cisco Unified Presence requires integration with Cisco Unified CM.

There are two check boxes, one for Unified Presence and one for Unified Personal Communicator. To enable the user to send and receive presence messaging updates, the Unified Presence checkbox must be enabled for that user. If the user is not enabled for Unified Presence, no presence messaging or status updates will be allowed for that user. To enable the use of Cisco Unified Personal Communicator, the Unified Personal Communicator checkbox must be enabled for the user.

For complete information regarding licensing on Unified CM, refer to the latest version of the *Cisco Unified Communications Manager Administration Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

Unified CM provides the ability to use adjunct licensing for a presence user who is using multiple devices. This feature allows the presence user, who is already using a Cisco Unified IP Phone, to share a Cisco Unified Personal Communicator or Cisco IP Communicator. The adjunct licensing is enabled via configuration on Unified CM, under the Primary Phone option for Cisco Unified Personal Communicator. When a primary phone is associated with Cisco Unified Personal Communicator, then the adjunct licensing is enabled and reflected in the License Unit Calculator.

Cisco Unified Presence Deployment

Cisco Unified Presence can be deployed in any of the following configurations:

- [Single-Cluster Deployment, page 23-18](#)
- [Multi-Cluster Deployment, page 23-21](#)
- [Clustering Over the WAN, page 23-22](#)
- [Federated Deployment, page 23-23](#)
- [Instant Messaging Only Deployment, page 23-27](#)

Single-Cluster Deployment

[Figure 23-9](#) represents the communication protocols between Cisco Unified Presence, the LDAP server, and Cisco Unified Communications Manager for basic functionality. For complete information on Cisco Unified Presence administration and configuration, refer to the Cisco Unified Presence installation, administration, and configuration guides, available at

http://www.cisco.com/en/US/products/ps6837/tsd_products_support_series_home.html

Figure 23-9 Interactions Between Cisco Unified Presence Components

Figure 23-9 depicts the following interactions between Cisco Unified Presence components:

1. The SIP connection between the Cisco Unified Presence server and Unified CM handles all the phone state presence information exchange.
 - a. Unified CM configuration requires the Cisco Unified Presence servers to be added as application servers on Unified CM and also requires a SIP trunk pointing to the Cisco Unified Presence server. The address configured on the SIP trunk could be a Domain Name System (DNS) server (SRV) fully qualified domain name (FQDN) that resolves to the Cisco Unified Presence servers, or it could simply be an IP address of an individual Cisco Unified Presence server. Cisco Unified Presence 7.0(3) and later releases handle the configuration of the Cisco Unified Communications Manager application server entry automatically through AXL/SOAP once the administrator adds a node in the system topology page through Cisco Unified Presence administration.
 - b. Configuration of Cisco Unified Presence occurs through the Unified CM Presence Gateway for presence information exchange with Unified CM. The following information is configured:
Presence Gateway: *server_fqdn:5070*

Note The *server_fqdn* could be the FQDN of the Unified CM publisher, a DNS SRV FQDN that resolves to the Unified CM subscriber servers, or an IP address.

If DNS is highly available within your network and DNS SRV is an option, configure the SIP trunk on Unified CM with a DNS SRV FQDN of the Cisco Unified Presence publisher and subscriber. Also configure the Presence Gateway on the Cisco Unified Presence server with a DNS SRV FQDN of the Unified CM subscribers, equally weighted. This configuration will allow for presence messaging to be shared equally among all the servers used for presence information exchange.

If DNS is not highly available or not a viable option within your network, use IP addressing. When using an IP address, presence messaging traffic cannot be equally shared across multiple Unified CM subscribers because it points to a single subscriber.

Unified CM provides the ability to further streamline communications and reduce bandwidth utilization by means of the service parameter CUP PUBLISH Trunk, which allows for the PUBLISH method (rather than SUBSCRIBE/NOTIFY) to be configured and used on the SIP trunk interface to Cisco Unified Presence. Once the CUP PUBLISH Trunk service parameter has been enabled, the users must be associated with a line appearance and not just a primary extension.

2. The Computer Telephony Integration Quick Buffer Encoding (CTI-QBE) connection between Cisco Unified Presence and Unified CM is the protocol used by presence-enabled users in Cisco Unified Presence to control their associated phones registered to Unified CM. This CTI communication occurs when Cisco Unified Personal Communicator is using Desk Phone mode to do Click to Call or when Microsoft Office Communicator is doing Click to Call through Microsoft Live Communications Server 2005 or Office Communications Server 2007.

- a. Unified CM configuration requires the user to be associated with a CTI Enabled Group, and the primary extension assigned to that user must be enabled for CTI control (checkbox on the Directory Number page). The CTI Manager Service must also be activated on each of the Unified CM subscribers used for communication with the Cisco Unified Presence publisher and subscriber. Integration with Microsoft Live Communications Server 2005 or Office Communications Server 2007 requires that you configure an Application User, with CTI Enabled Group and Role, on Unified CM.
- b. Cisco Unified Presence CTI configuration (CTI Server and Profile) for use with Cisco Unified Personal Communicator is automatically created during the database synchronization with Unified CM. All Cisco Unified Personal Communicator CTI communication occurs directly with Unified CM and not through the Cisco Unified Presence server.

Cisco Unified Presence CTI configuration (Desktop Control Gateway) for use with Microsoft Live Communications Server 2005 or Office Communications Server 2007 requires you to set the Desktop Control Gateway address (Cisco Unified Communications Manager Address) and a provider, which is the application user configured previously in Unified CM. Up to eight Cisco Unified Communications Manager Addresses can be provisioned for increased scalability. Only IP addresses can be used for Desktop Control Gateway configuration in the Cisco Unified Presence server.

3. The AXL/SOAP interface handles the database synchronization from Unified CM to populate the Cisco Unified Presence database.
 - a. No additional configuration is required on Unified CM.
 - b. Cisco Unified Presence security configuration requires you to set a user and password for the Unified CM AXL account in the AXL configuration.

The Sync Agent Service Parameter, User Assignment, set to **balanced** by default, will load-balance all users equally across all servers within the Cisco Unified Presence cluster. The administrator can also manually assign users to a particular server in the Cisco Unified Presence cluster by changing the User Assignment service parameter to **None**.

4. The LDAP interface is used for LDAP authentication of Cisco Unified Personal Communicator users during login. For more information regarding LDAP synchronization and authentication, see the chapter on [LDAP Directory Integration, page 16-1](#).

Unified CM is responsible for all user entries via manual configuration or synchronization directly from LDAP, and Cisco Unified Presence then synchronizes all the user information from Unified CM. If a Cisco Unified Personal Communicator user logs into the Cisco Unified Presence server and LDAP authentication is enabled on Unified CM, Cisco Unified Presence will go directly to LDAP for the Cisco Unified Personal Communicator user authentication using the Bind operation. Once Cisco Unified Personal Communicator is authenticated, Cisco Unified Presence forwards the information to Cisco Unified Personal Communicator to continue login.

When using Microsoft Active Directory, consider the choice of parameters carefully. Performance of Cisco Unified Presence might be unacceptable when a large Active Directory implementation exists and the configuration uses a Domain Controller. To improve the response time of Active Directory, it might be necessary to promote the Domain Controller to a Global Catalog and configure the LDAP port as 3268.

Multi-Cluster Deployment

The deployment topology in previous sections is for a single Cisco Unified Presence cluster communicating with a single Unified CM cluster. Presence and instant messaging functionality is limited by having communications within a single cluster only. Therefore, to extend presence and instant messaging capability and functionality, these standalone clusters can be configured for peer relationships for communication between clusters within the same domain. Figure 23-10 represents the peer relationship between Cisco Unified Presence clusters when interconnecting multiple clusters or sites. This functionality provides the ability for users in one cluster to communicate and subscribe to the presence of users in a different cluster within the same domain.

Figure 23-10 Multi-Cluster Deployment of Cisco Unified Presence

Note

Cisco Unified Presence 8.6 intercluster peer functionality is supported only with other Cisco Unified Presence 8.6 clusters as well as Cisco Unified Presence 7.x clusters. Cisco Unified Presence 8.6 clusters do not support intercluster peers with Cisco Unified Presence 8.5 or 8.0 clusters.

253860

To create a fully meshed presence topology, each Cisco Unified Presence cluster requires a separate peer relationship for each of the other Cisco Unified Presence clusters within the same domain. The address configured in this intercluster peer could be a DNS SRV FQDN that resolves to the remote Cisco Unified Presence cluster servers, or it could also simply be the IP address of the Cisco Unified Presence cluster servers.

The interface between each Cisco Unified Presence cluster is two-fold, an AXL/SOAP interface and a signaling protocol interface (SIP or XMPP). The AXL/SOAP interface handles the synchronization of user information for home cluster association, but it is not a full user synchronization. The signaling protocol interface (SIP or XMPP) handles the subscription and notification traffic, and it rewrites the host portion of the URI before forwarding if the user is detected to be on a remote Cisco Unified Presence cluster within the same domain.

When Cisco Unified Presence is deployed in a multi-cluster environment, a presence user profile should be determined. The presence user profile helps determine the scale and performance of a multi-cluster presence deployment and the number of users that can be supported. The presence user profile helps establish the number of contacts (or buddies) a typical user has, as well as whether those contacts are mostly local cluster users or users of remote clusters.

The traffic generated between Cisco Unified Presence clusters is directly proportional to the characteristics of the presence user profile. For example, assume presence user profile A has 30 contacts with 20% of the users on a local Cisco Unified Presence cluster and 80% of the users on a remote Cisco Unified Presence cluster, while presence user profile B has 30 contacts with 50% of the users on a local Cisco Unified Presence cluster and 50% of the users on a remote Cisco Unified Presence cluster. In this case, presence user profile B will provide for slightly better network performance and less bandwidth utilization due to a smaller amount of remote cluster traffic.

Clustering Over the WAN

A Cisco Unified Presence cluster can be deployed with one of the nodes of a subcluster deployed across the Wide Area Network (WAN). This allows for geographic redundancy of a subcluster and high availability for the users between the nodes across the sites. The following guidelines must be used when planning for a Cisco Unified Presence deployment with clustering over the WAN.

- Geographic datacenter redundancy and remote failover

A Cisco Unified Presence cluster can be deployed between two sites with a single subcluster topology, where one server of the subcluster is in one geographic site and the other server of the subcluster is in another site. This deployment must have a minimum bandwidth of 5 Mbps, a maximum latency of 80 ms round-trip time (RTT), and TCP method event routing.

- High availability and scale

Cisco Unified Presence high availability allows for users on one node within a subcluster to automatically fail-over to the other node within the subcluster. With a Cisco Unified Presence subcluster containing a maximum of two nodes, remote failover is essentially between two sites, one site for each node. A scalable highly available capacity for a Cisco Unified Presence cluster is up to three subclusters; therefore, a scalable highly available remote failover topology would consist of the following two sites:

- Site A: Subcluster 1 node A, subcluster 2 node A, and subcluster 3 node A
- Site B: Subcluster 1 node B, subcluster 2 node B, and subcluster 3 node B

This deployment must have a minimum bandwidth of 5 Mbps per subcluster, a maximum latency of 80 ms round-trip time (RTT), and TCP method event routing. Each new subcluster added to the deployment requires an additional 5 Mbps of dedicated bandwidth to handle the database and state replication.

- Local Failover

A Cisco Unified Presence cluster deployment between two sites may also contain a subcluster topology per site (single node or dual node for high availability), where one subcluster is in one geographic site and the other subcluster is in another geographic site. This topology allows for the users to remain at their local site (highly available or not) without the requirement or need to fail-over to a different site or location. This deployment must have a minimum bandwidth of 5 Mbps dedicated bandwidth between each subcluster in the respective sites, a maximum latency of 80 ms round-trip time (RTT), and TCP method event routing.

- Bandwidth and latency considerations

With a Cisco Unified Presence cluster that has a topology of nodes split across a WAN, the number of contacts within a user's client can impact the bandwidth needs and criteria for the deployment. The traffic generated within and between Cisco Unified Presence clusters is directly proportional to the characteristics of the presence user profile, and thus the amount of bandwidth required for deployment. Cisco recommends 25% or fewer remote contacts for a client in environments where the bandwidth is low (10 Mbps or less), and at all times the maximum round-trip latency must be 80 ms or less.

- Persistent Chat and Compliance logging considerations

When Cisco Unified Presence is enabled for persistent chat, message archiving, or compliance logging and a subcluster is split across a WAN, the external database server(s) must reside on the same side of the WAN as the Cisco Unified Presence servers that use them. With the ability to support multiple database instances on a single server and the requirement for an external database server to reside on the same side of the WAN, if a Cisco Unified Presence cluster is split across a WAN, then two external database servers will be required.

Federated Deployment

Cisco Unified Presence allows for business-to-business communications by enabling inter-domain federation, which provides the ability to share presence and instant messaging communications between different domains. Inter-domain federation requires two explicit DNS domains to be configured, as well as a security appliance (Cisco Adaptive Security Appliance) in the DMZ to terminate federated connections with the enterprise. If all the federated domains are within the same trust boundary, where a deployment has all components within a single datacenter, then the use of the Adaptive Security Appliance is not required. For information on inter-domain federation, refer to the *Integration Guide for Configuring Cisco Unified Presence Interdomain Federation*, available at

http://www.cisco.com/en/US/products/ps6837/products_installation_and_configuration_guides_list.html

Figure 23-11 shows the basic inter-domain federation deployment between two different domains, indicated by Domain A and Domain B. The Adaptive Security Appliance (ASA) in the DMZ is used as a demarcation into the enterprise. XMPP traffic is passed through, whereas SIP traffic is inspected. All federated incoming and outgoing traffic is routed through the Cisco Unified Presence server that is enabled as a federation node, and is routed internally to the appropriate server in the cluster where the user resides. For multi-cluster deployments, intercluster peers propagate the traffic to the appropriate home cluster within the domain. Multiple nodes can be enabled as federation nodes within large enterprise deployments, where each request is routed based on a round-robin implementation of the data returned from the DNS SRV lookup.

Figure 23-11 Cisco Unified Presence XMPP Federation (Inter-Domain)

Cisco Unified Presence also provides configuration through SIP to allow for inter-domain federation with Microsoft and AOL, as depicted in [Figure 23-12](#). Cisco Unified Presence inter-domain federation with Microsoft Lync Server, Office Communications Server (OCS), and Live Communications Server (LCS) provides basic presence (available, away, busy, offline) and point-to-point instant messaging. Rich presence capability (On the Phone, In a Meeting, On Vacation, and so forth), as well as advanced instant messaging features, are not supported. Cisco Unified Presence inter-domain federation with AOL allows federation with users of AOL public communities (aim.com, aol.com), with users of domains hosted by AOL, and with users of a far-end enterprise that federates with AOL (that is, AOL is being used as a clearing house).

**Note**

A SIP federation (inter-domain to AOL) on Cisco Unified Presence must be configured for each domain of the AOL network, which can consist of both hosted networks and public communities. Each unique hosted domain must be configured; however, only a single aol.com public community needs to be configured because the AOL network allows a user to be addressed as user@aol.com or user@aim.com

The inter-domain federation configuration also allows for a specific federation between Cisco Unified Presence and Microsoft Office Communications Server (OCS), as depicted in [Figure 23-12](#). Cisco Unified Presence provides inter-domain federation with Microsoft Office Communications Server (OCS) or Live Communications Server (LCS) to provide basic presence (available, away, busy, offline) and point-to-point instant messaging. Rich presence capability (On the Phone, In a Meeting, On Vacation, and so forth), as well as advanced instant messaging features, are not supported.

Figure 23-12 Cisco Unified Presence SIP Federation (Inter-Domain)

Table 23-5 lists the state mappings between Cisco Unified Presence and Microsoft Office Communications Server.

Table 23-5 Mapping of Presence States

| Cisco Status | Cisco Color | Status to Microsoft Office Communications Server | Status to AOL |
|---------------------|-------------|--|---------------|
| Out of office | RED | Away | Away |
| Do not disturb | RED | Busy | Away |
| Busy | RED | Busy | Away |
| On the phone | YELLOW | Busy | Away |
| In a meeting | YELLOW | Busy | Away |
| Idle on all clients | YELLOW | Away | Away |
| Available | GREEN | Available | Available |
| Unavailable/offline | GREY | Offline | Offline |

**Note**

Cisco Unified Presence must publish a DNS SRV record (SIP, XMPP, and each text conferencing node) for the domain to allow for other domains to discover the Cisco Unified Presence servers through DNS SRV. With a Microsoft Office Communications Server or Live Communications Server deployment, this is required because Cisco Unified Presence is configured as a Public IM Provider on the Access Edge server. If the Cisco Unified Presence server cannot discover the Microsoft domain using DNS SRV, you must configure a static route on Cisco Unified Presence for the external domain.

The Cisco Unified Presence federation deployment can be configured with redundancy using a load balancer between the Adaptive Security Appliance and the Cisco Unified Presence server, or redundancy can also be achieved with a redundant Adaptive Security Appliance configuration.

Additional configuration and deployment considerations regarding a federated deployment can be found in the latest version of the *Integration Guide for Configuring Cisco Unified Presence for Interdomain Federation*, available at

http://www.cisco.com/en/US/products/ps6837/products_installation_and_configuration_guides_list.html

An intra-domain partitioned federated deployment, shown in [Figure 23-13](#), is a secondary option that allows for Cisco Unified Presence and Microsoft Live Communications Server 2005 or Office Communications Server 2007 R2 to federate presence and instant messaging within the same presence domain. The users are partitioned across both deployments, within the single presence domain, and are licensed either on Cisco Unified Presence or on the Microsoft Live Communications Server or Office Communications Server. The user cannot be licensed on both the Cisco and Microsoft platforms at the same time.

Figure 23-13 Cisco Unified Presence Intra-Domain Federation

**Note**

Microsoft Office Communications Server 2007 R1 is not supported in an intra-domain partitioned federated deployment.

The partitioned intra-domain federation between the Cisco and Microsoft platforms is based on the SIP/SIMPLE protocol and allows for basic presence and instant messaging exchange, as supported with the Cisco Unified Presence inter-domain federation support for Microsoft Office Communications Server. Rich presence and group chat functionality are not supported with the partitioned intra-domain presence federation.

Inter-domain federation and partitioned intra-domain federation can be supported simultaneously with the following qualifications:

- XMPP federation may be enabled on the Cisco Unified Presence deployment but is available only to Cisco Unified Presence licensed users.
- SIP federation may be enabled either on Cisco Unified Presence or on Microsoft Live Communications Server 2005 or Office Communications Server 2007 R2; however, for SIP Federation to be available to both Cisco and Microsoft users, it must be enabled on Microsoft Live Communications Server 2005 or Office Communications Server 2007 R2.
- SIP intercluster trunking with Cisco Unified Presence 7.x is not available with partitioned intra-domain federation.
- If SIP/SIMPLE inter-domain federation with Microsoft Office Communications Server is required in parallel with the partitioned intra-domain federation, then the Microsoft Live Communications Server or Office Communications Server will manage that external federation. Cisco Unified Presence administration must be configured with static routes to the Microsoft environment for the external domain.

Instant Messaging Only Deployment

Cisco Unified Presence allows for an enterprise-class instant messaging only solution, which provides full presence and instant messaging support as defined in the section on [Cisco Unified Presence Enterprise Instant Messaging, page 23-29](#), to be deployed in cases where a full Unified Communications deployment is not yet provided. A Cisco Unified Presence cluster deployed in an instant messaging only environment supports up to three servers in a cluster (see [Figure 23-14](#)). Instant messaging only users on Cisco Unified Presence are still provisioned from Unified CM through the AXL/SOAP interface by means of LDAP synchronization or manual provisioning. Cisco Unified Personal Communicator 8.0 and third-party XMPP clients are the supported clients in a Cisco Unified Presence instant messaging only deployment, and all other design guidelines for Cisco Unified Presence apply.

Figure 23-14 Instant Messaging Only User Mode Deployment

Cisco Unified Presence Migration

Migration of a Cisco Unified Presence deployment to Release 8.x is supported from Cisco Unified Presence 7.x only. User assignments on a Cisco Unified Presence cluster will be maintained on a per-server basis with migration from version 7.x to 8.x.

The following guidelines apply to migration of Cisco Unified Presence:

- Cisco Unified Presence 7.x deployments with more than one cluster require you to deactivate the presence engine on each server in the cluster before upgrading to Cisco Unified Presence 8.x. The presence engine should be reactivated only after you have completed all server upgrades to Cisco Unified Presence 8.x.
- For Cisco Unified Presence 7.x deployments with more than one cluster, Cisco recommends upgrading all clusters to Cisco Unified Presence 8.x at the same time.
- Migrating Cisco Unified Presence deployments to version 8.x brings in a second standard protocol in XMPP, with the addition of the Jabber XCP architecture. Cisco Unified Personal Communicator 7.x, inter-domain federation with Microsoft Office Communications Server, and third-party applications all create SIP/SIMPLE subscriptions. The number of active SIP/SIMPLE subscriptions can be viewed using the Real-Time Monitoring Tool (RTMT) Active Subscription counter. Cisco Unified Presence 8.x manages these subscriptions using the SIP Federation Connection Manager. With a large number of active SIP/SIMPLE subscriptions (above 20,000), or if subscriptions begin to fail after upgrade, Cisco recommends increasing the SIP Federation Connection Manager service parameter **Pre-allocated SIP stack memory (bytes)** to twice the amount of its current default value.

Cisco Unified Presence Server Policy

Cisco Unified Presence server policy is set by the user and not the administrator. A default set of rules, with everything open and available, applies if the user does not make any modifications to the policy rules. All policy configuration control is provided in the User Options area of the Cisco Unified Presence user pages at https://<cup_server_address>/cupuser/.

The user can configure rule sets that contain access control lists (ACLs) of watchers for which these rules apply. There are three types of rules in each rule set:

- Visibility Rules
 - Polite Blocking — Watchers always see an unavailable presence status, with no device status for this user.
 - Reachability Only — Watchers see only the overall reachability of the user, with no device detail information.
 - All State (default) — Watchers see all unfiltered device state information in addition to the overall reachability.
- Reachability Rules
 - Based on precedence rules (first match) for determining reachability (away, available, busy, unavailable, do not disturb, unknown)
 - Based on device type, media type, and calendar (For example, if my cell phone is busy or my calendar is busy, mark me as busy. If any IM device is do-not-disturb, mark me as do-not-disturb.) Do-not-disturb set from the phone will not be propagated to the client device.
- Filtering Rules
 - Exclude presence status for specific device types, media types, or calendar

The filtering rules are applied prior to determining reachability; therefore, a device's filtered status does not affect the reachability status of the user. The user may also define device types (for example, mobile phone, office phone, and so forth) for use with the reachability and filtering rules.

Privacy lists are based on subscription, such that users in your contact list will always be allowed to see your presence. In order to block a user that is in a user's contact list, the blocked user must explicitly be added to the blocked list.

Cisco Unified Presence Enterprise Instant Messaging

Cisco Unified Presence incorporates the supported enterprise instant messaging features of the Jabber Extensible Communications Platform (XCP), while allowing for some modifications to enhance support for multi-device user experience. Cisco Unified Presence changes the Jabber XCP instant messaging routing architecture to allow for initial instant messages to be routed to all of the user's non-negative priority logged-in devices, rather than routing to the highest priority device as is done with existing Jabber XCP installations. Backward compatibility support for point-to-point instant messaging between Cisco Unified Presence SIP clients and XMPP clients is provided by an IM gateway.

Text conferencing, sometimes referred to as multi-user chat, is defined as ad-hoc group chat and persistent group chat and is supported as part of the Jabber XCP feature set. In addition, offline instant messaging (storing instant messages for users who are currently offline) is also supported as part of the Jabber XCP feature set. Cisco Unified Presence handles storage for each of these instant messaging features in different locations. Offline instant messaging is stored locally in the Cisco Unified Presence IDS database. Ad-hoc group chat is stored locally in memory on Cisco Unified Presence. Persistent group chat requires an external database to store chat rooms and conversations. The only external database supported is PostgreSQL (see <http://www.postgresql.org/>).

Cisco Unified Presence uses the basic interfaces of the external database and does not provide any administration, interface hooks, or configuration of the database. Cisco requires a separate database instance for each server in the cluster when Cisco Unified Presence is deployed with persistent group chat. (See [Figure 23-15](#).) The database instances can share the same hardware but are not required to do so.

Figure 23-15 Cisco Unified Presence Persistent Chat

Cisco Unified Presence Message Archiving and Compliance

As part of the Jabber XCP architecture, Cisco Unified Presence contains a Message Archiver component that allows for logging of text conferencing, federated, and intercluster messages into an external database as part of a non-blocking native compliance. Cisco Unified Presence native compliance and message archival requires a PostgreSQL database instance per cluster, as shown in Figure 23-16. The same database can be shared with multiple clusters; however, a large number of users in a multi-cluster deployment might require multiple database servers.

Figure 23-16 Cisco Unified Presence Native Compliance and Message Archiving

A blocking third-party compliance solution, which not only allows logging of messages but also applies policy to message delivery and message content, is provided through a third-party compliance server solution. Cisco Unified Presence third-party compliance requires a compliance server for each server in the cluster, as shown in Figure 23-17.

Figure 23-17 Cisco Unified Presence Third-Party Compliance

Instant Messaging Storage Requirements

The message archiving and Persistent Chat functionality use an external database to store messages offline. There are a number of factors to consider for the storage requirements of a deployment, such as the customer topology, how the database is tuned, and how messaging is used within the organization. The following calculations provide guidelines for these inputs to be used in estimating the raw database storage requirements of a deployment for external database storage. These calculations presume single-byte character data encoding; therefore, additional storage may be needed if internationalized character sets are used.

Cisco Unified Presence supports both SIP and XMPP clients, and there are slightly different amounts of overhead per message based on the protocol. The overhead per message for message archiving could actually be larger or smaller depending on deployment, Jabber Identifier/UserID size, client type, and thread ID; therefore, an average overhead amount is used. For SIP-based messages the average overhead is 800 bytes and for XMPP messages the average overhead is 600 bytes.

The minimum storage requirements (in bytes) for message archiving per month for Cisco Unified Personal Communicator 7.x users can be calculated as follows:

$$(\text{Number of users}) * (\text{Number of messages/hour}) * (\text{Number of Busy hours/month}) * (800 + (3 * \text{Number of characters/message}))$$

The minimum storage requirements (in bytes) for message archiving per month for Cisco Unified Personal Communicator 8.x users can be calculated as follows:

$$(\text{Number of users}) * (\text{Number of messages/hour}) * (\text{Number of busy hours/month}) * (600 + (3 * \text{Number of characters/message}))$$

The message archiving requirements above must be doubled if **Enable Outbound Message Logging** is enabled on Cisco Unified Presence compliance configuration.

The minimum storage requirements (in bytes) for persistent chat per month for Cisco Unified Personal Communicator 8.x users can be calculated as follows:

$$(\text{Number of users}) * (\text{Number of Persistent Chat messages/hour}) * (\text{Number of busy hours/month}) * (700 + (3 * \text{Number of characters/message}))$$

**Note**

Persistent Chat is supported only with XMPP clients and uses an average overhead of 700 bytes.

These message archive and Persistent Chat numbers are the minimum storage requirements based on an average over time; therefore, a buffer multiplier of 1.5 (150%) should be used to account for very large UserIDs, larger than expected instant message lengths, and other factors that tend to increase the storage requirements. [Table 23-6](#) and [Table 23-7](#) list some examples of storage requirements for Cisco Unified Personal Communicator 8.x and 7.x, respectively.

Table 23-6 Examples of Unified Personal Communicator 8.x Message Logging Storage Requirements

| Profile | Number of Users | Number of Messages per Hours | Number of Busy Hours per Month | Average Size of Message | Message Archive Storage Requirement | Persistent Chat Storage Requirement |
|---------|-----------------|------------------------------|--------------------------------|-------------------------|-------------------------------------|-------------------------------------|
| Light | 1500 | 10 | 200 | 100 | 2.7 GB | 3.0 GB |
| Medium | 2500 | 15 | 200 | 250 | 10.2 GB | 10.9 GB |
| High | 2500 | 25 | 200 | 500 | 26.3 GB | 27.5 GB |

Table 23-7 Examples of Unified Personal Communicator 7.x Message Logging Storage Requirements

| Profile | Number of Users | Number of Messages per Hour | Number of Busy Hours per Month | Average Size of Message | Message Archive Storage Requirement |
|---------|-----------------|-----------------------------|--------------------------------|-------------------------|-------------------------------------|
| Light | 1500 | 10 | 200 | 100 | 3.3 GB |
| Medium | 2500 | 15 | 200 | 250 | 11.7 GB |
| High | 2500 | 25 | 200 | 500 | 28.8 GB |

Cisco Unified Presence Calendar Integration

Cisco Unified Presence has the ability to retrieve calendar state and aggregate it into a presence status via the calendar module interface with Microsoft Exchange 2003, 2007, or 2010. Microsoft Exchange integration is supported with Microsoft Active Directory 2003 and Active Directory 2008 as well as Windows Server 2003 and Windows Server 2008. Microsoft Exchange 2003 or 2007 makes the calendar data available from the server through Outlook Web Access (OWA), which is built upon extensions to the WebDAV protocol (RFC 2518). Microsoft Exchange 2007 or 2010 makes the calendar data available from the server through Exchange Web Services (EWS), which allows submitting requests and receiving notifications from Microsoft Exchange. The integration with Microsoft Exchange is done through a separate Presence Gateway configuration for calendar applications. Once the administrator configures a Presence Gateway for Outlook, the user has the ability to enable or disable the aggregation of calendar information into their presence status (see [Table 23-8](#)).

Table 23-8 Aggregated Presence State Based on Calendar State

| Cisco Unified Presence State | Calendar State |
|------------------------------|------------------|
| Available | Free / Tentative |
| Idle/Busy | Busy |
| Away | Out of Office |

The exchange ID that is used to retrieve calendar information is taken from the email ID of the LDAP structure for that user. If the email ID does not exist or if LDAP is not being used, then the Cisco Unified Presence user ID is mapped as the exchange ID.

Information is gathered via a subscription for calendar state from the Cisco Unified Presence server to the Microsoft Exchange server. [Figure 23-18](#) depicts this communication.

Outlook Web Access Calendar Integration

This feature requires a service parameter that is the port address for the UDP HTTP (Microsoft Exchange Notification Port) listen port. This port is where Microsoft Exchange sends any notifications (indicated by the NOTIFY message) indicating a change to a particular subscription identifier for calendar events. (See [Figure 23-18](#).)

Figure 23-18 Outlook Web Access Communication Between Cisco Unified Presence and Microsoft Exchange

The SEARCH transaction is used to search a user's calendar relevant to a given interval, and is invoked when the user has set a preference to include the calendar information in the presence status. The results of the search are converted into a list of free/busy state transitions. The SUBSCRIBE message indicates the subscription for notifications to changes in the free/busy state of the user in the folder /exchange/userX/Calendar. The POLL method is used to acknowledge that the client has either received or responded to a particular event, while the UNSUBSCRIBE message is used to terminate a previous subscription or subscriptions.

Cisco Unified Presence Outlook Web Access integration supports enabling of Forms Based Authentication, which performs an additional HTTP POST transaction request containing the actual URL of the Exchange Server encoded as part of the header, as shown in [Figure 23-19](#).

Figure 23-19 Forms Based Authentication with Cisco Unified Presence Calendar**Note**

Cisco Unified Presence can be deployed with a single Microsoft Exchange Server or with multiple Microsoft Exchange Servers, in a single forest only. Microsoft Exchange deployment allows for clustering of multiple Exchange servers; therefore, Cisco Unified Presence will honor the REDIRECT message to the exchange server that is hosting the user for which Cisco Unified Presence is requesting status.

Multi-Language Calendar Support

In cases where the requirements for a calendar integration deployment specify more than one language, use the following design guidelines:

- Cisco Unified Presence, as well as Cisco Unified Communications Manager, must have the appropriate locales installed for the users to select their locale.
- Cisco Unified Presence supports all the standard Unified Communications locales for calendar integration.
- Users must be configured for the locale that is desired, either through the end user pages or administratively through the Bulk Administration Tool.
- Cisco Unified Presence sends the appropriate locale folder with the initial query. Queries are redirected, if required, through the response of the initial Front-End or Client Access Microsoft Exchange server.
- When using IP Phone Messenger and the Meeting Notification functionality, the user's locale must be configured to be the same as the locale where the phone's IP Phone Messenger service is being used.

Exchange Web Services Calendar Integration

Cisco Unified Presence can be configured to allow for Microsoft Exchange Web Services to collect calendar state information to be aggregated into an overall presence view of the user. If the user's mailbox is located on the configured Exchange server, Cisco Unified Presence will communicate directly with the Exchange server; whereas, if the user's mailbox is located on a different Exchange server than the one configured, Cisco Unified Presence will follow the Exchange server redirection to find the server where the user's mailbox is located. Only Exchange Servers from the server farm can serve as the configured Exchange server, and you are required to specify only one of these servers from the server farm.

Microsoft Exchange Web Services specifies the protocol used to transact with the Exchange Client Access Servers independent of the language that the end-user uses; therefore, there is no need to utilize the locale to determine the language of the end-user. Cisco Unified Presence calendar integration is supported with a single Microsoft Exchange forest only.

Cisco Unified Presence Exchange Web Services calendar integration supports both a polling of calendar information as shown in Figure 23-20 as well as a subscription/notification for calendar information as shown in Figure 23-21. Various configuration parameters control the rate of polling intervals, the frequency of subscriptions, and the fault tolerance of timers. For additional configuration details, refer to the *Integration Note for Configuring Cisco Unified Presence with Microsoft Exchange*, available at

http://www.cisco.com/en/US/products/ps6837/products_installation_and_configuration_guides_list.html

Figure 23-20 Exchange Web Services Polling with Cisco Unified Presence Calendar

Figure 23-21 Exchange Web Services Subscription/Notification with Cisco Unified Presence Calendar

Exchange Web Services Auto Discover is also supported by Cisco Unified Presence if a service connection point (SCP) Active Directory object has been created for each server where the Client Access Server (CAS) role is installed. The calendar gateway is configured with Auto Discover using the domain and optionally the site instead of a host and port. Cisco Unified Presence uses the auto-discover algorithm to determine which Exchange Web Services URL to use in contacting the correct Client Access Server Exchange Server.

Cisco Unified Presence Mobility Integration

Cisco Unified Presence has the ability to integrate contact lists and presence state with Cisco Unified Mobility Advantage and Cisco Unified Mobile Communicator. Cisco Unified Mobile Communicator continues to communicate directly with Cisco Unified Mobility Advantage, while Cisco Unified Mobility Advantage communicates with Cisco Unified Presence via AXL/SOAP and SIP.

An application user must be configured on Cisco Unified Presence and Cisco Unified Mobility Advantage before Cisco Unified Mobility Advantage can establish an administrative session with Cisco Unified Presence. Cisco Unified Mobile Communicator end-user logins will generate a Cisco Unified Mobility Advantage SOAP request to Cisco Unified Presence for system configuration, user configuration, contact list, presence rules, and application dial rules, followed by Unified Communicator Change Notifier (UCCN) configuration and Presence SIP subscriptions. [Figure 23-22](#) highlights the Cisco Unified Mobility Advantage interaction with Cisco Unified Presence.

Figure 23-22 Cisco Unified Mobile Communicator Call Flow

The call flow in [Figure 23-22](#) illustrates the following sequence of events:

1. Cisco Unified Mobility Advantage initiates a SOAP login request to Cisco Unified Presence via the super-user application user (CCMAdministrator), and Cisco Unified Presence returns a session key. This application user must be created on both Cisco Unified Presence and Cisco Unified Mobility Advantage.
2. A Cisco Unified Mobile Communicator end-user logs in, and Cisco Unified Presence returns a session key.
3. Cisco Unified Mobility Advantage initiates a **get-all-config** SOAP request (with session key) on behalf of the user to retrieve the system configuration, user configuration, contact list, presence rules, and application dial rules.
4. Cisco Unified Mobility Advantage submits a Unified Communicator Change Notifier (UCCN) subscription with the **profileconfig** event package for the user.
5. Cisco Unified Mobility Advantage submits a Presence subscription with the **presence** event package for the user.

Observe the following requirements when integrating Cisco Unified Mobility Advantage with Cisco Unified Presence:

- Cisco Unified Mobility Advantage must be deployed in a single Cisco Unified Communications Manager cluster and a single Cisco Unified Presence cluster.
- No more than 1000 Cisco Unified Mobile Communicator users can be integrated per Cisco Unified Mobility Advantage deployment.
- A Cisco Unified Presence cluster can have no more than 2 nodes.

Cisco Unified Presence Third-Party Open API

Cisco Unified Presence has the ability to integrate with third-party applications through HTTP in addition to SIP/SIMPLE and XMPP. The HTTP interface has a configuration interface as well as a presence interface via Representational State Transfer (REST). The Third-Party Open API provides two mechanisms to access presence: a real-time eventing model and a polling model.

Real-Time Eventing Model

The real-time eventing model uses an application user on Cisco Unified Presence to establish an administrative session, which allows for end users to log in with that session key. Once the end user has logged in, the user registers and subscribes for presence updates using Representational State Transfer (REST). [Figure 23-23](#) highlights the Third-Party Open API real-time eventing model interaction with Cisco Unified Presence.

Figure 23-23 Third-Party Open API Real-Time Eventing Model

The call flow in [Figure 23-23](#) illustrates the following sequence of events:

1. The application initiates a SOAP login request to Cisco Unified Presence via the super-user application user (APIUser), and Cisco Unified Presence returns a session key. The application can then log in the end-user with this session key (essentially, the end-user logs in via the application).
2. The end user registers the endpoint using the application-user session key.
3. The application initiates a subscribe request (using the session key) on behalf of the end user to retrieve user information, contact list, and presence rules.
4. Cisco Unified Presence sends a notification – unsecured.
5. The application requests the user's presence status.

Polling Model

The polling model uses an application user on Cisco Unified Presence to establish an administrative session, which allows for end users to log in with that session key. Once the end user has logged in, the application requests presence updates periodically, also using Representational State Transfer (REST). [Figure 23-24](#) highlights the Third-Party Open API polling model interaction with Cisco Unified Presence.

Figure 23-24 Third-Party Open API Polling Model

The call flow in [Figure 23-24](#) illustrates the following sequence of events:

1. The application initiates a SOAP login request to Cisco Unified Presence via the super-user application user (APIUser), and Cisco Unified Presence returns a session key. The application can then log in the end-user with this session key (essentially, the end-user logs in via the application).
2. The application requests presence state and bypasses the eventing model.
3. The application requests presence state and bypasses the eventing model.

Note Both Basic presence and Rich presence can be retrieved; however, the polling model puts an additional load on the presence server.

Extensible Messaging and Presence Protocol Interfaces

The Jabber XCP architecture allows for two additional open interfaces for presence, instant messaging, and roster management: a client XMPP interface and a JabberWerx AJAX interface. The client XMPP functionality enables third-party XMPP clients to integrate presence, instant messaging, and roster management, and it is a complementary interface to the SIP/SIMPLE interface on Cisco Unified Presence. The client XMPP interface is treated as a normal XMPP client within Cisco Unified Presence; therefore, sizing of the interface should be treated as a normal XMPP client.

The JabberWerx AJAX API provides a Web 2.0 style of interface to integrate Jabber XCP features into web applications and widgets, and it is made directly available from Cisco Unified Presence. The JabberWerx AJAX API is exclusively a client-side JavaScript library that communicates to the Bidirectional-streams Over Synchronous HTTP (BOSH) interface, which is essentially an XMPP over HTTP interface that allows the server to push data to a web browser through a long-polling technique.

Observe the following requirements when integrating either model of the Third-Party Open API with Cisco Unified Presence:

- Certificates are required for the presence interface (sipprox.y.der) and the configuration interface (tomcat_cert.der).
- No more than 1000 Third-Party Open API users can be integrated per Cisco Unified Presence deployment.
- To improve performance, balance the Third-Party Open API users across all servers in the Cisco Unified Presence cluster.

You can obtain additional information and support for use of the Cisco Unified Presence Third-Party Open API through Cisco Developer Services, available at:

<http://developer.cisco.com/web/cupapi>

Information and assistance for developers is also available from the Cisco Developer Community, which is accessible through valid Cisco login authentication at:

<http://developer.cisco.com/>

Design Considerations for Cisco Unified Presence

- If LDAP integration is possible, LDAP synchronization with Unified CM should be used to pull all user information (number, ID, and so forth) from a single source. However, if the deployment includes both an LDAP server and Unified CM that does not have LDAP synchronization enabled, then the administrator should ensure consistent configuration across Unified CM and LDAP when configuring user directory number associations.
- Cisco Unified Presence marks Layer 3 IP packets via Differentiated Services Code Point (DSCP). Cisco Unified Presence marks all IM and presence traffic based on the Differential Service Value service parameter under SIP Proxy, which defaults to a value of DSCP 24 (PHB CS3). With Cisco Unified Presence 8.5 and later releases, this setting is also applicable to XMPP traffic. (For Cisco Unified Presence 8.0 this value is hard-coded to DSCP 24 (PHB CS3) for XMPP traffic and is not configurable).
- Presence Policy for Cisco Unified Presence is controlled strictly by a defined set of rules created by the user.
- The Cisco Unified Presence publisher and subscriber must be co-located with the Unified CM publisher.
- Use the service parameter CUP PUBLISH Trunk to streamline SIP communication traffic with the Cisco Unified Presence server.
- Associate presence users in Unified CM with a line appearance, rather than just a primary extension, to allow for increased granularity of device and user presence status. When using the service parameter CUP PUBLISH Trunk, you must associate presence users in Unified CM with a line appearance.
- A Presence User Profile (the user activity and contact list contacts and size) must be taken into consideration for determining the server hardware and cluster topology characteristics.

- Use the User Assignment Mode sync agent parameter default of **balanced** for best overall cluster performance.
- Cisco Unified Presence requires an external database instance for each server within in the cluster for persistent chat, and one database instance per cluster for message archiving and native compliance. The database instances can share the same hardware; however, the only external database supported is PostgreSQL.
- Cisco Unified Presence supports a total of 15,000 users per cluster. The sizing for users must take into account the number of SIP/SIMPLE users and the number of XMPP users. XMPP users have slightly better performance because SIP/SIMPLE users employ the IM Gateway functionality into the Jabber XCP architecture.
- When migrating a Cisco Unified Presence deployment from version 7.x to 8.x, you must deactivate the presence engine service prior to the upgrade and re-enable it after all servers have been upgraded to 8.x.
- All eXtensible Communications Platform (XCP) communications and logging are stored in GMT and not localized to the installed location.
- Cisco Unified Presence 8.x is compatible with Unified CM 6.x, 7.x, and 8.x.
- Cisco Business Edition 7.x and later releases support LDAP synchronization, which should be enabled when integrating Cisco Business Edition with Cisco Unified Presence.
- For ease of user migration and contact list migration, Cisco Unified Presence Bulk Administration Tool supports bulk contact list importation using a comma-separated value (csv) file as input for this bulk importation.

For a complete listing of ports used by Cisco Unified Presence, refer to *Port Usage Information for Cisco Unified Presence*, available at

http://www.cisco.com/en/US/products/ps6837/products_device_support_tables_list.html

Third-Party Presence Server Integration

Cisco Unified Presence provides an interface based on SIP and SIP for Instant Messaging and Presence Leveraging Extensions (SIMPLE) for integrating SIP and SIMPLE applications into the Cisco Unified Communications solution. You can configure and integrate a third-party presence server or application with this SIP/SIMPLE interface to provide presence aggregation and federation.

Microsoft Communications Server

For all setup, configuration, and deployment of Microsoft Live Communications Server 2005 or Office Communications Server 2007 and Microsoft Office Communicator, refer to the documentation at:

<http://www.microsoft.com/>

Cisco does not provide configuration, deployment, or best practice procedures for Microsoft Communications products, but Cisco does provide the guidelines listed below for integrating Cisco Unified Presence with Microsoft Live Communications Server 2005 or Office Communications Server 2007.

Cisco Systems has developed an application note to show feature interoperability and configuration steps for integrating Cisco Unified Presence with Microsoft Live Communications Server 2005. You can access this application note at:

http://www.cisco.com/en/US/docs/voice_ip_comm/cucme/pbx/interop/notes/602270nt.pdf

Cisco Systems has also developed application notes to show feature interoperability and configuration steps for integrating Cisco Unified Presence with Microsoft Office Communications Server 2007. You can access the application notes at the following locations:

http://www.cisco.com/en/US/docs/voice_ip_comm/cucme/pbx/interop/notes/617030nt.pdf

<http://www.cisco.com/en/US/solutions/collateral/ns340/ns414/ns728/ns784/712410.pdf>

Cisco Systems has also developed a guide for integrating Cisco Unified Presence with Microsoft Office Communications Server 2007. This *Integration Note for Configuring Cisco Unified Presence with Microsoft LCS/OCS for MOC Call Control* is available at:

http://www.cisco.com/en/US/products/ps6837/products_installation_and_configuration_guides_list.html

Guidelines for Integrating Cisco Unified Presence with Microsoft Live Communications Server 2005 or Office Communications Server 2007

The following guidelines apply when integrating the Cisco Unified Presence server and Microsoft Live Communications Server 2005 or Office Communications Server 2007:

- Communications between Cisco Unified Presence and Microsoft Live Communications Server 2005 or Office Communications Server 2007 uses the SIP/SIMPLE interface. However, Microsoft Live Communications Server 2005 or Office Communications Server 2007 tunnels Computer-Supported Telecommunications Applications (CSTA) traffic over SIP. Therefore, the CTI gateway on the Cisco Unified Presence server must be configured to handle the CSTA-to-CTI conversion for Click to Call phone control.
- Cisco Unified Presence deployment with Microsoft Office Communications Server 2007 or Live Communications Server 2005 for Remote Call Control, should consist of a single subcluster pair of servers that make up the Cisco Unified Presence cluster.
- The following table lists the number of users supported per platform.

| Cisco Unified Presence Platform | Cisco Unified Communications Manager Platform | Number of Microsoft Office Communicator Users Supported per Server¹ | Number of Microsoft Office Communicator Users Supported per Cluster¹ |
|--|--|---|--|
| MCS 7825, 7835, or 7845 | MCS 7825-H4/I4 or earlier | 900 | 3,600 |
| MCS 7825, 7835, or 7845 | MCS 7825-H5/I5 or OVA equivalent servers | 1,000 | 4,000 |
| MCS 7825, 7835, or 7845 | MCS 7835-H2/I2 | 2,000 | 8,000 |
| MCS 7825, 7835, or 7845 | MCS 7835-H3/I3 or OVA equivalent servers | 2,500 | 10,000 |
| MCS 7825, 7835, or 7845 | MCS 7845-H2/I2 or OVA equivalent servers | 5,000 | 20,000 |
| MCS 7825, 7835, or 7845 | MCS 7845-I3 or OVA equivalent servers | 10,000 | 40,000 |

1. These numbers are based on Cisco Unified CM 7.1(3) and later releases.

- You must configure the same end-user ID in LDAP, Unified CM, and Microsoft Live Communications Server 2005 or Office Communications Server 2007. This practice avoids any conflicts between Microsoft Live Communications Server 2005 or Office Communications Server 2007 authentication with Active Directory (AD) and the end-user configuration on Unified CM, as well as conflicts with user phone control on Unified CM.

For Active Directory, Cisco recommends that the user properties of General, Account, and Live Communications all have the same ID. To ensure the Cisco Unified Presence users are consistent, LDAP Synchronization and Authentication should be enabled with Unified CM.

- You must configure Microsoft Live Communications Server 2005 or Office Communications Server 2007 Host Authentication to contain the Cisco Unified Presence publisher and subscriber.
- You can configure routing of the SIP messages to Cisco Unified Presence by means of Static Routes in the Microsoft Live Communications Server 2005 or Office Communications Server 2007 properties.
- You must configure an incoming and outgoing access control list (ACL) on the Cisco Unified Presence server to allow for communications with Microsoft Live Communications Server 2005 or Office Communications Server 2007.
- You must enable each user for use of Microsoft Office Communicator in the Cisco Unified Presence server configuration, in addition to enabling each user for presence in Unified CM.
- Take into account bandwidth considerations for Microsoft Office Communicator login due to the exchange of configuration information between Microsoft Office Communicator and the Microsoft Communications Server, and due to initial communication with the Cisco Unified Presence server CTI gateway.
- The parameters that are required for Microsoft Office Communications Server 2007 have changed names from Live Communications Server 2005. The TEL URI parameter defined in Live Communications Server 2005 is the same as the Line URI parameter in Office Communications Server 2007, and the Remote Call Control SIP URI parameter defined in Live Communications Server 2005 is the same as the Server URI parameter in Office Communications Server 2007.
- To address the issue of a reverse look-up of a directory number that corresponds to a user, use the guidelines documented in the *Release Notes for Cisco Unified Presence*, available at

http://www.cisco.com/en/US/products/ps6837/prod_release_notes_list.html

IBM Lotus Sametime

Cisco Systems, Inc. provides the following guidelines around how best to integrate IBM Lotus Sametime Server with Cisco Unified Communications, but does not contend configuration, deployment, or best practice procedures for IBM Communications products.

For all setup, configuration, and deployment of IBM Lotus Sametime Server, refer to the documentation at

<http://www.ibm.com/>

Cisco does not provide configuration, deployment, or best practice procedures for IBM communications products, but Cisco does provide the guidelines listed below for integrating IBM Lotus Sametime Server with a Cisco Unified Communications system.

Guidelines for Integrating Cisco Unified Presence with IBM Lotus Sametime Server (Version 7.5.1 and Later)

Click-to-call and click-to-conference functionality integrated within the IBM Lotus Sametime client is handled via a Cisco Call Control plugin resident on IBM Lotus Sametime Server. The integration into Cisco Unified Communications for click-to-call and click-to-conference functionality is handled via the SIP trunk interface with Unified CM. The integration into Cisco Unified Communications for presence functionality is handled via the SIP/SIMPLE interface with Cisco Unified Presence.

- The Unified CM SIP trunk for click-to-call and click-to-conference functionality must be configured for out-of-dialog REFER processing. Enable the Accept Out-of-Dialog REFER checkbox in the SIP Trunk Security Profile associated with the SIP trunk communicating with IBM Lotus Sametime Server.
- The Cisco Call Control plugin, resident on IBM Lotus Sametime Server, maintains a configured list of Unified CMs utilized in a round-robin manner. This list should be populated with the IP address of Unified CM subscribers that have been configured with the out-of-dialog REFER SIP trunks.
The Unified CM list can also be configured with DNS SRV; however, currently this SRV logic is used for redundancy only and not for load balancing, therefore it is not a recommended setting.
- Deployment topologies using IBM Lotus Sametime Server typically will integrate with multiple Unified CM clusters due to the capacity differences between the two systems. With the Cisco Click-to-Call plugin utilizing a list of Unified CMs in a round-robin fashion, a call initiation can result in a REFER being sent to a cluster different from the user's home cluster. The Unified CM receiving this call setup will process the REFER and generate an INVITE to the appropriate destination to complete the call setup.
- Traffic marking has not been implemented fully with the Cisco Call Control plugin. Therefore, follow the traffic marking guidelines in the *Enterprise QoS Solution Reference Network Design (SRND)*, available at

<http://www.cisco.com/go/designzone>

Cisco Unified Presence 8.0 integrates with IBM Lotus Sametime 8, from a server-to-server perspective, through the XMPP interface to allow for inter-domain federation between IBM Lotus Sametime clients and Cisco Unified Presence clients.

CHAPTER 24

Cisco Collaboration Clients and Applications

Revised: January 12, 2012; OL-21733-18

Note

This chapter has been revised significantly for the current release of this document. Cisco recommends that you read this entire chapter before attempting to deploy collaboration clients and applications in your Cisco Unified Communications System.

Cisco Collaboration Clients and Applications provide an integrated user experience and extend the capabilities and operations of the Cisco Unified Communications System. These clients and applications enable collaboration both inside and outside the company boundaries by bringing together, in a single easy to use collaboration client, applications such as online meetings, presence notification, instant messaging, audio, video, voicemail, and many more.

Several collaboration clients and applications are available, and each provides an architectural view, deployment considerations, planning, and design guidance around integration into the Cisco Unified Communications System. Use this chapter to determine which of the following collaboration clients and applications are best suited for your deployment:

- Cisco Unified Personal Communicator

Cisco Unified Personal Communicator is a desktop application that allows users to easily access voice, video, web conferencing, instant messaging, voicemail, and presence information from a rich media interface on their desktop (PC or Mac). Cisco Unified Personal Communicator enhances productivity between teams and allows knowledge workers to collaborate anytime, anywhere, and easily escalate their communications through an easy-to-use user interface. For additional information, see the chapter on [Cisco Unified Presence](#), page 23-1.

- Cisco WebEx Connect

Cisco WebEx Connect is a Unified Communications client application that is delivered through Software-as-a-Service (SaaS). WebEx Connect provides presence, instant messaging, voice and video, voice messaging, desktop sharing, and conferencing capabilities through a single client on your Windows desktop. WebEx Connect enhances productivity by empowering users to collaborate more securely and effectively from anywhere with colleagues, business partners, and customers.

- Cisco UC Integration™ for Microsoft Lync

Cisco UC Integration™ for Microsoft Lync allows for integrated Cisco Unified Communications services with Microsoft Lync using the Cisco Unified Client Services Framework, while delivering a consistent user experience. The solution extends the presence and instant messaging capabilities

of Microsoft Lync by providing access to a broad set of Cisco Unified Communications services, including standards-based audio and video, unified messaging, web conferencing, deskphone control, and telephony presence.

- Cisco Virtual Experience Clients

The Cisco Virtualization Experience Clients (VXC) are the integral collaboration components of the Cisco Virtualization Experience Infrastructure (VXI). The VXCs provide user access to data, applications, and services across various network environments, as well as user preferences and device form factors for a fully integrated voice, video, and virtual desktop environment.

- Cisco Unified Mobile Communicator

Cisco Unified Mobile Communicator is a mobility solution that gives users the ability to access and leverage Cisco Unified Communications applications from their mobile phones. The Cisco Unified Mobile Communicator and Cisco Mobile graphical clients work in conjunction with a server running the Cisco Unified Mobility Advantage software to provide a rich user interface for accessing and controlling mobile phone features and functionality. The system integrates into existing corporate LDAP directories, allowing users to use a single set of credentials across all devices. For more information, refer to the chapter on [Mobile Unified Communications, page 25-1](#).

- Third-party XMPP clients and applications

Cisco Unified Presence, with support for SIP/SIMPLE and Extensible Messaging and Presence Protocol (XMPP), provides support of third-party clients and applications to communicate presence and instant messaging updates between multiple clients. Third-party XMPP clients, MomentIM, Adium, Spark, Pidgin, and others, allow for enhanced interoperability across various desktop operating systems. In addition, web-based applications can obtain presence updates, instant messaging, and roster updates using the HTTP interface with SOAP, REST, or BOSH (based on JabberWerx AJAX API). For additional information on the third-party open interfaces, see the chapter on [Cisco Unified Presence, page 23-1](#).

What's New in This Chapter

[Table 24-1](#) lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Table 24-1 *New or Changed Information Since the Previous Release of This Document*

| New or Revised Topic | Described in: | Revision Date |
|---|---|-------------------|
| Minor corrections to a few illustrations | Figure 24-3 ; Figure 24-4 | January 12, 2012 |
| Cisco Virtualization Experience Infrastructure (VXI) and Virtualization Experience Client (VXC) | Cisco Virtualization Experience Client Architecture, page 24-33 | December 22, 2011 |
| Cisco WebEx Connect | Cisco WebEx Connect Architecture, page 24-16 | August 31, 2011 |
| High availability for Cisco Unified Personal Communicator | High Availability for Cisco Unified Personal Communicator, page 24-13 | January 31, 2011 |
| Microsoft Office Communicator name changed to Microsoft Lync | Various sections throughout this chapter | January 31, 2011 |

Cisco Unified Client Services Framework Architecture

Cisco Unified Personal Communicator, Cisco WebEx Connect, and Cisco UC Integration™ for Microsoft Lync all use the Client Services Framework as a base building block for the client application. Cisco Unified Client Services Framework is a software application that combines a number of services into an integrated client. An underlying framework is provided for integration of Unified Communications services, including audio, video, web collaboration, visual voicemail, and so forth, into a presence and instant messaging application.

Users are allowed to access a variety of communications services that interface into Cisco Unified Communications Manager (Unified CM), Cisco Unity, Cisco Unity Connection, Cisco Unified MeetingPlace, and a Lightweight Directory Access Protocol (LDAP) version 3 (v3) server. The Client Services Framework, shown in Figure 24-1, also allows for integration into various desktop clients such as Microsoft Lync, Cisco WebEx Connect, and Cisco Unified Personal Communicator.

The ability to communicate and abstract services and APIs, as shown in Figure 24-1, allows the Client Services Framework to coordinate the management of protocols to these services and APIs, handle event notifications, and control the low-level connection logic for local system resources.

Figure 24-1 Cisco Unified Client Services Framework

Contact Management

The Client Services Framework handles the management of contacts through a hierarchy of sources. These include directory integration, supporting LDAP and LDAPS, where a customizable attribute table mapping must be configured, Client Services Framework Cache, and Local Address Book contacts. The Client Services Framework contact management allows for up to five search bases to be defined for LDAP queries, and it handles reverse number lookup to map incoming telephone number to contact, in addition to photo retrieval.

Directory

LDAP Directory integration with the Client Services Framework allows attributes to be mapped and configured for contacts to be managed from a central directory location. The most common directory attribute mapping is listed in [Table 24-2](#).

Table 24-2 Directory Attribute Mapping

| Client Services Framework Name | LDAP Directory Attribute |
|--------------------------------|-----------------------------|
| businessPhone | telephoneNumber |
| commonName | cn |
| companyName | company |
| displayName | displayName |
| email | mail |
| firstName | givenName |
| homePhone | homePhone |
| lastName | sn |
| mobilePhone | mobile |
| objectclassKey | objectclass |
| objectclassValue | person |
| otherPhone | otherTelephone |
| photoUri | photoUri |
| title | title |
| uri | msRTCSIP-PrimaryUserAddress |
| userAccountName | sAMAccountName / uid |
| userLogonName | userPrincipalName / uid |

Client Services Framework Cache

The Client Services Framework maintains a local cache of contact information derived from previous directory queries and contacts already listed, as well as the local address book.

Directory Search

When a contact cannot be found in the local Client Services Framework cache, a directory search for the contact information can be made through LDAP or LDAPS. The Client Services Framework utilizes a predictive search whereby the local cache is queried as contact information is being entered. If no matches are found locally, then the user can use the directory search option, which forms a searchRequest, for matches with cn, sn, uid, and givenName, and can send the request to the LDAP server based on the LDAP profile configured. All results matching the request are returned and listed.

Call Control

Cisco Unified Client Services Framework can operate in two modes, softphone mode (audio on a computer) or deskphone control mode (using a deskphone for audio). The Client Services Framework in softphone mode (audio on a computer) is directly registered as a SIP endpoint to Unified CM for audio and video call control functionality, and is configured on Unified CM as a new device type, Client Services Framework. The Client Services Framework in deskphone control mode (using a deskphone for audio) uses CTI / JTAPI to initiate, monitor, and terminate calls, monitor line state, and provide call history, while controlling a Cisco Unified IP Phone. The CCMCIP service on Unified CM is used by the Client Services Framework to discover the users associated devices.

Softphone Mode (Audio on Computer)

When operating in softphone mode (audio on computer), the Client Services Framework is a SIP line-side registered device on Unified CM, utilizing all the call control capabilities and functionality of a Cisco Unified IP Phone, including configuration of registration, redundancy, regions, locations, dial plan management, authentication, encryption, user association, and so forth. The Client Services Framework supports a single line appearance for the user.

The SIP registered device of the Client Services Framework must be factored in as a regular SIP endpoint, as any other SIP registered endpoint, for purposes of sizing calculations for a Unified CM cluster.

Deskphone Control Mode (Using Deskphone for Audio)

When operating in deskphone control mode (using deskphone for audio), the Client Services Framework uses CTI / JTAPI to provide the ability to place, monitor, and receive calls using Cisco Unified IP Phones. When calls are received or placed in this mode, the audio path is through the Cisco Unified IP Phone. The Client Services Framework uses the CCMCIP service on Unified CM to discover the associated devices of the user. When using video, the Client Services Framework and the Unified IP Phone being controlled use Cisco Discovery Protocol (CDP) to discover one another, and they use Cisco Audio Session Tunnel (CAST) to set up and manage the video call. The PC being used for the Client Services Framework must be a 32-bit operating system and be physically plugged into the PC port of the Unified IP Phone, and that PC port of the Unified IP Phone must be enabled.

When using deskphone control mode for the Client Services Framework, factor the CTI scaling numbers into the Unified CM deployment calculations. For additional information around capacity planning, see the chapter on [Call Processing](#), page 8-1.

Media

A number of standard audio and video codecs for use in low bandwidth or high fidelity deployments are supported with the Client Services Framework. Audio codecs include G.729a, iLBC, G.711, G.722, and iSAC, while video codecs include H.264 AVC (Advanced Video Coding) with support for H.264 baseline profile levels 1 through 3.1. Video formats supported include QCIF, CIF, VGA, and 720p HD at a rate of up to 30 frames per second.

The Client Services Framework always attempts to transmit and receive high definition video; however, there are a number of throttling factors that need to be considered when deploying video. These throttling considerations include the capability of the device communicating with, the local processing capability of the PC, administrative or user settings, local camera capabilities, and any call admission control policies in place.

There are a number of decision points the Client Services Framework uses to determine the video frame rate for a call. One of the key decision points is based on the Windows Experience Index (WEI) for the personal computer being used (<http://technet.microsoft.com/en-us/library/cc507870.aspx>). The minimum values for encoding and decoding high definition video require a processor WEI encode value of 5.9 and a bandwidth requirement of 1 Mbps for 720p at 15 frames per second or 2 Mbps for 720p at 30 frames per second. For a listing of other video frame rates based on H.264 Level and WEI encode and decode values, refer to the following application release notes:

- Cisco Unified Personal Communicator release notes
http://www.cisco.com/en/US/products/ps6844/prod_release_notes_list.html
- Cisco UC Integration™ for Microsoft Lync release notes
http://www.cisco.com/en/US/products/ps10317/prod_release_notes_list.html

The receive levels for video can be controlled within the Client Services Framework by manually adjusting the video settings, either by administrative or user control. The ability to manually adjust the mode of operation and the corresponding H.264 level allows for throttling of the video stream rates and Windows Experience Index. These throttling considerations include the capability of the device communicating with the Client Services Framework, the local processing capability of the PC, administrative or user settings, local camera capabilities, and any call admission control policies in place. Refer to the application release notes for the relationship of the Windows Experience Index to video resolution.

Bandwidth utilization for audio and video calls from the Client Services Framework can be maintained using the Unified CM regions and locations call admission control mechanisms. Administratively placing the Client Services Framework in a device pool for a region provides the ability to control bandwidth usage in scenarios where network bandwidth is at a premium. Unified CM regions call admission control provides the ability to specify which codecs can be used, as well as the per-call inter-region and intra-region bandwidth allowed. Unified CM locations call admission control provides location-to-location audio and video bandwidth control, or the use of RSVP. The Client Services Framework requires the Unified CM region to be sufficient to cover both the audio and video portions of the call. For example, to have a video call at a frame size of 720p and a frame rate of 30 frames per second, the signaling bit rate needs to be 2,000 kbps just for video; therefore, the region bandwidth for a call must account for the audio portion at 64 kbps (assuming a G.711 or G.722 codec) as well as the video portion at 2,000 kbps (assuming 720p at 30 fps). For more information on Unified CM support for regions and locations call admission control, see the chapter on [Call Processing, page 8-1](#).

The signaling and media traffic, both audio and video, for the Client Service Framework is marked by means of Differentiated Services Code Point (DSCP) to allow for greater flexibility and control of a deployment. The Client Services Framework marks all signaling with a CS3 classification. The media associated with audio-only calls is marked EF, and video calls are marked with a DSCP value of AF41

for both audio and video. However, the operating system might not honor these markings, thus resulting in the traffic from the PC being untrusted. For additional details, see the QoS recommendations for [Software-Based Endpoints, page 18-44](#).

Dial Plan

Dial plan and number normalization considerations must be taken into account when deploying the Client Services Framework as part of any Unified Communications endpoint strategy. The Client Services Framework, as part of a Unified Communications collaboration client, will typically use the directory for searching, resolving, and adding contacts. The number that is associated with those contacts must be in a form that the client can recognize, resolve, and dial.

Deployments may vary, depending on the configuration of the directory and Unified CM. In the case where the directory contains E.164 numbering (for example, +18005551212) for business, mobile, and home telephone numbers and Unified CM also contains an E.164 dial plan (Unified CM 7.x or later releases), the need for additional dial rules is minimized because every lookup, resolution, and dialed event results in an E.164 formatted dial string.

When a deployment of Unified CM has implemented a private dial plan (for example, 51212), then translation of the E.164 number to a private directory number needs to occur on Unified CM. Outbound calls are translated by means of application dial rules. This allows the number being dialed, +18005551212, to be presented to the endpoint as the private number of 51212. Inbound calls are translated by means of directory lookup rules. This allows an incoming number of 51212 to be presented for reverse number lookup caller identification as +18005551212.

Private numbering plan deployments may arise, where the dial plan for your company and the telephone number information stored in the LDAP directory may require defining application dialing rules and directory lookup rules on Cisco Unified Communications Manager. These rules define how to reformat the inbound call ID to be used as a directory lookup key and how to transform a phone number retrieved from the LDAP directory for outbound dialing.

Application Dialing Rules

Application dialing rules are used to manipulate numbers that are dialed and to automatically strip numbers from, or add numbers to, phone numbers that the user dials. Cisco Unified CM 7.x and later releases supports rules that contain the plus (+) character in dialed numbers, whereas Unified CM releases prior to 7.x do not support the plus character. Application dial rules are configured on Unified CM and are downloaded through TFTP to the client from Unified CM.

Directory Lookup Rules

Directory lookup rules transform caller identification numbers into numbers that can be looked up in the directory, and a rule specifies which numbers to transform based on the initial digits and the length of the number. Directory Lookup rules are configured on Unified CM and are downloaded through TFTP to the client from Unified CM.

Translation Patterns

Translation patterns are used by Unified CM to manipulate the dialed digits before a call is routed, and they are strictly handled by Unified CM. When using Unified CM 7.x and later releases, Cisco recommends using translation patterns instead of application dialing rules for increased flexibility with number resolution in a Client Services Framework deployment.

For additional guidelines on translation pattern usage and dial plan management, see the chapter on [Dial Plan](#), page 9-1.

Client Transformation

Before a call is placed through contact information, the client application removes everything from the phone number to be dialed, except for letters and digits. The application transforms the letters to digits and applies the dialing rules. The letter-to-digit mapping is locale-specific and corresponds to the letters found on a standard telephone keypad for that locale. For example, for a US English locale, 1-800-4UCSRND transforms to 18004827763. Users cannot view or modify the client transformed numbers before the application places the call.

Deploying Client Services Framework

Because the Client Services Framework is a fundamental building block for desktop client integration and communication, it is necessary to deploy these devices to a number of users. Cisco recommends using the Bulk Administration Tool for the Client Services Framework deployment. The administrator can create a phone template for device pool, device security profile, and phone buttons, and can create a CSV data file for the mapping of device name to directory number. The administrator can also create a User template to include user groups and CTI, if enabled, as well as a CSV data file to map users to the appropriate controlled device.

Capacity Planning for Client Services Framework

Cisco Unified Client Services Framework operates as a SIP registered endpoint to Unified CM or as a deskphone controller of a Unified IP Phone using CTI to Unified CM. When planning a deployment using Client Services Framework, Cisco partners and employees can use the Cisco Unified Communications Sizing Tool (available at <http://tools.cisco.com/cucst>) to assist in the appropriate sizing of SIP registered endpoints or CTI controlled devices. The following additional items must be considered for a Client Services Framework deployment:

- TFTP — When configured in softphone (audio on computer) mode, a Client Services Framework device configuration file is downloaded to the client for Unified CM call control configuration information. In addition, any application dial rules or directory lookup rules are also downloaded through TFTP.
- CTI — When configured in deskphone (using desk phone for audio) mode, the Client Services Framework establishes a CTI connection to Unified CM upon login and registration to allow for control of the IP phone.
- CCMCIP — The Client Services Framework uses the Unified CM IP Phone Services to gather information about the devices associated with the user to be able to list the IP phones available for control.
- IMAP — When configured for voicemail, the Client Services Framework updates and retrieves voicemail through an IMAP connection to the mailstore.
- LDAP — Client login and authentication, contact profile information, and incoming caller identification are all handled through an LDAP query, unless stored in the local Client Services Framework cache.

With the exception of the integrated Extension Mobility and Unified CM Assistant applications' IP Phone Services, IP Phone Services must reside on a separate web server. Running phone services other than Extension Mobility and Unified CM Assistant on the Unified CM server is not supported.

High Availability for Client Services Framework

Cisco Unified Client Services Framework provides primary and secondary servers for each of the configuration components, TFTP Server, CTI Manager, CCMCIP Server, Voicemail Server, and LDAP Server. When operating in softphone (audio on computer) mode, the Client Services Framework is a SIP registered endpoint with Cisco Unified CM and supports all of the registration and redundancy capabilities of a registered endpoint of Unified CM. When operating in deskphone mode, the Client Services Framework is controlling a Cisco Unified IP Phone using CTI and supports configuration of a primary and secondary CTI Manager. For additional details on CTI deployment, see the chapter on [Call Processing, page 8-1](#)

Design Considerations for Client Services Framework

Observe the following design considerations when deploying the Cisco Unified Client Services Framework:

- The administrator must determine how to install, deploy, and configure the Unified Client Services Framework in their organization. Cisco recommends using a well known installation package such as Altiris to install the application, and use Group Policies to configure the user registry settings for the required components of TFTP Server, CTI Manager, CCMCIP Server, Voicemail Pilot, LDAP Server, LDAP Domain Name, and LDAP search contexts.
- The userid and password configuration of the Cisco Unified Client Services Framework user must match the userid and password of the user stored in the LDAP server to allow for proper integration of the Unified Communications and back-end directory components.
- The directory number configuration on Cisco Unified CM and the telephoneNumber attribute in LDAP should be configured with a full E.164 number. A private enterprise dial plan can be used, but it might involve the need to use application dialing rules, directory lookup rules, or translation patterns.
- The use of deskphone mode for control of a Cisco Unified IP Phone uses CTI; therefore, when sizing a Unified CM deployment, you must also account for other applications that require CTI usage.
- For firewall and security considerations, the port usage required for the Client Services Framework and corresponding applications being integrated can be found in the product release notes for each application.
- To reduce the impact on the amount of traffic (queries and lookups) to the back-end LDAP servers, configure concise LDAP search bases for the Client Services Framework rather than a top-level search base for the entire deployment.

Cisco Unified Personal Communicator Architecture

Cisco Unified Personal Communicator allows for a fully integrated Cisco Unified Communications solution, delivering a consistent user experience in a single desktop client using the Cisco Unified Client Services Framework. The solution incorporates the always-on presence and instant messaging capabilities of Cisco Unified Presence, while providing access to a broad set of Cisco Unified Communications services, including standards-based audio and video, unified messaging, web conferencing, deskphone control, and telephony presence.

The solution architecture for a Cisco Unified Personal Communicator deployment, shown in Figure 24-2, includes Cisco Unified Communications Manager for user association, audio, and video services, Cisco Unified Presence for presence and instant messaging services, LDAP for user account information, and Cisco Unified Client Services Framework for PC audio or deskphone control.

Figure 24-2 Cisco Unified Personal Communicator

With a Cisco Unified Personal Communicator deployment, Cisco recommends that the administrator populate the user directory number information with an E.164 value (for example, +18005551212) and enable LDAP synchronization and authentication on Unified CM for user account consistency. Cisco Unified Personal Communicator is tightly integrated with all the Cisco Unified Communications components using Cisco Unified CM for audio and video control and Cisco Unified Presence for presence and instant messaging. For those who are not deploying the full Unified Communications solution, Cisco Unified Personal Communicator can also operate in an IM-only configuration to provide presence and instant messaging services from Cisco Unified Presence. For deployment guidelines for an IM-only solution, see the chapter on [Cisco Unified Presence](#), page 23-1.

Deploying Cisco Unified Personal Communicator

When deploying Cisco Unified Personal Communicator, observe the following guidelines:

Configuration Settings

Cisco Unified Personal Communicator downloads its configuration information from Cisco Unified Presence over the SOAP interface. All the configuration information is created, stored, and assigned to the users in profiles on Cisco Unified Presence (Voicemail, Conferencing, CTI Gateway, LDAP, and CCMCIP profiles). Cisco recommends ensuring that the user is already created, licensed, and assigned prior to associating profile configuration settings to the user. For profile configuration details, refer to the Cisco Unified Personal Communicator documentation available at

http://www.cisco.com/en/US/products/ps6844/tsd_products_support_series_home.html

Software Installation

The software installation deployment can be handled a number of different ways and is designed to be deployed using desktop management tools such as Microsoft Active Directory Group Policy, Systems Management Server (SMS), Altiris, or self-extracting executable with script/batch file. Because customer topologies vary, there is no recommendation about which method to use. For details on the software deployment method, refer to the Cisco Unified Personal Communicator documentation available at

http://www.cisco.com/en/US/products/ps6844/tsd_products_support_series_home.html

Capacity Planning for Cisco Unified Personal Communicator

When designing and sizing a solution for Cisco Unified Personal Communicator, you must consider the following scalability impacts for all the components:

- Client scalability

The Cisco Unified Presence server hardware deployment determines the number of users a cluster can support. The Cisco Unified Personal Communicator deployment must balance all users equally across all servers in the cluster. This can be done automatically by setting the User Assignment Mode Sync Agent service parameter to **balanced**.

The maximum number of contacts in the contact list is 200.

- IMAP scalability

The number of IMAP or IMAP-Idle connections is determined by the platform overlay (Cisco Unity or Cisco Unity Connection) for messaging integration. For specific configuration sizing, refer to the Cisco Unity or Cisco Unity Connection product documentation available at <http://www.cisco.com>.

- Web conferencing

Cisco Unified MeetingPlace web licensing determines the number of concurrent web conferencing participants allowed. For specific configuration sizing, refer to the Cisco Unified MeetingPlace product documentation available at <http://www.cisco.com>.

- Video sizing capability

Videoconferencing and switching are determined by Cisco Unified Videoconferencing MCU sizing and configuration, by Cisco MeetingPlace Hardware Media Server (HMS) sizing and configuration, or by Cisco Unified MeetingPlace Express VT for concurrent voice, video, and web participants. For specific configuration sizing, refer to the Cisco Unified Videoconferencing or Cisco Unified MeetingPlace Express VT product documentation available at <http://www.cisco.com>.

Cisco Unified Personal Communicator interfaces with Unified CM. Therefore, the following guidelines for the current functionality of Unified CM apply when Cisco Unified Personal Communicator voice or video calls are initiated:

- CTI scalability

In Desk Phone mode, calls from Cisco Unified Personal Communicator use the CTI interface on Unified CM. Therefore, observe the CTI limits as defined in the chapter on [Call Processing, page 8-1](#). You must include these CTI devices when sizing Unified CM clusters.

- Call admission control

Cisco Unified Personal Communicator applies call admission control for voice and video calls by means of Unified CM locations or RSVP.

- Codec selection

Cisco Unified Personal Communicator voice and video calls utilize codec selection through the Unified CM regions configurations.

All Cisco Unified Personal Communicator configuration and contacts are stored in the Cisco Unified Presence database and have the potential to contain large amounts of data. The current conversation history list is limited to 50 entries for each tab (Chats, Voice Messages, Calls), while the contact list size is limited to 200 contacts. Therefore, bandwidth utilization must be taken into consideration for presence data exchange as well as for conferencing, video, and messaging traffic.

The following bandwidth considerations also apply to Cisco Unified Personal Communicator:

- A Presence User Profile (PUP) takes into consideration the number of logins, presence state changes, and roster changes to determine a user deployment traffic pattern. With a typical PUP, where the number of logins is 0.5 per hour, the number of presence state changes is 0.5 per hour, and the number of roster changes is 0.25 per hour, you can use the following formula as a general guideline for calculating bandwidth utilization (in kilobits per second) between Cisco Unified Presence and Unified Personal Communicator (see [Table 24-3](#) for examples):

$$\text{USERS} * [30 + \text{ROSTER} * 7 + \text{IM} * 3 + \text{CALLS} * (33 + 3 * \text{ROSTER})] / 1000$$

where:

- USERS = number of users using Unified Personal Communicator.
- ROSTER = average roster size of a Unified Personal Communicator user.
- IM = number of instant messages per hour for a Unified Personal Communicator user.
- CALLS = number of softphone calls per hour.

Table 24-3 Examples of Bandwidth Requirement for Unified Personal Communicator

| Enterprise | Number of Users | Roster Size | Number of IMs | Calls per Hour | Bandwidth Utilization |
|------------|-----------------|-------------|---------------|----------------|----------------------------|
| Small | 1,000 | 100 | 25 | 4 | 2,100 kbps (2.1 Mbps) |
| Large | 5,000 | 200 | 25 | 4 | 20,185 kbps (20.2 Mbps) |

- For Cisco Unified MeetingPlace voice, video, and web collaboration sessions, see [Cisco Unified MeetingPlace, page 22-13](#).
- For video calls, see the chapter on [IP Video Telephony, page 12-1](#).
- For Cisco Unity or Unity Connection, see the section on [Managing Bandwidth, page 21-34](#), in the chapter on [Cisco Voice Messaging, page 21-1](#).

High Availability for Cisco Unified Personal Communicator

All users in the Cisco Unified Presence cluster must be assigned to a server prior to any exchange of information. Cisco Unified Presence, by default, allows for automatic user assignment that is equally balanced across all servers in the cluster. The administrator can control where users are assigned by setting the User Assignment Mode Sync Agent service parameter to **None** instead of the default **balanced**. If this parameter is set to **None**, user assignment is done from the **System > Topology** menu.

Cisco Unified Personal Communicator provides for basic deployment, a highly available deployment for automatic redundancy, and an IM-only deployment. In a Cisco Unified Presence two-server subcluster, users associated with one server are known by the other server in the subcluster, thus allowing for automatic failover when service communication with the configured server is interrupted. Cisco Unified Personal Communicator high availability is supported only within a Cisco Unified Presence subcluster.

As illustrated in [Figure 24-3](#), the server recovery manager monitors the various services on Cisco Unified Presence to determine if a service has failed to initiate an XMPP failover event. The following sequence of events occurs during an XMPP failover:

1. When the server recovery manager determines that a service is no longer communicating, a failover user move operation from server 1A to server 1B is initiated. User123 is moved from home server 1A and is now homed to server 1B.
2. Unified Personal Communicator determines connectivity with server 1A is lost through time-out, connection loss, or XMPP protocol update, and it initiates a new connection to server 1B.

Figure 24-3 Unified Personal Communicator XMPP Failover

As illustrated in Figure 24-4, failure of Cisco Unified Presence server 1A initiates the following sequence of events for SIP-enabled clients:

1. Cisco Unified Presence server 1B sends a SIP NOTIFY message to Cisco Unified Personal Communicator 7.x, terminating its Presence and Unified Client Change Notification (UCCN) Subscription-State on server 1A.
2. Cisco Unified Personal Communicator 7.x sends a SIP SUBSCRIBE message to Cisco Unified Presence server 1B to reactivate its Presence and UCCN Subscription-State.

Figure 24-4 Unified Personal Communicator SIP Failover

Design Considerations for Cisco Unified Personal Communicator

The required interfaces for Cisco Unified Personal Communicator are Cisco Unified Presence, Cisco Unified Communications Manager (Unified CM), and an LDAP v3 compliant server. Cisco Unified Personal Communicator optional interfaces include Cisco Unity, Cisco Unity Connection, Cisco Unified MeetingPlace, Cisco Unified Videoconferencing, and Cisco Unified MeetingPlace Express VT. In addition to the capacity planning guidelines, when designing and sizing a solution, you must consider the following design considerations:

- The administrator must determine how to install, deploy, and configure the Cisco Unified Personal Communicator in their organization. Cisco recommends using a well known installation package such as Altiris to install the application. Cisco Unified Personal Communicator gathers its configuration information through the SOAP interface on Cisco Unified Presence for the LDAP, CTI, Voicemail, Conferencing, and CCMCIP profiles assigned for the user.
- When using text conferencing rooms, observe the following limits:
 - The maximum users in a text conference is 100 users.
 - The maximum number of messages displayed in the text conference history is 100.
- LDAP Search Context

The ability to specify an LDAP filter to search an object class, which allows for the retrieval of only users and not computers from the directory, is done by appending `&(objectclass=user)` to the search context. For example:

```
cn=user,dc=example,dc=com;&(objectclass=user)
```

The ability to specify more than a single LDAP search context is done using a `#` as a delimiter in the LDAP Search Context field on Cisco Unified Presence Administration. An example of the supported format is:

```
ou=test,dc=example,dc=com#ou=testing,dc=example,dc=com
```

The Cisco Unified Personal Communicator will search both Organizational Units in order, 'test' then 'testing'.

Note that the LDAP search context field is limited to 255 characters; thus, the number of supported Organizational Units can vary, depending on the size and number of characters for each individual search context.

Cisco Unified Personal Communicator also allows for federated contacts to be added once Cisco Unified Presence has been configured for a federated deployment. This allows for the user to input and control contacts within their existing domain as well as users of other domains. With this additional contact functionality there is also the ability for users to control privacy settings such as blocked lists and domains that are available for communication.

Cisco Unified Personal Communicator marks Layer 3 IP packets via Differentiated Services Code Point (DSCP). Cisco Unified Personal Communicator marks call signaling traffic with a value of DSCP 24 (PHB CS3), and it marks voice media traffic with a value of DSCP 46 (PHB EF). However, personal computer traffic is typically untrusted, and the network will strip DSCP markings made by an application from the PC. Therefore, access routers and switches must be configured to allow these DSCP markings for the port ranges that Cisco Unified Personal Communicator utilizes. For details on traffic marking, refer to the *Enterprise QoS Solution Reference Network Design (SRND)*, available at

<http://www.cisco.com/go/designzone>

Cisco WebEx Connect Architecture

Cisco WebEx Connect consists of two main components:

- [Cisco WebEx Connect Client, page 24-16](#)
- [Cisco WebEx Connect Platform, page 24-16](#)

Cisco WebEx Connect Client

The Cisco WebEx Connect client is a rich client that resides on an end user's personal computer, running Microsoft Windows XP, Vista, or Windows 7 Operating Systems, and provides availability status, enterprise-grade instant messaging, VoIP audio, PC-to-PC video, desktop sharing, Cisco WebEx meetings integration, Cisco Unified Communications integration, Microsoft Outlook integration for calendaring, presence, instant messaging, click to call, and IBM Lotus Notes calendar integration. Additional details can be found in the *Cisco WebEx Connect Data Sheet*, available at

<http://www.cisco.com/go/webexconnectds/>

Cisco WebEx Connect Platform

The Cisco Connect Platform is a multi-tenant Software-as-a-Service (SaaS) platform for synchronous and asynchronous collaboration. The WebEx Connect Platform is hosted inside the Cisco WebEx Collaboration Cloud and it enables collaborative applications and integrations, which allows for organizations and end users to customize their work environments. For additional WebEx Connect Platform information, refer to the *WebEx Connect Platform Technical Overview*, available at

http://developer.webex.com/c/document_library/get_file?folderId=11836&name=DLFE-260.pdf

For more information on the Cisco Collaboration Cloud, refer to

http://www.cisco.com/en/US/prod/ps10352/collaboration_cloud.html

Deploying Cisco WebEx Connect

Cisco WebEx Connect solution deployment consists of the following components, as depicted in [Figure 24-5](#):

- A secure connection (SSL and AES) to the Cisco WebEx Connect XMPP cloud platform for presence, instant messaging, VoIP, PC-to-PC video, media transfer (screen capture and file transfer), and desktop sharing
- Cisco WebEx Meetings
- XMPP federation with other Connect organizations and third-party XMPP clients and XMPP instant messaging (IM) networks
- Cisco Unified Communications integration for call control, voice messaging, and call history
- Microsoft Outlook and IBM Lotus Notes calendar integration
- Integration to Microsoft Outlook for presence and click-to-communicate functionality

Figure 24-5 Deploying Cisco WebEx Connect

Centralized Management

Cisco WebEx Connect provides a web-based administrative tool to manage the solution across the organization. Cisco WebEx Connect users are configured and managed through the Cisco WebEx Connect Administration Tool, which enables administrators to set up basic security and policy controls for features and services. These policies can be applied enterprise-wide, by group, or individually. There are various methods to provision the user database that are further described in the *Cisco WebEx Connect Administrator's Guide*, available at

<http://www.webex.com/webexconnect/orgadmin/help/index.htm>

Single Sign On

Single Sign On (SSO) enables companies to use their on-premises SSO system, including Security Assertion Markup Language (SAML) support, to simplify the management of Cisco WebEx Connect by allowing users to securely log into Cisco WebEx Connect using their corporate login credentials. The user's login credentials are not sent to Cisco, thus protecting the user's corporate login information. Figure 24-6 shows the credential handshake that occurs on user login to Cisco WebEx Connect.

Figure 24-6 User Login Authentication Process for Cisco WebEx Connect

A user account can be configured to automatically be created the first time a user logs into Cisco WebEx Connect. Users are prevented from accessing Cisco WebEx Connect if their corporate login account is deactivated.

For more information on Single Sign On with WebEx Connect, refer to the *Cisco WebEx Federated SSO Authentication Service Technical Overview*, available at

<http://developer.webex.com/documents/10465/22041/Federated+SSO+Authentication+Service.pdf>

Cisco Unified Communications Integration

Cisco WebEx Connect can be configured for Click-to-Call with Cisco Unified Communications Manager directly from within Cisco WebEx Connect. Cisco Unified Communications can be integrated into Cisco WebEx Connect by means of [Cisco Unified Communications Integration™ for Cisco WebEx Connect](#), page 24-19.

Cisco Unified Communications Integration™ for Cisco WebEx Connect

Cisco Unified Communications Integration™ for Cisco WebEx Connect provides tight integration between Unified CM and Cisco WebEx Connect through the Client Services Framework to enable full call control inside the Cisco WebEx Connect client, as shown in [Figure 24-7](#).

Figure 24-7 Cisco Unified Communications Integration™ for Cisco WebEx Connect

The Client Services Framework allows for softphone call control where the desktop client serves as the audio endpoint, or it allows for desk phone control where the desktop client controls the Cisco Unified IP Phone, and in both cases it is represented by the Phone tab within WebEx Connect. The solution incorporates the instant messaging capabilities, meetings, and calendar integration of Cisco WebEx Connect, while providing access to a broad set of Cisco Unified Communications services, including standards-based audio, unified messaging, deskphone control, and telephony presence, as shown in [Figure 24-7](#).

Security

The Cisco WebEx security model consists of functional layers of security. Figure 24-8 illustrates the separate but interrelated elements that compose each layer.

Figure 24-8 WebEx Security Model

The bottom layer represents the physical security in the Cisco WebEx data centers. All employees go through an extensive background check and must provide dual-factor authentication to enter the datacenter.

The next level is policy management, where the WebEx Connect organization administrator can set and manage access control levels by setting different policies for individual users, groups, or the entire Cisco WebEx Connect organization. White list policies, specific to external users or domains, can be created to allow instant messaging exchanges. The Cisco WebEx Connect organizational model also allows for the creation of specific roles and groups across the entire user base, which allows the administrator to assign certain privileges to roles or groups as well as to set policies, including access control, for the entire organization.

Access to Cisco WebEx Connect is controlled at the authentication layer. Every user has a unique login and password. Passwords are never stored or sent over email in clear text. Passwords can be changed only by the end-users themselves. The administrator can choose to reset a password, forcing the end-user to change his or her password upon the next login. Alternatively, an administrator may choose to use the Single Sign On (SSO) integration between Cisco WebEx Connect and the company's directory to simplify end-user access management. The Single Sign On integration is achieved through the use of an Identity Management System (IDMS).

The encryption layer ensures that all instant messaging communications between Cisco WebEx Connect users is encrypted. All instant messaging communication between Cisco WebEx Connect users and the server in the Connect Collaboration cloud is encrypted by default using SSL encryption. An additional level of security is available whereby IM communication can be encrypted end-to-end using 256-bit AES level encryption. Voice calls using Cisco Unified Communications Integration for Cisco WebEx

Connect in PC (softphone) mode can be encrypted using Secure Real-time Transport Protocol (SRTP). Instant messaging security options are controlled through policy by the Cisco WebEx Connect site administrator, while Cisco Unified Communications Integration for Cisco WebEx Connect security options are controlled by the Cisco Unified Communications Manager administrator or by the end user through the Cisco WebEx Connect client settings under the Unified Communications tab.

Cisco WebEx Connect Platform uses third-party audits such as the SAS70 Type II audit to provide customers with an independent semi-annual security report. This report can be reviewed by any customer upon request with the Cisco Security organization. For additional Cisco WebEx Connect security, refer to the Cisco WebEx Connect IM security white paper, available at

<http://www.in.cisco.com/csg/docs/CiscoWebExConnectSecurityWP.pdf>

Firewall Domain White List

Access control lists should be set specifically to allow all communications from the webex.com and webexconnect.com domains and all sub-domains for both webex.com and webexconnect.com. The WebEx Connect Platform sends email to end-users for username and password communications. These email messages come from the mda.webex.com domain.

Logging Instant Messages

Cisco WebEx Connect instant messaging communications are logged on the local hard drive of the personal computer where the user is logged in. Instant message logging is a capability in Cisco WebEx Connect that can be enabled by means of policy through the Org Admin tool. If instant message logging is enabled for Cisco WebEx Connect, instant messages are logged and kept in the following path:

- For Windows XP
C:\Documents and Settings*user*\Local Settings\Application Data\WebEx Connect\Archive
- For Windows 7
C:\Users*user*\AppData\Local\WebEx Connect\Archive

The end-user can set logging specifics, whether to enable or disable logging, and how long the logs are kept. These message history settings are located under General in the Cisco WebEx Connect client preferences.

Customers looking for advanced auditing and e-discovery capabilities should consider third-party solutions. Currently Cisco does not provide support for advanced auditing of instant messaging communications. Cisco WebEx Connect, however, does allow for logging and archiving of instant messages exchanged between users. Archiving of the logs is possible though the use of third-party SaaS archiving services, or the logs can be delivered securely to an on-premises SMTP server.

For additional information on instant message archiving, refer to the *Cisco WebEx Connect Administrator's Guide*, available at

<http://www.webex.com/webexconnect/orgadmin/help/index.htm>

Capacity Planning for Cisco WebEx Connect

A single end-user requires only a 56 kbps dial-up Internet connection to be able to log in to WebEx Connect and get the basic capabilities such as presence, instant messaging, and VoIP calling. However, for a small office or branch office, a broadband connection with a minimum of 512 kbps is required in

order to use the advanced features such as file transfer, screen capture, PC-to-PC video calling, and team spaces. For higher quality video such as High Definition 720p, the minimum bandwidth connection recommendation is 2 Mbps.

For additional information on network and desktop requirements, refer to the *Cisco WebEx Connect Administrator's Guide*, available at

<http://www.webex.com/webexconnect/orgadmin/help/index.htm>

The Cisco Unified Communications integrations use Unified CM CTI Manager for click-to-call applications, as well as deskphone control mode with the Cisco Unified Client Services Framework. Therefore, observe the CTI limits as defined in the chapter on [Call Processing, page 8-1](#). When Cisco UC Integration™ for WebEx Connect is operating in a softphone (audio on computer) mode, the Cisco Unified Client Services Framework is a SIP registered endpoint with Cisco Unified CM. When sizing a solution involving Cisco Unified Communications, you must include the CTI devices and the SIP endpoint devices utilizing resources on the Unified CM clusters.

Network Requirements

Cisco Webex Connect deployment network requirements are available at:

<http://www.webex.com/webexconnect/orgadmin/help/17161.htm>

High Availability for Cisco WebEx Connect

WebEx Connect is a Software-as-a-Service (SaaS) application. The end-user PC must be connected to the Internet for the end user to log in to WebEx Connect. A standard Internet connection is all that is required. If an end user is remote, it is not necessary for that user to be connected through the company VPN in order to log in to WebEx Connect. Cisco WebEx Connect can be deployed in a highly available redundant topology. Deployment of Cisco WebEx Connect Software-as-a-Service architecture consists of various network and desktop requirements described in this section.

High Availability

With the use of the multi-tenant Software-as-a-Service architecture, if any individual server in a group fails for any reason, requests can be rerouted to another available server in the Cisco WebEx Connect Platform.

The Cisco WebEx Network Operations Team provides 24x7 active monitoring of the Cisco WebEx Collaboration Cloud from the Cisco WebEx Network Operations Center (NOC). For a comprehensive overview of the Cisco WebEx technology, refer to the information at

http://www.cisco.com/en/US/prod/ps10352/collaboration_cloud.html

Redundancy, Failover, and Disaster Recovery

The Cisco WebEx Global Site Backup architecture handles power outages, natural disaster outages, service capacity overload, network capacity overload, and other types of service interruptions. Global Site Backup supports both manual and automatic failover. The manual failover mode is typically used during maintenance windows. The automatic failover mode is used in case of real-time failover due to a service interruption.

Global Site Backup is automatic and transparent to the end users, is available for all users, and imposes no limits on the number of users that can fail-over.

Global Site Backup consists of the following main components:

- Global Site Service — Is responsible for monitoring and switching traffic at the network level.
- Database Replication — Ensures that the data transactions occurring on the primary site are transferred to the backup site.
- File Replication — Ensures that any file changes are maintained in synchronization between the primary and the backup site.

Design Considerations for Cisco WebEx Connect

Cisco WebEx Connect is deployed as a Software-as-a-Service model, therefore design and deployment considerations are minimal. The Cisco WebEx Connect solution has client options available for the Windows and Mac desktop as well as the popular mobile devices such as Blackberry. Cisco WebEx Connect may also be deployed in a Citrix XenDesktop environment.

Design and deployment consists of interfacing with the Cisco WebEx Connect Platform, otherwise known as the Cisco Collaboration Cloud. Cisco WebEx Connect integrates with Cisco Unified Communications Manager and third-party applications. When deploying Cisco WebEx Connect, use the design considerations described in the following sections.

One Unified CM Integration per Managed Connect Domain

All end users on the same managed Cisco WebEx Connect domain have to use the same Unified CM integration. The creation of sub-groups of end users and the ability to assign a different Unified CM integration to different sub-groups, is currently not supported.

Unified CM CTI Manager

When integrating with Cisco Unified Communications for Cisco WebEx Connect, the Client Services Framework click-to-call is available from CTI. No other call flow and call control capabilities are available.

Refer to the chapter on [Call Processing, page 8-1](#), for supported maximum CTI limits. The CTI numbers are key when using CTI WebDialer with the Cisco Unified Communications Widgets for Cisco WebEx Connect, as well as for desk phone control mode with the Cisco Unified Communications Integration™ for Cisco WebEx Connect.

Third-Party XMPP Clients Connecting to Cisco WebEx Connect Platform

Although Cisco does not officially support any other XMPP clients to connect to the Cisco WebEx Connect Platform, the nature of the XMPP protocol is to allow end users to connect to presence clouds with various XMPP clients using their WebEx Connect credentials. A list of XMPP software clients is available at

<http://xmpp.org/software/clients.shtml>

Organization policies cannot be enforced on third-party XMPP clients, and features such as end-to-end encryption, desktop share, video calls, PC-to-PC calls, and teleconferences are not supported with third-party clients. To allow non-WebEx Connect XMPP IM clients to authenticate to your Connect domain(s), DNS SRV records must be updated. The specific DNS SRV entry can be found in the Cisco WebEx Connect site administration space, under Configuration and IM Federation.

The use of non-Connect XMPP clients in the Cisco WebEx Connect site administration space, under Configuration and XMPP IM Clients, must be explicitly allowed.

For additional information on enabling third-party XMPP clients to connect to the WebEx Connect platform, refer to the *Cisco WebEx Connect Administrator's Guide*, available at

<http://www.webex.com/webexconnect/orgadmin/help/index.htm>

Instant Message and Presence Federation Using Third-Party XMPP Clients

The Cisco WebEx Connect network can federate with XMPP-based instant messaging networks such as GoogleTalk and Jabber.org. (See [Figure 24-9](#).) A list of public instant messaging networks based on XMPP is available at

<http://xmpp.org/>

Figure 24-9 Inter-Domain Federation

WebEx Connect can federate with IBM Lotus Sametime through the IBM Lotus Sametime XMPP gateway and with Microsoft Office Communications Server through the Microsoft Office Communications Server XMPP gateway. When using these third-party XMPP gateways, the configuration must be enabled at the back end of the IBM Lotus Sametime and Microsoft Office Communications Server deployments. Cisco does not officially support these configurations, nor does Cisco guarantee interoperability between clients.

Currently WebEx Connect does not interoperate with Yahoo! Messenger and Windows Live Messenger, but it can federate with AIM through a federation gateway.

Other Resources and Documentation

The *Cisco WebEx Connect Administrator's Guide* is available at

<http://www.webex.com/webexconnect/orgadmin/help/index.htm>

The Cisco WebEx Connect end-user guide is available at

<http://www.webex.com/webexconnect/help/wwhelp/wwhimpl/js/html/wwhelp.htm>

Cisco UC Integration™ for Microsoft Lync Architecture

Cisco UC Integration™ for Microsoft Lync allows for tightly integrated Cisco Unified Communications services for Microsoft Lync using the Cisco Unified Client Services Framework, while delivering a consistent user experience. The solution extends the presence and instant messaging capabilities of Microsoft Lync by providing access to a broad set of Cisco Unified Communications services, including standards-based audio and video, unified messaging, web conferencing, deskphone control, and telephony presence.

The solution architecture for a Cisco UC Integration™ for Microsoft Lync deployment, shown in Figure 24-10, includes Cisco Unified Communications Manager for audio and video services, Microsoft Office Communications Server 2007 for presence and instant messaging services, Microsoft Active Directory for user account information, Cisco Unified Client Services Framework for PC audio or deskphone control, and Microsoft Lync.

Figure 24-10 Cisco UC Integration™ for Microsoft Lync

With a deployment of Cisco UC Integration™ for Microsoft Lync, the client utilizes user information from the Office Communications Server Address Book that gets downloaded to the client. The address book is generated and delivered to the clients from the Office Communications Server once the user is enabled for presence and instant messaging. Cisco recommends that administrators populate the user

directory number information with an E.164 value (for example, +18005551212) and enable LDAP synchronization and authentication on Unified CM for user account consistency. Cisco UC Integration™ for Microsoft Lync connects to both Cisco Unified CM and Microsoft Active Directory and provides for account credential synchronization rules.

Deploying Cisco UC Integration™ for Microsoft Lync

When deploying Cisco UC Integration™ for Microsoft Lync, observe the guidelines presented in this section.

Configuration Settings

Cisco UC Integration™ for Microsoft Lync reads its configuration settings from a series of registry entries that the administrator must configure. Cisco recommends pushing these registry configuration settings from Microsoft Active Directory by means of Group Policy to distribute the configuration settings automatically to the client computer. Although Group Policy is the recommended installation mechanism, there are other methods available as well, including third-party software deployment tools, batch files, Vbscript, or manual configuration.

Microsoft Active Directory group policies can be extended using administration templates, and the Cisco UC Integration™ for Microsoft Lync provides an administrative template that the administrator can add to provide the group policy support. After the administrative template is loaded, a Cisco UC Integration™ configuration policy can be created by the administrator for the registry configuration settings (TFTP servers, CTI servers, CCMCIP Servers, Voicemail, and LDAP Servers). The registry location where these settings are stored is:

HKCU\Software\Policies\Cisco Systems, inc.\Client Services Framework\AdminData

The Group Policy Management Console can be used to control how and where these group policies are applied to different organizational units. From a client policy perspective, when deploying Cisco UC Integration™ for Microsoft Lync, Cisco recommends setting the Microsoft Telephony Mode Policy to **IM and Presence Only** and **DisableAVConferencing**. These client policy changes will allow for only a single set of call options to be displayed in the Microsoft Lync user experience.

A Cisco UC Integration™ for Microsoft Lync deployment also allows for custom presence states to be defined and deployed in the `cisco-presence-states-config.xml` file that gets installed. However, Cisco recommends that administrators relocate this file to a HTTPs location, such as the Microsoft Office Communications Server, to allow Microsoft Lync to use this custom presence state file based on the following registry location:

HKLM\Software\Policies\Microsoft\Communicator\CustomStateURL

Software Installation

The software installation can be handled a number of different ways and is designed to be deployed using desktop management tools such as Microsoft Active Directory Group Policy, Systems Management Server (SMS), Altiris, or self-extracting executable with script/batch file. Because customer topologies vary, there is no recommendation about which method to use. For details on the software deployment method, refer to the Cisco UC Integration™ for Microsoft Lync documentation available at

<http://www.cisco.com/en/US/products/ps10317/index.html>

Capacity Planning for Cisco UC Integration™ for Microsoft Lync

Cisco UC Integration™ for Microsoft Lync uses Unified CM CTI Manager for click-to-dial applications, as well as deskphone control mode with the Cisco Unified Client Services Framework. Therefore, observe the CTI limits as defined in the chapter on [Call Processing, page 8-1](#). When Cisco UC Integration™ for Microsoft Lync is operating in a softphone (audio on computer) mode, the Cisco Unified Client Services Framework is a SIP registered endpoint with Cisco Unified CM. When sizing a solution involving Cisco Unified Communications, you must include the CTI devices and the SIP endpoint devices utilizing resources on the Unified CM clusters.

High Availability for Cisco UC Integration™ for Microsoft Lync

Cisco Unified Client Services Framework provides primary and secondary servers for each of the configuration components, TFTP Server, CTI Manager, CCMCIP Server, Voicemail Server, and LDAP Server. When operating in softphone (audio on computer) mode, the Client Services Framework is a SIP registered endpoint with Cisco Unified CM and it supports all of the registration and redundancy capabilities of a registered endpoint of Unified CM. When operating in deskphone mode, the Client Services Framework is controlling a Cisco Unified IP Phone using CTI, and it supports configuration of a primary and secondary CTI Manager. For additional details on CTI deployment refer to the chapter on [Call Processing, page 8-1](#). The Client Services Framework does not rely on Microsoft Lync being online to support high availability.

Microsoft Lync provides primary and secondary servers with the configuration of enterprise pools for an Office Communications Server deployment. For additional details, refer to the Microsoft Office Communications Server 2007 deployment documentation available at

<http://technet.microsoft.com/en-us/library/dd425168%28office.13%29.aspx>

Design Considerations for Cisco UC Integration™ for Microsoft Lync

Observe the following design considerations when deploying Cisco UC Integration™ for Microsoft Lync:

- The administrator must determine how to install, deploy, and configure the Cisco UC Integration™ for Microsoft Lync in their organization. Cisco recommends using a well known installation package such as Altiris to install the application, and use Group Policies to configure the user registry settings for the required components of TFTP Server, CTI Manager, CCMCIP Server, Voicemail Pilot, LDAP Server, LDAP Domain Name, and LDAP search contexts.
- Cisco UC Integration™ for Microsoft Lync connects to both Cisco Unified CM and Microsoft Active Directory; therefore, Cisco recommends enabling LDAP Synchronization and LDAP Authentication on Unified CM to allow for integration of the Unified Communications and back-end directory components.
- The address book generated by the Microsoft Office Communications Server and distributed to the clients is used by Cisco UC Integration™ for Microsoft Lync to initiate voice and video calls. Before enabling the user for Microsoft Office Communications Server instant messaging and presence, Cisco recommends configuring the user with an E.164 telephone number in Microsoft Active Directory.

Cisco IP Phone Messenger Application Architecture

Cisco IP Phone Messenger is a Cisco Unified IP Phone Service that provides users with the ability to create a buddy list, watch their buddies' aggregated presence information, and exchange instant messages with their buddies' Cisco Unified IP Phone or compliant SIP or SIMPLE client or gateway.

The Cisco IP Phone Messenger (IPPM) application, which is a component of Cisco Unified Presence, serves as a protocol translator between HTTP and SIP messaging. The IPPM application communicates with the Cisco Unified IP Phones using XML over HTTP (<http://www.cisco.com/go/apps>), and it communicates with the SIP Proxy/Registrar Server using SIP. The IPPM application can distinguish between two devices with the same directory number in different partitions and can also function when the user is logged in through Extension Mobility. However, it does rely on the availability of the Cisco Unified Presence publisher for new user logins.

The IPPM application provides the following presence functionality (see [Figure 24-11](#)):

- Shows aggregated presence status of a buddy.
- Supports overriding the presence status manually (Available, Busy, Do Not Disturb).
- Upon phone login, SUBSCRIBE to all phone buddies' presence statuses. Upon phone logout, SUBSCRIBE with Expires=0 (terminate subscription).
- Update buddy presence status in the IPPM application upon receipt of a NOTIFY message from the presence engine.
- Manage the contact list from both the phone (Phone Messenger Service) and the web user interface (http://<cup_server_address>/ccmuser).

Figure 24-11 IPPM Protocol Translation Presence

The IPPM application provides the following instant messaging (IM) functionality (see [Figure 24-12](#)):

- Translates HTTP instant messages from the phone to outbound SIP MESSAGE messages.
- Translates inbound SIP MESSAGE messages to HTTP instant messages to the phone.
- Provides the ability to dial-back a buddy from either the buddy information screen or the IM screen.
- Manages the message history from the phone (Phone Messenger Service).
- Provides the ability to configure canned system-wide and personal IM responses as well as the ability to compose messages.

Figure 24-12 IPPM Protocol Translation Instant Message

The IPPM application provides the following meeting notification functionality (see [Figure 24-13](#)):

- Meeting reminders can be sent from Cisco Unified Presence to registered IPPM phones without requiring the user to log in to their desktop calendar clients.
- Provides the ability to join a meeting from the IPPM service (through join, dial, or callback).
- Users can control whether to block the meeting reminder feature by means of the end-user configuration page.
- Users can browse the meeting roster list inside the meeting detail screen. The IPPM module will then send a SUBSCRIBE message per participant to the Presence Engine for their presence status. Meeting reminders and instant messages can then be sent to the users on the roster list, based on current availability.

Figure 24-13 IPPM Protocol Translation Meeting Notification

For a listing of the phone models that support Cisco IP Phone Messenger, consult the *Hardware and Software Compatibility Information for Cisco Unified Presence*, available at

http://www.cisco.com/en/US/products/ps6837/products_device_support_tables_list.html

High Availability for Cisco IP Phone Messenger

Current IP Phone Services in the Cisco Unified Communications System are configured with either an IP address or DNS A record entry for the HTTP Service URL, which can result in a single point of failure if no IP Phone Service redundancy is configured.

Without IP Phone Services redundancy, the IP Phone Messenger deployment should be load-balanced by means of configuration across both the Cisco Unified Presence publisher and subscriber.

On Unified CM, configure two phone services for IP Phone Messenger, one that uses the Cisco Unified Presence publisher and one that uses the Cisco Unified Presence subscriber, as illustrated in the following example:

- PhoneMessenger1:
`http://publisher.cups.com:8081/ippm/default?name=#DEVICENAME#`
- PhoneMessenger2:
`http://subscriber.cups.com:8081/ippm/default?name=#DEVICENAME#`

With Cisco IP Phone Messenger, you can deploy the Cisco Unified IP Phones in either of the following ways:

- Single phone service

With the single phone service, you configure half of the Cisco Unified IP Phones to point to the Cisco Unified Presence publisher (PhoneMessenger1 in the example above), while the other half is configured to point to the Cisco Unified Presence subscriber (PhoneMessenger2 in the example above).

Advantage — The administrator load-balances the IP Phone Messenger users by means of configuration.

Disadvantage — If the Cisco Unified Presence server running that phone service fails, the IP Phone Messenger service is unavailable to the users.

- Dual phone service

With the dual phone service, you configure all Cisco Unified IP Phones to have two IP Phone Messenger services (both PhoneMessenger1 and PhoneMessenger2 in the above example).

Advantage — If the Cisco Unified Presence server running the phone service fails, the user can try using the IP Phone Messenger service running on the second server.

Disadvantage — This method relies on the phone user to pick the IP Phone Messenger service to use from the Services menu. This method potentially leads to one Cisco Unified Presence server being selected more than the other, thus resulting in a disproportionate number of users on one particular Cisco Unified Presence server.

With IP Phone Services redundancy (see [High Availability for IP Phone Services, page 19-5](#)), IP Phone Messenger can be configured on Unified CM as a single phone service by using the server load balancer (SLB) IP address, as illustrated in the following example:

- PhoneMessenger:

```
http://slb_ip_address:8081/ippm/default?name=#DEVICENAME#
```

Capacity Planning for Cisco IP Phone Messenger

The user message history and contact list are both stored in the Cisco Unified Presence database and have the potential to contain large quantities of data. Every user login to the IP Phone Messenger application will download the message history and contact list. Therefore, if bandwidth might be a concern, you can limit the message history size and contact list size through Cisco Unified Presence administration by setting the **Max Instant Message History Size** and **Max Contact List Size** under the IP Phone Messenger settings.

The user has the ability to set a Session Timer parameter for controlling the amount of time the user is logged into the current session and a Refresh Interval parameter for controlling the rate at which presence status updates occur. The administrator currently has no control over these parameters; therefore, the default settings (Session Timer = 480 minutes and Refresh Interval = 30 seconds) are most likely to be used.

Cisco Virtualization Experience Client Architecture

Cisco Virtualization Experience Client (VXC) endpoints enable the end users to have secure real-time access to content and business applications as well as a rich collaborative user experience. These endpoints provide access to collaboration services that are part of the larger Cisco Virtualization Experience Infrastructure (VXI) solution. For information on a complete end-to-end VXI solution design, refer to the documentation available at

http://www.cisco.com/en/US/solutions/ns340/ns414/ns742/ns1100/landing_vxi.html

Deploying Cisco Virtualization Experience Clients

Cisco Virtualization Experience Clients (VXC) are endpoints in the Cisco Unified Communications portfolio; however, they are more than just simple endpoints because they interact with a user's working environment by providing voice, video, and virtual desktop capability and functionality. A user's work environment can assume various profiles (for example, task worker, knowledge worker, or mobile worker), and Cisco has various Virtualization Experience Clients to meet those different needs.

The Cisco VXC 2111 and VXC 2112 provide an integrated form factor that is paired with a Cisco Unified IP Phone 8961, 9951, or 9971 for a fully integrated voice, video, and virtual desktop environment. The Cisco VXC 2211 and VXC 2212 provide a standalone form factor that can be used as simply a virtual desktop (for a task worker) or can be paired with an IP phone for a fully integrated user environment. The Cisco VXC 4000 provides a software-only solution by using a repurposed PC to provide the user with voice and virtual desktop functionality, while the Cisco VXC 6215 provides a Linux-based thin client for fully integrated voice, video, and virtual desktop in a single device. For the mobile worker, Cisco Cius provides a fully secure and integrated voice, video, and virtual desktop environment.

Cisco Virtualization Experience Client Manager

Cisco Virtualization Experience Client (VXC) Manager is a critical and mandatory component of any Virtualization Experience Client deployment. Cisco VXC Manager uses industry standard protocols to manage network intelligent devices simply, efficiently, remotely, and securely using a component-based architecture. As a required component of any VXC deployment, VXC Manager is used to easily manage, organize, upgrade, control, and support various Cisco VXC devices running Independent Computing Architecture (ICA) or PC over IP (PCoIP) protocol.

**Note**

Cisco VXC 4000 is installed on Microsoft Windows only, thus is not managed by VXC Manager. The VXC 4000 Windows installer can be deployed using any common software deployment utility.

Power Over Ethernet

The Cisco Virtualization Experience Client 2111 and 2112 integrated form factor receives power from the spine connector on the unit, which attaches to the Key Expansion port on the Cisco Unified IP Phone 8961, 9951, and 9971. Power to the Cisco Unified IP Phone 8961, 9951, and 9971 is provided through a PWR-CUBE-4 or through 802.3at inline power.

The Cisco Virtualization Experience Client 2211 and 2212 standalone form factor receives power from one of three sources: the PWR-CUBE-4, 802.3at inline power, or 802.3af inline power.

Cisco Cius media station can receive power from the PWR-CUBE-4 or 802.3at inline power.

The Cisco Virtualization Experience Client 4000 and 6215 do not support inline power over ethernet.

Network Considerations (Call Admission Control, Quality of Service, and Bandwidth)

Cisco VXC zero clients (VXC 2111, 2112, 2211, and 2212) provide a virtual desktop environment through display protocol interaction between the zero client and the connection broker datacenter back end. Quality of Service (QoS) is best-effort, and the Cisco VXC zero clients should be placed in the data VLAN. Display protocols inherently use as much bandwidth as a link provides; therefore, bandwidth controls can be put in place at the network port level, or they can be configured through the back-end Citrix or VMware connection broker settings. When a Cisco Unified IP Phone is paired with a VXC zero client, follow existing Unified Communications call admission control, QoS, and bandwidth guidelines.

Cisco VXC 4000 is a software-only solution that uses applications running locally on the PC for a fully integrated solution that includes a thick Virtual Desktop Infrastructure (VDI) client (Citrix Receiver 3.0 or VMware View Client 5.0) and the VXC 4000 software application. With the VXC 4000, QoS is best-effort, and the VXC 4000 should be placed in the data VLAN because all the traffic, voice, and virtual desktop will originate from the local PC resource.

The Cisco VXC 6215 thin client provides a fully integrated software appliance running locally on the device, and it provides display protocol interaction through standard APIs with the hosted virtual desktop environment when used in a fully integrated Unified Communications deployment. The VXC 6215 can operate as a VDI-only endpoint, similar to a Cisco VXC zero client deployment, or it can operate in a fully integrated voice, video, virtual desktop deployment. In both deployments, QoS is best-effort, and the Cisco VXC 6215 should be placed in the data VLAN. Call admission control for voice and video follow existing Cisco Unified IP Phone guidelines, and bandwidth controls for the virtual desktop are provided through the connection broker settings.

Capacity Planning for Cisco Virtualization Experience Clients

All Cisco Virtualization Experience Clients are deployed with a Virtual Desktop Infrastructure (VDI) component, while some of the deployments may also contain a Unified Communications component. Capacity planning and datacenter resource utilization for VDI when using the Cisco Virtualization Experience Clients is covered as part of the Virtualization Experience Infrastructure (VXI) sizing. For details, refer to the VXI documentation available at

http://www.cisco.com/en/US/solutions/ns340/ns414/ns742/ns1100/landing_vxi.html

Capacity planning for the Unified Communications components depends on which Virtualization Experience Client is deployed:

- Cisco VXC 2111 and 2112 integrated form factor zero clients are paired with a Cisco Unified IP Phone 8961, 9951, or 9971. The Cisco client running in the user's virtual desktop uses the deskphone control mode of the Cisco Unified IP Phone; therefore, Computer Telephony Integration (CTI) planning guidelines must be followed for each client deployed.
- Cisco VXC 2211 and 2212 standalone form factor zero clients can be deployed as VDI-only or as a fully integrated voice, video, and virtual desktop with a number of different Cisco Unified IP Phones. When deployed in a Unified Communications environment, the Cisco client running in the user's virtual desktop uses the deskphone control mode of the Cisco Unified IP Phone; therefore, CTI planning guidelines must be followed for each client deployed.
- Cisco VXC 4000 software appliance is a software-only VXC deployment option. The Cisco client running in the user's virtual desktop uses the deskphone control mode of the VXC 4000; therefore, CTI planning guidelines must be followed for each VXC 4000 deployed.

- Cisco VXC 6215 thin client running in VDI-only mode follows VDI capacity planning; however, when the VXC 6215 is deployed as a fully integrated voice, video, and virtual desktop, additional Unified Communications capacity must be accounted for. The Cisco client running in the user's virtual desktop uses the deskphone control mode of the VXC software appliance running locally on the Linux thin client; therefore, CTI planning guidelines must be followed for each client deployed. The VXC software appliance is a SIP line-side registered device on Cisco Unified CM; therefore, for each VXC 6215 thin client running as a fully integrated voice, video, and virtual desktop, a SIP line device and CTI connection is used.

High Availability for Cisco Virtualization Experience Clients

A Cisco Virtualization Experience Client deployment has several aspects that involve high availability: the Virtual Desktop Infrastructure (VDI), the Cisco client running within the hosted virtual desktop (HVD), and the Unified Communications endpoint registered to Unified CM. A user's desktop virtualization environment can be deployed according to Citrix or VMware high availability guidelines. The Cisco client running within the user's virtual desktop supports high availability according to the guidelines listed for Cisco Unified Personal Communicator (see [High Availability for Cisco Unified Personal Communicator, page 24-13](#)) and Cisco UC Integration™ for Microsoft Lync (see [High Availability for Cisco UC Integration™ for Microsoft Lync, page 24-28](#)). The Unified Communications endpoint registered to Unified CM can be either a Cisco Unified IP Phone when using the Cisco VXC 2111, 2112, 2211, and 2212 zero clients, or the VXC software appliance if using the Cisco VXC 4000 or 6215. These Unified CM registered endpoints support failover for the devices as part of their call control group assignment.

Note

CTI failover is not supported with Cisco Virtualization Experience Clients. Survivable Remote Site Telephony (SRST) is supported with the Cisco Unified IP Phones, but SRST is not supported with the VXC software appliance.

Design Considerations for Cisco Virtualization Experience Clients

The following design considerations apply to the Cisco Virtualization Experience Clients:

- Cisco VXC Manager is a required component to manage, configure, and upgrade Cisco Virtualization Experience Clients.
- Cisco Virtualization Experience Clients provide end-user access as part of the larger Cisco Virtualization Experience Infrastructure deployment. Cisco VXi end-to-end solution deployment design guidance is tested and documented as a Cisco Validated Design.
- CTI guidelines must be observed when deploying Cisco Virtualization Experience Clients in a fully integrated voice, video, and virtual desktop environment.
- With the Cisco VXC Software Appliance, QoS is best-effort and the VXC 6215 should be placed in the data VLAN. For details on traffic marking, refer to the *Enterprise QoS Solution Reference Network Design Guide*, available at

<http://www.cisco.com/go/designzone>

CHAPTER 25

Mobile Unified Communications

Revised: July 31, 2012; OL-21733-18

Mobile Unified Communications solutions and applications provide the ability to deliver features and functionality of the enterprise IP communications environment to mobile workers wherever they might be. With mobile Unified Communications solutions, mobile users can handle business calls on a multitude of devices and access enterprise applications whether moving around the office building, between office buildings, or between geographic locations outside the enterprise. Mobile Unified Communications solutions provide mobile workers with persistent reachability and improved productivity as they move between, and work at, a variety of locations.

Unified Communications mobility solutions can be divided into two main categories:

- Mobility within the enterprise

This type of mobility is limited to movement of users within enterprise locations.

- Mobility beyond the enterprise

This type of mobility refers to mobility beyond the enterprise infrastructure and typically involves some form of Internet, mobile voice network, and/or mobile data network traversal.

Mobility within the enterprise is limited to utilization within the network boundaries of the enterprise, whether those boundaries span only a single physical building, multiple physical buildings in close proximity or separated by long distances, or even home offices where network infrastructure is still controlled and managed by the enterprise when it is extended to the home office.

On the other hand, mobility beyond the enterprise involves a bridging of the enterprise infrastructure to the Internet or mobile provider infrastructures and finds users leveraging public and private networks for connectivity to enterprise services. In some cases the lines between these two types of mobility are somewhat blurred, especially in scenarios where mobile devices are connecting back to the enterprise for Unified Communications services over the Internet or mobile data and mobile voice networks.

Mobility within the enterprise can be divided into three main areas based on feature sets and solutions:

- Campus or single-site mobility

With this type of enterprise mobility, users move around within a single physical location typically bounded by a single IP address space and PSTN egress/ingress boundary. This type of mobility involves operations and features such as phone movement from one physical network port to another, wireless LAN device roaming between wireless infrastructure access points, and even Cisco Extension Mobility (EM), where users temporarily apply their device profile including their enterprise number to a particular phone in a different area.

- Multisite mobility

With this type of mobility, users move within the enterprise from one physical location to another, and this movement typically involves crossing IP address spaces as well as PSTN egress/ingress boundaries. This type of mobility involves the same types of operations and features as with campus mobility (physical hardware moves, WLAN roaming, and Cisco Extension Mobility) but replicated at each site within the enterprise. In addition, the Device Mobility feature can be leveraged to ensure that, as user's move devices between sites, phone calls are routed through the local site egress gateway, media codecs are negotiated appropriately, and call admission control mechanisms are aware of the device's location.

- Remote site mobility

With this type of mobility, users move to a location outside the enterprise but still have some form of secure connection back to the enterprise, which virtually extends the enterprise network to the remote location. This type of mobility typically involves remote teleworker solutions such as Cisco Virtual Office as well as other remote connectivity methods such as VPN-based phones and the Office Extend Access Point feature.

Mobility beyond the enterprise can be divided into four high-level Cisco solution sets:

- Cisco Unified Mobility

As part of Cisco Unified Communications Manager (Unified CM), the Cisco Unified Mobility feature suite offers the ability to associate a mobile user's enterprise number to their mobile or remote devices and provides connectivity between the user's fixed enterprise desk phone on the enterprise network and the user's mobile device on the mobile voice provider network. This type of functionality is sometimes referred to as fixed mobile convergence.

- Dual-mode phones and clients

Dual-mode phones and devices provide dual radio antennas for connecting to both 802.11 wireless LAN networks and cellular voice and data networks. With a dual-mode client deployed on these devices, they can be associated to Unified CM through the enterprise wireless LAN or over a secure Internet-based connection (public or private WLAN hot spot or mobile data network) and can in turn leverage the IP telephony infrastructure of the enterprise for making and receiving calls. When mobile users do not have connectivity to the enterprise with these devices, phone calls are made using the mobile voice provider network.

- Cisco Unified Mobile Communicator

The Cisco Unified Mobile Communicator solution provides remote access to a variety of enterprise Unified Communications applications from a user's mobile device. By connecting to the enterprise over a secure mobile data connection, the Cisco Unified Mobile Communicator client has access to enterprise mobility features as well as call routing, voicemail, and presence services.

- Direct connect mobile clients

Direct connect mobile clients also provide secure remote access to enterprise voice and collaboration applications and services such as call routing, corporate directory access, and presence and instant messaging services, all from a user's mobile device. These clients also provide dual-mode functionality, enabling voice over WLAN capabilities when connected to the enterprise WLAN network.

The various applications and features discussed in this chapter apply to all Cisco Unified Communications deployment models unless otherwise noted.

This chapter begins with a discussion of mobility features and solutions available within the enterprise infrastructure. It includes an examination of functionality and design considerations for campus or single-site deployments, multisite deployments, and even remote site deployments. This comprehensive set of solutions provides many benefits for mobile workers within the enterprise, including

enterprise-class communications and improved productivity regardless of physical location. This discussion of mobility within the enterprise paves the way for examination of mobility solutions beyond the enterprise that leverage the mobile provider and Internet provider infrastructure and capabilities. These solutions enable a bridging of the enterprise network infrastructure and mobile functionality to the provider network infrastructure in order to leverage advanced mobile features and communication flows that can be built on the solid enterprise mobility infrastructure.

This chapter provides a comprehensive examination of mobility architectures, functionality, and design and deployment implications for enterprise Unified Communications mobility solutions. The analysis and discussions contained within this chapter are organized at a high level as follows:

- Mobility within the Enterprise

Mobility Within the Enterprise

This section examines mobility features and solutions available within the enterprise. This examination includes discussions related to architecture, functionality, and design and deployment implications for the following types of enterprise mobility

- [Campus Enterprise Mobility, page 25-5](#)
- [Multisite Enterprise Mobility, page 25-13](#)
- [Remote Enterprise Mobility, page 25-32](#)

Campus Enterprise Mobility

Campus or single-site enterprise mobility refers to mobility within a single physical location typically bounded by a single IP address space and PSTN egress/ingress boundary. Mobility here not only includes the movement of users within this physical location but also the movement of endpoint devices.

Campus Enterprise Mobility Architecture

As illustrated in [Figure 25-1](#), the enterprise campus mobility architecture is based on a single physical location that may include a single building or multiple buildings (as depicted) in close proximity, such that users are able to move freely within the campus and maintain IP and PSTN connectivity. Typically campus deployments involve a shared common connection or set of connections to the PSTN and Internet provider networks bound by a single IP address space and PSTN egress/ingress boundary. All users within this enterprise campus are connected to and reachable from a common network infrastructure.

Figure 25-1 Campus Enterprise Mobility Architecture

Types of Campus Mobility

Mobility within the campus enterprise typically involves the movement of devices, users, or both throughout the campus infrastructure. Campus enterprise mobility within Cisco Unified Communications deployments can be divided into three main categories: physical wired phone movement, wireless device movement, and user movement without phone hardware or software. Each of these types of movements are discussed below.

Physical Wired Device Moves

As shown in [Figure 25-1](#), movement of physical wired phones is easily accommodated within the campus infrastructure. These types of phone movements can occur within a single floor of a building, across multiple floors of a building, or even between buildings within the campus. Unlike with traditional PBX deployments where physical phone ports are fixed to a particular office, cubicle, or other space within the building, in IP telephony deployments a phone can be plugged into any IP port within the network infrastructure in order to connect to the IP PBX.

In a Cisco environment, this means a user can simply unplug a Cisco Unified IP Phone from the network, pick it up and carry it to another location within the campus, and plug it into another wired network port. Once connected to the new network location, the phone simply re-registers to Unified CM and is able to make and receive calls just like in the previous location.

This same physical device movement also applies to software-based phones running on wired personal computers. For example, a user can move a laptop computer running Cisco IP Communicator or Cisco Unified Personal Communicator from one location to another within the campus, and after plugging the laptop into a network port in the new location, the software-based phone can re-register to Unified CM and begin to handle phone calls again.

To accommodate physical device mobility within the campus, care should be taken when physically moving phone devices or computers running software-based phones to ensure that the network connection used at a new location has the same type of IP connectivity, connection speed, quality of service, security, and network services such as in-line power and dynamic host control protocol (DHCP), as were provided by the previous location. Failure to replicate these connection parameters, services, and features will lead to reduced functionality or in some cases complete loss of functionality.

Wireless Device Roaming

Wireless devices can move or roam throughout the enterprise campus, as shown in [Figure 25-1](#), provided a wireless LAN network has been deployed to provide wireless network connectivity to the campus edge.

Examples of wireless devices include Cisco Unified Wireless IP Phone 7925G, wirelessly attached Cisco Unified IP Phone 9971, Cisco Cius, direct connect mobile clients such as Cisco Mobile 8.5 for Nokia (see [Direct Connect Mobile Clients, page 25-102](#)), and dual-mode phone clients such as Cisco Jabber and Nokia Call Connect (see [Dual-Mode Phones and Clients, page 25-66](#)).

A WLAN network consists of one or more wireless access points (APs), which provide wireless network connectivity for wireless devices. Wireless APs are the demarcation point between the wireless network and the wired network. Multiple APs are deployed and distributed over a physical area of coverage in order to extend network coverage and capacity.

Because wireless phones rely on the underlying WLAN infrastructure to carry both critical signaling and the real-time voice media traffic, it is necessary to deploy a WLAN network optimized for both data and real-time voice traffic. A poorly deployed WLAN network will be subjected to large amounts of interference and diminished capacity, leading not only to poor voice quality but in some cases dropped or missed calls. This will in turn render the WLAN deployment unusable for making and receiving voice calls. Therefore, when you deploy wireless phones and client devices, it is imperative to conduct a WLAN radio frequency (RF) site survey before, during, and after the deployment to determine appropriate cell boundaries, configuration and feature settings, capacity, and redundancy to ensure a successful voice over WLAN (VoWLAN) deployment.

APs can be deployed autonomously within the network so that each AP is configured, managed, and operated independently from all other APs, or they can be deployed in a managed mode in which all APs are configured, managed, and controlled by a WLAN controller. In the latter mode, the WLAN controller is responsible for managing the APs as well as handling AP configuration and inter-AP roaming. In either case, to ensure successful VoWLAN deployment, APs should be deployed using the following general guidelines:

- As shown in [Figure 25-2](#), non-adjacent WLAN AP channel cells should overlap by a minimum of 20%. This overlap ensures that a wireless device can successfully roam from one AP to the next as the device moves around within the campus location while still maintaining voice and data network connectivity. A device that successfully roams between two APs is able to maintain an active voice call without any noticeable change in the voice quality or path.

Figure 25-2 WLAN Channel Cell Overlap

- As shown in [Figure 25-3](#), WLAN AP channel cells should be deployed with cell power-level boundaries (or channel cell radius) of -67 decibels per milliwatt (dBm). Additionally, the same-channel cell boundary separation should be approximately 19 dBm.

A cell radius of approximately -67 dBm (or less) minimizes packet loss, which can be problematic for real-time voice traffic. A same-channel cell separation of 19 dBm is critical to ensure that APs or clients do not cause co-channel interference to other devices associated to the same channel, which would likely result in poor voice quality. The cell radius guideline of -67 dBm applies for both 2.4 GHz (802.11b/g) and 5 GHz (802.11a) deployments.

Figure 25-3 WLAN Cell Radius and Same Channel Cell Separation

Note

The 19 dBm same-channel cell separation is simplified and is considered ideal. It is very unlikely that this 19 dBm of separation can be achieved in most deployments. The most important RF design criteria are the -67 dBm cell radius and the minimum 20% recommended overlap between cells. Designing to these constraints optimizes channel separation.

Wireless roaming is not limited to wireless phones but also applies to software-based phones running on wireless personal computers. For example, a user can roam wirelessly throughout the campus with a laptop computer running Cisco IP Communicator or Cisco Unified Personal Communicator.

Most wireless APs, wireless phones, and wireless PC clients provide a variety of security options for providing secure access to the enterprise WLAN. In all cases, select a security method supported by both the WLAN infrastructure and the wireless devices that matches the security policies and requirements of the enterprise.

For more information on the Cisco Unified Wireless Network Infrastructure, see [Wireless LAN Infrastructure, page 3-57](#). For more details on Voice over WLAN design, refer to the *Voice over Wireless LAN Design Guide*, available at

http://www.cisco.com/en/US/solutions/ns340/ns414/ns742/ns820/landing_voice_wireless.html

Extension Mobility (EM)

As shown in [Figure 25-1](#), in addition to physical movement of wired and wireless phones, the users themselves can also move around within the campus infrastructure without phone or PC hardware. In these cases, a user can move their enterprise extension or number from one device to another by applying a device profile containing the user's enterprise number and other settings.

The EM feature allows users to log on to IP phones located throughout the campus using a set of security credentials (user ID and PIN number). Once logged on, the user's personal device profile, including their enterprise phone number, calling privileges, and even their configured speed dials, is applied to the phone temporarily until the user logs out of the device or the login times out. The EM feature is available as part of Unified CM.

This feature is particularly useful for mobile enterprise users who spend considerable amounts of time outside the enterprise and are physically in the office only occasionally. By providing temporary office space for these types of mobile users, sometimes referred to as hot seating or free seating, a system administrator can accommodate large numbers of mobile users who only occasionally and temporarily need to use IP phone hardware.

To leverage EM within the campus the Unified CM administrator must configure user device profile(s) and user credentials, and subscribe IP phone(s) to the EM phone service.

For more information about EM, see [Extension Mobility, page 19-7](#).

Campus Enterprise Mobility High Availability

Campus enterprise mobility features and solutions should be configured and deployed in a redundant fashion to ensure high availability of mobility functions and features.

For example, to effectively support hard-wired IP phones and computers running software-based IP phones, redundant and prevalent network connections or ports should be made available. Furthermore, these redundant network connections should be deployed with appropriate characteristics, including appropriate security, quality of service, and other network-based features to ensure optimal operation and voice quality for wired devices as they are moved from location to location. Ultimately a successful campus mobility deployment is possible only if the underlying network connectivity, PSTN connectivity, and other applications and services are deployed in a highly available fashion.

Likewise, when deploying or tuning a WLAN network for wireless device connectivity and roaming, it is also important to consider high availability for wireless services. To ensure resilient and sufficient coverage for the number of devices being deployed, a WLAN network should be deployed in a manner that ensures that adequate and redundant cells of coverage are provided without overlapping same-channel cells. Network connectivity for wireless devices and clients can be made highly available by providing ample cell coverage without same-channel cell overlap and sufficient overlap of different channel cells in order to facilitate roaming between APs.

Finally, when leveraging EM for user mobility within the campus, you should deploy this feature in a redundant fashion so that the failure of a single node within the Unified CM cluster does not prevent the operation of the Extension Mobility feature. For information on deploying Cisco Extension Mobility in a highly available manner, see [High Availability for Extension Mobility, page 19-14](#).

Capacity Planning for Campus Enterprise Mobility

Deploying campus enterprise mobility successfully requires providing ample capacity to accommodate all mobile users exercising these mobility features and solutions.

Capacity considerations for physical movement of wired devices and computers depend completely on the number of network ports that are made available within the campus network infrastructure. In order for users to move devices around the campus, there must be some number of available network ports in each location that can be used to connect these mobile users' devices. A shortage of network ports to accommodate this wired device movement can result in an inability to move a device physically from one location to another.

When deploying wireless devices and leveraging wireless device roaming within the enterprise WLAN, it is also important to consider the device connectivity and call capacity of the WLAN infrastructure. Oversubscription of the campus WLAN infrastructure in terms of number of devices or number of active calls will result in dropped wireless connections, poor voice quality, and delayed or failed call setup. The chances of oversubscribing a VoWLAN deployment are greatly minimized by deploying sufficient numbers of APs to handle required call capacities. AP call capacities are based on the number of simultaneous VoWLAN bidirectional streams that can be supported in a single channel cell area. The general rule for VoWLAN call capacities is as follows:

- Maximum of 27 simultaneous VoWLAN bidirectional streams per 802.11g/n (2.4 GHz) channel cell with Bluetooth disabled and 24 Mbps or higher data rates.
- Maximum of 27 simultaneous VoWLAN bidirectional streams per 802.11a/n (5 GHz) channel cell with 24 Mbps or higher data rates.

These call capacity values are highly dependent upon the RF environment, the VoWLAN wireless handset features, and underlying WLAN system features. Actual capacities for a particular deployment could be less.

**Note**

A single call between two wireless phones associated to the same AP is considered to be two simultaneous VoWLAN bidirectional streams.

Scalability of EM is dependent almost completely on the login/logout rate of the feature within Unified CM. A maximum of 375 sequential login and logout operations per minute is supported per Unified CM cluster when login and logout operational load is spread across two nodes of the cluster. Depending on the Unified CM cluster server hardware, the capacity of a deployment could be much less than this. Therefore, it is important to know the number of extension mobility users enabled within the Unified CM cluster as well as how many users are moving around the campus and exercising this feature at any given time to ensure that sufficient EM login/logout capacity can be provided to these mobile users. For more information on EM capacity planning, see [Capacity Planning for Extension Mobility, page 19-16](#).

In all cases, the Unified CM cluster within the campus must have sufficient device registration capacity to handle device registration for moved devices, regardless of whether they are wired or wireless devices. Of course, assuming all devices being moved throughout the campus are already deployed within the campus network, then sufficient capacity within Unified CM should already be in place prior to the movement of devices. If new devices are added to the deployment for mobility purposes, however, device registration capacity should be considered and, if necessary, additional capacity should be added.

Finally, given the many features and functions provided by Unified CM, configuration and deployment of these mobility solutions does have sizing implications for the overall system. Determining actual system capacity is based on considerations such as the number of endpoint devices, EM users, busy hour

call attempt (BHCA) rates, and number of CTI applications deployed. For more information on general system sizing, capacity planning, and deployment considerations, see the chapter on [Unified Communications Design and Deployment Sizing Considerations, page 29-1](#).

Design Considerations for Campus Enterprise Mobility

Observe the following design recommendations when deploying campus enterprise mobility features and solutions:

- To accommodate physical device mobility within the campus ensure that the network connection used at a new location has the same type of IP connectivity (VLANs, inter-VLAN routing, and so forth), connection speed, quality of service, security, and network services (in-line power, dynamic host control protocol (DHCP), and so forth) as provided by the previous network connection. Failure to replicate these connection parameters, services, and features will lead to diminished functionality and in some case complete loss of functionality.
- When deploying wireless IP devices and software-based clients, it is imperative to conduct a WLAN radio frequency (RF) site survey before, during, and after the deployment to determine appropriate cell boundaries, configuration and feature settings, capacity, and redundancy to ensure a successful voice over WLAN (VoWLAN) deployment.
- APs should be deployed with a minimum cell overlap of 20%. This overlap ensures that a dual-mode device can successfully roam from one AP to the next as the device moves around within a location, while still maintaining voice and data network connectivity.
- APs should be deployed with cell power level boundaries (or channel cell radius) of -67 dBm in order to minimize packet loss. Furthermore, the same-channel cell boundary separation should be approximately 19 dBm. A same-channel cell separation of 19 dBm is critical for ensuring that APs or clients do not cause co-channel interference to other devices associated to the same channel, which would likely result in poor voice quality.
- Deploy EM services in a highly redundant manner so that the loss of a single Unified CM node does not have adverse effects on the feature operation. If EM services are critical, consider deploying a server load balancing solution to route around Unified CM node failures and provide highly available functionality. For more information on EM high availability, see [High Availability for Extension Mobility, page 19-14](#).
- Provide sufficient wireless voice call capacity on the campus network by deploying the appropriate number of wireless APs to handle the desired call capacity based on wireless user BHCA rates. Each 802.11g (2.4 GHz) or 802.11a (5 GHz) channel cell can support a maximum of 27 simultaneous bidirectional streams or calls with 24 Mbps or higher data rates. For 802.11g deployments, Bluetooth must be disabled to achieve this capacity.
- A maximum of 375 sequential EM logins and logouts per minute can be supported across a single Unified CM cluster. A maximum of two Unified CM subscriber nodes can actively handle EM logins. For more information on EM capacity, see [Capacity Planning for Extension Mobility, page 19-16](#).

Multisite Enterprise Mobility

Multisite enterprise mobility refers to mobility within an enterprise with multiple physical locations, each with a unique IP address space and PSTN egress/ingress boundary. Mobility in this case includes not only the movement of users and endpoint devices within each physical location but also movement of users and endpoint devices between sites and locations.

Multisite Enterprise Mobility Architecture

As shown in [Figure 25-4](#), the multisite enterprise mobility architecture is based on two or more locations or sites geographically separated. Sites may vary in size from large numbers of users and devices in a central or campus site to smaller numbers of users and devices in medium-sized regional sites or smaller branch sites. Typically multisite enterprise deployments consist of IP WAN links interconnecting sites as well as local PSTN egress/ingress at each location. In addition, critical services are often replicated at each physical site in order to maintain features and functions during network outages between sites. From a mobility perspective, users and their devices may be mobile within a site or between sites.

Figure 25-4 Multisite Enterprise Mobility Architecture

Note

While [Figure 25-4](#) depicts a multisite deployment with centralized call processing (as evidenced by a single Unified CM cluster within the central site), the same design and deployment considerations for multisite enterprise mobility deployments apply to distributed call processing environments. Differences in mobility feature operation when deployed in distributed call processing environments are described in the following discussions.

Types of Multisite Enterprise Mobility

Mobility within a multisite enterprise deployment involves not only the movement of devices, users, or both within a single site, but also movement of users and devices between sites.

The same types of mobility features and solutions supported with campus or single site enterprise deployments apply to intra-site movement of users and devices within any single site of a multisite deployment. These include physical wired phone movement, wireless phone roaming, and extension mobility. For information on these types of mobility solutions and functions, see [Campus Enterprise Mobility, page 25-5](#).

For inter-site mobility in a multisite deployment, these same mobility features are also supported in much the same way. However, the key difference with these features when applied between two or more sites is that they are augmented with the Device Mobility feature. The Device Mobility feature provides a mechanism for dynamic location awareness of devices based on the IP address the device uses when connecting to the enterprise network.

Physical Wired Device Moves

Movement of physical wired phones is easily accommodated within each site of a multisite deployment as well as between sites. Just as with a campus or single-site deployment, wired device movement limited to a single site of a multisite deployment simply involves unplugging a Cisco Unified IP Phone from the network, moving it to another location within the site, and plugging it into another wired network port. Once connected to the new network location, the phone simply re-registers to Unified CM and is able to make and receive calls just like in the previous location.

Movement of wired devices between sites or locations in a multisite deployment involve the same basic behavior. However, the Device Mobility feature, when combined with this type of mobility, ensures that call admission control operations and gateway and codec selection are appropriate once the device re-registers in the new location to which it has been moved. See [Device Mobility, page 25-16](#), for information about this feature.

Wireless Device Roaming

Just as with a single-site campus deployment, wireless devices can move or roam throughout a multisite enterprise deployment, as shown in [Figure 25-4](#), provided wireless LAN network infrastructure is available at each site to provide wireless network connectivity. However, as with the movement of wired phones between sites, the Device Mobility feature should also be deployed for wireless devices to ensure that the correct gateway and codec are used when making and receiving calls and that call admission control manages bandwidth appropriately. See [Device Mobility, page 25-16](#), for information about this feature.

For distributed call processing environments, just as with wired phones, wireless devices should be configured to register with only a single Unified CM cluster to avoid potential issues with call routing.

Extension Mobility (EM)

In addition to supporting EM within a single site, as illustrated in [Figure 25-4](#), this feature is also supported between sites to enable users to move between sites within the enterprise and log on to phones in each location.

EM is also supported in distributed call processing deployments when users move between sites and phones on different Unified CM clusters. To support extension mobility in distributed call processing environments, you might need to configure the Cisco Extension Mobility Cross Cluster (EMCC) feature. For information about this feature, see [Extension Mobility Cross Cluster \(EMCC\)](#), page 19-9.

Device Mobility

In Cisco Unified Communications Manager (Unified CM), a site or a physical location is identified using various settings such as locations, regions, calling search spaces, and media resources. Cisco Unified IP Phones residing in a particular site are statically configured with these settings. Unified CM uses these settings for proper call establishment, call routing, media resource selection, and so forth. However, when dual-mode phones and other mobile client devices such as Cisco IP Communicator, Cisco Cius, or Cisco Unified Wireless IP Phones are moved from their home site to a remote site, they retain the home settings that are statically configured on the phones. Unified CM then uses these home settings on the phones in the remote site. This situation is undesirable because it can cause problems with call routing, codec selection, media resource selection, and other call processing functions.

Cisco Unified CM uses a feature called Device Mobility, which enables Unified CM to determine if the IP phone is at its home location or at a roaming location. Unified CM uses the device's IP subnets to determine the exact location of the IP phone. By enabling device mobility within a cluster, mobile users can roam from one site to another, thus acquiring the site-specific settings. Unified CM then uses these dynamically allocated settings for call routing, codec section, media resource selection, and so forth.

This section begins with a discussion surrounding the main purpose for the Device Mobility feature, followed by an in-depth discussion of the Device Mobility feature itself. This discussion covers the various components and configuration constructs of the Device Mobility feature. This section also presents an in-depth discussion of the impact of the Device Mobility feature on the enterprise dial plan, including the implication for various dial plan models.

Need for Device Mobility

This section explains the need for device mobility when there are many mobile users in a Unified CM cluster.

Figure 25-5 illustrates a hypothetical network containing a Unified CM cluster without the Device Mobility feature, located at the headquarter site (HQ). The cluster has two remote sites, Branch1 and Branch2. All intra-site calls use G.711 voice codecs, while all inter-site calls (calls across the IP WAN) use G.729 voice codecs. Each site has a PSTN gateway for external calls.

Figure 25-5 Example Network with Two Remote Sites

When a user in Branch1 moves to Branch2 and calls a PSTN user in Denver, the following behavior occurs:

- Unified CM is not aware that the user has moved from Branch1 to Branch2. An external call to the PSTN is sent over the WAN to the Branch1 gateway and then out to the PSTN. Thus, the mobile user continues to use its home gateway for all PSTN calls.
- The mobile user and Branch1 gateway are in the same Unified CM region and location. Location-based call admission control is applicable only for devices in different locations, and an intra-region call uses the G.711 voice codec. Thus, the call over the IP WAN to the Branch1 gateway uses the G.711 codec and is not tracked by Unified CM for purposes of call admission control. This behavior can result in over-subscription of the IP WAN bandwidth if all the remote links are low-speed links.
- The mobile user creates a conference by adding multiple Branch2 users to the existing call with the PSTN user in Denver. The mobile user uses the conferencing resource that is on the Branch1 gateway, therefore all conference streams flow over the IP WAN.

**Note**

Device Mobility is an intra-cluster feature and does not span multiple Unified CM clusters. In distributed call processing environments, Device Mobility must be enabled and configured on each Unified CM cluster within the deployment.

Device Mobility Architecture

The Unified CM Device Mobility feature helps solve the problems mentioned above. This section briefly explains how the feature works. However, for a detailed explanation of this feature, refer to the product documentation available on <http://www.cisco.com>.

Some of the device mobility elements include:

- Device Mobility Info — Configures IP subnets and associates device pools to the IP subnets.
- Device Mobility Group — Defines a logical group of sites with similar dialing patterns (for example, US_dmg and EUR_dmg in Figure 25-6).
- Physical Location — Defines the physical location of a device pool. In other words, this element defines the geographic location of IP phones and other devices associated with the device pool. (For example, all San Jose IP phones in Figure 25-6 are defined by physical location SJ_phyloc.)

Figure 25-6 illustrates the relationship between all these terms.

Figure 25-6 Relationship of Device Mobility Components

Unified CM assigns a device pool to an IP phone based on the device's IP subnet. The following steps, illustrated in Figure 25-7, describe the behavior:

1. The IP phone tries to register to Unified CM by sending its IP address in the Skinny Client Control Protocol (SCCP) or Session Initiation Protocol (SIP) registration message.
2. Unified CM derives the device's IP subnet and matches it with the subnet configured in the Device Mobility Info.

- If the subnet matches, Unified CM provides the device with a new configuration based on the device pool configuration.

Figure 25-7 Phone Registration Process

Unified CM uses a set of parameters under the device pool configuration to accommodate Device Mobility. These parameters are of the following two main types:

- [Roaming Sensitive Settings, page 25-19](#)
- [Device Mobility Related Settings, page 25-20](#)

Roaming Sensitive Settings

The parameters under these settings will override the device-level settings when the device is roaming within or outside a Device Mobility Group. The parameters included in these settings are:

- Date/time Group
- Region
- Media Resource Group List
- Location
- Network Locale
- SRST Reference
- Physical Location
- Device Mobility Group

The roaming sensitive settings primarily help in achieving proper call admission control and voice codec selection because the location and region configurations are used based on the device's roaming device pool.

For more details on various call admission control techniques, see the chapter on [Call Admission Control, page 11-1](#).

The roaming sensitive settings also update the media resource group list (MRGL) so that appropriate remote media resources are used for music on hold, conferencing, transcoding, and so forth, thus utilizing the network efficiently.

The roaming sensitive settings also update the Survivable Remote Site Telephony (SRST) gateway. Mobile users register to a different SRST gateway while roaming. This registration can affect the dialing behavior when the roaming phones are in SRST mode.

For example, if a user moves with their phone to a new location that loses connectivity to Unified CM, then based on the roaming sensitive Device Mobility settings, a new SRST reference is configured for the moved phone and the moved phone will now be under control of the local roaming location SRST router. When this occurs, not only would the user's phone be unreachable from the PSTN or other sites because the device's DID will not have changed and will still be anchored at their home location, but in addition reachability from devices within the local failed site might be difficult without the use of abbreviated dialing as implemented within SRST.

As an example, assume that a user moves a phone from their home location in San Jose, which has a directory number of 51234 and an associated DID of 408 555 1234 to a remote location in New York, and that the link between the New York site and San Jose fails shortly after the user roams to the New York location. In this scenario the phones in the New York site will all fail-over to the SRST router in that site. The roaming/moved phone will also register to the New York SRST router because its SRST reference was updated based on the device mobility roaming sensitive settings. In this scenario, the local New York devices will register to the SRST router with five-digit extensions just as they do to Unified CM, and as a result the roaming phone still has a directory number of 51234. To reach the roaming phone from all other sites and from the PSTN, the number 408 555 1234 will be routed to the San Jose PSTN gateway to which this particular DID is anchored. Because the New York site is disconnected from the San Jose site, any such calls will be routed to the users' voicemail boxes since they will be unreachable at their desk phones. Likewise, calls internally within the local failed site will have to be dialed using five-digit abbreviated dialing or based on the configured digit prefixing as defined by the **dialplan-pattern** and **extension-length** commands within the SRST router. In either case, local callers will have to understand the required dialing behavior for reaching the local roaming device by abbreviated dialing. In some cases this may be simply five-digit dialing or it may be that users have to dial a special digit prefix to reach the local roaming phone. The same logic applies to outbound dialing from the moved or roaming phone in New York because its dialing behavior might have to be altered in order to reach local extensions using abbreviated dialing. Outbound dialing to the PSTN from the local roaming device should remain the same, however.

Device Mobility Related Settings

The parameters under these settings will override the device-level settings only when the device is roaming within a Device Mobility Group. The parameters included in these settings are:

- Device Mobility Calling Search Space
- AAR Calling Search Space
- AAR Group
- Calling Party Transformation CSS

The device mobility related settings affect the dial plan because the calling search space dictates the patterns that can be dialed or the devices that can be reached.

Device Mobility Group

Device Mobility Group, as explained earlier, defines a logical group of sites with similar dialing patterns (for example, sites having the same PSTN access codes and so forth). With this guideline, all sites have similar dialing patterns in the site-specific calling search spaces. Sites having different dialing behavior are in a different Device Mobility Group. As illustrated in [Figure 25-6](#), the San Jose and RTP sites' Device Mobility Info, Device Pools, and Physical Locations are different; however, all of these have been assigned to the same Device Mobility Group US_dmg because the required dialing patterns and PSTN access codes are the same between the two locations. On the other hand, the London site is assigned to a separate Device Mobility Group EUR_dmg due to the fact that the required dialing patterns and PSTN access codes there are different than those of the US sites. A user roaming within a Device

Mobility Group may preserve his dialing behavior at the remote location even after receiving a new calling search space. A user roaming outside the Device Mobility Group may still preserve his dialing behavior at the remote location because he uses his home calling search space.

However, if a Device Mobility Group is defined with sites having different dialing patterns (for example, one site requires users to dial 9 to get an outside line while another site requires users to dial 8 to get an outside line), then a user roaming within that Device Mobility Group might not preserve his same dialing behavior at all locations. A user might have to dial digits differently at different locations after receiving a new calling search space at each location. This behavior can be confusing for users, therefore Cisco recommends against assigning sites with different dialing patterns to the same Device Mobility Group.

Device Mobility Operation

The flowchart in Figure 25-8 represents the operation of the Device Mobility feature.

Figure 25-8 Operation of the Device Mobility Feature

The following guidelines apply to the Device Mobility feature:

- If the overlapping parameters listed in [Figure 25-8](#) have the same configurations on the device as well as the device pool, then these parameters may be set to NONE on the device. These parameters must then be configured on the device pool. This practice can greatly reduce the amount of configuration because the devices do not have to be configured individually with all the parameters.
- Define one physical location per site. A site may have more than one device pool.
- Define sites with similar dialing patterns for PSTN or external/off-net access with the same Device Mobility Group.
- A "catch-all" Device Mobility Info with IP subnet 0.0.0.0 may be defined for all non-defined subnets, depending on the company policy. This Device Mobility Info may be used to assign a device pool that can restrict access or usage of the network resources. (For example, the device pool may be configured with a calling search space NONE that will block any calls from the device associated with this device pool while roaming.) However, by doing so, administrators must be aware of the fact that this will block all calls, even 911 or other emergency calls. The calling search space may be configured with partitions that will give access only to 911 or other emergency calls.

Dial Plan Design Considerations

When using the Device Mobility feature, the dialing behavior of the phone depends on the roaming (or home) location of a phone. As discussed earlier, the device mobility related settings within the device pool affect the call flow behavior because the calling search space dictates the reachability of destination patterns within Unified CM. This section discusses several dial plan approaches for Device Mobility.

For detailed explanations of various dial plan approaches, see the chapter on [Dial Plan, page 9-1](#).

Device Mobility Considerations for Building Classes of Service

Typically, a mobile user should have the same calling privileges while he is roaming as he would have at his home location. The chapter on [Dial Plan, page 9-1](#), discusses two approaches for building classes of service: [Traditional Approach, page 25-23](#), and [Line/Device Approach, page 25-23](#).

Traditional Approach

With the traditional approach, both path selection and class of service are determined by the device-level calling search space. With the line/device approach, path selection is determined by the device-level calling search space and class of service is determined by the line-level calling search space. For all deployments, the line/device approach is recommended for building classes of service. In particular with deployments utilizing Device Mobility, it is important to use the line/device approach because this approach ensures that all calls made by a mobile device will use the roaming site or local gateway rather than the home site gateway. While the traditional approach can certainly be used, this chapter covers only the recommended line/device approach. For a general discussion of the traditional approach, see the chapter on [Dial Plan, page 9-1](#).

Line/Device Approach

Unified CM concatenates the line and device calling search spaces for a given IP phone. The following key concepts apply to the line/device approach:

- The device calling search space provides call routing information.
- The line calling search space provides class-of-service information.

With the Device Mobility feature, the device calling search space is dynamically associated to the phone based on its location. The key concept of the line/device remains the same when using Device Mobility. The line calling search space provides the class-of-service information, while the roaming or home device calling search space that is selected provides the call routing information.

Figure 25-9 shows an example of building classes of service with the line/device approach when using Device Mobility in a cluster.

Figure 25-9 Line/Device Approach to Building Classes of Service

Cisco recommends using the line/device approach for building classes of service. This model has significant advantages when using Device Mobility because it greatly reduces the number of device pools needed, as indicated by the following formula:

$$\text{Total device pools} = (\text{Number of sites})$$

The following design considerations apply to this approach:

- The calling search space on the phone device can be configured to NONE. The calling search space configuration on the device pool will be assigned to the phone device. This method can greatly reduce the amount of configuration because you do not have to configure the phones individually with a device calling search space.

- There is no restriction on having the same classes of service or calling privileges for all mobile users. Because the classes of service are defined using the line calling search space, a mobile user keeps the same class of service while roaming.
- A mobile user may have both Device Mobility and Extension Mobility enabled in his profile.

Choosing a Dial Plan Model

As discussed in the chapter on [Dial Plan, page 9-1](#), there are three main approaches for the dial plan model:

- Uniform on-net dialing
- Variable length on-net dialing with partitioned addressing
- Variable length on-net dialing with flat addressing

The following sections present various dial plan models combined with an approach for building classes of service.

Uniform On-Net Dialing Using the Line/Device Approach

Figure 25-10 shows a uniform on-net dial plan for Device Mobility.

Figure 25-10 Uniform On-Net Dial Plan for Device Mobility

This is the most basic dial plan model, and it has the following characteristics:

- Mobile users can use abbreviated dialing (four digits for the example in Figure 25-10) from any location.
- Abbreviated speed dialing for internal extensions continues to work on the mobile user's phone in roaming locations.
- Mobile users use a "roaming" calling search space when they are at a remote location. Cisco recommends having the same access codes for PSTN calls at all sites. If the PSTN access codes are not the same, users must learn the different access codes.

Variable Length On-Net Dialing with Partitioned Addressing Using the Line/Device Approach

Figure 25-11 shows a variable-length on-net dial plan with partitioned addressing for Device Mobility.

Figure 25-11 Variable-Length On-Net Dial Plan with Partitioned Addressing for Device Mobility

190170

The following design considerations apply to the dial plan model in [Figure 25-11](#):

- Calls might be routed to the wrong destination when mobile users use abbreviated dialing from a roaming location. For the example in [Figure 25-11](#), assume that mobile user 1 in Site 1 with extension 1000 moves to Site 2. If user 1 dials 1001 with the intention of calling a person in Site 1, the call will be routed to extension 1001 in Site 2 instead. If this behavior is not desired, consider defining each site as a Device Mobility Group. As shown in [Figure 25-8](#), when devices roam, if the Device Mobility Group of the "home" device pool is different from the Device Mobility Group defined by the "roaming" device pool of the Device Mobility Info, then only the roaming sensitive settings from the "roaming" device pool are applied. This means that the Device Mobility calling search space that is not a roaming sensitive setting will not be used, and instead the "home" calling search space (as defined at the device level setting or the device pool setting of the phone) would be used when the roaming phone makes a call. This means that for the example shown in [Figure 25-11](#), when user 1 dials extension 1001 while in Site 2, the call will be routed using the "home" site calling search space, resulting in the call being routed to extension 1001 in Site 1. However, in this call scenario WAN bandwidth would be consumed. Further, for any external PSTN calls dialed by user 1 in this example, the roaming phone would also use the home gateway and also consume WAN bandwidth because the "home" site calling search space is used.
- Additional device calling search spaces may be configured for roaming users with access only to the PSTN and translation partitions. This configuration will need at least one additional device pool and calling search space per site. Thus, N sites will need N device pools and N calling search spaces. However, this configuration will not require defining each site as a Device Mobility Group.
- Abbreviated speed dials should not be used. Cisco recommends configuring speed dials in a universal way that enables the users to use speed dials at any location. For example, users may configure speed dials using E.164 numbers or using site codes and access codes.
- Overlapping extensions at multiple sites might cause problems when a roaming user registers to a remote SRST gateway. For the example in [Figure 25-11](#), assume that mobile user A in Site 1 with extension 1000 moves to Site 2. Also assume that the WAN link at Site 2 goes down, causing the phones to register to an SRST gateway at Site 2. An incoming call on the SRST gateway for extension 1000 will be routed to actual extension 1000 in Site 2 as well as to the mobile user with extension 1000. Thus, calls might not be routed properly. This issue can be avoided by using unique extensions throughout the network.

Variable Length On-Net Dialing with Flat Addressing Using the Line/Device Approach

Figure 25-12 shows a variable-length on-net dial plan with flat addressing for Device Mobility.

Figure 25-12 Variable-Length On-Net Dial Plan with Flat Addressing for Device Mobility

190171

The following design considerations apply to the dial plan model in [Figure 25-12](#):

- Mobile users cannot use abbreviated dialing after roaming to another site because calls might be routed to the wrong destination. If this behavior is not desired, consider defining each site as a Device Mobility Group. However, users must be aware that, for any external PSTN calls, the mobile phone continues to use the home gateway and therefore consumes WAN bandwidth.
- Additional device calling search spaces may be configured for roaming users with access only to the PSTN and internal phones partitions. This configuration will need at least one additional device pool and calling search space per site. Thus, N sites will need N device pools and N calling search spaces. However, this configuration will not require defining each site as a Device Mobility Group.
- Mobile users registered with a remote SRST gateway have unique extensions. However, mobile users must be aware that no PSTN user can call them when they are registered to a remote SRST gateway.

Multisite Enterprise Mobility High Availability

Multisite enterprise mobility features and solutions should be configured and deployed in a redundant fashion in order to ensure high availability of mobility functionality. High availability considerations for wired phone moves, wireless roaming, and EM in multisite mobility deployments are similar to those for campus mobility deployments. Just as with campus environments, redundant network ports, wireless cell coverage, and Unified CM nodes handling extension mobility logins and logouts should be provided to ensure highly available services.

Similarly, it is important to consider high availability of the Device Mobility feature. Because Device Mobility is natively integrated within Unified CM, the failure of a cluster node should have no impact on the functionality of Device Mobility. Device pool, Device Mobility Info, Device Mobility Group, and all other configurations surrounding Device Mobility are preserved if there is a failure of the publisher node or a call processing (subscriber) node. Additionally, if there is a call processing node failure, affected phones will fail-over to their secondary call processing node or SRST reference router as usual based on the Unified CM Group construct.

Capacity Planning for Multisite Enterprise Mobility

As for Device Mobility scalability considerations, there are no specific or enforced capacity limits surrounding this feature and the various configuration constructs (device pools, device mobility groups, and so forth). For more information on general system sizing, capacity planning, and deployment considerations, see the chapter on [Unified Communications Design and Deployment Sizing Considerations, page 29-1](#).

Design Considerations for Multisite Enterprise Mobility

All campus enterprise mobility design considerations apply to multisite enterprise mobility deployments as well (see [Design Considerations for Campus Enterprise Mobility, page 25-12](#)). The following additional design recommendations apply specifically to multisite mobility environments:

- Ensure that all critical services (device registration, PSTN connectivity, DNS, DHCP, and so forth) are deployed at each site in a multisite deployment so that failure of the connection between the site and other sites does not disrupt critical operations. In addition, ensure that a sufficient number of physical network ports and wireless LAN APs are available at each site to support movement of devices and required call capacity.

- In situations in which sites with different dialing patterns (for example, sites having different PSTN access codes) are configured in the same Device Mobility Group, roaming users might have to dial numbers differently based on their location, which can be confusing. For this reason, Cisco recommends assigning sites with similar dialing patterns (for example, sites having the same PSTN access codes) to the same Device Mobility Group. Doing so ensures that roaming users can dial numbers the same way at all sites within the Device Mobility Group.
- The Device Mobility settings from the "roaming" device pool are applied only when users roam within the same Device Mobility Group; therefore, avoid roaming between different Device Mobility Groups because the resulting call routing behavior will cause originated calls from the moved phone to be routed using the "home" or device-configured calling search space. This can lead to unnecessary consumption of WAN bandwidth because the call might be routed through a different site's gateway rather than the local "roaming" gateway.
- Define only one physical location per site. This ensures that device mobility is engaged only in scenarios in which a user is roaming between sites. For roaming within the same site, the concerns that mandate Device Mobility (for example, WAN bandwidth consumption, codec selection, and call admission control) are not present because low-speed links typically are not deployed within a single site.
- In failover scenarios, "roaming" phones will utilize the SRST reference/gateway as dictated by the "roaming" device pool's roaming sensitive settings. Therefore, in these situations the "roaming" phone is unreachable from the PSTN due to the fact that the DID for this phone is anchored in another location's PSTN gateway. Furthermore, for outbound calls from the "roaming" phone, dialing behavior might have to be altered for things such as PSTN access codes, and speed dials configured on the phone might not be usable.
- While the general recommendation is to always use the line/device approach to the dial plan, it is especially important when deploying Device Mobility because it allows different classes of service or calling privileges for each mobile user. With the line/device approach, the classes of service are defined using the line calling search space of the device, which stays the same when roaming and allows a mobile user to keep the same class of service while roaming.
- If your system requires the ability to use abbreviated dialing or to use speed dials that rely on abbreviated dialing, Cisco recommends using the Uniform On-net dial plan model because it will ensure that abbreviated dialing (direct or through speed dials) continues to work even when the mobile user's phone is in a roaming location. Abbreviated dialing is still possible with this dial plan model because all extensions or directory numbers are unique across all sites, and therefore abbreviated dialing can be used universally due to the fact that there are no overlapping extensions.
- If your system uses a Variable Length On-net dial plan model (with either partitioned addressing or flat addressing), Cisco recommends configuring speed dials in a universal way so that a single unique extension can be reached when called. By configuring speed dials using full E.164 numbers or using site or access codes, you can enable roaming users to use the same speed dials at any location.
- If Device Mobility is enabled for users who on occasion access the enterprise network through a VPN connection, Device Mobility Info (DMI) for VPN attached phones should contain IP subnets distributed or owned by the VPN concentrators to ensure that "roaming" to a VPN location results in appropriate dynamic Device Mobility configuration changes. Be sure to associate the DMI with the same device pool that is used for any devices co-located with the VPN concentrators.

Remote Enterprise Mobility

Remote enterprise mobility refers to mobile users in locations remote from the enterprise but still attached to the enterprise network infrastructure through secure connections over the public Internet. Mobility here deals with the placement of endpoint devices in these remote locations and the movement of users, and in some cases their mobile devices, between the enterprise and these locations either frequently or on occasion.

Remote Enterprise Mobility Architecture

As illustrated in [Figure 25-13](#), the remote enterprise mobility architecture is based on a remote physical location, typically an employee home office but also any remote location capable of secure connection back to the enterprise over the Internet. These remote sites typically consist of an IP network with connections for a user's computer, telephone, and other equipment or endpoints. In some cases this IP network may be behind an enterprise controlled and configured VPN router that provides a secure tunnel between the remote location and the enterprise network. In other cases, the remote site IP network is connected to the Internet through a user-provided router, and user computer or endpoint devices must use software-based VPN client capabilities to create secure connections back to the enterprise network. Wireless connectivity may also be provided in the remote location to allow wireless attachment of the user's computer or endpoint. When wireless connectivity is provided at the remote location, wireless phones may be moved from the enterprise network to the home office, allowing users to leverage wireless enterprise devices or mobile phones within the remote location to make and receive calls.

Figure 25-13 Remote Enterprise Mobility Architecture

254812

Types of Remote Enterprise Mobility

Remote enterprise mobility deployments focus predominately on supporting remote users as opposed to supporting regular user or device movement. Certainly users may regularly move with or without an endpoint device between the enterprise location or locations and the remote site; however, the predominate purpose of these deployments is to support remote connectivity for enterprise users. Remote site mobility typically involves two main types of remote connectivity: router-based secure connectivity and client-based secure connectivity. Both types support remote site secure connectivity and both can accommodate various endpoint devices that can be moved between the remote site and the enterprise, including dual-mode mobile phones, wireless IP phones and tablets, and even wired IP phones.

Client-Based Secure Remote Connectivity

Wireless and wired IP phones and software-based PC telephony clients can be connected to remote site locations, as shown in [Figure 25-13](#). These devices and endpoints are responsible for creating secure VPN connections back to the enterprise VPN head-end termination concentrator.

Examples of these types of devices include wirelessly attached dual-mode phones and clients using VPN client or application capabilities such as the Cisco Jabber for iPhone and Android clients (see [Dual-Mode Phones and Clients, page 25-66](#)), Cisco Mobile 8.5 Nokia client (see [Direct Connect Mobile Clients, page 25-102](#)), wired Cisco Unified IP Phones such as the Cisco Unified IP Phone 7965 that uses a built-in VPN client, and personal computers running software-based telephony clients such as Cisco IP Communicator that uses a software-based VPN client for connectivity to the enterprise network.

Router-Based Secure Remote Connectivity

On the other hand, remote site connectivity can be handled through router-based secure VPN tunnels. In these types of scenarios the deployed remote site router, which may be able to provide wireless network connectivity as well, is responsible for setting up and securing a VPN tunnel back to the enterprise network. This in effect extends the enterprise network boundary to the remote site location. The advantage of this type of connectivity is that a wider range of devices and endpoints may be deployed in the remote site because these devices are not responsible for providing secure connectivity and therefore do not require special software or configuration. Instead, these devices simply connect to the remote site network and leverage the secure VPN IP path from the remote site router to the enterprise VPN head-end.

An example of this type of route-based remote site connectivity is the Cisco Virtual Office solution.

Device Mobility and VPN-Based Remote Enterprise Connectivity

Whether you are deploying client-based or router-based secure remote connectivity, the Device Mobility feature may be used to ensure that call admission control and codec are correctly negotiated for endpoint devices and that the appropriate enterprise site PSTN gateway and media resources are utilized. Based on the IP address of the endpoint device as received over the VPN connection, Unified CM will dynamically determine the location of the device.

[Figure 25-14](#) shows an example of client-based secure remote connectivity where a Cisco IP Communicator software phone is running on a remote site computer. This software-based IP phone is connected through a client-based VPN back to the enterprise and registered to Unified CM.

Figure 25-14 Client-Based VPN Connection for Remote Site Cisco IP Communicator

The following design guidelines pertain to enabling the Device Mobility feature for user devices at a remote site connected to the enterprise through a VPN connection:

- Configure Device Mobility Info (DMI) with the IP subnets distributed or owned by the VPN concentrators.
- Associate the DMI with the same device pool that is used for devices co-located with the VPN concentrators. However, parameters such as calling privileges, network locale, and so forth, must be taken into consideration.
- Educate the remote site users to point to the geographically nearest enterprise VPN concentrator when making client-based or router-based VPN connections.

These guidelines ensure that call admission control is correctly applied on the enterprise WAN and over the connection to the remote site.

For information on deploying a VPN, refer to the various VPN design guides available under the *Security in WAN* subsection of the Design Zone for Security, available at:

http://www.cisco.com/en/US/solutions/ns340/ns414/ns742/ns744/landing_wan_security.html

Remote Enterprise Mobility High Availability

For remote site mobility environments, it is imperative that enterprise VPN services are configured and deployed in a redundant manner within the enterprise. This ensures that both client-based and router-based secure connections are highly available. If a VPN concentrator within the enterprise fails, a new secure connection can be set up with another VPN concentrator. Device registration and voice services are highly available in this type of deployment simply by virtue of the built-in Unified CM cluster node redundancy.

Capacity Planning for Remote Enterprise Mobility

The most critical scalability consideration for remote enterprise mobility environments is VPN concentrator capacity. Administrators must deploy sufficient VPN session capacity to accommodate all remote site connectivity, whether they are client-based or router-based secure tunnel connections. Failure to provide appropriate capacity will prevent some remote sites from connecting to the enterprise, thus eliminating access to even basic telephony services. Furthermore, just as with campus and multisite enterprise mobility deployments, it is important to provide sufficient device registration capacity within the enterprise to handle all remote user devices.

Design Considerations for Remote Enterprise Mobility

Consider the following design recommendations when enabling remote site connectivity for mobile users:

- When using Device Mobility, remember to configure Device Mobility Info (DMI) with the IP subnets distributed or owned by the VPN concentrators, and assign the DMI to the same device pool that is configured for devices deployed in the same location as the VPN concentrators.
- Educate remote site users to select the nearest VPN concentrator for VPN connection.
- Ensure appropriate VPN session capacity is available in order to provide connectivity to all remote site users.

Mobility Beyond the Enterprise

With Cisco's mobile Unified Communications, mobility users can handle calls to their enterprise directory number, not only on their desk phone, but also on one or more remote phones. Mobility users can also make calls from a remote phone as if they are dialing inside the enterprise. In addition, mobility users can take advantage of enterprise features such as hold, transfer, and conference as well as enterprise applications such as voicemail, conferencing, and presence on their mobile phones. This ensures continued productivity for users even when they are traveling outside the organization.

Further, with dual-mode phones that provide connectivity to mobile voice and data provider network as well as 802.11 WLAN, users not only have the ability to leverage enterprise applications while away from the enterprise, but they can also leverage the enterprise telephony infrastructure when inside the enterprise or remotely attached to the enterprise network to make and receive calls without incurring mobile voice network per-minute charges.

Mobility functionality delivered within the Cisco Unified Mobility solution is provided through Cisco Unified Communications Manager (Unified CM) and can be used in conjunction with the Cisco Unified Mobile Communicator application and dual-mode and direct-connect client devices.

Cisco Unified Mobility provides the following mobility application functionality:

- Mobile Connect

Mobile Connect, also known as Single Number Reach, provides Cisco Unified Communications users with the ability to be reached at a single enterprise phone number that rings on both their IP desk phone and their mobile phone simultaneously. Mobile Connect users can pick up an incoming call on either their desk or mobile phones and at any point can move the in-progress call from one of these phones to the other without interruption.

- Mid-Call Features

Mid-call features allow a user to invoke hold, resume, transfer, conferencing, and directed call park features from their mobile phone during in-progress mobility calls. These features are invoked from the mobile phone keypad and take advantage of enterprise media resources such as music on hold and conference bridges.

- Single Enterprise Voicemail Box

Single Enterprise Voicemail box provides mobile voicemail avoidance capabilities and ensures that any unanswered calls made to the user's enterprise number and extended to the user's mobile phone will end up in the enterprise voicemail system rather than in a mobile voicemail system. This provides a single consolidated voicemail box for all business calls and eliminates the need for users to check multiple voicemail systems for messages.

- Mobile Voice Access and Enterprise Feature Access two-stage dialing

Mobile Voice Access and Enterprise Feature Access two-stage dialing provide mobile users with the ability to make calls from their mobile phone as if they were calling from their enterprise IP desk phone. These features provide a cost savings in terms of toll charges for long distance or international calls as well as calls to internal non-DID extensions on the system that would not normally be reachable from outside the enterprise. These two-stage dialing features also provide the enterprise with an easy way to track phone calls made by users via a uniform and centrally located set of call detail records. Furthermore, these features provide the ability to mask a user's mobile phone number when sending outbound caller ID. Instead, the user's enterprise number is sent as caller ID. This ensures that returned calls to the user are made to the enterprise number, thus resulting in enterprise call anchoring.

Dual-mode phones and clients provide the ability to attach to both the mobile voice and data networks as well as to enterprise wireless networks for voice and data connectivity. This enables users to leverage both enterprise call control and mobile network call control from a single device. By leveraging the enterprise telephony infrastructure for making and receiving calls whenever possible and falling back to the mobile voice network only when enterprise connectivity is unavailable, dual-mode phones can help reduce telephony costs. Dual-mode phones and the clients that run on them also provide a handoff mechanism so that in-progress voice calls can be moved easily between the WLAN and mobile voice interfaces as a user moves in or out of the enterprise.

The Cisco Unified Mobile Communicator application includes a mobile client that provides enterprise Unified Communications features on a user's mobile phone through the use of a back-hauled data channel. The data channel is sent by means of the service provider data service over the Internet and is terminated at the Cisco Adaptive Security Appliance (ASA) and forwarded on to the Unified Mobility Advantage server, which interfaces with various applications and components within the enterprise Unified Communications infrastructure. The PSTN and mobile voice network are utilized for voice services.

Enterprise applications and features that can be integrated with the Cisco Unified Mobile Communicator application include:

- LDAP directory with Microsoft Active Directory for user authentication and directory lookups
- Voicemail with Cisco Unity or Unity Connection for message waiting indication and visual navigation of the user's enterprise voicemail box
- Conferencing and collaboration with Cisco Unified MeetingPlace for receiving conference notifications
- Presence integration with Cisco Unified Presence, allowing exchange of presence information and synchronization of buddy lists with other clients and applications such as Cisco Unified Personal Communicator

- Enterprise call log and dial-via-office with Cisco Unified Communications Manager (Unified CM) for receiving call history logs from the user's desk phone and for providing the ability to dial calls via the enterprise IP telephony infrastructure.
- Messaging for sending and receiving text messages with other Cisco Unified Mobile Communicator clients

In addition to providing the ability to integrate with various enterprise unified communication applications, Cisco Unified Mobile Communicator mobile client can be integrated with Unified Mobility to take advantage of these features including Mobile Connect and Single Enterprise Voicemail Box.

Direct connect mobile clients enable mobile phones to connect remotely to the enterprise network through the mobile data network or to connect locally through the enterprise WLAN in order to leverage voice features such as dial-via-office and voice over WLAN as well as other unified communications services such as corporate directories access, presence and instant messaging (IM). By providing similar features to Cisco Unified Mobile Communicator (dial-via-office, corporate directory access, presence, and so forth) and voice WLAN capabilities such as dual-mode phones and clients, these direct connect clients enable mobile users to remain productive whether inside or outside the enterprise by providing access to collaboration applications while at the same time enabling users to make and receive enterprise calls from their mobile devices, whether outside the enterprise over public or private Wi-Fi hot spots or the mobile data network, or inside the enterprise and over the WLAN network.

This section begins with a discussion of Unified Mobility features, functionality, and design and deployment considerations. Given the various benefits of Unified Mobility and the fact that dual-mode phones and clients can be integrated to take advantage of the features provided, this discussion paves the way for examination of dual-mode client applications such as Cisco Jabber. Following the dual-mode mobile phone client discussion, Cisco Unified Mobile Communicator is explained and direct connect mobile clients are examined. This section includes a discussion of architecture, functionality, and design and deployment implications for the following mobility applications and features:

- [Cisco Unified Mobility, page 25-38](#)
- [Dual-Mode Phones and Clients, page 25-66](#)
- [Cisco Unified Mobile Communicator, page 25-87](#)
- [Direct Connect Mobile Clients, page 25-102](#)

Cisco Unified Mobility

Cisco Unified Mobility refers to the native mobility functionality within the Cisco Unified Communications Manager (Unified CM) and includes the Mobile Connect, Mobile Voice Access, and Enterprise Feature Access features.

Unified Mobility functionality depends on the appropriate configuration of Unified CM. For this reason, it is important to understand the nature of this configuration as well as the logical components.

[Figure 25-15](#) illustrates the configuration requirements for Unified Mobility. First, as for all users, a mobility user's enterprise phone is configured with appropriate line-level settings such as directory number, partition, and calling search space. In addition, the device-level settings of the enterprise phone include parameters such as device pool, common device configuration, calling search space, media resource group list, and user and network hold audio sources. All of these line and device settings on the user's enterprise phone affect the call routing and music on hold (MoH) behavior for incoming and outgoing calls.

Next, a remote destination profile must be configured for each mobility user in order for them to take advantage of Unified Mobility features. The remote destination profile is configured at the line level with the same directory number, partition, and calling search space as the user's enterprise phone line. This

results in a shared line between the remote destination profile and the enterprise phone. The remote destination profile configuration includes device pool, calling search space, rerouting calling search space, and user and network hold audio source parameters. The remote destination profile should be thought of as a virtual phone whose configuration mirrors the user's line-level enterprise phone settings, but whose profile-level configuration combined with the line-level settings determines the call routing and MoH behavior that the user's remote destination phone will inherit. The user's enterprise directory number, which is shared between the remote destination profile and the enterprise phone, allows calls to that number to be extended to the user's remote destination.

Figure 25-15 Cisco Unified Mobility Configuration Architecture

As further shown in Figure 25-15, a mobility user can have one or more remote destinations configured and associated with their remote destination profile. A remote destination represents a single PSTN phone number where a user can be reached. A user can have up to 10 remote destinations defined. Call routing timers can be configured for each remote destination to adjust the amount of time a call will be extended to a particular remote phone, as well as the amount of time to wait before extending the call and the amount of time that must pass before a call can be answered at the remote phone. Mobility users can also configure filters for each remote destination to allow or deny calls from certain phone numbers to be extended to that remote phone.

Note Cisco Business Edition supports a maximum of four remote destinations per mobility user.

Mobile Connect

The Mobile Connect feature allows an incoming call to an enterprise user to be offered to the user's IP desk phone as well as up to 10 configurable remote destinations. Typically a user's remote destination is their mobile or cellular telephone. Once the call is offered to both the desktop and remote destination phone(s), the user can answer at any of those phones. Upon answering the call on one of the remote destination phones or on the IP desk phone, the user has the option to hand off or pick up the call on the other phone.

Mobile Connect Functionality

Figure 25-16 illustrates a basic Mobile Connect call flow. In this example, Phone A on the PSTN calls a Mobile Connect user's enterprise directory number (DN) 408-555-1234 (step 1). The call comes into the enterprise PSTN gateway and is extended through Unified CM to the IP phone with DN 408-555-1234 (step 2), and this phone begins to ring. The call is also extended to the user's Remote Destination Profile, which shares the same DN (step 3). In turn, a call is placed to the remote destination associated with the user's remote destination profile (in this case 408-555-7890) (step 4). The outgoing call to the remote destination is routed through the PSTN gateway (step 5). Finally the call rings at the remote destination PSTN phone with number 408 555-7890 (step 6). The call can then be answered at either phone.

Figure 25-16 Mobile Connect

Typically a Mobile Connect user's configured remote destination is their mobile phone on a mobile voice or cellular provider network; however, any destination reachable by means of the PSTN can be configured as a user's remote destination. Furthermore, a Mobile Connect user can have up to 10 remote

destinations configured, so an incoming call could potentially ring as many as 10 PSTN phones as well as the user's desk phone. Once the call is answered at the desk phone or at a remote destination phone, any other call legs that have been extended to ring additional remote destinations or the desk phone (if not answered at the desk phone) will be cleared. If the incoming call is answered at the remote destination, the voice media path will be hairpinned within the enterprise PSTN gateway utilizing two gateway ports. This utilization must be considered when deploying the Mobile Connect feature.

**Note**

Mobility users on a Cisco Business Edition system can have a maximum of four remote destinations.

**Note**

In order for Mobile Connect to work as in [Figure 25-16](#), ensure that the user-level Enable Mobility check box under the End User configuration page has been checked and that at least one of the user's configured remote destinations has the Enable Mobile Connect check box checked.

Desk Phone Pickup

As illustrated in [Figure 25-17](#), once a user answers a Mobile Connect call at the remote destination device (step 1: in this case, 408 555-7890), at any point the user can hang up the call at the remote destination and pick it up again at their desk phone by simply pressing the Resume softkey on the desk phone (step 2: at DN 408 555-1234 in this case). The call resumes between the original caller at Phone A and the desk phone (step 3).

Figure 25-17 Desk Phone Pickup

Desk phone pickup can be performed whenever an enterprise-anchored call is in progress at a configured remote destination phone and that phone hangs up the call.

**Note**

An enterprise-anchored call refers to any call that has at least one call leg connected through an enterprise PSTN gateway and that originated either from a remote destination to an enterprise DID or from Mobile Connect, Mobile Voice Access, Enterprise Feature Access, or Intelligent Session Control.

The option to pick up or resume the call at the desk phone is available for a certain amount of time. For this reason, it is good practice for the Mobile Connect user to ensure that the calling phone hangs up before the remote destination phone is hung up. This ensures that the call cannot be resumed at the desk

phone by someone else. By default, the call remains available for pickup at the desk phone for 10 seconds after the remote destination phone hangs up; however, this time is configurable and can be set from 0 to 30000 milliseconds on a per-user basis by changing the Maximum Wait Time for Desk Pickup parameter under the End User configuration page. Desk phone pickup can also be performed after invoking the mid-call hold feature at the remote destination phone. However, in these cases, the Maximum Wait Time for Desk Pickup parameter setting has no effect on the amount of time the call will be available for pickup. A call placed on mid-call hold will remain on hold and be available for desk phone pickup until manually resumed at either the remote or desktop phone.

Another method for performing desk phone pickup is to use the mid-call session handoff feature. This mid-call feature is invoked by manually keying *74, the default enterprise feature access code for session handoff, which in turn generates a DTMF sequence back to Unified CM. When this feature is invoked, Unified CM sends a new call to the user's enterprise desk phone. Once this new call is flashing or ringing at the desk phone, the user then must answer the call to complete the session handoff.

The benefit of this desk phone pickup method over other methods (such as hanging up the call at the mobile phone or using the mid-call hold feature) is that the conversation between the user and the far-end phone is maintained throughout the handoff process. Once the *74 sequence has been keyed, the user can continue the conversation because the handoff call is sent to the user's desk phone. When the user answers the call at the desk phone, the call legs are shuffled so that the call leg to the far-end is connected to the new call leg created at the desk phone, thus resulting in an uninterrupted or near-instantaneous cut-through of the audio path. The original call leg at the mobile device is subsequently cleared.

Unlike the hang-up method for invoking desk phone pickup, where the end-user's Maximum Wait Time for Desk Pickup setting determines how long the call will be available for pickup at the desk phone, with session handoff the Session Handoff Alerting Timer service parameter determines the amount of time the call will ring or flash at the desk phone before the handoff call is cleared. The default handoff alerting time is 10 seconds. Further, with session handoff, any call forward settings configured on the desk phone do not get invoked. As a result, the handoff feature does not forward to voicemail or any other call-forward destination. If a call is not answered by the end of Session Handoff Alerting Timer period, then the call is cleared and the Remote In Use state is removed from the user's desk phone line. However, in this scenario the original call is maintained at the mobile phone.

For additional information about session handoff and other mid-call features, see [Mid-Call Features](#), page 25-43.

Remote Destination Phone Pickup

[Figure 25-18](#) illustrates Mobile Connect remote destination phone pickup functionality. Assuming Phone A calls the Mobile Connect user's enterprise DN 408 555-1234 and the call is answered at the user's desk phone and is in progress (step 1), the user must push the Mobility softkey. Assuming the Mobile Connect feature is enabled for this phone and remote destination pickup is available, the user presses the Select softkey (step 2). A call is generated to the user's remote destination phone (in this case, 408 555-7890), and the remote phone begins to ring. Once the call is answered at the remote phone, the call resumes between Phone A and the Mobile Connect user's remote phone with number 408 555-7890 (step 3).

Figure 25-18 Remote Destination Phone Pickup

When a Mobile Connect user has multiple remote destinations configured, each remote destination will ring when the Select softkey is pressed, and the user can answer the desired phone.

**Note**

In order for remote destination phone pickup to work as in [Figure 25-18](#), ensure that at least one of the user's configured remote destinations has the Mobile Phone check box checked. In addition, the Mobility softkey must be configured for all mobility users by adding the softkey to each user's associated desk phone softkey template. Failure to check the Mobile Phone check box and to make the Mobility softkey available to mobility users will prevent the use of remote destination phone pickup functionality.

Mid-Call Features

As illustrated in [Figure 25-19](#), once a user answers a Mobile Connect call at the remote destination device (step 1: in this case, 408 555-7890), the user can invoke mid-call features such as hold, resume, transfer, conference, directed call park, and session handoff by sending DTMF digits from the remote destination phone to Unified CM via the enterprise PSTN gateway (step 2). When the mid-call feature hold, transfer, conference, or directed call park is invoked, MoH is forwarded from Unified CM to the held party (step 3: in this case, Phone A). In-progress calls can be transferred to another phone or directed call park number, or additional phones can be conferenced using enterprise conference resources (step 4).

Figure 25-19 Mobility Mid-Call Feature

Mid-call features are invoked at the remote destination phone by a series of DTMF digits forwarded to Unified CM. Once received by Unified CM, these digit sequences are matched to the configured Enterprise Feature Access Codes for Hold, Exclusive Hold, Resume, Transfer, Conference, and Session Handoff, and the appropriate function is performed.

**Note**

To enable the Directed Call Park mid-call feature, you must configure Cisco Unified CM with directed call park numbers and call park retrieval prefixes.

**Note**

In order to perform the transfer, conference, and directed call park mid-call features, a second call leg is generated by the remote destination phone to a system-configured Enterprise Feature Access DID that answers the call, takes user input (including PIN number, mid-call feature access code, and target number), and then creates the required call leg to complete the transfer, conference, or directed call park operation.

With the mid-call session handoff feature, MoH is not forwarded to the far-end because the far-end is never placed on hold. Instead, the original audio path is maintained until the mobile user answers the handoff call at the desk phone. Once the call is answered, the call legs are shuffled at the enterprise gateway and the audio path is maintained.

Mid-call features are invoked by manually keying the feature access codes and entering the appropriate key sequences. [Table 25-2](#) indicates the required key sequences for invoking mid-call features.

Table 25-2 Manual Mid-Call Feature Key Sequences

| Mid-Call Feature | Enterprise Feature Access Code (default) | Manual Key Sequence |
|--------------------|--|--|
| Hold | *81 | Enter: *81 |
| Exclusive Hold | *82 | Enter: *82 |
| Resume | *83 | Enter: *83 |
| Transfer | *84 | <ol style="list-style-type: none"> 1. Enter: *82 (Exclusive Hold) 2. Make new call to Enterprise Feature Access DID. 3. On connect, enter: <PIN_number> # *84 # <Transfer_Target/DN> # 4. Upon answer by transfer target (for consultive transfer) or upon ringback (for early attended transfer), enter: *84 |
| Directed Call Park | N/A | <ol style="list-style-type: none"> 1. Enter: *82 (Exclusive Hold) 2. Make new call to Enterprise Feature Access DID. 3. On connect, enter: <PIN_number> # *84 # <Directed_Call_Park_Number> # *84 # <p>Note To retrieve a parked call, the user must use Mobile Voice Access or Enterprise Feature Access Two-Stage Dialing to place a call to the directed call park number. When entering the directed call park number to be dialed, it must be prefixed with the appropriate call park retrieval prefix.</p> |
| Conference | *85 | <ol style="list-style-type: none"> 1. Enter: *82 (Exclusive Hold) 2. Make new call to Enterprise Feature Access DID. 3. On connect enter: <PIN_number> # *85 # <Conference_Target/DN> # 4. Upon answer by conference target, enter: *85 |
| Session Handoff | *74 | <ol style="list-style-type: none"> 1. Enter: *74 2. Answer at the desk phone upon ring and/or flash. |

**Note**

Media resource allocation for mid-call features such as hold and conference is determined by the Remote Destination Profile configuration or, in the case of dual-mode phones and Unified Mobile Communicator, the device configuration. The media resource group list (MRGL) of the device pool configured for the Remote Destination Profile or the mobile client device is used to allocate a conference bridge for the conferencing mid-call feature. The User Hold Audio Source and Network Hold MoH Audio Source settings of the Remote Destination Profile or the mobile client device, in combination with the media resource group list (MRGL) of the device pool, is used to determine the appropriate MoH stream to be sent to a held device.

Mobile Voicemail Avoidance with Single Enterprise Voicemail Box

An additional consideration with Unified Mobility Mobile Connect is mobile voicemail avoidance. The single enterprise voicemail box feature ensures that all unanswered enterprise business calls end up at the enterprise voicemail system. This prevents a user from having to check multiple mailboxes (enterprise, mobile, home, and so forth) for unanswered calls to their enterprise phone number. To implement this feature, the system relies on a set of timers (one per remote destination) in conjunction with system call-forward timers. The purpose of these timers is to ensure that, when and if a call is forwarded to a voicemail box on ring-no-answer, the call is forwarded to the enterprise voicemail box rather than any remote destination voicemail box. These timers, in conjunction with other system forward-no-answer timers, should be configured to avoid non-enterprise voicemail systems as follows:

- Ensure the system forward-no-answer time is shorter at the desk phone than at the remote destination phones.

To do so, ensure that the global Forward No Answer Timer field in Unified CM or the No Answer Ring Duration field under the individual phone line is configured with a value that is less than the amount of time a remote destination phone will ring before forwarding to the mobile voicemail system. In addition, the Delay Before Ringing Timer parameter under the Remote Destination configuration page can be used to delay the ringing of the remote destination phone in order to further lengthen the amount of time that must pass before a remote destination phone will forward to its own mobile voicemail box. However, when adjusting the Delay Before Ringing Timer parameter, take care to ensure that the global Unified CM Forward No Answer Timer (or the line-level No Answer Ringer Duration field) is set sufficiently high enough so that the mobility user has time to answer the call on the remote destination phone. The Delay Before Ringing Timer parameter can be set for each remote destination and is set to 4000 milliseconds by default.

- Ensure that the remote destination device stops ringing before the incoming call is forwarded to the mobile voicemail system.

You can accomplish this with the Answer Too Soon and Answer Too Late timers for each remote destination. First the Answer Too Soon Timer parameter under the Remote Destination configuration page should be configured with a value that is more than the amount of time it takes a call extended to a powered-off or out-of-range mobile phone to be forwarded to the mobile voicemail system. By default this timer is set 1,500 milliseconds (or 1.5 seconds). If the call is answered before the Answer Too Soon Timer expires, the system will disconnect the call leg to the remote destination. This ensures that calls forwarded immediately to the mobile voicemail system are not connected, but those answered by the user after ring-in are connected.

Next configure the Answer Too Late Timer parameter under the Remote Destination configuration page with a value that is less than the amount of time a remote destination phone will ring before forwarding to its voicemail box. By default this timer is set to 19,000 milliseconds (or 19 seconds). If the call is not answered before this timer expires, the system will disconnect the call leg to the remote destination. This ensures that the remote destination phone stops ringing before the call is forwarded to the mobile voicemail system.

Note

Incoming calls to a remote destination that are manually diverted by the mobility user can end up in the mobile voicemail box if the manual divert occurs after the Answer Too Soon timer has expired. To prevent this from happening, mobility users should be advised to ignore or silence the ringing of incoming calls they wish to divert to voicemail. This will ensure that unanswered calls always end up in the enterprise voicemail system.

**Note**

In most deployment scenarios, the default Delay Before Ringing Timer, Answer Too Late Timer, and Answer Too Soon Timer values are sufficient and do not need to be changed.

Enabling and Disabling Mobile Connect

The Mobile Connect feature can be enabled or disabled by using one of the following methods:

- Cisco Unified CM Administration or Cisco Unified CM User Options pages

An administrator or user unchecks the Mobile Connect box to disable, or checks the Mobile Connect box to enable, the feature. This is done per remote destination.

- Mobile Voice Access or Enterprise Feature Access

A Mobility-enabled user dials into the Mobile Voice Access or Enterprise Feature Access DID and, after entering appropriate credentials, enters the digit 2 to enable or 3 to disable. With Mobile Voice Access, the user is prompted to enable or disable Mobile Connect for a single remote destination or all of their remote destinations. With Enterprise Feature Access, the user can enable or disable Mobile Connect only for the remote destination device from which they are calling.

- Desk phone Mobility softkey

The user presses the Mobility softkey when the phone is in the on-hook state and selects either Enable Mobile Connect or Disable Mobile Connect. With this method, Mobile Connect is enabled or disabled for all of the user's remote destinations.

- Mobile Clients

Users with a mobile device running Cisco Unified Mobile Communicator or direct connect mobile clients can toggle the Mobile Connect feature status by changing the Mobile Connect or Single Number Reach setting to Enable or Disable under the client configuration settings. This will enable or disable Mobile Connect for the Cisco Unified Mobile Communicator or direct connect mobile client mobility identity only.

Access Lists for Allowing or Blocking Mobile Connect Calls

Access lists can be configured within Cisco Unified CM and associated to a remote destination. Access lists are used to allow or block inbound calls (based on incoming caller ID) from being extended to a mobility-enabled user's remote destinations. Furthermore, these access lists are invoked based on the time of day.

Access lists are configured for mobility-enabled users as either blocked or allowed. Access lists contain one or more members or filters consisting of a specific number or number mask, and the filters are compared against the incoming caller ID of the calling party. In addition to containing specific number strings or number masks for matching caller ID, access lists can also contain a filter for incoming calls where the caller ID is not available or is set to private. A blocked access list contains an implicit "allow all" at the end of the list so that calls from any numbers entered in the access list will be blocked but calls from all other numbers will be allowed. An allowed access list contains an implicit "deny all" at the end of the list so that calls from any numbers entered in the access list will be allowed but calls from all other numbers will be blocked.

Once configured access lists are associated with a configured Ring Schedule under the Remote Destination configuration screen, the configured Ring Schedule in combination with the selected access list provides time-of-day call filtering for Mobile Connect calls on a per-remote-destination basis. Access lists and Ring Schedules can be configured and associated to a remote destination by an administrator using the Cisco Unified CM Administration interface or by an end user using the Cisco Unified CM User Options interface.

Mobile Connect Architecture

The architecture of the Mobile Connect feature is as important to understand as its functionality. Figure 25-20 depicts the message flows and architecture required for Mobile Connect. The following sequence of interactions and events can occur between Unified CM, the Mobile Connect user, and the Mobile Connect user's desk phone:

1. The Mobile Connect phone user who wishes to either enable or disable the Mobile Connect feature or to pick up an in-progress call on their remote destination phone pushes the Mobility softkey on their desk phone (see step 1 in Figure 25-20).
2. Unified CM returns the Mobile Connect status (On or Off) and offers the user the ability to select the Send Call to Mobile Phone option when the phone is in the Connected state, or it offers the user the ability to enable or disable the Mobile Connect status when the phone is in the On Hook state (see step 2 in Figure 25-20).
3. Mobile Connect users can use the Unified CM User Options interface to configure their own mobility settings via the web-based configuration pages at

http://<Unified-CM_Server_IP_Address>/ccmuser/

where <Unified-CM_Server_IP_Address> is the IP address of the Unified CM publisher server (see step 3 in Figure 25-20).

Figure 25-20 Mobile Connect Architecture

High Availability for Mobile Connect

The Mobile Connect feature relies on the following components:

- Unified CM servers
- PSTN gateway

Each component must be redundant or resilient in order for Mobile Connect to continue functioning fully during various failure scenarios.

Unified CM Server Redundancy

The Unified CM server is required for the Mobile Connect feature. Unified CM server failures are non-disruptive to Mobile Connect functionality, assuming phone and gateway registrations are made redundant using Unified CM Groups.

In order for Mobile Connect users to use the Unified CM User Options web interface to configure their mobility settings (remote destinations and access lists), the Unified CM publisher server must be available. If the publisher is down, users will not be able to change mobility settings. Likewise, administrators will be unable to make mobility configuration changes to Unified CM; however, existing mobility configurations and functionality will continue. Finally, changes to Mobile Connect status must be written by the system on the Unified CM publisher server; if the Unified CM publisher is unavailable, then enabling or disabling Mobile Connect will not be possible.

PSTN Gateway Redundancy

Because the Mobile Connect feature relies on the ability to extend additional call legs to the PSTN to reach the Mobile Connect users' remote destination phones, PSTN gateway redundancy is important. Should a PSTN gateway fail or be out of capacity, the Mobile Connect call cannot complete. Typically, enterprise IP telephony dial plans provide redundancy for PSTN access by providing physical gateway redundancy and call re-routing capabilities as well as enough capacity to handle expected call activity. Assuming that Unified CM has been configured with sufficient capacity, multiple gateways, and route group and route list constructs for call routing resiliency, the Mobile Connect feature can rely on this redundancy for uninterrupted functionality.

Mobile Voice Access and Enterprise Feature Access

Mobile Voice Access (also referred to as System Remote Access) and Enterprise Feature Access two-stage dialing are features built on top of the Mobile Connect application. Both features allow a mobility-enabled user who is outside the enterprise to make a call as though they are directly connected to Unified CM. This functionality is commonly referred to as Direct Inward System Access (DISA) in traditional telephony environments. These features benefit the enterprise by limiting toll charges and consolidating phone billing directly to the enterprise rather than billing to each mobile user. In addition, these features allow the users to mask their mobile phone or remote destination numbers when sending outbound caller ID. Instead, the user's enterprise directory number is sent as caller ID. This ensures that returned calls to the user are made to the enterprise number, thus resulting in enterprise call anchoring. These features also enable mobile users to dial internal extensions or non-DID enterprise numbers that would not normally be reachable from outside the enterprise.

Mobile Voice Access is accessed by calling a system-configured DID number that is answered and handled by an H.323 or SIP VoiceXML (VXML) gateway. The VoiceXML gateway plays interactive voice response (IVR) prompts to the Mobile Voice Access user, requesting user authentication and input of a number to be dialed via the user phone keypad.

Enterprise Feature Access functionality includes the previously discussed mid-call transfer and conference features as well as two-stage dialing functionality. Two-stage dialing works the same way as Mobile Voice Access, but without the IVR prompts. The system-configured Enterprise Feature Access DID is answered by Unified CM. The user then uses the phone keypad or Smart Phone softkeys to input authentication and the number to be dialed. These inputs are received without prompts.

With both the Mobile Voice Access and Enterprise Feature Access two-stage dialing features, once the call to the input number is connected, users can invoke mid-call features or pick up the call on their desk phones just as with a Mobile Connect calls. This is possible because the call is anchored at the enterprise gateway.

Mobile Voice Access IVR VoiceXML Gateway URL

The Mobile Voice Access feature requires the Unified CM VoiceXML application to reside on the H.323 or SIP gateway. The URL used to load this application is:

```
http://<Unified-CM-Publisher_IP-Address>:8080/ccmivr/pages/IVRMainpage.vxml
```

where *<Unified-CM-Publisher_IP-Address>* is the IP address of the Unified CM publisher node.

Mobile Voice Access Functionality

Figure 25-21 illustrates a Mobile Voice Access call flow. In this example, the Mobile Voice Access user on PSTN phone 408 555-7890 dials the Mobile Voice Access enterprise DID DN 408-555-2345 (step 1).

The call comes into the enterprise PSTN H.323 or SIP gateway, which also serves as the VoiceXML gateway. The user is prompted via IVR to enter their numeric user ID (followed by the # sign), PIN number (followed by the # sign), and then a 1 to make a Mobile Voice Access call, followed by the phone number they wish to reach. In this case, the user enters 9 1 972 555 3456 as the number they wish to reach (followed by the # sign) (step 2).

Note

If the PSTN phone from which the Mobile Voice Access user is calling is configured as a Mobile Connect remote destination for that user and the incoming caller ID can be matched against this remote destination by Unified CM, the user does not have to enter their numeric user ID. Instead they will be prompted to enter just the PIN number.

In the meantime, Unified CM has forwarded IVR prompts to the gateway, the gateway has played these prompts to the user, and the gateway has collected user input including the numeric ID and PIN number of the user. This information is forwarded to Unified CM for authentication and to generate the call to 9 1 972 555 3456 (step 3). After authenticating the user and receiving the number to be dialed, Unified CM generates a call via the user's Remote Destination Profile (step 4). The outbound call to 972 555-3456 is routed via the PSTN gateway (step 5). Finally, the call rings at the PSTN destination phone with number 972 555-3456 (step 6).

Figure 25-21 Mobile Voice Access

**Note**

In order for Mobile Voice Access to work as in [Figure 25-21](#), ensure that the system-wide Enable Mobile Voice Access service parameter is set to True and that the per-user Enable Mobile Voice Access check box on the End User configuration page is also checked.

**Note**

The Mobile Voice Access feature relies on the Cisco Unified Mobile Voice Access Service, which must be activated manually from the Unified CM Serviceability configuration page. This service can be activated on the publisher node only.

Mobile Voice Access Using Hairpinning

In deployments where the enterprise PSTN gateways are not using H.323 or SIP, Mobile Voice Access functionality can still be provided using hairpinning on a separate gateway running H.323. Mobile Voice Access using hairpinning relies on off-loading the VoiceXML functionality to a separate H.323 gateway. [Figure 25-22](#) illustrates a Mobile Voice Access call flow using hairpinning. In this example, just as in the previous example, the Mobile Voice Access user on PSTN phone 408 555-7890 dials the Mobile Voice Access enterprise DID DN 408-555-2345 (step 1). The call comes into the enterprise PSTN gateway (step 2) and is forwarded to Unified CM for call handling (step 3). Unified CM next routes the inbound call to the H.323 VoiceXML gateway (step 4). The user is then prompted by IVR to enter their numeric user ID, PIN, and then a 1 to make a Mobile Voice Access call, followed by the phone number they wish to reach. Again the user enters 9 1 972 555 3456 as the number they wish to reach (followed by the # sign).

**Note**

When using Mobile Voice Access with hairpinning, users calling into the system will not be identified automatically by their caller ID. Instead, users will have to key in their remote destination number manually prior to entering their PIN. The reason the user is not automatically identified is that, for hairpinning deployments, the PSTN gateway must first route the call to Unified CM to reach the

hairpinned Mobile Voice Access gateway. Because the call is routed to Unified CM first, the conversion of the calling number from a mobile number to an enterprise directory number occurs prior to the call being handled by the Mobile Voice Access gateway. This results in the Mobile Voice Access gateway being unable to match the calling number with a configured remote destination, and therefore the system prompts the user to enter their remote destination number. This is unique to hairpinning deployments; with normal Mobile Voice Access flows, the PSTN gateway does not have to route the call to Unified CM first in order to access Mobile Voice Access because the functionality is available on the local gateway.

In the meantime, the H.323 VoiceXML gateway collects and forwards the user input to Unified CM and then plays the forwarded IVR prompts to the PSTN gateway and the Mobile Voice Access user. Unified CM in turn receives user input, authenticates the user, and forwards appropriate IVR prompts to the H.323 VoiceXML gateway based on user input (step 5). After receiving the number to be dialed, Unified CM generates a call using the user's Remote Destination Profile (step 6). The outbound call to 972 555-3456 is routed through the PSTN gateway (step 7). Finally, the call rings at the PSTN destination phone with number 972 555-3456 (step 8).

Figure 25-22 Mobile Voice Access Using Hairpinning

Note

When deploying Mobile Voice Access in hairpinning mode, Cisco recommends configuring the Mobile Voice Access DID at the PSTN gateway and the Mobile Voice Access Directory Number within Cisco Unified CM (under **Media Resources > Mobile Voice Access**) as different numbers. A translation pattern within Unified CM can then be used to translate the called number of the Mobile Voice Access DID to the configured Mobile Voice Access directory number. Because the Mobile Voice Access directory number configured within Unified CM is visible to the administrator only, translation between the DID and directory number will be invisible to the end user and there will be no change in end-user dialing behavior. This is recommended in order to prevent mobility call routing issues in multi-cluster environments. This recommendation does not apply to Mobile Voice Access in non-hairpinning mode.

**Note**

Mobile Voice Access in hairpinning mode is supported only with H.323 VXML gateways.

Enterprise Feature Access with Two-Stage Dialing Functionality

Figure 25-23 illustrates the call flow for Enterprise Feature Access two-stage dialing. In this example, the mobility user at remote destination phone 408 555-7890 dials the Enterprise Feature Access DID 408 555-2345 (step 1). Once the call is connected, the remote destination phone is used to send DTMF digits to Unified CM via the PSTN gateway, beginning with the user's PIN (followed by the # sign) which is authenticated with Unified CM. Next a 1 (followed by the # sign) is sent to indicate a two-stage dialed call is being attempted, followed by the phone number the user wishes to reach. In this case the user enters 9 1 972 555 3456 as the destination number (step 2).

**Note**

Unlike with Mobile Voice Access, Enterprise Feature Access requires that all two-stage dialed calls must originate from a phone that has been configured as a remote destination in order to match the caller ID and PIN against the end-user account. There is no provision within Enterprise Feature Access in which the mobility user can enter their remote destination number or ID to identify themselves to the system. Identity can be established only via the combination of incoming caller ID and entered PIN.

Next the outgoing call is originated via the user's remote destination profile (step 3), and the call to PSTN number 972 555-3456 is routed via the enterprise PSTN gateway (step 4). Finally, the call rings the PSTN phone (step 5: in this case, 972 555-3456). As with Mobile Voice Access, the voice media path of each Enterprise Feature Access two-stage dialed call is hairpinned within the enterprise PSTN gateway utilizing two gateway ports.

Figure 25-23 Enterprise Feature Access Two-Stage Dialing Feature

**Note**

In order for Enterprise Feature Access two-stage dialing to work as in [Figure 25-23](#), ensure that the system-wide Enable Enterprise Feature Access service parameter is set to True.

Desk and Remote Destination Phone Pickup

Because Mobile Voice Access and Enterprise Feature Access functionality is tightly integrated with the Mobile Connect feature, once a Mobile Voice Access or Enterprise Feature Access two-stage dialed call has been established, the user does have the option of using Mobile Connect functionality to pick up the in-progress call on their desk phone by simply hanging up the call on the originating phone and pushing the Resume softkey on their desk phone or by using the mid-call hold feature. In turn, the call can then be picked up on the user's configured remote destination phone by pressing the Mobility softkey and selecting Send Call to Mobile Phone.

Enabling and Disabling Mobile Connect

In addition to providing users of Mobile Voice Access and Enterprise Feature Access with the ability to make calls from the PSTN as though they are within the enterprise, the functionality provided by Mobile Voice Access on the H.323 or SIP VoiceXML gateway and provided by Enterprise Feature Access also gives users the ability to remotely enable and disable their Mobile Connect functionality for each remote destination via their phone keypad. Rather than entering a 1 to make a call, users enter a 2 to turn the Mobile Connect feature on and a 3 to turn the Mobile Connect feature off.

If a user has more than one remote destination configured when using Mobile Voice Access, they are prompted to key in the remote destination phone number for which they wish to enable or disable the Mobile Connect feature. When using Enterprise Feature Access, a user can enable or disable Mobile Connect only for the remote destination phone from which they are calling.

**Note**

When the Enable Mobile Voice Access service parameter is set to False, resulting in an inability to make two-stage dialed calls, Mobile Voice Access still provides users with the ability to enable and disable mobile connect remotely. As long as the Mobile Voice Access Directory Number has been configured on the system, the user's account has been enabled for Mobile Voice Access, and the Cisco Unified Mobile Voice Access service is running on the publisher, a calling user can still enable or disable Mobile Connect.

Mobile Voice Access and Enterprise Feature Access Number Blocking

Administrators might want to prevent users of Mobile Voice Access and Enterprise Feature Access two-stage dialing from dialing certain numbers when using these features. In order to restrict or block calls to certain numbers when using these features for off-net calls, a comma-separated list of those numbers can be configured in the System Remote Access Blocked Numbers service parameter field. Once this parameter is configured with blocked numbers, those numbers will not be reachable from a user's remote destination phone when using Mobile Voice Access or Enterprise Feature Access features. Numbers that administrators might want to block can include emergency numbers such as 911. When configuring blocked numbers, ensure they are configured as they would be dialed by an enterprise user, with appropriate prefixes or steering digits. For example, if an emergency number is to be blocked and the emergency number is dialed by system users as 9911, then the number configured in the System Remote Access Blocked Numbers field should be 9911.

Access Numbers for Mobile Voice Access and Enterprise Feature Access

While the Unified CM system allows the configuration of only a single Mobile Voice Access Directory Number, this does not preclude the use of multiple externally facing numbers that can access these internally configured numbers. For example, consider a system deployed in the US in New York with a remote site in San Jose as well as an overseas site in London. Even though the system may have the Mobile Voice Access directory number configured as 555-1234, the gateways at each location can be configured to map a local or toll-free DID number to this Mobile Voice Access directory number. For example, the gateway in New York may have DIDs of +1 212 555 1234 and +1 800 555 1234, which both map to the Mobile Voice Access number, while the gateway in San Jose has a DID of +1 408 666 5678 and the gateway in London has a DID of +44 208 777 0987, which also map to the Mobile Voice Access number of the system.

The Unified CM system does permit the configuration of multiple Enterprise Feature Access Numbers so that location-specific system access numbers can be configured for each geographic location of the deployment. This enables local or toll-free Enterprise Feature Access two-stage dialing functionality for all users regardless of geographic location.

By acquiring multiple local or toll-free DID numbers, system administrators can ensure that two-stage dialed calls will always originate as a call into the system that is either local or toll-free, thus providing further reductions in telephony costs.

Remote Destination Configuration and Caller ID Matching

When authenticating users for Mobile Voice Access and Enterprise Feature Access two-stage dialing functionality as well as the DTMF-based mid-call features Transfer and Conference, the caller ID of the calling remote destination phone is matched against all remote destinations configured within the system. Matching of this caller ID depends on a number of factors, including how the remote destination numbers are configured, whether digit prefixing is required to include PSTN steering digits on the system, and whether the Matching Caller ID with Remote Destination parameter is set to Partial or Complete Match.

To control the nature of this matching, consider the following two approaches.

Using Digit Prefix Mechanism

With this approach, remote destinations are configured just as the caller ID would be presented from the PSTN. For example, if the caller ID from the PSTN for a remote destination phone is presented as 4085557890, then this number should be configured on the Remote Destination configuration page. In order to route Mobile Connect calls appropriately to this remote destination, it is then necessary to use a digit prefixing mechanism to prefix necessary PSTN access codes and other required digits. For example, if 9 is required to reach the PSTN when dialing calls and a 1 is required for dialing long distance, then digit prefixing must be configured to add the 9 and 1 to the beginning of the dial string. Digit prefixing is facilitated by using translation patterns, route patterns, or route list constructs within the Unified CM system. Alternatively, Application Dial Rules may be used to provide digit prefixing. When using this approach, the Matching Caller ID with Remote Destination parameter should be left at the default setting of Complete Match.

Note

Not only are Application Dial Rules applied to Mobile Connect, Mobile Voice Access, and Enterprise Feature Access calls, but they are also applied to calls made with Cisco WebDialer, Cisco Unified CM Assistant, Cisco Unified Personal Communicator, and Cisco Jabber applications. For this reason, exercise care when configuring these rules to ensure that dialing behavior across all applications is as expected.

Using Partial Caller ID Matching

With this approach, remote destinations are configured as they would be dialed from the system to the PSTN. For example, if the number for the remote destination is 14085557890 and PSTN access from the system requires a 9, then this number should be configured on the Remote Destination configuration page as 914085557890. This approach precludes the need for configuration of a digit prefixing mechanism on the system, but it requires that the Matching Caller ID with Remote Destination service parameter be set to Partial Match and that the Number of Digits for Caller ID Partial Match be set to the appropriate number of consecutive digits that should be matched against the remote destination caller ID. For example, if the caller ID for a remote destination is 14085557890 and the remote destination is configured as 914085557890, then the Number of Digits for Caller ID Partial Match would ideally be set to 10 or 11. In this example, this parameter could be set to a lower number of digits; however, always take care to ensure that enough consecutive digits are matched so that all configured remote destinations in the system are matched uniquely. If there is no exact match and more than one configured remote destination number is matched when using partial caller ID matching, the system treats this as if there is no matching remote destination number, thus requiring the user to enter their remote destination number/ID manually in the case of Mobile Voice Access before providing their PIN. With Enterprise Feature Access, there is no mechanism for the user to enter their remote destination number; therefore, when using this functionality, take care to ensure that only unique matches occur.

**Note**

If the PSTN service provider sends variable-length caller IDs, using partial caller ID matching is not recommended because ensuring a unique caller ID match for each inbound call might not be possible. In these scenarios, using complete caller ID matching is the preferred method.

Mobile Voice Access and Enterprise Feature Access Architecture

The architecture of the Mobile Voice Access and Enterprise Feature Access feature is as important to understand as their functionality. [Figure 25-24](#) depicts the message flows and architecture required for Mobile Voice Access and Enterprise Feature Access. The following sequence of interactions and events can occur between Unified CM, the PSTN gateway, and the H.323 or SIP VXML gateway:

1. Unified CM forwards IVR prompts and instructions to the H.323 or SIP VXML gateway via HTTP (see step 1 in [Figure 25-24](#)). This provides the VXML gateway with the ability to play these prompts for the inbound Mobile Voice Access callers.
2. The H.323 or SIP VXML gateway uses HTTP to forward Mobile Voice Access user input back to Unified CM (see step 2 in [Figure 25-24](#)).
3. The PSTN gateway forwards DTMF digits in response to user or Smart Phone key sequences from the remote destination phone for Enterprise Feature Access two-stage dialing and mid-call features (see step 3 in [Figure 25-24](#)).

Figure 25-24 Mobile Voice Access and Enterprise Feature Access Architecture**Note**

While [Figure 25-24](#) depicts the H.323 or SIP VoiceXML gateway as a separate box from the PSTN gateway, this is not an architectural requirement. Both VoiceXML functionality and PSTN gateway functionality can be handled by the same box, provided there are no requirements for the PSTN gateway to run a protocol other than H.323 or SIP. An H.323 or SIP gateway is required for Mobile Voice Access VoiceXML functionality.

High Availability for Mobile Voice Access and Enterprise Feature Access

The Mobile Voice Access and Enterprise Feature Access features rely on the same components and redundancy mechanisms as the Mobile Connect feature (see [High Availability for Mobile Connect](#), [page 25-48](#)). Unified CM Groups are necessary for PSTN gateway registration redundancy. Likewise, PSTN physical gateway and gateway connectivity redundancy should be provided. Redundant access between the PSTN and the enterprise is required for remote destination phones to access Mobile Voice Access and Enterprise Feature Access features in the event of a gateway failure. However, while physical redundancy can and should be provided for the H.323 or SIP VoiceXML gateway, there is no redundancy mechanism for the Cisco Unified Mobile Voice Access service on Unified CM. This service can be enabled and run on the publisher node only. Therefore, if the publisher node fails, Mobile Voice Access functionality will be unavailable. Enterprise Feature Access and two-stage dialing functionality have no such dependency on the publisher and can therefore provide equivalent functionality to mobility users (without the IVR prompts).

Designing Cisco Unified Mobility Deployments

The Cisco Unified Mobility solution delivers mobility functionality via Cisco Unified CM. Functionality includes Mobile Connect, Mobile Voice Access, and Enterprise Feature Access. When deploying this functionality it is important to understand dial plan implications, guidelines and restrictions, and performance and capacity considerations.

Dial Plan Considerations for Cisco Unified Mobility

In order to configure and provision Unified Mobility appropriately, it is important to understand the call routing behavior and dial plan implications of the remote destination profile configuration.

Remote Destination Profile Configuration

When configuring Unified Mobility, you must consider the following two settings on the Remote Destination Profile configuration page:

- Calling Search Space

This setting combines with the directory number or line-level calling search space (CSS) to determine which partitions can be accessed for mobility dialed calls. This affects calls made by the mobility user from the remote destination phone, including Mobile Voice Access and Enterprise Feature Access two-stage dialing as well as calls made in conjunction with mid-call transfer and conferencing features. Ensure that this CSS, in combination with the line-level CSS, contains all partitions that need to be accessed for enterprise calls originating from a user's remote destination phone.

- Rerouting Calling Search Space

This setting determines which partitions are accessed when calls are sent to a user's remote destination phone. This applies to all Mobile Connect calls. When a call to a user's enterprise directory number is also sent via Mobile Connect to a user's remote destination, this CSS determines how the system reaches the remote destination phone. For this reason, the CSS should provide access to partitions with appropriate route patterns and gateways for reaching the PSTN or mobile voice network.

When configuring the Remote Destination Profile Rerouting CSS, Cisco recommends that the route patterns within this CSS point to a gateway that is in the same call admission control location as the gateway used to route the inbound call to the user's desk phone. This ensures that a call admission control denial due to insufficient bandwidth between two locations will not occur when routing calls out to the remote destination. Further, because subsequent call admission control checks after the initial Mobile Connect call is routed will not result in a denial if there is insufficient WAN bandwidth, routing the inbound and outbound call legs out a gateway or gateways in the same call admission control location ensures that subsequent desk phone or remote destination pickup operations during this call will not require call admission control, which could result in WAN bandwidth oversubscription.

Likewise, when configuring the Remote Destination Profile CSS for outbound Mobile Voice Access or Enterprise Feature Access 2-Stage dialing call routing, Cisco recommends that the route patterns within this calling search space point to a gateway that is in the same call admission control location as the gateway that handles the inbound call leg to the Mobile Voice Access or Enterprise Feature Access DID. This ensures that a call admission control denial due to insufficient bandwidth will not occur during initial outbound call routing to the dialed number. However, be aware that a subsequent desk phone pickup can result in WAN bandwidth oversubscription if the desk phone is in a different call admission control location than the gateway through which the Mobile Voice Access or Enterprise Feature Access DIDs are reached.

Finally, because inbound PSTN calls to the mobility-enabled user will always come in their home location gateway based on the DID of their enterprise desk phone, in situations where the mobility-enabled user has moved call admission control locations either due to an Extension Mobility login at another site or due to the physical movement of the user's desk phone to another call admission control location, pointing to an outbound gateway that is located in the same call admission control location with the gateway that the inbound call came in on will not be possible in most cases. For this reason, Cisco recommends avoiding scenarios or deployments in which mobility-enabled users use extension mobility to log on to phones in call admission control locations outside their home location or physically move devices between call admission control locations. If these types of scenarios are not avoided or minimized, there is an increased potential for call leg failures due to call admission control denial or WAN oversubscription due to desk phone or remote destination pickup activity.

Automatic Caller ID Matching and Enterprise Call Anchoring

Another aspect of the Unified Mobility dial plan that is important to understand is the system behavior with regard to automatic caller ID identification for inbound calls from configured remote destination phones. Whenever an inbound call comes into the system, the presented caller ID for that call is compared against all configured remote destination phones. If a match is found, the call will automatically be anchored in the enterprise, thus allowing the user to invoke mid-call features and to pick up in-progress calls at their desk phone. This behavior occurs for all inbound calls from any mobility user's remote destination phone, even if the inbound call is not originated as a mobility call using Mobile Voice Access or Enterprise Feature Access.

Note

Automatic inbound caller ID matching for configured remote destination numbers is affected by whether the Matching Caller ID with Remote Destination service parameter is set to Partial or Complete Match. See [Remote Destination Configuration and Caller ID Matching, page 25-55](#), for more information about this setting.

In addition to automatic enterprise call anchoring, inbound and outbound call routing must also be considered when a configured remote destination phone is calling into the enterprise. Inbound call routing for calls from configured remote destinations occurs in one of two ways, depending on the setting of the service parameter Inbound Calling Search Space for Remote Destination. By default, this service parameter is set to **Trunk or Gateway Inbound Calling Search Space**. With the service parameter set to the default value, inbound calls from configured remote destinations will be routed using the Inbound Calling Search Space (CSS) of the PSTN gateway or trunk on which the call is coming in. If, on the other hand, the parameter Inbound Calling Search Space for Remote Destination is set to the value **Remote Destination Profile + Line Calling Search Space**, inbound calls coming from remote destinations will bypass the Inbound CSS of the PSTN gateway or trunk and will instead be routed using the associated Remote Destination Profile CSS (in combination with the line-level CSS).

Given the nature of inbound call routing from remote destination phones, it is important to make sure that calling search spaces are configured appropriately in order to provide access for these inbound calls to any partitions required for reaching internal enterprise phones, thus ensuring proper call routing from remote destination phones.

Note

Incoming calls that do not come from a configured remote destination phone are not affected by the Inbound Calling Search Space for Remote Destination service parameter because they will always use the trunk or gateway inbound CSS.

Outbound call routing for Mobile Voice Access or Enterprise Feature Access calls always uses a concatenation of the Remote Destination Profile line CSS and device-level CSS, therefore it is important to make sure that these calling search spaces are configured appropriately in order to provide access to any route patterns necessary for off-net or PSTN access, thus ensuring proper outbound call routing from remote destination phones.

Intelligent Session Control

The Intelligent Session Control feature enables automatic call anchoring for enterprise-originated calls made directly to configured remote destination numbers. Normally, mobility call anchoring is dependent exclusively on calls made to or on behalf of a user's enterprise number. The system already anchors externally originated calls made by dial-via-office or enterprise two-stage dialing because these call are routed as internal calls. With the Intelligent Session Control feature enabled, the system will also anchor internally originated calls made directly to configured remote destinations.

This feature is enabled by setting the Reroute Remote Destination Calls to Enterprise Number service parameter to True. By default, this service parameter is set to False and the feature is disabled. When the feature is enabled, not only will the system route the call to the dialed remote destination by way of the PSTN, but it will also automatically anchor the call inside the enterprise gateway. By anchoring these types of calls, the system enables the called mobile user to invoke mid-call features and desk phone pickup or session handoff.

As an example, assume that the Intelligent Session Control feature has been enabled and that a mobility-enabled user has a remote destination number configured as 408 555 1234, which corresponds to their mobile number. If another system user dials the mobility-enabled user's remote destination number (408 555 1234) from their desk phone, the system will route the call through the PSTN to the remote destination and will simultaneously anchor the call in the enterprise gateway. Once the call is set up and anchored, the called mobility-enabled user now has the ability to invoke mid-call features such as hold, transfer, and conference, as well as the ability to perform a desk phone pickup or session handoff.

Taking this same example and assuming instead that the Intelligent Session Control feature is disabled, then when a system user dials the mobility-enabled user's remote destination directly from a desk phone inside the enterprise, the call will still be routed to the called remote destination through the PSTN; however, the call will not be anchored. As a result, the mobile user would not be able to invoke mid-call hold or transfer and would have no ability to perform a desk phone pickup or session handoff.

When enabling this feature, it is important to understand the implications to dial plan configuration and call routing. To invoke the feature, the number dialed by an internal user to reach a remote destination number on the PSTN (including any required PSTN steering digits) must match the remote destination (or mobility identity) number as it is configured on the system. For example, if the remote destination number is configured on the system as 408 555 1234 but internal users must normally dial PSTN steering digits 91 in addition to the number they are calling, then rerouting and resulting enterprise call anchoring will not occur. This is because the user dialed 91 408 555 1234 to reach the remote destination on the PSTN but the remote destination was configured as 408 555 1234, so there is no match.

For this feature to function properly, matching must occur between the configured remote destination and the number that must be dialed to reach this remote destination on the PSTN. To ensure that this matching happens, set the service parameter Matching Caller ID with Remote Destination to **Partial Match**. By setting this parameter to Partial Match and then specifying the number of digits to partially match using the Number of Digits for Caller ID Partial Match service parameter, it is still possible to match the configured remote destination number with the dialed number even if it contains PSTN steering digits.

Using the previous example and assuming that system has been set to use partial match on ten digits, the dialed number 9 1 408 555 1234 can be matched to the configured remote destination 408 555 1234. This is because, with partial matching, the system attempts to match the same number of digits as specified by the Number of Digits for Caller ID Partial Match, which in this case is ten digits. The system attempts to match the two numbers by matching digits from right to left. The last ten digits of the dialed number 9 1 408 555 1234 are 408 555 1234, and these ten digits match the ten digits of the configured remote destination (408 555 1234). In this example, the resulting call is anchored in the enterprise and the called mobile user is able to invoke mid-call features and perform desk phone pickup or session handoff.

At first glance it might appear that an easier way to handle this feature would be to configure remote destination or mobility identity numbers that include any required PSTN steering digits. However, when configuring these numbers with required PSTN steering digits, if you do not also configure partial caller ID matching, the system will not be able to perform automatic caller ID matching and enterprise anchoring for inbound calls from configured remote destinations or mobility identities. In the previous example, if the remote destination number had been configured as 9 1 408 555 1234 and complete caller ID matching had been used, an inbound call from the remote destination would present caller ID of 408 555 1234 and a match would not occur, meaning the inbound call from the remote destination would not be anchored as expected.

Based on this potential for mismatch between dialed numbers for outbound calls and configured remote destination numbers for inbound calls, Cisco recommends enabling partial (rather than complete) caller ID matching when using the Intelligent Session Control feature for all deployments that require one or more steering digits to reach the PSTN. This ensures that calls made directly to the remote destination number using PSTN steering digits are still matched and anchored. On the other hand, if steering digits are not required to reach the PSTN and users are able to dial the full E.164 number to route calls to the PSTN, then Cisco recommends the complete caller ID matching setting because the remote destination is configured to match the caller ID and is the same number as dialed by internal users to reach the remote destination or mobility identity on the PSTN.

When enabling the Intelligent Session Control feature, it is also important to understand the behavior of the enterprise and remote destination lines during the reroute feature operation. On call reroute, remote destination line settings Do Not Disturb (DND), Access Lists and Time of Day call filtering, and the Delay Before Ringing Timer are ignored. All reroute calls are routed unfiltered and immediately. Enterprise desk phone line settings are also ignored or bypassed by default. However, Call Forward All settings on the enterprise desk phone line can be honored during reroute feature operation by setting the Ignore Call Forward All on Enterprise DN service parameter to False. If this parameter is set to False, on reroute operation, calls will not be routed to the remote destination if the enterprise desk phone line has a call-forward-all destination set. Instead, the call will be routed to the call-forward-all destination. By default, this service parameter is set to True, and call-forward-all settings on enterprise desk phone lines are ignored.

Caller ID Transformations

Any calls made into the cluster by configured remote destination numbers will automatically have their caller ID or calling number changed from the calling remote destination phone number to the enterprise directory number of the associated desk phone. For example, if a remote destination phone with number 408 555-7890 has been configured and associated to a user's enterprise desk phone with number 555-1234, then any call from the user's remote destination phone destined for any directory number in the cluster will automatically have the caller ID changed from the remote destination number of 408 555-7890 to the enterprise directory number of 555-1234. This ensures that the active call caller ID display and call history log caller ID reflect a mobility user's enterprise desk phone number rather than their mobile phone number, and it ensures that any return calls are made to the user's enterprise number, thus anchoring those calls within the enterprise.

Likewise, calls from a remote destination phone to external PSTN destinations and anchored in the enterprise via Mobile Voice Access or Enterprise Feature Access two-stage dialing, or those calls forked to the PSTN as a result of Mobile Connect, will also have caller ID changed from the calling remote destination phone number to the associated enterprise directory number.

Finally, in order to deliver the calling party number as an enterprise DID number rather than an enterprise directory number to external PSTN phones, calling party transformation patterns can be used. By using calling party transformation patterns to transform caller IDs from enterprise directory numbers to enterprise DIDs, return calls from external destinations will be anchored within the enterprise because they will be dialed using the full enterprise DID number. For more information about these transformations and dial plan implications, see [Special Considerations for Cisco Unified Mobility, page 9-115](#).

Guidelines and Restrictions for Unified Mobility

The following guidelines and restrictions apply with regard to deployment and operation of Mobile Connect within the Unified CM telephony environment:

- Mobile Connect is supported only with PRI TDM PSTN connections. T1 or E1-CAS, FXO, FXS, and BRI PSTN connections are not supported. This PRI requirement is based on the fact that Cisco Unified CM must receive expeditious answer and disconnect indication from the PSTN in order to ensure full feature support. Answer indication is needed in order for Cisco Unified CM to stop ringing the desk phone and other remote destinations when a Mobile Connect call is answered at a particular remote destination. In addition, answer indication is required in order to support the single enterprise voicemail box feature. Finally, disconnect indication is required for desk phone pickup. A PRI PSTN connection will always provide answer or disconnect indication.
- Mobile Connect is also supported over SIP trunk VoIP PSTN connections as long as the Cisco IOS Unified Border Element provides the demarcation point between the Unified CM SIP trunk and the service provider trunk and as long as mid-call features (or other DTMF-dependent features) are not in use. Mid-call features are not supported over VoIP PSTN connections. A VoIP-based PSTN connection is still able to provide expeditious answer and disconnect indication to Unified CM due to the end-to-end signaling path provided by VoIP-based PSTN connections.
- Mobile Connect can support up to two simultaneous calls per user. Any additional calls that come in are automatically transferred to the user's voicemail.
- Mobile Connect does not work with Multilevel Precedence and Preemption (MLPP). If a call is preempted with MLPP, Mobile Connect features are disabled for that call.
- Mobile Connect services do not extend to video calls. A video call received at the desktop phone cannot be picked up on the cellular phone.
- The Unified CM Forced Authorization Code and Client Matter Code (FAC/CMC) feature does not work with Mobile Voice Access or Enterprise Feature Access.
- Remote destinations must be Time Division Multiplex (TDM) devices or off-system IP phones on other clusters or systems. You cannot configure IP phones within the same Unified CM cluster as remote destinations.

For additional guidelines and restrictions, refer to the information on Cisco Unified Mobility in the latest version of the *Cisco Unified Communications Manager Features and Services Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

Capacity Planning for Cisco Unified Mobility

Cisco Unified Mobility supports the following capacities:

- Maximum of 15,000 mobility-enabled users per cluster with Cisco MCS 7845 server or Open Virtualization Archive (OVA) equivalent servers.
- Maximum of 10,000 mobility-enabled users per cluster with Cisco MCS-7835 or OVA equivalent servers.
- Maximum of 4,000 mobility-enabled users per cluster with Cisco MCS 7825 or OVA equivalent servers.
- Maximum of 3,750 remote destinations per MCS 7845 node or OVA equivalent server, or 15,000 destinations per cluster.
- Maximum of 2,500 remote destinations per MCS 7835 or OVA equivalent server, or 10,000 per cluster.
- Maximum of 1,000 remote destinations per MCS 7825 or OVA equivalent server, or 4,000 per cluster.

Note

A mobility-enabled user is defined as a user that has a remote destination profile and at least one remote destination or a mobility identity configured.

The maximum number of supported mobility-enabled users will depend on the number of remote destinations or mobility identities configured for each user. The capacity numbers for maximum number of mobility-enabled users given above assume one remote destination or mobility identity per user. As the number of remote destinations or mobility identities per user increases, the number of supported mobility-enabled users decreases.

The above numbers are maximum capacities; however, Cisco Unified Mobility scalability and performance ultimately depend on the number of mobility users, the number of remote destinations or mobility identities each user has, and the busy hour call attempt (BHCA) rates of those users. Multiple remote destinations per user and/or high BHCA per user will result in lower capacity for Cisco Unified Mobility.

The capacity for Unified Mobility users on Cisco Business Edition systems depends exclusively on both the number of remote destinations per user and the BHCA of the users enabled for Unified Mobility, rather than on server hardware. Thus, the number of remote destinations supported on Cisco Business Edition depends directly on the BHCA of these users. The guidelines for sizing Unified Mobility for Cisco Business Edition are as follows:

- No more than 4 remote destinations can be configured per user. Given a maximum of 500 users per Cisco Business Edition system, the theoretical limit in terms of remote destinations is 2,000. However, given that the maximum BHCA per Cisco Business Edition is 3,600, it is possible that the system might not be able to support 2,000 remote destinations. Instead, BHCA calculations should be used to properly size the number of remote destinations that can be handled by the system.
- Each configured remote destination has potential BHCA implications. For every remote destination configured for a user, one additional call leg is used. Because each call consists of two call legs, one remote destination ring is equal to half (0.5) of a call. Therefore, you can use the following formula to calculate the total remote destination BHCA:

$$\text{Total remote destination BHCA} = (\text{Number of users}) * (\text{Number of remote destination per user}) * (\text{User BHCA}) * 0.5$$

For example:

Assuming a system of 300 users at 5 BHCA each, with each user having one remote destination (total of 300 remote destinations), the calculation for the total remote destination BHCA would be:

$$\text{Total remote destination BHCA} = (300 \text{ users}) * (1 \text{ remote destination per user}) * (5 \text{ BHCA per user}) * 0.5 = 750 \text{ BHCA}$$

Total user BHCA in this example is $(300 \text{ users}) * (5 \text{ BHCA per user})$, which is 1500 total user BHCA. By adding the total remote destination BHCA of 750 to this value, we get a total system BHCA of 2250 (1500 total user BHCA + 750 total remote destination BHCA).

If other applications or additional BHCA variables are in use on the system in the example above, the capacity might be limited. (See [Cisco Business Edition Capacity Planning, page 8-28](#), for further details.)

Note

A mobility identity is configured just like a remote destination within the system, and it has the same capacity implications as a remote destination. Unlike a remote destination, however, the mobility identity is associated directly to a phone device rather than a remote destination profile. The mobility identity applies only to mobile client devices such as dual-mode phones, direct connect clients, and Cisco Unified Mobile Communicator clients.

Cisco Unified Mobility scalability and performance ultimately depends on the number of mobility users, the number of remote destinations or mobility identities each user has, and the busy hour call attempt (BHCA) rates of those users. Multiple remote destinations per user and/or high BHCA per user may result in lower capacity for Cisco Unified Mobility. For information on general Unified CM system sizing, see the chapter on [Unified Communications Design and Deployment Sizing Considerations, page 29-1](#).

Design Considerations for Cisco Unified Mobility

Observe the following design recommendations when deploying Unified Mobility:

- Ensure that the PSTN gateway protocol is capable of out-of-band DTMF relay or allocate media termination points (MTPs) in order to covert in-band DTMF to out-of-band DTMF. When using Cisco IOS gateways for PSTN connectivity, out-of-band DTMF relay will be supported. However, third-party gateways might not support a common out-of-band DTMF method, and as a result an MTP might be required. In order to use Enterprise Feature Access Two-Stage Dialing and mid-call features, DTMF digits must be received out-of-band by Cisco Unified CM.

Note

When relying on MTP for converting in-band DTMF to out-of-band DTMF, be sure to provide sufficient MTP capacity. If heavy or frequent use of Enterprise Feature Access Two-Stage Dialing or mid-call features is anticipated, Cisco recommends a hardware-based MTP or Cisco IOS software-based MTP.

- Prior to deploying Unified Mobility, it is important to work with the PSTN provider to ensure the following:
 - Caller ID is provided by the service provider for all inbound calls to the enterprise. This is a requirement if Enterprise Feature Access Two-Stage Dialing or mid-call transfer, conference, and directed call park features are needed.

- Outbound caller ID is not restricted by the service provider. This is a requirement if there is an expectation that mobility-enabled users will receive the caller ID of the original caller at their remote destination rather than a general enterprise system number or other non-meaningful caller ID.

Note Some providers restrict outbound caller ID on a trunk to only those DIDs handled by that trunk. For this reason, a second PRI trunk that does not restrict caller ID might have to be acquired from the provider. To obtain an unrestricted PRI trunk, some providers might require a signed agreement from the customer indicating they will not send or make calls to emergency numbers over this trunk.

Note Some providers allow unrestricted outbound caller ID on a trunk as long as the Redirected Dialed Number Identification Service (RDNIS) field or SIP Diversion Header contains a DID handled by the trunk. The RDNIS or SIP Diversion Header for forked calls to remote destinations can be populated with the enterprise number of the user by checking the Redirecting Number IE Delivery - Outbound check box on the gateway or trunk configuration page. Contact your service provider to determine if they honor the RDNIS or SIP Diversion Header and allow unrestricted outbound caller ID.

- Because mobility call flows typically involve multiple PSTN call legs, planning and allocation of PSTN gateway resources is extremely important for Unified Mobility. In cases where there are large numbers of mobility-enabled users, PSTN gateway resources will have to be increased. The following methods are recommend to minimize or reduce PSTN utilization:
 - Limit the number of remote destinations per mobility-enabled user to one (1). This will reduce the number of DS0s that are needed to extend the inbound call to the user's remote destination. One DS0 is consumed for each configured remote destination when a call comes into the user's enterprise directory number, even if the call is not answered at one of the remote destinations. Note that a DS0 per remote destination may be used for as long as 10 seconds, even if the call is not answered at the remote destination.
 - Use access lists to block or restrict the extension of calls to a particular remote destination based on incoming caller ID. Because access lists can be invoked based on the time of day, this eliminates the need for repeated updates of access lists by the end-user or the administrator.
 - Educate end-users to disable Mobile Connect when not needed, to further eliminate DS0 utilization when a call comes in for that user's enterprise number. If Mobile Connect is disabled, incoming calls will still ring the desk phone and will still forward to enterprise voicemail if the call goes unanswered.
- Due to the potential for call admission control denials resulting from insufficient WAN bandwidth between locations and the possibility that a desk phone pickup or remote destination pickup may result in a WAN bandwidth oversubscription, Cisco recommends configuring Remote Destination Profile CSS and Rerouting CSS so that route patterns within these CSSs point to gateways that are located within the same call admission control location as the gateway on which the inbound call leg comes in. For more information, see [Remote Destination Profile Configuration, page 25-58](#).
- If you enable the Intelligent Session Control feature in deployments where PSTN steering digits must be dialed to access the PSTN, Cisco recommends setting the Matching Caller ID with Remote Destination service parameter to **Partial Match** and configuring the appropriate number of digits (Number of Digits for Caller ID Partial Match service parameter) to achieve a partial match of

configured remote destinations or mobility identities. This will ensure proper functioning of the Intelligent Session Control feature and the mobility automatic caller ID matching and anchoring features.

Dual-Mode Phones and Clients

As the prevalence of mobile users, mobile phones, and mobile carrier services continues to increase, the ability to use a single device for voice and data services both inside and outside the enterprise becomes increasingly attractive. Dual-mode phones and the clients that run on them afford an enterprise the ability to provide customized voice and data services to users while inside the enterprise and to leverage the mobile carrier network as a backup provider of general voice and data services, all by using a single mobile phone. By enabling voice and data services inside the enterprise and providing network connectivity for dual-mode phones, enterprises are able to provide these services locally at reduced connectivity costs. For example, voice over IP (VoIP) calls made on the enterprise network will typically incur less cost than those same calls made over the mobile voice network.

This section examines dual-mode phone architecture and common functions and features provided by dual-mode phones and clients, including remote secure attachment and handoff considerations related to moving an active voice call between the enterprise WLAN network and the mobile voice network. After covering general dual-mode solution architecture and features and functions, this section provides coverage of various capabilities and integration considerations for the following specific dual-mode clients:

- Cisco Mobile — A dual-mode client for the iPhone 3G mobile device, providing the ability to make VoIP calls on the enterprise WLAN network as well as to access corporate directory and voicemail services.
- Cisco Jabber — A dual-mode client for Android and iPhone mobile devices, providing the ability to make VoIP calls on the enterprise WLAN network or over private/public 802.11 WLAN hot spots or the mobile data network as well as the ability to access the corporate directory and receive enterprise voicemail message waiting indication and message count.
- Nokia Call Connect — A dual-mode client for Nokia mobile devices, providing the ability to make VoIP calls on the enterprise WLAN network or over private/public 802.11 WLAN hot spots or the mobile data network as well as the ability to access corporate directory and other applications and services.

**Note**

End-of-Sale for the Nokia Call Connect client is July 10, 2012. There is no replacement mobile client for Nokia mobile devices. For more information, see the End-of-Sale (EoS) and End-of-Life (EoL) announcement at http://www.cisco.com/en/US/prod/collateral/voicesw/ps6789/ps7290/ps10589/end_of_life_notice_c51-696647.html.

In addition, this section discusses high availability and capacity planning considerations for dual-mode phones and clients.

Dual-Mode Phone Architecture

Dual-mode phones provide two physical interfaces or radios that enable the device to connect to both mobile voice and data carrier networks by means of traditional cellular or mobile network technologies and wireless local area networks (WLANs) using IEEE 802.11 standards. Dual-mode phones and the

clients that run on them enable on-premises data and voice connectivity through 802.11 WLAN as well as remote data and voice connectivity to the enterprise via public or private WLANs or over the mobile data network.

**Note**

The use of the term *dual-mode phone* in this section refers specifically to devices with 802.11 radios in addition to the cellular radio for carrier voice and data network connectivity. Dual-mode devices that provide Digital Enhanced Cordless Telecommunications (DECT) or other wireless radios and/or multiple cellular radios are outside the scope of this section.

Figure 25-25 depicts the basic dual-mode solution architecture for incorporating dual-mode devices into a Cisco Unified Communications System. The dual-mode phone connects to the enterprise network, and then the dual-mode client registers to Cisco Unified CM as an enterprise phone. Once registered, the dual-mode device relies on the underlying enterprise Cisco IP telephony network for making and receiving calls. Only when enterprise network connectivity is unavailable, will the dual-mode phone fall back to the mobile voice network for making and receiving calls. When the dual-mode phone is connected to the enterprise network and the client is registered to Unified CM, the phone will be reachable through the user's enterprise number. Any inbound calls to the user's enterprise number will ring the dual-mode phone. If the user has a Cisco IP desk phone, then the dual-mode client registration enables a shared line instance for the user's enterprise number so that an incoming call rings both the user's desk phone and the dual-mode phone. When unregistered, the dual-mode client will not receive incoming enterprise calls at the dual-mode phone unless the user has been enabled for Cisco Unified Mobility and Mobile Connect (or single number reach) has been turned on for the user's mobile number.

Figure 25-25 Dual-Mode Phone Architecture

Note

The voice quality of calls will vary depending on the Wi-Fi or mobile data network connection. Cisco Technical Assistance Center (TAC) is not able to troubleshoot connectivity or voice quality issues over mobile data networks or non-corporate Wi-Fi networks when using the secure connect feature of Cisco Jabber or the Cisco AnyConnect Secure Mobility Client.

Dual-mode phones must be capable of dual transfer mode (DTM) in order to be connected simultaneously to both the mobile voice and data network and the WLAN network. This allows the device to be reachable and able to make and receive calls on both the cellular radio and the IP interface (WLAN or mobile data) of the device. In some cases proper dual-mode client operation might not be possible if mobile voice and data networks do not support dual-connected devices.

Voice over Wireless LAN Network Infrastructure

Before considering the various dual-mode features and functions and the impact these features and functions have on the enterprise telephony infrastructure, it is critical to plan and deploy a finely tuned, QoS-enabled, and highly available WLAN network. Because dual-mode phones rely on the underlying WLAN infrastructure for carrying both critical signaling and other traffic for setting up calls and accessing various applications as well as the real-time voice media traffic, deploying a WLAN network optimized for both data and real-time voice traffic is necessary. A poorly deployed WLAN network will be subjected to large amounts of interference and diminished capacity, leading not only to poor voice quality but in some cases dropped or missed calls. This will in turn render the WLAN deployment unusable for making and receiving voice calls. Therefore, when deploying dual-mode phones, it is imperative to conduct a WLAN radio frequency (RF) site survey before, during, and after the deployment to determine appropriate cell boundaries, configuration and feature settings, capacity, and redundancy to ensure a successful voice over WLAN (VoWLAN) deployment. Each dual-mode phone device type and/or client should be tested on the WLAN deployment to ensure proper integration and operation prior to a production deployment. Using a WLAN that has been deployed and configured to provide optimized VoWLAN services (such as the Cisco Unified Wireless Network), including quality of service, will ensure a successful dual-mode phone deployment.

For more information on Voice over WLAN deployments and wireless device roaming, see [Wireless Device Roaming, page 25-7](#).

Note

While dual-mode phones and clients are capable of connecting back to the enterprise through the Internet for call control and other Unified Communications services, Cisco cannot guarantee voice quality or troubleshoot connectivity or voice quality issues for these types of connections. These types of connections include remote connections to the enterprise through public or private WLAN access points (APs) or hot spots or through the mobile data network. Cisco recommends an enterprise class voice-optimized WLAN network for connecting dual-mode phones and clients. Most public and private WLAN APs and hot spots are tuned for data applications and devices. In these cases, the AP radios are turned to maximum power, and dynamic-power control results in devices enabling maximum power on network attachment, which allows for larger client capacities. While this may be ideal for data applications that are capable of retransmitting dropped or lost packets, for voice applications this can result in very poor voice quality due to the potential for large numbers of dropped packets. Likewise, mobile provider data networks are susceptible to congestion and/or dropped connections, which can also result in poor voice quality and dropped calls.

Dual-Mode Features and Functions

Dual-mode devices provide a range of features and functions. While features and operations may vary from device to device, the common operations and behaviors described in this section apply to all dual-mode devices.

Enterprise Call Routing

Because dual-mode phones leverage the enterprise telephony infrastructure and call control services at least some of the time, it is important to understand the nature and behavior of call routing when the dual-mode device is inside the enterprise.

Inbound Call Routing

Because the dual-mode device registers to Unified CM as a user's enterprise extension with enterprise number, the dual-mode device rings when incoming calls to the system are destined for the user's enterprise number. This occurs for incoming calls originated on the PSTN or from other Unified CM clusters or enterprise IP telephony systems as well as for incoming calls originated within the Unified CM cluster by other users. If the dual-mode user has other devices or clients that are also associated to the enterprise number, these devices will also ring as shared lines; and once the call is answered at one of the devices or clients, ringing of all other devices and clients ceases.

In scenarios where a user has been enabled for Cisco Unified Mobility, and when Mobile Connect or single number reach is enabled for the user's dual-mode phone mobile number, the incoming call may also be extended to the mobility identity corresponding to the dual-mode mobile number. However, this depends on whether the dual-mode device is connected to the enterprise WLAN network or attached to the enterprise network through secure VPN and registered to Unified CM. In situations in which the dual-mode device is connected to the enterprise network directly or through a secure remote connection, an incoming call to the user's enterprise number will not be extended by Mobile Connect to the mobility identity of the dual-mode device even if Mobile Connect is turned on for this mobile number. The reason an incoming call to the enterprise number is not extended to the mobility identity of a dual-mode device when it is registered to Unified CM is that the system is aware the device is connected to the enterprise network and available. Thus, in order to reduce utilization of enterprise PSTN resources, Unified CM does not extend the call to the dual-mode device's mobile voice network interface through the PSTN. Instead, only the WLAN interface corresponding to the enterprise number is called.

Note

For inbound calls to the enterprise number, the amount of time Unified CM waits for the SIP dual-mode client to respond before extending an incoming call to the mobility identity or mobile number via Mobile Connect, is determined by the SIP Dual Mode Alert Timer service parameter. By default this timer is set to 1,500 milliseconds. Cisco recommends increasing this timer to a minimum of 3,000 milliseconds to ensure that dual-mode clients have more time to respond to an inbound call on the IP interface of the device. After adjusting this global timer to 3,000 milliseconds, if users are still receiving calls at the cellular voice interface or mobility identity when the client appears to be registered, then adjust the timer upward to 4,500 milliseconds or higher. This is especially important for dual-mode client devices that are connected to the enterprise network remotely using VPN.

For situations in which the dual-mode device is not connected to the enterprise and/or not registered to Unified CM, incoming calls to the enterprise number will be extended to the dual-mode device according to the configured mobility identity, assuming that the user has been enabled for Unified Mobility and that Mobile Connect for the mobility identity is turned on. For more information on integration of dual-mode devices and clients with Unified Mobility, see [Interactions Between Cisco Mobile or Cisco Jabber and Cisco Unified Mobility, page 25-79](#), and [Interactions Between Nokia Call Connect and Cisco Unified Mobility, page 25-83](#).

In all cases, incoming calls made directly to the dual-mode device's mobile phone number will always be routed directly to the cellular radio of the dual-mode device on the mobile network, unless the provider network or device settings are such that calls are not extended to the device by the mobile network. This is considered appropriate behavior because these calls were not made to the user's enterprise number. These would be considered personal calls, and as such should not be routed through the enterprise.

Outbound Call Routing

For outbound calls from the dual-mode device, the interface used depends on the location and connectivity of the device at that particular time. If the dual-mode device is not connected to the enterprise and not registered to Unified CM, then calls are routed by the cellular voice radio interface to the mobile voice network as usual. However, when connected to the enterprise and registered to Unified CM, the dual-mode device should make all calls through the enterprise telephony infrastructure. If no enterprise connectivity is available or if the dual-mode client is unregistered, then outbound calling is not possible from the enterprise number, and instead callers would have to use the mobile number of the mobile device for making calls over the mobile voice network. Alternatively, users may use the two-stage dialing features provided with Cisco Unified Mobility (see [Mobile Voice Access and Enterprise Feature Access, page 25-49](#)).

In the case of some dual-mode clients, there may be a need for configuration of one or more settings in order to have the client register automatically to Unified CM when enterprise network connectivity is available. Whenever the dual-mode client is not registered to Unified CM, then outbound calls will be made using the mobile voice network rather than the enterprise network.

Dial Plan

The enterprise dial plan determines the dialing behavior of the dual-mode device when it is connected to the enterprise and registered to Unified CM. For example, if the enterprise dial plan is configured to allow abbreviated dialing to reach internal extensions, then a dual-mode device registered to Unified CM can leverage this abbreviated dialing. While it is certainly a convenience for dual-mode mobile phone users to be able to dial within the enterprise using enterprise dialing habits and leveraging abbreviated dialing as well as site-based and/or PSTN steering digits for outbound calls, it is also a somewhat unnatural dialing scheme because mobile phone users typically dial numbers for outgoing calls on their mobile phone by using full E.164 dial strings since this is what is expected by the mobile voice network for outbound calling.

The enterprise dialing experience for an end-user is ultimately up to the enterprise policies and administrator of the enterprise telephony deployment. However, for dual-mode client devices, Cisco recommends normalizing required dialing strings so that user mobile device dialing habits are maintained whether the device is connected to the enterprise network and registered to Unified CM or not. Because dialing on the mobile voice network is typically done using full E.164 (with or without a preceding '+') and mobile phone contacts are typically stored with full E.164 numbers, Cisco recommends configuring the enterprise dial plan to accommodate full E.164 or full E.164 with preceding '+' for dual-mode client devices. When the dial plan is configured within Unified CM to handle this type of outbound dialing for dual-mode phones, it is possible for users to store a single set of contacts on the phone in the E.164 format and, when dialed from these contacts or manually using the full E.164 number, calls will always be routed to the appropriate destination, whether the device is connected to the enterprise network directly or over a secure remote connection and registered to Unified CM or connected only to the mobile voice network. Configuring the enterprise dial plan in this manner provides the best possible end-user dialing experience so that users' mobile device dialing habits are maintained and they do not have to be aware of whether the device has enterprise connectivity and is registered to Unified CM.

To achieve normalized dialing from dual-mode phones, whether connected to the enterprise or just to the mobile voice network, configure the dial plan within Unified CM with the following considerations in mind:

- Ensure that the enterprise dial plan is capable of handling dial strings from dual-mode phones typically used on the mobile voice network. For example, the dial plan should be configured to handle the following strings, which might be dialed from a mobile phone to reach a particular phone through the mobile voice network: +1 408 555 1234, 408 555 1234.
- For calls destined for other enterprise numbers, systems configured for abbreviated dialing should be capable of modifying dial strings and rerouting to enterprise extensions as appropriate. For example, assuming the enterprise dial plan is based on five-digit internal dialing, the system should be configured to handle call routing to an enterprise extension so that a call made to +1 408 555 1234 or 408 555 1234 is modified and rerouted to 51234 if the call is made while the dual-mode device is registered to Unified CM.
- Ensure that all inbound calls to the enterprise destined for dual-mode devices have the calling number and/or caller ID prefixed with appropriate digits so that missed, placed, and received call history lists are in full E.164 formats. This will allow dual-mode device users to dial from call history lists without the need for editing the dial string. Instead, users will be able to select a number from the call history list to redial, whether connected to the enterprise or not. For example, if an incoming call from inside the enterprise originates from 51234 to a dual-mode user's enterprise number and the call goes unanswered, Unified CM should be configured to manipulate the calling number so that the resulting entry within the history list of the dual-mode device shows either 408 555 1234 or +1 408 555 1234. This number can be dialed without the need for further manipulation, whether the dual-mode device is connected to the enterprise or just to the mobile voice network.

The one exception to normalized dialing for dual-mode devices is for scenarios in which some enterprise extensions or phones are reachable only internally (that is, they have no externally reachable corresponding DID number). In these situations, non-externally reachable numbers can be dialed (manually or from contacts) using abbreviated formats. Because these numbers will never be available externally and can be dialed only from inside the enterprise, some sort of enterprise-only indication should be made when storing these numbers in the contact list. Further, incoming calls from these internal-only numbers should not have the calling number modified for call history lists because these numbers may be called only inside the enterprise. Instead, calls from these extensions should be listed in all call history lists without modification so that the abbreviated dial strings can be successfully dialed only while the device is connected to the enterprise and registered to Unified CM.

Emergency Services and Dialing Considerations

Dual-mode phones do present a slight challenge when it comes to making calls to emergency service numbers such as 911, 999, and 112. Because the dual-mode device may be located inside or outside the enterprise, providing location information for a dual-mode phone and its user in the event of an emergency must be considered. Dual-mode mobile devices with cellular voice radios receive location services from their provider networks, and these location services are always available when the device is connected and typically are able to pinpoint locations far more precisely than enterprise wireless networks; therefore Cisco recommends that dual-mode device users rely on the mobile voice network for making emergency calls and determining device and user location. To ensure that dual-mode client devices rely exclusively on the mobile provider voice network for emergency and location services, these clients force all calls made to numbers configured in the Emergency Numbers field on the mobile client device configuration page to route over the mobile voice network. Further, dual-mode phone users should be advised to make all emergency calls over the mobile voice network rather than the enterprise network.

Enterprise Caller ID

When dual-mode devices are connected to the enterprise and registered to Unified CM, all calls made with the enterprise line over the WLAN or mobile data network are routed with the user's enterprise number as caller ID. This ensures that returned calls made from call history lists at the far-end are always routed through the enterprise because the return call is to the user's enterprise number. If the dual-mode user has been enabled for Cisco Unified Mobility, and Mobile Connect is turned on for the mobile number, return calls to the enterprise number would also be extended to the dual-mode device through the PSTN whenever it is not connected to the enterprise.

Mid-Call Features

When dual-mode phone clients are connected to the enterprise and registered to Unified CM as enterprise endpoints, they are able to invoke call processing supplementary services such as hold, resume, transfer, and conference, using call signaling methods as supported by Unified CM. Just as with any IP phone or client registered to Unified CM, these devices are able to leverage enterprise media resources such as music on hold (MoH), conference bridges, media termination points, and transcoders.

External Call Routing

When the dual-mode device is not connected to the enterprise and is not registered to Unified CM, it may make and receive calls only through the mobile voice network. For this reason, Unified CM has no visibility into any calls being made or received at the dual-mode mobile device while it is unregistered. The mobile number is the caller ID being sent to the network when calls are made from dual-mode phones not connected to the enterprise. This will likely result in unanswered calls being made directly back to the dual-mode device's mobile number instead of being routed back through the enterprise.

If the dual-mode phone is integrated with Cisco Unified Mobility, enterprise two-stage dialing services may be leveraged for making calls through the enterprise network even when the dual-mode device is outside the enterprise and not registered to Unified CM. Unified Mobility two-stage dialing is done using either Mobile Voice Access or Enterprise Feature Access and requires the user to dial an enterprise system access DID number and enter credentials prior to dialing the number they are calling. For more information on Unified Mobility two-stage dialing features, see [Mobile Voice Access and Enterprise Feature Access, page 25-49](#).

Likewise, if the dual-mode phone is integrated with Unified Mobility, a user can also receive incoming calls to their enterprise number at the mobile number through Mobile Connect; can invoke mid-call features using DTMF key sequences including hold, resume, transfer, and conference; and can perform desk phone pickup to move an active call from the mobile phone to the enterprise desk phone.

Remote Secure Enterprise Connectivity

Dual-mode client devices can utilize the IP telephony infrastructure for enterprise VoIP calling even when outside the enterprise, provided they have a secure connection back to the enterprise in order to register the client with Unified CM. Remote secure connectivity for these devices requires the use of a VPN solution such as Cisco AnyConnect or the Cisco Jabber secure connect feature in order to secure the client connection over the Internet.

Voice quality and user experience for remotely attached dual-mode client devices will vary depending on the nature of the Internet-based network connection. Cisco cannot guarantee acceptable voice quality nor successful connectivity for these types of client connections. Care should be taken when relying on these types of connections for business-critical communications. In the case of unreliable or low-bandwidth Internet connections, users should be advised to make calls over the mobile voice network rather than relying on the enterprise telephony infrastructure.

Additional Services and Features

In addition to call processing or call control services, dual-mode phones and clients are capable of providing the additional features and services described in this section.

Dual-Mode Call Handoff

One very important aspect of dual-mode phone deployments is call preservation as a user moves in and out of the enterprise and network connectivity changes from the cellular voice radio to the WLAN radio, and vice versa. Because dual-mode phone users are often mobile, it is important to maintain any active call as a dual-mode user moves in or out of the enterprise. For this reason, dual-mode clients and the underlying enterprise telephony network should be capable of some form of call handoff.

There are two types of call handoff that should be accommodated by both the dual-mode client and the underlying IP telephony infrastructure:

- Hand-out

Call hand-out refers to the movement of an active call from the WLAN or mobile data network interface of the dual-mode phone to the cellular voice interface of the dual mode phone. This requires the call to be handed out from the enterprise IP network to the mobile voice network through the enterprise PSTN gateway.

- Hand-in

Call hand-in refers to the movement of an active call from the cellular voice interface of the dual mode phone to the WLAN or mobile data network interface of the dual mode phone. This requires the call to be handed in from the mobile voice network to the enterprise IP network through the enterprise PSTN gateway.

The handoff behavior of a dual-mode phone depends on the nature of the dual-mode client and its particular capabilities. Some dual-mode clients are capable of providing only manual handoff, while other clients are able to invoke handoff automatically based on network conditions. In manual handoff scenarios, the dual-mode users are responsible for engaging and completing the handoff operation based on their location and needs. With automatic handoff, the dual-mode client monitors the WLAN signal and makes handoff decisions based on strengthening or weakening of the WLAN signal at the client. Hand-out is engaged in the case of a weakening WLAN signal, while hand-in is engaged in the case of a strengthening WLAN signal. Automatic handoff depends on the mobile device to provide capabilities for monitoring WLAN signal strength.

Handoff operations are critical for maximizing utilization of the enterprise IP telephony infrastructure for phone calls. These operations are also necessary for providing voice continuity and good user experience so that users do not have to hang up the original call and make another call to replace it.

Corporate Directory Access

Some dual-mode clients are capable of accessing enterprise directory services, including directory lookups and personal contact lists. While this is not a required feature for dual-mode devices and clients, it does provide productivity improvements for dual-mode phone users when they are able to access corporate directory information from their mobile device.

Enterprise Voicemail Services

Many dual-mode clients are also capable of accessing enterprise voicemail services. Most dual-mode clients are capable of receiving enterprise message waiting indication whenever an unread voicemail is in the user's enterprise voicemail box and the dual-mode phone is connected to the enterprise network. Further, dual-mode clients can be used to retrieve enterprise voicemail messages. Typically enterprise voicemail messages are retrieved when the user dials the voicemail system number and navigates to their voicemail box after providing required credentials. However, some dual-mode clients provide the ability to retrieve voicemail messages from the voicemail box by downloading and displaying a list of all

messages in the voicemail box and then by selecting individual messages to be downloaded to the dual-mode phone for listening. This is sometimes referred to as visual voicemail. Both the dual-mode phone client and the enterprise voicemail system must be capable of providing and receiving message waiting indication (MWI), voicemail message information, and downloads of the messages over the network. Cisco Unity Connection supports visual voicemail through IMAP, and it can provide MWI and voicemail lists and downloads, but only if the mobile client also supports this functionality.

Dual-Mode Clients: Cisco Mobile and Cisco Jabber

This section describes characteristics and deployment considerations for Cisco Mobile and Cisco Jabber.

Cisco Mobile

Cisco Mobile is a dual-mode client for the Apple iPhone. Once the client application is downloaded from the Apple Application Store and installed on the iPhone using iTunes, the iPhone can associate to the enterprise WLAN network and register to Unified CM as a SIP enterprise phone.

To provide registration and call control services to the Cisco Mobile dual-mode iPhone client, the device must be configured within Unified CM as a **Cisco Dual Mode for iPhone** device type. Next the iPhone must be configured to access the enterprise WLAN for connectivity based on the enterprise WLAN infrastructure and security policies. Once the iPhone has been configured to access the WLAN, when the Cisco Mobile client is launched, it will register the device to Unified CM.

To integrate to Unified Mobility and to leverage handoff functionality, the mobile number of the iPhone must be configured as a mobility identity associated to the Cisco Dual-Mode for iPhone device within Unified CM.

The Cisco Mobile 8.0 client is supported on iPhone models 3G, 3GS, and 4 running firmware version 3.0.1 or later. The iPhone WLAN interface supports 802.11b and 802.11g network connectivity.

Note

When deploying iPhone 3GS and 4 devices, use the Cisco Jabber for iPhone client rather than the Cisco Mobile 8.0 client. The Cisco Jabber for iPhone client provides support for multitasking or backgrounding of the application and provides a superior user experience. The iPhone 3G is supported only with Cisco Mobile 8.0.

The Cisco Mobile client not only provides dual-mode phone services but also provides directory lookup services when configured to access the enterprise Microsoft Active Directory and provides visual voicemail services when configured to access the user's voicemail box on Cisco Unity Connection.

Note

When simultaneously deploying both Cisco Mobile and the Cisco Unified Mobile Communicator client for the iPhone, Cisco Mobile should not be configured to access the user's enterprise voicemail box. Instead, the Cisco Mobile client should be used for visual voicemail access because it provides more features and a superior user experience.

The Cisco Mobile client is capable of performing only manual hand-out as described in the section on [Cisco Mobile and Cisco Jabber Handoff, page 25-76](#).

For more information about the Cisco Mobile dual-mode iPhone client, additional feature details, and supported hardware and software versions, refer to the Cisco Unified Mobile Communicator documentation available at

http://www.cisco.com/en/US/products/ps7271/tsd_products_support_series_home.html

Cisco Jabber

Cisco Jabber is a dual-mode client for Android, iPhone, and other Apple iOS mobile devices. Once the client application is downloaded from the appropriate store or market (Apple Application Store or Google Play, formerly Android Market) and installed on the Apple iOS or Android device, it can connect to the enterprise network and register to Unified CM as a SIP enterprise phone.

To provide registration and call control services to the Cisco Jabber dual-mode Android or iPhone client, the device must be configured within Unified CM as a **Cisco Dual Mode for Android or iPhone** device type. Next, the mobile device must be configured to access the enterprise WLAN for connectivity based on the enterprise WLAN infrastructure and security policies. Alternatively the mobile device can be connected to the enterprise network through the mobile data network or over non-enterprise WLANs. Once the mobile device has been configured to access the enterprise network, if the Cisco Jabber client is launched, it will register the device to Unified CM. To integrate to Unified Mobility and to leverage handoff functionality, the mobile number of the Android or iPhone must be configured as a mobility identity associated to the Cisco Dual-Mode for Android or iPhone device within Unified CM.

The Cisco Jabber client is supported on the following devices:

- Android

Samsung Galaxy S International, Samsung Galaxy Tab International, and Samsung Galaxy S2. These devices must be running a minimum firmware version of 2.2.1. Although not officially supported, Cisco Jabber for Android runs on many Android devices running version 2.2 and later with various degrees of limitations depending on the device. The WLAN interfaces of most Android devices support 802.11b, 802.11g, and 802.11n network connectivity.

- Apple iOS

iPhone 3GS, 4, and 4S; iPod Touch 3rd and 4th generation; and iPad and iPad 2. These devices must be running a minimum iOS version of 5.0. The WLAN interfaces of Apple iOS devices support 802.11b, 802.11g, and 802.11n network connectivity.

For details on the latest specific device and firmware version support, refer to the product release notes for:

- Android

http://www.cisco.com/en/US/products/ps11678/prod_release_notes_list.html

- iPhone

http://www.cisco.com/en/US/products/ps11596/prod_release_notes_list.html

The Cisco Jabber client not only provides voice over IP (VoIP) phone services but also provides directory lookup services when configured to access the enterprise LDAP directory and provides enterprise voicemail message waiting indication (MWI) and message count or visual voicemail when integrated to Cisco Unity Connection.

The Cisco Jabber client is capable of performing only manual hand-out as described in the section on [Cisco Mobile and Cisco Jabber Handoff](#), page 25-76.

For more information about the Cisco Jabber dual-mode Android and iPhone clients, additional feature details, and supported hardware and software versions, refer to the Cisco Jabber documentation for:

- Android

http://www.cisco.com/en/US/products/ps11678/tsd_products_support_series_home.html

- iPhone

http://www.cisco.com/en/US/products/ps11596/tsd_products_support_series_home.html

Cisco Mobile and Cisco Jabber Handoff

To properly deploy Cisco dual-mode clients such as Cisco Mobile and Cisco Jabber, it is important to understand the nature of handoff operations within the client. The handoff method used by the Cisco Mobile and Cisco Jabber dual-mode client depends on the **Transfer to Mobile Network** setting on the Cisco Dual-Mode for iPhone or Cisco Dual-Mode for Android device configuration page.

There are two methods of handoff, depending on the Transfer to Mobile Network setting:

- [Mobility Softkey Method of Hand-Out, page 25-76](#)

With this method the Transfer to Mobile Network setting should be set to **Use Mobility Softkey (user receives call)**. In this type of handoff, the Unified CM system generates a call over the PSTN to the user's mobile number. This hand-out method is supported with both Cisco Mobile and Cisco Jabber dual-mode clients.

- [Handoff Number Method of Hand-Out, page 25-77](#)

With this method the Transfer to Mobile Network setting should be set to **Use HandoffDN Feature (user places call)**. In this type of handoff, the dual-mode client generates a call over the mobile voice network to the handoff number configured within the Unified CM system. This hand-out method is supported only with iPhone dual-mode clients.

Mobility Softkey Method of Hand-Out

The operation depicted in [Figure 25-26](#) is of an active call on an iPhone or Android dual-mode device within the enterprise being moved manually from the WLAN interface to the mobile voice network or cellular interface of the device through the enterprise PSTN gateway. As shown, there is an existing call between the dual-mode device associated to the enterprise WLAN and registered to Unified CM, and a phone on the PSTN network (step 1). Because this is a manual process, the user must select the Use Mobile Network button from the in-call menu within the Cisco Mobile or Cisco Jabber dual-mode client, which signals to Unified CM the intention to hand-out the call (step 2). Next Unified CM generates a call to the configured mobility identity number corresponding to this dual-mode device through the enterprise PSTN gateway (step 3). This call to the mobility identity is made to the mobile voice network or cellular interface of the iPhone or Android device. The user can now move out of the enterprise and away from WLAN network coverage (step 4). In the meantime, the inbound call from Unified CM is received at the mobile voice network interface, and the user must answer the call manually to complete the hand-out. Once the inbound call on the cellular interface is answered, the RTP stream that was traversing the WLAN is redirected to the PSTN gateway, and the call continues uninterrupted between the dual-mode client and the original PSTN phone with the call anchored in the enterprise gateway (step 5).

Figure 25-26 Cisco Mobile or Cisco Jabber Dual-Mode Hand-Out (WLAN-to-Mobile Voice Network): Mobility Softkey Method

Handoff Number Method of Hand-Out

Figure 25-27 illustrates the same hand-out operation as in Figure 25-26, where an active call on an iPhone dual-mode phone within the enterprise is moved manually from the WLAN interface to the mobile voice network or cellular interface of the device through the enterprise PSTN gateway. However, in this case the Handoff Number method of hand-out is used.

Note

The Handoff Number method of hand-out is supported only with iPhone dual-mode clients.

As shown in Figure 25-27, there is an existing call between the iPhone dual-mode device associated to the enterprise WLAN and registered to Unified CM, and a phone on the PSTN network (step 1). Because this is a manual process, the user must select the Use Mobile Network button from the in-call menu within the Cisco Mobile dual-mode client, which signals to Unified CM the intention to hand-out the call (step 2). Next the Cisco Mobile client automatically generates a call through the cellular interface over the mobile voice network to the configured Handoff Number within the Unified CM system (step 3). The user can now move out of the enterprise and away from WLAN network coverage (step 4). In the meantime, the inbound call from the Cisco Mobile client is received by Unified CM. Assuming the inbound calling number matches the user's configured mobility identity, the RTP stream that was traversing the WLAN is redirected to the PSTN gateway, and the call continues uninterrupted between the Cisco Mobile dual-mode client and the original PSTN phone, with the call anchored in the enterprise gateway (step 5).

Figure 25-27 Cisco Mobile Dual-Mode Hand-Out: Handoff Number Method

254273

Note

The Handoff Number method of hand-out requires that Unified CM receive an inbound calling number from the PSTN network that matches the mobility identity number configured under the Cisco Dual Mode for iPhone device attempting the hand-out. If the caller ID is not sent by the iPhone, if the PSTN provider does not send the inbound caller ID to the enterprise, or if the inbound caller ID does not match the user's configured mobility identity, the hand-out operation will fail.

Note

Cisco Mobile and Cisco Jabber dual-mode clients do not support hand-in. In scenarios where an in-progress call is active between the dual-mode mobile voice network or cellular interface and an enterprise phone (or a PSTN phone with the call anchored in the enterprise gateway), the only way to move the call to the WLAN interface of the dual-mode device is to hang up the call and redial once the dual-mode client has connected to the enterprise network and registered to Unified CM.

Cisco Mobile and Jabber for iPhone Desk Phone Integration

The Cisco Mobile or Jabber iPhone Dual-Mode client enables the user to move an active or held call from the user's desk phone to the dual-mode device. This feature relies on CTI monitoring of the primary line of the user's desk phone as well as the call park feature.

The functionality provided by desk phone integration relies on active CTI monitoring of the primary line of the user's desk phone. Whenever an active or held call is sensed by the Cisco Mobile or Jabber client, it prompts the user as to whether they want to transfer the call to the dual-mode device. If the user indicates they wish to transfer the call, the desk phone automatically parks the call and the dual-mode client automatically retrieves the call from the park number.

To enable desk phone integration, ensure that the user's end-user account is assigned to a CTI-enabled user group and that the user's desk phone is enabled to allow CTI control. In addition, the CTI Control Username field on the **Cisco Dual Mode for iPhone** device must be configured with the user's end-user account userID.

Cisco Jabber for Android Desk Phone Integration

The Cisco Jabber for Android dual-mode client enables the user to move an active call from the Android device to the IP desk phone sharing a line with the dual-mode device. This feature is invoked by placing the active call on hold through the Cisco Jabber client. When the call is placed on hold, the call can be resumed at either the shared-line IP desk phone or on the Cisco Jabber client.

WLAN Design Considerations for Cisco Mobile and Cisco Jabber Dual-Mode Clients

Consider the following WLAN guidelines when deploying Cisco Mobile and Cisco Jabber dual-mode clients:

- Whenever possible, ensure that Cisco Mobile and Cisco Jabber dual-mode clients roam on the WLAN only at Layer 2 so that the same IP address can be used on the WLAN interface of the dual-mode device. In Layer 3 roaming scenarios where subnet boundaries are crossed due to device IP address changes, calls will be dropped.
- Deploy Cisco Mobile and Cisco Jabber dual-mode clients on a WLAN network where the same SSID is used across APs. Roaming between APs is much slower if SSIDs are different.
- Ensure all APs in the WLAN broadcast their SSID(s). If the SSID is not broadcast by the AP, the user may be prompted by the device to join other Wi-Fi networks or the device may automatically join other Wi-Fi networks. When this occurs the call is interrupted.

Interactions Between Cisco Mobile or Cisco Jabber and Cisco Unified Mobility

The Cisco Mobile and Cisco Jabber dual-mode clients can be integrated with Cisco Unified Mobility to leverage Cisco Mobile Connect, mid-call DTMF features, two-stage dialing, and single enterprise voicemail box mobile voicemail avoidance.

Integration with Unified Mobility requires the iPhone or Android dual-mode mobile phone number to be configured within Unified CM as a mobility identity associated with the Cisco Dual Mode for iPhone or Cisco Dual Mode for Android device. Once the mobile number is configured as a mobility identity within the system, Mobile Connect can be leveraged so that incoming calls to the user's enterprise number will be extended to the iPhone or Android dual-mode device through the mobile voice network as long as the iPhone or Android dual-mode device is not connected to the enterprise and not registered to Unified CM. In situations where the dual-mode device is connected to the enterprise and registered to Unified CM, an inbound call to the enterprise number will not be extended to the mobile voice network interface of the device. When the iPhone or Android dual-mode device is connected to the enterprise, only the WLAN or mobile data interface of the device will receive the inbound call. This prevents unnecessary consumption of enterprise PSTN gateway resources.

When not connected to the enterprise and not registered to Unified CM, the iPhone or Android dual-mode device can invoke mid-call features by means of DTMF and perform desk phone pickup for any enterprise anchored call. The dual-mode device can also leverage Mobile Voice Access and Enterprise Feature Access two-stage dialing features when making outbound calls to route these calls through the enterprise and anchor them in the enterprise PSTN gateway.

In addition to configuring a mobility identity for the iPhone or Android dual-mode device, you can configure additional mobile phone numbers or off-system phone numbers as remote destinations and associate them to the Cisco Dual Mode for iPhone or Cisco Dual Mode for Android device within Unified CM. When associating the mobility identity and additional remote destinations to the dual-mode device, you do not have to configure a remote destination profile.

For more information about the Cisco Unified Mobility feature set as well as design and deployment considerations, see [Cisco Unified Mobility, page 25-38](#).

Cisco AnyConnect and Secure Connect

The Cisco AnyConnect mobile client and Cisco Jabber secure connect feature provide secure remote connectivity capabilities for Cisco Jabber mobile device clients, enabling connectivity over mobile data networks and non-enterprise WLANs. The Cisco AnyConnect mobile client can be downloaded from the Apple Application Store or Google Play (formerly Android Market). This client application provides SSL VPN connectivity for Apple iOS and Android mobile devices through the Cisco AnyConnect VPN solution available with the Cisco Adaptive Security Appliance (ASA) head-end.

Cisco secure connect is a Cisco Jabber mobile client feature that uses the same Cisco AnyConnect solution ASA head-end infrastructure and provides application-level SSL secure connectivity without requiring a separate Cisco AnyConnect client application. This feature enables secure connectivity for the Cisco Jabber mobile client application without securing the whole mobile device. This ensures that only Cisco Jabber traffic traverses the enterprise network while all other traffic traverses the public or private WLAN or mobile data network.

When employing VPN network connectivity for connections over the mobile data network or public or private Wi-Fi hot spots, it is important to deploy a high-bandwidth secure VPN infrastructure that adheres to the enterprise's security requirements and policies. Careful planning is needed to ensure that the VPN infrastructure provides high bandwidth, reliable connections, and appropriate session or connection capacity based on the number of users and devices using this connectivity.

For more information on secure remote VPN connectivity solutions, including Cisco AnyConnect, refer to the secure mobility documentation available at

<http://www.cisco.com/en/US/products/hw/vpndevc/products.html#mobi>

For information on the Cisco Jabber secure connect feature, refer to the *Cisco Jabber Secure Connect Deployment Guide*, available at

http://www.cisco.com/en/US/products/ps11678/products_implementation_design_guides_list.html

Dual-Mode Clients: Nokia Call Connect

Note

End-of-Sale for the Nokia Call Connect client is July 10, 2012. There is no replacement mobile client for Nokia mobile devices. For more information, see the End-of-Sale (EoS) and End-of-Life (EoL) announcement at

http://www.cisco.com/en/US/prod/collateral/voicesw/ps6789/ps7290/ps10589/end_of_life_notice_c51-696647.html.

Nokia Call Connect is a dual-mode client for Nokia mobile smart phones. Once installed on the Nokia device, the client can associate to the enterprise WLAN network and register to Unified CM as a Skinny Client Control Protocol (SCCP) enterprise phone.

To provide registration and call control services to Nokia dual-mode devices, Unified CM must support the Nokia S60 device type, which is available only after loading the Nokia-provided Cisco options package (COP) file onto Unified CM.

Once the dual-mode device has been configured within Unified CM, it is necessary to load the Nokia Call Connect client onto the Nokia device. This can be done using a computer with a USB, Bluetooth, or infrared port running the Nokia PC Suite. After the Nokia Call Connect Symbian installation system (SIS) file has been loaded on the Nokia device, the device must be configured to access the enterprise WLAN for connectivity based on the enterprise WLAN infrastructure and security policies. Once the handset has been configured to access the WLAN, when the Nokia Call Connect client is launched, it will register the device to Unified CM. To integrate the Nokia dual-mode device with Unified Mobility so the user can leverage features such as Mobile Connect, configure the Nokia mobile phone number as a mobility identity and associate it to the Nokia S60 device within Unified CM.

**Note**

Cisco recommends configuring the Nokia Call Connect client SCCP registration setting to **Always On** to ensure that, whenever the Nokia device is associated to the enterprise WLAN network, it will attempt to register to Unified CM. Cisco also recommends setting the Nokia dual-mode phone's preferred or default call type setting to **Internet Call** to ensure that, when the Nokia Call Connect client is registered to Unified CM, the device will always attempt to route outbound calls through the WLAN interface of the dual-mode phone. These recommended settings ensure that the Nokia dual-mode phone maximizes its use of the enterprise IP telephony infrastructure for making and receiving business calls.

The Nokia Call Connect 2.2 client is supported on Nokia Symbian 3 handsets (including Nokia C7, E6, and N8) and Nokia S60 3.2 handsets (including Nokia E52, E55, E72, and E75). Nokia S60 3.1 handsets, including the E51, E61i, E63, E66, E71, and E90, are also supported but might not support advanced features such as automatic handoff. Nokia mobile phone WLAN interfaces support 802.11b, 802.11g, and in some cases 802.11n network connectivity.

The Nokia Call Connect client not only provides dual-mode phone services but also provides directory lookup services when configured to access the Unified CM directory as well as enterprise-based XML phones services like those supported on Cisco IP desk phones.

Nokia Call Connect 2.0 and later clients are capable of performing automatic hand-out and hand-in as outlined in the sections below.

For more information about the Nokia Call Connect dual-mode client, supported handsets, and software versions, and to access the latest client and COP file, refer to:

http://www.cisco.com/en/US/products/ps10589/tsd_products_support_series_home.html

Nokia Call Connect Dual-Mode Handoff

To properly deploy Nokia Call Connect dual-mode clients, it is necessary to understand the nature of the handoff operation within the Nokia dual-mode client.

In the following examples, the handoff number is +1 408 555 1234 (this is the full E.164 handoff number). The Cellular Handover Number under the Nokia Call Connect Voice Call Continuity (VCC) settings is configured with this number.

All inbound calls are stripped to four digits by the upstream gateway, so the Handoff Number configured within Unified CM is 1234. The VoIP Handover Number is configured as 1234 under the Nokia Call Connect VCC settings.

Hand-Out (WLAN to Cellular)

Figure 25-28 shows a hand-out operation in which an active call on a Nokia dual-mode phone within the enterprise is moved from the WLAN interface to the mobile voice network or cellular interface of the device through the enterprise PSTN gateway. As shown, there is an existing call between the Nokia dual-mode device associated to the enterprise WLAN and registered to Unified CM, and a phone on the PSTN network (step 1). The Nokia dual-mode user begins to leave the enterprise (step 2), and as the WLAN signal strength drops below -78 dBm (default value for the WLAN HO threshold setting in VCC) for a period of 1,000,000 microseconds (1 second, default value for the WLAN HO hysteresis setting in VCC), a silent background call is opened to +1 408 555 1234 (the configured Cellular Handover Number in VCC and corresponding to the Handoff Number configured in Unified CM) over the mobile voice network and PSTN into the enterprise PSTN gateway and is delivered to Unified CM (step 3). Once received, the calling number is checked against all configured mobility identities on the system, and assuming a match is found, the RTP stream that was traversing the WLAN is now redirected to the PSTN gateway and the call is continued uninterrupted between the dual-mode device and the original PSTN phone with the call anchored in the enterprise gateway (step 4).

Figure 25-28 Nokia Call Connect Dual-Mode Hand-Out (WLAN-to-Mobile Voice Network)

The Nokia Call Connect dual-mode client also supports manual hand-out using the Switch to Cellular or Handover to GSM in-call menu options. The availability and behavior of these manual hand-out methods depends on the device type and firmware version. For devices running firmware version 3.1 and earlier, the Switch to Cellular menu option when selected performs a blind transfer of the active call to the mobile voice network interface of the device through the enterprise PSTN gateway. For devices running firmware version 3.2 and later, the Handover to GSM menu option when selected performs a manual handoff using the Unified CM Handoff Number as shown in step 3 of [Figure 25-28](#) without relying on WLAN handover thresholds and hysteresis VCC settings.

Hand-In (Cellular to WLAN)

[Figure 25-29](#) depicts a hand-in operation in which an active call on a Nokia dual-mode phone outside the enterprise is moved from the mobile voice network interface to the WLAN interface of the device through the enterprise PSTN gateway. As shown, there is an existing call between the Nokia dual-mode device on the mobile voice network and a phone on the PSTN network (step 1). The Nokia dual-mode user moves into the enterprise (step 2), and the device associates in the background to the WLAN infrastructure and registers to Unified CM. After registration, the device will wait for the amount of time specified by the WLAN HO hysteresis high setting in VCC (60 seconds by default), and then a silent background call is opened to 1234 (the configured VoIP Handover Number in VCC, which corresponds to the Unified CM Handoff Number configured in Unified CM) and delivered to Unified CM (step 3). Once received, the enterprise calling number is checked against configured Nokia S60 dual-mode phones on the system, and assuming a match is found, the call that was traversing the mobile voice network/PSTN and the enterprise PSTN gateway is now redirected to the WLAN network, and the call is continued uninterrupted between the dual-mode device and the original PSTN phone (step 4).

Figure 25-29 Nokia Call Connect Dual-Mode Hand-In (Mobile Voice Network-to-WLAN)

WLAN Design Considerations for Nokia Call Connect Dual-Mode Client

Consider the following WLAN guidelines when deploying Nokia Call Connect dual-mode clients:

- Leave the **WLAN HO Threshold** setting under Voice Continuity Configuration (VCC) at default setting (73 for Nokia Call Connect 2.1 and later) unless users are experiencing delayed automatic handoff when leaving the WLAN coverage area.
- The **WLAN HO Threshold** can be adjusted lower to engage automatic handoff more quickly when users leave the WLAN coverage area.
- Adjusting the **WLAN HO Threshold** also affects trigger thresholds for roaming between WLAN Access Points (APs). Lowering the **WLAN HO Threshold** setting also lowers the AP-to-AP roaming threshold, resulting in faster AP-to-AP roaming. If users are experiencing poor voice quality on the WLAN or if AP-to-AP roaming is too slow, consider adjusting this setting lower, but be aware that automatic handoff will also engage more quickly when this value is lowered.

For more information about Nokia Call Connect VCC settings, refer to the *Nokia Call Connect for Cisco User's Guide*, available at

<http://europe.nokia.com/support/download-software/nokia-call-connect-for-cisco>

Interactions Between Nokia Call Connect and Cisco Unified Mobility

The Nokia Call Connect dual-mode client can be integrated with Cisco Unified Mobility to leverage Cisco Mobile Connect, mid-call DTMF features, two-stage dialing, single enterprise voicemail box, and desk phone pickup.

Integration with Unified Mobility requires the Nokia dual-mode phone mobile number to be configured within Unified CM as a mobility identity associated with the Nokia S60 device. Once the mobile number is configured as a mobility identity within the system, Mobile Connect can be leveraged so that incoming calls to the user's enterprise number will be extended to the Nokia dual-mode device through the mobile voice network as long as the Nokia dual-mode device is outside the enterprise and is not registered to

Unified CM. In situations where the Nokia dual-mode device is inside the enterprise and registered to Unified CM, an inbound call to the enterprise number will not be extended to the mobile voice network interface of the device. When the Nokia dual-mode device is inside the enterprise, only the WLAN interface of the device will receive the inbound call. This prevents unnecessary consumption of enterprise PSTN gateway resources.

When outside the enterprise and not registered to Unified CM, the Nokia dual-mode device can invoke mid-call features by means of DTMF and can perform desk phone pickup for any enterprise anchored call. The Nokia Call Connect 2.1 and later client provides automation of the Cisco Enterprise Feature Access two-stage dialing feature for scenarios when the user is outside the enterprise and wishes to make outbound calls through the enterprise in order to anchor them in the enterprise PSTN gateway. For information about Enterprise Feature Access two-stage dialing, see [Enterprise Feature Access with Two-Stage Dialing Functionality](#), page 25-53.

When the Two-Stage Dialing feature of the Nokia Call Connect client is enabled, all calls made by the device over the cellular interface will leverage the Enterprise Feature Access two-stage dialing functionality within Unified CM. The configured **Two-stage dialing no.** setting within the Nokia Call Connect client determines the number the client will dial for all outbound cellular calls. This configured number should correspond to the Enterprise Feature Access number on the Unified CM system. The configured **Two-stage dialing PIN** setting within the Nokia Call Connect client determines the authentication key sequence sent to Unified CM once the call to the Enterprise Feature Access number is connected. This configured PIN should correspond to the user's PIN as configured under the end-user account within Unified CM. The Nokia Call Connect client uses these two settings as well as the number the user dialed or selected to facilitate the two-stage dialed call.

**Note**

Enterprise Feature Access two-stage dialing automation is available with only Nokia S60 3.2 firmware versions.

Alternatively, the Nokia dual-mode user can leverage the manual IVR-based Mobile Voice Access two-stage dialing feature to dial calls through the enterprise and anchor those calls in the enterprise gateway.

If the Nokia device is also running the Cisco Unified Mobile Communicator client, then the user should leverage the Dial-via-Office feature available with that client rather than the Enterprise Feature Access or Mobile Voice Access two-stage dialing methods because the user experience with Dial-via-Office is far superior.

In addition to configuring a mobility identity for the Nokia dual-mode device, you can configure additional mobile phone numbers or off-system phone numbers as remote destinations and associate them to the Nokia S60 device within Unified CM. When associating the mobility identity and additional remote destinations to the Nokia device, you do not have to configure a remote destination profile.

For more information about the Unified Mobility feature set as well as design and deployment considerations, see [Cisco Unified Mobility](#), page 25-38.

High Availability for Dual-Mode Phones

Although dual-mode phones by their nature are highly available with regard to network connectivity (when connectivity to the enterprise network is unavailable, the mobile voice and data networks can be used for voice and data services), enterprise WLAN and IP telephony infrastructure high availability must still be considered.

First, the enterprise WLAN must be deployed in a manner that provides redundant WLAN access. For example, APs and other WLAN infrastructure components should be deployed so that the failure of a wireless AP does not impact network connectivity for the dual-mode device. Likewise, WLAN

management and security infrastructure must be deployed in a highly redundant fashion so that dual-mode devices are always able to connect securely to the network. Controller-based wireless LAN infrastructures are recommended because they enable centralized configuration and management of enterprise APs, thus allowing the WLAN to be adjusted dynamically based on network activity and AP failures.

Next, VPN infrastructure components, including the Cisco ASA head-end VPN or AnyConnect session terminator, should be deployed in a highly redundant fashion so that loss of a VPN session terminator does not impact or prevent remote secure enterprise connectivity for the dual-mode client device.

Next, Unified CM call processing and registration service high availability must be considered. Just as with other devices within the enterprise that leverage Unified CM for call processing services, dual-mode phones must register with Unified CM. Given the redundant nature of the Unified CM cluster architecture, which provides primary and backup call processing and device registration services, dual-mode device registration as well as call routing are still available even in scenarios in which a Unified CM server node fails.

Similar considerations apply to PSTN access. Just as with any IP telephony deployment, multiple PSTN gateways and call routing paths should be deployed to ensure highly available access to the PSTN. This is not unique to dual-mode mobile client device deployments, but is an important consideration none the less.

Capacity Planning for Dual-Mode Phones

Capacity planning considerations for dual-mode phones are the same as for other IP telephony endpoints or devices that rely on the IP telephony infrastructure and applications for registration, call processing, and PSTN access services.

When deploying dual-mode phones, it is important to consider the registration load on Unified CM as well as the Unified Mobility limits. A single Unified CM cluster is capable of handling a maximum of 40,000 device configurations and registrations. When deploying dual-mode phones, you must consider the per-cluster maximum device support, and you might have to deploy additional call processing subscriber nodes or even clusters to handle the added load.

In addition, as previously mentioned, the maximum number of remote destinations and mobility identities within a single Unified CM cluster is 15,000. Because most dual-mode devices will likely be integrated with Unified Mobility to take advantage of features such as Mobile Connect and two-stage dialing, the mobile phone number of each of these dual-mode devices must be configured as a mobility identity within the Unified CM cluster. This is necessary to facilitate integration to Unified Mobility as well as to facilitate handoff in some cases. Therefore, when integrating dual-mode phones with Unified Mobility, it is important to consider the overall remote destination and mobility identity capacity of the Unified CM cluster to ensure sufficient capacity exists. If additional users or devices are already integrated to Unified Mobility within the system, they can limit the amount of remaining remote destination and mobility identity capacity available for dual-mode devices.

CTI capacity must also be considered when deploying the Cisco Mobile or Jabber dual-mode client for iPhone with desk phone integration. Because this feature relies on CTI monitoring of the primary line of the user's desk phone, each Cisco Mobile dual-mode user enabled for desk phone integration will consume a CTI connection on the Unified CM system. This load must be considered in relation to the overall CTI capacity of the system.

Overall call processing capacity of the Unified CM system and PSTN gateway capacity must also be considered when deploying dual-mode phones. Beyond handling the actual dual-mode device configuration and registration, the system must also have sufficient capacity to handle the added BHCA impact of dual-mode phones and users. Likewise, it is critical to ensure sufficient PSTN gateway capacity is available to accommodate dual-mode devices. This is especially the case for dual-mode

devices that are integrated to Unified Mobility because the types of users that would have dual-mode devices are typically highly mobile. Highly mobile users typically generate more enterprise PSTN gateway load from mobility features such as Mobile Connect, where an incoming call to a mobile user's enterprise number generates one or more calls to the PSTN, or from two-stage dialing, where a user makes a call through the enterprise by leveraging the enterprise PSTN gateway.

The above considerations are certainly not unique to dual-mode phones. They apply to all situations in which devices and users are added to Unified CM, resulting in additional load to the overall Unified Communications System.

For more information on general system sizing, capacity planning, and deployment considerations, see the chapter on [Unified Communications Design and Deployment Sizing Considerations, page 29-1](#).

Design Considerations for Dual-Mode Phones

Observe the following design recommendations when deploying dual-mode phones and clients:

- Dual-mode mobile devices must be capable of dual transfer mode (DTM) in order to be connected simultaneously to both the mobile voice and data network and the WLAN network so that the device is reachable and able to make and receive calls on both the cellular radio and WLAN interface of the device. In some cases, proper dual-mode client operation might not be possible if mobile voice and data networks do not support dual-connected devices.
- WLAN APs should be deployed with a minimum cell overlap of 20%. This overlap ensures that a dual-mode device can successfully roam from one AP to the next as the device moves around within a location, while still maintaining voice and data network connectivity.
- WLAN APs should be deployed with cell power level boundaries (or channel cell radius) of -67 dBm in order to minimize packet loss. Furthermore, the same-channel cell boundary separation should be approximately 19 dBm. A same-channel cell separation of 19 dBm is critical for ensuring that APs or clients do not cause co-channel interference to other devices associated to the same channel, which would likely result in poor voice quality.
- Cisco recommends using only an enterprise class voice-optimized WLAN network for connecting dual-mode phones and clients. While most dual-mode phones and clients are capable of attaching to public or private WLAN access points or hot spots for connecting back to the enterprise through the Internet for call control and other Unified Communications services, Cisco cannot guarantee voice quality for these types of connections.
- The Unified Mobility Mobile Connect feature will not extend incoming calls to the dual-mode device's configured mobility identity if the dual-mode device is connected to the enterprise and registered to Unified CM. This is by design in order to reduce utilization of enterprise PSTN resources. Because the dual-mode device registers to Unified CM, the system knows whether the device is reachable inside the enterprise; and if it is, there is no reason to extend the call to the PSTN in order to ring the dual-mode device's cellular voice radio. Only when the dual-mode device is unregistered will Mobile Connect extend incoming calls to the user's enterprise number out to the mobility identity number on the mobile voice network. The global SIP Dual Mode Alert Timer service parameter should be adjusted to a minimum of 3,000 milliseconds to ensure that calls are not prematurely or unnecessarily routed to the mobility identity.
- When deploying dual-mode phones, Cisco recommends normalizing required dialing strings so that users are able to maintain their dialing habits, whether the mobile device is connected to the enterprise or not. Because dialing on the mobile network is typically done using full E.164 (with or without a preceding '+') and mobile phone contacts are typically stored with full E.164 numbers, Cisco recommends configuring the enterprise dial plan to accommodate full E.164 or full E.164 with

preceding '+' for dual-mode phones. By configuring the enterprise dial plan in this manner, you can provide the best possible end-user dialing experience so that users do not have to be aware of whether the device is registered to the Unified CM.

- Cisco recommends that dual-mode phone users rely exclusively on the mobile voice network for making emergency calls and determining device and user location. This is because mobile provider networks typically provide much more reliable location indication than WLAN networks. To ensure that dual-mode phones rely exclusively on the mobile voice network for emergency and location services, configure the Emergency Numbers field of the dual-mode devices within Unified CM with emergency numbers such as 911, 999, and 112 in order to force these calls over the mobile voice network. Dual-mode phone users should be advised to make all emergency calls over the mobile voice network rather than the enterprise network.
- Cisco recommends the following Nokia Call Connect client configuration settings in order to maximize the dual-mode device's use of the enterprise IP telephony infrastructure for making and receiving business calls:
 - Configure the Nokia Call Connect client SCCP registration setting to **Always On** to ensure that, whenever the Nokia device is associated to the enterprise WLAN network, it will attempt to register to Unified CM.
 - Configure the Nokia dual-mode phone's preferred or default call type setting to **Internet Call** to ensure that, when the Nokia Call Connect client is registered to Unified CM, the device will always attempt to route outbound calls through the WLAN interface of the dual-mode phone.
- When deploying Cisco Mobile or Cisco Jabber Apple iOS clients with desk phone integration, the end-user account for the Cisco Mobile or Jabber user must be enabled for CTI. In addition, call park should be configured at a system level so that the desk phone can auto-park the call and Cisco Mobile or Jabber client can retrieve whenever a call is moved from the desk phone to the client. CTI overhead of this feature should be considered when sizing the overall Unified CM system.
- When deploying Cisco Mobile, Cisco Jabber for iPhone, or Cisco Jabber for Android dual-mode clients, configure the WLAN network to accommodate the following deployment guidelines:
 - Minimize roaming of Cisco Mobile, Cisco Jabber for iPhone, and Cisco Jabber for Android dual-mode devices at Layer 3 within the WLAN. Layer 3 roaming where a device IP address changes will result in longer roam times and dropped voice packets and could even result in dropped calls.
 - Configure the same SSID across all APs utilized by the Cisco Mobile and Cisco Jabber dual-mode devices within the WLAN to ensure the fastest AP-to-AP roaming.
 - Configure all WLAN APs to broadcast their SSIDs in order to prevent mid-call prompts to join other APs within the WLAN infrastructure, which could result in interrupted calls.
- For deployments of Nokia Call Connect dual-mode clients, lower the WLAN HO Threshold setting within the Nokia Call Connect client to engage automatic hand-out more quickly. However, note that lowering this setting also increases the AP-to-AP roaming speed.

Cisco Unified Mobile Communicator

Note

Cisco Unified Mobile Communicator has reached End-of-Sale (EoS) and End-of-Life (EoL). Cisco Jabber is the replacement mobile client for mobile devices. For more information, see the announcement at http://www.cisco.com/en/US/prod/collateral/voicesw/ps6789/ps7290/ps7271/end_of_life_notice_c51-677140.html.

Cisco Unified Mobile Communicator is a mobility solution that provides users the ability to access and leverage Cisco Unified Communications applications from their mobile phones. The Cisco Unified Mobile Communicator and Cisco Mobile graphical clients work in conjunction with a server running the Cisco Unified Mobility Advantage software to provide a rich user interface for accessing and controlling mobile phone features and functionality. The system integrates into existing corporate LDAP directories, allowing users to use a single set of credentials across all devices. Further, all traffic between Unified Mobile Communicator and Unified Mobility Advantage is protected by the Secure Socket Layer (SSL) protocol. Unified Mobile Communicator provides the following functionality for mobile phone users:

- Access to corporate and personal directories
- Presence and buddy synchronization with the enterprise
- Visual access to corporate voicemail
- Visibility into desk phone history of missed, placed, and received calls
- Secure store-and-forward text messaging
- Reception of conference notifications
- Dial-via-office using Cisco Unified CM

**Note**

Not all functionality listed above is available on all supported handsets or mobile operating systems.

**Note**

Cisco Unified Mobility Advantage 7.1(3) will continue to be supported and to interoperate with Cisco Unified CM 8.x and other Cisco Unified Communications System 8.x applications. All discussions and descriptions in this section are based on version 7.1(3) of the Unified Mobility Advantage server. For more details on specific hardware and software requirements for this solution, refer to the *Compatibility Matrix for Cisco Unified Mobility Advantage, Cisco Mobile, and Cisco Unified Mobile Communicator*, available at http://www.cisco.com/en/US/products/ps7270/products_device_support_tables_list.html.

Cisco Unified Mobile Communicator Phone Support and Data Plan Requirements

While the Cisco Unified Mobile Communicator client application runs on a variety of mobile devices, the sophisticated functionality imposes minimum device requirements that restrict the application to a set of supported phones.

Cisco Unified Mobile Communicator is designed to run on the following mobile operating systems or handsets:

- Windows Mobile 6.0 or 6.1 Standard
- Nokia Symbian and Nokia S60 Third Edition (Nokia handsets)
- Apple iPhone 3G or 3GS running firmware version 3.0.1 or later (iPhone handsets)
- Research in Motion (RIM) Blackberry (Blackberry handsets)

**Note**

The Cisco Unified Mobile Communicator client for the iPhone and Blackberry devices is called Cisco Mobile.

Handset model support varies according to the mobile operating system (OS); however, specific handset support certification is not required. For each mobile OS, Cisco requires handsets to support a minimum set of requirements. These requirements vary per mobile OS, but the following list contains general requirements that handsets must meet in order to be supported:

- Specific version of mobile OS (varies per OS)
- Specific form factors, screen sizes, and keyboard technologies (varies per operating system)
- Installed root certificate from recognized Certificate Authority (VeriSign or GeoTrust)
- No restrictions on installing or running third-party applications

**Note**

Actual user experience can vary between devices.

For more details on specific handset requirements, refer to the *Compatibility Matrix for Cisco Unified Mobility Advantage and Cisco Unified Mobile Communicator*, available at

http://www.cisco.com/en/US/products/ps7270/products_device_support_tables_list.html

In addition to providing a supported device, the user must also be using that device with a supported data plan. The client uses a mobile data network to communicate with the Cisco Unified Mobility Advantage Server. While the client and server use SSL to secure all data traffic, the client initiates connections to the server using the mobile data network on the port that the Unified Mobility Advantage administrator specified during installation.

Because this may be a non-traditional port, the client requires that the mobile data network be accessed with an unrestricted plan. By contrast, many operators offer a low-end "web only" plan that allows the client to access HTTP over port 80 only. This type of plan is incompatible with Unified Mobile Communicator and will not work. Instead, the user must subscribe to a plan that allows arbitrary TCP traffic to pass from the client to any port on the server. This is sometimes referred to as a VPN plan. However, the client does not require a routable or static IP address because the Unified Mobility Advantage Server maps dynamic and translated addresses appropriately.

Because the Cisco Unified Mobile Communicator client relies on a data connection back to the enterprise for all application integration and functionality, this data connection is extremely important. The amount of bandwidth consumed by this critical connection is highly variable. Given the variable nature of these connections, Cisco highly recommends an unlimited data plan for all users rather than per-minute or per-byte plans. However, in some deployments unlimited data plans might be cost prohibitive. For bandwidth estimation and planning purposes, Cisco has found that on average most Unified Mobile Communicator users consume approximately 5.6 megabytes of bandwidth per month, provided they are not using visual voicemail functionality. Of course, bandwidth consumption will vary widely depending on end-user behavior. For example, a user who performs large numbers of directory lookups, sends many text messages, or makes large numbers of dial-via-office calls will consume considerably more bandwidth than a user who uses these features less frequently. For this reason, the average of 5.6 megabytes per month is merely a guideline. With visual voicemail, a one-minute voicemail message consumes approximately 354 kilobits, meaning that approximately two hours of visual messages will consume all of this monthly average. Therefore, it is easy to see that bandwidth requirements will be considerably higher when visual voicemail is in use.

Cisco Unified Mobile Communicator Architecture

The solution consists of three primary components: Cisco Unified Mobile Communicator, the Adaptive Security Appliance (ASA) TLS Proxy, and the Cisco Unified Mobility Advantage Server. (See [Figure 25-30](#).) The Cisco Unified Mobility Advantage Server accesses existing Unified Communications applications and corporate systems, including as shown in [Figure 25-30](#).

Figure 25-30 Cisco Unified Mobile Communicator Architecture

A user session is initiated when Unified Mobile Communicator starts on the mobile device. When the application starts, it prompts the user for their Microsoft Active Directory password. (Because the device is associated with the user account during provisioning, the client does not have to collect a user ID). The client then initiates an SSL connection to the ASA TLS Proxy using the mobile data network. This appears at the proxy as an inbound connection from the Internet. The protocol used over this connection is the Mobile Multiplexing Protocol (MMP). This protocol is optimized to conserve handset battery life. The MMP protocol is encapsulated in standards-based SSL packets.

Once the SSL connection is established, the ASA passes the request to the Unified Mobility Advantage Server, which then authenticates the user against the LDAP directory. The TCP connection carrying the SSL traffic is maintained by the client, allowing the server to push traffic down to the client regardless of address translation, dynamic client addresses, and so forth. Throughout the life of the client connection, the ASA TLS Proxy de-encrypts incoming packets from the client and does deep packet inspection to ensure that the packets are valid and are from the authorized client. If they are, the ASA proxy re-encrypts the packets and passes them to the Cisco Unified Mobility Advantage Server.

In addition to using the LDAP credentials for authenticating the Unified Mobile Communicator client user, the Unified Mobility Advantage Server also uses the credentials to connect to other back-end application systems. For example, the server uses this information to connect to the Microsoft Exchange server as the user, accessing their calendar, personal contacts, and conference notifications.

Whether deploying the ASA as both a TLS Proxy and firewall or deploying the ASA as simply a TLS Proxy in a DMZ and relying on some external firewall, you must configure two ports and open them on both the externally facing firewall or interface (between the Internet and the DMZ) and the internally facing firewall or interface (between the DMZ and the enterprise). A port in each of the following sets of ranges must be opened for both the external and internal firewalls:

- External Firewall Ports
 - Client Connection Port (TCP/SSL) in the range of 5400 to 5500
 - Provisioning Port (HTTP) in the range of 9000 to 9100
- Internal Firewall Ports
 - Client Connection Port (TCP/SSL) in the range of 5400 to 5500
 - Provisioning Port (HTTP) in the range of 9000 to 9100

**Note**

The default client connection port (TCP/SSL) is 5443, and the default provisioning port (HTTP) is 9080.

**Note**

You do not have to open the provisioning port in the firewall if you are deploying only iPhone or Blackberry handsets because these handsets do not download the Cisco Unified Mobile Communicator client over the provisioning port. For iPhone handsets, the client is downloaded from the Apple App Store; and for Blackberry handsets, the client is pushed to the handset via the Blackberry Enterprise Server (BES).

If you deploy Blackberry handsets in a Cisco Unified Mobile Communicator environment, the architecture changes slightly in that Blackberry devices running the Cisco Mobile client must connect to the Cisco Unified Mobility Advantage server through a Blackberry Enterprise Server (BES) deployed inside the enterprise. Unlike with other Cisco Unified Mobile Communicator and Cisco Mobile clients, the Blackberry client does not securely connect to the Unified Mobility Advantage server through the ASA. Instead, the secure connection between the Blackberry device and the BES server is used, and the BES server is integrated directly with the Unified Mobility Advantage server. The BES server must be deployed and configured with Mobile Data Service (MDS). As shown in [Figure 25-30](#), both the BES server and the ASA can be integrated to the Unified Mobility Advantage server so that Blackberry and other supported mobile handsets can be deployed within the same system. For information on integrating BES with MDS directly to the Unified Mobility Advantage server for Blackberry devices, refer to the configuration guide for *Enabling Support for Clients in Cisco Unified Mobility Advantage*, available at

http://www.cisco.com/en/US/products/ps7270/products_installation_and_configuration_guides_list.html

In a Microsoft Active Directory (AD) environment, there are no server-specific requirements for the LDAP server; any Domain Controller will work, provided it is a member of the appropriate domain. The Unified Mobility Advantage Server submits LDAP version 3 authentication and search requests to this server, and they propagate through the AD domain as expected. In an environment that contains multiple Exchange servers, the Cisco Unified Mobility Advantage Server will query AD to determine the appropriate server for each user.

Cisco Unified Mobile Communicator Features and Functionality

Cisco Unified Mobile Communicator provides users traveling outside the organization with the ability to use their mobile device to access and utilize various Unified Communications applications that reside inside the enterprise. The following enterprise applications can be integrated with the Unified Mobile Communicator solution. Each application provides the features and functionality outlined below.

For a complete list of the supported applications and versions that can integrate with the Cisco Unified Mobile Communicator solution, refer to the *Compatibility Matrix for Cisco Unified Mobility Advantage and Cisco Unified Mobile Communicator*, available at

http://www.cisco.com/en/US/products/ps7270/products_device_support_tables_list.html

LDAP Directory

The Cisco Unified Mobility Advantage server integrates with Microsoft Active Directory. This integration is required because Active Directory is used to authenticate Unified Mobile Communicator client connections. The user's Active Directory account password is never stored on the Cisco Unified Mobility Advantage server or the Unified Mobile Communicator client. In addition to providing an authentication mechanism for clients, Active Directory is also used to resolve directory lookups from the client, providing user's with the ability to search the corporate directory from their mobile device. As shown in [Figure 25-30](#), the integration with Active Directory is via LDAP.

Cisco Unified CM

Cisco Unified Mobility Advantage Server can be integrated with Cisco Unified CM to provide desk phone call log synchronization, dial-via-office, and Unified Mobility integration. This integration requires an administrator to perform a number of configuration steps on Unified CM. For enterprise call log integration, application user accounts must be configured within Cisco Unified CM, and Unified Mobile Communicator users' desk phones must be associated to these accounts. These accounts are used by the Unified Mobility Advantage Server to monitor the desk phones of all Unified Mobile Communicator users to collect missed, received, and dialed calls. Each of these application user accounts is limited to a maximum of 250 monitored devices, and the Unified Mobility Advantage Server configuration allows a maximum of four account names, resulting in a maximum of 1,000 users. Each application user account within Cisco Unified CM must be assigned to both the Standard CTI Allow Call Monitoring group and Standard CTI Enabled group.

For dial-via-office functionality and integration with Unified Mobility, each user's Unified Mobile Communicator device must be configured as a device within Cisco Unified CM, this device must be configured with the user's enterprise number (the same directory number as the user's desk phone), and a mobility identity configured with the phone number of the user's mobile phone must be associated to this device.

For more information on integration with Unified CM, including configuration steps for enterprise call log integration, dial-via-office, and Unified Mobility integration, refer to the Cisco Unified Mobility Advantage installation and configuration documentation available at

http://www.cisco.com/en/US/products/ps7270/prod_installation_guides_list.html

Desk Phone Call Log Integration

Unified Mobile Communicator users with call log integration enabled are able to view call history lists (missed, placed, and received calls) from their desk phone on the Unified Mobile Communicator client.

As shown in [Figure 25-30](#), a JTAPI connection is made between the Unified Mobility Advantage Server and Unified CM. This JTAPI connection utilizes CTI to monitor incoming and outgoing calls to the primary line of the user's desk phone. Note that call logs are synchronized only from the desk phone to the Unified Mobile Communicator client. Call logs are not synchronized from the Unified Mobile Communicator client to the desk phone.

Dial-via-Office

Dial-via-office functionality provides the ability to initiate a call from the mobile phone running the Cisco Unified Mobile Communicator client, using the Cisco Unified CM telephony infrastructure and enterprise PSTN gateway. This functionality is facilitated by SIP signaling over a SIP connection between the Unified Mobility Advantage Server and Unified CM, as shown in [Figure 25-30](#).

Utilization of dial-via-office can be mandated by the Unified Mobility Advantage administrator for all calls made from the mobile phone by the Unified Mobile Communicator user. However, calls to configured emergency numbers or direct-dial numbers will bypass the dial-via-office mandate. Administrators may also choose to allow Unified Mobile Communicator users to decide if and when they use the dial-via-office feature. In those situations, the end-user can configure the phone to always use dial-via-office when making calls (except for calls to emergency numbers or direct-dial numbers they have configured, which are always signaled over the mobile voice network) or to prompt them on a per-call basis.

There are two types of dial-via-office supported with the Cisco Unified Mobile Communicator solution:

- [Dial-Via-Office Reverse Callback, page 25-93](#)
- [Dial-Via-Office Forward, page 25-94](#)

Dial-Via-Office Reverse Callback

[Figure 25-31](#) illustrates a dial-via-office reverse callback call flow. In this example, a Unified Mobile Communicator user wishes to dial the PSTN phone 972-555-7890. The user dials the number or selects the number from a contact or directory list, which generates a SIP INVITE over the data connection to the enterprise and the Cisco Unified Mobility Advantage Server (step 1). This SIP INVITE is encapsulated in the MMP protocol and sent over the secure connection through the ASA or BES server (depending on the client type) between the client and the Cisco Unified Mobility Advantage server. The request is then forwarded by the Cisco Unified Mobility Advantage server over the SIP connection to Cisco Unified CM (step 2). Unified CM then generates a callback to the user's mobile phone number using the enterprise PSTN gateway (step 3). Once the incoming call from Unified CM is auto-answered at the mobile device, a call is extended to the number the user called or selected (step 4; in this case, 972-555-7890). Once the call is answered at the far end, the call is anchored through the enterprise PSTN gateway (step 5). Because the call is now anchored in the enterprise gateway, the user has the ability at any point during this call to use the Unified Mobility desk phone pickup feature as well as to invoke Unified Mobility mid-call features.

Note

All voice or media from the user's mobile phone will always travel over the mobile voice network. Media never traverses the data connection to the enterprise. The mobile data network connection is used only for call signaling traffic and other application interactions.

Figure 25-31 Cisco Unified Mobile Communicator, Dial-via-Office Reverse Callback

In addition to having the dial-via-office reverse callback feature call back to the Cisco Unified Mobile Communicator device; users are also given the option of providing, within the Unified Mobile Communicator client configuration, an alternative number on which to be called back. For example, rather than receiving the callback on the mobile phone, the user could direct the callback to a conference room phone.

Note

When invoking the dial-via-office reverse callback feature, if the callback from Unified CM is directed to a user-specified alternate number, users will have no ability to perform desk phone pickup or to invoke mid-call features for that call.

Dial-via-office reverse callback is supported for Windows Mobile, Nokia, and Blackberry mobile handsets.

Dial-Via-Office Forward

Figure 25-32 illustrates a dial-via-office forward call flow. In this example, a Unified Mobile Communicator user wishes to dial the PSTN phone 972-555-7890. The user dials the number or selects the number from a contact or directory list, which generates a SIP INVITE over the data connection to the enterprise and the Cisco Unified Mobility Advantage Server (step 1). This SIP INVITE is encapsulated in the MMP protocol and sent over the secure connection through the ASA or BES server (depending on the client type) between the client and the Cisco Unified Mobility Advantage server. The request is then forwarded by the Cisco Unified Mobility Advantage server over the SIP connection to Cisco Unified CM (step 2). Unified CM then responds back to the Cisco Unified Mobility Advantage server with the configured system-wide Enterprise Feature Access number, which is then forwarded back to the user's mobile device over the secure connection through the ASA or BES server, depending on the client type (step 3). Once the number is received at the mobile device, the Cisco Unified Mobile Communicator client automatically generates an outgoing call from the mobile device to the Enterprise Feature Access number (step 4). Once this call is received by Unified CM, the system matches the

inbound caller ID against the configured mobility identity for the user. If the inbound caller ID matches the user's configured mobility identity, a call is made by the system to the number the user dialed or selected (step 5; in this case, 972-555-7890). Once the call is answered at the far end, the call is anchored through the enterprise PSTN gateway (step 6). Because the call is now anchored in the enterprise PSTN gateway, the user has the ability at any point during this call to use the Unified Mobility desk phone pickup feature as well as to invoke Unified Mobility mid-call features.

**Note**

In order for the dial-via-office forward call to be completed successfully, Unified CM must receive an inbound caller ID from the PSTN network that matches the mobility identity number configured for the Unified Mobile Communicator device placing the dial-via-office call. If the inbound caller ID from the PSTN is not received or does not match the user's configured mobility identity, the dial-via-office forward call will fail.

**Note**

All voice or media from the user's mobile phone will always travel over the mobile voice network. Media never traverses the data connection to the enterprise. The mobile data network connection is used only for call signaling traffic and other application interactions.

Figure 25-32 Cisco Unified Mobile Communicator, Dial-via-Office Forward

**Note**

If the iPhone firmware version is earlier than 3.1, then the dial-via-office forward call will require manual intervention by the user to complete the call. With iPhone firmware versions prior to 3.1, the dial-via-office call will not complete automatically. Instead the user will receive a dialog box on the client in step 3 of Figure 25-32 and must select 'Call' in order for the call to the Enterprise Feature Access number in step 4 to be generated.

In order for Cisco Unified Mobile Communicator to be able to dial the Enterprise Feature Access number sent by Unified CM for a dial-via-office forward call, the number sent must be a full E.164 number so that it can be dialed via the mobile voice network. If the number configured in the Enterprise Feature Access Directory Number field within Unified CM (under **Call Routing > Mobility Configuration**) is not a full E.164 number, the administrator should configure the Dial-via-Office Forward Service Access Number service parameter for the Cisco CallManager service with the full E.164 number that corresponds to the Enterprise Feature Access directory number configured within Unified CM. If the Dial-via-Office Forward Service Access Number service parameter is not configured, Unified CM will send the Enterprise Feature Access directory number exactly as configured. If this number is not a full E.164, the call from the Cisco Unified Mobile Communicator into the Unified CM system (step 4 of [Figure 25-32](#)) will fail, thus rendering the dial-via-office forward feature inoperable.

As an example, suppose the Enterprise Feature Access directory number is configured within Unified CM as 51234. Then in situations where the Dial-via-Office Forward Service Access Number is not configured, Unified CM will forward the Enterprise Feature Access number back to Unified Mobility Advantage as 51234, resulting in the call dialog at the Unified Mobile Communicator device to display 51234. If the user selects the Call option, the phone will attempt to call 51234 over the mobile voice network, and this call will fail. However, if the Dial-via-Office Forward Service Access Number is configured as 9195551234, then Unified CM will forward the Enterprise Feature Access number back to Unified Mobility Advantage as 9195551234. This ensures that, when the user selects the Call option, the call will be routed properly over the mobile voice network and PSTN back to the enterprise.

Dial-via-office forward is supported with Cisco Mobile, the Cisco Unified Mobile Communicator clients for the iPhone and Blackberry.

Interactions Between Nokia Call Connect and Cisco Unified Mobile Communicator

The Nokia Call Connect dual-mode client can be used in parallel with the Cisco Unified Mobile Communicator client for Nokia. When both clients are deployed, not only is the Nokia device able to leverage the enterprise IP telephony infrastructure for making and receiving calls inside the enterprise, but it is also able to leverage Unified Mobile Communicator features such as directory lookups, desk phone call log integration, presence, visual voicemail, text messaging, and dial-via-office. To integrate Nokia Call Connect dual-mode client with Unified Mobile Communicator, check the **Enable Cisco Unified Mobile Communicator** checkbox on the Nokia S60 device configuration page within Unified M.

Once configured within Unified CM, both clients can be run on the Nokia dual-mode device; however, it is important to understand the implications for the dial-via-office feature. While all other features and functions within the two clients will operate normally, the dial-via-office interaction behaves somewhat differently when the Nokia Call Connect client is installed on the same device. The dial-via-office feature within Unified Mobile Communicator will engage only for calls routed through the mobile voice network or cellular interface. For this reason, calls made by the Nokia Call Connect client through the WLAN interface will not engage dial-via-office, which is preferable behavior because the call is already being made over the enterprise IP telephony infrastructure.

However, for calls made from the mobile voice or cellular interface, the dial-via-office feature may be engaged, depending on the dial-via-office settings within the Unified Mobile Communicator client and/or the dial-via-office settings on the Cisco Unified Mobility Advantage server. If the administrator of the Unified Mobility Advantage server forces dial-via-office for users, then the Unified Mobile Communicator client will attempt to invoke dial-via-office for every call made out the cellular interface of the device. In these situations, the user should set the configuration parameter **Allow dial via office for to Call from this app** on the Unified Mobile Communicator client so that only calls made directly from the Unified Mobile Communicator client will attempt to invoke dial-via-office. By configuring the client this way, the user can ensure that dial-via-office will not be engaged when calls are made through the cellular interface outside of the Unified Mobile Communicator client. For example, it would be undesirable to engage dial-via-office on the Nokia device when the Nokia Call Connect client is

attempting to hand-out a call from the enterprise WLAN to the mobile voice network. During hand-out, the cellular interface of the Nokia dual-mode device calls the Unified CM Handoff Number, and having dial-via-office engage would cause additional unnecessary call legs to be created and might in fact result in a failure to hand-off the original call.

Likewise, if the administrator has allowed individual Unified Mobile Communicator users to configure their own dial-via-office settings within the client, then the users can set the client to prompt them to choose between making the call directly and using dial-via-office each time a call is attempted through the cellular interface. By setting the Unified Mobile Communicator **When dialing** setting to **Let me choose** and the **Allow dial via office for** setting to **Call from this app**, the user has maximum control over when dial-via-office will be used. In all cases, users should use dial-via-office only when the Nokia dual-mode device is outside the enterprise and not registered to Unified CM.

For more information about the Cisco Unified Mobile Communicator solution, feature set, and design and deployment considerations, see [Dual-Mode Phones and Clients, page 25-66](#).

Unified Mobility Integration

In addition to integrating with Unified CM for call log integration and dial-via-office, Unified Mobile Communicator users may also be integrated with Unified Mobility to take advantage of Mobile Connect, thus ensuring that incoming calls to a user's enterprise number will be extended to the user's mobile phone. The integration of Cisco Unified Mobile Communicator clients with Unified Mobility is done through a configured mobility identity associated directly to the Cisco Unified Mobile Communicator device within Unified CM. The configuration settings for a mobility identity within Unified CM are the same as a remote destination. Furthermore, all of the guidelines surrounding configuration of the remote destination number and caller ID matching (see [Remote Destination Configuration and Caller ID Matching, page 25-55](#)) apply to configuration of the mobility identity number as well. Within the Unified Mobile Communicator client interface, the user has the ability to enable or disable Mobile Connect (Single Number Reach) under the General settings menu.

Cisco Unified Presence

The Unified Mobility Advantage Server can be integrated with Cisco Unified Presence so that Unified Mobile Communicator users are able to update their presence status or availability to the enterprise network. Likewise, the Unified Mobile Communicator client receives presence information for other enterprise clients within the user's buddy list, directory list, contact list, voicemail message list, and call history logs. Presence status and buddy lists are synchronized between the Unified Mobile Communicator client and the user's Cisco Unified Personal Communicator client. Unified Mobile Communicator users can manually adjust their availability within the client or rely on automatic updates to availability based on Microsoft Exchange personal calendar availability and desk phone line status. As shown in [Figure 25-30](#), integration with Cisco Unified Presence is done using a SIP/SIMPLE connection between the Unified Mobility Advantage Server and the Cisco Unified Presence server.

Note

Cisco Mobile, the Unified Mobile Communicator client for the iPhone, does not display presence status or support sending or receiving of presence status updates.

Cisco Unity and Unity Connection Voice Mail

The Unified Mobility Advantage server can be integrated with Cisco Unity (in Unified Messaging or Integrated Messaging mode) and Cisco Unity Connection voicemail systems to provide the Unified Mobile Communicator client with message waiting indication (MWI) status for the user's enterprise

voicemail box. With this integration, a user can also visually navigate their voicemail box using their mobile device. The user is able to navigate a list of all messages in the voicemail box. This list includes the following information:

- Time the message was left
- Length of the message
- Caller ID or name (if available) of the person who left the message
- Priority indication for the message
- Current presence or availability indication of the person who left the message, if that person is providing presence status to the enterprise presence infrastructure

When the user selects a message from the list, the message is downloaded by the Unified Mobile Communicator client using the data connection, and the user is able to play the message and then delete or save the message on the voicemail system. Changes to the status of a voicemail message made by the Cisco Unified Mobile Communicator client (for example, marking the message as read or deleting the message) are propagated to the voicemail system and are appropriately reflected on the user's desk phone and other clients such as Cisco Unified Personal Communicator. Voicemail messages can be navigated in any order. As shown in [Figure 25-30](#), Unified Mobility Advantage Server integrates with Cisco Unity or Unity Connection using the IMAP protocol.

Cisco Unified MeetingPlace

The Unified Mobility Advantage Server can be integrated with Cisco Unified MeetingPlace so that Unified Mobile Communicator users can receive conference notifications or invitations to MeetingPlace meetings. These meeting notifications include the subject, the time and date, dial-in number, and meeting ID of the conference. The user can then click to call the dial-in number.

Note

Click-to-join is supported only with Cisco Mobile, the Cisco Unified Mobile Communicator for the iPhone and Blackberry. For all other Cisco Unified Mobile Communicator clients, the user must manually enter the meeting ID once the call is connected.

Integration with Cisco Unified MeetingPlace is done via a direct connection from the Unified Mobility Advantage Server to the Microsoft Exchange server utilized by the conferencing system. This connection uses the web-based Distributed Authoring and Versioning (WebDAV) protocol, as shown in [Figure 25-30](#).

In order for conference notifications to be received by Cisco Unified Mobile Communicator clients (including Cisco Mobile), the system administrator must modify the Cisco Unified MeetingPlace meeting notification email templates to include a **cump://** prefixed link in each meeting notification. The Cisco Unified Mobility Advantage server looks for this link in all meeting notifications contained within the user's Exchange mailbox. If this link is not present in a meeting notification, then notification of the meeting will not be listed or received by the client. For details surrounding the required modifications to the Cisco Unified MeetingPlace meeting notification email templates, refer to *Configuring Features in Cisco Unified Mobility Advantage: Meeting Features*, available at

http://www.cisco.com/en/US/products/ps7270/products_installation_and_configuration_guides_list.html

Integration to MeetingPlace not only supports conference notifications but also allows the user to click-to-join a conference without the need to enter a password or meeting ID. This click-to-join functionality is facilitated by a SOAP call to the Web Services API of the MeetingPlace server, as shown in [Figure 25-30](#).

**Note**

Click-to-join is supported only with Cisco Mobile, the Unified Mobile Communicator clients for the iPhone and Blackberry.

In deployments where Cisco WebEx is providing web sharing capabilities for Cisco Unified MeetingPlace meetings, the iPhone Cisco Mobile client will cross-launch the Cisco WebEx Meeting Center application on the iPhone (assuming this application has already been installed on the device). For this cross-launch to work, the Cisco Unified MeetingPlace system must be successfully integrated with Cisco WebEx.

Microsoft Exchange

In addition to communicating with Microsoft Exchange for Cisco Unified MeetingPlace conferencing integration, the Cisco Unified Mobility Advantage Server also integrates with Microsoft Exchange via WebDAV to facilitate maintenance of the user's personal contact lists that are stored on Exchange. Integration with Exchange also provides the ability to update a user's presence status automatically based on their Exchange calendar availability. Microsoft Exchange is an optional component and is required only if conference notifications, personal contact lists, or calendar integration are needed.

Secure Text Messaging

In addition to the above application integrations and functionality, Unified Mobile Communicator users can also send secure text messages to one another using the Unified Mobile Communicator client. This message exchange is facilitated natively within the Cisco Unified Mobility Advantage Server. These messages are exchanged using the mobile data connection, therefore no SMS provider charges are incurred.

**Note**

Cisco Mobile, the Unified Mobile Communicator client for the iPhone, does not support secure text messaging using the Cisco Unified Mobility Advantage server.

High Availability for Cisco Unified Mobile Communicator

The Cisco Unified Mobile Communicator client is completely reliant upon the backhauled data connection across the mobile data network to the Cisco Unified Mobility Advantage Server for application interaction and functionality. If this data connection is lost due to a failure in the mobile data network, loss of connectivity to the mobile data network, or failure of the ASA TLS Proxy, BES Server, or the Cisco Unified Mobility Advantage Server, then access to enterprise applications will be unavailable. Given any of these types of failures, users will be unable to access Unified Mobile Communicator to take advantage of the various application integrations. For example, the user would be unable to perform directory lookups, send text messages to other clients, access visual voicemail, access personal contacts, receive message waiting indication, receive conference notifications, update or synchronize buddy lists and presence information, or make calls using the dial-via-office feature.

**Note**

Given a failure of the data connection between the Cisco Unified Mobile Communicator client and Cisco Unified Mobility Advantage or a failure of the connection between Cisco Unified Mobility Advantage and Cisco Unified CM, the client will fall back to direct dial even in cases where dial-via-office has been mandated administratively.

While the features and functions provided by Unified Mobile Communicator will be unavailable if the data connection to the enterprise is unavailable, the user will still be able to make and receive phone calls with their mobile device using the mobile voice network as usual. In addition, if the user and the mobile phone have been integrated with Unified Mobility on Unified CM, then Mobile Connect functionality as well as features such as Mobile Voice Access and Enterprise Feature Access will still be available.

Failure of enterprise applications such as Cisco Unified Presence, Cisco Unified CM, or Cisco Unity and Unity Connection can result in loss of particular functions, depending on the nature of these applications within the deployment. However, in many cases multiple adapters can be configured within the Unified Mobility Advantage Server and, assuming redundancy has also been provided for the various applications, often functionality can be maintained given an application or application server failure.

Capacity Planning for Cisco Unified Mobile Communicator

The Cisco Unified Mobility Advantage Server supports the following user capacities:

- Cisco MCS 7845-H2/I2 supports up to 1,000 Unified Mobile Communicator clients.
- Cisco MCS 7825-H4/I4 supports up to 500 Unified Mobile Communicator clients.
- Cisco MCS 7825-H2/I2 or 7825-H3/I3 supports up to 250 Unified Mobile Communicator clients.

To support more than 1,000 Unified Mobile Communicator users within a deployment, additional Unified Mobility Advantage Servers may be installed. However, Unified Mobile Communicator clients configured and associated to one Cisco Unified Mobility Advantage Server will not be able to send text messages to clients on another server.

When integrating Unified Mobile Communicator with Cisco Unified CM for enterprise call log integration, the Unified Mobility Advantage Server interacts with Unified CM CTIManager for desk phone line monitoring. For each Unified Mobile Communicator enabled for call log integration, the Cisco Unified Mobility Advantage Server generates one CTI connection to the CTIManager. Therefore, with a deployment of Unified Mobile Communicator with one fully populated Unified Mobility Advantage Server running on an MCS 7845 with call log integration enabled for all users, 1,000 CTI connections will be consumed. For this reason, when you deploy Unified Mobile Communicator with call log integration, you must consider the number of required CTI connections with regard to the following cluster-wide limits for CTI connections:

- 40,000 CTI connections per Unified CM cluster with MCS 7845-I3 or OVA equivalent servers.
- 20,000 CTI connections per Unified CM cluster with Cisco MCS 7845-H2/I2 or OVA equivalent servers.
- 10,000 CTI connections per Unified CM cluster with Cisco MCS 7835-H3/I3 or OVA equivalent servers.
- 8,000 CTI connections per Unified CM cluster with Cisco MCS 7835-H2/I2 servers.
- 4,000 CTI connections per Unified CM cluster with Cisco MCS 7825-H5/I5 or OVA equivalent servers.
- 3,600 CTI connections per Unified CM cluster with all other currently supported Cisco MCS 7825 and MCS 7835 servers.

If additional CTI connections are required for other applications, they can limit the capacity of Unified Mobile Communicator users with call log integration enabled.

Integration of Unified Mobile Communicator with Unified CM for dial-via-office and Unified Mobility functionality requires the configuration of each Unified Mobile Communicator as a Unified CM device and configuration of the mobile number as a mobility identity. Therefore, when implementing these integrations, you must also consider overall Unified CM phone and mobility-enabled user capacities.

Design Considerations for Cisco Unified Mobile Communicator

Observe the following design considerations when deploying Cisco Unified Mobile Communicator:

- For security reasons, the Cisco Unified Mobility Advantage server should be deployed behind the enterprise firewall because it is the integration point for all enterprise services and applications.
- Because the Cisco Adaptive Security Appliance (ASA) serves as a proxy server for communications between Cisco Unified Mobile Communicator clients and the Cisco Unified Mobility Advantage server, the ASA should be deployed in the enterprise DMZ.
- An SSL certificate from a Certificate Authority must be obtained. The certificate is required in order to enable encryption of data flowing between Cisco Unified Mobile Communicator clients and the Cisco Unified Mobility Advantage server.
- SSL certificates must be obtained from well-known certificate authorities VeriSign or GeoTrust because mobile phones have limited capabilities in terms of importing root certificates. Root certificates from VeriSign and GeoTrust are commonly available on most mobile handsets.
- Firewall ports in the corporate firewall must be opened to allow connectivity from the Cisco Unified Mobile Communicator clients on the Internet to the ASA in the DMZ and from the ASA in the DMZ to the Cisco Unified Mobility Advantage server in the enterprise. The following firewall ports must be opened:
 - Client connection port (SSL): a single TCP port in the range 5400 to 5500 (default port is 5443)
 - Provisioning port (HTTP): a single TCP port in the range 9000 to 9100 (default port is 9080)

Note You do not have to open the provisioning port in the firewall if you are deploying only iPhone or Blackberry handsets because these handsets do not download the Cisco Unified Mobile Communicator client over the provisioning port. For iPhone handsets, the client is downloaded from the Apple App Store; and for Blackberry handsets, the client is pushed to the handset via the Blackberry Enterprise Server (BES).

- Microsoft Active Directory is required to authenticate Cisco Unified Mobile Communicator users. All Cisco Unified Mobile Communicator users must have a valid account within Microsoft Active Directory, otherwise authentication will fail and user will not be able to utilize features and services provided by this solution.
- Always ensure that appropriate back-end enterprise application servers have been deployed and configured appropriately based on the Cisco Unified Mobile Communicator solution features and functionality required. For a complete list of supported features and the required back-end application servers, refer to the *Compatibility Matrix for Cisco Unified Mobility Advantage and Cisco Unified Mobile Communicator*, available at http://www.cisco.com/en/US/products/ps7270/products_device_support_tables_list.html
- If you deploy Cisco Mobile, the Unified Mobile Communicator client for the Blackberry, you must also deploy a Blackberry Enterprise Server (BES) with Mobile Data Services (MDS) and integrate it directly to the Unified Mobility Advantage server. Cisco Mobile clients on Blackberry devices do not connect to the enterprise ASA, but instead use the secure Research In Motion (RIM) mobile network operations center (NOC) and the secure connection from the NOC to the enterprise BES server before connecting to the Unified Mobility Advantage server.

- In situations where both the Nokia Call Connect dual-mode client and the Cisco Unified Mobile Communicator Nokia client are deployed on the same handset, avoid using dial-via-office whenever the dual-mode device is inside the enterprise and registered to Unified CM. Cisco recommends the following:
 - When dual-mode phones are deployed in the enterprise, the administrator of the Cisco Unified Mobility Advantage Server should not force dial-via-office by using the Dial Via Office Policy setting. Instead, the administrator should allow users to choose whether they use dial-via-office.
 - If dial-via-office is forced for Cisco Unified Mobile Communicator by the administrator of the Cisco Unified Mobility Advantage server, the user should configure the **Allow dial via office for** setting to **Call from this app** within the Unified Mobile Communicator client so that only calls made directly from within the Unified Mobile Communicator client will attempt to invoke dial-via-office. By configuring the client this way, the user can ensure that dial-via-office will not be engaged unexpectedly. If the Unified Mobile Communicator client is not in the foreground, then the user can be sure that dial-via-office will not be invoked.
 - If dial-via-office is not forced by the Unified Mobility Advantage administrator, the Unified Mobile Communicator user should set the **When dialing** setting to **Let me choose** and the **Allow dial via office for** setting to **Call from this app**. By configuring the settings in this manner, the user has maximum control over when dial-via-office will be used. In all cases, users should use dial-via-office only when the Nokia dual-mode device is outside the enterprise and not registered to Unified CM.

Direct Connect Mobile Clients

Direct connect mobile clients provide a solution that gives mobile users the ability to access and leverage Cisco Unified Communications applications from their mobile phones. Similar to the Cisco Unified Mobile Communicator solution, direct connect client applications running on mobile smart phones work in conjunction with one or more application servers within the enterprise to provide a rich user interface for accessing and leveraging enterprise voice and collaboration applications. However, unlike the Cisco Unified Mobile Communicator solution, direct connect mobile clients communicate directly with back-end application servers rather than through an intermediary server such as Cisco Unified Mobility Advantage, thus the "direct connect" moniker. Direct connect mobile clients leverage the inherent scalability and reliability of the various enterprise back-end application servers.

Direct connect mobile clients not only provide the ability to access and use collaboration applications, but they can also leverage Voice over WLAN (VoWLAN) functionality to make and receive calls, thus providing dual-mode functionality as well. With support for both dial-via-office operations and voice over WLAN calling, enterprises can drastically reduce their mobile calling costs by off-loading voice traffic from the cellular network to the enterprise data network and, barring that, providing reduced cost call routing through the enterprise by means of local toll or even toll-free system access numbers.

This section examines direct connect mobile client architecture and common functions and features provided by these clients, including dial-via-office and XMPP-based IM and presence. After covering general direct connect mobile client architecture and features and functions, this section provides coverage of various capabilities and integration considerations for the Cisco Mobile 8.5 for Nokia direct connect mobile client.

In addition, this section discusses high availability and capacity planning considerations for direct connect mobile clients.

and the mobile phone. When not connected to the enterprise network, the client device becomes unregistered and will be able to receive enterprise calls only if the user has been enabled for Unified Mobility and Mobile Connect (or single number reach) has been turned on for the mobile number.

Likewise the direct connect client allows users to access IM and presence services through XMPP and directory services through LDAP when connected to the enterprise directly or remotely.

Network Connectivity: WLAN and VPN

Direct connect mobile clients are capable of connecting to the enterprise network using both WLAN and the mobile data network. For connecting to the enterprise remotely, a VPN secure connection is typically required. To enable this network connectivity for these clients, it is critical to provide the appropriate WLAN and/or VPN infrastructure, depending on the connection method(s) the enterprise plans to leverage.

WLAN Infrastructure

When leveraging WLAN for network connectivity, it is imperative to deploy a finely tuned, QoS-enabled, and highly available WLAN network. Because the direct connect mobile clients must rely in whole or in part on the underlying WLAN infrastructure for carrying both critical signaling and real-time voice media traffic as well as data traffic for accessing various applications, deploying a WLAN network optimized for both data and real-time voice traffic is necessary. A poorly deployed WLAN network will be subjected to large amounts of interference and diminished capacity, leading not only to poor voice quality but in some cases also to dropped or missed calls. This will in turn render the WLAN deployment unusable for making and receiving voice calls. Therefore, when leveraging WLAN connectivity for deployed direct connect mobile clients, you must conduct a WLAN radio frequency (RF) site survey before, during, and after the deployment to determine appropriate cell boundaries, configuration and feature settings, capacity, and redundancy to ensure a successful Voice over WLAN (VoWLAN) deployment. As with other WLAN-enabled clients, each mobile phone device and client should be tested on the WLAN deployment to ensure proper integration and operation prior to a production deployment. Using a WLAN that has been deployed and configured to provide optimized VoWLAN services (such as the Cisco Unified Wireless Network), including quality of service, will ensure a successful direct-connect device deployment.

For more information on Voice over WLAN deployments and wireless device roaming, see [Wireless Device Roaming, page 25-7](#).

VPN Infrastructure

When employing VPN network connectivity for connections over the mobile data network or public or private Wi-Fi hot spots, it is important to deploy a high-bandwidth secure VPN infrastructure that adheres to the enterprise's security requirements and policies. Careful planning is needed to ensure that the VPN infrastructure provides high bandwidth, reliable connections, and appropriate session or connection capacity based on the number of users and devices using this connectivity.

VPN connection types and methods vary, with options ranging from standards-based IPSec, leveraging Cisco IOS VPN or Cisco Adaptive Security Appliance (ASA), to Cisco AnyConnect and the Cisco Jabber secure connect feature, both also leveraging the Cisco ASA. The type of VPN method or client used will often depend on the mobile device or devices being deployed.

For more information on secure remote VPN connectivity solutions, including Cisco AnyConnect, refer to the secure mobility documentation available at

<http://www.cisco.com/en/US/products/hw/vpndevc/products.html#mobi>

For information on Cisco Jabber secure connect, refer to the *Cisco Jabber Secure Connect Deployment Guide*, available at

http://www.cisco.com/en/US/products/ps11678/products_implementation_design_guides_list.html

**Note**

While dual-mode phones and direct connect clients are capable of connecting back to the enterprise through the Internet for call control and other Unified Communications services, Cisco cannot guarantee voice quality or troubleshoot connectivity or voice quality issues for these types of connections. These types of connections include remote connections to the enterprise through public or private WLAN access points or hot spots or through the mobile data network. Cisco recommends an enterprise-class voice-optimized WLAN network for connecting mobile client devices. Most public and private WLAN APs and hot spots are tuned for data applications and devices. In these cases, the AP radios are turned to maximum power, and dynamic-power control results in devices enabling maximum power upon network attachment, which allows for larger client capacities. While this may be ideal for data applications that are capable of retransmitting dropped or lost packets, for voice applications this can result in very poor voice quality due to the potential for large numbers of dropped packets. Likewise, mobile provider data networks are susceptible to congestion and/or dropped connections, which can also result in poor voice quality and dropped calls.

Direct Connect Mobile Client Features and Functions

Direct connect mobile clients provide a range of features and functions. While the supported features and operations may vary from client to client, the features and behaviors described in this section apply to all direct connect mobile clients.

Call Routing

Because direct connect mobile clients are capable of making and receiving calls using the enterprise telephone infrastructure, it is important to understand the nature of call routing as it pertains to direct connect mobile client behavior.

Inbound Call Routing

While the direct connect mobile clients are able to register to Unified CM to leverage both dial-via-office and VoIP calling, depending on the network connectivity, inbound call routing behavior varies slightly. When the client is connected and registered to Unified CM over the enterprise WLAN network or through secure VPN to the enterprise, the client receives inbound calls to the enterprise number (whether sourced internally or from the PSTN) just like a registered IP desk phone. If the user has a desk phone, the inbound call rings the shared line on both the mobile client device and the desk phone. On the other hand, if the client is not connected to the enterprise network directly or through a secure remote connection, then inbound calls to the enterprise number (whether sourced internally or from the PSTN) will ring the mobile number of the device provided that the user has been enabled for Cisco Unified Mobility and Mobile Connect (single number reach) is enabled for the user's direct connect client device mobile number. As with dual-mode client devices, incoming calls to the enterprise numbers are not extended to the mobile number of the direct connect client device through Mobile Connect if the client device is connected to the enterprise network and registered to Unified CM.

In all cases, incoming calls made directly to the direct connect client device's mobile phone number will always be routed directly to the device on the mobile network, unless the provider network or device settings are such that calls are not extended to the device by the mobile network. This is considered appropriate behavior because these calls were not made to the user's enterprise number. They would be considered personal calls, and as such should not be routed through the enterprise.

Outbound Call Routing

Depending on the nature of network connectivity for the direct connect mobile client device, outbound call routing behavior will be slightly different. If the device is connected to the enterprise WLAN and registered to Unified CM, then outbound calls, whether destined for internal enterprise numbers or external PSTN numbers, are routed by means of the enterprise telephony infrastructure based on the dial plan configuration within Unified CM. If instead the device is securely connected to the enterprise through the mobile data network or through a public or private Wi-Fi hot spot, then depending on the quality of the connection, outbound call routing is facilitated by either VoIP or the dial-via-office feature within Unified CM. In the case of dial-via-office, call signaling traverses the mobile data connection to the enterprise, and voice media traverses the mobile voice network and PSTN. If no enterprise connectivity is available, then outbound calling is not possible from the enterprise number, and instead calls would have to leverage the mobile number of the direct connect client device for making calls over the mobile voice network. Alternatively, users may leverage the two-stage dialing features provided with Cisco Unified Mobility (see [Mobile Voice Access and Enterprise Feature Access, page 25-49](#)).

Dial Plan

Dial-via-office and VoIP calling enable the direct connect mobile client to dial outgoing calls using enterprise dialing methods including use of abbreviated extension dialing and PSTN and inter-site steering digit dialing. However, in situations in which the dial-via-office feature or VoIP calling is not available due to lack of enterprise connectivity, enterprise dialing methods are not possible and users must dial outgoing calls using full-length E.164 number dialing as required on mobile voice networks and the PSTN.

While enterprise dialing may allow for convenience of abbreviated dialing, because of the differences between enterprise dialing and PSTN or mobile voice network dialing, normalization of required dialing patterns is recommended so that users dial the same number to reach a called destination whether they are connected to the enterprise or not. By normalizing the dial plan and dialing behavior within Unified CM for direct connect mobile client users, administrators are able to provide the best possible end-user dialing experience so that users do not have to be aware of whether the client device is connected to the enterprise and registered to Unified CM.

For more information on dial plan normalization for mobile clients, see the section on dual-mode phones and clients [Dial Plan, page 25-70](#).

Caller ID

When direct connect mobile client devices are connected to the enterprise (directly, or through a public or private Wi-Fi hot spot or over the mobile data network) and registered to Unified CM, all calls made by dial-via-office or over the IP network will be routed with the user's enterprise number as caller ID. This ensures that returned calls made from call history lists at the far end are always routed through the enterprise because the return call is to the user's enterprise number. If the direct connect mobile client user has been enabled for Cisco Unified Mobility, and Mobile Connect is turned on for the direct connect client device mobile number, return calls to the enterprise number will also be extended to the direct connect mobile client device through the PSTN whenever the client device has no enterprise network connectivity.

Emergency Services

As with other mobility client solutions, direct connect mobile clients can present challenges when it comes to making emergency calls to public service numbers such as 911, 999, and 112. Because the direct connect mobile client device may be located inside or outside the enterprise, providing location indication in the event of an emergency must be considered. Mobile phones already receive location services from their provider networks, and these location services are always available and typically able to pinpoint locations far more precisely than enterprise wireless networks; therefore, Cisco recommends relying on the mobile voice network for making emergency calls and determining device and user

location. To ensure that direct connect mobile client devices rely exclusively on the mobile voice network for emergency and location services, Unified CM will force all calls made to numbers configured in the Emergency Numbers field on the direct connect client device configuration page to route over the mobile voice network.

External Call Routing

When the direct connect mobile client device is located outside the enterprise and has no enterprise connectivity, it may make and receive calls only through the mobile voice network. Unified CM will have no visibility to these directly dialed calls on the mobile voice network because they are not anchored in the enterprise. As a result, users will not be able to invoke enterprise mid-call features or perform desk phone pickup for these calls. In these situations, if made available by the system administrator, users can leverage Unified Mobility Enterprise Feature Access or Mobile Voice Access two-stage dialing features to anchor the calls in the enterprise.

Dial-via-Office

Dial-via-office functionality provides the ability for direct connect mobile clients to initiate calls from the mobile phone using the Cisco Unified CM telephony infrastructure and enterprise PSTN gateway. This functionality is facilitated by SIP signaling over the IP network connection between the direct connect mobile client and Unified CM. Utilization of dial-via-office can be mandated by the Unified CM system administrator, or the administrator may choose to allow users to decide whether they want to use dial-via-office or dial their calls directly over the mobile voice network. As previously mentioned, calls to emergency numbers (as configured in the Emergency Numbers field on the direct connect client device configuration page) will always be dialed directly over the mobile voice network even when dial-via-office calling has been mandated.

Dial-via-office operation and behavior is nearly identical to that described for the Cisco Unified Mobile Communicator solution (see [Dial-via-Office, page 25-93](#)), with the only difference being that the Cisco Unified Mobility Advantage server and Cisco Unified Mobile Communication client are not involved. Instead the communication for dial-via-office call setup occurs directly between the direct connect mobile client and Unified CM over the IP network connection.

Just as with the Cisco Unified Mobile Communicator solution, direct connect mobile clients can perform either Dial-via-Office Reverse Call Back (DVO-R) or Dial-via-Office Forward (DVO-F) operations.

See [Dial-via-Office, page 25-93](#), for more information about dial-via-office call flows and operation.

Session Resumption

Beginning with Cisco Unified CM 8.5, direct connect mobile client users are able to redial Dial-via-Office Forward calls during a call set up or network failure. With Unified CM 8.5 and later releases, the system caches the last target number the user dialed for the amount of time specified in the Redial Await Timer service parameter. By default, the target number will be cached for three minutes. Given a call set up or network failure, if the user presses the redial softkey or selects the last call in the call history list of the mobile phone, the system will automatically reconnect the user to the last dialed number by means of the Dial-via-Office Forward feature, provided the Redial Await Time has not expired.

Note

The Session Resumption or Dial-via-Office Forward Redial feature provided in Unified CM 8.5 and later releases may also be used with both new and existing deployments of Cisco Unified Mobile Communicator 7.x clients and Cisco Unified Mobility Advantage 7.1(3) that are capable of Dial-via-Office Forward. No configuration changes are required on Unified Mobile Communicator or Unified Mobility Advantage in order to leverage this feature.

Mobile Toll Bypass Optimization

In order to provide least-cost routing for dial-via-office calls, beginning with Cisco Unified CM 8.5, administrators can configure multiple enterprise feature access numbers on the system for use by the dial-via-office operation. In addition these numbers can be assigned to users through a new mobility profile configuration construct. By allowing multiple enterprise feature access numbers, the system can accommodate local access numbers for Dial-via-Office Forward calls as well as locally significant caller IDs for Dial-via-Office Reverse calls. The Dial-via-Office Forward access numbers and Dial-via-Office Reverse caller IDs can be based on geographic location of users according to assignment of geographically appropriate mobility profiles.

The Mobile Toll Bypass Optimization feature involves first configuring multiple enterprise feature access numbers on the system, each corresponding to a specific geographic location. On a globally deployed system, the administrator would provide local access numbers or DIDs for locations throughout the world based on user populations and office locations. As an example, local numbers might be configured for US cities San Jose, New York, and Miami as well as London, England, Berlin, Germany, and Tokyo, Japan.

Next these multiple access numbers are assigned to users based on configuration of mobility profiles. A mobility profile would be created for each geographic location and assigned to users in that location. For example, mobility profiles would be configured for users in San Jose, New York, Miami, London, Berlin, and Tokyo, with each profile containing the locally significant access number or DID for that particular geographic location. In this way, users in each of these locations will be able to access Dial-via-Office Forward services using a local number rather than a long distance or international number. By providing local numbers for each geographic location, cost savings can be realized due to the less expensive billing rates typically provided for local calls.

Each mobility profile is configured with up to three different numbers depending on dial plan and dial-via-office method. Under the Dial-via-Office Forward portion of each profile, the administrator may configure an Enterprise Feature Access Number and a Service Access Number. The Service Access Number and Enterprise Feature Access Number are used as a pair, with the Service Access Number serving as the E.164 form of the Enterprise Feature Access Number when it has been configured in abbreviated form. If the Enterprise Feature Access Number is configured as the full E.164 form, then the Service Access Number does not have to be configured. One or both of these numbers are used for Dial-via-Office Forward operations as the number forwarded by the system to the direct connect mobile client and, in turn, the number the client uses to call into the system to complete a Dial-via-Office Forward call. The other number that may be configured on the mobility profile is the Callback Caller ID number under the Dial-via-Office Reverse Callback portion of each profile. This number specifies the caller ID that the Unified CM system uses when placing outbound calls to the direct connect mobile client device on the PSTN for Dial-via-Office Reverse Callback calls.

The mobility profile also contains the Mobile Client Calling Option field, which enables the system administrator to specify either Dial-via-Office Reverse or Dial-via-Office Forward when dial-via-office calls are made. This provides administrative control over the dial-via-office call direction that a mobile client uses and enables the administrator to force use of the least expensive method for making a dial-via-office call.

Mobility profiles should be assigned to users based on the location where the user will typically use the client. If a user moves between geographic locations, the administrator will have to assign the user manually to a different profile based on the new location. The system does not dynamically update the mobility profile based on a user's location.

Mobility profiles can be assigned only to mobile devices configured with mobility identities and capable of leveraging the dial-via-office feature. Direct connect mobile clients such as Cisco Mobile 8.5 for Nokia as well as the older Cisco Unified Mobile Communicator clients are devices configured with a mobility identity and capable of dial-via-office. Mobility profiles cannot be configured for regular Unified Mobility remote destinations.

**Note**

The Mobile Toll Bypass Optimization feature provided in Unified CM 8.5 and later releases may be used with both new and existing deployments of Cisco Unified Mobile Communicator 7.x clients and Cisco Unified Mobility Advantage 7.1(3). No configuration changes are required on Unified Mobile Communicator or Unified Mobility Advantage in order to leverage this feature. The Unified Mobility Advantage server will automatically use the access numbers forwarded to it by Unified CM 8.5 and later releases. However, the Mobile Client Calling Option field, where the administrator can indicate Dial-via-Office Reverse or Dial-via-Office Forward, has no impact on dial-via-office call flow for Cisco Unified Mobile Communicator devices. Dial-via-office direction for Cisco Unified Mobile Communicator clients is controlled exclusively by the client itself.

Additional Services and Features

In addition to dial-via-office and VoIP call processing or call control services, direct connect mobile client are capable of providing the features and services described in this section.

XMPP-Based IM and Presence

Cisco Mobile 8.5 for Nokia and the Cisco Jabber IM direct connect mobile clients support the use of Extensible Messaging and Presence Protocol (XMPP) for enterprise IM and presence services through integration to either an on-premises Cisco Unified Presence server or an off-premises Cisco WebEx Connect cloud service. In both cases, the IM and presence capabilities of these direct connect mobile client allow the following:

- Adding users to contact or buddy lists
- Setting and propagating user presence and availability status
- Reception of presence status for a buddy or contact
- Creating and sending of instant messaging (IM) or text messages
- Reception of IM or text messages
- Escalation of an IM or text message to a voice call

A Cisco Jabber IM client is available for Apple iOS iPhone, iPod Touch, and iPad devices with a minimum Apple iOS version of 4.2. A Cisco Jabber IM client is also available for a wide range of BlackBerry devices running BlackBerry OS 4.6 and later versions.

Cisco Jabber IM enables cross-launch of the Cisco Jabber mobile client (if installed) for VoIP calling. In turn, Cisco Jabber mobile clients are able to cross-launch Cisco Jabber IM (if installed) for contact-based enterprise IM and chat.

For more information on Cisco Jabber IM clients, refer to the *Cisco Jabber IM for BlackBerry* data sheet, available at http://www.cisco.com/en/US/products/ps11763/products_data_sheets_list.html, and the *Cisco Jabber IM for iPhone* data sheet, available at http://www.cisco.com/en/US/products/ps11596/products_data_sheets_list.html.

Corporate Directory Access

Direct connect mobile clients are capable of accessing an enterprise directory for directory lookups using LDAP, provided the client device is connected to the enterprise through either a mobile data network or WLAN. While this is not a required feature for direct connect mobile clients, it does provide productivity improvements for direct connect client users when they are able to access corporate directory information from their mobile phones.

Enterprise MWI and Message Count Indication

Direct connect mobile clients are also capable of accessing enterprise voicemail services. Direct connect clients are able to receive enterprise message waiting indication (MWI) and message count, and/or access their enterprise voicemail box visually. Direct connect mobile clients must be connected to the enterprise network (through a mobile data network or WLAN) in order to receive MWI and message count indication or to access visual voicemail.

Just as with regular enterprise phones, direct connect mobile clients can also be used to retrieve enterprise voicemail messages by dialing into the voicemail system number and navigating to the appropriate voicemail box after providing required credentials.

Mobile Connect On/Off

If integrated with Unified Mobility and enabled for Mobile Connect, direct connect mobile clients are able to view Mobile Connect status and turn Mobile Connect on or off through the client settings interface. This allows users to enable or disable Mobile Connect or single number reach functionality for the direct connect mobile client device mobile number even when connected to the enterprise remotely over the mobile data network.

Direct Connect Mobile Client: Cisco Mobile 8.5 for Nokia

Note

End-of-Sale for the Cisco Mobile 8.5 for Nokia client is July 10, 2012. There is no replacement mobile client for Nokia mobile devices. For more information, see the End-of-Sale (EoS) and End-of-Life (EoL) announcement at http://www.cisco.com/en/US/prod/collateral/voicesw/ps6789/ps7290/ps10589/end_of_life_notice_c51-696647.html.

Cisco Mobile 8.5 for Nokia is a direct-connect mobile client for Nokia mobile smart phones. Once installed on the Nokia device, the client can associate to either the local enterprise WLAN network or remotely to the enterprise through the mobile data network. The client registers to and communicates with Unified CM.

To provide registration and dial-via-office services to Cisco Mobile 8.5 direct connect mobile clients, Unified CM must support the appropriate Nokia S60 device type, which is available only after loading the necessary Cisco Options Package (COP) file onto Unified CM. The COP file (cmterm-nokia_s60_8.5.2v06-sccp.cop.sgn) can be found at the following location:

[http://www.cisco.com/cisco/software/release.html?mdfid=281001428&release=8.5\(2\)&flowid=&softwareid=282074304&os=null](http://www.cisco.com/cisco/software/release.html?mdfid=281001428&release=8.5(2)&flowid=&softwareid=282074304&os=null)

Once the COP file is installed and the direct connect client device has been configured within Unified CM, it is necessary to load the Cisco Mobile 8.5 for Nokia client onto the Nokia device. This can be done using a computer with a USB, Bluetooth, or infrared port. After the Cisco Mobile 8.5 Symbian installation system (SIS) file has been loaded on the Nokia device, the device must at a minimum be configured to access the local enterprise WLAN for connectivity based on the enterprise WLAN infrastructure and security policies. Additional configuration is required in order to enable remote enterprise network connectivity using a VPN.

To integrate the Cisco Mobile 8.5 Nokia device with Unified Mobility so that the user can leverage features such as Mobile Connect, configure the Nokia mobile phone number as a mobility identity and associate it to the Nokia S60 device within Unified CM.

The Cisco Mobile 8.5 client is supported on Nokia handsets running Symbian Series 60 Third Edition Feature Pack 1 (3.1) or Feature Pack 2 (3.2) firmware. Example devices include the Nokia E55, E66, E71, E72, and E75.

Nokia mobile phone WLAN interfaces typically support 802.11b and 802.11g network connectivity.

The Cisco Mobile 8.5 client not only provides dial-via-office voice services but also provides directory lookup services when configured to point to an LDAP compliant directory, and it provides XMPP-based presence and IM when integrated with Cisco Unified Presence or Cisco WebEx Connect.

For information about system requirements and supported devices, refer to the release notes for Cisco Mobile 8.5 for Nokia, available at

http://www.cisco.com/en/US/docs/voice_ip_comm/cumc/cisco_mobile/nokia/8_x/Release_Notes/Cisco_Mobile_Nokia_8_x_RN.html

For installation and configuration information for Cisco Mobile 8.5 for Nokia, refer to the administration guide available at

http://www.cisco.com/en/US/docs/voice_ip_comm/cumc/cisco_mobile/nokia/8_x/admin/Cisco_Mobile_for_Nokia_8.5_Admin_Guide.html

Co-Residency of Cisco Mobile 8.5 with Nokia Call Connect

In order to support dual-mode voice over IP (VoIP) functionality, Cisco Mobile 8.5 must be installed co-resident with the Nokia Call Connect dual-mode client on the device. The Nokia Call Connect client provides support for VoIP calling. Both clients are associated to the Nokia S60 device configuration for the Nokia device within Unified CM.

When running co-resident, the Nokia Call Connect dual-mode client behaves as previously described in the section on [Dual-Mode Clients: Nokia Call Connect, page 25-80](#). Operation and deployment of the Nokia Call Connect dual-mode client co-resident with Cisco Mobile 8.5 is identical in operational and functional behavior to a standalone Nokia Call Connect dual-mode client installation. The same design and deployment requirements related to handoff operations and configuration must be considered. Likewise, all design recommendations and requirements covered in the section on [Wireless Device Roaming, page 25-15](#), apply to the Nokia Call Connect client running co-resident with Cisco Mobile 8.5.

When deploying co-resident Cisco Mobile 8.5 and Nokia Call Connect clients, the Unified CM administrator should not force dial-via-office. Instead the Dial Policy parameter on the Nokia S60 device configuration page should be configured as **Let User Choose**. This gives the user maximum control over when dial-via-office will be used, thus ensuring that this feature is used only when the user is not connected to the enterprise or when voice quality over the IP network is poor.

If the administrator must force dial-via-office for Cisco Mobile 8.5, the user should configure the **Allow dial via office for** setting to **Calls from this app** within the Cisco Mobile 8.5 client so that only calls made directly from within the client application will attempt to invoke dial-via-office. By configuring the client this way, the user can ensure that dial-via-office will not be engaged unexpectedly. If the Cisco Mobile 8.5 client is not in the foreground, then the user can be sure that dial-via-office will not be invoked.

When running these two clients co-resident, consider the following:

- The Nokia Call Connect dual-mode client should be used for making and receiving VoIP calls when WLAN or mobile data network connection signal strength is strong and reliable.
- If voice quality is poor or IP connectivity is unreliable, then the Cisco Mobile 8.5 direct connect client should be used for dial-via-office calls.

In all cases, users should use dial-via-office only when the direct connect mobile client device is outside the enterprise or when voice quality over the IP network connection is poor.

Interactions Between Cisco Mobile 8.5 and Cisco Unified Mobility

The Cisco Mobile 8.5 direct connect mobile client for Nokia can be integrated with Cisco Unified Mobility to leverage Cisco Mobile Connect, mid-call DTMF features (when mobile data connection or WLAN connection is unavailable), single enterprise voicemail box, and desk phone pickup.

Integration with Unified Mobility requires the Nokia direct connect client device mobile phone number to be configured within Unified CM as a mobility identity associated with the Nokia S60 device. Once the mobile number is configured as a mobility identity within the system, Mobile Connect can be leveraged so that incoming calls to the user's enterprise number will be extended to the Nokia direct connect client device through the mobile voice network. The Mobile Connect feature can also be enabled or disabled remotely within the Cisco Mobile 8.5 client. In situations where the Nokia device is also running Nokia Call Connect dual-mode client, when the device is connected to the enterprise and registered to Unified CM, an inbound call to the enterprise number will not be extended to the mobile voice network interface of the device. When the Nokia device is connected to the enterprise, the device will receive the inbound call through the IP network. This prevents unnecessary consumption of enterprise PSTN gateway resources.

When outside the enterprise, if a public or private Wi-Fi hot spot or the mobile data network is reachable from the Nokia device and secure connectivity to the enterprise is available, the Cisco Mobile 8.5 client can use VoIP or dial-via-office for making outbound calls, depending on the quality of the enterprise connection. However, if no IP network connectivity is available, the user can still make enterprise calls by using the Unified Mobility two-stage dialing features Mobile Voice Access or Enterprise Feature Access. Further, for any enterprise anchored call (dial-via-office, two-stage dialed, or direct dialed enterprise numbers as well as Mobile Connect), users can move an active call to their desk phones by using the Move Call to Desk feature of the Cisco Mobile 8.5 client. And if enterprise connectivity is not available, mid-call features may be invoked by means of DTMF feature access codes.

In addition to configuring a mobility identity for the Nokia direct connect mobile client device, you can configure additional mobile phone numbers or off-system phone numbers as remote destinations and associate them to the Nokia S60 device within Unified CM. When associating the mobility identity and additional remote destinations to the Nokia device, you do not have to configure a remote destination profile. If existing Nokia mobile phone users are already enabled for Unified Mobility and are being migrated to Cisco Mobile 8.5, the existing remote destination profile should be removed and any configured remote destinations should be deleted and re-added directly to the Nokia S60 device. This is necessary because remote destination and mobility identities must be unique within the Unified CM system.

For more information about the Cisco Unified Mobility feature set as well as design and deployment considerations, see [Cisco Unified Mobility, page 25-38](#).

High Availability for Direct Connect Mobile Clients

Although direct connect mobile client devices by their nature are highly available with regard to network connectivity (when connectivity to the enterprise network over WLAN or mobile data network is unavailable, the mobile voice network can be used for voice), enterprise WLAN, VPN infrastructure, and IP telephony infrastructure high availability must still be considered.

First, the enterprise WLAN must be deployed in a manner that provides redundant WLAN access. For example, APs and other WLAN infrastructure components should be deployed so that the failure of a wireless AP does not impact network connectivity for the direct connect mobile client. Likewise, WLAN management and security infrastructure must be deployed in a highly redundant fashion so that dual-mode devices are always able to connect securely to the network. Controller-based wireless LAN infrastructures are recommended because they enable centralized configuration and management of enterprise APs, thus allowing the WLAN to be adjusted dynamically based on network activity and AP failures.

Next, VPN infrastructure components, including Cisco IOS or ASA head-end VPN or AnyConnect session terminator, should be deployed in a highly redundant fashion so that loss of a VPN session terminator does not impact or prevent remote enterprise connectivity for the mobile client.

Unified CM call processing and registration service high availability must also be considered. Just as with other devices within the enterprise that leverage Unified CM for call processing services, direct connect mobile clients must register with Unified CM. Given the redundant nature of the Unified CM cluster architecture, which provides primary and backup call processing and device registration services, direct connect mobile client device registration as well as call routing is still available even in scenarios in which a Unified CM server node fails.

Similar considerations apply to PSTN access. Just as with any IP telephony deployment, multiple PSTN gateways and call routing paths should be deployed to ensure highly available access to the PSTN. This is not unique to direct connect mobile client deployments, but is an important consideration nonetheless.

Capacity Planning for Direct Connect Mobile Clients

Capacity planning considerations for direct connect mobile clients are the same as for other IP telephony endpoints or devices that rely on the IP telephony infrastructure and applications for registration, call processing, and PSTN access services.

When deploying direct connect mobile clients, it is important to consider the registration load on Unified CM as well as the Unified Mobility limits. A single Unified CM cluster is capable of handling a maximum of 40,000 device configurations and registrations. When deploying direct connect mobile client devices, you must consider the per-server maximum device support, and you might have to deploy additional call processing subscriber nodes or even clusters to handle the added load.

In addition, as discussed in [Capacity Planning for Cisco Unified Mobility, page 25-63](#), the maximum number of remote destinations and mobility identities within a single Unified CM cluster is 15,000. Because most direct connect mobile clients will likely be integrated with Unified Mobility to take advantage of features such as Mobile Connect and desk phone pickup, the mobile phone number of each of these direct connect client devices must be configured as a mobility identity within the Unified CM cluster. This is necessary to facilitate integration to Unified Mobility as well as to facilitate handoff in some cases. Therefore, when integrating these direct connect client devices with Unified Mobility, it is important to consider the overall remote destination and mobility identity capacity of the Unified CM cluster to ensure sufficient capacity exists. If additional users or devices are already integrated to Unified Mobility within the system, they can limit the amount of remaining remote destination and mobility identity capacity available for direct connect client devices.

Overall call processing capacity of the Unified CM system and PSTN gateway capacity must also be considered when deploying direct connect mobile clients. Beyond handling the actual client device configuration and registration, the system must also have sufficient capacity to handle the added BHCA impact of these devices and users. Likewise, it is critical to ensure that sufficient PSTN gateway capacity is available to accommodate direct connect clients.

The above considerations are certainly not unique to direct connect client devices. They apply to all situations in which devices and users are added to Unified CM, resulting in additional load to the overall Unified Communications System.

For more information on general system sizing, capacity planning, and deployment considerations, see the chapter on [Unified Communications Design and Deployment Sizing Considerations, page 29-1](#).

Design Considerations for Direct Connect Mobile Clients

Observe the following design recommendations when deploying direct connect mobile clients:

- Cisco recommends that direct connect mobile client users rely on the mobile voice network for making emergency calls and determining device and user location. This is because mobile provider networks typically provide much more reliable location indication than enterprise WLAN networks. To ensure that these client devices rely exclusively on the mobile voice network for emergency and location services, ensure that emergency numbers such as 911, 999, and 112 have been configured in the Emergency Numbers field on the direct connect client device configuration page to force all calls made to these numbers to be sent over the mobile voice network.
- When deploying direct connect mobile clients for users across geographic locations, consider using the Mobile Toll Bypass Optimization feature in order to assign location-specific system access numbers for dial-via-office. In scenarios where the dial-via-office direction impacts call cost, consider the use of the mobility profile Mobile Client Calling Option field in order to force a specific dial-via-office direction (forward or reverse).
- In deployments where both the Cisco Mobile 8.5 direct connect client and Nokia Call Connect dual-mode are deployed on the same handset, Cisco recommends the following:
 - Follow all recommendations and requirements related to voice over WLAN as outlined in the section on [Wireless Device Roaming, page 25-15](#).
 - Follow all recommendations and requirements related to configuration and deployment of the Nokia Call Connect as outlined in the section on [Dual-Mode Phones and Clients, page 25-66](#).
 - When dual-mode functionality is enabled, the Unified CM administrator should not force dial-via-office. Instead the Dial Policy parameter on the Nokia S60 device configuration page should be configured as **Let User Choose**.
 - If the administrator forces dial-via-office for Cisco Mobile 8.5, the user should configure the **Allow dial via office for** setting to **Calls from this app** Cisco Mobile 8.5 client so that only calls made directly from within the client application will attempt to invoke dial-via-office. By configuring the client this way, the user can ensure that dial-via-office will not be engaged unexpectedly. If the Cisco Mobile 8.5 client is not in the foreground, then the user can be sure that dial-via-office will not be invoked.
- Consider the following as it relates to making calls with the Cisco Mobile 8.5 and Nokia Call Connect clients running co-resident:
 - The Nokia Call Connect dual-mode client should be used for making and receiving voice over IP (VoIP) calls when the WLAN or mobile data connection signal strength is strong.
 - If voice quality is poor or IP network connectivity is unavailable, then the Cisco Mobile 8.5 direct connect client should be used for dial-via-office calling.

CHAPTER 26

Cisco Unified Contact Center

Revised: April 30, 2012; OL-21733-18

This chapter describes the Cisco Unified Contact Center solutions available with the Cisco Unified Communications System. It includes information on Cisco products such as Cisco Unified Contact Center Express, Cisco Unified Contact Center Enterprise, Cisco Unified Customer Voice Portal, and Cisco Unified Expert Advisor. It also covers the design considerations for deploying these Cisco Unified Contact Center products with Cisco Unified Communications Manager and other Unified Communications components.

This chapter covers the following topics:

- [Cisco Contact Center Architecture, page 26-2](#)
- [Contact Center Deployment Models, page 26-6](#)
- [Design Considerations for Contact Center Deployments, page 26-11](#)
- [Capacity Planning for Contact Centers, page 26-15](#)
- [Network Management Tools, page 26-16](#)

This chapter starts with a high-level overview of the main Cisco Unified Contact Center Portfolio. Then it covers the various Unified Communications deployment models for contact centers. Finally, it discusses design considerations on topics such as bandwidth, latency, Cisco Unified Communications Manager integration, and sizing.

The intent of this chapter is not to provide details on each contact center product and their various components but rather to discuss the design considerations for their integration with the Cisco Unified Communications System. Detailed design guidance for each Unified Contact Center product is covered in specific Solution Reference Network Design (SRND) guides for the Cisco Unified Contact Center Express, Cisco Unified Contact Center Enterprise, and Cisco Unified Customer Voice Portal products. These product-specific SRNDs are available at

<http://www.cisco.com/go/ucsrnd>

What's New in This Chapter

Table 26-1 lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Table 26-1 New or Changed Information Since the Previous Release of This Document

| New or Revised Topic | Described in: | Revision Date |
|---|---|------------------|
| Cisco Unified Intelligence Center (Unified IC) | Reporting, page 26-5 | April 30, 2012 |
| Cisco MediaSense | Cisco MediaSense, page 26-6 | June 2, 2011 |
| Product name change from Cisco Unified Media Capture Platform (Unified MCP) to Cisco MediaSense | Cisco MediaSense, page 26-6 | January 31, 2011 |

Cisco Contact Center Architecture

This chapter discusses the following main Cisco Contact Center products:

- Cisco Unified Contact Center Enterprise (Unified CCE)
- Cisco Unified Customer Voice Portal (Unified CVP)
- Cisco Unified Contact Center Express (Unified CCX)
- Cisco Unified Expert Advisor (Unified Expert Advisor)

Cisco Unified Contact Center Enterprise

Cisco Unified Contact Center Enterprise (Unified CCE) provides a VoIP contact center solution that enables you to integrate inbound and outbound voice applications with Internet applications, including real-time chat, Web collaboration, and email. This integration provides for unified capabilities, helping a single agent support multiple interactions simultaneously, regardless of the communications channel the customer has chosen. Because each interaction is unique and may require individualized service, Cisco provides contact center solutions to manage each interaction based on virtually any contact attribute. The Unified CCE deployments are typically used for large size contact centers and can support thousands of agents.

Unified CCE employs the following major software components:

- Call Router

The Call Router makes all the decisions on how to route a call or customer contact.
- Logger

The Logger maintains the system database that stores contact center configurations and temporarily stores historical reporting data for distribution to the data servers. The combination of Call Router and Logger is called the *Central Controller*.
- Peripheral Gateway

The Peripheral Gateway (PG) interfaces to various "peripheral" devices, such as Unified CM, Cisco Unified IP Interactive Voice Response (Unified IP IVR), Unified CVP, or multichannel products. A Peripheral Gateway that interfaces with Unified CM is also referred to as an *Agent PG*.

- CTI Server and CTI Object Server (CTI OS)

The CTI Server and CTI Object Server interface with the agent desktops. Agent desktops can be based on the Cisco Agent Desktop (CAD) solution, Cisco CTI Desktop Toolkit, or customer relationship management (CRM) connectors to third-party CRM applications.

- Administration & Data Server

The Administration & Data Server provides a configuration interface as well as real-time and historical data storage.

The Cisco Unified CCE solution is based on the integration with Cisco Unified Communications Manager (Unified CM), which controls the agent phones. For deployments without Unified CM but with traditional ACD, use Cisco Unified Intelligent Contact Management Enterprise (Unified ICME) instead of Unified CCE.

The queuing and self-service functions are provided by Cisco Unified IP Interactive Voice Response (Unified IP IVR) or Cisco Unified Customer Voice Portal (Unified CVP) and are controlled by the Unified CCE Call Router.

Most of the Unified CCE servers are required to be redundant, and the redundant instances are referred to as side A and side B instances. For example, Call Router A and Call Router B are redundant instances of the Call Router component running on two different servers.

Cisco Unified Customer Voice Portal

Cisco Unified Customer Voice Portal (Unified CVP) provides carrier-class IVR services on Voice over IP (VoIP) networks. It can perform basic prompt-and-collect or advanced self-service applications with CRM database integration and with automated speech recognition (ASR) and text-to-speech (TTS) integration. Unified CVP also provides IP-based call switching services by routing and transferring calls between voice gateways and IP endpoints.

Unified CVP is based on the Voice Extension Markup Language (VXML), which is an industry standard markup language similar to HTML and which is used to develop IVR services that leverage the power of web development and content delivery.

Unified CVP can be deployed standalone or integrated with Unified CCE to offer self-service and queuing functions. It supports voice calls as well as video calls.

The Unified CVP solution employs the following main components:

- Unified CVP Call Server

The Unified CVP Call Server provides call control capabilities for SIP and H.323 through the SIP and H.323 services. The Unified CVP Call Server can also integrate with the Unified CCE Call Router through the Intelligent Contact Management (ICM) service. The IVR service allows the server to run VXML Micro applications and to create VoiceXML pages.

- Unified CVP VXML Server

This component executes complex IVR applications by exchanging VoiceXML pages with the VoiceXML gateway's built-in voice browser. Unified CVP VXML Server applications are written using Cisco Unified Call Studio and are deployed to the Unified CVP VXML Server for execution. Note that there is no RTP traffic going through the Unified CVP Call Server or the Unified CVP VXML Server.

- Cisco Voice Gateway

The Cisco Voice Gateway is the point at which a call enters or exits the Unified CVP system. The Cisco Voice Gateway could have a TDM interface to the PSTN. Alternatively, Cisco Unified Border Element could be used when the interface to the PSTN is an IP voice trunk.

- Cisco VoiceXML Gateway

The VoiceXML Gateway hosts the Cisco IOS Voice Browser. This component interprets VoiceXML pages from either the Unified CVP Server IVR Service or the Unified CVP VXML Server. The VoiceXML Gateway can play prompts based on .wav files to the caller and can accept input from the caller through DTMF input or speech (when integrated with Automatic Speech Recognition). It then returns the results to the controlling application and waits for further instructions.

The Cisco VoiceXML Gateway can be deployed on the same router as the Cisco Voice Gateway. This model is typically desirable in deployments with small branch offices. But the VoiceXML Gateway can also run on a separate router platform, and this model might be desirable in large centralized deployments with multiple voice gateways.

For more information, refer to the latest version of the *Cisco Unified Customer Voice Portal SRND*, available at

<http://www.cisco.com/go/ucsrnd>

Cisco Unified Contact Center Express

Cisco Unified Contact Center Express (Unified CCX) meets the needs of departmental, enterprise branch, or small to medium-sized companies that need easy-to-deploy, easy-to-use, highly available and sophisticated customer interaction management for up to 400 agents. It is designed to enhance the efficiency, availability, and security of customer contact interaction management by supporting a highly available virtual contact center with integrated self-service applications across multiple sites.

Unified CCX can integrate with Unified CM by means of JTAPI or with Unified CME by means of SIP.

All the Unified CCX components, including the Unified CCX engine, Unified CCX database, CAD Server, Unified CCX Outbound Dialer, and Express E-mail Manager, are installed on a single server. When Unified CCX is integrated with Unified CM, a second Unified CCX server can be added to provide system redundancy.

Unified CCX has built-in email, outbound dialer, and agent silent monitoring and recording capabilities. It can integrate with video endpoints such as Cisco TelePresence and can support advanced features such as Automated Speech Recognition (ASR) and Text to Speech (TTS), HTTP, and VXML. It also supports products such as Cisco Unified Workforce Optimization to optimize performance and quality of the contact center.

Cisco Unified IP IVR shares the same software architecture as Unified CCX. It provides prompting, collecting, and queuing capability for the Unified CCE solution. It could also be used as a standalone self-service application.

Cisco Unified Expert Advisor

Cisco Unified Expert Advisor expands the scope of customer care by allowing presence-enabled enterprise knowledge workers to handle incoming customer calls without the need for the rigid tools and business rules typically found in formal contact centers. It provides intelligent routing of calls to

available enterprise knowledge workers or experts who can accept calls and receive pre-call data with enterprise presence clients such as Cisco Unified Personal Communicator or Microsoft Office Communicator.

Cisco Unified Expert Advisor can be deployed as an add-on to a Unified CCE solution or as a standalone application without Unified CCE agents.

The knowledge workers can use any phone that is reachable by Unified CM, including IP phones or cell phones.

Administration and Management

Cisco Contact Center products have built-in administration and management capabilities. For example, Unified CCE can be administered with the Configuration Manager tool that is installed with Unified CCE, and Unified CVP can be administered with the Unified CVP Operations Console, also known as Operations, Administration, Maintenance, and Provisioning (OAMP).

In addition, Cisco Unified Contact Center Management Portal (Unified CCMP) can be deployed to simplify the operations and procedures for performing basic administrative functions such as managing agents and equipment. Unified CCMP is a browser-based management application designed for use by contact center system administrators, business users, and supervisors. It is a dense multi-tenant provisioning platform that overlays the Cisco Unified CCE, Unified ICM, Unified CM, and Unified CVP equipment.

Reporting

Cisco Unified Intelligence Center (Unified IC) is the main reporting tool for the Cisco Contact Center solutions. It is supported by Unified CCE, Unified CVP, and Unified Expert Advisor. This platform is a web-based application offering many Web 2.0 features, high scalability, performance, and advanced features such as the ability to integrate data from other Cisco Unified Communications products or third-party data sources.

Cisco Unified Intelligence Center gets source data from a database, such as an Unified CCE Administration & Data Server database or the Unified CVP Reporting Informix database. Reports are then generated and provided to a reporting client.

Multichannel Support

The Cisco Unified Enterprise solution supports web interaction and email interaction for multichannel support. Cisco Unified Web Interaction Manager (Unified WIM) technology helps ensure that communication can be established from nearly any web browser. Cisco Unified E-Mail Interaction Manager (Unified EIM) provides inbound email routing, automated or agent assisted email responses, real-time and historical reporting, and role-based hierarchical rights management for agents, supervisors, administrators, and knowledge base administrators.

For more design information on these products, refer to the *Cisco Unified Web and E-Mail Interaction Manager Solution Reference Network Design Guide*, available at

http://www.cisco.com/en/US/products/ps7236/products_implementation_design_guides_list.html

Recording and Silent Monitoring

Cisco Unified Contact Center solutions provide recording and silent monitoring capabilities based on the following options:

- The SPAN feature in Cisco switches
This feature replicates the network traffic to a destination port to which a Cisco contact center server is connected.
- The ability of the phone to span the voice stream to the PC that is connected to it
In this case, the agent desktop receives the voice packets and sends them to a recording server or to a supervisor desktop for silent monitoring.
- Unified CM and media replication by the built-in-bridge (BIB) in Cisco IP Phones
With this option, Unified CM is involved in setting up the recording flows and can perform call admission control for those flows.

Cisco MediaSense

Cisco MediaSense is an IP-based media (voice and video) recording and playback system that implements the Open Recording Architecture (ORA) open interfaces. Cisco MediaSense is integrated into the Cisco Unified Communications architecture and provides a recording solution for both contact center deployments and non-contact center deployments. Recording is accomplished by media forking, where the built-in bridge (BIB) in Cisco IP Phones is used to replicate media to the Cisco MediaSense recording server.

Cisco MediaSense supports a redundant, highly available architecture. It can be deployed as a non-redundant, single server or as a highly available, redundant system with two recording servers in active/active mode. Additional servers can be added to expand storage capacity.

For more details on the Cisco MediaSense recording system, refer to the *Solution Reference Network Design for Cisco MediaSense*, available at

http://www.cisco.com/en/US/products/ps11389/products_implementation_design_guides_list.html

Contact Center Deployment Models

This section describes the various design models used for deploying Cisco Unified Contact Center solutions. For more details on these deployment models, refer to the Cisco Unified Contact Center SRNDs, available at <http://www.cisco.com/go/ucsrnd>

Single-Site Contact Center

In this deployment, all the components such as call processing servers, voice gateways, and contact center servers are in the same site. Agents and supervisors are also located at that site. The main benefit of the single-site deployment model is that there is no WAN connectivity required and, therefore, no need to use a low-bandwidth codec such as G.729, transcoders, compressed Real-Time Transport Protocol (cRTP), or call admission control.

Multisite Contact Center with Centralized Call Processing

A multisite deployment with centralized call processing consists of a single call processing cluster that provides services for many remote sites and uses the IP WAN. Cisco Contact Center applications (Unified CCE, Unified CCX, Unified CVP, and Unified Expert Advisor) are also typically centralized to reduce the overall costs of management and administration. [Figure 26-1](#) illustrates this type of deployment.

Figure 26-1 Multisite Contact Center with Centralized Call Processing

Because the agents or the voice gateways in this type of deployment are located in remote sites, it is important to consider the bandwidth requirements between the sites. It is also important to carefully configure call admission control, Quality of Service (QoS), codecs, and so forth. For more information on the general design considerations for Unified Communications solutions, refer to the chapter on [Unified Communications Deployment Models](#), page 5-1.

Contact center deployments in a Unified Communications system typically have the following additional bandwidth requirements:

- The traffic volume handled by the agents is higher than that of typical users, and therefore voice and signaling traffic is also higher for agents.
- Agents and supervisors use desktops with screen popup, reports and statistics, and so forth. This causes data traffic between the agent or supervisor desktops and the contact center servers. In addition, bandwidth calculations must account for reporting information if, for example, an agent or

supervisor is remote and pulls data from a server in a central location. For more information and guidance, refer to the design guides for the individual Cisco Contact Center products, available at <http://www.cisco.com/go/ucsrnd>.

- Depending on type of IVR solution, there could be traffic between the voice gateway and the IVR system. For example, if the voice gateways are distributed and calls arrive at a voice gateway located in a remote site with Unified IP IVR, there would be voice traffic across the WAN between the voice gateway and Unified IP IVR. With Unified CVP, the call could be queued at the remote site, with the VXML Gateway providing call treatment and queuing and therefore avoiding voice traffic across the WAN for IVR and reducing overall WAN bandwidth requirements.

Remote agents (for example, agents working from home) are also supported with Cisco Unified Contact Center. There are mainly two solutions. The first one requires the agent to use an IP phone that is connected to the central site by a broadband internet connection. In this solution, the phone is CTI controlled by the Cisco Unified Contact Center application. The second solution is based on Cisco Unified Mobile Agent, which enables an agent to participate in a call center with any PSTN phone such as cell phone.

Multisite Contact Center with Distributed Call Processing

The model for a multisite deployment with distributed call processing consists of multiple sites, each with its own call processing cluster connected to an IP WAN. This section assumes that each Unified CM cluster has agents registered to it.

A Unified CCX deployment cannot be shared across multiple Unified CM clusters. Each Unified CM cluster requires its own Unified CCX deployment, as illustrated in [Figure 26-2](#).

Figure 26-2 Multisite Unified CCX Deployment with Distributed Call Processing

Requirements for Unified CCE differ from Unified CCX. A single Unified CCE system can span across multiple Unified CM clusters distributed across multiple geographic locations. A Unified CCE Agent PGs must be installed in each Unified CM cluster location and could be physically remote from the Unified CCE Central Controller (Call Router + Logger). [Figure 26-3](#) illustrates this type of deployment and highlights the placement of the Agent PG.

Figure 26-3 Multisite Unified CCE Deployment with Distributed Call Processing

If you require multiple contact center deployments, you could connect those deployments through Unified ICM by using the parent/child deployment model to form a single virtual contact center. The parent/child model provides several benefits, such as enterprise queuing and enterprise reporting across all the contact center deployments. It also provides complete site redundancy and higher scalability. For more details on the parent/child model, refer to the following documents:

- *Cisco Unified Contact Center Enterprise SRND*, available at <http://www.cisco.com/go/ucsrnd>
- *Cisco Contact Center Gateway Deployment Guide for Cisco Unified ICME/CCE/CCX*, available at http://www.cisco.com/en/US/products/sw/custcosw/ps1001/prod_installation_guides_list.html

Similarly to the multisite model with centralized call processing, multisite deployments with distributed call processing require careful configuration of QoS, call admission control, codecs, and so forth.

Clustering Over the IP WAN

In this deployment model, a single Unified CM cluster is deployed across multiple sites that are connected by an IP WAN with QoS features enabled. Cisco Unified Contact Center solutions can be deployed with this model. In fact, the Cisco Unified Contact Center components themselves can also be clustered over the WAN.

For example, with Unified CCE, the side A servers could be remote from the Unified CCE side B servers and separated from them by an IP WAN connection. (For more details on Unified CCE high availability, see [High Availability for Contact Centers, page 26-11](#).) The following design considerations apply to this type of deployment:

- The IP WAN between the two sites must be highly available, with no single point of failure. For example, the IP WAN links, routers, and switches must be redundant. WAN link redundancy could be achieved with multiple WAN links or with a SONET ring, which is highly resilient and has built-in redundancy. For more details, refer to the Unified CCE SRND, available at <http://www.cisco.com/go/ucsrnd>.
- The Agent Peripheral Gateway (PG) must be co-located with the CTI Manager server to which it is connected. Because of the large amount of redirect and transfer traffic and additional CTI traffic, the Intra-Cluster Communication Signaling (ICCS) bandwidth requirements between the Unified CM servers are higher when deploying Unified CCE. For more details, refer to the Unified CCE SRND, available at <http://www.cisco.com/go/ucsrnd>.
- If the primary Unified CCE and Unified CM servers are located in one site and the secondary Unified CCE and Unified CM servers are in another site, the maximum latency between the two sites is dictated by the Unified CM latency requirement of 80 ms round trip time (RTT). However, if the Unified CCE servers are in different locations than the Unified CM servers, it is possible to have a higher latency between the redundant Unified CCE servers. For more information, refer to the Unified CCE SRND, available at <http://www.cisco.com/go/ucsrnd>.

Figure 26-4 illustrates a deployment of Unified CCE using clustering over the WAN.

Figure 26-4 Unified CCE Deployment with Clustering Over the WAN

With Unified CCX and Unified IP IVR solutions, the primary Unified CCX or Unified IP IVR server could also be remote from the backup server. The requirements for Unified CCX deployments are different than the ones for Unified CCE deployments. For example, redundant WAN links are not

required with Unified CCX. Also, the maximum latency between the primary and backup Unified CCX servers is 80 ms RTT. Figure 26-5 illustrates this type of deployment. For more details, refer to the Unified CCX SRND, available at <http://www.cisco.com/go/ucsrnd>.

Figure 26-5 Unified CCX Deployment with Clustering Over the WAN

Unified Expert Advisor supports deployment where the Unified Communications components such as Unified CM and Unified CCE are clustered over the WAN, but the Unified Expert Advisor primary and secondary runtime servers must be located at the same site.

Design Considerations for Contact Center Deployments

This section summarizes the following major design considerations for contact center deployments:

- [High Availability for Contact Centers, page 26-11](#)
- [Bandwidth, Latency, and QoS Considerations, page 26-12](#)
- [Call Admission Control, page 26-13](#)
- [Integration with Unified CM, page 26-13](#)
- [Other Design Considerations for Contact Centers, page 26-14](#)

High Availability for Contact Centers

All Cisco Unified Contact Center products provide high availability. For example, when you integrate Unified CCX or Unified IP IVR with Unified CM, you could add a second Unified CCX or Unified IP IVR server to provide high availability. One of the servers would be the active server and would handle all the call processing. The other server would be in standby mode and become active only if the primary server fails. Unified CVP also supports high available deployments with multiple Unified CVP servers, voice gateways, VXML gateways, SIP proxies, and so forth.

With Unified CCE, most of the servers are required to be redundant, and the redundant instances are referred to as side A and side B instances. For example, Call Router A and Call Router B are redundant instances of the Call Router module (process) running on two different servers. This redundant configuration is also referred to as *duplex mode*. The Call Routers run in synchronized execution across

the two servers, which means both sides of the duplex servers process every call. Other components, such as the Peripheral Gateways, run in hot-standby mode, meaning that only one of the Peripheral Gateways is actually active at any given time.

In addition to the redundancy of the Unified Contact Center components themselves, their integration with Unified CM can also be redundant. For example, each Unified CCX or Unified IP IVR server can connect to a primary CTI Manager and also to a backup CTI Manager in case the primary CTI Manager fails. With Unified CCE, a PG side A would connect to a primary CTI Manager, while the redundant PG side B connects to the secondary CTI Manager, thus providing high availability if one CTI Manager fails.

For more details, refer to the Cisco Unified Contact Center SRNDs, available at <http://www.cisco.com/go/ucsrnd>.

Bandwidth, Latency, and QoS Considerations

This section describes how to provision WAN bandwidth in a multisite contact center deployment, taking into account different types of call control traffic and real-time voice traffic. It is important to understand the latency and QoS parameters because adequate bandwidth provisioning and implementation of QoS are critical components in the success of contact center deployments.

Bandwidth Provisioning

Contact center solutions require sufficient WAN bandwidth to accommodate the following main types of traffic:

- Voice traffic between the ingress gateway and the IVR system. With Unified IP IVR, if the Unified IP IVR servers are in a central location and PSTN gateways are in remote locations, there will be voice traffic over the WAN. With Unified CVP, it is possible to queue the call at the edge and therefore keep the voice traffic local to the remote site to avoid voice traffic across a WAN link.
- Voice traffic between the ingress gateway and the agent.
- Voice signaling traffic. This is typically for the signaling traffic between the ingress gateway and Unified CM, and between the agent phone and Unified CM.
- VXML Gateway traffic if Unified CVP is deployed. The traffic includes media file retrieval from the media server and VXML documents exchanged with the VXML server.
- Data traffic between the agent or supervisor desktop and the Unified Contact Center server (CAD or CTI-OS traffic).
- Reporting traffic between the reporting user and the Unified Contact Center Reporting server.
- Traffic between Unified Contact Center servers if they are remote from each other. For example, this type of traffic occurs with clustering over the IP WAN or with multisite and distributed call processing with PGs remote from the Unified CCE Central Controller.
- Additional Intra-Cluster Communication Signaling (ICCS) traffic between the Unified CM subscribers due to the large amount of redirect and transfer traffic and additional CTI traffic.
- Voice traffic due to recording and silent monitoring. Depending on the solution, one or two RTP streams could be sent in order to silently monitor or record the conversation with an agent.

Bandwidth calculations and guidelines are provided in the Cisco Unified Contact Center SRNDs, available at <http://www.cisco.com/go/ucsrnd>.

Latency

Agents and supervisors can be located remotely from the call processing server and contact center server. Technically, the delay between the CTI OS server and CTI OS client, as well as between the CAD server and CAD or CSD desktop, could be very high because of high time-out values. Long latency will affect the user experience and might cause confusion or become unacceptable from the user perspective. For example, the phone could start ringing but the desktop might not be updated until later.

Latency requirements between the contact center components and the call processing servers, and between the contact center components themselves, depend on the contact center solutions. For example, the Unified CCX redundant servers can be located remotely from each other, with a maximum latency of 80 ms RTT. With Unified CCE, the maximum latency between the Unified CCE servers and Unified CM, or between the Unified CCE servers themselves, is higher than 80 ms RTT.

For more details, refer to the Cisco Unified Contact Center SRNDs, available at <http://www.cisco.com/go/ucsrnd>.

QoS

Similar to deployments with other Unified Communications components, contact center deployments require the configuration of Quality of Service (QoS) to prioritize time-sensitive or critical traffic. QoS marking for voice and voice signaling in a contact center environment is the same as with other Unified Communications deployments. Traffic specific to the contact center must be marked with specific QoS markings. For example, some of the traffic for the Unified CCE private network must be marked as AF31, while other traffic must be marked as AF11. The QoS marking recommendations and QoS design guidance are documented for each Unified Contact Center solution in their respective Cisco Unified Contact Center SRNDs, available at <http://www.cisco.com/go/ucsrnd>.

Call Admission Control

Similar to deployments with other Unified Communications components, contact center deployments require careful provisioning of call admission control. The same mechanisms described in the chapter on [Call Admission Control, page 11-1](#), also apply to contact center environments.

Voice traffic associated with silent monitoring and recording might not be accounted for in the call admission control calculation. For example, voice traffic from silent monitoring and recording by Unified CM (voice traffic forked at the phone) is properly accounted for, but voice traffic from desktop-based silent monitoring (desktop connected to the back of the agent IP phone) is not counted in call admission control calculations.

Call admission control for Mobile Agent and Unified CVP involves special considerations. For more details, refer to the Cisco Unified Contact Center SRNDs, available at <http://www.cisco.com/go/ucsrnd>.

Integration with Unified CM

Observe the following design considerations apply when integrating Cisco Unified Contact Center components with Unified CM:

- For administration and upgrade purposes, Cisco recommends separate Unified CM clusters for contact center and non-contact center deployments. If separate clusters are not possible, then Cisco recommends separate Unified CM subscriber servers for contact center and non-contact center applications. For more details, refer to the Unified CCE SRND, available at <http://www.cisco.com/go/ucsrnd>.

- With contact center deployments, Cisco recommends that you do not use a 2:1 redundancy scheme for the Unified CM servers. Use 1:1 redundancy to provide higher resiliency and faster upgrades. For more details, refer to the Unified CCE SRND, available at <http://www.cisco.com/go/ucsrnd>.
- The integration between Unified CM and Unified CCX, Unified IP IVR, or Unified CCE is done through JTAPI. The Unified CCX server connects to a primary CTI Manager. It also has a backup connection to a secondary CTI Manager. With Unified CCE, the Agent PG connects to only one CTI Manager. The redundant Agent PG connects to the backup CTI Manager only. If the primary CTI Manager fails, the primary Agent PG will also fail and trigger the failover.
- There are several ways to deploy CTI Manager with the Unified CCE PG. For example, in a Unified CCE deployment that requires four Unified CM subscriber pairs, four Agent PGs could be deployed and each Agent PG could be connected to a separate Unified CM subscriber pair that is also running the CTI Manager Service. Alternatively, a single PG could connect to only one of the Unified CM subscriber pairs that is running the CTI Manager Service, and through this Unified CM pair, the PG would be able to control/monitor agent phones on all four Unified CM subscriber pairs. This configuration is common in centralized deployments and is illustrated in Figure 26-6. For more details, refer to the Unified CCE SRND, available at <http://www.cisco.com/go/ucsrnd>.
- It is possible to integrate multiple Unified CCX deployments with a single Unified CM cluster. For more details, refer to the Unified CCX SRND, available at <http://www.cisco.com/go/ucsrnd>.

Figure 26-6 Deployment with One Agent PG and Four Unified CM Subscriber Pairs

Other Design Considerations for Contact Centers

The following additional design considerations apply in the situations indicated:

- Because Unified CVP allows queuing at the edge, deploying Unified CVP instead of Unified IP IVR could lower the bandwidth requirements for multisite deployments.
- Most of the Cisco Unified Contact Center products and components can be installed in a virtualized environment based on VMware. For details, consult the respective Cisco Unified Contact Center SRNDs, available at <http://www.cisco.com/go/ucsrnd>.
- Media termination point (MTP) resources might be required in some scenarios. For example, with Mobile Agents, MTPs are required for the associated CTI ports when RFC 2833 is negotiated. MTPs are also required in some scenarios with Unified CVP. For details, consult the respective Cisco Unified Contact Center SRNDs, available at <http://www.cisco.com/go/ucsrnd>.
- Some third-party contact center products are also supported with Unified CM. The integration with Unified CM could be based on JTAPI and could use CTI ports for call treatment and queuing and CTI route points. To size Unified CM correctly, it is important to have a good understanding of the call flows and their impact on Unified CM. It is also important to understand how the redundancy is implemented and whether or not it impacts Unified CM or CTI scalability.

Capacity Planning for Contact Centers

All deployments must be sized with the Cisco Unified Communications Sizing Tool (Unified CST). This tool performs sizing of the contact center products such as Unified CCE, Unified IP IVR, Unified CVP, Unified CCX, and Expert Advisor. It determines the contact center resources required for your deployment, such as number of agents, number of IVR ports, and number of gateway ports. In addition to performing sizing for the contact center components themselves, the tool also sizes the rest of the Unified Communications solution, including Unified CM and voice gateways. This tool is available to Cisco employees and partners only (with proper login authentication) at <http://tools.cisco.com/cucst>.

In general, sizing of the contact center depends heavily on the busy hour call attempts (BHCA) for calls coming into the contact center. It also depends on other parameters such as the Service Level Goal and Target Answer Time. For example, a deployment where 90% of the calls must be answered within 30 seconds will require more contact center resources than a deployment where 80% of the calls must be answered within 2 minutes. Another parameter that impacts the sizing is whether CAD or CTI OS is used, which could result in different Agent PG scalability. Use the Unified CST for sizing, and consult the respective Cisco Unified Contact Center SRNDs, available at <http://www.cisco.com/go/ucsrnd>, for more details.

The contact center design also impacts Unified CM sizing. The following considerations apply to sizing Unified CM when it is deployed in contact center solutions:

- The maximum number of Unified CCE agents in a single Unified CM cluster depends on the IVR solution. With Unified IP IVR, CTI route points and CTI ports are used during the call treatment queuing, which consume Unified CM resources. With Unified CVP, the call treatment and queuing are typically handled by the VXML Gateway, Unified CVP VXML server, and Unified CVP call server, with no impact on Unified CM. Therefore, a single Unified CM cluster can support more agents with Unified CVP than with Unified IP IVR.
- The Unified CCE Mobile Agent feature relies on CTI ports and therefore needs additional resources from Unified CM subscribers. Therefore, Unified CM scalability is reduced when Mobile Agents are deployed.
- With Unified CCE deployments, two types of outbound dialers are available. With the SCCP dialer, the dialer ports are registered to Unified CM, and each outbound call involves Unified CM even if the outbound call does not reach a live customer. With the SIP dialer, each outbound call is placed directly from the SIP dialer port to the egress voice gateway. With the SIP dialer, the call reaches Unified CM only when the call is transferred to an agent. Therefore, Unified CM capacity is much higher when the SIP dialer is used.
- When sizing Unified CM, it is also important to account for any additional CTI applications. For example, some PC clients can control a phone remotely through CTI. Some call recording applications can also integrate directly with Unified CM through the CTI Manager and can monitor agent phones, which could require additional resources from Unified CM. For more details, refer to [Computer Telephony Integration \(CTI\), page 8-31](#), and to the Cisco Unified Contact Center SRNDs available at <http://www.cisco.com/go/ucsrnd>.
- Some silent monitoring and recording solutions (such as the silent monitoring and recording feature based on Unified CM) consume resources from Unified CM, whereas other solutions such as SPAN or desktop silent monitoring and recording do not.
- Again, due to the complexity associated with sizing, all deployments must be sized with the Cisco Unified Communications Sizing Tool, available to Cisco employees and partners only (with proper login authentication) at <http://tools.cisco.com/cucst>

For more details, refer to the Cisco Unified Contact Center SRNDs, available at <http://www.cisco.com/go/ucsrnd>.

Network Management Tools

Unified CCE is managed with the Simple Network Management Protocol (SNMP). Unified CCE devices have a built-in SNMP agent infrastructure that supports SNMP v1, v2c, and v3, and it exposes instrumentation defined by the CISCO-CONTACT-CENTER-APPS-MIB. This MIB provides configuration, discovery, and health instrumentation that can be monitored by standard SNMP management stations. Moreover, Unified CCE provides a rich set of SNMP notifications that alert administrators of any faults in the system. Unified CCE also provides a standard syslog event feed (conforming to RFC 3164) for those administrators who want to take advantage of a more verbose set of events.

For more information about configuring the Unified CCE SNMP agent infrastructure and the syslog feed, refer to the *SNMP Guide for Cisco ICM/IPCC Enterprise & Hosted Editions*, available at

http://www.cisco.com/en/US/products/sw/custcosw/ps1001/products_installation_and_configuration_guides_list.html

Unified CVP health monitoring can be performed by using any SNMP standard monitoring tool to get a detailed visual and tabular representation of the health of the solution network. All Unified CVP product components and most Unified CVP solution components also issue SNMP traps and statistics that can be delivered to any standard SNMP management station or monitoring tool.

Unified CCX can also be managed with SNMP and a syslog interface.

PART 5

Unified Communications Operations and Serviceability

CHAPTER 27

Overview of Cisco Unified Communications Operations and Serviceability

Revised: February 29, 2012; OL-21733-18

Once the network, call routing, call control infrastructure, and applications and services have been put in place for your Cisco Unified Communications System, network and application management components can be added or layered on top of that infrastructure. There are numerous operations and serviceability applications and services that can be deployed in an existing Cisco Unified Communications infrastructure. These applications and services can be classified into four basic areas:

- **User and Device Provisioning Services** — Provide the ability to centrally provision and configure users and devices for unified communications applications and services.
- **Voice Quality Monitoring and Alerting** — Provide the ability to monitor on an ongoing basis various call flows occurring within the system to determine whether voice quality is acceptable and to alert administrators when the voice quality is not acceptable.
- **Operations and Fault Monitoring** — Provides the ability to centrally monitor all application and service operations and to issue alerts to administrators regarding network and application failures.
- **Network and Application Probing** — Provides the ability to probe and collect network and application traffic information at various locations throughout the deployment and to allow administrators to access and retrieve this information from a central location.

This part of the SRND covers the applications and services mentioned above. It provides an introduction to the various network management applications and services, followed by discussions surrounding architecture, high availability, capacity planning, and design considerations. The discussions focus on design-related aspects of the applications and services rather than product-specific support and configuration information, which is covered in related product documentation.

This part of the SRND includes the following chapters:

- [Network Management, page 28-1](#)

This chapter examines unified communications network and application management services, a common and prevalent set of services within most unified communications deployments, which allows administrators to provision and configure users and devices, monitor network and application operations as well as voice quality, and receive alerts and alarms when issues arise. This chapter also examines the impact of these management applications and services on deployment models and provides design and deployment best practices for network and application management services and applications.

- [Unified Communications Design and Deployment Sizing Considerations, page 29-1](#)

This chapter discusses the sizing of individual Unified Communications components as well as systems consisting of several components communicating with each other. This chapter also discusses the performance impact of the different functions that the various Unified Communications products support, and it explains why "designing by datasheets" is not the preferred way to deploy a complex Unified Communications network. In addition, this chapter provides insights on how to work with the various sizing tools available, mostly notably the Cisco Unified Communications Sizing Tool.

Architecture

As with other network and application technology systems, operations and serviceability applications and services must be layered on top of the underlying network, system, and application infrastructures in order to be able to monitor and control these infrastructures. Figure 27-1 shows the logical location of unified communications operations and serviceability in the overall Cisco Unified Communications System architecture.

Figure 27-1 Cisco Unified Communications Operations and Serviceability Architecture

Unified communications operations and serviceability services such as user and device provisioning, voice quality monitoring and altering, operations and fault monitoring, and network and application probing, all rely on the underlying network infrastructure for network connectivity for various operations and serviceability applications and probes. While there is no direct reliance on the unified communications call routing, call control infrastructure, or unified communications applications and services, these infrastructures and applications are what the various operational and management services actually manage and configure. For example, user and device provisioning services as well as various monitoring and alerting services leverage the network infrastructure for connectivity to various

253671

unified communications applications and service nodes in order to configure and monitor various components and operations. These same services also communicate directly with, and in some cases change configurations on or receive alerts from, components such as call processing agents, PSTN and IP gateways, media resources, endpoints, and various unified communications applications for voice messaging, rich media conferencing, and collaboration clients. In addition to relying on these infrastructure layers and basic unified communications services and applications, services pertaining to operations and serviceability are also often dependent upon each other for full functionality.

High Availability

As with network, call routing, and call control infrastructures and critical unified communications applications and services, unified communications operations and serviceability services should be made highly available to ensure that required provisioning, monitoring, and altering will continue even if failures occur in the network or applications. It is important to understand the various types of failures that can occur as well as the design considerations around those failures. In some cases, the failure of a single operations and management application or server can impact multiple services because the unified communications operations and serviceability components are dependent on other components or services. For example, while the various application service components of a network management deployment might be functioning properly, the loss of network connectivity to, or a failure of, a network probe would effectively eliminate the ability to monitor network health or voice quality unless redundant network probes had been deployed along with alternate paths of connectivity.

For operations and serviceability functions such as user and device provisioning, high availability considerations include temporary loss of functionality due to network connectivity or application server failures resulting in the inability of administrators to provision users and devices or to make changes to these user account or device configurations. In addition, failover considerations for these types of operations include scenarios in which portions of the functionality can be handled by a redundant operation or management application that allows administrators to continue to facilitate some configuration changes in the event of certain failures.

High availability considerations are also a concern for operations and serviceability applications that provide services such as voice quality monitoring or application and operations fault monitoring. Interrupted network connectivity or server or application failures will typically result in a reduced ability to monitor and/or alert, and in some cases complete loss of such functionality. For voice quality monitoring, this can mean that voice quality measurements for some call flows or devices will be unavailable. For operations and fault monitoring services, high availability considerations include the potential for loss of operational change tracking data or fault alerts and indications.

Capacity Planning

Network, call routing, and call control infrastructures as well as unified communications applications and services must be designed and deployed with an understanding of the capacity and scalability of the individual components and the overall system. Similarly, deployments of operations and serviceability components and services must also be designed with attention to capacity and scalability considerations. When deploying various operations and serviceability applications and components, not only is it important to consider the scalability of these applications themselves, but you must also consider the scalability of the underlying infrastructures. Certainly the network infrastructure must have available bandwidth and be capable of handling the additional traffic load these operations will create. Likewise, the call routing and control infrastructure must be capable of handling required inputs and outputs as facilitated by the various operations and serviceability components in use. For example, with operational applications and services such as voice quality monitoring and alerting and operations and fault

monitoring, there are capacity implications for each of these individual applications or services in terms of the number of devices and call flows that can be monitored at a given time, but just as important is the scalability of the underlying infrastructure and monitored applications to handle the added network traffic and connections required for monitoring and alerting. While the monitoring and alerting application or service itself may be able to support the monitoring of many network devices and call flows, the underlying network or devices might not have available capacity to handle the probing connections or the alarm messaging load generated by these monitoring and alerting services.

For operation applications or services that provide user or device provisioning capabilities, capacity planning considerations include things such as ensuring that the provisioning application can handle the requested load and also that user or device provisioning operations not only do not exceed the number of support devices or users for a particular underlying unified communications application or service, but also that provisioning or configuration change transactions do not exceed either the capacity of the underlying network or the rate at which a particular application can handle transactions. In most cases additional capacity can be added by increasing the number of operational provisioning application servers or by increasing the size or number of underlying unified communications applications or service instances, assuming the underlying network and call routing and control infrastructures are capable of handling this additional load.

For a complete discussion of system sizing, capacity planning, and deployment considerations related to sizing, refer to the chapter on [Unified Communications Design and Deployment Sizing Considerations](#), page 29-1.

CHAPTER 28

Network Management

Revised: February 29, 2012; OL-21733-18

Network management is a service consisting of a wide variety of tools, applications, and products to assist network system administrators in provisioning, operating, monitoring and maintaining new and existing network deployments. A network administrator faces many challenges when deploying and configuring network devices and when operating, monitoring, and reporting on the health of the network infrastructure and components such as routers, servers, switches and so forth. Network management helps system administrators monitor each network device and network activity so that they can isolate and investigate problems in a timely manner for better performance and productivity.

With the convergence of rich media and data, the need for unified management is greater than ever. The Cisco Unified Communications Management Suite offers a set of integrated tools that help to test, deploy, and monitor the Cisco Unified Communications system. A network manager implements the various management phases to strategically manage the performance and availability of Cisco Unified Communications applications including voice, video, contact center, and rich media applications. The network management phases typically include: plan, design, implement, and operate (PDIO). [Table 28-1](#) lists the PDIO phases and the major tasks involved with each phase.

Table 28-1 *Network Management Phases and Tasks*

| Plan & Design | Implement | Operate |
|---|--|---|
| Assess the network infrastructure for Cisco Unified Communications capability. For example, predict overall call quality. Prepare the network to support Cisco Unified Communications. Analyze network management best practices. | Deploy and provision Cisco Unified Communications. For example, configure the dial plan, partitioning, user features, and so forth. Enable features and functionality on the existing infrastructure to support Cisco Unified Communications. For example, configure voice ports, gateway functionality on routers, and so forth. | Manage changes for users, services, IP phones, and so forth. Generate reports for operations, capacity planning, executive summaries, and so forth. Track and report on user experiences. For example, use sensors to monitor voice quality. Monitor and diagnose problems such as network failures, device failures, call routing issues, and so forth. |

This chapter provides the design guidance for the following management tools and products that fit into the implementation and operation phases of Cisco Unified Communications Management:

- Implement & Operate
 - Cisco Prime Unified Provisioning Manager (Unified PM) manages provisioning of initial deployments and ongoing operational activation for IP communications services. For details, refer to the related product documentation available at http://www.cisco.com/en/US/products/ps7125/tsd_products_support_series_home.html.
- Operate
 - Cisco Prime Unified Operations Manager (Unified OM) provides comprehensive monitoring with proactive and reactive diagnostics for the entire Cisco Unified Communications system. For details, refer to the related product documentation available at http://www.cisco.com/en/US/products/ps6535/tsd_products_support_series_home.html.
 - Cisco Prime Unified Service Monitor (Unified SM) provides a reliable method of monitoring and evaluating voice quality in Cisco Unified Communications systems. For details, refer to the related product documentation available at http://www.cisco.com/en/US/products/ps6536/tsd_products_support_series_home.html.
 - Cisco Unified Service Statistics Manager (Unified SSM) provides advanced statistics analysis and reporting capabilities for Cisco Unified Communications deployments. For details, refer to the related product documentation available at http://www.cisco.com/en/US/products/ps7285/tsd_products_support_series_home.html.

The Unified OM, Unified PM and Unified SM 8.7 products are now Cisco Prime compliant. Cisco Prime compliance involves meeting the following criteria:

- Prime experience
 - Consistent look and feel across the Cisco Prime portfolio
- Simplified navigation
 - Provisioning: Consolidated view of system, capacity, and actions
 - Monitoring: At-a-glance Unified Communications Services dashboard
- Integrated best practices
 - Faster branch roll-outs
 - Reduce time to troubleshoot core Unified Communications issues
- Service-centric foundation
 - Drill down from service issues to root-cause network element

For information on which software versions are supported with Cisco Unified Communications Manager (Unified CM), refer to the *Cisco Unified Communications Manager Software Compatibility Matrix*, available at

http://www.cisco.com/en/US/docs/voice_ip_comm/cucm/compat/ccmcompmatr.html

What's New in This Chapter

Table 28-2 lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Table 28-2 *New or Changed Information Since the Previous Release of This Document*

| New or Revised Topic | Described in: | Revision Date |
|--|---|-------------------|
| Cisco Prime compliance | Various sections throughout this chapter | February 29, 2012 |
| Trunk utilization | Trunk Utilization, page 28-11 | June 2, 2011 |
| Cisco Unified Analysis Manager | Cisco Unified Analysis Manager, page 28-21 | April 2, 2010 |
| Cisco Unified Reporting | Cisco Unified Reporting, page 28-22 | April 2, 2010 |
| Monitoring of virtualized Unified Communications Systems by Cisco Unified Operations Manager | Cisco Prime Unified Operations Manager, page 28-4 | April 2, 2010 |

Network Infrastructure Requirements for Cisco Unified Network Management Applications

A well designed network is the foundation for operating and managing a Cisco Unified Communications network. Cisco highly recommends that you design your Cisco Unified Communications network to conform to the following strict requirements:

- Average IP packet loss $\leq 1\%$
- Average delay variation (jitter) ≤ 30 ms
- Average one-way packet delay ≤ 150 ms

You should enable Domain Name Service (DNS) in the network to perform a reverse lookup on the IP address of the device to get the hostname for the device. If DNS is not desired, then host files may be used for IP address-to-hostname resolution.

Network Time Protocol (NTP) must be implemented to allow network devices to synchronize their clocks to a network time server or network-capable clock. NTP is a critical network service for network operation and management because it ensures accurate time-stamps within all logs, traps, polling, and reports on devices throughout the network.

You should enable Cisco Discovery Protocol (CDP) within the network to ensure proper monitoring. Unified OM's automated device discovery is based on a CDP table. Ping Sweep may be used instead of CDP, but IP phones discovered using Ping Sweep are reported in "unmanaged" state. Simple Network Management Protocol (SNMP) must also be enabled on network devices to allow Cisco Unified OM to get information on network devices at configured polling intervals and to receive alerts and faults via trap notification sent by the managed devices.

Trivial File Transfer Protocol (TFTP) must be enabled in the network for deployments with Cisco 1040 Sensors. TFTP provides the Cisco 1040 Sensor with a TFTP-based process to download its configuration files.

For more information on Cisco Unified Communications network requirements, see the chapter on [Network Infrastructure, page 3-1](#).

Cisco Prime Unified Operations Manager

Cisco Prime Unified Operations Manager (Unified OM) provides a unified view of the entire Cisco Unified Communications infrastructure and presents the current operational status of each element of the Cisco Unified Communications network. Unified OM also provides diagnostic capabilities for faster problem isolation and resolution. In addition to monitoring Cisco gateways, routers, and switches, Unified OM continuously monitors the operational status of various Cisco Unified Communications elements such as:

- Cisco Unified Communications Manager (Unified CM)
- Cisco Unified Communications Manager Express (Unified CME)
- Cisco Unified Communications Manager Session Management Edition
- Cisco Unity and Unity Connection
- Cisco Unity Express
- Cisco Unified Contact Center Enterprise (Unified CCE), Unified Contact Center Express (Unified CCX), and Unified Customer Voice Portal (Unified CVP)

Note Cisco Operations Manager Service Level View does not support multiple Cisco Unified System Contact Center Enterprise (SCCE) deployments.

- Cisco Unified Presence
- Cisco Emergency Responder
- Cisco Unified MeetingPlace and Unified MeetingPlace Express
- Cisco Unified Border Element
- Cisco Unified Endpoints

Note

Unified OM supports Unified Communications applications running in a virtualized environment but does not provide monitoring of VMware.

For more information on the supported products (particularly Cisco endpoints) and versions supported by Unified OM, refer to the Cisco Prime Unified Operations Manager data sheet available at

http://www.cisco.com/en/US/products/ps6535/products_device_support_tables_list.html

One protocol Unified OM uses to monitor the Unified Communications elements is Simple Network Management Protocol (SNMP). SNMP is an application-layer protocol using UDP as the transport layer protocol. There are three key elements in SNMP managed network:

- Managed devices — Network devices that have an SNMP agent (for example, Unified CM, routers, switches, and so forth).
- Agent — A network management software module that resides in a managed device. This agent translates the local management information on the device into SNMP messages.
- Manager — Software running on a management station that contacts different agents in the network to get the management information (for example, Unified OM).

The SNMP implementation supports three versions: SNMP v1, SNMP v2c, and SNMP v3. SNMP v3 supports authentication, encryption, and message integrity. SNMP v3 may be used if security is desired for management traffic. Unified OM supports all three versions of SNNP. SNMP v1 and v2c read/write

community strings or SNMP v3 credentials must be configured on each device for agent and manager to communicate properly. Unified OM needs only SNMP read access to collect network device information.

For more information on SNMP, refer to the *User Guide for Cisco Prime Unified Operations Manager*, available at

http://www.cisco.com/en/US/products/ps6535/products_user_guide_list.html

Cisco Prime Unified Operations Manager Design Considerations

Unified OM interfaces with other devices in the network in the following ways:

- Simple Network Management protocol (SNMP) to manage all Cisco Unified Communications servers, gateways, and switches.
- Administrative XML Layer (AXL) to manage Unified CM. AXL is implemented as a Simple Object Access Protocol (SOAP) over HTTPS web service.
- HTTP to the IP phone to collect serial number and switch information. HTTP must be enabled on the IP phones.
- Enhanced event processing with Cisco Unified CM remote syslog integration, and leveraging the Cisco Real-Time Monitoring Tool (RTMT) interface for pre-collected Unified CM cluster-wide data
- Skinny Client Control Protocol (SCCP) and Session Initiation Protocol (SIP) to Cisco Unified IP Phones for synthetic tests.
- Internet Control Message Protocol (ICMP) or Ping Sweep for Cisco IOS routers and switches, and for other voice as well as non-voice devices.
- Windows Management Instrumentation (WMI) for Cisco Unity servers.

Figure 28-1 shows the system-level overview of Unified OM how it leverages multiple interfaces with Unified CM to gather performance counters and alarms.

Figure 28-1 Unified OM and Unified CM System-Level Integration

Failover and Redundancy

Unified OM provides a choice of the following optional failover and redundancy configurations:

- Warm standby — All unified OM servers are active and polling
- Cold standby — Only one Unified OM server is active and polling

In warm standby mode, one backup Unified OM server can be deployed in the network. All the Unified OM servers are actively polling or collecting information from the network devices. Cisco recommends having a default polling interval on one of the active Unified OM servers, which is referred to as the primary Unified OM server. All the other active or secondary Unified OM servers must be configured with a longer polling interval (for example, 15 minutes). This will help reduce the bandwidth needed for management data as well as prevent the managed devices from frequently responding to SNMP queries from multiple Unified OM servers. If the primary Unified OM server fails, the polling interval on the secondary Unified OM server can be reduced to resume normal operation and collection of data.

In cold standby mode, two or more Unified OM servers can be deployed in the network. Only one Unified OM server is actively polling or collecting information from the network devices. Cisco recommends having a default polling interval on the active Unified OM server, which is referred to as the primary Unified OM server. All the other secondary Unified OM servers are configured, but polling is disabled on these servers. If the primary Unified OM server fails, the polling on the secondary Unified OM server can be enabled to resume normal operation and collection of data.

In both modes, the secondary servers must be backed up periodically with the configuration on the primary servers. This keeps all the servers in synchronization with the configuration and reduces downtime if the primary Unified OM server fails.

Server platforms with dual Ethernet network interface cards (NICs) can support NIC teaming for Network Fault Tolerance with Unified OM. This feature allows a server to be connected to the Ethernet through two NICs and, therefore, two cables. NIC teaming prevents network downtime by transferring the workload from the failed port to the working port. NIC teaming cannot be used for load balancing or increasing the interface speed.

For more information on multiple server and redundant design considerations, refer to the document on *Unified Communications Operations Manager/Service Monitor Multiple Server and Redundant Design Considerations*, available at

http://www.cisco.com/en/US/prod/collateral/netmgtsw/ps6491/ps6705/ps6535/white_paper_c07-469725.html

Ports and Protocols

Table 28-3 lists the ports used by the various protocol interfaces for Cisco Prime Unified Operations Manager. Cisco recommends opening these ports in the corporate internal firewalls (if applicable) to allow communication between Unified OM and other devices in the network.

Table 28-3 Unified OM Port Utilization

| Protocol | Port | Service |
|----------|------|--|
| UDP | 161 | SNMP polling |
| UDP | 162 | SNMP traps |
| TCP | 80 | HTTP |
| TCP | 443 | HTTPS |
| TCP | 1741 | CiscoWorks HTTP server |
| UDP | 514 | Syslog |
| TCP | 8080 | Determining status of Unified CM web service |
| TCP | 8443 | SSL port between Unified CM and Unified OM |

All the management traffic (SNMP) originating from Unified OM or managed devices is marked with a default marking of DSCP 0x00 (PHB 0). The goal of network management systems is to respond to any problem or misbehavior in the network. To ensure proper and reliable monitoring, network management data must be prioritized. Implementing QoS mechanisms ensures low packet delay, low loss, and low jitter. Cisco recommends marking the network management traffic with an IP Precedence of 2, or DSCP 0x16 (PHB CS2), and providing a minimal bandwidth guarantee. The DSCP value must be configured in the Windows Operating System.

If managed devices are behind a firewall, the firewall must be configured to allow management traffic. Unified OM has limited support in a network that uses Network Address Translation (NAT). Unified OM must have IP and SNMP connectivity from the Unified OM server to the NAT IP addresses for the devices behind the NAT. Unified OM 8.5 has static NAT support.

Bandwidth Requirements

Unified OM polls the managed devices for operational status information at every configured interval, and it has the potential to contain a lot of important management data. Bandwidth must be provisioned for management data, especially if you have many managed devices over a low-speed WAN. The amount

of traffic varies for different types of managed devices. For example, more management messages may be seen when monitoring a Unified CM as compared to monitoring a Cisco Voice Gateway. Also, the amount of management traffic will vary if the managed devices are in a monitored or partially monitored state and if any synthetic tests are performed. Unified OM 8.x has a Bandwidth Estimator that is available at

<http://www.cisco.com/web/applicat/ombwcalc/OMBWCalc.html>

Cisco Prime Unified Operations Manager Server Performance

Unified OM is supported in single-server mode. However, multiple Unified OM servers can be deployed to manage large networks. Each Unified OM can be configured to send management information to a higher-level “manager of managers”. For hardware requirements and capacity information for Unified OM, refer to the *Cisco Prime Unified Operations Manager Data Sheet*, available at

http://www.cisco.com/en/US/products/ps6535/products_data_sheets_list.html

Cisco Prime Unified Service Monitor

Cisco Prime Unified Service Monitor (Unified SM) monitors voice quality of calls on the Cisco Unified Communications network. It relies on Unified CM, Cisco 1040 Sensor, and Network Analysis Modules (NAMs) to monitor and gather voice quality statistics on real calls rather than simulated calls in the network. Then it compares the collected voice quality statistics against a predefined Mean Opinion Score (MOS) threshold. If the voice quality falls below the threshold, Unified SM sends SNMP trap messages to Unified OM to indicate that a potential issue has been identified. Unified SM is also responsible for sending voice quality information to Cisco Unified Service Statistics Manager (Unified SSM) so that Unified SSM can perform call data analysis and generate reports.

Note

A set of global call quality thresholds can be defined in Unified SM, one per supported codec type. Different thresholds can be grouped together based on the Cisco 1040 Sensor being implemented or the Unified CM cluster being monitored. Unified SM is bundled with Unified OM, and you may choose to install both Unified OM and Unified SM.

Voice Quality Measurement

Voice quality is the qualitative and quantitative measure of the sound and conversational quality of the IP phone call. Voice quality measurement describes and evaluates the clarity and intelligibility of voice conversations. Unified SM uses the Cisco 1040 Sensor, the Network Analysis Module (NAM), and Unified CM to monitor and report voice quality information.

Cisco 1040 Sensor Voice Quality Monitoring

The Cisco 1040 Sensor is a hardware device that predicts a subjective quality rating that an average listener might experience on the VoIP calls. It operates by measuring various quality impairment metrics that are included in the IP header of RTP streams, such as packet loss, delay, jitter, and concealment

ratio. This computed quality rating is converted to a MOS value. The MOS value is included in Syslog messages that are sent to Unified SM every 60 seconds, thus the Cisco 1040 Sensor monitors the voice quality almost on a real-time basis.

The Cisco 1040 Sensor has two Fast Ethernet interfaces, one of which is used to manage the sensor itself and the other is connected to the Switch Port Analyzer (SPAN) port on the Cisco Catalyst switch to monitor the actual RTP streams. To monitor voice quality of calls across the WAN, you must deploy a pair of Cisco 1040 Sensors at both sides of the WAN cloud, as illustrated in [Figure 28-2](#).

Figure 28-2 Voice Quality Monitoring with the Cisco 1040 Sensor

There are two call legs, transmitting and receiving, for each phone. Each call leg can be divided into three segments along the call path. For example, for the transmitting call leg of phone A in [Figure 28-2](#), segment 1 runs between phone A and the campus access switch, segment 2 is between the two access switches, and segment 3 is between the access switch at the branch site and phone B. Segments 1 and 3 are within a local area network, which presents the fewest transmission impairments to voice quality. Therefore, it is reasonably safe to assume that voice quality degradation will not occur in these two segments, and it is unnecessary to monitor those RTP streams.

Segment 2 spans across the WAN circuit and several network devices along the call path. It is more likely to experience degradation of voice quality due to packet loss, delay, and jitter inherent in the WAN. Therefore, the RTP streams (from campus to branch) should be monitored by the Cisco 1040 Sensor at the branch site. By the same token, the sensor in the central site should monitor the incoming RTP streams in that segment across the WAN. These RTP streams provide important voice quality statistics, and their associated MOS values should be analyzed carefully.

Strategic vs. Tactical Monitoring

There are two strategies for deploying Cisco 1040 Sensors: strategic monitoring and tactical monitoring. With strategic monitoring, the Cisco 1040 Sensor is deployed to continuously monitor all or subsets of IP phones in the network. With tactical monitoring, the Cisco 1040 Sensor is deployed in a site where a voice quality issue has been identified. The Cisco 1040 Sensor complies with FCC Class-B standards, and it can be deployed easily in the enterprise environment.

In a small network, Cisco recommends deploying strategic monitoring to monitor all IP phones on a continuous basis. In a medium to large network, Cisco recommends deploying strategic monitoring to continuously monitor a subset of IP phones, while using tactical monitoring to troubleshoot any voice quality issues experienced by the rest of the IP phones.

Design Considerations for the Cisco 1040 Sensor

Consider the following design factors when deploying a Cisco 1040 Sensor:

- A Cisco 1040 Sensor can monitor 100 simultaneous RTP streams. By monitoring the incoming RTP stream only, as illustrated in [Figure 28-2](#), the Cisco 1040 Sensor can provide the full benefit of monitoring 100 (instead of 50) simultaneous voice calls. An environment with a high call volume tends to require the use of more Cisco 1040 Sensors.
- If there are more RTP streams than the Cisco 1040 Sensor can handle, the Cisco 1040 Sensor will randomly select RTP streams.
- The Cisco 1040 Sensor utilizes the SPAN port on the Cisco Catalyst Switch to monitor the actual RTP streams. Different types of Catalyst switches have different quantities of SPAN ports that can be configured. For example, a maximum of two SPAN ports can be configured on the Cisco Catalyst 6500 and 4500 switches, while the maximum limit for Cisco Catalyst 3550 switch is only one. Therefore, the types of Catalyst switches that have been deployed in the network will determine how many Cisco 1040 Sensors can be deployed.
- If there is a trunking connection between multiple Cisco Catalyst switches and if the call volume is low, there is no need to deploy a Cisco 1040 Sensor for every Catalyst switch. Remote Switch Port Analyzer (RSPAN) can be used so that a single Cisco 1040 Sensor can monitor IP phones on other switches within the same VLAN.
- It is inefficient to deploy a Cisco 1040 Sensor at every site that has just a few IP phones and a small call volume. In such cases, Cisco Enhanced Switched Port Analyzer (ESpan) can be used so that one Cisco 1040 Sensor can monitor voice streams across multiple networks.

Unified CM Voice Quality Monitoring

Unified CM utilizes the Cisco Voice Transmission Quality (CVTQ) algorithm to monitor voice quality. CVTQ is based on the Klirrfaktor (K-factor) method to estimate the MOS value of voice calls. At the end of each call, Unified CM stores the MOS value in Call Management Records (CMRs). The CMRs and Call Detail Records (CDRs) are transferred to Unified SM via Secure File Transfer Protocol (SFTP) every 60 seconds. To integrate with Unified CM, Unified SM must be configured as a Billing Application Server in the Unified CM Unified Serviceability configuration web page. Up to three Billing Application Servers can be configured per Unified CM cluster. The following settings must be configured for the Billing Application Server:

- Hostname or IP address of the Unified SM server
- Username and password for SFTP file transfer
- Protocol: SFTP
- Directory path on the Unified SM server to which CDR and CMR files are transferred

CVTQ is supported natively by Unified CM 7.x and Cisco Unified IP Phones running in both SCCP and SIP modes. The phone models that support CVTQ are listed in the compatibility information at

http://www.cisco.com/en/US/products/ps6535/products_device_support_tables_list.html

As a comparison to the Cisco 1040 Sensor, which performs a full-depth inspection on various quality impairment metrics, the K-factor method inspects only one dimension of quality impairments, packet loss, which is really a network effect. Thus, CVTQ is a less sophisticated algorithm than the one that the Cisco 1040 Sensor uses to monitor the quality of calls. Cisco recommends using CVTQ to flag a voice quality issue and using the Cisco 1040 Sensor to validate and troubleshoot the issue.

Cisco Network Analysis Module (NAM)

Cisco NAM is a traffic analysis module that leverages Remote Monitoring (RMON) and some SNMP Management Information Bases (MIBs) to enable network administrators to view all layers of the Unified Communications infrastructure to monitor, analyze, and troubleshoot applications and network services such as QoS for voice and video applications. Voice instrumentation added in Cisco NAM 4.0 enables NAM integration with Unified SM for call metrics through NAM-embedded data collection and performance analysis.

The Cisco NAM complements the Cisco Unified Communications Management Suite to deliver an enterprise-wide voice management solution. Cisco NAMs are available in different configurations for Cisco Catalyst 6000 Series, 7600 Series, and Integrated Services Routers. The NAM Appliances come with a graphical user interface for troubleshooting and analysis, and they provide a rich feature set for voice quality analysis with RTP and voice control and signaling monitoring. [Table 28-4](#) lists the maximum number of concurrent RTP streams (single direction) that each type of NAM can support.

Table 28-4 Number of Supported Concurrent RTP Streams per NAM Type

| Cisco NAM Type | 1040 Sensor | NME-NAM | NAM-2 | NAM 2204 Appliance | NAM 2220 Appliance |
|--|-------------|---------|-------|--------------------|--------------------|
| Number of concurrent RTP streams supported | 100 | 100 | 400 | 1500 | 4000 |

Unified SM polls the NAM every 60 seconds for voice quality metrics. Unified SM consolidates the data collection module for both the Cisco 1040 Sensor and NAM, and it uses the same method for MOS calculation on both the Cisco 1040 Sensor and NAM. This enables Unified SM to correlate CDR and call stream reports from the Cisco 1040 Sensor and NAM for enhanced analysis.

For more information on Cisco NAM, refer to the following site:

<http://www.cisco.com/go/nam>

Trunk Utilization

Unified SM is tightly integrated with Unified OM and Cisco Unified Service Statistics Manager (Unified SSM). Unified SM provides the call information it collects to Unified SSM for long-term trending and reporting purposes and to Unified OM for real-time trunk utilization performance graphs. The call information is provided from the CDR and CMR records Unified SM gathers from Unified CM.

Failover and Redundancy

A primary and secondary Unified SM can be configured to provide redundancy and failover support to the Cisco 1040 Sensor. After missing three consecutive SCCP keepalive messages from the primary Unified SM, the Cisco 1040 Sensor will try to register with the secondary Unified SM. The Cisco 1040 Sensor will also send Syslog messages to the secondary Unified SM after the registration failover process succeeds.

You can configure up to three Unified SMs, or Billing Application Servers, in Unified CM. Failure of one Unified SM will not prevent the remaining two servers from obtaining CDR and CMR files from Unified CM.

**Note**

The Unified CM publisher server is responsible for transferring CDR and CMR files to Unified SM via SFTP. If the publisher server is unavailable, there is no failover mechanism for Unified SM to obtain the new CDR and CMR files that contain MOS values of calls in the Unified CM cluster. The Cisco Network Analysis Module (NAM) does not provide a secondary Unified SM for failover or high availability support.

Unified SM Server Performance

Unified SM operates only in single-server mode. However, multiple Unified SMs (all connected to Cisco Unified Operations Manager) can be deployed to manage large networks. For hardware requirements and information about Unified SM, refer to the *Cisco Prime Unified Service Monitor Data Sheet*, available at

http://www.cisco.com/en/US/products/ps6536/products_data_sheets_list.html

Unified SM supports the following voice quality monitoring capacities:

- Unified SM supports up to 50 Cisco 1040 Sensors.
- Unified SM supports up to 45,000 IP phones
- Unified SM supports any of the following scenarios:
 - 5,000 sensor-based RTP streams per minute (with Cisco 1040 Sensors or NAM modules)
 - 1,600 CVTQ-based calls per minute
 - 1,500 RTP streams and 666 CVTQ calls per minute
- Unified SM automatically selects and gathers voice quality information (via CDR and CMR files) for all Cisco Unified IP Phones configured in a given Unified CM cluster. There is no configuration option to monitor only certain IP phones in the cluster.

**Note**

When Unified SM is operating at full capacity, its projected database growth (for Syslog, CDR, and CMR files) is estimated to be about 2.4 GB per day.

Ports and Protocol

Table 28-5 lists the ports used by the various protocol interfaces for Cisco Unified Service Monitor. Cisco recommends opening these ports in the corporate internal firewalls (if applicable) to allow communication between Unified SM and other devices in the network.

Table 28-5 Unified SM Port Utilization

| Protocol | Port | Service |
|----------|------|------------------------|
| TCP | 80 | HTTP |
| TCP | 443 | HTTPS |
| TCP | 1741 | CiscoWorks HTTP server |
| UDP | 22 | SFTP |
| UDP | 162 | SNMP traps |

Table 28-5 Unified SM Port Utilization (continued)

| Protocol | Port | Service |
|----------|-------|---------------------|
| TCP | 43459 | Database |
| UDP | 5666 | Syslog ¹ |
| TCP | 2000 | SCCP ² |
| UDP | 69 | TFTP ³ |

1. Unified SM receives Syslog messages from the Cisco 1040 Sensor.
2. Unified SM communicates with the Cisco 1040 Sensor via SCCP.
3. The Cisco 1040 Sensor downloads its configuration file via TFTP.

**Note**

The Cisco NAM is accessed remotely over HTTPS with a non-default port. Unified SM will authenticate with each Cisco NAM and maintain the HTTP/S session.

Comparison of Voice Quality Monitoring Methods

Cisco 1040 Sensors, CVTQ, and NAM complement each other and provide a total solution for voice quality measurement. The following list notes key differences between voice quality monitoring with the Cisco 1040 Sensor, CVTQ, and Cisco NAM:

- The Cisco 1040 Sensor monitors voice calls based on packet loss, delay, jitter, and concealment ratio. CVTQ monitors voice calls based on packet loss only.
- The Cisco 1040 Sensor and Cisco NAM provide voice quality statistics every 60 seconds. CVTQ provides voice quality statistics after the call is completed.
- The Cisco 1040 Sensor is compatible with all Cisco Unified CM releases and all types of endpoints connecting to the Cisco Catalyst switch. CVTQ supports only Unified CM 4.2 and later releases.
- For inter-cluster calls, the Cisco 1040 Sensor monitors the end-to-end call segment. CVTQ monitors only the call segment within its own cluster.
- Cisco recommends using the Cisco 1040 Sensor to monitor key IP phone devices, gateway devices, and application servers in the network and to investigate and troubleshoot voice quality issues. CVTQ-based voice quality monitoring should be used to gauge the overall voice call quality in the network.

Even if CVTQ is not used, Unified SM uses CDR information to correlate with the NAM report for the following metrics:

- Source and/or destination extension number
- Device types
- Interface through which the call flowed in case of call to or from a gateway
- Call disconnect reason, where possible
- Exact Unified CM server (not just the Unified CM cluster) to which the phone is connected

Cisco Unified Service Statistics Manager

The Cisco Unified Service Statistics Manager (Unified SSM) performs advanced call statistics analysis and generates reports for executives, operations, and capacity planning functions. Unified SSM is fully dependent on Unified OM and Unified SM to obtain call statistics information; therefore, Unified OM and Unified SM must be implemented and operating before you deploy Unified SSM. Unified SSM provides both out-of-the-box reports as well as customizable reports that provide visibility into key metrics such as call volume, service availability, call quality, resource and trunk utilization, and capacity across the Cisco Unified Communications system. For the detailed information on feature support and functionality, refer to the Cisco Unified Service Statistics Manager product documents available at <http://www.cisco.com>.

Integration with Unified OM and Unified SM

Unified SSM can integrate with only one Unified OM but with multiple Unified SMs. Unified SSM extracts call statistics data from Unified OM and Unified SM databases. The data extraction process is performed by the Unified SSM agent.

The Unified SSM agent facilitates communication between Unified SSM and Unified OM or Unified SM, and it is responsible for transmitting call statistics data from Unified OM or Unified SM to Unified SSM. Unified SSM then stores the extracted data in its own SQL database.

If Unified OM and Unified SM are deployed on the same Cisco Media Convergence Server (MCS) as Unified SSM, there is no need to install the Unified SSM agent on Unified OM or Unified SM. With such a co-resident deployment, Unified SSM is able to extract call statistic data directly from the Unified OM and Unified SM databases instead of transferring the data across the network.

If Unified OM and Unified SM are deployed separately from Unified SSM, then the Unified SSM agent must be installed on every instance of Unified OM and Unified SM. The executable installation file of the Unified SSM agent can be downloaded from the Unified SSM Web Administration page and installed locally on Unified OM and Unified SM. With Unified SSM agents distributed on Unified OM and Unified SM, Unified SSM is able to control and manage the data extraction process. Unified SSM connects all distributed Unified SSM agents via TCP on port 12124, and Unified SSM agents send call statistics data back to Unified SSM via TCP on port 12126.

There are two different data collection approaches within Unified SSM. The first approach is called *raw data collection*. With this approach, Unified SSM instructs the Unified SSM agent to retrieve all call statistics data directly from the Unified OM and Unified SM databases. All retrieved data is then saved in Unified SSM's database for up to 30 days. The advantage of this approach is that it provides Unified SSM with a comprehensive data source to perform detailed analysis and report generation.

The second approach is called *monitor-based data collection*. With this approach, Unified SSM instructs the Unified SSM agent to transfer the processed call statistics data only. The advantage of this approach is fewer traffic loads over the network, and the processed data can be stored in the Unified SSM database for up to three months. To process the original call statistics data in the Unified OM and Unified SM databases, a specific monitor instance must be created in the Unified SSM Administration console and that monitor instance must be associated with the appropriate Unified SSM agent. The monitor instance extracts only the data based on predefined attributes. For example, for Call Volume Monitor, the attributes include number of completed calls on-net, number of failed calls on-net, average duration per call on-net, and so forth. Each monitor instance has a unique list of predefined attributes. The monitor instance then polls and extracts the data every 15 minutes, and the Unified SSM agent aggregates the processed data from its associated monitor instance(s) and sends it to Unified SSM every 30 minutes.

For a comprehensive list on all attributes of each monitor type and its configuration guidelines, refer to the Cisco Unified Service Statistics Manager product documents available at <http://www.cisco.com>.

**Note**

Currently there is no redundancy or failover support with Unified SSM. Unified SSM can still provide reports for more than three months because data is not completely purged but is summarized or aggregated and kept in its database.

The following guidelines summarize the integration options for Unified SM, Unified OM, and Unified SSM:

- Unified SSM and Unified OM integrate 1 to 1.
- Unified SSM and Unified SM integrate 1 to 5.
- The Unified SM diagnostics page can launch the Unified OM device detail page for phones and gateways.
- Unified OM reports voice quality details for the NAM. Cross Launch to the NAM user interface from Unified OM quality alerts is supported.
- Unified SM integrates with the Unified OM Service Quality alert dashboard.
- Unified SM integrates with Unified SSM long-term reporting and trending functions.

Unified SSM Server Performance

Unified SSM operates only in a single-server mode. For hardware requirements and information about Unified SSM, refer to the *Cisco Unified Service Statistics Manager Data Sheet*, available at

http://www.cisco.com/en/US/products/ps7285/products_data_sheets_list.html

Ports and Protocol

Table 28-6 lists the ports used by the various protocol interfaces for Cisco Unified Service Statistics Manager. Cisco recommends opening these ports in the corporate internal firewalls (if applicable) to allow communication between Unified SSM and other devices in the network.

Table 28-6 Unified SSM Port Utilization

| Protocol | Port | Service |
|----------|-------|--|
| TCP | 48101 | HTTP |
| TCP | 48443 | HTTPS |
| TCP | 12123 | Unified SSM Agent Controller Listener |
| TCP | 12124 | Unified SSM Agent Listener ¹ |
| TCP | 12125 | Unified SSM and Unified SSM agent communication ² |

1. Unified SSM connects all distributed Unified SSM agents.
2. Unified SSM agents send call statistics data back to Unified SSM.

Cisco Prime Unified Provisioning Manager

The Cisco Prime Unified Provisioning Manager (Unified PM) is a web-based provisioning application based on the Java 2 Enterprise Edition (J2EE) architecture. Unified PM provides a simplified web-based provisioning interface for both new and existing deployments of Cisco Unified Communications Manager (Unified CM), Cisco Unified Communications Manager Express (Unified CME), Cisco Unity, Cisco Unity Connection, and Cisco Unity Express. Unified PM provides provisioning for both the infrastructure and subscribers (or phone users) for Day 1 and Day 2 needs. Day 1 needs include configuring new deployments and adding more sites or locations; Day 2 needs include services for ongoing moves, adds, and changes on various components of the Cisco Unified Communications solution.

Cisco Prime Unified Provisioning Manager also exposes northbound APIs to allow Cisco and third parties to integrate with external applications such as HR systems, custom or branded user portals, other provisioning systems, and directory servers.

Unified PM can be installed in simple or advanced mode to support up to 60,000 phones and 120,000 lines. In simple mode, Unified PM is installed on one system as a single server to support up to 10,000 phones. Advanced mode allows a two-system installation, where the Unified PM database server is installed on one server and the web and application server are on a separate system to support 10,000 to 60,000 phones.

For more details on system requirements and installation steps, provisioning users and the infrastructure of supported components, and capacity information, refer to the Cisco Prime Unified Provisioning Manager documentation available at

<http://www.cisco.com/go/cupm>

To provide a better understanding of how Unified PM can be used as a network management solution for provisioning various Cisco Unified Communications components, the next section presents some of the basic concepts of Unified PM.

Unified PM Concepts

Unified PM serves as a provisioning interface for the following components of a Cisco Unified Communications system:

- Call processors
 - Cisco Unified Communication Manager (Unified CM)
 - Cisco Unified Communications Manager Express (Unified CME)
- Message processors
 - Cisco Unity
 - Cisco Unity Connection
 - Cisco Unity Express
- Presence processors
 - Cisco Unified Presence
 - Cisco Voice Gateways
 - Cisco VG224, VG204, and VG202 Analog Voice Gateways

**Note**

For more information on component version compatibility, refer to the Unified PM information at http://www.cisco.com/en/US/products/ps7125/products_device_support_tables_list.html.

The following sections describe some of the Unified PM concepts involved in configuring those components.

Domain

Domains are used for administrative purposes to create multiple logical groups within a system. Domains have the following characteristics:

- A domain can be mapped to a geographical location or an organization unit.
- One domain can contain multiple call processors and multiple optional message processors.
- A given call processor or message processor can be a member of multiple domains.
- A domain can partition subscribers so that they can be administered separately.

Service Area

Service areas represent offices. Service areas determine the dial plans and other voice-related configuration settings in the domain. In reality, each office may have multiple service areas. The service area determines attributes such as device group, route partition, and calling search space used within Unified CM. Service areas have the following characteristics:

- Each service area is assigned to a single call processor and one optional message processor.
- Each service area should be associated with one dial plan.

Users and Subscribers

A *user* is a person who is authorized to perform various tasks in Unified PM, based on assigned user roles. When installed, Unified PM creates a Unified PM Admin (also called a Super Admin in Unified PM) who has global administrative rights and complete authorization to perform all tasks in Unified PM.

User roles determine the level of access within Unified PM. Domain-specific users can be assigned more than one user role to have rights to specific tasks in a domain. Individual user roles are related to either policy or workflow tasks. A user can be an administrator or a phone user.

A *subscriber* in Unified PM is an entity that uses IP telephony services provided by the underlying voice applications. A subscriber is the same as a phone user in Unified CM. Users in Unified PM can also have services themselves; thus, a user (an administrator) can also be a subscriber (or a phone user). There can also be pseudo-subscribers (for example, conference rooms and lobby phones) in Unified PM that are not present in Unified CM.

Work Flow and Managing Orders

When deploying a new site or making moves, adds and changes to an existing site, users make all changes to the underlying systems through a two-stage process of creating an order and then processing that order. You can set policies for both of these stages. For example, you can configure the system so that one group of users can only create and submit orders, while another group of users can view and perform processing-related activities. Unified PM contains an automation engine that performs the order processing, including service activation and business flow, based on how Unified PM is configured.

The workflow coordinates activities of the ordering process (approval, phone assignment, shipping, and receiving).

Configuration Templates

Unified PM enables you to configure Unified CM, Unified CME, Cisco Unity, Cisco Unity Express, and Cisco Unity Connection in a consistent way through the use of configuration templates. You can use these templates to configure any of these products, to perform an incremental rollout on these existing products, and to deploy a new service across existing customers.

Batch Provisioning

Creating users and provisioning their services can also be done automatically through batch provisioning for rolling out a new office or transitioning from legacy systems.

Best Practices

The following best practices and guidelines apply when using Unified PM to provision Cisco Unified Communications components for any new and/or existing deployments:

- Managed devices must be up and running before using Unified PM for further day-one activities such as rolling out a new site and day-two activities such as moves, adds, and changes.
- Pre-configuration is required for Cisco Unified CM, Cisco Unity, Unified CME, Survivable Remote Site Telephony (SRST), Cisco Unity Express, and Cisco Unified Presence Server.
- Define the correct domains, service areas, and provisioning attributes.
- Modify only the workflow rules if necessary.
- Consider the use of Subscriber Types, Advanced Rule settings, and other configuration parameters.

The following basic tasks help support these best practices:

- Add call processors such as Unified CM, and/or Unified CME and message processors such as Cisco Unity, Unity Connection, and/or Unity Express.
- Create domains and assign call processors and message processors to the created domains.
- Provision the voice network by creating and using templates to configure Unified CMs or Unified CMEs, or import current voice infrastructure configurations from an existing deployment.
- Perform bulk synchronization of LDAP users into Unified PM, if applicable.
- Set up the deployment by creating service areas for each domain (typically one per dial plan) and assigning subscriber (user) types to each service area.
- Create administrative users for each domain.
- Order, update, or change subscriber or user services.

Note

Unified PM does not provide distributed installation of the application server and database server, nor does it support any of the clustering features of the application server.

For more information on Unified PM, refer to the guide on *Getting Started with Cisco Prime Unified Provisioning Manager Deployment and Best Practices*, available at

http://www.cisco.com/en/US/prod/collateral/netmgtsw/ps6491/ps6705/ps7125/white_paper_c07-523344.html

Unified PM Design Considerations

The following design considerations apply to Unified PM:

- Deploy a one-system simple-mode installation of Unified PM for up to 10,000 phones.
- Deploy a two-system or dual-processor Microsoft Windows system in advanced mode, with the Unified PM database installed on a separate system from the web and application server.
- If a two-system advanced-mode installation is used for 10,000 to 60,000 phones, both the database server and the web and application server must be co-located, regardless of the deployment model used.
- One Unified PM can support up to 60,000 phones or 120,000 lines (DNs).
- Set up domains in one of the following ways:
 - Create a single domain for multiple sites, with multiple call processors and multiple message processors.
 - Create a domain for each site, consisting of one call processor and zero or more optional message processors.
 - Create multiple domains if different administrators are required to manage a subset of the subscribers.
- Create multiple service areas for multiple dial plans.
- Add only the Unified CM publisher as the call processor for Unified PM. Any changes made to the Unified CM publisher through Unified PM will be synchronized to all the Unified CM subscriber servers.
- Use configuration templates for Unified CM, Unified CME, or Cisco Unity Express.
- Use Cisco IOS commands for Unified CME and Cisco Unity Express configuration templates.
- Add Cisco Unified CM infrastructure data objects for Unified CM configuration templates.
- Change and modify the existing configuration templates for batch provisioning for large quantities of phones and lines (DNs).
- Create multiple domains if you want different domain administrators to manage different sets of subscribers for Day 2 moves, adds, and changes of services (such as phones, lines, and voicemail), even for a single-site deployment.
- Create one service area for one dial plan.
- Create multiple service areas if multiple dial plans are required for the device pools, location, calling search space, and phones.
- Unified PM is an IPv6-aware application with the following characteristics:
 - Unified PM communicates with Unified CM over an IPv4 link. The Unified PM user configuration interface allows users to enter only IPv4 IP addresses because Unified CM has SOAP AXL interfaces in IPv4 only. Therefore, Unified PM must use IPv4 addresses to communicate with the AXL interfaces on Unified CM.
 - Unified PM handles the IPv6 addresses contained in SIP trunk AXL response messages.
 - Support of IPv6-aware functions does not affect support for current Cisco Unified Communications Manager Express, Cisco Unity, Cisco Unity Express, and Cisco Unity Connection devices.

Integration with Cisco Prime Unified Operations Manager

Unified PM can launch Cisco Prime Unified Operations Manager (Unified OM) to obtain subscriber or user phone information. Unified PM allows its users to launch Unified OM by means of the Details button on the subscriber record. The Details button launches the IP Phone Details dialog box from Unified OM.

For information on how to configure the integration with Unified OM, refer to the *User Guide for Cisco Prime Unified Operations Manager*, available at:

http://www.cisco.com/en/US/products/ps6535/products_user_guide_list.html

Redundancy and Failover

Unified PM currently does not have true redundancy and failover support. When multiple Unified PM systems are deployed, there is no synchronization between their multiple databases.

If Unified PM fails in the middle of the configuration process, changes made to the configured devices from the Unified PM GUI might not be saved and cannot be restored. Administrators must use manual steps to continue the configuration process by using other tools such as telnet or login (HTTP) to the managed devices until Unified PM comes back live. Manually added configuration changes to the managed device will not automatically show up in the Unified PM dashboard or database unless one of the following steps is performed:

- Synchronization from Unified PM for the call processors (Unified CM and/or Unified CME), message processors (Cisco Unity, Unity Connection, and/or Unity Express), and domains
- Periodic synchronization (for example, every night) by using a script under the Microsoft Windows scheduler that comes with the Unified PM installation

Cisco Prime Unified Provisioning Manager Server Performance

For hardware requirements and information about Unified PM, refer to the Cisco Prime Unified Provisioning Manager data sheet, available at:

http://www.cisco.com/en/US/products/ps7125/products_data_sheets_list.html

Unified PM requires a 100 Mbps network interface card (NIC). Default licensing for Unified PM supports up to 750 call processors (Unified CM and Unified CME), 750 message processors (Cisco Unity, Unity Express, and Unity Connection), or 20 presence processors. Synchronization time depends upon the number of deployed phones and lines (DNs).

Ports and Protocol

Table 28-7 lists the ports used by the various protocol interfaces for Unified PM. Cisco recommends opening those ports in the corporate internal firewalls (if applicable) to allow communication between Unified PM and other devices in the network.

Table 28-7 Unified PM Port Utilization

| Protocol | Port | Service |
|----------|------|-----------------------|
| TCP | 80 | HTTP ^{1 2} |
| TCP | 8443 | HTTPS ² |
| TCP | 22 | SSH ³ |
| SSH | 23 | Telnet ³ |
| TCP | 1433 | Database ⁴ |

1. To access the Unified PM Administration web page.
2. Unified PM provisions Unified CM via Administrative XML Layer (AXL) Simple Object Access Protocol (SOAP).
3. For Unified PM to communicate with Unified CME and Cisco Unity Express.
4. For Unified PM to connect to the database of Cisco Unity and Cisco Unity Connection.

Additional Tools

In addition to the network management tools mentioned above, the following tools also provide troubleshooting and reporting capabilities for Cisco Unified Communications systems:

- [Cisco Unified Analysis Manager, page 28-21](#)
- [Cisco Unified Reporting, page 28-22](#)

Cisco Unified Analysis Manager

Cisco Unified Analysis Manager is included with the Cisco Unified Communications Manager Real-Time Monitoring Tool (RTMT). Unlike the other RTMT functions, Unified Analysis Manager is unique in that it supports multiple Unified Communications elements instead of just one. When the Unified Analysis Manager is launched, it collects troubleshooting information from your Unified Communications system and provides an analysis of that information. You can use this information to perform your own troubleshooting operations, or you can send the information to Cisco Technical Assistance Center (TAC) for analysis.

Unified Analysis Manager supports the 8.x versions of the following Unified Communications elements:

- Cisco Unified Communications Manager
- Cisco Unified Contact Center Enterprise
- Cisco Unified Contact Center Express
- Cisco IOS Voice Gateways (3700 Series, 2800 Series, 3800 Series, 5350XM, and 5400XM)
- Cisco Unity Connection
- Cisco Unified Presence

Unified Analysis Manager provides the following key features and capabilities:

- Supports collection of Unified Communications application hardware, software, and license information from Unified Communications elements.
- Supports setting and resetting of trace level across Unified Communications elements.
- Supports collection and export to a define FTP server of log and trace files from Unified Communications elements.
- Supports analysis of the call path (call trace capability) across Unified Communications elements.

For more details on the report options, refer to the information about the Cisco Unified Analysis Manager in the *Cisco Unified Real-Time Monitoring Tool Administration Guide*, available at

http://www.cisco.com/en/US/docs/voice_ip_comm/cucm/service/8_5_1/rtmt/RTMT.html

Cisco Unified Reporting

The Cisco Unified Reporting web application generates reports for troubleshooting or inspecting Cisco Unified Communications Manager cluster data. It is a convenient tool that you can access from the Unified Communications Manager console. The tool facilitates gathering data from existing sources, comparing the data, and reporting irregularities. For example, you can view a report that shows the hosts file for all servers in the cluster. The application gathers information from the publisher server and each subscriber server. Each report provides data for all active cluster nodes that are accessible at the time the report is generated.

For example, the following reports can be used for general management of a Unified CM cluster:

- Unified CM Cluster Overview — Provides an overview of the cluster, including Unified CM version, hostname, and IP address of all servers, a summary of the hardware details, and so forth.
- Unified CM Device Counts Summary — Provides the number of devices by model and protocol that exist in the Cisco Unified Communications Manager database.

The following report can be used for debugging a Unified CM cluster:

- Unified CM Database Replication Debug — Provides debugging information for database replication.

The following report can be used for maintenance of a Unified CM cluster:

- Unified CM Database Status - Provides a snapshot of the health of the Unified CM database. This report should be generated before an upgrade to ensure the database is healthy.

For more information on the report options, refer to the latest version of the *Cisco Unified Reporting Administration Guide*, available at

http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html

Integration with Cisco Unified Communications Deployment Models

This section discusses how to deploy Cisco Unified Network Management applications in various Cisco Unified Communications deployment models. For detailed information on the deployment models, see the chapter on [Unified Communications Deployment Models, page 5-1](#).

The Cisco Unified Communications Management Suite supports standalone, co-resident, and VMware environments. The following supported limits and capacities apply to all the deployment models discussed in this chapter:

- Standalone environment
 - Standalone Unified OM, Unified SM, or Unified SSM supports up to 45,000 phones. Standalone Unified PM supports up to 60,000 phones.
 - For more than 10,000 IP phones, deploy standalone Unified PM, Unified OM, Unified SM, and Unified SSM.
- Co-resident environment
 - Unified PM, Unified SM, Unified OM, and Unified SSM can reside on the same physical server for deployments of up to 10,000 phones.
 - For less than 10,000 IP phones, deploy co-resident Unified PM, Unified OM, Unified SM, and Unified SSM. The system requirements for Unified PM, Unified OM, Unified SM, and Unified SSM co-residency can be found in the installation manuals for these products.
- VMware environment
 - Run each Unified PM, Unified OM, Unified SM, and Unified SSM as a dedicated instance on a separate VMware server.
 - The maximum number of Unified OM instances is 3.
 - The maximum number of Unified SM instances is 2.

**Note**

System hardware requirements for a VMware environment follow all the requirements from VMware in addition to the hardware system requirements specified for each of the deployment models described in this chapter.

Single Site

In the single-site model, Cisco Unified Network Management applications, along with call processing agents, are deployed at a single site (or campus) with no telephony services provided over an IP WAN. An enterprise would typically deploy the single-site model over a LAN or metropolitan area network (MAN). [Figure 28-3](#) illustrates the deployment of Cisco Unified Network Management applications in the single-site model.

Figure 28-3 Single-Site Deployment

191973

The following design characteristics and recommendations apply to the single-site model for deploying Unified OM, Unified SM, Unified SSM, and Unified PM:

- Cisco recommends deploying CVTQ-based voice quality monitoring to monitor overall voice quality in the network.
- Cisco recommends deploying the Cisco 1040 Sensor or NAM to monitor key IP phone devices, gateway devices, and application servers in the network and to investigate and troubleshoot voice quality issues.
- Each Unified OM can support a maximum of 45,000 IP phones and 30 Unified CM clusters.
- Unified SM can support, concurrently, a maximum of 90,000 RTP streams per hour being monitored by the Cisco 1040 Sensor and 15,000 CVTQ-based calls per hour being monitored by Unified CM.
- Each Unified PM can support a maximum of 60,000 IP phones and multiple Unified CM clusters.

Multisite WAN with Centralized Call Processing

The multisite WAN model with centralized call processing is really an extension of single-site model, with an IP WAN between the central site and remote sites. The IP WAN is used to transport voice traffic between the sites and call control signaling between the central site and the remote sites. Figure 28-4 illustrates the deployment of Cisco Unified Network Management applications in a multisite WAN model with centralized call processing.

Figure 28-4 Multisite WAN Deployment with Centralized Call Processing

The following design characteristics and recommendations apply to the multisite model for deploying Unified OM, Unified SM, Unified SSM, and Unified PM with centralized call processing:

- Cisco recommends deploying all network management applications (including Unified OM, Unified SM, Unified SSM, and Unified PM) in the central site to locate them with the call processing agent. The benefit of such an implementation is that it keeps the network management traffic between call processing agent and network management applications within the LAN instead of sending that traffic over the WAN circuit.
- Multiple Unified OMs can be deployed, with each instance managing multi-site and multi-cluster Unified Communications environments. In this deployment scenario, Cisco recommends that you deploy a Manager of Managers (MoM). Each Unified OM can provide real-time notifications to the higher-level MoM using SNMP traps, syslog notifications, and email to report the status of the network being monitored.
- Each Unified OM can support a maximum 45,000 IP phones.
- Cisco recommends deploying CVTQ-based voice quality monitoring to monitor overall voice quality in the network.
- Cisco recommends deploying the Cisco 1040 Sensor or NAM to monitor key IP phone devices, gateway devices, and application servers in the network and to investigate and troubleshoot voice quality issues.

- Unified SM can support, concurrently, a maximum of 90,000 RTP streams per hour being monitored by the Cisco 1040 Sensor and 15,000 CVTQ-based calls per hour being monitored by Unified CM.
- Each Unified SSM can support a maximum of 45,000 IP phones.
- Each Unified PM can support a maximum of 60,000 IP phones.

Multisite WAN with Distributed Call Processing

The multisite WAN model with distributed call processing consists of multiple independent sites, each with its own call processing agent connected to an IP WAN. [Figure 28-5](#) illustrates the deployment of Cisco Unified Network Management applications in a multisite WAN model with distributed call processing.

Figure 28-5 Multisite WAN Deployment with Distributed Call Processing

A multisite WAN deployment with distributed call processing has many of the same requirements as a single site or a multisite WAN deployment with centralized call processing in terms of deploying Unified OM, Unified SM, Unified SSM, and Unified PM. Follow the best practices and recommendations from these other models in addition to the ones listed here for the distributed call processing model:

- If only one Cisco Unified Network Management system is deployed to manage multiple Unified CM clusters, Cisco recommends deploying Unified OM, Unified SM, Unified SSM, and Unified PM along with the Unified CM cluster that has the highest call volume and the most endpoints.

- Multiple Unified OMs can be deployed, with each instance managing multi-site and multi-cluster Unified Communications environments. In this deployment scenario, Cisco recommends that you deploy a Manager of Managers (MoM). Each Unified OM can provide real-time notifications to the higher-level MoM using SNMP traps, syslog notifications, and email to report the status of the network being monitored.
- Each Unified OM can support a maximum 45,000 IP phones.
- Cisco recommends deploying CVTQ-based voice quality monitoring to monitor overall voice quality in the network.
- Cisco recommends deploying the Cisco 1040 Sensor or NAM to monitor key IP phone devices, gateway devices, and application servers in the network and to investigate and troubleshoot voice quality issues.

Clustering over the WAN

Clustering over the WAN refers to a single Cisco Unified CM cluster deployed across multiple sites that are connected by an IP WAN with QoS features enabled. This deployment model is designed to provide call processing resiliency if the IP WAN link fails. [Figure 28-6](#) illustrates the deployment of Cisco Unified Network Management applications with clustering over the WAN.

Figure 28-6 Clustering over the WAN

Note

There is no native high-availability or redundancy support for Unified SM, Unified SSM, or Unified PM with this model.

The following design characteristics and recommendations apply when deploying Unified OM, Unified SM, Unified SSM, and Unified PM with clustering over the WAN:

- Cisco recommends deploying Unified OM, Unified SM, Unified SSM, and Unified PM in the headquarter site where Unified CM publisher is located.
- Cisco recommends deploying a pair of Unified OMs. Deploy the active Unified OM in the one site to manage all the sites under normal conditions. The warm-standby Unified OM should be located in the other site and should have a longer polling interval. The warm-standby Unified OM will take

over for the active server and provide redundancy support (shorten its polling interval) when the active Unified OM is unavailable. Additional WAN bandwidth should be provisioned for the SNMP polling messages of the warm-standby server.

- Multiple Unified OMs can be deployed, with each instance managing multi-site and multi-cluster Unified Communications environments. In this deployment scenario, Cisco recommends that you deploy a Manager of Managers (MoM). Each Unified OM can provide real-time notifications to the higher-level MoM using SNMP traps, syslog notifications, and email to report the status of the network being monitored.
- Cisco recommends deploying CVTQ-based voice quality monitoring to monitor overall voice quality in the network.
- Cisco recommends deploying the Cisco 1040 Sensor or NAM to monitor key IP phone devices, gateway devices, and application servers in the network and to investigate and troubleshoot voice quality issues.
- Each Unified OM can support a maximum 45,000 IP phones.
- Unified SM can support, concurrently, a maximum of 90,000 RTP streams per hour being monitored by the Cisco 1040 Sensor and 15,000 CVTQ-based calls per hour being monitored by Unified CM.
- Each Unified SSM can support a maximum of 45,000 IP phones.
- Each Unified PM can support a maximum of 60,000 IP phones.

CHAPTER 29

Unified Communications Design and Deployment Sizing Considerations

Revised: July 31, 2012; OL-21733-18

An accurate estimation of the type and quantity of hardware platforms is a prerequisite to a successful deployment of Unified Communications products. Adequate computing and network resources must be provided so that the expected service goals are met.

Each Unified Communications product publishes its capacity limits on each hardware server platform where it runs. These published limits are obviously an important part of determining the needed amount of hardware resources. Individual products, however, may publish only their best-case performance numbers, or may publish numbers for a typical deployment. Both of these numbers are very useful but insufficient for a real-world sizing exercise. For example, Cisco Unified Communications Manager (Unified CM) publishes the maximum number of endpoints that a cluster consisting of Cisco MCS-7845-I3 servers can support. This number may assume average call rates and the absence of any other major activity in the cluster. In an actual usage scenario the call rate might be higher than that assumed, or there might be a requirement to support other services, and even though the nominal number of phones is not exceeded, a single cluster might be inadequate.

Another complexity arises from the fact that each product is rarely used just by itself. Most products are used as part of a larger deployment containing other Unified Communications products. For example, Cisco Unity Connection is likely used with Unified CM and gateways. Larger, more complex deployments may consist of several Unified Communications products, including those from the Cisco Contact Center portfolio (Cisco Unified Contact Center Enterprise, Unified Customer Voice Portal, Unified Intelligence Center, and others), which must work with Unified CM, gateways, Cisco Unified MeetingPlace, Cisco Unity Connection voice messaging, and network management applications. Interaction of each of these components on the others must be taken into account. For example, Unified CM might have to manage not only its regular phones but also the ones assigned to agents who can experience much higher call volumes. Also, gateways might have to handle VXML calls in addition to the regular voice calls. All of these interactions must be taken into account for an accurate sizing estimation.

This chapter discusses the sizing of individual Unified Communications components as well as systems consisting of several components communicating with each other. This chapter also discusses the performance impact of the different functions that the various Unified Communications products support, and it explains why "designing by datasheets" is not the preferred way to deploy a complex Unified Communications network. In addition, this chapter provides insights on how to work with the various sizing tools available, mostly notably the Cisco Unified Communications Sizing Tool.

What's New in This Chapter

This chapter is a new addition for this release of the *Cisco Unified Communications System 8.x SRND*. It borrows some information from the capacity planning sections of other chapters in this document, and it goes into greater detail about sizing in the context of the whole system deployment.

[Table 29-1](#) lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

Table 29-1 New or Changed Information Since the Previous Release of This Document

| New or Revised Topic | Described in: | Revision Date |
|---|---|----------------|
| Collaborative conferencing capacity information | Collaborative Conferencing, page 29-39 | July 31, 2012 |
| CTI resources | Applications and CTI, page 29-23 | July 31, 2012 |
| Presence capacity information | Table 29-22 | July 31, 2012 |
| Maximum number of servers per cluster was corrected from 12 to 20 | Server and Cluster Maximums, page 29-18 | April 30, 2012 |

Factors That Affect Sizing

Unified Communications products are designed to be scalable. Capacity of a particular service can generally be increased either by stepping up to a higher-capacity server or by increasing the number of servers. Each product lists the servers it supports and its scalability model. The products also list their tested limits on the servers they support. In theory, one can simply follow these limits and models and come up with the required number of servers for a particular deployment.

In practice, however, sizing is not so simple. For one thing, there are several limits that apply to any deployment. For example, a Unified CM server may be qualified to register 2,500 users and define up to 500 regions. The Unified CM cluster composed of such servers will need more servers if either of these limits is exceeded while the other values are still within limits. Moreover, some of these limits are not absolute but change dynamically based on what else has been configured in the system.

The other major challenge in a sizing exercise is the interaction among components. Unified CM plays a central role in almost all Unified Communications deployments, and it is affected by how customers choose to use other systems. For example, the addition of Cisco Unified MeetingPlace to enable conferencing would tend to concentrate a large number of call setups into a short period (at the beginning of conferencing sessions) and thereby increase the stress on Unified CM during that short period, and this must be accounted for in Unified CM sizing.

Server variations also need to be considered. For example, Unified CM running on a Cisco MCS-7815 or MCS-7816 server is only a standalone entity and may not be clustered. Similarly, different models of Cisco Integrated Service Routers (ISR) have restrictions on the number and types of network modules or Services Ready Engine (SRE) modules they can host.

From a customer perspective, the sizing exercise consists of itemizing all of the functions that are expected in the proposed deployment. Some of these performance factors are obvious, but others are not. For example, one may correctly surmise that the busy hour call attempts (BHCA) that the system is expected to handle is a key factor of performance expectations. But there are nuances even in BHCA that need consideration, such as the types of calls. There are variations in resources consumed by each call type: calls between phones in the same server, calls between two servers in the same cluster, calls between two clusters, and calls that flow to and from the PSTN. Even calls from different types of phones and gateways are different, depending on the protocol and services such as video. The expected

number of phones and users is another example of an obvious factor that would affect sizing. Here again, the type of phones, the number of lines that they are configured with, and whether they are in secure mode, among other things, have an impact on Unified CM sizing.

Because of all these factors and possible variations, a proper sizing exercise is complex and must be well understood, especially for large deployments. This chapter provides guidance on the significant factors that consume resources, and their impact on the system, which must be estimated accurately in order to do a complete and accurate sizing.

Cisco Unified Communications Sizing Tools

You should not expect to be able to perform sizing for complex systems after reading this chapter. On the contrary, manual calculations of all the sizing factors is not practical. However, this chapter will enable you to gain an appreciation of the factors that significantly affect the performance of the system as a whole and that must be accounted for in any sizing effort.

To assist in accurate sizing, Cisco provides several tools that do the calculations based on these significant performance factors. These tools take into account data from testing, individual server performance, advanced and new features in product releases, design recommendations from this SRND, and other factors. The tools allow you to enter specific deployment information, and they apply their sizing algorithms on your supplied data to recommend a set of hardware resources. Obviously, for a desired deployment, this recommendation is only as good as the accuracy of the input data. User guides for the tools contain an explanation of the inputs and how they can best be collected from an existing system or estimated for a system still in the design stage.

The sizing tools are available at <http://tools.cisco.com/cucst> and they include the following:

- Cisco Unified Communications Sizing Tool — Guides users through a complete system deployment consisting of Cisco Unified CM, voice messaging, conferencing, gateways, Cisco intercompany Media Engine (IME), Cisco TelePresence Management Suite (TMS), and Cisco Unified Contact Center components.
- Cisco Unified Communications Manager Session Management Edition (SME) Sizing Tool — A specialized tool that focuses on the specific functions of a Unified CM Session Management Edition deployment.
- Cisco VXi Sizing and Configuration Tool — A specialized tool for sizing the Cisco Virtual Experience Infrastructure (VXI).

Access to the sizing tools is limited to users who have a qualified Cisco login account. For more information on these tools and their access privileges, refer to the *Unified Communications Sizing Tool Frequently Asked Questions (FAQ)*, available at

http://tools.cisco.com/cucst/help/ucst_faq.pdf

Unified Communications Sizing Compared with PBX Sizing

PBX sizing in the past has mostly been about PSTN access trunks. Consequently, the processes for determining how many trunk circuits are required for a given user base and the desired level of service are well documented. Well known models such as the Erlang B, Extended Erlang B, Erlang C, and other models are used for that purpose. However, sizing a Unified Communications system is inherently more complex for the following reasons:

- Unified Communications is not a monolithic system. Rather, it is composed of several servers doing different things but communicating with each other.
- Unified CM performs many more functions and provides many more services than a PBX.

Definition of Terms

The following terms are used throughout this chapter:

Simultaneous Calls

The number of calls that are all active in the system at the same time.

Maximum Simultaneous Calls

The maximum number of simultaneous calls in active (talk) state that the system can handle at one time.

Calls per Second

The call arrival rate, described as the number of calls that arrive (that is, new call setup attempts) in one second. Call arrival rates are also often quoted in calls per hour, but this metric is looser in the sense that 100 calls arriving in the last five seconds of an hour provides an average call arrival rate of 100 calls per hour (which is an extremely low rate for a communications system), while it also provides an arrival rate of 20 calls per second (which is a high rate). Sustaining 20 calls per second for an entire hour would result in 72,000 calls per hour. Therefore calls-per-hour is not a very useful metric for ascertaining a system's ability to handle bursty call arrival traffic patterns.

Busy Hour

The busiest hour of the day when people are most likely to use their phones. This hour varies from organization to organization and from industry to industry. But for most it is likely to be either in the morning (for example, 9AM to 10AM) or in the afternoon (for example, 2PM to 3PM).

Busy Hour Call Attempts (BHCA)

The number of calls attempted during the busiest hour of the day (the peak hour). This is the same as the calls-per-second (cps) rating for the busiest hour of the day, but it is expressed over a period of an hour rather than a second. For example, 10 cps would be equal to 36,000 calls per hour. There is also a metric for Busy Hour Call Completions (BHCC), which can be lower than the BHCA (call attempts) under the assumption that not all calls are successful (as when a blocking factor exists). This chapter assumes 100% call completions, so that $BHCA = BHCC$.

Blocking Factor

The maximum percentage or fraction of call attempts that may be blocked during the busy hour. A blocking factor of 0.0 would mean that the number of circuits is equal to the number of callers, which is unrealistic for most deployments.

Average Hold Time

This is the period of "talk time" on a voice call; that is, the period of time between call setup and tear-down when there is an open speech path between the two parties. A hold time of 3 minutes (180 seconds) is an industry average used for traffic engineering of voice systems. The shorter the hold time on the average call, the greater the percentage of system CPU time spent on setting up and tearing down calls compared to the CPU time spent on maintaining the speech path.

Bursty Traffic

Steady arrival means the call attempts are spaced more or less equally over a period of time. For example, 60 calls per hour at a steady arrival rate would present one call attempt roughly every minute (or approximately 0.02 cps). With bursty arrival, the calls arriving over a given period of time (such as an hour) are not spaced equally but are clumped together in one or more spikes. In the worst case, an arrival rate of 60 calls per hour could offer all 60 calls in a single second of the hour, thus averaging 0 cps for most of the hour with a peak of 60 cps for that one second. This kind of traffic is extremely stressful to communications systems.

Erlang

An Erlang is a unit of measure for communications traffic. It is used to represent the utilization of a resource over a one-hour period. One Erlang means that one resource was used 100% of the hour. This could be due to a single call of one-hour duration or multiple sequential calls whose durations total to one hour. Therefore, if 10 Erlangs are required, it is necessary to have 10 resources to ensure that all traffic is serviced.

Designing for Performance

After analyzing the functional requirements and determining the appropriate products for a Unified Communications system, the next major question is how to design the network so that it is able to adequately deliver acceptable performance as measured by availability, reliability, response time, and quality of service. Can the system cope with the real-time performance requirements, support the desired number of users, and still scale up to meet the increasing needs of the foreseeable future?

To aid the Unified Communications network designers with answers to these questions, Cisco tests each of the products for its performance characteristics. The results are published and broad recommendations are made regarding the size and number of clusters, servers, and other components that should be deployed for supporting the given number of users. To a large extent these test results, combined with the design recommendations in this document, provide sufficient information for most Unified Communications deployments. For others, however, the system designers will need a deeper understanding of how each product works and how users will use it before a viable hardware set can be selected. The selection of such a set can also be complicated by the following concerns that should be addressed:

- System release
- Complexity of the configuration
- Utilization of options such as trace compression, call detail recording (CDR), call management record (CMR) generation, and so forth
- Interaction between individual products
- Anticipated growth
- Use of external applications
- Average and peak usage

Quantitative Analysis of Performance

Testing for performance analyzes the product under test for a set of basic functions it is designed to perform. For example, Unified CM performs many functions and each function requires a finite amount of CPU and memory. Unified CM handles endpoint registrations, user initiated calls, database queries, and many other functions. Performance testing involves testing of each of these basic functions in isolation, measuring the computing resources that are utilized as these functions are executed in an increasing volume.

A quantitative analysis of the performance characteristics of a software system given the hardware platform is done in a series of tests that aim to determine the linear range of the system operations. A linear range is where the amount of resources used and the throughput achieved vary in direct proportion with each other. This range is critical because, if the system does not exhibit linear behavior, its performance is unpredictable. Most systems exhibit linearity within a certain range, beyond which the system's performance becomes unpredictable. Therefore, the design must ensure that the system operates within the parameters of the linear range.

Conversely, putting together a system for deployment consists of decomposing the requirements into sets of basic functions, comparing them against the published test results, and determining the set of servers that meets the performance needs in their linear range of operation.

Performance Modeling of Computer Systems

The first step in determining how much a computer system can accomplish is to itemize the various tasks it is called upon to perform. For example, Unified CM may be required to do all of the following tasks:

- Initialize configured values such as those for endpoints, directory numbers, dial plans, and so forth.
- Perform endpoint registrations, which requires handling the initial registration messages, looking up databases to find their configuration information, and creating configuration files for the endpoints to download.
- Maintain endpoint registrations by handling periodic registration messages
- Handle new call requests, which can be a fairly complex process consisting of ensuring user entitlement, analyzing dialed digits, determining the destination (either another phone, gateway, or trunk), assembling the correct signaling based on rules stored in the database, and transmitting and receiving call signaling messages.
- Provide mid-call feature requests such as transfer and conference.
- Offer user management and requests for functions such as Do Not Disturb, Call Forward, and so forth.

Each of the functions that a computer system performs requires it to spend some of its resources consisting of CPU, memory, and disk I/O.

The linear operating range of the system under test is determined by subjecting the system to a battery of tests. Some tests that attempt to find this range are described in this section. From this linear range of operation, the cost incurred in terms of CPU, memory, and disk I/O can be determined for each incremental unit of the operation.

For example, memory utilization of each additional endpoint of a certain type can be determined from the slope of the line depicting the amount of memory used for a range of endpoints. Similarly, memory utilization for each registering endpoint and for each additional call can be quantified by using the same techniques.

Memory Usage Analysis

Two types of memory usage are identified in the system: static and dynamic. Static memory is defined as the amount of memory that is in use even when there is zero call traffic. This usage of memory arises from configuration data, registration of endpoints, and other factors. Dynamic usage of memory results from call activity. Each active call requires its context to be saved, which results in a certain amount of memory being utilized for the duration of the active call. Thus, whereas static memory is a function of the number of endpoints, dynamic memory is a function of the number of concurrent calls, which itself is a function of the call rate (calls per second) and the average hold time (AHT) per call.

In practice, system memory is also required by the operating system (OS) and by other processes, so the net memory available for operations (static and dynamic memories) is somewhat less than the total memory available on the platform. In addition, some memory is needed for other processes and services running in the system and for any unforeseen spikes in usage.

Figure 29-1 shows the results of a test conducted to determine the memory requirements for configuring one-line phones. It shows the memory consumed by simply configuring 1500, 4500, and 7500 IP phones in Unified CM. Linear regression techniques are used to draw a trend line through the data points. The equation of this trend line is then determined, as is the correlation coefficient R^2 . A correlation coefficient of 1 or very close to it (at least 0.99) indicates that the trend is linear and that the equation of the trend line is valid and may be used to predict the dependent variable (in this case memory) based on the control variable (the number of phones).

Figure 29-1 Memory Required for Configuration of One-Line Phones

In this particular experiment the R^2 value is extremely close to 1 (discounting small errors in measurement) and the equation for the trend line is valid. From the equation we can derive that the memory consumed with no phones is 452,394 Kbytes (the Y-intercept) and that each additional one-line phone configured in the system consumes 8.91 Kbytes.

Figure 29-2 depicts the memory requirements for configuring six-line phones. In this chart R^2 is actually equal to 1, indicating that the trend line is a valid model. From the equation we can determine that configuring each six-line IP phone consumes approximately 33 Kbytes of memory.

Figure 29-2 Memory Required for Configuring Six-Line Phones

The other component that makes up the static memory – the memory required for registration of phones – can also be estimated in the same manner. Figure 29-3 shows the tested, measured, and plotted memory requirements for configuring and registering 1500, 4500, and 7500 phones, each with six lines. Note that R^2 is close enough to 1 to make the trend line a valid model. From the equation we can determine that registration of each six-line IP phone consumes approximately 128 Kbytes of memory.

Figure 29-3 Memory for Configuration and Registration of Six-Line Phones

Static memory also includes other configuration items such as partitions, translation patterns, route lists and groups, as well as memory used for CTI and other applications.

Another type of memory called the dynamic memory is defined as the memory used for active calls. In contrast to static memory, which stays allocated all the time, dynamic memory is allocated for each call attempt and remains only until the end of the call. [Figure 29-4](#) shows how the memory is utilized for 180, 540, and 900 active calls on one subscriber node of the Unified CM cluster. The graph shows that the trend line is a good fit and that approximately 294 Kbytes are used for each active call.

Figure 29-4 Memory Consumption Per Active Call

The preceding graphs and analysis are indicative of how memory is measured in the system. From a set of these observations, data may be interpolated that can start to build a memory model for various activities going on in the system. For example, we can estimate:

- Incremental memory required for configuring each additional line
- The maximum number of calls that can exist in the system before it runs out of memory and starts paging

A major determinant of dynamic memory usage is the average call holding time (ACHT), which is the average duration of each call. A longer ACHT means that more memory will be used in the system because there will be a larger number of active calls present at any time.

The description provided in this section has been simplified. Further complexities arise from the variety of phones that can be configured on Unified CM with different protocols, capabilities, security status, and other variables. Each of these variants is tested and analyzed. Furthermore, each of these variables depends on the software release, which could add improvements and new features. For active call measurements, the various types of calls that can be made between different destinations, such as between two SCCP phones or between a SIP phone and an MGCP gateway, is also considered.

CPU Usage Analysis

Analysis of CPU usage follows the methodology used for memory analysis. While there is some CPU activity even when there are no calls being initiated or terminated, most of the CPU utilization occurs during the process of setting up or tearing down calls. Therefore, one of the key determinants of CPU usage is the call rate.

There are significant differences between the types of calls being made. Calls can originate and terminate within the same server, or they can be made between two servers. Calls can also originate from the Unified CM cluster and travel across a gateway or a trunk. All of these different call activity types impact the CPU differently, so it is important to consider them carefully.

Figure 29-5 shows CPU utilization as measured at 1, 3, and 5 calls per second. Because the trend line is linear, we can conclude that the CPU processing cost required to process one incoming call each second is about 1%.

Figure 29-5 CPU Consumption Per Call Setup

As with memory analysis, CPU usage involves many complexities that must also be considered. For example, CPU usage analysis must account for different costs of terminating and originating calls, different protocols, whether the calls are secure or not, and so forth. CPU usage also depends on whether or not the configuration database is complex or relatively simple, whether CDRs and/or CMRs are being generated, whether detailed tracing is being used, and so forth.

Whereas incremental memory usage is fairly independent of the actual server platform, CPU usage will vary substantially with the actual hardware being tested. Therefore, the same tests must be repeated on all servers that are supported.

Other CPU-intensive call operations such as call transfers, conferences, media resource functions such as MTP or music on hold, and so forth, should also be considered when sizing CPU resources.

Shared lines also consume CPU resources. Not only do shared lines count as extra lines on the phones that share DNs, but each call from or to any of the shared line phones is reflected on all of the other phones as well.

Fundamentals of Voice Traffic Engineering

Traffic engineering is the science of determining an optimum number of resources given the key usage data. In telephony this user data includes the busy hour call attempts (BHCA) and the average hold time (AHT). The BHCA measures all the calls that an average user initiates or receives during the busiest hour of the day. The AHT measures the time that the user spends on the phone for each initiated or received call. An individual's BHCA, when multiplied by the number of users, gives the volume of calls that the system must be able to handle. Once we have the total BHCA and the AHT, we can calculate the Erlang value that the system should be able to handle. One Erlang is a full hour of telephone conversation. For example, if the system BHCA is 10 and the calls last for 3 minutes each, then the system is being used for a total of 30 minutes and the equivalent Erlang value is 0.5.

Note

This document assumes that traffic follows the Extended Erlang B model with random arrival pattern and that blocked callers make multiple attempts to complete their calls. For a more thorough discussion of the various Erlang models used in the industry, refer to the information at <http://www.erlang.com/calculator/>.

While this analysis reveals the total BHCA that the system must be able to handle at the given AHT, another key piece required for analysis is the blocking factor. It is well understood that deploying a telephony system that has enough capacity for all of the users to be on the phone all of the time would be prohibitively expensive, especially for larger systems. It follows, therefore, that if more than a certain number of callers try to access the system at the same time, some callers will necessarily be blocked. A key decision in system deployment is how many over-the-limit callers may be blocked during peak calling times. The amount of resources required for providing a smaller probability of being blocked, say 0.01 or 1%, would be more than the amount required to provide a blocking factor of 0.1 or 10%.

The Erlang value and the blocking factor are useful for calculating the amount of shared resources that must be provisioned in the system. For example, with these pieces of information one can figure out how many DS0s will be required on gateways for a system that has a given number of Erlangs of through traffic with the required blocking factor. This is generally done through an Erlang calculator or lookup tables. The number of required DS0s would increase with the number of Erlangs and decrease with an increase in the blocking probability.

Table 29-2 illustrates the relationship between number of circuits, blocking probability, and busy hour traffic.

Table 29-2 Erlang C Traffic Table (Maximum Offered Load)

| Number of Circuits | Blocking Probability | | | | | | | |
|--------------------|----------------------|--------|--------|--------|--------|--------|--------|--------|
| | 0.01% | 0.05% | 0.1% | 0.5% | 1.0% | 2.0% | 5.0% | 10.0% |
| 1 | 0.0001 | 0.0005 | 0.0010 | 0.0050 | 0.0100 | 0.0200 | 0.0500 | 0.1000 |
| 2 | 0.0142 | 0.0319 | 0.0452 | 0.1025 | 0.1465 | 0.2103 | 0.3422 | 0.5000 |
| 3 | 0.0860 | 0.1490 | 0.1894 | 0.3339 | 0.4291 | 0.5545 | 0.7876 | 1.0400 |
| 4 | 0.2310 | 0.3533 | 0.4257 | 0.6641 | 0.8100 | 0.9939 | 1.3190 | 1.6530 |
| 5 | 0.4428 | 0.6289 | 0.7342 | 1.0650 | 1.2590 | 1.4970 | 1.9050 | 2.3130 |

From Table 29-2 we can determine the following information:

- The number of Erlangs that the system can handle increases with the number of circuits and with the blocking factor. Whereas the first relationship is obvious, the second can be understood by realizing that a greater number of calls are being blocked.
- Given an Erlang requirement of 0.50 and a blocking factor of 0.1%, the system would need 5 circuits.
- Assuming we have 5 circuits and a blocking factor of 1%, there would be 1.259 Erlangs available. It then follows that if we have 10 users, each user can talk for $(1.259 * 3600 / 10) = 453.24$ seconds during the busy hour.

**Note**

Specifically for Cisco Unified Contact Center deployments, there might be other resources that have to be sized according to the same principles. For example, requirements for the number of interactive voice response (IVR) ports and agents are modeled using similar quantitative analysis. Some of the considerations here besides average hold time and BHCA include time waiting in queues and other factors, which means that a higher number of DS0 circuits will be required. For a full description, refer to the *Cisco Unified Contact Center Enterprise SRND*, available at http://www.cisco.com/en/US/products/sw/custcosw/ps1844/products_implementation_design_guides_list.html.

Sizing by Product

This section discusses significant factors that influence sizing of the following individual products and describes how these individual products influence the sizing considerations of other products in the system deployment:

- [Cisco Unified Communications Manager Express, page 29-14](#)
- [Cisco Business Edition, page 29-14](#)
- [Cisco Unified Communications Manager, page 29-18](#)
- [Cisco Unified CM Megacluster Deployment, page 29-30](#)
- [Cisco Unified CM Session Management Edition, page 29-30](#)
- [Cisco Intercompany Media Engine, page 29-31](#)
- [Emergency Services, page 29-32](#)
- [Media Resources, page 29-28](#)
- [Gateways, page 29-32](#)
- [Voice Messaging, page 29-38](#)
- [Collaborative Conferencing, page 29-39](#)
- [Cisco Unified Presence, page 29-45](#)
- [Cisco Unified Communications Management Suite, page 29-46](#)

Cisco Unified Communications Manager Express

Cisco Unified Communications Manager Express (Unified CME) runs on one of the Cisco IOS Integrated Services Router (ISR) platforms, from the low-end Cisco 1861 ISR to the high-end Cisco 3945E ISR 2. Each of these routers has an upper limit on the number of phones that it can support. The actual capacity of these platforms to do call processing may be limited by the other functions that they are performing, such as IP routing, Domain Name System (DNS), Dynamic Host Control Protocol (DHCP), and so forth.

Unified CME can support a maximum of 450 endpoints on a single Cisco IOS platform; however, each router platform has a different endpoint capacity based on the size of the system. Because Unified CME is not supported within the Cisco Unified Communications Sizing Tool, it is imperative to follow the capacity information provided in the Unified CME product data sheets available at

http://www.cisco.com/en/US/products/sw/voicesw/ps4625/products_data_sheets_list.html

Cisco Business Edition

The three models of Cisco Business Edition – Business Edition 3000, 5000, and 6000 – offer different capacities measured in terms of number of users, number of endpoints, and maximum call volumes. [Table 29-3](#) describes the pertinent performance characteristics of the three models.

Table 29-3 Capacities of Cisco Business Edition Models

| Model | Maximum Number of Users | Maximum Number of Endpoints | Maximum BHCA |
|----------------------------------|-------------------------|-----------------------------|--------------|
| Business Edition 3000 (MCS 7816) | 300 | 400 | 2,200 |
| Business Edition 5000 (MCS 7828) | 500 | 575 | 3,600 |
| Business Edition 6000 (UCS C200) | 1,000 | 1,200 | 5,000 |

Busy Hour Call Attempts (BHCA) for Cisco Business Edition

As shown in [Table 29-3](#), Business Edition 3000 supports a maximum of 2,200 BHCA, Business Edition 5000 supports a maximum of 3,600 BHCA, and Business Edition 6000 supports a maximum of 5,000 BHCA. When calculating your system usage, stay at or below the BHCA maximum shown in [Table 29-3](#) to avoid oversubscribing Cisco Business Edition.

The BHCA consideration becomes significant when the usage for any phone is above 4 BHCA. A true BHCA value can be determined only by taking a baseline measurement of usage for the phone during the busy hour. Extra care is needed when estimating this usage without a baseline.

Device Calculations for Cisco Business Edition

Devices can be grouped into two main categories for the purpose of this calculation: phone devices and trunk devices.

A phone device is a single callable endpoint. It can be any single client device such as a Cisco Unified IP Phone 7900 Series, a software client such as Cisco IP Communicator, an analog phone port, or an H.323 client. While Cisco Business Edition supports a maximum number of endpoints as indicated in [Table 29-3](#), actual endpoint capacity depends on the total system BHCA.

**Note**

Business Edition 3000 supports a limited set of endpoints. For a list of the supported endpoints, refer to the *Administration Guide for Cisco Business Edition 3000*, available at http://www.cisco.com/en/US/products/ps11370/prod_maintenance_guides_list.html.

A trunk device carries multiple calls to more than one endpoint. It can be any trunk or gateway device such as a SIP trunk, a gatekeeper-controlled H.323 trunk, or in the case of Business Edition 3000 an MGCP backhauled PRI trunk.

Business Edition 5000 and 6000 both support intercluster trunking as well as H.323, SIP, and MGCP trunks or gateways and analog gateways. However, Business Edition 3000 does not support intercluster trunking. Business Edition 3000 trunk and gateway support is limited to the Cisco 2901 Integrated Services Router (ISR) for MGCP PSTN connectivity over a maximum of two E1/T1 PRIs. Business Edition 3000 also supports the Cisco VG224 Analog Voice Gateway for analog phones.

The method for calculating BHCA is much the same for both types of devices, but trunk devices typically have a much higher BHCA because a larger group of endpoints is using them to access an external group of users (PSTN or other PBX extensions).

You can define groups of devices (phone devices or trunk devices) with usage characteristics based on BHCA, and then you can add the BHCA for each device group to get the total BHCA for the system, always ensuring that you are within the supported BHCA maximum specified in [Table 29-3](#).

For example, you can calculate the total BHCA for 100 phones at 4 BHCA each and 80 phones at 12 BHCA each as follows:

100 phones at 4 BHCA is $100 * 4 = 400$

80 phones at 12 BHCA is $80 * 12 = 960$

Total BHCA = $(100 * 4) + (80 * 12) = 1,360$ BHCA for all phones

For trunk devices, you can calculate the BHCA on the trunks if you know the percentage of calls made by the devices that are originating or terminating on the PSTN. For this example, if 50% of all device calls originate or terminate at the PSTN, then the net effect that the device BHCA (1360 in this case) would have on the gateways would be 50% of 1360, or 680 BHCA. Therefore, the total system BHCA for phone devices and trunk devices in this example would be:

Total system BHCA = $1,360 + 680 = 2,040$ BHCA

If you have shared lines across multiple phones, the BHCA should include one call leg (there are two call legs per each call) for each phone that shares that line. Shared lines across multiple groups of devices will affect the BHCA for that group. That is, one call to a shared line is calculated as one call leg per line instance, or half (0.5) of a call. If you have different groups of phones that generate different BHCA values, use the following method to calculate the BHCA value:

Shared line BHCA = $0.5 * (\text{Number of shared lines}) * (\text{BHCA per line})$

For example, assume there are two classes of users with the following characteristics:

100 phones at 8 BHCA = 800 BHCA

150 phones at 4 BHCA = 600 BHCA

Also assume 10 shared lines for each group, which would add the following BHCA values:

10 shared lines in the group at 8 BHCA = $0.5 * 10 * 8 = 40$ BHCA

10 shared lines in the group at 4 BHCA = $0.5 * 10 * 4 = 20$ BHCA

The total BHCA for all phone devices in this case is the sum of the BHCA for each phone group added to the sum of the BHCA for the shared lines:

$$800 + 600 + 40 + 20 = 1,460 \text{ total BHCA}$$

Note that the total BHCA in each example above is acceptable because it is below the system maximum BHCA as shown in [Table 29-3](#).

If you are using Cisco Unified Mobility for Mobile Connect (also known as single number reach, or SNR) on Business Edition 5000 or 6000, or if you are using the Reach Me Anywhere feature (also SNR), keep in mind that calls extended to remote destinations or off-system phone numbers affect BHCA. In order to avoid oversubscribing the appliance, you have to account for this SNR remote destination or off-system phone BHCA. To calculate the BHCA for these SNR features, see [Capacity Planning for Cisco Unified Mobility, page 25-63](#), and add that value to your total BHCA calculation.

**Note**

Media authentication and encryption using Secure RTP (SRTP) impacts the system resources and affects system performance. If you plan to use media authentication or encryption, keep this fact in mind and make the appropriate adjustments. Typically, 100 IP phones without security enabled results in the same system resource impact as 90 IP phones with security enabled (10:9 ratio).

**Note**

Cisco Business Edition 3000 does not support media authentication or encryption.

Another aspect of capacity planning to consider for Cisco Business Edition is call coverage. Special groups of devices can be created to handle incoming calls for a certain service according to different rules (top-down, circular hunt, longest idle, or broadcast). This is done through hunt or line group configuration within Cisco Business Edition. BHCA can also be affected by this factor, but only as it pertains to the line group distribution broadcast algorithm (ring all members). For Business Edition, Cisco recommends configuring no more than three members of a hunt or line group when a broadcast distribution algorithm is required. Depending on the load of the system, doing so could greatly affect the BHCA of the system and possibly oversubscribe the platform's resources. The number of hunt or line groups that have a distribution algorithm of broadcast should also be limited to no more than three.

Business Edition 5000 with Cisco Unified Contact Center

For this example, assume that Cisco Unified Contact Center Express (Unified CCX) is integrated with Business Edition 5000 and that the system has the following characteristics:

- The required specification is for 15 contact center agents with a maximum of 30 calls per hour during the busiest hour.
- There are 96 non-agent users with average usage of 4 BHCA, and each user has the ability to configure one remote destination for single number reach with Cisco Unified Mobility.
- There are 36 non-agent users with heavy usage of 10 BHCA, and each also has the ability to configure one remote destination for single number reach.
- There are 20 extra shared lines, 10 of which are shared across 10 users from the average usage pool as well as 10 in the heavy usage pool.
- There are 7 T1 trunks (allowing for up to 161 simultaneous calls) with a total of 1200 BHCA across all trunks.

**Note**

Cisco Business Edition 5000 is not supported with Cisco Unified Contact Center Enterprise.

**Note**

This example groups the BHCA for all gateway trunks into a single total trunk BHCA value. This method would be typical for a single-site deployment. However, in a multisite deployment, the various sites' trunks could have different BHCA requirements and thus require different BHCA groupings.

The BHCA calculations for this system are as follows:

15 contact center agents at 30 BHCA = 450 BHCA

96 average-usage users at 4 BHCA = 384 BHCA

36 heavy-usage users at 10 BHCA = 360 BHCA

10 shared lines in the 4 BHCA group = 20 BHCA

10 shared lines in the 10 BHCA group = 50 BHCA

Total of 1200 BHCA for all T1 trunks = 1200 BHCA

One remote destination for single number reach across each of the 96 average-usage users at 4 BHCA = 192 BHCA. (See [Capacity Planning for Cisco Unified Mobility, page 25-63](#), for details on this calculation.)

One remote destination for single number reach across each of the 36 heavy-usage users at 10 BHCA = 180 BHCA. (See [Capacity Planning for Cisco Unified Mobility, page 25-63](#), for details on this calculation.)

Total BHCA for all endpoint devices in this case is:

$$(450 + 384 + 360 + 20 + 50 + 192 + 180 + 1200) = 2,836 \text{ BHCA}$$

This level of usage is acceptable because it is below the system maximum of 3,600 BHCA, and it allows for future growth of approximately 800 BHCA.

This sizing example applies exclusively to Business Edition 5000. Business Edition 3000 is not capable of trunking to Unified Contact Center deployments. Business Edition 6000 runs Unified Contact Center Express co-resident; and although sizing considerations are similar, this example is specifically related to Business Edition 5000.

For more information on Cisco Business Edition capacity planning as well as all other Business Edition product information, refer to the following product documentation:

Cisco Unified Communications Manager

Cisco Unified Communications Manager (Unified CM) is the hub of any Unified Communications deployment. It performs the most basic functions and controls endpoints, routes calls, enforces policies, hosts applications, and in general anchors other Unified Communications products such as gateways, Cisco Unity Connection, Cisco Unified MeetingPlace, Cisco Unified Contact Center suite of products, and others. These applications depend on Unified CM to function and in turn affect Unified CM's performance, which must be accounted for in Unified CM sizing.

The following factors affect Unified CM performance and must be considered when sizing a Unified CM deployment:

- Server and cluster maximum capacities
- System-level settings such as database complexity, trace level, and so forth
- Number and types of endpoints that are registered on Unified CM
- Number of users
- Traffic mix
- Dial plan
- Applications within Unified CM (Extension Mobility, WebDialer, and other CTI-enabled applications)
- Media resources hosted by the subscribers using the Cisco IP Voice Media Streaming Application

Server and Cluster Maximums

Although it is not practical to list every minute detail needed to accurately determine the number of Unified CM servers required for a particular sizing calculation, there are certain server and cluster maximums that must be observed, and some of these values change with Unified CM software version:

- Each cluster can support configuration and registration for a maximum of 40,000 secured or unsecured SCCP or SIP phones with Unified CM 8.6(1) and later releases.
- Each cluster can support configuration and registration for a maximum of 30,000 secured or unsecured SCCP or SIP phones with Unified CM 8.5 and earlier releases.
- Two TFTP servers are required if the number of endpoints in the cluster exceeds 1,250.
- Support for CTI connections has improved over the last several releases, and each cluster can support a maximum of 40,000 CTI connections.
- The number of call processing subscribers in a cluster cannot exceed 4, plus 4 standby, for a total of 8 call processing servers. Also, the total number of servers in a cluster, including the publisher, TFTP, and media servers, may not exceed 20.

The following sections describe how each of these components of Unified CM affects its sizing and therefore must be considered in an analysis of a given system description.

Deployment Options

The following deployment options are overall settings that affect all operations in the system, and they are independent of how many endpoints are registered or how many calls are in progress.

Tracing Level

The system supports two tracing levels: default and detailed. When the level is set to detailed, about 20% more CPU resources are required as compared to the default option.

Database Complexity

There is really no one measurement to determine if the database of configuration information in Unified CM should be considered as simple or complex. As a general rule, if you have more than a few thousand endpoints and more than a few hundred dial plan elements such as translation and route patterns, hunt pilots, shared lines, and so forth, then the resulting database should be considered complex. The CPU usage is considerably higher when the underlying database is complex.

Call Detail and Call Management Records

Generation of call detail records (CDR) and call management records (CMR) places a heavier burden on the CPU.

Trace Compression

Beginning with Cisco Unified CM 8.0, traces are always compressed and the compression may not be turned on or off. For earlier releases, turning on compression saves disk space but adds to CPU utilization.

Number of Regions and Locations

Configuration of regions and locations in the Unified CM cluster requires both database and static memory. The number of gateways that can be defined in the cluster is also tied to the number of locations that can be defined. [Table 29-4](#) lists these limits for some of the Unified CM server platforms.

Table 29-4 Maximum Number of Regions, Locations, Gateways, and Trunks

| Server Platform | Maximum Number of Regions | Maximum Number of Locations | Maximum Number of Trunks and Gateways |
|--|---------------------------|-----------------------------|---------------------------------------|
| MCS-7815 and 7816 | 100 | 100 | 110 |
| MCS-7825 | 1,000 | 1,000 | 1,100 |
| MCS-7835 or Open Virtualization Archive (OVA) equivalent | 1,000 | 1,000 | 1,100 |
| MCS-7845 or OVA equivalent | 2,000 | 2,000 | 2,100 |

Whether or not you can actually define the maximum number of locations and regions in a cluster depends on how "sparse" your codec matrix is. If you have too many non-default values in the inter-region codec setting, you might not be able to scale the system to its full capacity for regions and locations. As a general rule, the change from default should not exceed 10% of the maximum number.

High Availability

Deploying redundant servers increases the number of total servers required in the solution. After figuring out the minimum number of servers required for the specified deployment, add the desired number of subscriber servers. Redundancy options are described in the chapter on [Unified Communications Deployment Models, page 5-1](#). Note that some servers do not lend themselves well to redundancy.

Number of Servers per Cluster

A cluster may be configured to consist of from one to four subscriber pairs. Reducing the number of subscriber pairs per cluster may increase the number of clusters, and hence the number of total servers, required for a given sizing analysis. An increase in the number of clusters can sometimes be desirable if the deployment consists of geographically distributed equally large locations or if any cluster-wide limit is forcing a new cluster even if the per-server utilization is low.

Choice of Servers and UCS Platforms

Unified CM is supported on a variety of Cisco Media Convergence Server (MCS) and Unified Computing System (UCS) platforms. For defining the Unified CM Virtual Machine on a UCS platform, Cisco provides Open Virtualization Archive (OVA) templates that can be loaded onto the hypervisor. Different templates specify different capacities. For example, the 10000 template defines a virtual machine with 4 virtual CPUs, 6 GB of RAM, and 160 GB of hard disk space that has a maximum capacity of serving up to 10,000 endpoints. There are similar templates defined for 1000, 2500, and 7500 endpoints as well.

The formal definitions of the OVA templates for Unified CM and other Unified Communication products are available at

[http://docwiki.cisco.com/wiki/Unified_Communications_Virtualization_Downloads_\(including_OVA/OVF_Templates\)](http://docwiki.cisco.com/wiki/Unified_Communications_Virtualization_Downloads_(including_OVA/OVF_Templates))

**Note**

Choice of placement of virtual machines running Unified CM and other Unified Communications products can have an impact on performance and availability. For a discussion of these and other considerations for Unified Communications on UCS deployments, refer to the documentation at <http://www.cisco.com/go/uc-virtualized>.

Endpoints and Users

The type and number of endpoints are an important part of the net load that the system must support. There are different types of endpoints, and each type imposes a different load on the Unified CM. Endpoints can be differentiated by:

- Digital (IP) or analog (using an adaptor)
- Software-based or hardware
- The protocol they support (SIP or SCCP)
- Whether they are configured with security
- Dialing modes (en-bloc or overlap)
- Audio only or both audio and video
- Other devices such as gateways (H.323 or MGCP)

Each type of endpoint defined in the system uses system resources – for example, static memory just by being defined and registered, and CPU and dynamic memory based on its call rate. Each endpoint could also place additional load on Unified CM by running applications interacting with services running inside of Unified CM.

There are defined maximum supported quantities of endpoints for a given server, as shown in [Table 29-5](#). Note that these values are guidelines only, and it is possible that the system may not be able to support these maximum amounts because of other applications running in the deployment.

Table 29-5 Maximum Number of Endpoints Per Server Platform or OVA Template

| Server Platform Characteristics | Maximum Endpoints per Server or OVA Template | High-Availability Server |
|---|--|--------------------------|
| Cisco MCS 7845-I3 or OVA equivalent | 10,000 | Yes |
| Cisco MCS 7845 (All other supported models) or OVA equivalent | 7,500 | Yes |
| Cisco MCS 7835 (All supported models) or OVA equivalent | 2,500 | Yes |
| Cisco MCS 7825 (All supported models) or OVA equivalent | 1,000 | No |
| Cisco MCS 7816 (All supported models) | 500 | No |
| Cisco MCS 7815 (All supported models) | 300 | No |

The designation of High Availability in [Table 29-5](#) indicates whether those servers may be paired for high availability within a cluster consisting of those servers.

Some endpoints may operate in one of two modes. Endpoints such as Cisco Unified Personal Communicator and those based on Common Services Framework (CSF), such as Cisco WebEx Connect, Cisco UC Integration™ for Microsoft Lync, and others, can work either as soft-phones registered directly with Unified CM as phones, or in desk-phone control mode where they act as applications that use CTI to communicate with Unified CM to control a desk phone. Either way, they use Unified CM resources (endpoints or CTI applications) but count against different operating limits.

Along with the endpoints, the number of busy hour users must also be taken into account. The number of users and their collective usage of the endpoints determine the call processing load on the system.

Call Traffic

Next to the number of endpoints, the quantity and quality of call traffic places the second biggest requirement on Unified CM. It is important to differentiate between call types because call origination and termination are considered as distinct events in the half-call model. A single server needs to handle both halves for calls made between two endpoints registered on it. For calls made between two servers in the same cluster, each of the participating servers needs to handle only half of the call. For calls made between endpoints registered on different clusters, a server and the cluster as a whole need to handle only half of each call. For calls made between an endpoint in a cluster and the PSTN, a PSTN gateway needs to handle half of the call, and these calls form the basis for sizing the gateways themselves.

When considering call traffic, other complexities arise from calls between endpoints that work on different protocols, such as between SIP and SCCP-based phones, if calls are transferred, and if conferencing is invoked.

In general, the following factors require consideration:

- Overall Busy Hour Call Attempts (BHCA) per user
- Average Call Holding Time (ACHT) per call
- BHCA from and to the PSTN using MGCP, H.323, and SIP protocols
- BHCA from and to other clusters using H.323 intercluster trunks or SIP protocols
- BHCA from and to other enterprises using Cisco Intercompany Media Engine (IME)
- BHCA within the cluster

Each different type of call takes a different amount of CPU resources to set up. The rate of call placement, or the BHCA, determines the CPU usage. CPU requirements vary directly with the call placement rate. The ACHT determines the dynamic memory requirements to sustain calls for their duration. A higher ACHT means that more dynamic memory must remain allocated, thus increasing the memory requirement.

Call traffic can arise from other sources as well. Each time a call is redirected in a transfer or to voicemail, it requires processing by the CPU. If a directory number is configured on multiple phones, an incoming call to that number needs to be presented to all of those phones, thus increasing CPU usage at call setup time. As another example, if advanced features such as the Intercompany Media Engine (IME) are being used, calls made using this technology, and the percentage of these calls that need to be redirected to the PSTN because of call quality, must also be accounted for.

Dial Plan

The dial plan in Unified CM consists of static configuration elements that determine call routing and associated policies. In general, dial plan elements occupy static memory space in Unified CM servers, and the following dial plan elements impact the amount of memory required:

- Directory numbers
- Shared directory numbers and the average number of endpoints that share the same DN
- Partitions, calling search spaces, and translation patterns
- Route patterns, route lists, and route groups
- Advertised and learned DN patterns
- Hunt pilots and hunt lists
- Circular, sequential, and broadcast line groups and their membership

There are no hard limits enforced by Unified CM for any of the dial plan elements, but there is only a limited amount of shared system memory available.

Of the above dial plan elements, the number of lines shared across multiple endpoints is of particular interest. Each shared line multiplies the CPU cost of a call setup because the call has to be presented to all the endpoints that share that particular directory number.

Another aspect of a large dial plan that comes into play is the space required to hold the elements of the plan in the Informix Database System. There is only a finite amount of disk space available to hold the entire configuration of Unified CM, and extra-large dial plans can overwhelm it. In this case, the only option may be to break up the dial plan and use its parts in multiple clusters.

Applications and CTI

In the context of Unified CM, applications are the "extra" functions beyond simple call processing provided by Unified CM. In general these applications make use of Computer Telephone Integration (CTI), which allows users to initiate, terminate, reroute, or otherwise monitor and treat calls. Features such as Cisco Unified CM Assistant, Attendant Console, and Contact Center depend on CTI to function.

Historically CTI interactions have been relatively expensive operations in Unified CM that severely limited system scalability, but recent optimizations have reduced their impact on scalability. Although the high-end server platforms for Unified CM 8.6(1) and later releases are able to support CTI for all of their registered devices, the lower-end platforms do not scale that high. [Table 29-6](#) lists the maximum number of CTI resources supported by each type of server platform. These maximum values apply to the following types of CTI resources:

- The maximum number of CTI controlled and/or monitored endpoints that can be registered to a Unified CM subscriber node.
- The maximum number of endpoints that a Unified CM subscriber node running the CTI Manager service can monitor or control.
- The maximum number of TAPI/JTAPI application instances that can connect to a Unified CM subscriber node running the CTI Manager service. The TAPI/JTAPI application instances that can connect to a Unified CM subscriber node running the CTI Manager service are sometimes referred to as CTI connections.

Note that the numbers for the high end of each class of server equal the number of devices that the class can support.

In addition to native applications provided by Unified CM, third-party applications may also be deployed that use Unified CM CTI resources. When counting CTI ports and route points, be sure to account for the third-party applications as well.

Table 29-6 *CTI Resource Limits in Unified CM*

| Server Platform | Maximum CTI Resources per Server |
|--------------------------------|--|
| MCS 7815 | 150 |
| MCS 7816-I2/I3/I4 | 400 |
| MCS 7816-I5 | 500 with Unified CM 8.6 and later releases; otherwise 400 |
| MCS 7825-I1/I2 | 800 |
| MCS 7825-I3/I4 | 900 |
| MCS 7825-I5 and OVA equivalent | 1,000 with Unified CM 8.6 and later releases; otherwise 900 |
| MCS 7835-I1/I2 | 2,000 |
| MCS 7835-I3 and OVA equivalent | 2,500 with Unified CM 8.6 and later releases; otherwise 2,000 |
| MCS 7845-I1 | 2,500 |
| MCS 7845-I2 and OVA equivalent | 5,000 |
| MCS 7845-I3 and OVA equivalent | 10,000 with Unified CM 8.6 and later releases; otherwise 5,000 |

In addition to the maximum number of connections and devices, CTI limits are also influenced by:

- The number of lines on each of the controlled devices (up to 5 lines per controlled device with Unified CM 8.6 and later releases; otherwise up to 2 lines per controller device)
- The number of shared occurrences of a line controlled by CTI (up to 5 per line with Unified CM 8.6 and later releases; otherwise up to 2 per line)
- The number of active CTI applications (up to 5 for any device with Unified CM 8.6 and later releases; otherwise up to 2 for any device)
- A maximum BHCA of 6 per controlled device

The CTI resources available on Unified CM are reduced if any of these values is exceeded.

Table 29-7 lists the number of supported CTI devices for Cisco Business Edition.

Table 29-7 Users and CTI Devices in Cisco Business Edition

| Model | Maximum Number of Users | Maximum CTI Devices |
|-----------------------|-------------------------|---------------------|
| Business Edition 3000 | 300 | 400 |
| Business Edition 5000 | 500 | 575 |
| Business Edition 6000 | 1,000 | 1,200 |

Determining CTI Resources Required for a Unified CM Cluster

Step 1 Determine the total CTI device count.

Count the number of CTI devices that will be in use on the cluster.

Step 2 Determine the CTI line factor.

Determine the CTI line factor of all devices in the cluster, according to Table 29-8.

Table 29-8 CTI Line Factor

| Number of Lines per CTI Device | CTI Line Factor |
|--------------------------------|-----------------|
| 1 to 5 lines | 1.0 |
| 6 lines | 1.2 |
| 7 lines | 1.4 |
| 8 lines | 1.6 |
| 9 lines | 1.8 |
| 10 lines | 2.0 |

Note If there are multiple line factors for the devices within a cluster; determine the average line factor across all CTI devices in the system.

Step 3 Determine the application factor.

Determine the application factor of all devices in the cluster, according to Table 29-9.

Table 29-9 CTI Application Factor

| Number of Applications per CTI Device | CTI Application Factor |
|---------------------------------------|------------------------|
| 1 to 5 applications | 1.0 |
| 6 applications | 1.2 |
| 7 applications | 1.4 |
| 8 applications | 1.6 |
| 9 applications | 1.8 |
| 10 applications | 2.0 |

Step 4 Calculate the required number of CTI resources according to the following formula:

Required Number of CTI Resources = (Total CTI Device Count) * (The greater of the CTI Line Factor or the CTI Application Factor)

The following examples illustrate the process.

Example 1: 500 CTI devices deployed with an average of 9 lines per device and an average of 4 applications per device. According to the factor lists in [Table 29-8](#) and [Table 29-9](#), 9 lines per device renders a line factor of 1.8, while 4 applications per device renders an application factor of 1.0. Applying these values in the formula from [Step 4](#) yields:

$$(500 \text{ CTI Devices}) * (\text{Greater of } \{1.8 \text{ Line Factor or } 1.0 \text{ Application Factor}\})$$

$$(500 \text{ CTI Devices}) * (1.8 \text{ Line Factor}) = 900 \text{ total CTI resources required}$$

Example 2: 2,000 CTI devices deployed with an average of 5 lines per device and an average of 9 applications per device. According to the factor lists in [Table 29-8](#) and [Table 29-9](#), 5 lines per device renders a line factor of 1.0, while 9 applications per device renders an application factor of 1.8. Applying these values in the formula from [Step 4](#) yields:

$$(2000 \text{ CTI Devices}) * (\text{Greater of } \{1.0 \text{ Line Factor or } 1.8 \text{ Application Factor}\})$$

$$(2000 \text{ CTI Devices}) * (1.8 \text{ Application Factor}) = 3,600 \text{ total CTI resources required}$$

Example 3: 5,000 CTI devices deployed with an average of 2 lines per device and an average of 3 applications per device. According to the factor lists in [Table 29-8](#) and [Table 29-9](#), 2 lines per device renders a line factor of 1, while 3 applications per device renders an application factor of 1. Applying these values in the formula from [Step 4](#) yields:

$$(5,000 \text{ CTI Devices}) * (\text{Greater of } \{1 \text{ Line Factor or } 1 \text{ Application Factor}\})$$

$$(5,000 \text{ CTI Devices}) * (1 \text{ Line or Application Factor}) = 5,000 \text{ total CTI resources required}$$

Cisco Extension Mobility and Extension Mobility Cross Cluster

Using Extension Mobility (EM) impacts the system performance in the following ways:

- Creation of EM profiles requires both disk database space and static memory.
- The rate at which users may log into their EM accounts affects both CPU and memory usage. Servers have bounds on the maximum number of logins per minute that they can support.

- Extension Mobility Cross Cluster (EMCC) has a higher impact on resources. There is a limit on the number of EMCC users that a server can support. The maximum EMCC login rates supported are lower than those supported for EM. In addition, there is a trade-off between EM and EMCC login rates. If both are occurring at the same time, then the maximum capacity for each will be reduced.
- EM and EMCC login rates per cluster are not simply the login rate of each server multiplied by the number of servers in the cluster because profiles in a shared database have to be accessed. The maximum login rate in a cluster consisting of more than one call processing subscriber should be limited to 1.5 times that of a single server.

Table 29-10 shows the maximum number of EM and EMCC logins per minute for each type of server.

Table 29-10 EM and EMCC Rates Per Server Type

| Server Types | Maximum EM Login Rate (per Server) | Maximum EM Login Rate (Dual Servers) | Maximum EMCC Login Rate (Per Server) | Maximum EMCC Login Rate (Dual Servers) | Maximum Concurrent EMCC Devices |
|--|------------------------------------|--------------------------------------|--------------------------------------|--|----------------------------------|
| MCS-7815, MCS-7816 | 15 | 22 | 5 | 7 | 100 (MCS-7815) or 167 (MCS-7816) |
| MCS-7825 and OVA equivalent | 200 | 300 | 60 | 70 | 333 |
| MCS-7835 (I2/H2, I3/H3) and OVA equivalent | 235 | 352 | 71 | 80 | 833 |
| MCS-7845 and OVA equivalent | 250 | 375 | 75 | 90 | 2,500 |

Cisco Extension Mobility login and logout functionality can be distributed across a pair of subscriber nodes to increase login/logout cluster capacity. When the EM load is distributed evenly between two MCS 7845-H2/I2 servers, the maximum cluster-wide capacity is 375 sequential logins and/or logouts per minute.

Note

The Cisco Extension Mobility service can be activated on more than two nodes for redundancy purposes, but Cisco supports a maximum of two subscriber nodes actively handling logins/logouts at any given time.

Note

Enabling EM Security does not diminish performance.

The EMCC login/logout process requires more processing resources than intracluster EM login/logout, therefore the maximum supported login/logout rates are lower for EMCC. In the absence of any intracluster EM logins/logouts, Unified CM 8.x supports a maximum rate of 75 EMCC logins/logouts per minute with Cisco MCS 7845-H2/I2 and MCS 7845-I3 servers. Most deployments will have a combination of intracluster and intercluster logins/logouts occurring. For this more common scenario, the mix of EMCC logins/logouts (whether acting as home cluster or visiting cluster) should be modeled for 40 per minute, while the intracluster EM logins should be modeled for 185 logins/logouts when using a single EM login server. The intracluster EM login rate can be increased to 280 logins/logouts per minute when using MCS 7845-H2/I2 or MCS 7845-I3 servers in dual EM server configuration. (See Table 29-10.)

EMCC logged-in devices (visiting phones) consume twice as many resources as any other endpoint in a cluster. The maximum supported number of EMCC logged-in devices is 2,500 per cluster, but this also decreases the theoretical maximum number of other devices per cluster from 30,000 to 25,000. Even if the number of other registered devices in the cluster is reduced, the maximum supported number of EMCC logged-in devices is still 2,500.

Cisco Unified CM Assistant

The Cisco Unified CM Assistant application uses CTI resources in Unified CM for line monitoring and phone control. Each line (including intercom lines) on a Unified CM Assistant or Manager phone requires a CTI line from the CTIManager. In addition, each Unified CM Assistant route point requires a CTI line instance from the CTIManager. When you configure Unified CM Assistant, the number of required CTI lines or connections must be considered with regard to the overall cluster limit for CTI lines or connections.

The following limits apply to Unified CM Assistant:

- A maximum of 10 Assistants can be configured per Manager.
- A maximum of 33 Managers can be configured for a single Assistant (if each Manager has one Unified CM Assistant-controlled line).
- A maximum of 3,500 Assistants and 3,500 Managers (7,000 total users) can be configured per cluster using the Cisco MCS 7845 server.
- A maximum of three pairs of primary and backup Unified CM Assistant servers can be deployed per cluster if the **Enable Multiple Active Mode** advanced service parameter is set to **True** and a second and third pool of Unified CM Assistant servers are configured.

In order to achieve the maximum Unified CM Assistant user capacity of 3,500 Managers and 3,500 Assistants (7,000 users total), multiple Unified CM Assistant server pools must be defined. (For more information, see [Unified CM Assistant, page 19-19](#).)

Cisco WebDialer

Cisco WebDialer provides a convenient way for users to initiate a call. Its impact on Unified CM is fairly limited because extra resources are required only at call initiation and are not tied up for the duration of the call. Once the call has been established, its impact on Unified CM is just like any other call.

The WebDialer and Redirector services can run on one or more subscriber nodes within a Unified CM cluster, and they support the following capacities:

- Each WebDialer service can handle up to 2 call requests per second (7,200 calls per hour) per node.
- Each Redirector service can handle up to 8 call requests per second.

The following general formula can be used to determine the number of WebDialer calls per second (cps):

$$(\text{Number of WebDialer users}) * ((\text{Average BHCA}) / (3600 \text{ seconds/hour}))$$

When performing this calculation, it is important to estimate properly the number of BHCA per user that will be initiated specifically from using the WebDialer service. The following example illustrates the use of these WebDialer design calculations for a sample organization.

Example: Calculating WebDialer Calls per Second

Company XYZ wishes to enable click-to-call applications using the WebDialer service, and their preliminary traffic analysis resulted in the following information:

- 10,000 users will be enabled for click-to-call functionality.
- Each user averages 6 BHCA.

- 50% of all calls are dialed outbound, and 50% are received inbound.
- Projections estimate 30% of all outbound calls will be initiated using the WebDialer service.

Note These values are just examples used to illustrate a WebDialer deployment sizing exercise. User dialing characteristics vary widely from organization to organization.

10,000 users each with 6 BHCA equates to a total of 60,000 BHCA. However, WebDialer deployment sizing calculations must account for placed calls only. Given the initial information for this sizing example, we know that 50% of the total BHCA is for placed or outbound calls. This results in a total of 30,000 placed BHCA for all the users enabled for click-to-call using WebDialer.

Of these placed calls, the percentage that will be initiated using the WebDialer service will vary from organization to organization. For the organization in this example, several click-to-call applications are made available to the users, and it is projected that 30% of all placed calls will be initiated using WebDialer.

$$(30,000 \text{ placed BHCA}) * 0.30 = 9,000 \text{ placed BHCA using WebDialer}$$

To determine the number of WebDialer servers required to support a load of 9,000 BHCA, we convert this value to the average call attempts per second required to sustain this busy hour:

$$(9,000 \text{ call attempts / hour}) * (\text{hour}/3,600 \text{ seconds}) = 2.5 \text{ cps}$$

Each WebDialer service can support up to 2 cps, therefore 2 nodes should be configured to run the WebDialer service in this example. This would allow for future growth of WebDialer usage. In order to maintain WebDialer capacity during a server failure, additional backup WebDialer servers should be deployed to provide redundancy.

Attendant Console

The integration of Cisco Unified CM with the Cisco Unified Department, Unified Business, and Unified Enterprise Attendant Consoles centers on their CTI resource usage. These applications monitor the last 2,000 users to whom the attendant sent calls, thus increasing CTI resource usage. In addition, each call uses a number of CTI route points and ports for greetings, queuing, and so forth.

Media Resources

The Unified CM server, by the virtue of the Cisco IP Voice Media Streaming Application, may be used for certain media functions that can be performed in software only and do not require hardware resources. Unified CM can act as a media termination point (MTP), as a conference bridge, or as a source of music-on-hold streams. Although the capabilities of Unified CM are limited in comparison to similar functions provided by Cisco Integrated Service Routers (ISRs), they are generally the key source of music-on-hold streams (both unicast and multicast).

The Cisco IP Voice Media Streaming Application may be deployed in one of two ways:

- Co-resident deployment

In a co-resident deployment, the streaming application runs on any server (either publisher or subscriber) in the cluster that is also running the Unified CM software.

Note The term *co-resident* refers to two or more services or applications running on the same server.

- Standalone deployment

A standalone deployment runs the streaming application on a dedicated server within the Unified CM cluster. That is, the Cisco IP Voice Media Streaming Application service is the only service enabled on the server. The sole function of this dedicated server is to provide media resources to devices within the network.

While the Cisco IP Voice Media Streaming Application provides MTP, announcement, and conferencing capabilities, you might find it more scalable to place this functionality on external Cisco Integrated Service Routers (ISRs). The music-on-hold functionality of this application is, however, not so easily placed on external sources. [Table 29-11](#) lists the maximum values that may be configured for each of these services.

Table 29-11 Cisco IP Voice Media Streaming Application Capacity Limits

| Service | Maximum Number of Streams |
|-------------------------|---------------------------|
| Annunciator | 400 |
| Conference Bridge | 256 |
| Media Termination Point | 512 |

Note

To calculate the capacities of each of the media functions on the DSPs supported by each individual ISR, refer to the Cisco ISR product data sheets or to the chapter on [Media Resources, page 17-1](#).

Music on Hold

[Table 29-12](#) lists the server platforms and the maximum number of simultaneous music-on-hold (MoH) sessions each can support. You should ensure that the actual usage does not exceed these limits because, once MoH sessions have reached these limits, additional load could result in poor MoH quality, erratic MoH operation, or even loss of MoH functionality.

Table 29-12 Music on Hold Capacity Limits

| Server Platform | Codecs Supported | Maximum Number of MoH Sessions |
|--|--|---|
| MCS 7816 MCS 7825 MCS 7878 and OVA equivalent | G.711 (A-law and mu-law) G.729a Wideband audio | Co-resident or standalone server: 250 MoH sessions |
| MCS 7835 MCS 7845 and OVA equivalent | G.711 (A-law and mu-law) G.729a Wideband audio | Co-resident or standalone server: 500 MoH sessions |

You can define a maximum of 51 unique sources of Music on Hold on a Unified CM cluster. Considering that each MoH source may be streamed in up to four encodings, there can be a maximum of 204 multicast streams in the cluster. The limits described in [Table 29-12](#) apply to any combination of unicast, multicast, or simultaneous unicast and multicast sessions.

Impact on Unified CM

Whether deployed in co-resident or standalone mode, the Cisco IP Voice Media Streaming Application consumes CPU and memory resources. This impact must be considered in the overall sizing of Unified CM. In general, usage of media resources can be considered to add to the BHCA that needs to be processed by Unified CM.

Cisco Unified CM Megacluster Deployment

A Unified CM cluster is considered to be a megacluster when the number of call processing subscribers exceeds the normal maximum of 4 pairs. A megacluster may have up to 8 pairs of call processing subscribers and no more than 21 servers in all.

A Unified Communications deployment can be simplified in certain cases with a Unified CM megacluster. The following limits increase with such a deployment:

- Maximum number of endpoints supported is now twice the number in a normal cluster (up to 80,000 using MCS-7845-I3 or OVA equivalent).
- Maximum number of CTI devices and connections also doubles.

However, some cluster-wide constants do not increase. Chief among these are:

- Size of the configuration database
- Number of locations and regions

Therefore, care should be taken when deciding whether or not to deploy a megacluster.

Cisco Unified CM Session Management Edition

The Session Management Edition (SME) is Unified CM in a specific deployment mode. Thus, all the sizing discussion for Unified CM applies to SME as well. The big distinction is that the call traffic in a pure SME deployment is solely through trunk interfaces rather than through line interfaces. Therefore, sizing an SME cluster is in general a simpler exercise than for Unified CM as a whole.

An SME cluster follows the same guidance as that for a regular Unified CM cluster. A publisher server provides the master configuration repository. A TFTP server may be co-resident with the publisher server if the number of phones or MGCP gateways in the cluster is relatively small. A redundancy ratio of 1:1 is recommended for call processing subscribers.

To size an SME cluster, assess the functionality that it is expected to perform. In a base configuration, the SME acts as a routing aggregation point for a number of leaf clusters. It also provides centralized PSTN access for all of the leaf clusters connected to it. In more advanced configurations, the SME may also host centralized voice messaging, mobility, and conferencing. The performance of the SME is influenced by the type of trunk protocols that the leaf clusters use to connect to it and by the BHCA across these trunks.

The following considerations apply when sizing an SME cluster:

- The various types of trunk interfaces that the cluster services. The following trunk protocols are supported by the SME:
 - SIP
 - H.323
 - MGCP (Q.931)

- SIP (Q.SIG)
- H.323 Annex M1
- MGCP (Q.SIG)
- The number of users that access SME cluster services through each type of trunk interface
- BHCA per user for each trunk interface to leaf clusters for intercluster calls
- BHCA per user for each trunk interface to leaf clusters for off-net (PSTN) calls
- The type of trunk interface used by the SME cluster to connect to the PSTN
- Average holding time for calls
- Number of route and translation patterns

If the SME acts as a service aggregation point, the following relevant sizing parameters come into play as well:

- If using centralized voice messaging, the percentage of calls that are sent to voice mail
- If using mobility, the number of users and the remote destinations per user
- If using conferencing, the conferencing dial-in interval

The performance of the SME is measured as calls per second across each pair of protocols. There are variations across the hardware platforms and software versions.

For SME sizing calculations, use the Cisco Unified CM SME Sizing Tool, available at <http://tools.cisco.com/cucst>.

Cisco Intercompany Media Engine

The sizing of servers used for running the Cisco Intercompany Media Engine (IME) depends solely on the quantity of directory numbers enrolled for the IME service. [Table 29-13](#) lists the capacity of each supported server.

Table 29-13 IME Server Supported Capacities

| Server Platform | Maximum Number of Enrolled DIDs |
|-------------------------------|---------------------------------|
| MCS 7825-I2/H2 and 7825-I4/H4 | 20,000 |
| MCS 7845-I2/H2 and 7845-I3 | 40,000 |

Because all IME call media (audio and video) flow through the IME-enabled Cisco Adaptive Security Appliance (ASA), capacity depends on the type and number of calls flowing through it. The IME-enabled ASA monitors only the audio stream incoming from the internet for voice quality. The video media is not monitored for voice quality, but it does flow through the IME-enabled ASA for RTP-to-SRTP conversion, and the bandwidth of the video directly affects the number of sessions each ASA can handle. [Table 29-14](#) provides capacity limits for the ASA-5550 and ASA-5580. Performance limits of other ASA models have not been validated yet.

Table 29-14 Maximum Number of IME Calls per Type of Call and ASA Model

| ASA Model | Voice G.711 | Video 300 kbps | Video 800 kbps | Video 1 Mbps |
|------------------|-------------|----------------|----------------|--------------|
| ASA-5500 4 GB | 480 Calls | 240 Calls | 120 Calls | 80 Calls |
| ASA-5580-20 4 GB | 900 Calls | 600 Calls | 300 Calls | 200 Calls |

Impact of IME on Unified CM

Unified CM does not have a limit on the number of IME calls it can handle, but IME calls should be factored into the overall call capacity provided by the cluster. In addition, some calls through IME might need to be re-routed mid-call through gateways if the call quality is not considered acceptable. The expected number of calls re-routed this way should be considered both for Unified CM processing and for number of calls through the gateways.

Emergency Services

The Cisco Emergency Responder tracks the locations of phones and the access switch ports to which they are connected. The phones may be discovered automatically or entered manually into the Emergency Responder. Table 29-15 shows the server platforms that support the Emergency Responder and their maximum capacities.

Table 29-15 Cisco Emergency Responder Server Platforms and Capacities

| Server Platform | Maximum Number of Automatically Tracked Phones | Maximum Number of Manually Configured Phones | Maximum Number of Roaming Phones | Maximum Number of Switches | Maximum Number of Switch Ports | Maximum Number of Emergency Response Locations |
|-----------------------------|--|--|----------------------------------|----------------------------|--------------------------------|--|
| MCS-7816 | 6,000 | 1,000 | 600 | 200 | 12,000 | 1,000 |
| MCS-7825 and OVA equivalent | 12,000 | 2,500 | 1,200 | 500 | 30,000 | 3,000 |
| MCS-7835 and OVA equivalent | 20,000 | 5,000 | 2,000 | 1,000 | 60,000 | 7,500 |
| MCS 7845 and OVA equivalent | 30,000 | 10,000 | 3,000 | 2,000 | 120,000 | 10,000 |

The formal definitions of the OVA templates for Cisco Emergency Responder and other Unified Communication products are available at

[http://docwiki.cisco.com/wiki/Unified_Communications_Virtualization_Downloads_\(including_OVA/OVF_Templates\)](http://docwiki.cisco.com/wiki/Unified_Communications_Virtualization_Downloads_(including_OVA/OVF_Templates))

The capacity of Emergency Responder also affects the Unified CM cluster size. There can be only one Emergency Responder active per cluster. Therefore, choose the server that has sufficient resources to provide emergency coverage to all of the phones in the cluster.

For more details on network hardware and software requirements for Emergency Responder, refer to the *Cisco Emergency Responder Administration Guide*, available at

http://www.cisco.com/en/US/products/sw/voicew/ps842/prod_maintenance_guides_list.html

Gateways

The expected traffic in and out of gateways is the key to calculating the number of DS0s required. To calculate this traffic, consider the sources where the traffic can originate and terminate. The endpoints registered to Unified CM are, of course, the major traffic consumers, but there may be others such as interactive voice response (IVR) applications and other parts of a contact center deployment.

In addition to voice call termination, gateways can also perform a variety of other functions that require resources (either CPU and memory or DSP). These functions include media processing such as media termination point (MTP), transcoding, conference bridge, RSVP Agents, and others.

Gateways, especially those based on the Cisco Integrated Service Routers (ISRs), can provide services beyond just terminating PSTN traffic, such as serving as VXML processing engines, acting as border elements, doubling as Cisco Unified Communications Manager Express or Survivable Remote Site Telephony (SRST), or performing WAN edge functions. All of these other activities that the gateway is performing need to be taken into account when calculating the gateway load.

Gateway Groups

When considering the number of gateways, you also need to consider the geographical placement of physical gateway servers. In a deployment model where PSTN access is distributed, you need to size those gateways as a group by themselves and assign the appropriate amount of load to each such group.

A grouping might also be appropriate if certain gateways are expected to be dedicated for certain functions and share common characteristics.

Therefore, to accurately estimate the number of gateways required, the following information is required:

- Groups of gateways that share a common group profile. The common profiles will depend on the complexity of the deployment.
- For each group, the traffic patterns, platform, blocking probability, and so forth, that make up the profile.
- The individual gateway platform that makes up the group. In deciding on a particular gateway model, ensure that the model can support the capabilities and the capacity that is expected of it. Note that more than one gateway might be required in a gateway group, depending on the ability of the selected platform to meet the performance requirements.

PSTN Traffic

The discussion on voice traffic analysis earlier in this chapter ([Call Traffic, page 29-21](#)) is particularly pertinent to gateways in deciding the number of PSTN circuit DSOs that are required for time-division multiplexing (TDM) voice termination. Because there are likely to be fewer PSTN circuits than the number of system users, a decision has to be made about the optimum number of such circuits, and consequently the DSP requirements, for the gateways. The blocking factor determines the percentage of calls that may not be serviced at peak traffic levels. A smaller blocking factor requires more circuits.

Traffic is measured in Erlangs, and an Erlang is defined as one call lasting for one hour. This section does not go into any further detail on Erlangs other than to say that there are mathematical tables (Erlang-B and Erlang-C) that are used to calculate how many circuits are required for a given amount of offered traffic.

The amount of traffic received and generated by your business determines the size of the external circuits required. However, many customers typically continue to use the same number of circuits for their IP-based communications system as they previously used for a TDM-based system. While this sizing method might work if no issues are encountered, the process of ongoing system traffic analysis should be part of any routine maintenance practices. Traffic analysis can show that the system is over-provisioned for the current levels of traffic (and, therefore, the customer is paying for circuits that are not needed) or, conversely, that the system is under-provisioned and might be suffering from occasional blocked and/or lost calls, in which case increasing the number of circuits will remedy the situation.

Normal Business Traffic Profile

Most customers have a normal traffic profile, which means that they typically have two busy hours per day, one occurring during the morning from 10:00 to 11:00 and the other in the afternoon from 14:00 to 15:00. These busy-hour patterns can often be attributed to such things as employees starting the work day or returning from a lunch break. The calls tend to have longer hold times, and they tend to arrive and leave in a steady manner. A generally accepted industry average holding time to use for traffic calculations is 3 minutes.

Assuming that the communications system is engineered with the busy-hour traffic in mind, no issues should arise. Engineering a system below these levels will result in blocked and/or lost calls, which can have a detrimental effect on business.

Contact Center Traffic Profile

Contact centers present somewhat different patterns of traffic in that these systems typically handle large volumes of calls for the given number of agents or interactive voice response (IVR) systems available to service them. Contact centers want to get the most out of their resources, therefore their agents, trunks, and IVR systems are kept busy all the while they are in operation, which usually is 24 hours a day. Call queuing is typical (when incoming call traffic exceeds agent capacity, calls wait in queue for the next available agent), and the agents are usually dedicated during their work shifts to taking contact center calls.

Call holding times in contact centers are often of a shorter average duration than normal business calls. Contributing to the shorter average call holding time is the fact that many calls interact only with the IVR system and never need to speak to a human agent (also termed self-service calls). A representative holding time for self-service calls is about 30 seconds, while a call that talks to an agent has an average holding time of 3 minutes (the same as normal business traffic), making the overall average holding time in the contact center shorter than for normal business traffic.

The goal of contact centers to optimize resource use (including IVR ports, PSTN trunks, and human agents), combined with the fact that contact centers are systems dedicated to taking telephone calls, also presents the system with higher call arrival rates than in a typical business environment. These call arrival rates can also peak at different times of day and for different reasons (not the usual busy hour) than normal business traffic. For example, when a television advertisement runs for a particular holiday package with a 1-800 number, the call arrival rate for the system where those calls are received will experience a peak of traffic for about 15 minutes after the ad airs. This call arrival rate can exceed the average call arrival rate of the contact center by an order of magnitude.

Gateway Sizing for Contact Center Traffic

Short call durations as well as bursty call arrival rates impact the PSTN gateway's ability to process the traffic. Under these circumstances the gateway needs more resources to process all calls in a timely manner, as compared to gateways that receive calls of longer duration that are presented more uniformly over time. Because gateways have varying capabilities to deal with these traffic patterns, careful consideration should be given to selecting the appropriate gateway for the environment in which it will operate. Some gateways support more T1/E1 ports than others, and some are more able than others to deal with multiple calls arriving at the same time.

For a traffic pattern with multiple calls arriving in close proximity to each other (that is, high or bursty call arrival rates), a gateway with a suitable rating of calls per second (cps) is the best fit. Under these conditions, using calls with 15-second hold times, the Cisco AS5400XM Universal Gateway can maintain 16 cps with 250 calls active at once, the Cisco 3845 Integrated Services Router can maintain

13 cps with 200 calls active at once, and the Cisco 3945 Integrated Services Router can maintain 28 cps with 420 calls active at once. The performance of the Cisco AS5350XM Universal Gateway is identical to that of the AS5400XM in terms of calls per second.

For traffic patterns with a steady arrival rate, the maximum number of active calls that a gateway can handle is generally the more important consideration. Under these conditions, using calls with 180-second hold times, the Cisco AS5400XM Universal Gateway can maintain 600 simultaneously active calls with a call arrival rate of up to 3.3 cps, the Cisco 3845 Integrated Services Router can maintain 450 simultaneously active calls with a call arrival rate of up to 2.5 cps, and the Cisco 3945 Integrated Services Router can maintain 720 simultaneously active calls with a call arrival rate of up to 4 cps.

These numbers assume that all of the following conditions apply:

- CPU utilization does not exceed 75%
- PSTN gateway calls are made with ISDN PRI trunks using H.323
- The Real Time Control Protocol (RTCP) timer is set to the default value of 5 seconds
- Voice Activity Detection (VAD) is off
- G.711 uses 20 ms packetization
- Cisco IOS Release 15.0.1M is used
- Dedicated voice gateway configurations are used, with Ethernet (or Gigabit Ethernet) egress and no QoS features. (Using QoS-enabled egress interfaces or non-Ethernet egress interfaces, or both, will consume additional CPU resources.)
- No supplementary call features or services are enabled – such as general security (for example, access control lists or firewalls), voice-specific security (TLS, IPsec and/or SRTP), AAA lookups, gatekeeper-assisted call setups, VoiceXML or TCL-enabled call flows, call admission control (RSVP), and SNMP polling/logging. Such extra call features use additional CPU resources.

Voice Activity Detection (VAD)

Voice Activity Detection (VAD) is a digital signal processing feature that suppresses the creation of most of the IP packets during times when the speech path in a particular direction of the call is perceived to be silent. Typically only one party on a call speaks at a time, so that packets need to flow in only one direction, and packets in the reverse (or silent) direction need not be sent except as an occasional keepalive measure. VAD can therefore provide significant savings in the number of IP packets sent for a VoIP call, and thereby save considerable CPU cycles on the gateway platform. While the actual packet savings that VAD can provide varies with the call flow, the application, and the nature of speaker interactions, it tends to use 10% to 30% fewer packets than would be sent for a call made with VAD turned off.

VAD is most often turned off in endpoints and voice gateways deployed in Unified CM networks; VAD is most often turned on in voice gateways in other types of network deployments.

Codec

Both G.711 and G.729A use as their default configuration a 20 ms sampling time, which results in a 50 packets-per-second (pps) VoIP call in each direction. While a G.711 IP packet (200 bytes) is larger than a G.729A packet (60 bytes), this difference has not proven to have any significant effect on voice gateway CPU performance. Both G.711 and G.729 packets qualify as "small" IP packets to the router, therefore the packet rate is the salient codec parameter affecting CPU performance.

Performance Overload

Cisco IOS is designed to have some amount of CPU left over during peak processing, to handle interrupt-level events. The performance figures in this section are measured with the processor running at an average load of approximately 75%. If the load on a given Cisco IOS gateway continually exceeds this threshold, the following results will occur:

- The deployment will not be supported by Cisco Technical Assistance Center (TAC).
- The Cisco IOS Gateway will display anomalous behavior, including Q.921 time-outs, longer post-dial delay, and potentially interface flaps.

Cisco IOS Gateways are designed to handle a short burst of calls, but continual overloading of the recommended call rate (calls per second) is not supported.

Note

With any gateway, you might be tempted to assign unused hardware ports to other tasks, such as on a Cisco Communication Media Module (CMM) gateway where traffic calculations have dictated that only a portion of the ports can be used for PSTN traffic. However, the remaining ports must remain unused, otherwise the CPU will be driven beyond supported levels.

Performance Tuning

The CPU utilization of a Cisco IOS Voice Gateway is affected by every process that is enabled in a chassis. Some of the lowest level processes such as IP routing and memory defragmentation will occur even when there is no live traffic on the chassis.

Lowering the CPU utilization can help to increase the performance of a Cisco IOS Voice Gateway by ensuring that there are enough available CPU resources to process the real-time voice packets and the call setup instructions. [Table 29-16](#) describes some of the techniques for decreasing CPU utilization.

Table 29-16 *Techniques for Reducing Gateway CPU Utilization*

| Technique | CPU Savings | Description |
|---|-------------|--|
| Enable Voice Activity Detection (VAD) | Up to 20% | Enabling VAD can result in up to 45% fewer voice packets in typical conversations. The difficulty is that, in scenarios where voice recognition is used or there are long delays, a reduction in voice quality can occur. Voice appears to "pop" in at the beginning and "pop" out at the end of talk spurts. |
| Disable Real Time Control Protocol (RTCP) | Up to 5% | Disabling RTCP results in less out-of-band information being sent between the originating and terminating gateways. This results in lower quality of statistics displayed on the paired gateway. This can also result in the terminating gateway having a call "hang" for a longer period of time if RTCP packets are being used to determine if a call is no longer active. |

Table 29-16 *Techniques for Reducing Gateway CPU Utilization (continued)*

| Technique | CPU Savings | Description |
|--|-------------|---|
| Disable other non-essential functions such as: Authentication, Authorization, and Accounting (AAA); Simple Network Management Protocol (SNMP); and logging | Up to 2% | Any of these processes, when not required, can be disabled and will result in lower CPU utilization by freeing up the CPU to provide faster processing of real-time traffic. |
| Change the call pattern to increase the length of the call (and reduce the number of calls per second) | Varies | This can be done by a variety of techniques such as including a long(er) introduction prompt played at the beginning of a call or adjusting the call script at the call center. |

Additional Information

A full discussion of every gateway, its capabilities, and call processing capacities is not possible in this chapter. For more information on Cisco Voice Gateways, refer to the following documentation:

- Various voice traffic calculators, including Erlang calculators:
<http://www.erlang.com/calculator/>

Voice Messaging

Voice messaging is an application that needs to be sized not only by itself but also for its effect on other Unified Communications components, mainly Unified CM.

In sizing hardware for the voice messaging system itself (either Cisco Unity or Cisco Unity Connection), the total number of users in the system should be considered. Other items that impact messaging hardware are as follows:

- Number of calls during the busy hour that the application has to handle
- Average length of messages left on the servers
- Number of users who check their messages during the busy hour
- Average length of user sessions
- Any advanced operations such as voice recognition or text-to-speech sessions
- Any media transcoding
- Ports on the voice messaging system are analogous to the DS0s on a gateway and are shared resources that need to be optimized. The same considerations of probabilistic arrival and the need for blocking apply to both types of resources.

Table 29-17 shows the applicability of the various voice messaging solutions to the scalability requirements of the deployment.

Table 29-17 *Scaling Voice Messaging Solutions*

| Solutions | Maximum Number of Users Supported on a Single Server (Failover or Clustered Deployment) | | | Maximum Number of Users in a Digital Networking Solution | |
|---|---|--------|--------|--|---------|
| | 500 | 15,000 | 20,000 | 100,000 | 250,000 |
| Cisco Unity Express | Y | N | N | Y | Y |
| Cisco Business Edition | Y | N | N | N | N |
| Cisco Unity Connection (unified/integrated messaging) | Y | Y | Y | Y | N |
| Cisco Unity (unified and voice messaging) | Y | Y | N | Y | Y |

Table 29-18 shows the maximum limits of various functions of different servers running Cisco Unity Connection.

Table 29-18 Servers and Capacities for Cisco Unity Connection

| Server Platform | Maximum Number of Ports | Maximum Voice Recognition Sessions | Maximum Text to Speech Sessions | Maximum Number of Voicemail Users |
|-------------------------------|-------------------------|------------------------------------|---------------------------------|-----------------------------------|
| MCS-7825 | 48 | 48 | 48 | 2,000 |
| MCS-7835 | 150 | 150 | 150 | 4,000 |
| MCS-7845 | 250 | 250 | 250 | 20,000 |
| OVA Template for 5,000 users | 100 | 100 | 100 | 5,000 |
| OVA Template for 10,000 users | 150 | 150 | 150 | 10,000 |
| OVA Template for 20,000 users | 250 | 250 | 250 | 20,000 |

The formal definitions of the OVA templates for Cisco Unity Connection and other Unified Communication products are available at

[http://docwiki.cisco.com/wiki/Unified_Communications_Virtualization_Downloads_\(including_OVA/OVF_Templates\)](http://docwiki.cisco.com/wiki/Unified_Communications_Virtualization_Downloads_(including_OVA/OVF_Templates))

Impact on Unified CM

The impact of a voice messaging system on Unified CM can be gauged by considering the extra processing that Unified CM needs to do. These extra call flows add to the sizing load of Unified CM and is as follows:

- Calls that need to be forwarded to the voice messaging system when the user is not present or if the user deliberately forwards the calls using Do Not Disturb (DND) or other features.
- Calls from users who dial the voice messaging pilot number to access their voice messages go through Unified CM, and these calls must be added to the calls being handled by Unified CM, including both the number and the duration of these calls.

Collaborative Conferencing

Like voice messaging, a conferencing system in a Unified Communications environment should be considered not only for the functions it performs but also for its impact to Unified CM.

There are many deployment options possible using a combination of Cisco Unified MeetingPlace, WebEx as Software-as-a-Service (SaaS), WebEx Node for Aggregation Services Router (ASR), and WebEx Node for Media Convergence Server (MCS), to perform audio, video, and content sharing functions. Sizing consideration for a conferencing system can vary significantly based on the selected deployment option. Typically an enterprise would need to size only its on-premises equipment.

A conferencing system may consist of some or all of the following:

- Meeting directors
- Application servers with Express Media Server (EMS)
- Audio blades (optional)
- Video blades (optional)
- MeetingPlace Web servers

When sizing a conferencing system, you typically will have to consider the following parameters to determine the type and number of application servers:

- Number of users who could use the system at any one time
- Number of audio, video, and web users on the system at the peak usage time
- Required dial-in duration
- Whether Cisco WebEx or Unified MeetingPlace will be used to schedule meetings

The following parameters should be considered for determining whether a Hardware Media Server (HMS) is required or if an Express Media Server (EMS) would be sufficient:

- Usage of iLBC or other high-complexity audio codecs. Usage of these codecs would require an HMS.
- Media options such as video continuous presence and echo cancellation. Both of these options need an HMS.

Video usage characteristics such as bandwidth and resolution are an important aspect for the sizing of both kinds of media servers (HMS and EMS).

The capacity of a given Cisco Unified MeetingPlace solution depends on the platform on which the Unified MeetingPlace Meeting Directors, Application servers with EMS or HMS, or WebEx Node for MCS or ASR servers are installed, followed by the capacity of the Unified MeetingPlace Media Servers deployed. For example, with the Unified MeetingPlace Application server installed on a Cisco MCS 7845-I3 (or equivalent) server, voice conferencing can scale to 1,200 ports (G.711) with EMS or 2,000 ports (G.711) with HMS in a single system or conferencing node.

Express Media Server

The Cisco Unified MeetingPlace Express Media Server (EMS) capacity is directly related to codec and video bandwidth because it is installed co-resident with the Unified MeetingPlace Application server. When the Unified MeetingPlace Application server is installed on a Cisco MCS 7835-H2/I2 server, the overall system capacity decreases for both EMS and HMS deployments. Standards-based video as well as G.729 and G.722 audio codecs all affect the capacity of the EMS system. For the detailed capacity numbers, refer to the latest version of the *Planning Guide for Cisco Unified MeetingPlace*, available at

http://www.cisco.com/en/US/products/sw/ps5664/ps5669/products_implementation_design_guides_list.html

The EMS introduces the concept of System Resource Units (SRUs), where the system capacity (or the Total SRUs value) is based on the type of hardware platform on which the Unified MeetingPlace Application Server resides and the speed and number of processors on that system. The system immediately consumes some of these SRUs from the total for normal operation, and it puts the remaining resources in an SRU pool and makes them available for enhanced audio and video features. [Table 29-19](#) shows the number of total SRUs available for enhanced audio and video per supported platform.

Table 29-19 Total System Resource Units per Supported EMS Platform

| Server Platform | Total System Resource Units (SRUs) Available for Enhanced Audio and Video |
|-----------------|---|
| MCS 7835-I3 | 400 |
| MCS 7845-I2/H2 | 500 |
| MCS 7845-I3 | 1,200 |

Table 29-19 Total System Resource Units per Supported EMS Platform (continued)

| Server Platform | Total System Resource Units (SRUs) Available for Enhanced Audio and Video |
|-------------------------|---|
| UCS B200 or C210 Series | 1,200 (with or without Meeting Director co-resident) |
| UCS C200 Series | 500 (2 nodes with redundancy) |

Table 29-20 Number of System Resource Units Consumed for Various Audio Codecs and Video Bandwidths

| Session Type | Number of SRUs Used |
|---|---------------------|
| One G.711 audio port | 1 |
| One G.729 or one G.722 audio port | 6 |
| One video port at 320 kbps ¹ | 1 |
| One video port at 384 kbps | 1 |
| One video port at 768 kbps | 2 |
| One video port at 2,000 kbps | 6 |

1. The lowest rate that is guaranteed for a video license is 320 kbps.

As shown by the data in [Table 29-19](#) and [Table 29-20](#), on an MCS 7845-I3 server handling only G.711 audio calls, the EMS supports 1,200 audio sessions. Alternatively, it supports 600 video sessions at up to 384 kbps with G.711 audio (a video session also consumes SRUs for the audio session).

In Unified CM, the regions setting of the SIP trunk used for call delivery to Unified MeetingPlace can be configured to control the audio codec and video bandwidth of calls sent to the EMS. Understanding the nature and capabilities of the endpoints dialing into Unified MeetingPlace is critical to proper design. For more information on EMS capacity planning, refer to the latest version of the *Planning Guide for Cisco Unified MeetingPlace*, available at

http://www.cisco.com/en/US/products/sw/ps5664/ps5669/products_implementation_design_guides_list.html

Hardware Media Server

The Cisco Unified MeetingPlace Hardware Media Server (HMS) uses some different settings than the EMS. The Global Audio Mode setting in Unified MeetingPlace Application Administration directly affects the voice capacity of Unified MeetingPlace HMS audio blades. The Global Audio Mode can be configured in either of the following ways:

- G.711 and G.729 without Line Echo Cancellation (LEC)

With this configuration setting, a single audio blade in the HMS can support a maximum of 250 voice ports. It would require 8 audio blades to reach the maximum supported system limit of 2,000 concurrent audio sessions.

- G.711, G.722, iLBC, or G.729 with Line Echo Cancellation (LEC)

With this configuration, a single audio blade can support a maximum of 166 voice ports. With 8 audio blades, the maximum supported number of concurrent audio sessions using these additional codecs is 1,328.

The Global Video Mode setting in Unified MeetingPlace Application Administration determines the video capacity of Unified MeetingPlace HMS video blades. The Global Video Mode can be configured in either of the following ways:

- Standard Rate (video call speed up to 384 kbps)
In this mode, a video blade in the HMS can support a maximum of 40 video ports.
- High Rate (video call speed up to 2,048 kbps)
In this mode, a video blade can support a maximum of 20 video ports.

For a complete list of the video formats supported by Unified MeetingPlace, refer to the latest version of the *Compatibility Matrix for Cisco Unified MeetingPlace*, available at

http://www.cisco.com/en/US/products/sw/ps5664/ps5669/products_device_support_tables_list.html

Unified MeetingPlace Hardware Media Servers can be either the Cisco Unified MeetingPlace 3515 or the Cisco Unified MeetingPlace 3545 chassis. The Unified MeetingPlace 3515 is a fixed platform that comes with one audio blade and one video blade pre-installed. The Unified MeetingPlace 3545 is a modular platform consisting of a chassis that supports four audio blades or video blades in various combinations.

Cascading of Audio and Video Blades

If multiple audio blades and video blades are installed in the Unified MeetingPlace 3545, the media server uses virtual cascading to overflow voice and video streams from one audio or video blade to another. The audio blade has built-in cascading ports that do not decrease the audio session capacity. With a single video blade deployed in the Unified MeetingPlace system, all video ports are available for video conferencing. With multiple video blades deployed, the media server will automatically reserve video ports for cascading purposes. For Standard Rate video, 8 video ports are reserved for cascading, leaving 40 video ports available. For High Rate video, 4 video ports are reserved for cascading, leaving 20 video ports available.

Example 29-1 Unified MeetingPlace Audio Conference

A Unified MeetingPlace 3545 Media Server is deployed with two audio blades and two video blades. A meeting is scheduled with 350 audio ports and the Global Audio Mode is configured for G.711 with LEC. In this case:

- The media server allocates 251 ports from the first audio blade, out of which 250 ports are used for audio participants and one port is used for voice cascading or connecting to the second audio blade.
- The media server allocates 101 ports from the second audio blade, out of which 100 ports are used for audio participants and one port is used for voice cascading.

Example 29-2 Unified MeetingPlace Video Conference

A Unified MeetingPlace 3545 Media Server is deployed with two audio blades and two video blades. For this example, assume a meeting is scheduled with 65 video ports and the Global Video Mode is configured for Standard Rate video. In this case:

- The media server allocates 41 ports from the first video blade, out of which 40 ports are used for video participants and one port is used for video cascading or connecting to the second video blade.
- The media server allocates 26 ports from the second video blade, out of which 25 ports are used for video participants and one port is used for video cascading.

Sizing Guidelines for Unified MeetingPlace Audio Conferencing

Cisco recommends the following methods for calculating Unified MeetingPlace audio conferencing capacity:

- Calculation based on average monthly usage

If you know the average voice conferencing usage (average minutes per month), use [Table 29-21](#) to calculate the Unified MeetingPlace audio conferencing capacity.

Table 29-21 Unified MeetingPlace Audio Conferencing Capacity Based on Average Monthly Usage

| Average Monthly Usage (minutes) | Baseline Usage (minutes per user license per month) | Estimated Number of Ports |
|---------------------------------|---|---------------------------|
| 20,000 to 50,000 | 1,500 | 15 to 35 |
| 50,000 to 500,000 | 2,000 | 25 to 250 |
| 500,000 to 1,000,000 | 3,000 | 165 to 335 |
| 1,000,000 to 2,000,000 | 3,500 | 285 to 570 |
| 2,000,000 to 8,000,000 | 4,000 | 500 to 2,000 |

- Calculation based on number of users

You should plan on having one port for every 20 users with average usage. If the users are heavy conference users, then provision one port for every 15 users. For example, in a system with 6000 users, you should provision 300 audio ports; however, if those users heavily use conferencing, then plan for 400 audio ports.

- Calculation based on actual peak usage

Actual voice conferencing usage during peak hours usually can be obtained from existing voice conferencing system logs or service provider bills. Cisco recommends provisioning 30% extra capacity based on the actual peak usage in order to protect against extra conferencing volume.

Factors Affecting System Sizing

In addition to the estimates provided by the methods described above for the system baseline port requirement, the following factors also affect system sizing:

- When migrating from an "operator-scheduled" model to a user-scheduled or reservationless model on Cisco Unified MeetingPlace, you might need to add another 20% to the baseline.
- The default average meeting size is 4.5 callers per meeting. Use the value that is applicable to your case if it is different than the default.
- Increase the baseline estimate accordingly if the following condition applies:
 $(\text{Estimated meetings per day}) * (\text{Estimated users}) > 80\% \text{ of baseline}$
- If the largest single meeting exceeds 20% of the estimated capacity, increase the estimate accordingly.
- If there are continuous meetings with dedicated ports, then you must add those additional ports $((\text{Meetings}) * (\text{Dedicated callers}))$ to the baseline.

The total number of ports will include all the above factors in addition to the baseline.

When planning for Unified MeetingPlace capacity expansion, also consider whether the following conditions apply to your system:

- The total estimated port capacity exceeds 80% of the maximum supported ports as listed in the latest version of the *Planning Guide for Cisco Unified MeetingPlace*, available at http://www.cisco.com/en/US/products/sw/ps5664/ps5669/products_implementation_design_guides_list.html
- An audio codec other than G.711 is desired. However, transcoders based on Cisco Integrated Services Routers (ISR) can be used if needed to achieve maximum capacity for other codec types in the meetings.
- Line Echo Cancellation (LEC) is provided by an external device such as an ISR, rather than Unified MeetingPlace providing echo cancellation functionality.

Sizing Guidelines for Unified MeetingPlace Video Conferencing

Cisco recommends the following three methods for calculating Unified MeetingPlace video conferencing capacity:

- Calculation based on number of knowledgeable workers
Cisco recommends provisioning a video user license for every 40 knowledgeable workers.
- Calculation based on number of voice conferencing user licenses
Cisco recommends provisioning video conferencing capacity in the range of 17% to 25% of existing audio user licenses. The percentage depends on business requirements regarding video conferencing and on the size of the Unified MeetingPlace system.
- Calculation based on existing video Multipoint Control Unit (MCU)
Cisco recommends deploying a direct replacement for an existing video conferencing system. A video conferencing license on the existing system can be replaced by a Cisco Unified MeetingPlace user license.

Unified MeetingPlace Web Server

The Unified MeetingPlace Web Server is required only for Unified MeetingPlace scheduling deployments to schedule and attend meetings from a Web user interface, for Lotus Notes integrations, or for processing the recording storage. There is no capacity planning consideration for these servers. Cisco MCS 7835 servers are sufficient for the largest Unified MeetingPlace deployment, but MCS 7845 servers may be used as well.

WebEx Node for MCS

Web conferencing optionally using Cisco WebEx Node for MCS can accommodate up to 500 web sessions, depending on the type of hardware on which the WebEx Node for MCS resides. A maximum of four WebEx Nodes for MCS can be deployed per solution, or an unlimited number of nodes can be deployed with WebEx Node for ASR, allowing for scalability up to 2,000 web sessions on-premises with redundancy. WebEx Nodes can be distributed anywhere in a customer network, but Cisco recommends deploying them closest to the larger groups of web users. Only internal users will have web sessions with

the WebEx Node for MCS or ASR; external users will always connect to the cloud. For detailed capacities of the Cisco WebEx Node for MCS or ASR, refer to the latest version of the *Planning Guide for Cisco Unified MeetingPlace*, available at

http://www.cisco.com/en/US/products/sw/ps5664/ps5669/products_implementation_design_guides_list.html

Impact on Unified CM

The impact to Unified CM can be analyzed by the extra call traffic that the conferencing system generates. The most impact occurs when conference users dial into their meetings that are typically scheduled at the top of the hour or half-hour. A large amount of call traffic within a few minutes of conference start times increases the load on Unified CM for just those few minutes that must be designed in appropriately. In addition, if conference users include callers from the PSTN or from other clusters, those parameters must also be considered to gauge their impact on the gateways.

Cisco Unified Presence

As with all other applications, sizing for Cisco Unified Presence is accomplished in the following manner:

- Decomposing the system into its most elemental services
- Measuring the unit cost of each of these services
- Analyzing the given system description as an aggregation of the identified services and arriving at a net system cost
- Determining the number of required servers based on system cost and deployment options

For Unified Presence the following system variables in the system under analysis are relevant and must be considered for accurate sizing:

- Number and type of users
 - Clients employed by users to obtain presence services
 - Operating mode for users (instant messaging only or full Unified Communications facilities)
- Presence-related activities performed by typical users
 - Contact list size and composition (intra-cluster, inter-cluster, and federated)
 - Number of instant messages (directly between two users) per user during the busy hour
 - Chat support with number of chat rooms, users per chat room, and instant messages per user per chat room
 - State changes per user (both call related and user initiated)
- Deployment model
 - Whether intercluster presence is supported
 - Whether federation is supported
 - Whether high availability is desired
- Server preferences
 - The class of server or voice messaging platform desired

- System options
 - Whether compliance recording is required

Once the system requirements are quantified, the number of required servers can be determined from the data in [Table 29-22](#).

Table 29-22 Maximum Number of Users Supported per Unified Presence Server

| Server Platform | Maximum Users Supported in Full Unified Communications Mode | Maximum Users Supported in Instant Messaging Only Mode |
|----------------------------------|---|--|
| Cisco MCS 7816 | 3,000 | 7,500 |
| Cisco MCS 7825 | 6,000 | 15,000 |
| Cisco MCS 7835 or OVA equivalent | 15,000 | 37,500 |
| Cisco MCS 7845 or OVA equivalent | 45,000 | 75,000 |

The formal definitions of the OVA templates for Cisco Unified Presence and other Unified Communication products are available at

[http://docwiki.cisco.com/wiki/Unified_Communications_Virtualization_Downloads_\(including_OVA/OVF_Templates\)](http://docwiki.cisco.com/wiki/Unified_Communications_Virtualization_Downloads_(including_OVA/OVF_Templates))

Impact on Unified CM

The Unified Presence server influences the performance of Unified CM in the following ways:

- User synchronization through an AXL/SOAP interface
- Presence information through a SIP trunk
- CTI traffic to enable phone control

In general, the impact of user synchronization (except for a one-time hit) and that of presence information through the SIP trunk are negligible. The affect of CTI control of phones, however, must be counted against CTI limits.

Cisco Unified Communications Management Suite

The Cisco Unified Communications Management Suite consists of four applications. Sizing for these applications is relatively simple and depends directly on the number of endpoints or network devices that they are expected to manage. These applications can work either in a standalone mode hosted on separate hardware servers or in a co-resident environment on a single server.

The server characteristics to host the Unified Communications Management Suite applications are generally stated in terms of hardware specifications: CPU characteristics (processor speed and number of cores), memory, and disk space for each level of desired capacity.

The co-resident server, for example, can host from one to all four of the Unified Communications Management Suite applications, and can be used to manage up to 10,000 endpoints. The specification for such a co-resident server is:

- Processor: 3 GHz, 8 Core
- Memory: 16 GB
- Disk space: 320 GB

These hardware characteristics can be mapped to the equivalent Cisco MCS or UCS servers.

Cisco Prime Unified Provisioning Manager

The Cisco Prime Unified Provisioning Manager (Unified PM) can support up to 60,000 phones and can be implemented either on a single machine or on two machines. A two-machine deployment is recommended when the number of phones exceeds 30,000.

Hardware resources required for various levels of performance are described in the *Cisco Unified Provisioning Manager Data Sheet*, available at

http://www.cisco.com/en/US/products/ps7125/products_data_sheets_list.html

Cisco Prime Unified Operations Manager

The Cisco Prime Unified Operations Manager (Unified OM) can manage phones and other network devices such as routers and switches. The Unified Operations Manager operates in a single machine configuration. The Unified OM supports up to 45,000 phones and 2,000 other IP devices.

Hardware resources required for various levels of performance are described in the *Cisco Unified Operations Manager Data Sheet*, available at

http://www.cisco.com/en/US/products/ps6535/products_data_sheets_list.html

Cisco Prime Unified Service Monitor

The Cisco Prime Unified Service Monitor (Unified SM) consists of not only the server to run the Unified SM software but also on Cisco 1040 Sensor and Network Analysis Modules (NAMs) to measure voice quality.

Table 29-23 Performance for 1040 Sensor and Different NAM Types

| | Cisco Network Analysis Module Type | | | | |
|--|------------------------------------|---------|-------|--------------------|--------------------|
| | 1040 Sensor | NME-NAM | NAM-2 | NAM 2204 Appliance | NAM 2220 Appliance |
| Maximum number of concurrent RTP streams supported | 100 | 100 | 400 | 1,500 | 4,000 |

Hardware resources required for various levels of performance are described in the *Cisco Unified Service Monitor Data Sheet*, available at

http://www.cisco.com/en/US/products/ps6536/products_data_sheets_list.html

Unified SM supports the following voice quality monitoring capacities:

- Up to 50 Cisco 1040 Sensors
- Up to 45,000 IP phones
- Up to 5,000 sensor-based RTP streams per minute (with Cisco 1040 Sensors or NAM modules)
- Up to 1,600 Cisco Voice Transmission Quality (CVTQ) calls per minute
- Up to 1,500 RTP streams and 666 CVTQ calls per minute

Cisco Unified Service Statistics Manager

The Cisco Unified Service Statistics Manager (Unified SSM) operates in a single server mode and can scale to manage up to 45,000 phones.

Hardware resources required for various levels of performance are described in the *Cisco Unified Service Statistics Manager Data Sheet*, available at

http://www.cisco.com/en/US/products/ps7285/products_data_sheets_list.html

Conclusion

In summary, it can be challenging to determine the hardware composition of a large Unified Communications system consisting of a number of separate applications working together. However, an understanding of the functional requirements of the software and the performance capabilities of the hardware platforms certified for running the software, can be very helpful in making an accurate estimation of the servers required. Tools developed by Cisco for this purpose are available as described in this chapter. For further assistance, contact your Cisco Partner or Cisco Systems Engineer, and they can use the Cisco Unified Communications Sizing Tool (<http://tools.cisco.com/cucst>) to validate all designs.

GLOSSARY

Revised: December 22, 2011; OL-21733-18

A

| | |
|--------------|---|
| AA | Automated attendant |
