- [Configuring Web Auth Proxy, page 7-130](#)
- [Detecting Active Exploits, page 7-132](#)

# Information about Cisco Unified Wireless Network Solution Security

This section contains the following topics:

- [Security Overview, page 7-2](#)
- [Layer 1 Solutions, page 7-2](#)
- [Layer 2 Solutions, page 7-2](#)
- [Layer 3 Solutions, page 7-3](#)
- [Integrated Security Solutions, page 7-3](#)

## Security Overview

The Cisco Unified Wireless Network (UWN) security solution bundles potentially complicated Layer 1, Layer 2, and Layer 3 802.11 Access Point security components into a simple policy manager that customizes system-wide security policies on a per-WLAN basis. The Cisco UWN security solution provides simple, unified, and systematic security management tools.

One of the biggest hurdles to WLAN deployment in the enterprise is WEP encryption, which is a weak standalone encryption method. A newer problem is the availability of low-cost access points, which can be connected to the enterprise network and used to mount man-in-the-middle and denial-of-service attacks.

## Layer 1 Solutions

The Cisco UWN security solution ensures that all clients gain access within a user-set number of attempts. If a client fails to gain access within that limit, it is automatically excluded (blocked from access) until the user-set timer expires. The operating system can also disable SSID broadcasts on a per-WLAN basis.

## Layer 2 Solutions

If a higher level of security and encryption is required, you can also implement industry-standard security solutions such as Extensible Authentication Protocol (EAP), Wi-Fi Protected Access (WPA), and WPA2. The Cisco UWN solution WPA implementation includes AES (Advanced Encryption Standard), TKIP and Michael (temporal key integrity protocol and message integrity code checksum) dynamic keys, or WEP (Wired Equivalent Privacy) static keys. Disabling is also used to automatically block Layer 2 access after a user-set number of failed authentication attempts.

Regardless of the wireless security solution selected, all Layer 2 wired communications between controllers and lightweight access points are secured by passing data through CAPWAP tunnels.

Cisco Aironet client adapter version 4.2 does not authenticate if WPA/WPA2 is used with CCKM as auth key management and a 2 second latency between the controller and AP.

## Layer 3 Solutions

The WEP problem can be further solved using industry-standard Layer 3 security solutions such as passthrough VPNs (virtual private networks).

The Cisco UWN solution supports local and RADIUS MAC (media access control) filtering. This filtering is best suited to smaller client groups with a known list of 802.11 access card MAC addresses.

The Cisco UWN solution supports local and RADIUS user/password authentication. This authentication is best suited to small to medium client groups.

## Integrated Security Solutions

The integrated security solutions are as follows:

- Cisco Unified Wireless Network (UWN) solution operating system security is built around a 802.1X AAA (authorization, authentication and accounting) engine, which allows users to rapidly configure and enforce a variety of security policies across the Cisco UWN solution.
- The controllers and lightweight access points are equipped with system-wide authentication and authorization protocols across all ports and interfaces, maximizing system security.
- Operating system security policies are assigned to individual WLANs, and lightweight access points simultaneously broadcast all (up to 16) configured WLANs, which can eliminate the need for additional access points, which can increase interference and degrade system throughput.
- Operating system security uses the RRM function to continually monitor the air space for interference and security breaches and to notify the user when they are detected.
- Operating system security works with industry-standard authorization, authentication, and accounting (AAA) servers.

## Configuring RADIUS

This section contains the following topics:

- [Information About RADIUS, page 7-3](#)
- [Guidelines and Limitations, page 7-4](#)
- [Configuring RADIUS on the ACS, page 7-5](#)
- [Configuring RADIUS, page 7-6](#)
- [RADIUS Authentication Attributes Sent by the Access Point, page 7-14](#)
- [RADIUS Accounting Attributes, page 7-16](#)

## Information About RADIUS

Remote Authentication Dial-In User Service (RADIUS) is a client/server protocol that provides centralized security for users attempting to gain management access to a network. It serves as a backend database similar to local and TACACS+ and provides authentication and accounting services:

- **Authentication**—The process of verifying users when they attempt to log into the controller.

Users must enter a valid username and password in order for the controller to authenticate users to the RADIUS server. If multiple databases are configured, you can specify the sequence in which the backend database must be tried.

- **Accounting**—The process of recording user actions and changes.

Whenever a user successfully executes an action, the RADIUS accounting server logs the changed attributes, the user ID of the person who made the change, the remote host where the user is logged in, the date and time when the command was executed, the authorization level of the user, and a description of the action performed and the values provided. If the RADIUS accounting server becomes unreachable, users are able to continue their sessions uninterrupted.

RADIUS uses User Datagram Protocol (UDP) for its transport. It maintains a database and listens on UDP port 1812 for incoming authentication requests and UDP port 1813 for incoming accounting requests. The controller, which requires access control, acts as the client and requests AAA services from the server. The traffic between the controller and the server is encrypted by an algorithm defined in the protocol and a shared secret key configured on both devices.

You can configure multiple RADIUS accounting and authentication servers. For example, you may want to have one central RADIUS authentication server but several RADIUS accounting servers in different regions. If you configure multiple servers of the same type and the first one fails or becomes unreachable, the controller automatically tries the second one, then the third one if necessary, and so on.

## Guidelines and Limitations

This section contains the following topics:

- [RADIUS Server Support, page 7-4](#)
- [Radius ACS Support, page 7-4](#)
- [Primary and Fallback RADIUS Servers, page 7-5](#)

### RADIUS Server Support

- You can configure up to 17 RADIUS authentication and accounting servers each.
- If multiple RADIUS servers are configured for redundancy, the user database must be identical in all the servers for the backup to work properly.
- To create a read-only controller user on the RADIUS sever, you must set the service type to NAS prompt instead of Callback NAS prompt. If you set the service type to Callback NAS Prompt, the user authentication fails while setting it to NAS prompt gives the user read-only access to the controller.

Also, the Callback Administrative service type gives the user the lobby ambassador privileges to the controller.

### Radius ACS Support

- You must configure RADIUS on both your CiscoSecure Access Control Server (ACS) and your controller.
- RADIUS is supported on CiscoSecure ACS version 3.2 and later releases. See the *CiscoSecure ACS* documentation for the version that you are running.

## Primary and Fallback RADIUS Servers

The primary RADIUS server (the server with the lowest server index) is assumed to be the most preferable server for the controller. If the primary server becomes unresponsive, the controller switches to the next active backup server (the server with the next lowest server index). The controller continues to use this backup server, unless you configure the controller to fall back to the primary RADIUS server when it recovers and becomes responsive or to a more preferable server from the available backup servers.

## Configuring RADIUS on the ACS

- Step 1** Choose **Network Configuration** on the ACS main page.
- Step 2** Choose **Add Entry** under AAA Clients to add your controller to the server. The Add AAA Client page appears.

**Figure 7-1** Add AAA Client Page on CiscoSecure ACS

- Step 3** In the AAA Client Hostname text box, enter the name of your controller.
- Step 4** In the AAA Client IP Address text box, enter the IP address of your controller.
- Step 5** In the Shared Secret text box, enter the shared secret key to be used for authentication between the server and the controller.

**Note** The shared secret key must be the same on both the server and the controller.

- Step 6** From the Authenticate Using drop-down list, choose **RADIUS (Cisco Aironet)**.
- Step 7** Click **Submit + Apply** to save your changes.
- Step 8** Choose **Interface Configuration** on the ACS main page.
- Step 9** Choose **RADIUS (Cisco Aironet)**. The RADIUS (Cisco Aironet) page appears.
- Step 10** Under User Group, select the **Cisco-Aironet-Session-Timeout** check box.
- Step 11** Click **Submit** to save your changes.
- Step 12** On the ACS main page, from the left navigation pane, choose **System Configuration**.
- Step 13** Choose **Logging**.
- Step 14** When the Logging Configuration page appears, enable all of the events that you want to be logged and save your changes.
- Step 15** On the ACS main page, from the left navigation pane, choose **Group Setup**.
- Step 16** Choose a previously created group from the Group drop-down list.

**Note** This step assumes that you have already assigned users to groups on the ACS according to the roles to which they will be assigned.

- Step 17** Click **Edit Settings**. The Group Setup page appears.
- Step 18** Under **Cisco Aironet Attributes**, select the **Cisco-Aironet-Session-Timeout** check box and enter a session timeout value in the edit box.
- Step 19** Specify read-only or read-write access to controllers through RADIUS authentication, by setting the Service-Type attribute (006) to **Callback NAS Prompt** for read-only access or to **Administrative** for read-write privileges. If you do not set this attribute, the authentication process completes successfully (without an authorization error on the controller), but you might be prompted to authenticate again.

**Note** If you set the Service-Type attribute on the ACS, make sure to select the **Management** check box on the RADIUS Authentication Servers page of the controller GUI. See [Step 16](#) in the next section for more information.

**Note** The [“RADIUS Authentication Attributes Sent by the Access Point”](#) section on [page 7-14](#) lists the RADIUS attributes that are sent by a lightweight access point to a client in access-request and access-accept packets.

- Step 20** Click **Submit** to save your changes.

## Configuring RADIUS

This section contains the following topics:

- [Configuring RADIUS \(GUI\), page 7-7](#)
- [Configuring RADIUS \(CLI\), page 7-10](#)

## Configuring RADIUS (GUI)

**Step 1** Choose **Security > AAA > RADIUS**.

**Step 2** Perform one of the following:

- If you want to configure a RADIUS server for authentication, choose **Authentication**.
- If you want to configure a RADIUS server for accounting, choose **Accounting**.

**Note**

The pages used to configure authentication and accounting contain mostly the same text boxes. Therefore, these instructions walk through the configuration only once, using the Authentication pages as examples. You would follow the same steps to configure multiple services and/or multiple servers.

The RADIUS Authentication (or Accounting) Servers page appears.

**Figure 7-2** *RADIUS Authentication Servers Page*

Network User	Management	Server Index	Server Address	Port	IPSec	Admin Status
<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	1	209.165.200.225	1812	Disabled	Enabled

This page lists any RADIUS servers that have already been configured.

- If you want to delete an existing server, hover your cursor over the blue drop-down arrow for that server and choose **Remove**.
- If you want to make sure that the controller can reach a particular server, hover your cursor over the blue drop-down arrow for that server and choose **Ping**.

**Step 3** From the Call Station ID Type drop-down list, choose **IP Address**, **System MAC Address**, or **AP MAC Address** to specify whether the IP address, system MAC address, or AP MAC address of the originator will be sent to the RADIUS server in the Access-Request message.

**Step 4** Enable RADIUS-to-controller key transport using AES key wrap protection by selecting the **Use AES Key Wrap** check box. The default value is unselected. This feature is required for FIPS customers.

**Step 5** Click **Apply** to commit your changes. Perform one of the following:

- To edit an existing RADIUS server, click the server index number for that server. The RADIUS Authentication (or Accounting) Servers > Edit page appears.
- To add a RADIUS server, click **New**. The RADIUS Authentication (or Accounting) Servers > New page appears.

**Step 6** If you are adding a new server, choose a number from the Server Index (Priority) drop-down list to specify the priority order of this server in relation to any other configured RADIUS servers providing the same service.

- Step 7** If you are adding a new server, enter the IP address of the RADIUS server in the Server IP Address text box.
- Step 8** From the Shared Secret Format drop-down list, choose **ASCII** or **Hex** to specify the format of the shared secret key to be used between the controller and the RADIUS server. The default value is ASCII.
- Step 9** In the Shared Secret and Confirm Shared Secret text boxes, enter the shared secret key to be used for authentication between the controller and the server.

---

**Note** The shared secret key must be the same on both the server and the controller.

---

- Step 10** If you are configuring a new RADIUS authentication server and want to enable AES key wrap, which makes the shared secret between the controller and the RADIUS server more secure, follow these steps:

---

**Note** AES key wrap is designed for Federal Information Processing Standards (FIPS) customers and requires a key-wrap compliant RADIUS authentication server.

---

- a. Select the **Key Wrap** check box.
  - b. From the Key Wrap Format drop-down list, choose **ASCII** or **HEX** to specify the format of the AES key wrap keys: Key Encryption Key (KEK) and Message Authentication Code Key (MACK).
  - c. In the Key Encryption Key (KEK) text box, enter the 16-byte KEK.
  - d. In the Message Authentication Code Key (MACK) text box, enter the 20-byte KEK.
- Step 11** If you are adding a new server, enter the RADIUS server's UDP port number for the interface protocols in the Port Number text box. The valid range is 1 to 65535, and the default value is 1812 for authentication and 1813 for accounting.
- Step 12** From the Server Status text box, choose **Enabled** to enable this RADIUS server or choose **Disabled** to disable it. The default value is enabled.
- Step 13** If you are configuring a new RADIUS authentication server, choose **Enabled** from the **Support for RFC 3576** drop-down list to enable RFC 3576, which is an extension to the RADIUS protocol that allows dynamic changes to a user session, or choose **Disabled** to disable this feature. The default value is Enabled. RFC 3576 includes support for disconnecting users and changing authorizations applicable to a user session and supports disconnect and change-of-authorization (CoA) messages. Disconnect messages cause a user session to be terminated immediately where CoA messages modify session authorization attributes such as data filters.
- Step 14** In the Server Timeout text box, enter the number of seconds between retransmissions. The valid range is 2 to 30 seconds, and the default value is 2 seconds.

---

**Note** We recommend that you increase the timeout value if you experience repeated reauthentication attempts or the controller falls back to the backup server when the primary server is active and reachable.

---

- Step 15** Select the **Network User** check box to enable network user authentication (or accounting), or unselect it to disable this feature. The default value is selected. If you enable this feature, this entry is considered the RADIUS authentication (or accounting) server for network users. If you did not configure a RADIUS server entry on the WLAN, you must enable this option for network users.

- Step 16** If you are configuring a RADIUS authentication server, select the **Management** check box to enable management authentication, or unselect it to disable this feature. The default value is selected. If you enable this feature, this entry is considered the RADIUS authentication server for management users, and authentication requests go to the RADIUS server.
- Step 17** Select the **IPSec** check box to enable the IP security mechanism, or unselect it to disable this feature. The default value is unselected.

**Note** The IPsec option appears only if a crypto card is installed in the controller.

- Step 18** If you enabled IPsec in [Step 17](#), follow these steps to configure additional IPsec parameters:
- From the IPsec drop-down list, choose one of the following options as the authentication protocol to be used for IP security: **HMAC MD5** or **HMAC SHA1**. The default value is HMAC SHA1.

A message authentication code (MAC) is used between two parties that share a secret key to validate information transmitted between them. HMAC (Hash MAC) is based on cryptographic hash functions. It can be used in combination with any iterated cryptographic hash function. HMAC MD5 and HMAC SHA1 are two constructs of the HMAC using the MD5 hash function and the SHA1 hash function. HMAC also uses a secret key for calculation and verification of the message authentication values.
  - From the IPsec Encryption drop-down list, choose one of the following options to specify the IP security encryption mechanism:
    - DES**—Data Encryption Standard that is a method of data encryption using a private (secret) key. DES applies a 56-bit key to each 64-bit block of data.
    - 3DES**—Data Encryption Standard that applies three keys in succession. This is the default value.
    - AES CBS**—Advanced Encryption Standard that uses keys with a length of 128, 192, or 256 bits to encrypt data blocks with a length of 128, 192, or 256 bits. AES 128 CBC uses a 128-bit data path in Cipher Block Chaining (CBC) mode.
  - From the IKE Phase 1 drop-down list, choose one of the following options to specify the Internet Key Exchange (IKE) protocol: **Aggressive** or **Main**. The default value is Aggressive.

IKE Phase 1 is used to negotiate how IKE should be protected. Aggressive mode passes more information in fewer packets with the benefit of slightly faster connection establishment at the cost of transmitting the identities of the security gateways in the clear.
  - In the Lifetime text box, enter a value (in seconds) to specify the timeout interval for the session. The valid range is 1800 to 57600 seconds, and the default value is 1800 seconds.
  - From the IKE Diffie Hellman Group drop-down list, choose one of the following options to specify the IKE Diffie Hellman group: **Group 1 (768 bits)**, **Group 2 (1024 bits)**, or **Group 5 (1536 bits)**. The default value is Group 1 (768 bits).

Diffie-Hellman techniques are used by two devices to generate a symmetric key through which they can publicly exchange values and generate the same symmetric key. Although all three groups provide security from conventional attacks, Group 5 is considered more secure because of its larger key size. However, computations involving Group 1 and Group 2 based keys might occur slightly faster because of their smaller prime number size.
- Step 19** Click **Apply** to commit your changes.
- Step 20** Click **Save Configuration** to save your changes.
- Step 21** Repeat the previous steps if you want to configure any additional services on the same server or any additional RADIUS servers.

- Step 22** Specify the RADIUS server fallback behavior, as follows:
- Choose **Security > AAA > RADIUS > Fallback to open the RADIUS > Fallback Parameters** to open the fallback parameters page.
  - From the Fallback Mode drop-down list, choose one of the following options:
    - Off**—Disables RADIUS server fallback. This is the default value.
    - Passive**—Causes the controller to revert to a server with a lower priority from the available backup servers without using extraneous probe messages. The controller ignores all inactive servers for a time period and retries later when a RADIUS message needs to be sent.
    - Active**—Causes the controller to revert to a server with a lower priority from the available backup servers by using RADIUS probe messages to proactively determine whether a server that has been marked inactive is back online. The controller ignores all inactive servers for all active RADIUS requests. Once the primary server receives a response from the recovered ACS server, the active fallback RADIUS server no longer sends probe messages to the server requesting the active probe authentication.
  - If you enabled Active fallback mode in [Step b](#), enter the name to be sent in the inactive server probes in the Username text box. You can enter up to 16 alphanumeric characters. The default value is “cisco-probe.”
  - If you enabled Active fallback mode in [Step b](#), enter the probe interval value (in seconds) in the Interval in Sec text box. The interval serves as inactive time in passive mode and probe interval in active mode. The valid range is 180 to 3600 seconds, and the default value is 300 seconds.
- Step 23** Specify the order of authentication when multiple databases are configured by choosing **Security > Priority Order > Management User**. The Priority Order > Management User page appears.
- Step 24** In the Order Used for Authentication text box, specify which servers have priority when the controller attempts to authenticate management users. Use the > and < buttons to move servers between the Not Used and Order Used for Authentication text boxes. After the desired servers appear in the Order Used for Authentication text box, use the **Up** and **Down** buttons to move the priority server to the top of the list.
- By default, the local database is always queried first. If the username is not found, the controller switches to the RADIUS server if configured for RADIUS or to the TACACS+ server if configured for TACACS+. The default setting is local and then RADIUS.
- Step 25** Click **Apply** to commit your changes.
- Step 26** Click **Save Configuration** to save your changes.

## Configuring RADIUS (CLI)

- Step 1** Specify whether the IP address, system MAC address, or AP MAC address of the originator will be sent to the RADIUS server in the Access-Request message by entering this command:
- ```
config radius callStationIdType {ip_address | mac_address | ap_mac_address | ap_macaddr_ssid}
```

### Note

The default is MAC address.

**Note**

Do not use callStation IdType for IPv6-only clients.

- Step 2** Specify the delimiter to be used in the MAC addresses that are sent to the RADIUS authentication or accounting server in Access-Request messages by entering this command:

```
config radius {auth | acct} mac-delimiter {colon | hyphen | single-hyphen | none}
```

where

- **colon** sets the delimiter to a colon (the format is xx:xx:xx:xx:xx:xx).
- **hyphen** sets the delimiter to a hyphen (the format is xx-xx-xx-xx-xx-xx). This is the default value.
- **single-hyphen** sets the delimiter to a single hyphen (the format is xxxxxx-xxxxxx).
- **none** disables delimiters (the format is xxxxxxxxxxxx).

- Step 3** Configure a RADIUS authentication server by entering these commands:

- **config radius auth add index server\_ip\_address port# {ascii | hex} shared\_secret**—Adds a RADIUS authentication server.
- **config radius auth keywrap {enable | disable}**—Enables AES key wrap, which makes the shared secret between the controller and the RADIUS server more secure. AES key wrap is designed for Federal Information Processing Standards (FIPS) customers and requires a key-wrap compliant RADIUS authentication server.
- **config radius auth keywrap add {ascii | hex} kek mack index**—Configures the AES key wrap attributes

where

- *kek* specifies the 16-byte Key Encryption Key (KEK).
- *mack* specifies the 20-byte Message Authentication Code Key (MACK).
- *index* specifies the index of the RADIUS authentication server on which to configure the AES key wrap.
- **config radius auth rfc3576 {enable | disable} index**—Enables or disables RFC 3576, which is an extension to the RADIUS protocol that allows dynamic changes to a user session. RFC 3576 includes support for disconnecting users and changing authorizations applicable to a user session and supports disconnect and change-of-authorization (CoA) messages. Disconnect messages cause a user session to be terminated immediately where CoA messages modify session authorization attributes such as data filters.
- **config radius auth retransmit-timeout index timeout**—Configures the network login retransmission timeout value for a RADIUS authentication server.
- **config radius auth mgmt-retransmit-timeout index timeout**—Configures the management login retransmission timeout value for a RADIUS authentication server.
- **config radius auth network index {enable | disable}**—Enables or disables network user authentication. If you enable this feature, this entry is considered the RADIUS authentication server for network users. If you did not configure a RADIUS server entry on the WLAN, you must enable this option for network users.
- **config radius auth management index {enable | disable}**—Enables or disables management authentication. If you enable this feature, this entry is considered the RADIUS authentication server for management users, and authentication requests go to the RADIUS server.
- **config radius auth ipsec {enable | disable} index**—Enables or disables the IP security mechanism.

- **config radius auth ipsec authentication {hmac-md5 | hmac-sha1} index**—Configures the authentication protocol to be used for IP security.
- **config radius auth ipsec encryption {3des | aes | des | none} index**—Configures the IP security encryption mechanism.
- **config radius auth ipsec ike dh-group {group-1 | group-2 | group-5} index**—Configures the IKE Diffie Hellman group.
- **config radius auth ipsec ike lifetime interval index**—Configures the timeout interval for the session.
- **config radius auth ipsec ike phase1 {aggressive | main} index**—Configures the Internet Key Exchange (IKE) protocol.
- **config radius auth {enable | disable} index**—Enables or disables a RADIUS authentication server.
- **config radius auth delete index**—Deletes a previously added RADIUS authentication server.

**Step 4** Configure a RADIUS accounting server by entering these commands:

- **config radius acct add index server\_ip\_address port# {ascii | hex} shared\_secret**—Adds a RADIUS accounting server.
- **config radius acct server-timeout index timeout**—Configures the retransmission timeout value for a RADIUS accounting server.
- **config radius acct network index {enable | disable}**—Enables or disables network user accounting. If you enable this feature, this entry is considered the RADIUS accounting server for network users. If you did not configure a RADIUS server entry on the WLAN, you must enable this option for network users.
- **config radius acct ipsec {enable | disable} index**—Enables or disables the IP security mechanism.
- **config radius acct ipsec authentication {hmac-md5 | hmac-sha1} index**—Configures the authentication protocol to be used for IP security.
- **config radius acct ipsec encryption {3des | aes | des | none} index**—Configures the IP security encryption mechanism.
- **config radius acct ipsec ike dh-group {group-1 | group-2 | group-5} index**—Configures the IKE Diffie Hellman group.
- **config radius acct ipsec ike lifetime interval index**—Configures the timeout interval for the session.
- **config radius acct ipsec ike phase1 {aggressive | main} index**—Configures the Internet Key Exchange (IKE) protocol.
- **config radius acct {enable | disable} index**—Enables or disables a RADIUS accounting server.
- **config radius acct delete index**—Deletes a previously added RADIUS accounting server.

**Step 5** Configure the RADIUS server fallback behavior by entering this command:

**config radius fallback-test mode {off | passive | active}**

where

- **off** disables RADIUS server fallback.
- **passive** causes the controller to revert to a server with a lower priority from the available backup servers without using extraneous probe messages. The controller simply ignores all inactive servers for a time period and retries later when a RADIUS message needs to be sent.

- **active** causes the controller to revert to a server with a lower priority from the available backup servers by using RADIUS probe messages to proactively determine whether a server that has been marked inactive is back online. The controller simply ignores all inactive servers for all active RADIUS requests. Once the primary server receives a response from the recovered ACS server, the active fallback RADIUS server no longer sends probe messages to the server requesting the active probe authentication.

**Step 6** If you enabled Active mode in [Step 5](#), enter these commands to configure additional fallback parameters:

- **config radius fallback-test username** *username*—Specifies the name to be sent in the inactive server probes. You can enter up to 16 alphanumeric characters for the *username parameter*.
- **config radius fallback-test interval** *interval*—Specifies the probe interval value (in seconds).

**Step 7** Save your changes by entering this command:

**save config**

**Step 8** Configure the order of authentication when multiple databases are configured by entering this command:

**config aaa auth mgmt** *AAA\_server\_type* *AAA\_server\_type*

where *AAA\_server\_type* is local, radius, or tacacs.

To see the current management authentication server order, enter the **show aaa auth** command.

**Step 9** See RADIUS statistics by entering these commands:

- **show radius summary**—Shows a summary of RADIUS servers and statistics.
- **show radius auth statistics**—Shows the RADIUS authentication server statistics.
- **show radius acct statistics**—Shows the RADIUS accounting server statistics.
- **show radius rfc3576 statistics**—Shows a summary of the RADIUS RFC-3576 server.

**Step 10** See active security associations by entering these commands:

- **show ike {brief | detailed}** *ip\_or\_mac\_addr*—Shows a brief or detailed summary of active IKE security associations.
- **show ipsec {brief | detailed}** *ip\_or\_mac\_addr*—Shows a brief or detailed summary of active IPsec security associations.

**Step 11** Clear the statistics for one or more RADIUS servers by entering this command:

**clear stats radius {auth | acct} {index | all}**

**Step 12** Make sure that the controller can reach the RADIUS server by entering this command:

**ping** *server\_ip\_address*

---

## RADIUS Authentication Attributes Sent by the Access Point

Table 7-1 through Table 7-5 identify the RADIUS authentication attributes sent by a lightweight access point to a client in access-request and access-accept packets.

**Table 7-1 Authentication Attributes Sent in Access-Request Packets**

| Attribute ID | Description                      |
|--------------|----------------------------------|
| 1            | User-Name                        |
| 2            | Password                         |
| 3            | CHAP-Password                    |
| 4            | NAS-IP-Address                   |
| 5            | NAS-Port                         |
| 6            | Service-Type <sup>1</sup>        |
| 12           | Framed-MTU                       |
| 30           | Called-Station-ID (MAC address)  |
| 31           | Calling-Station-ID (MAC address) |
| 32           | NAS-Identifier                   |
| 33           | Proxy-State                      |
| 60           | CHAP-Challenge                   |
| 61           | NAS-Port-Type                    |
| 79           | EAP-Message                      |
| 243          | TPLUS-Role                       |

1. To specify read-only or read-write access to controllers through RADIUS authentication, you must set the Service-Type attribute (6) on the RADIUS server to **Callback NAS Prompt** for read-only access or to **Administrative** for read-write privileges. See [Step 19](#) in the “Configuring RADIUS on the ACS” section for more information.

**Table 7-2 Authentication Attributes Honored in Access-Accept Packets (Cisco)**

| Attribute ID | Description                 |
|--------------|-----------------------------|
| 1            | Cisco-LEAP-Session-Key      |
| 2            | Cisco-Keywrap-Msg-Auth-Code |
| 3            | Cisco-Keywrap-NonCE         |
| 4            | Cisco-Keywrap-Key           |
| 5            | Cisco-URL-Redirect          |
| 6            | Cisco-URL-Redirect-ACL      |

**Note**

These Cisco-specific attributes are not supported: Auth-Algo-Type and SSID.

**Table 7-3 Authentication Attributes Honored in Access-Accept Packets (Standard)**

| Attribute ID | Description                                                                                                                                                                                                                                                        |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6            | Service-Type. To specify read-only or read-write access to controllers through RADIUS authentication, you must set the Service-Type attribute (6) on the RADIUS server to Callback NAS Prompt for read-only access or to Administrative for read-write privileges. |
| 8            | Framed-IP-Address                                                                                                                                                                                                                                                  |
| 25           | Class                                                                                                                                                                                                                                                              |

## Configuring TACACS+

This section contains the following topics:

- [Information About TACACS+, page 7-17](#)
- [Guidelines and Limitations, page 7-19](#)
- [Configuring TACACS+ on the ACS, page 7-19](#)
- [Configuring TACACS+, page 7-21](#)
- [Viewing the TACACS+ Administration Server Logs, page 7-24](#)

## Information About TACACS+

Terminal Access Controller Access Control System Plus (TACACS+) is a client/server protocol that provides centralized security for users attempting to gain management access to a controller. It serves as a backend database similar to local and RADIUS. However, local and RADIUS provide only authentication support and limited authorization support while TACACS+ provides three services:

- **Authentication**—The process of verifying users when they attempt to log into the controller.  
Users must enter a valid username and password in order for the controller to authenticate users to the TACACS+ server. The authentication and authorization services are tied to one another. For example, if authentication is performed using the local or RADIUS database, then authorization would use the permissions associated with the user in the local or RADIUS database (which are read-only, read-write, and lobby-admin) and not use TACACS+. Similarly, when authentication is performed using TACACS+, authorization is tied to TACACS+.

**Note**

When multiple databases are configured, you can use the controller GUI or CLI to specify the sequence in which the backend databases should be tried.

- **Authorization**—The process of determining the actions that users are allowed to take on the controller based on their level of access.

For TACACS+, authorization is based on privilege (or role) rather than specific actions. The available roles correspond to the seven menu options on the controller GUI: MONITOR, WLAN, CONTROLLER, WIRELESS, SECURITY, MANAGEMENT, and COMMANDS. An additional role, LOBBY, is available for users who require only lobby ambassador privileges. The roles to which users are assigned are configured on the TACACS+ server. Users can be authorized for one or more roles. The minimum authorization is MONITOR only, and the maximum is ALL, which authorizes the user to execute the functionality associated with all seven menu options. For example, a user who is assigned the role of SECURITY can make changes to any items appearing on the Security menu (or designated as security commands in the case of the CLI). If users are not authorized for a particular role (such as WLAN), they can still access that menu option in read-only mode (or the associated CLI **show** commands). If the TACACS+ authorization server becomes unreachable or unable to authorize, users are unable to log into the controller.

**Note**

If users attempt to make changes on a controller GUI page that are not permitted for their assigned role, a message appears indicating that they do not have sufficient privilege. If users enter a controller CLI command that is not permitted for their assigned role, a message may appear indicating that the command was successfully executed although it was not. In this case, the following additional message appears to inform users that they lack sufficient privileges to successfully execute the command: “Insufficient Privilege! Cannot execute command!”

- **Accounting**—The process of recording user actions and changes.

Whenever a user successfully executes an action, the TACACS+ accounting server logs the changed attributes, the user ID of the person who made the change, the remote host where the user is logged in, the date and time when the command was executed, the authorization level of the user, and a description of the action performed and the values provided. If the TACACS+ accounting server becomes unreachable, users are able to continue their sessions uninterrupted.

TACACS+ uses Transmission Control Protocol (TCP) for its transport, unlike RADIUS which uses User Datagram Protocol (UDP). It maintains a database and listens on TCP port 49 for incoming requests. The controller, which requires access control, acts as the client and requests AAA services from the server. The traffic between the controller and the server is encrypted by an algorithm defined in the protocol and a shared secret key configured on both devices.

You can configure up to three TACACS+ authentication, authorization, and accounting servers each. For example, you may want to have one central TACACS+ authentication server but several TACACS+ authorization servers in different regions. If you configure multiple servers of the same type and the first one fails or becomes unreachable, the controller automatically tries the second one and then the third one if necessary.

**Note**

If multiple TACACS+ servers are configured for redundancy, the user database must be identical in all the servers for the backup to work properly.

## TACACS+ VSA

The Internet Engineering Task Force (IETF) draft standard specifies a method for communicating vendor-specific attributes (VSAs) between the network access server and the TACACS+ server. The IETF uses attribute 26. VSAs allow vendors to support their own extended attributes that are not suitable for general use.

The Cisco TACACS+ implementation supports one vendor-specific option using the format recommended in the IETF specification. The Cisco vendor ID is 9, and the supported option is vendor type 1, which is named `cisco-av-pair`. The value is a string with the following format:

```
protocol : attribute separator value *
```

The protocol is a Cisco attribute for a particular type of authorization, the separator is = (equal sign) for mandatory attributes, and \* (asterisk) indicates optional attributes.

## Guidelines and Limitations

- You must configure TACACS+ on both your CiscoSecure Access Control Server (ACS) and your controller. You can configure the controller through either the GUI or the CLI.
- TACACS+ is supported on CiscoSecure ACS version 3.2 and later releases. See the *CiscoSecure ACS* documentation for the version that you are running.

## Configuring TACACS+ on the ACS

- 
- |               |                                                                                                                  |
|---------------|------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Choose <b>Network Configuration</b> on the ACS main page.                                                        |
| <b>Step 2</b> | Choose <b>Add Entry</b> under AAA Clients to add your controller to the server. The Add AAA Client page appears. |

**Figure 7-3 Add AAA Client Page on CiscoSecure ACS**

- Step 3** In the AAA Client Hostname text box, enter the name of your controller.
- Step 4** In the AAA Client IP Address text box, enter the IP address of your controller.
- Step 5** In the Shared Secret text box, enter the shared secret key to be used for authentication between the server and the controller.

**Note** The shared secret key must be the same on both the server and the controller.

- Step 6** From the Authenticate Using drop-down list, choose **TACACS+ (Cisco IOS)**.
- Step 7** Click **Submit + Apply** to save your changes.
- Step 8** On the ACS main page, in the left navigation pane, choose **Interface Configuration**.
- Step 9** Choose **TACACS+ (Cisco IOS)**. The TACACS+ (Cisco) page appears.
- Step 10** Under TACACS+ Services, select the **Shell (exec)** check box.
- Step 11** Under New Services, select the first check box and enter **ciscowlc** in the Service text box and **common** in the Protocol text box.
- Step 12** Under Advanced Configuration Options, select the **Advanced TACACS+ Features** check box.
- Step 13** Click **Submit** to save your changes.
- Step 14** On the ACS main page, in the left navigation pane, choose **System Configuration**.
- Step 15** Choose **Logging**.
- Step 16** When the Logging Configuration page appears, enable all of the events that you want to be logged and save your changes.
- Step 17** On the ACS main page, in the left navigation pane, choose **Group Setup**.

**Step 18** From the Group drop-down list, choose a previously created group.

**Note** This step assumes that you have already assigned users to groups on the ACS according to the roles to which they will be assigned.

**Step 19** Click **Edit Settings**. The Group Setup page appears.

**Step 20** Under **TACACS+ Settings**, select the **ciscowlc common** check box.

**Step 21** Select the **Custom Attributes** check box.

**Step 22** In the text box below Custom Attributes, specify the roles that you want to assign to this group. The available roles are MONITOR, WLAN, CONTROLLER, WIRELESS, SECURITY, MANAGEMENT, COMMANDS, ALL, and LOBBY. The first seven correspond to the menu options on the controller GUI and allow access to those particular controller features. You can enter one or multiple roles, depending on the group's needs. Use ALL to specify all seven roles or LOBBY to specify the lobby ambassador role. Enter the roles using this format:

`roleX=ROLE`

For example, to specify the WLAN, CONTROLLER, and SECURITY roles for a particular user group, you would enter the following text:

```
role1=WLAN
role2=CONTROLLER
role3=SECURITY
```

To give a user group access to all seven roles, you would enter the following text:

```
role1=ALL
```

**Note** Make sure to enter the roles using the format shown above. The roles must be in all uppercase letters, and there can be no spaces within the text.

**Note** You should not combine the MONITOR role or the LOBBY role with any other roles. If you specify one of these two roles in the Custom Attributes text box, users will have MONITOR or LOBBY privileges only, even if additional roles are specified.

**Step 23** Click **Submit** to save your changes.

## Configuring TACACS+

This section contains the following topics:

- [Configuring TACACS+ \(GUI\), page 7-21](#)
- [Configuring TACACS+ \(CLI\), page 7-23](#)

### Configuring TACACS+ (GUI)

**Step 1** Choose **Security > AAA > TACACS+**.

**Step 2** Perform one of the following:

- If you want to configure a TACACS+ server for authentication, choose **Authentication**.
- If you want to configure a TACACS+ server for authorization, choose **Authorization**.
- If you want to configure a TACACS+ server for accounting, choose **Accounting**.

**Note**

The pages used to configure authentication, authorization, and accounting all contain the same text boxes. Therefore, these instructions walk through the configuration only once, using the Authentication pages as examples. You would follow the same steps to configure multiple services and/or multiple servers.

**Note**

For basic management authentication via TACACS+ to succeed, it is required to configure authentication and authorization servers on the WLC. Accounting configuration is optional.

The TACACS+ (Authentication, Authorization, or Accounting) Servers page appears. This page lists any TACACS+ servers that have already been configured.

- If you want to delete an existing server, hover your cursor over the blue drop-down arrow for that server and choose **Remove**.
- If you want to make sure that the controller can reach a particular server, hover your cursor over the blue drop-down arrow for that server and choose **Ping**.

**Step 3** Perform one of the following:

- To edit an existing TACACS+ server, click the server index number for that server. The TACACS+ (Authentication, Authorization, or Accounting) Servers > Edit page appears.
- To add a TACACS+ server, click **New**. The TACACS+ (Authentication, Authorization, or Accounting) Servers > New page appears.

**Step 4** If you are adding a new server, choose a number from the Server Index (Priority) drop-down list to specify the priority order of this server in relation to any other configured TACACS+ servers providing the same service. You can configure up to three servers. If the controller cannot reach the first server, it tries the second one in the list and then the third if necessary.

**Step 5** If you are adding a new server, enter the IP address of the TACACS+ server in the Server IP Address text box.

**Step 6** From the Shared Secret Format drop-down list, choose **ASCII** or **Hex** to specify the format of the shared secret key to be used between the controller and the TACACS+ server. The default value is ASCII.

**Step 7** In the Shared Secret and Confirm Shared Secret text boxes, enter the shared secret key to be used for authentication between the controller and the server.

**Note**

The shared secret key must be the same on both the server and the controller.

**Step 8** If you are adding a new server, enter the TACACS+ server's TCP port number for the interface protocols in the Port Number text box. The valid range is 1 to 65535, and the default value is 49.

**Step 9** In the Server Status text box, choose **Enabled** to enable this TACACS+ server or choose **Disabled** to disable it. The default value is Enabled.

**Step 10** In the Server Timeout text box, enter the number of seconds between retransmissions. The valid range is 5 to 30 seconds, and the default value is 5 seconds.

**Note**

We recommend that you increase the timeout value if you experience repeated reauthentication attempts or the controller falls back to the backup server when the primary server is active and reachable.

- Step 11** Click **Apply** to commit your changes.
- Step 12** Click **Save Configuration** to save your changes.
- Step 13** Repeat the previous steps if you want to configure any additional services on the same server or any additional TACACS+ servers.
- Step 14** Specify the order of authentication when multiple databases are configured by choosing **Security > Priority Order > Management User**. The Priority Order > Management User page appears.
- Step 15** In the Order Used for Authentication text box, specify which servers have priority when the controller attempts to authenticate management users. Use the > and < buttons to move servers between the Not Used and Order Used for Authentication text boxes. After the desired servers appear in the Order Used for Authentication text box, use the **Up** and **Down** buttons to move the priority server to the top of the list.
- By default, the local database is always queried first. If the username is not found, the controller switches to the RADIUS server if configured for RADIUS or to the TACACS+ server if configured for TACACS+. The default setting is local and then RADIUS.
- Step 16** Click **Apply** to commit your changes.
- Step 17** Click **Save Configuration** to save your changes.

## Configuring TACACS+ (CLI)

- Configure a TACACS+ authentication server by entering these commands:
  - **config tacacs auth add index server\_ip\_address port# {ascii | hex} shared\_secret**—Adds a TACACS+ authentication server.
  - **config tacacs auth delete index**—Deletes a previously added TACACS+ authentication server.
  - **config tacacs auth (enable | disable) index**—Enables or disables a TACACS+ authentication server.
  - **config tacacs auth server-timeout index timeout**—Configures the network login retransmission timeout value for a TACACS+ authentication server.
  - **config tacacs auth mgmt-server-timeout index timeout**—Configures the management login retransmission timeout value for a TACACS+ authentication server.
- Configure a TACACS+ authorization server by entering these commands:
  - **config tacacs athr add index server\_ip\_address port# {ascii | hex} shared\_secret**—Adds a TACACS+ authorization server.
  - **config tacacs athr delete index**—Deletes a previously added TACACS+ authorization server.
  - **config tacacs athr (enable | disable) index**—Enables or disables a TACACS+ authorization server.
  - **config tacacs athr server-timeout index timeout**—Configures the network login retransmission timeout value for a TACACS+ authorization server.

- **config tacacs mgmt-athr server-timeout index timeout**—Configures the management login retransmission timeout value for a TACACS+ authorization server.
- Configure a TACACS+ accounting server by entering these commands:
  - **config tacacs acct add index server\_ip\_address port# {ascii | hex} shared\_secret**—Adds a TACACS+ accounting server.
  - **config tacacs acct delete index**—Deletes a previously added TACACS+ accounting server.
  - **config tacacs acct (enable | disable) index**—Enables or disables a TACACS+ accounting server.
  - **config tacacs acct server-timeout index timeout**—Configures the retransmission timeout value for a TACACS+ accounting server.
- See TACACS+ statistics by entering these commands:
  - **show tacacs summary**—Shows a summary of TACACS+ servers and statistics.
  - **show tacacs auth stats**—Shows the TACACS+ authentication server statistics.
  - **show tacacs athr stats**—Shows the TACACS+ authorization server statistics.
  - **show tacacs acct stats**—Shows the TACACS+ accounting server statistics.
- Clear the statistics for one or more TACACS+ servers by entering this command:  
**clear stats tacacs [auth | athr | acct] {index | all}**
- Configure the order of authentication when multiple databases are configured by entering this command. The default setting is **local** and then **radius**.  
**config aaa auth mgmt [radius | tacacs]**  
 See the current management authentication server order by entering the **show aaa auth** command.
- Make sure the controller can reach the TACACS+ server by entering this command:  
**ping server\_ip\_address**
- Enable or disable TACACS+ debugging by entering this command:  
**debug aaa tacacs {enable | disable}**
- Save your changes by entering this command:  
**save config**

## Viewing the TACACS+ Administration Server Logs

### Prerequisites

You must have configured TACACS+ accounting server on the controller.

- 
- Step 1** On the ACS main page, in the left navigation pane, choose **Reports and Activity**.
  - Step 2** Under Reports, choose **TACACS+ Administration**.
  - Step 3** Click the .csv file corresponding to the date of the logs you want to view. The TACACS+ Administration .csv page appears.

Figure 7-4 TACACS+ Administration .csv Page on CiscoSecure ACS

The screenshot shows the CiscoSecure ACS web interface in Microsoft Internet Explorer. The browser address bar shows <http://172.19.27.31:2197/index2.htm>. The page title is "Reports and Activity". On the left, there is a "Select" menu with options: User Setup, Group Setup, Shared Profile Components, Network Configuration, System Configuration, Interface Configuration, Administration Control, External User Databases, Reports and Activity (selected), and Online Documentation. The "Reports" section is expanded, showing a list of reports: TACACS+ Accounting, TACACS+ Administration, RADIUS Accounting, VoIP Accounting, Passed Authentications, Failed Attempts, Logged-in Users, Disabled Accounts, ACS Backup And Restore, Administration Audit, User Password Changes, and ACS Service Monitoring. The "TACACS+ Administration" report is selected. The main content area shows a table titled "Tacacs+ Administration active.csv". The table has columns: Date, Time, User-Name, Group-Name, cmd, priv-ly, service, task\_id, NAS-IP-Address, and addr. The table contains six rows of data, all for the date 01/24/2007 and time 19:35:42, with User-Name "avinash\_wlan" and Group-Name "Group 12".

| Date       | Time     | User-Name    | Group-Name | cmd                            | priv-ly | service | task_id | NAS-IP-Address  | addr            |
|------------|----------|--------------|------------|--------------------------------|---------|---------|---------|-----------------|-----------------|
| 01/24/2007 | 19:35:42 | avinash_wlan | Group 12   | wlan interface 1 dyn1          | 9       | shell   | 1937    | 209.165.200.225 | 209.165.200.225 |
| 01/24/2007 | 19:35:42 | avinash_wlan | Group 12   | wlan enable 1                  | 9       | shell   | 1952    | 209.165.200.225 | 209.165.200.225 |
| 01/24/2007 | 19:35:42 | avinash_wlan | Group 12   | wlan mac-filtering enable 1    | 9       | shell   | 1948    | 209.165.200.225 | 209.165.200.225 |
| 01/24/2007 | 19:35:42 | avinash_wlan | Group 12   | wlan security 802.1X disable 1 | 9       | shell   | 1946    | 209.165.200.225 | 209.165.200.225 |
| 01/24/2007 | 19:35:42 | avinash_wlan | Group 12   | wlan qos 1 bronze              | 9       | shell   | 1944    | 209.165.200.225 | 209.165.200.225 |
| 01/24/2007 | 19:35:42 | avinash_wlan | Group 12   | wlan dhcp_server 1             | 9       | shell   | 1942    | 209.165.200.225 | 209.165.200.225 |

This page displays the following information:

- Date and time the action was taken
- Name and assigned role of the user who took the action
- Group to which the user belongs
- Specific action that the user took
- Privilege level of the user who executed the action
- IP address of the controller
- IP address of the laptop or workstation from which the action was executed

Sometimes a single action (or command) is logged multiple times, once for each parameter in the command. For example, if you enter the **snmp community ipaddr ip\_address subnet\_mask community\_name** command, the IP address may be logged on one line while the subnet mask and community name are logged as "E." On another line, the subnet mask maybe logged while the IP address and community name are logged as "E." See the first and third lines in the example in Figure 7-5.

**Figure 7-5 TACACS+ Administration .csv Page on CiscoSecure ACS**

The screenshot shows the CiscoSecure ACS web interface in Microsoft Internet Explorer. The browser address bar shows 'http://172.19.27.31:2955/index2.htm'. The page title is 'Reports and Activity'. On the left is a navigation menu with options like User Setup, Group Setup, Shared Profile Components, Network Configuration, System Configuration, Interface Configuration, Administration Control, External User Databases, Reports and Activity (selected), and Online Documentation. The main content area is titled 'Reports' and lists various report categories: TACACS+ Accounting, TACACS+ Administration, RADIUS Accounting, VoIP Accounting, Passed Authentications, Failed Attempts, Logged-in Users, Disabled Accounts, ACS Backup And Restore, Administration Audit, User Password Changes, ACS Service, and Monitoring. The 'TACACS+ Administration' report is selected, displaying a table titled 'Tacacs+ Administration active.csv'. The table has columns: Date, Time, User-Name, Group-Name, cmd, priv-lev, service, task\_id, and NAS-IP-Address. It contains five rows of data for the date 02/13/2007 at time 14:07:19, all for user 'avinash\_management' and group 'Group 16'. The commands include 'snmp community ipaddr 255.255.255.0 E', 'snmp community mode enable cisco', 'snmp community ipaddr 209.165.200. E E', 'snmp community accessmode rw cisco', and 'snmp community'. The NAS-IP-Address for all entries is 209.165.200.

| Date       | Time     | User-Name          | Group-Name | cmd                                    | priv-lev | service | task_id | NAS-IP-Address |
|------------|----------|--------------------|------------|----------------------------------------|----------|---------|---------|----------------|
| 02/13/2007 | 14:07:19 | avinash_management | Group 16   | snmp community ipaddr 255.255.255.0 E  | 129      | shell   | 217     | 209.165.200.   |
| 02/13/2007 | 14:07:19 | avinash_management | Group 16   | snmp community mode enable cisco       | 129      | shell   | 219     | 209.165.200.   |
| 02/13/2007 | 14:07:19 | avinash_management | Group 16   | snmp community ipaddr 209.165.200. E E | 129      | shell   | 216     | 209.165.200.   |
| 02/13/2007 | 14:07:19 | avinash_management | Group 16   | snmp community accessmode rw cisco     | 129      | shell   | 218     | 209.165.200.   |
| 02/13/2007 | 14:07:19 | avinash_management | Group 16   | snmp community                         | 129      | shell   | 215     | 209.165.200.   |

## Configuring Maximum Local Database Entries

This section contains the following topics:

- [Information About Configuring Maximum Local Database Entries, page 7-26](#)
- [Configuring Maximum Local Database Entries \(GUI\), page 7-26](#)
- [Configuring Maximum Local Database Entries \(CLI\), page 7-27](#)

## Information About Configuring Maximum Local Database Entries

You can configure the controller to specify the maximum number of local database entries used for storing user authentication information. The database entries include local management users (including lobby ambassadors), local network users (including guest users), MAC filter entries, exclusion list entries, and access point authorization list entries. Together, they cannot exceed the configured maximum value.

## Configuring Maximum Local Database Entries (GUI)

**Step 1** Choose **Security > AAA > General** to open the General page.

**Figure 7-6**      **General Page**

- Step 2**      In the Maximum Local Database Entries text box, enter a value for the maximum number of entries that can be added to the local database the next time the controller reboots. The currently configured value appears in parentheses to the right of the text box. The valid range is 512 to 2048, and the default setting is 2048.
- The Number of Entries, Already Used text box shows the number of entries currently in the database.
- Step 3**      Click **Apply** to commit your changes.
- Step 4**      Click **Save Configuration** to save your settings.
- 

## Configuring Maximum Local Database Entries (CLI)

- Step 1**      Specify the maximum number of entries that can be added to the local database the next time the controller reboots by entering this command:
- config database size** *max\_entries*
- Step 2**      Save your changes by entering this command:
- save config**
- Step 3**      View the maximum number of database entries and the current database contents by entering this command:
- show database summary**
- 

## Configuring Local Network Users on the Controller

This section contains the following topics:

- [Information About Local Network Users on Controller, page 7-28](#)
- [Configuring Local Network Users for the Controller, page 7-28](#)
- [Additional References, page 7-30](#)

## Information About Local Network Users on Controller

You can add local network users to the local user database on the controller. The local user database stores the credentials (username and password) of all the local network users. These credentials are then used to authenticate the users. For example, local EAP may use the local user database as its backend database to retrieve user credentials.

### Note

The controller passes client information to the RADIUS authentication server first. If the client information does not match a RADIUS database entry, the local user database is polled. Clients located in this database are granted access to network services if the RADIUS authentication fails or does not exist.

## Configuring Local Network Users for the Controller

This section contains the following topics:

- [Configuring Local Network Users for the Controller \(GUI\), page 7-28](#)
- [Configuring Local Network Users for the Controller \(CLI\), page 7-29](#)

### Configuring Local Network Users for the Controller (GUI)

**Step 1** Choose **Security > AAA > Local Net Users** to open the Local Net Users page.

**Figure 7-7** Local Net Users Page

| User Name | WLAN Profile | Guest User | Role     | Description  |
|-----------|--------------|------------|----------|--------------|
| abc       | All WLAN     | No         | N/A      | User A       |
| devel@    | All WLAN     | No         | N/A      | User B       |
| bill      | Guest WLAN   | Yes        | Contrast | Guest User 1 |

This page lists any local network users that have already been configured. It also specifies any guest users and the QoS role to which they are assigned (if applicable).

### Note

If you want to delete an existing user, hover your cursor over the blue drop-down arrow for that user and choose **Remove**.

**Step 2** Perform one of the following:

- To edit an existing local network user, click the username for that user. The Local Net Users > Edit page appears.
- To add a local network user, click **New**. The Local Net Users > New page appears.

- Step 3** If you are adding a new user, enter a username for the local user in the User Name text box. You can enter up to 24 alphanumeric characters.

**Note** Local network usernames must be unique because they are all stored in the same database.

- Step 4** In the Password and Confirm Password text boxes, enter a password for the local user. You can enter up to 24 alphanumeric characters.

- Step 5** If you are adding a new user, select the **Guest User** check box if you want to limit the amount of time that the user has access to the local network. The default setting is unselected.

- Step 6** If you are adding a new user and you selected the Guest User check box, enter the amount of time (in seconds) that the guest user account is to remain active in the Lifetime text box. The valid range is 60 to 2,592,000 seconds (30 days) inclusive, and the default setting is 86,400 seconds.

- Step 7** If you are adding a new user, you selected the Guest User check box, and you want to assign a QoS role to this guest user, select the **Guest User Role** check box. The default setting is unselected.

**Note** If you do not assign a QoS role to a guest user, the bandwidth contracts for this user are defined in the QoS profile for the WLAN.

- Step 8** If you are adding a new user and you selected the Guest User Role check box, choose the QoS role that you want to assign to this guest user from the Role drop-down list.

- Step 9** From the WLAN Profile drop-down list, choose the name of the WLAN that is to be accessed by the local user. If you choose **Any WLAN**, which is the default setting, the user can access any of the configured WLANs.

- Step 10** In the Description text box, enter a descriptive title for the local user (such as "User 1").

- Step 11** Click **Apply** to commit your changes.

- Step 12** Click **Save Configuration** to save your changes.

## Configuring Local Network Users for the Controller (CLI)

- Configure a local network user by entering these commands:
  - **config netuser add username password wlan wlan\_id userType permanent description description**—Adds a permanent user to the local user database on the controller.
  - **config netuser add username password {wlan | guestlan} {wlan\_id | guest\_lan\_id} userType guestlifetime seconds description description**—Adds a guest user on a WLAN or wired guest LAN to the local user database on the controller.

**Note** Instead of adding a permanent user or a guest user to the local user database from the controller, you can choose to create an entry on the RADIUS server for the user and enable RADIUS authentication for the WLAN on which web authentication is performed.

- **config netuser delete username**—Deletes a user from the local user database on the controller.

**Note** Local network usernames must be unique because they are all stored in the same database.

- See information related to the local network users configured on the controller by entering these commands:
  - **show netuser detail *username***—Shows the configuration of a particular user in the local user database.
  - **show netuser summary**—Lists all the users in the local user database.
- Save your changes by entering this command:
  - save config**

## Additional References

To know more about configuring local network users, see [“Configuring Local EAP” section on page 7-36](#) for more information.

If you want to create a new QoS role, see the [“Configuring Quality of Service” section on page 4-66](#) for instructions.

## Configuring Password Policies

This section contains the following topics:

- [Information About Password Policies, page 7-30](#)
- [Configuring Password Policies \(GUI\), page 7-30](#)
- [Configuring Password Policies \(CLI\), page 7-31](#)

## Information About Password Policies

The password policies allows you to enforce strong password checks on newly created passwords for additional management users of controller and access point. The following are the requirements enforced on the new password:

- When the controller is upgraded from old version, all the old passwords are maintained as it is, even though the passwords are weak. After the system upgrade, if strong password checks are enabled, the same is enforced from that time and the strength of previously added passwords will not be checked or altered.
- Depending on the settings done in the Password Policy page, the local management and access point user configuration is affected.

## Configuring Password Policies (GUI)

- 
- Step 1** Choose **Security > AAA > Password Policies** to open the Password Policies page.
  - Step 2** Select the **Password must contain characters from at least 3 different classes** check box if you want your password to contain characters from at least three of the following classes: lower case letters, upper case letters, digits, and special characters.
  - Step 3** Select **No character can be repeated more than 3 times consecutively** check box if you do not want character in the new password to repeat more than three times consecutively.

- Step 4** Select the **Password cannot be the default words like cisco, admin** check box if you do not want the password to contain words such as Cisco, ocsic, admin, nimda, or any variant obtained by changing the capitalization of letters or by substituting 1, l, or! or substituting 0 for o or substituting \$ for s.
- Step 5** Select the **Password cannot contain username or reverse of username** check box if you do not want the password to contain a username or the reverse letters of a username.
- Step 6** Click **Apply** to commit your changes.
- Step 7** Click **Save Configuration** to save your changes.
- 

## Configuring Password Policies (CLI)

- Step 1** Enable or disable strong password check for AP and WLC by entering this command:
- ```
config switchconfig strong-pwd { case-check | consecutive-check | default-check | username-check | all-check } { enable | disable }
```
- where
- **case-check**—Checks the occurrence of same character thrice consecutively
  - **consecutive-check**—Checks the default values or its variants are being used.
  - **default-check**—Checks either username or its reverse is being used.
  - **all-checks**—Enables/disables all the strong password checks.
- Step 2** See the configured options for strong password check by entering this command:
- ```
show switchconfig
```
- 

### Example: Show Command for Password Policies

Information similar to the following appears:

```
802.3x Flow Control Mode..... Disabled
FIPS prerequisite features..... Disabled
secret obfuscation..... Enabled
Strong Password Check Features:

    case-check .....Enabled
    consecutive-check ...Enabled
    default-check .....Enabled
    username-check .....Enabled
```

## Configuring LDAP

This section explains how to configure a Lightweight Directory Access Protocol (LDAP) server as a backend database, similar to a RADIUS or local user database.

This section contains the following topics:

- [Information About LDAP, page 7-32](#)
- [Configuring LDAP \(GUI\), page 7-32](#)

- [Configuring LDAP \(CLI\), page 7-34](#)
- [Additional References, page 7-36](#)

## Information About LDAP

An LDAP backend database allows the controller to query an LDAP server for the credentials (username and password) of a particular user. These credentials are then used to authenticate the user. For example, local EAP may use an LDAP server as its backend database to retrieve user credentials.

### Note

The LDAP backend database supports these local EAP methods: EAP-TLS, EAP-FAST/GTC, and PEAPv1/GTC. LEAP, EAP-FAST/MSCHAPv2, and PEAPv0/MSCHAPv2 are also supported but only if the LDAP server is set up to return a clear-text password.

### Note

Cisco wireless LAN controllers support Local EAP authentication against external LDAP databases such as Microsoft Active Directory and Novell's eDirectory. For more information about configuring the controller for Local EAP authentication against Novell's eDirectory, see the *Configure Unified Wireless Network for Authentication Against Novell's eDirectory Database* whitepaper at [http://www.cisco.com/en/US/products/ps6366/products\\_white\\_paper09186a0080b4cd24.shtml](http://www.cisco.com/en/US/products/ps6366/products_white_paper09186a0080b4cd24.shtml).

## Configuring LDAP (GUI)

- Step 1** Choose **Security > AAA > LDAP** to open the LDAP Servers page.

**Figure 7-8** LDAP Servers Page

| Server Index | Server Address  | Port | Server State | Bind          |
|--------------|-----------------|------|--------------|---------------|
| 1            | 2.3.1.4         | 389  | Disabled     | Anonymous     |
| 2            | 209.186.200.225 | 389  | Enabled      | Authenticated |

This page lists any LDAP servers that have already been configured.

- If you want to delete an existing LDAP server, hover your cursor over the blue drop-down arrow for that server and choose **Remove**.
- If you want to make sure that the controller can reach a particular server, hover your cursor over the blue drop-down arrow for that server and choose **Ping**.

- Step 2** Perform one of the following:

- To edit an existing LDAP server, click the index number for that server. The LDAP Servers > Edit page appears.

- To add an LDAP server, click **New**. The LDAP Servers > New page appears. If you are adding a new server, choose a number from the Server Index (Priority) drop-down list to specify the priority order of this server in relation to any other configured LDAP servers. You can configure up to 17 servers. If the controller cannot reach the first server, it tries the second one in the list and so on.

- Step 3** If you are adding a new server, enter the IP address of the LDAP server in the Server IP Address text box.
- Step 4** If you are adding a new server, enter the LDAP server's TCP port number in the Port Number text box. The valid range is 1 to 65535, and the default value is 389.
- Step 5** Select the **Enable Server Status** check box to enable this LDAP server or unselect it to disable it. The default value is disabled.
- Step 6** From the Simple Bind drop-down list, choose **Anonymous** or **Authenticated** to specify the local authentication bind method for the LDAP server. The Anonymous method allows anonymous access to the LDAP server. The Authenticated method requires that a username and password be entered to secure access. The default value is **Anonymous**.
- Step 7** If you chose Authenticated in [Step 6](#), follow these steps:
- a. In the Bind Username text box, enter a username to be used for local authentication to the LDAP server. The username can contain up to 80 characters.

**Note**

If the username starts with "cn=" (in lowercase letters), the controller assumes that the username includes the entire LDAP database path and does not append the user base DN. This designation allows the authenticated bind user to be outside the user base DN.

- b. In the Bind Password and Confirm Bind Password text boxes, enter a password to be used for local authentication to the LDAP server. The password can contain up to 32 characters.
- Step 8** In the User Base DN text box, enter the distinguished name (DN) of the subtree in the LDAP server that contains a list of all the users. For example, ou=organizational unit, .ou=next organizational unit, and o=corporation.com. If the tree containing users is the base DN, type **o=corporation.com** or **dc=corporation,dc=com**.
- Step 9** In the User Attribute text box, enter the name of the attribute in the user record that contains the username. You can obtain this attribute from your directory server.
- Step 10** In the User Object Type text box, enter the value of the LDAP objectType attribute that identifies the record as a user. Often, user records have several values for the objectType attribute, some of which are unique to the user and some of which are shared with other object types.
- Step 11** In the Server Timeout text box, enter the number of seconds between retransmissions. The valid range is 2 to 30 seconds, and the default value is 2 seconds.
- Step 12** Click **Apply** to commit your changes.
- Step 13** Click **Save Configuration** to save your changes.
- Step 14** Specify LDAP as the priority backend database server for local EAP authentication as follows:
- a. Choose **Security > Local EAP > Authentication Priority** to open the Priority Order > Local-Auth page.
  - b. Highlight **LOCAL** and click < to move it to the left User Credentials box.
  - c. Highlight **LDAP** and click > to move it to the right User Credentials box. The database that appears at the top of the right User Credentials box is used when retrieving user credentials.

**Note**

If both LDAP and LOCAL appear in the right User Credentials box with LDAP on the top and LOCAL on the bottom, local EAP attempts to authenticate clients using the LDAP backend database and fails over to the local user database if the LDAP servers are not reachable. If the user is not found, the authentication attempt is rejected. If LOCAL is on the top, local EAP attempts to authenticate using only the local user database. It does not fail over to the LDAP backend database.

- d. Click **Apply** to commit your changes.
- e. Click **Save Configuration** to save your changes.

**Step 15** (Optional) Assign specific LDAP servers to a WLAN as follows:

- a. Choose **WLANs** to open the WLANs page.
- b. Click the ID number of the desired WLAN.
- c. When the WLANs > Edit page appears, choose the **Security > AAA Servers** tabs to open the WLANs > Edit (Security > AAA Servers) page.
- d. From the LDAP Servers drop-down lists, choose the LDAP server(s) that you want to use with this WLAN. You can choose up to three LDAP servers, which are tried in priority order.

**Note**

These LDAP servers apply only to WLANs with web authentication enabled. They are not used by local EAP.

- e. Click **Apply** to commit your changes.
- f. Click **Save Configuration** to save your changes.

## Configuring LDAP (CLI)

- Configure an LDAP server by entering these commands:
  - **config ldap add index server\_ip\_address port# user\_base user\_attr user\_type**—Adds an LDAP server.
  - **config ldap delete index**—Deletes a previously added LDAP server.
  - **config ldap {enable | disable} index**—Enables or disables an LDAP server.
  - **config ldap simple-bind {anonymous index | authenticated index username username password password}**—Specifies the local authentication bind method for the LDAP server. The anonymous method allows anonymous access to the LDAP server whereas the authenticated method requires that a username and password be entered to secure access. The default value is **anonymous**.

**Note**

The username can contain up to 80 characters.

**Note**

If the username starts with “cn=” (in lowercase letters), the controller assumes that the username includes the entire LDAP database path and does not append the user base DN. This designation allows the authenticated bind user to be outside the user base DN.

- **config ldap retransmit-timeout** *index timeout*—Configures the number of seconds between retransmissions for an LDAP server.
- Specify LDAP as the priority backend database server by entering this command:

**config local-auth user-credentials ldap**

**Note**

If you enter the **config local-auth user-credentials ldap local** command, local EAP attempts to authenticate clients using the LDAP backend database and fails over to the local user database if the LDAP servers are not reachable. If the user is not found, the authentication attempt is rejected. If you enter the **config local-auth user-credentials local ldap** command, local EAP attempts to authenticate using only the local user database. It does not fail over to the LDAP backend database.

- (Optional) Assign specific LDAP servers to a WLAN by entering these commands:
  - **config wlan ldap add** *wlan\_id server\_index*—Links a configured LDAP server to a WLAN.

**Note**

The LDAP servers specified in this command apply only to WLANs with web authentication enabled. They are not used by local EAP.

- **config wlan ldap delete** *wlan\_id {all | index}*—Deletes a specific or all configured LDAP server(s) from a WLAN.
- View information pertaining to configured LDAP servers by entering these commands:
  - **show ldap summary**—Shows a summary of the configured LDAP servers.

| Idx | Server Address | Port | Enabled |
|-----|----------------|------|---------|
| 1   | 2.3.1.4        | 389  | No      |
| 2   | 10.10.20.22    | 389  | Yes     |

- **show ldap index**—Shows detailed LDAP server information. Information similar to following appears:

```

Server Index..... 2
Address..... 10.10.20.22
Port..... 389
Enabled..... Yes
User DN.....
ou=active,ou=employees,ou=people,
                                     o=cisco.com
User Attribute..... uid
User Type..... Person
Retransmit Timeout..... 2 seconds
Bind Method ..... Authenticated
Bind Username..... user1

```

- **show ldap statistics**—Shows LDAP server statistics.

```

Server Index..... 1

```

```

Server statistics:
  Initialized OK..... 0
  Initialization failed..... 0
  Initialization retries..... 0
  Closed OK..... 0
Request statistics:
  Received..... 0
  Sent..... 0
  OK..... 0
  Success..... 0
  Authentication failed..... 0
  Server not found..... 0
  No received attributes..... 0
  No passed username..... 0
  Not connected to server..... 0
  Internal error..... 0
  Retries..... 0

Server Index..... 2
..

```

– **show wlan wlan\_id**—Shows the LDAP servers that are applied to a WLAN.

- Make sure the controller can reach the LDAP server by entering this command:  
**ping server\_ip\_address**
- Save your changes by entering this command:  
**save config**
- Enable or disable debugging for LDAP by entering this command:  
**debug aaa ldap {enable | disable}**

## Additional References

For more information about configuring LEAP, see the [“Configuring Local EAP”](#) section on page 7-36.

## Configuring Local EAP

This section contains the following topics:

- [Information About Local EAP, page 7-36](#)
- [Configuring Local EAP \(GUI\), page 7-38](#)
- [Configuring Local EAP \(CLI\), page 7-42](#)
- [Additional References, page 7-47](#)

## Information About Local EAP

Local EAP is an authentication method that allows users and wireless clients to be authenticated locally. It is designed for use in remote offices that want to maintain connectivity to wireless clients when the backend system becomes disrupted or the external authentication server goes down. When you enable local EAP, the controller serves as the authentication server and the local user database, which removes dependence on an external authentication server. Local EAP retrieves user credentials from the local user

database or the LDAP backend database to authenticate users. Local EAP supports LEAP, EAP-FAST, EAP-TLS, PEAPv0/MSCHAPv2, and PEAPv1/GTC authentication between the controller and wireless clients.

**Note**

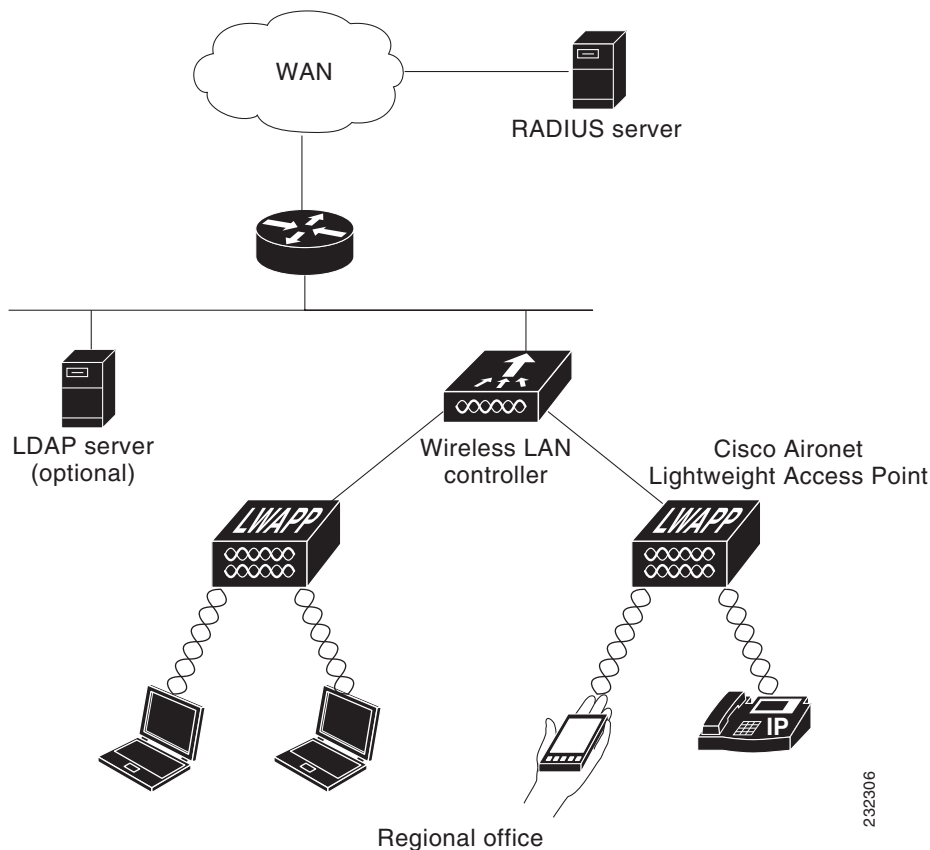

The LDAP backend database supports these local EAP methods: EAP-TLS, EAP-FAST/GTC, and PEAPv1/GTC. LEAP, EAP-FAST/MSCHAPv2, and PEAPv0/MSCHAPv2 are also supported but only if the LDAP server is set up to return a clear-text password.

**Note**

Cisco wireless LAN controllers support Local EAP authentication against external LDAP databases such as Microsoft Active Directory and Novell's eDirectory. For more information about configuring the controller for Local EAP authentication against Novell's eDirectory, see the *Configure Unified Wireless Network for Authentication Against Novell's eDirectory Database* whitepaper at [http://www.cisco.com/en/US/products/ps6366/products\\_white\\_paper09186a0080b4cd24.shtml](http://www.cisco.com/en/US/products/ps6366/products_white_paper09186a0080b4cd24.shtml).

If any RADIUS servers are configured on the controller, the controller tries to authenticate the wireless clients using the RADIUS servers first. Local EAP is attempted only if no RADIUS servers are found, either because the RADIUS servers timed out or no RADIUS servers were configured. If four RADIUS servers are configured, the controller attempts to authenticate the client with the first RADIUS server, then the second RADIUS server, and then local EAP. If the client attempts to then reauthenticate manually, the controller tries the third RADIUS server, then the fourth RADIUS server, and then local EAP. If you never want the controller to try to authenticate clients using an external RADIUS server, enter these CLI commands in this order:

- **config wlan disable** *wlan\_id*
- **config wlan radius\_server auth disable** *wlan\_id*
- **config wlan enable** *wlan\_id*

**Figure 7-9 Local EAP Example**

## Guidelines and Limitations

Local EAP Profiles are not supported on AP602 OEAP.

## Configuring Local EAP (GUI)

### Note

EAP-TLS, PEAPv0/MSCHAPv2, and PEAPv1/GTC use certificates for authentication, and EAP-FAST uses either certificates or PACbs. The controller is shipped with Cisco-installed device and Certificate Authority (CA) certificates. However, if you want to use your own vendor-specific certificates, they must be imported on the controller.

- 
- Step 1** If you are configuring local EAP to use one of the EAP types listed in the note above, make sure that the appropriate certificates and PACs (if you will use manual PAC provisioning) have been imported on the controller.
- Step 2** If you want the controller to retrieve user credentials from the local user database, make sure that you have properly configured the local network users on the controller.
- Step 3** If you want the controller to retrieve user credentials from an LDAP backend database, make sure that you have properly configured an LDAP server on the controller.

- Step 4** Specify the order in which user credentials are retrieved from the backend database servers as follows:
- Choose **Security > Local EAP > Authentication Priority** to open the Priority Order > Local-Auth page.
  - Determine the priority order in which user credentials are to be retrieved from the local and/or LDAP databases. For example, you may want the LDAP database to be given priority over the local user database, or you may not want the LDAP database to be considered at all.
  - When you have decided on a priority order, highlight the desired database. Then use the left and right arrows and the Up and Down buttons to move the desired database to the top of the right User Credentials box.

**Note** If both LDAP and LOCAL appear in the right User Credentials box with LDAP on the top and LOCAL on the bottom, local EAP attempts to authenticate clients using the LDAP backend database and fails over to the local user database if the LDAP servers are not reachable. If the user is not found, the authentication attempt is rejected. If LOCAL is on the top, local EAP attempts to authenticate using only the local user database. It does not fail over to the LDAP backend database.

- Click **Apply** to commit your changes.

- Step 5** Specify values for the local EAP timers as follows:

- Choose **Security > Local EAP > General** to open the General page.
- In the Local Auth Active Timeout text box, enter the amount of time (in seconds) in which the controller attempts to authenticate wireless clients using local EAP after any pair of configured RADIUS servers fails. The valid range is 1 to 3600 seconds, and the default setting is 100 seconds.
- In the Identity Request Timeout text box, enter the amount of time (in seconds) in which the controller attempts to send an EAP identity request to wireless clients using local EAP. The valid range is 1 to 120 seconds, and the default setting is 30 seconds.
- In the Identity Request Max Retries text box, enter the maximum number of times that the controller attempts to retransmit the EAP identity request to wireless clients using local EAP. The valid range is 1 to 20 retries, and the default setting is 20 retries.
- In the Dynamic WEP Key Index text box, enter the key index used for dynamic wired equivalent privacy (WEP). The default value is 0, which corresponds to a key index of 1; the valid values are 0 to 3 (key index of 1 to 4).
- In the Request Timeout text box, enter the amount of time (in seconds) in which the controller attempts to send an EAP request to wireless clients using local EAP. The valid range is 1 to 120 seconds, and the default setting is 30 seconds.
- In the Request Max Retries text box, enter the maximum number of times that the controller attempts to retransmit the EAP request to wireless clients using local EAP. The valid range is 1 to 120 retries, and the default setting is 20 retries.
- From the Max-Login Ignore Identity Response drop-down list, choose **Enable** to limit the number of devices that can be connected to the controller with the same username. You can log in up to eight times from different devices (PDA, laptop, IP phone, and so on) on the same controller. The default value is enabled.
- In the EAPOL-Key Timeout text box, enter the amount of time (in seconds) in which the controller attempts to send an EAP key over the LAN to wireless clients using local EAP. The valid range is 1 to 5 seconds, and the default setting is 1 second.

**Note** If the controller and access point are separated by a WAN link, the default timeout of 1 second may not be sufficient.

- j. In the EAPOL-Key Max Retries text box, enter the maximum number of times that the controller attempts to send an EAP key over the LAN to wireless clients using local EAP. The valid range is 0 to 4 retries, and the default setting is 2 retries.
- k. Click **Apply** to commit your changes.

**Step 6** Create a local EAP profile, which specifies the EAP authentication types that are supported on the wireless clients as follows:

- a. Choose **Security > Local EAP > Profiles** to open the Local EAP Profiles page.

This page lists any local EAP profiles that have already been configured and specifies their EAP types. You can create up to 16 local EAP profiles.

**Note** If you want to delete an existing profile, hover your cursor over the blue drop-down arrow for that profile and choose **Remove**.

- b. Click **New** to open the Local EAP Profiles > New page.
- c. In the Profile Name text box, enter a name for your new profile and then click **Apply**.

**Note** You can enter up to 63 alphanumeric characters for the profile name. Make sure not to include spaces.

- d. When the Local EAP Profiles page reappears, click the name of your new profile. The Local EAP Profiles > Edit page appears.
- e. Select the **LEAP**, **EAP-FAST**, **EAP-TLS**, and/or **PEAP** check boxes to specify the EAP type that can be used for local authentication.

**Note** You can specify more than one EAP type per profile. However, if you choose multiple EAP types that use certificates (such as EAP-FAST with certificates, EAP-TLS, PEAPv0/MSCHAPv2, and PEAPv1/GTC), all of the EAP types must use the same certificate (from either Cisco or another vendor).

**Note** If you select the PEAP check box, both PEAPv0/MSCHAPv2 or PEAPv1/GTC are enabled on the controller.

- f. If you chose EAP-FAST and want the device certificate on the controller to be used for authentication, select the **Local Certificate Required** check box. If you want to use EAP-FAST with PACs instead of certificates, leave this check box unselected, which is the default setting.

**Note** This option applies only to EAP-FAST because device certificates are not used with LEAP and are mandatory for EAP-TLS and PEAP.

- g. If you chose EAP-FAST and want the wireless clients to send their device certificates to the controller in order to authenticate, select the **Client Certificate Required** check box. If you want to use EAP-FAST with PACs instead of certificates, leave this check box unselected, which is the default setting.

**Note** This option applies only to EAP-FAST because client certificates are not used with LEAP or PEAP and are mandatory for EAP-TLS.

- h. If you chose EAP-FAST with certificates, EAP-TLS, or PEAP, choose which certificates will be sent to the client, the ones from **Cisco** or the ones from another **Vendor**, from the Certificate Issuer drop-down list. The default setting is Cisco.
- i. If you chose EAP-FAST with certificates or EAP-TLS and want the incoming certificate from the client to be validated against the CA certificates on the controller, select the **Check against CA certificates** check box. The default setting is enabled.
- j. If you chose EAP-FAST with certificates or EAP-TLS and want the common name (CN) in the incoming certificate to be validated against the CA certificates' CN on the controller, select the **Verify Certificate CN Identity** check box. The default setting is disabled.
- k. If you chose EAP-FAST with certificates or EAP-TLS and want the controller to verify that the incoming device certificate is still valid and has not expired, select the **Check Certificate Date Validity** check box. The default setting is enabled.

**Note** Certificate date validity is checked against the current UTC (GMT) time that is configured on the controller. Timezone offset will be ignored.

- l. Click **Apply** to commit your changes.

**Step 7** If you created an EAP-FAST profile, follow these steps to configure the EAP-FAST parameters:

- a. Choose **Security > Local EAP > EAP-FAST Parameters** to open the EAP-FAST Method Parameters page.
- b. In the Server Key and Confirm Server Key text boxes, enter the key (in hexadecimal characters) used to encrypt and decrypt PACs.
- c. In the Time to Live for the PAC text box, enter the number of days for the PAC to remain viable. The valid range is 1 to 1000 days, and the default setting is 10 days.
- d. In the Authority ID text box, enter the authority identifier of the local EAP-FAST server in hexadecimal characters. You can enter up to 32 hexadecimal characters, but you must enter an even number of characters.
- e. In the Authority ID Information text box, enter the authority identifier of the local EAP-FAST server in text format.
- f. If you want to enable anonymous provisioning, select the **Anonymous Provision** check box. This feature allows PACs to be sent automatically to clients that do not have one during PAC provisioning. If you disable this feature, PACs must be manually provisioned. The default setting is enabled.

**Note** If the local and/or client certificates are required and you want to force all EAP-FAST clients to use certificates, unselect the **Anonymous Provision** check box.

- g. Click **Apply** to commit your changes.

- Step 8** Enable local EAP on a WLAN as follows:
- Choose **WLANs** to open the WLANs page.
  - Click the ID number of the desired WLAN.
  - When the WLANs > Edit page appears, choose the **Security > AAA Servers** tabs to open the WLANs > Edit (Security > AAA Servers) page.
  - Select the **Local EAP Authentication** check box to enable local EAP for this WLAN.
  - From the EAP Profile Name drop-down list, choose the EAP profile that you want to use for this WLAN.
  - If desired, choose the LDAP server that you want to use with local EAP on this WLAN from the LDAP Servers drop-down lists.
  - Click **Apply** to commit your changes.
- Step 9** Click **Save Configuration** to save your changes.
- 

## Configuring Local EAP (CLI)

### Note

EAP-TLS, PEAPv0/MSCHAPv2, and PEAPv1/GTC use certificates for authentication, and EAP-FAST uses either certificates or PACbs. The controller is shipped with Cisco-installed device and Certificate Authority (CA) certificates. However, if you want to use your own vendor-specific certificates, they must be imported on the controller.

---

- Step 1** If you are configuring local EAP to use one of the EAP types listed in the note above, make sure that the appropriate certificates and PACs (if you will use manual PAC provisioning) have been imported on the controller.
- Step 2** If you want the controller to retrieve user credentials from the local user database, make sure that you have properly configured the local network users on the controller.
- Step 3** If you want the controller to retrieve user credentials from an LDAP backend database, make sure that you have properly configured an LDAP server on the controller.
- Step 4** Specify the order in which user credentials are retrieved from the local and/or LDAP databases by entering this command:

```
config local-auth user-credentials {local | ldap}
```

### Note

If you enter the **config local-auth user-credentials ldap local** command, local EAP attempts to authenticate clients using the LDAP backend database and fails over to the local user database if the LDAP servers are not reachable. If the user is not found, the authentication attempt is rejected. If you enter the **config local-auth user-credentials local ldap** command, local EAP attempts to authenticate using only the local user database. It does not fail over to the LDAP backend database.

---

- Step 5** Specify values for the local EAP timers by entering these commands:

- **config local-auth active-timeout** *timeout*—Specifies the amount of time (in seconds) in which the controller attempts to authenticate wireless clients using local EAP after any pair of configured RADIUS servers fails. The valid range is 1 to 3600 seconds, and the default setting is 100 seconds.
- **config advanced eap identity-request-timeout** *timeout*—Specifies the amount of time (in seconds) in which the controller attempts to send an EAP identity request to wireless clients using local EAP. The valid range is 1 to 120 seconds, and the default setting is 30 seconds.
- **config advanced eap identity-request-retries** *retries*—Specifies the maximum number of times that the controller attempts to retransmit the EAP identity request to wireless clients using local EAP. The valid range is 1 to 20 retries, and the default setting is 20 retries.
- **config advanced eap key-index** *index*—Specifies the key index used for dynamic wired equivalent privacy (WEP). The default value is 0, which corresponds to a key index of 1; the valid values are 0 to 3 (key index of 1 to 4).
- **config advanced eap request-timeout** *timeout*—Specifies the amount of time (in seconds) in which the controller attempts to send an EAP request to wireless clients using local EAP. The valid range is 1 to 120 seconds, and the default setting is 30 seconds.
- **config advanced eap request-retries** *retries*—Specifies the maximum number of times that the controller attempts to retransmit the EAP request to wireless clients using local EAP. The valid range is 1 to 120 retries, and the default setting is 20 retries.
- **config advanced eap eapol-key-timeout** *timeout*—Specifies the amount of time (in seconds) in which the controller attempts to send an EAP key over the LAN to wireless clients using local EAP. The valid range is 1 to 5 seconds, and the default setting is 1 second.

**Note**

If the controller and access point are separated by a WAN link, the default timeout of 1 second may not be sufficient.

- **config advanced eap eapol-key-retries** *retries*—Specifies the maximum number of times that the controller attempts to send an EAP key over the LAN to wireless clients using local EAP. The valid range is 0 to 4 retries, and the default setting is 2 retries.
- **config advanced eap max-login-ignore-identity-response** {**enable** | **disable**}—When enabled, this command limits the number of devices that can be connected to the controller with the same username. You can log in up to eight times from different devices (PDA, laptop, IP phone, and so on) on the same controller. The default value is enabled.

**Step 6** Create a local EAP profile by entering this command:

**config local-auth eap-profile add** *profile\_name*

**Note**

Do not include spaces within the profile name.

**Note**

To delete a local EAP profile, enter the **config local-auth eap-profile delete** *profile\_name* command.

**Step 7** Add an EAP method to a local EAP profile by entering this command:

**config local-auth eap-profile method add** *method profile\_name*

The supported methods are leap, fast, tls, and peap.

**Note** If you choose peap, both PEAPv0/MSCHAPv2 or PEAPv1/GTC are enabled on the controller.

**Note** You can specify more than one EAP type per profile. However, if you create a profile with multiple EAP types that use certificates (such as EAP-FAST with certificates, EAP-TLS, PEAPv0/MSCHAPv2, and PEAPv1/GTC), all of the EAP types must use the same certificate (from either Cisco or another vendor).

**Note** To delete an EAP method from a local EAP profile, enter the **config local-auth eap-profile method delete method profile\_name** command:

**Step 8** Configure EAP-FAST parameters if you created an EAP-FAST profile by entering this command:

**config local-auth method fast ?**

where ? is one of the following:

- **anon-prov {enable | disable}**—Configures the controller to allow anonymous provisioning, which allows PACs to be sent automatically to clients that do not have one during PAC provisioning.
- **authority-id auth\_id**—Specifies the authority identifier of the local EAP-FAST server.
- **pac-ttl days**—Specifies the number of days for the PAC to remain viable.
- **server-key key**—Specifies the server key used to encrypt and decrypt PACs.

**Step 9** Configure certificate parameters per profile by entering these commands:

- **config local-auth eap-profile method fast local-cert {enable | disable} profile\_name**—Specifies whether the device certificate on the controller is required for authentication.

**Note** This command applies only to EAP-FAST because device certificates are not used with LEAP and are mandatory for EAP-TLS and PEAP.

- **config local-auth eap-profile method fast client-cert {enable | disable} profile\_name**—Specifies whether wireless clients are required to send their device certificates to the controller in order to authenticate.

**Note** This command applies only to EAP-FAST because client certificates are not used with LEAP or PEAP and are mandatory for EAP-TLS.

- **config local-auth eap-profile cert-issuer {cisco | vendor} profile\_name**—If you specified EAP-FAST with certificates, EAP-TLS, or PEAP, specifies whether the certificates that will be sent to the client are from Cisco or another vendor.
- **config local-auth eap-profile cert-verify ca-issuer {enable | disable} profile\_name**—If you chose EAP-FAST with certificates or EAP-TLS, specifies whether the incoming certificate from the client is to be validated against the CA certificates on the controller.
- **config local-auth eap-profile cert-verify cn-verify {enable | disable} profile\_name**—If you chose EAP-FAST with certificates or EAP-TLS, specifies whether the common name (CN) in the incoming certificate is to be validated against the CA certificates' CN on the controller.

- **config local-auth eap-profile cert-verify date-valid {enable | disable} profile\_name**—If you chose EAP-FAST with certificates or EAP-TLS, specifies whether the controller is to verify that the incoming device certificate is still valid and has not expired.

**Step 10** Enable local EAP and attach an EAP profile to a WLAN by entering this command:

**config wlan local-auth enable** profile\_name wlan\_id

**Note** To disable local EAP for a WLAN, enter the **config wlan local-auth disable** wlan\_id command.

**Step 11** Save your changes by entering this command:

**save config**

**Step 12** View information pertaining to local EAP by entering these commands:

- **show local-auth config**—Shows the local EAP configuration on the controller.

```
User credentials database search order:
  Primary ..... Local DB

Timer:
  Active timeout ..... 300

Configured EAP profiles:
  Name ..... fast-cert
  Certificate issuer ..... vendor
  Peer verification options:
    Check against CA certificates ..... Enabled
    Verify certificate CN identity ..... Disabled
    Check certificate date validity ..... Enabled
  EAP-FAST configuration:
    Local certificate required ..... Yes
    Client certificate required ..... Yes
    Enabled methods ..... fast
    Configured on WLANs ..... 1

  Name ..... tls
  Certificate issuer ..... vendor
  Peer verification options:
    Check against CA certificates ..... Enabled
    Verify certificate CN identity ..... Disabled
    Check certificate date validity ..... Enabled
  EAP-FAST configuration:
    Local certificate required ..... No
    Client certificate required ..... No
    Enabled methods ..... tls
    Configured on WLANs ..... 2

EAP Method configuration:
  EAP-FAST:
    Server key ..... <hidden>
    TTL for the PAC ..... 10
    Anonymous provision allowed ..... Yes
    Accept client on auth prov ..... No
    Authority ID ..... 436973636f0000000000000000000000
    Authority Information ..... Cisco A-ID
```

- **show local-auth statistics**—Shows the local EAP statistics.
- **show local-auth certificates**—Shows the certificates available for local EAP.

- **show local-auth user-credentials**—Shows the priority order that the controller uses when retrieving user credentials from the local and/or LDAP databases.
- **show advanced eap**—Shows the timer values for local EAP.
 

```
EAP-Identity-Request Timeout (seconds)..... 1
EAP-Identity-Request Max Retries..... 20
EAP Key-Index for Dynamic WEP..... 0
EAP Max-Login Ignore Identity Response..... enable
EAP-Request Timeout (seconds)..... 20
EAP-Request Max Retries..... 20
EAPOL-Key Timeout (seconds)..... 1
EAPOL-Key Max Retries..... 2
```
- **show ap stats wlan Cisco\_AP**—Shows the EAP timeout and failure counters for a specific access point for each WLAN.
- **show client detail client\_mac**—Shows the EAP timeout and failure counters for a specific associated client. These statistics are useful in troubleshooting client association issues.

...

Client Statistics:

```
Number of Bytes Received..... 10
Number of Bytes Sent..... 10
Number of Packets Received..... 2
Number of Packets Sent..... 2
Number of EAP Id Request Msg Timeouts..... 0
Number of EAP Id Request Msg Failures..... 0
Number of EAP Request Msg Timeouts..... 2
Number of EAP Request Msg Failures..... 1
Number of EAP Key Msg Timeouts..... 0
Number of EAP Key Msg Failures..... 0
Number of Policy Errors..... 0
Radio Signal Strength Indicator..... Unavailable
Signal to Noise Ratio..... Unavailable
```

- **show wlan wlan\_id**—Shows the status of local EAP on a particular WLAN.

**Step 13** (Optional) Troubleshoot local EAP sessions by entering these commands:

- **debug aaa local-auth eap method {all | errors | events | packets | sm} {enable | disable}**—Enables or disables debugging of local EAP methods.
- **debug aaa local-auth eap framework {all | errors | events | packets | sm} {enable | disable}**—Enables or disables debugging of the local EAP framework.

**Note** In these two debug commands, **sm** is the state machine.

- **clear stats local-auth**—Clears the local EAP counters.
- **clear stats ap wlan Cisco\_AP**—Clears the EAP timeout and failure counters for a specific access point for each WLAN.

```
WLAN      1
EAP Id Request Msg Timeouts..... 0

# Configuring the System for SpectraLink NetLink Telephones

This section contains the following topics:

- [Information About SpectraLink NetLink Telephones, page 7-47](#)
- [Configuring SpectraLink NetLink Phones, page 7-47](#)

## Information About SpectraLink NetLink Telephones

For the best integration with the Cisco UWN solution, SpectraLink NetLink Telephones require an extra operating system configuration step: **enable long preambles**. The radio preamble (sometimes called a header) is a section of data at the head of a packet that contains information that wireless devices need when sending and receiving packets. Short preambles improve throughput performance, so they are enabled by default. However, some wireless devices, such as SpectraLink NetLink phones, require long preambles.

## Configuring SpectraLink NetLink Phones

This section contains the following topics:

- [Enabling Long Preambles \(GUI\), page 7-47](#)
- [Enabling Long Preambles \(CLI\), page 7-48](#)
- [Configuring Enhanced Distributed Channel Access \(CLI\), page 7-49](#)

## Enabling Long Preambles (GUI)

- 
- |               |                                                                                                                                                                                                                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Choose <b>Wireless &gt; 802.11b/g/n &gt; Network</b> to open the 802.11b/g Global Parameters page.                                                                                                                                                                                                  |
| <b>Step 2</b> | If the Short Preamble check box is selected, continue with this procedure. However, if the Short Preamble check box is unselected (which means that long preambles are enabled), the controller is already optimized for SpectraLink NetLink phones and you do not need to continue this procedure. |
| <b>Step 3</b> | Unselect the <b>Short Preamble</b> check box to enable long preambles.                                                                                                                                                                                                                              |
| <b>Step 4</b> | Click <b>Apply</b> to update the controller configuration.                                                                                                                                                                                                                                          |

**Note**

If you do not already have an active CLI session to the controller, we recommend that you start a CLI session to reboot the controller and watch the reboot process. A CLI session is also useful because the GUI loses its connection when the controller reboots.

- Step 5** Choose **Commands > Reboot > Reboot > Save and Reboot** to reboot the controller. Click **OK** in response to this prompt:
- Configuration will be saved and the controller will be rebooted. Click ok to confirm.
- The controller reboots.
- Step 6** Log back into the controller GUI to verify that the controller is properly configured.
- Step 7** Choose **Wireless > 802.11b/g/n > Network** to open the 802.11b/g Global Parameters page. If the Short Preamble check box is unselected, the controller is optimized for SpectraLink NetLink phones.

## Enabling Long Preambles (CLI)

- Step 1** Log on to the controller CLI.
- Step 2** Enter the **show 802.11b** command and select the **Short preamble mandatory** parameter. If the parameter indicates that short preambles are enabled, continue with this procedure. This example shows that short preambles are enabled:
- ```
Short Preamble mandatory..... Enabled
```
- However, if the parameter shows that short preambles are disabled (which means that long preambles are enabled), the controller is already optimized for SpectraLink NetLink phones and you do not need to continue this procedure.
- Step 3** Disable the 802.11b/g network by entering this command:
- ```
config 802.11b disable network
```
- You cannot enable long preambles on the 802.11a network.
- Step 4** Enable long preambles by entering this command:
- ```
config 802.11b preamble long
```
- Step 5** Reenable the 802.11b/g network by entering this command:
- ```
config 802.11b enable network
```
- Step 6** Enter the **reset system** command to reboot the controller. Enter **y** at the prompt to save the system changes. The controller reboots.
- Step 7** Verify that the controller is properly configured by logging back into the CLI and entering the **show 802.11b** command to view these parameters:
- ```
802.11b Network..... Enabled
Short Preamble mandatory..... Disabled
```

These parameters show that the 802.11b/g network is enabled and that short preambles are disabled.

## Configuring Enhanced Distributed Channel Access (CLI)

To configure 802.11 enhanced distributed channel access (EDCA) parameters to support SpectraLink phones, enter this command:

```
config advanced edca-parameters {svp-voice | wmm-default}
```

where

**svp-voice** enables SpectraLink voice priority (SVP) parameters and **wmm-default** enables wireless multimedia (WMM) default parameters.

### Note

To propagate this command to all access points connected to the controller, make sure to disable and then reenable the 802.11b/g network after entering this command.

## Configuring RADIUS NAC Support

This section contains the following topics:

- [Information About RADIUS NAC Support, page 7-49](#)
- [Guidelines and Limitations, page 7-50](#)
- [Configuring RADIUS NAC Support \(GUI\), page 7-51](#)
- [Configuring RADIUS NAC Support \(CLI\), page 7-51](#)

## Information About RADIUS NAC Support

The Cisco Identity Services Engine (ISE) is a next-generation, context-based access control solution that provides the functions of Cisco Secure Access Control System (ACS) and Cisco Network Admission Control (NAC) in one integrated platform.

ISE has been introduced in the 7.0.116.0 release of the Cisco Unified Wireless Network. ISE can be used to provide advanced security for your deployed network. It is an authentication server that you can configure on your controller. When a client associates to the controller on a RADIUS NAC-enabled WLAN, the controller forwards the request to the ISE server.

The ISE server validates the user in the database and on successful authentication, the URL and pre-AUTH ACL are sent to the client. The client then moves to the Posture Required state and is redirected to the URL returned by the ISE server. The NAC agent in the client triggers the posture validation process. On successful posture validation by the ISE server, the client is moved to the run state.

## Device Registration

To get devices such as tablets or smart phones to be connected to the corporate wireless network, the device must first be registered. The device is registered with the ISE server before being allowed complete access. Device registration occurs in an open WLAN with MAC filtering enabled before it is connected to the corporate network WLAN.

## Central Web Authentication

In the case of Central Web Authentication (CWA), the web-authentication occurs on the ISE server. The web portal in the ISE server provides a login page to the client. Once the credentials are verified on the ISE server, the client is provisioned. The client remains in the POSTURE\_REQD state until a CoA is reached. The credentials and ACLs are received from the ISE server.

## Local Web Authentication

In the case of Local Web Authentication (LWA), the controller provides a web-auth login page against which the username and password are verified. Once the client credentials are verified, the ISE server with the restricted ACL and the URL are sent to the client.

The client remains in POSTURE\_REQD state until a change of authorization (CoA) is reached.

Table 7-8 describes the possible combinations in a typical ISE deployment with device registration, CWA, and LWA enabled.

## Guidelines and Limitations

- A RADIUS NAC-enabled WLAN supports Open Authentication and MAC filtering. If you are using local web authentication with RADIUS NAC, the Layer 3 web authentication must also be enabled.
- In local web authentication, the Web Auth priority order must be configured as RADIUS.
- RADIUS NAC functionality does not work if the configured accounting server is different from the authentication (ISE) server. You should configure the same server as the authentication and accounting server if ISE functions are used. If ISE is used only for ACS functionality, the accounting server can be flexible. Dot1x authentication must be enabled.
- When clients move from one WLAN to another, the controller retains the client's audit session ID if it returns to the WLAN before the idle timeout occurs. As a result, when the clients join the controller before the idle timeout session expires, they are immediately moved to the RUN state. The clients are validated if they reassociate with the controller after the session timeout.
- Suppose you have two WLANs, where WLAN 1 is configured on a controller (WLC1) and WLAN2 is configured on another controller (WLC2) and both are RADIUS NAC enabled. The client first connects to WLC1 and moves to the RUN state after posture validation. Assume that the client now moved to WLC2. If the client connects back to WLC1 before the PMK expires for this client in WLC1, the posture validation is skipped for the client. The client directly moves to the RUN state and bypasses the posture validation because the controller retains the old audit session ID for the client that is already known to ISE.
- When deploying RADIUS NAC in your wireless network, do not configure a primary and secondary ISE server. Instead, we recommend that you configure HA between the two ISE servers. Having a primary and secondary ISE setup will require a posture validation to happen before the clients move to the RUN state. If HA is configured, the client is automatically moved to the RUN state in the fallback ISE server.
- The controller software configured with RADIUS NAC does not support a change of authorization (CoA) on the service port.
- Do not swap AAA server indexes in a live network because clients might get disconnected and have to reconnect to the RADIUS server, which might result in log messages to be appended to the ISE server logs.

- You must enable AAA override on the WLAN to use RADIUS NAC.
- WPA and WPA2 or dot1X must be enabled on the WLAN.
- During slow roaming, the client goes through posture validation.
- Guest tunneling mobility is not supported for ISE NAC-enabled WLANs.
- VLAN select is not supported
- Workgroup bridges are not supported.
- The AP Group over NAC is not supported over RADIUS NAC.
- FlexConnect local switching is not supported.
- With RADIUS NAC enabled, the RADIUS server overwrite interface is not supported.

## Configuring RADIUS NAC Support (GUI)

- 
- Step 1** Choose the **WLANs** tab.
- Step 2** Click the WLAN ID of the WLAN for which you want to enable ISE.  
The **WLANs > Edit** page appears.
- Step 3** Click the **Advanced** tab.
- Step 4** From the NAC State drop-down list, choose **Radius NAC**:
- **SNMP NAC**—Uses SNMP NAC for the WLAN.
  - **Radius NAC**—Uses Radius NAC for the WLAN

---

**Note** AAA override is automatically enabled when you use RADIUS NAC on a WLAN.

---

- Step 5** Click **Apply**.
- 

## Configuring RADIUS NAC Support (CLI)

```
config wlan nac radius {enable | disable} wlan wlan_id
```

## Using Management Over Wireless

This section contains the following topics:

- [Information About Management Over Wireless](#), page 7-52
- [Enabling Management over Wireless \(GUI\)](#), page 7-52
- [Enabling Management over Wireless \(CLI\)](#), page 7-52

## Information About Management Over Wireless

The management over wireless feature allows you to monitor and configure local controllers using a wireless client. This feature is supported for all management tasks except uploads to and downloads from (transfers to and from) the controller.

### Enabling Management over Wireless (GUI)

- 
- Step 1** Choose **Management > Mgmt Via Wireless** to open the Management Via Wireless page.
  - Step 2** Select the **Enable Controller Management to be accessible from Wireless Clients** check box to enable management over wireless for the WLAN or unselect it to disable this feature. The default value is unselected.
  - Step 3** Click **Apply** to commit your changes.
  - Step 4** Click **Save Configuration** to save your changes.
- 

### Enabling Management over Wireless (CLI)

- 
- Step 1** Verify whether the management over wireless interface is enabled or disabled by entering this command:  
**show network summary**  
If disabled, continue with Step 2. Otherwise, continue with Step 3.
  - Step 2** Enable management over wireless by entering this command:  
**config network mgmt-via-wireless enable**
  - Step 3** Use a wireless client to associate with an access point connected to the controller that you want to manage.
  - Step 4** Log into the CLI to verify that you can manage the WLAN using a wireless client by entering this command:  
**telnet controller-ip-address command**
- 

## Using Dynamic Interfaces for Management

This section contains the following topics:

- [Information About Using Dynamic Interfaces for Management, page 7-53](#)
- [Enabling Management using Dynamic Interfaces \(CLI\), page 7-53](#)

## Information About Using Dynamic Interfaces for Management

You can access the controller with one of its dynamic interface IP addresses. While wired computers can have only CLI access with the dynamic interface of the WLC, wireless clients have both CLI and GUI access with the dynamic interface.

When the management using dynamic interfaces is disabled, a device can open an SSH connection if the protocol is enabled. However, users are not prompted to log on. Additionally, the management address remains accessible from a dynamic interface VLAN unless a CPU ACL is in place.

## Enabling Management using Dynamic Interfaces (CLI)

```
config network mgmt-via-dynamic-interface {enable | disable}
```

**Note**

When the management using dynamic interfaces feature is disabled, ensure that ports 22 and 443 on the dynamic interface are closed. Use the **config network ssh disable** command to close port 22; and use the **config network secureweb disable** command to close port 443.

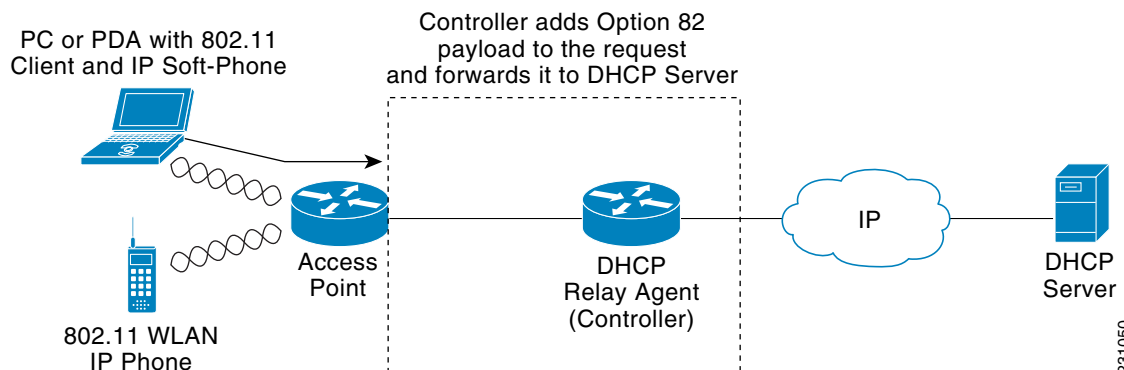

## Configuring DHCP Option 82

This section contains the following topics:

- [Information About DHCP Option 82, page 7-53](#)
- [Guidelines and Limitations, page 7-54](#)
- [Configuring DHCP Option 82 \(GUI\), page 7-54](#)
- [Configuring DHCP Option 82 \(CLI\), page 7-55](#)
- [Additional References, page 7-56](#)

## Information About DHCP Option 82

DHCP option 82 provides additional security when DHCP is used to allocate network addresses. Specifically, it enables the controller to act as a DHCP relay agent to prevent DHCP client requests from untrusted sources. The controller can be configured to add option 82 information to DHCP requests from clients before forwarding the requests to the DHCP server.

**Figure 7-10 DHCP Option 82**

The access point forwards all DHCP requests from a client to the controller. The controller adds the DHCP option 82 payload and forwards the request to the DHCP server. The payload can contain the MAC address or the MAC address and SSID of the access point, depending on how you configure this option.

**Note**

Any DHCP packets that already include a relay agent option are dropped at the controller.

## Guidelines and Limitations

DHCP option 82 is not supported for use with auto-anchor mobility, which is described in [Chapter 15, “Configuring Mobility Groups.”](#)

In controller software release 4.0 or later releases, you can configure DHCP option 82 using the controller CLI. In controller software release 6.0 or later releases, you can configure this feature using either the GUI or CLI.

## Configuring DHCP Option 82 (GUI)

**Step 1** Choose **Controller > Advanced > DHCP** to open the DHCP Parameters page.

**Figure 7-11 DHCP Parameters Page**

**Step 2** Select the **Enable DHCP Proxy** check box to enable DHCP proxy.

**Step 3** Choose one of the following options from the DHCP Option 82 Remote ID text box Format drop-down list to specify the format of the DHCP option 82 payload:

- **AP-MAC**—Adds the MAC address of the access point to the DHCP option 82 payload. This is the default value.

- **AP-MAC-SSID**—Adds the MAC address and SSID of the access point to the DHCP option 82 payload.
- **AP-ETHMAC**—Adds the Ethernet MAC address of the access point to the DHCP option 82 payload.

**Note** If the SSID is associated with a dynamic interface, then the DHCP Option 82 that you configure must be enabled on the dynamic interface.

**Step 4** Click **Apply** to commit your changes.

**Step 5** Click **Save Configuration** to save your changes.

## Configuring DHCP Option 82 (CLI)

- Configure the format of the DHCP option 82 payload by entering one of these commands:
  - **config dhcp opt-82 remote-id ap\_mac**  
This command adds the MAC address of the access point to the DHCP option 82 payload.
  - **config dhcp opt-82 remote-id ap\_mac:ssid**  
This command adds the MAC address and SSID of the access point to the DHCP option 82 payload.
  - **config dhcp opt-82 remote-id ap-ethmac**  
Adds the Ethernet MAC address of the access point to the DHCP option 82 payload.
- Override the global DHCP option 82 setting and disable (or enable) this feature for the AP-manager or management interface on the controller by entering this command:

**config interface dhcp {ap-manager | management} option-82 {disable | enable}**

- See the status of DHCP option 82 on the controller by entering the **show interface detailed ap-manager** command.

```
Interface Name..... ap-manager
MAC Address..... 00:0a:88:25:10:c4
IP Address..... 10.30.16.13
IP Netmask..... 255.255.248.0
IP Gateway..... 10.30.16.1
External NAT IP State..... Disabled
External NAT IP Address..... 0.0.0.0
External NAT IP Netmask..... 0.0.0.0
VLAN..... untagged
Active Physical Port..... LAG (29)
Primary Physical Port..... LAG (29)
Backup Physical Port..... Unconfigured
Primary DHCP Server..... 10.1.0.10
Secondary DHCP Server..... Unconfigured
DHCP Option 82..... Enabled
ACL..... Unconfigured
AP Manager..... Yes
Guest Interface..... No
```

## Additional References

**Note**

In order for DHCP option 82 to operate correctly, DHCP proxy must be enabled. See the [“Configuring DHCP Proxy” section on page 4-37](#) for instructions on configuring DHCP proxy.

## Configuring and Applying Access Control Lists

This section contains the following topics:

- [Information About Access Control Lists, page 7-56](#)
- [Guidelines and Limitations, page 7-56](#)
- [Configuring and Applying Access Control Lists \(GUI\), page 7-57](#)
- [Configuring and Applying Access Control Lists \(CLI\), page 7-63](#)

## Information About Access Control Lists

An access control list (ACL) is a set of rules used to limit access to a particular interface (for example, if you want to restrict a wireless client from pinging the management interface of the controller). After ACLs are configured on the controller, they can be applied to the management interface, the AP-manager interface, any of the dynamic interfaces, or a WLAN to control data traffic to and from wireless clients or to the controller central processing unit (CPU) to control all traffic destined for the CPU.

You may also want to create a preauthentication ACL for web authentication. Such an ACL could be used to allow certain types of traffic before authentication is complete.

Both IPv4 and IPv6 ACLs are supported. IPv6 ACLs support the same options as IPv4 ACLs including source, destination, source and destination ports.

**Note**

You can enable only IPv4 traffic in your network by blocking IPv6 traffic. That is, you can configure an IPv6 ACL to deny all IPv6 traffic and apply it on specific or all WLANs.

## Guidelines and Limitations

- You can define up to 64 ACLs, each with up to 64 rules (or filters) for both IPv4 and IPv6. Each rule has parameters that affect its action. When a packet matches all of the parameters for a rule, the action set for that rule is applied to the packet.
- When you apply CPU ACLs on a Cisco 5500 Series Controller or a Cisco WiSM2, you must permit traffic towards the virtual interface IP address for web authentication.
- ACLs in your network might need to be modified if CAPWAP uses different ports than LWAPP.
- Adding an ACL on the controller results in the degradation of throughput and could even result in packet loss.
- All ACLs have an implicit “deny all rule” as the last rule. If a packet does not match any of the rules, it is dropped by the controller.

- If you are using an external web server with a Cisco 5500 Series Controller, a controller network module, you must configure a preauthentication ACL on the WLAN for the external web server.
- ACL counters are available only on the following controllers: 5500 series, 2500 series, Cisco WiSM2 and 7500 series Wireless LAN Controller Switch.
- If you apply an ACL to an interface or a WLAN, wireless throughput is degraded when downloading from a 1-Gbps file server. To improve throughput, remove the ACL from the interface or WLAN, move the ACL to a neighboring wired device with a policy rate-limiting restriction, or connect the file server using 100 Mbps rather than 1 Gbps.
- Multicast traffic received from wired networks that is destined to wireless clients is not processed by WLC ACLs. Multicast traffic initiated from wireless clients, destined to wired networks or other wireless clients on the same controller, is processed by WLC ACLs.
- ACLs are configured on the controller directly or configured through NCS templates. The ACL name must be unique.

## Configuring and Applying Access Control Lists (GUI)

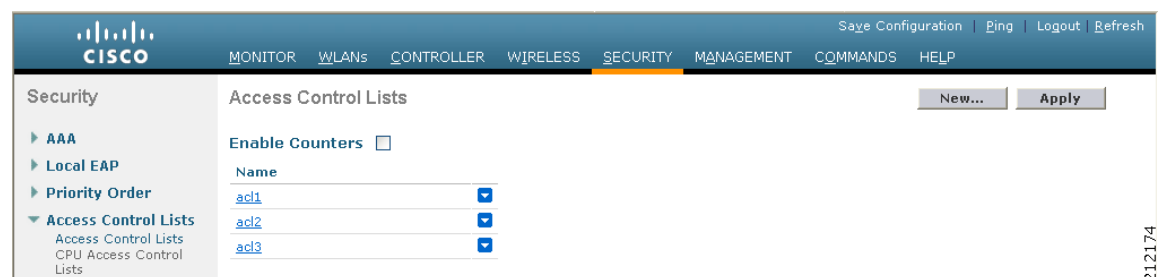

This section contains the following topics:

- [Configuring Access Control Lists, page 7-57](#)
- [Applying an Access Control List to an Interface, page 7-60](#)
- [Applying an Access Control List to the Controller CPU, page 7-61](#)
- [Applying an Access Control List to a WLAN, page 7-61](#)

## Configuring Access Control Lists

**Step 1** Choose **Security > Access Control Lists > Access Control Lists** to open the Access Control Lists page.

**Figure 7-12** Access Control Lists Page

This page lists all of the ACLs and their types (IPv4 or IPv6) that have been configured for this controller.

**Note** If you want to delete an existing ACL, hover your cursor over the blue drop-down arrow for that ACL and choose **Remove**.

- Step 2** If you want to see if packets are hitting any of the ACLs configured on your controller, select the **Enable Counters** check box and click **Apply**. Otherwise, leave the check box unselected, which is the default value. This feature is useful when troubleshooting your system.

**Note** If you want to clear the counters for an ACL, hover your cursor over the blue drop-down arrow for that ACL and choose **Clear Counters**.

- Step 3** Add a new ACL by clicking **New**. The Access Control Lists > New page appears.
- Step 4** In the Access Control List Name text box, enter a name for the new ACL. You can enter up to 32 alphanumeric characters.
- Step 5** Choose the ACL type. There are two ACL types: IPv4 and IPv6.
- Step 6** Click **Apply**. When the Access Control Lists page reappears, click the name of the new ACL.
- Step 7** When the Access Control Lists > Edit page appears, click **Add New Rule**. The Access Control Lists > Rules > New page appears.
- Step 8** Configure a rule for this ACL as follows:
- The controller supports up to 64 rules for each ACL. These rules are listed in order from 1 to 64. In the Sequence text box, enter a value (between 1 and 64) to determine the order of this rule in relation to any other rules defined for this ACL.

**Note** If rules 1 through 4 are already defined and you add rule 29, it is added as rule 5. If you add or change a sequence number for a rule, the sequence numbers for other rules adjust to maintain a continuous sequence. For instance, if you change a rule's sequence number from 7 to 5, the rules with sequence numbers 5 and 6 are automatically reassigned as 6 and 7, respectively.

- From the Source drop-down list, choose one of these options to specify the source of the packets to which this ACL applies:
  - Any**—Any source (this is the default value).
  - IP Address**—A specific source. If you choose this option, enter the IP address and netmask of the source in the text boxes. If you are configuring an IPv6 ACL, enter the IPv6 address and prefix length of the destination in the text boxes.
- From the Destination drop-down list, choose one of these options to specify the destination of the packets to which this ACL applies:
  - Any**—Any destination (this is the default value).
  - IP Address**—A specific destination. If you choose this option, enter the IP address and netmask of the destination in the text boxes. If you are configuring an IPv6 ACL, enter the IPv6 address and prefix length of the destination in the text boxes.
- From the Protocol drop-down list, choose the protocol ID of the IP packets to be used for this ACL. These are the protocol options:
  - Any**—Any protocol (this is the default value)
  - TCP**—Transmission Control Protocol
  - UDP**—User Datagram Protocol
  - ICMP/ICMPv6**—Internet Control Message Protocol

**Note** ICMPv6 is only available for IPv6 ACL.

- **ESP**—IP Encapsulating Security Payload
- **AH**—Authentication Header
- **GRE**—Generic Routing Encapsulation
- **IP in IP**—Internet Protocol (IP) in IP (permits or denies IP-in-IP packets)
- **Eth Over IP**—Ethernet-over-Internet Protocol
- **OSPF**—Open Shortest Path First
- **Other**—Any other Internet Assigned Numbers Authority (IANA) protocol

**Note** If you choose **Other**, enter the number of the desired protocol in the Protocol text box. You can find the list of available protocols in the INAI website.

- The controller can permit or deny only IP packets in an ACL. Other types of packets (such as ARP packets) cannot be specified.
- e. If you chose TCP or UDP in the previous step, two additional parameters appear: Source Port and Destination Port. These parameters enable you to choose a specific source port and destination port or port ranges. The port options are used by applications that send and receive data to and from the networking stack. Some ports are designated for certain applications such as Telnet, SSH, HTTP, and so on.

**Note** Source and Destination ports based on the ACL type.

- f. From the DSCP drop-down list, choose one of these options to specify the differentiated services code point (DSCP) value of this ACL. DSCP is an IP header text box that can be used to define the quality of service across the Internet.
  - **Any**—Any DSCP (this is the default value)
  - **Specific**—A specific DSCP from 0 to 63, which you enter in the DSCP edit box
- g. From the Direction drop-down list, choose one of these options to specify the direction of the traffic to which this ACL applies:
  - **Any**—Any direction (this is the default value)
  - **Inbound**—From the client
  - **Outbound**—To the client

**Note** If you are planning to apply this ACL to the controller CPU, the packet direction does not have any significance, it is always 'Any'.

- h. From the Action drop-down list, choose **Deny** to cause this ACL to block packets or **Permit** to cause this ACL to allow packets. The default value is Deny.
- i. Click **Apply** to commit your changes. The Access Control Lists > Edit page reappears, showing the rules for this ACL.

The Deny Counters fields shows the number of times that packets have matched the explicit deny ACL rule. The Number of Hits field shows the number of times that packets have matched an ACL rule. You must enable ACL counters on the Access Control Lists page to enable these fields.

**Note**

If you want to edit a rule, click the sequence number of the desired rule to open the Access Control Lists > Rules > Edit page. If you want to delete a rule, hover your cursor over the blue drop-down arrow for the desired rule and choose **Remove**.

- j. Repeat this procedure to add any additional rules for this ACL.

**Step 9** Click **Save Configuration** to save your changes.

**Step 10** Repeat this procedure to add any additional ACLs.

## Applying an Access Control List to an Interface

**Step 1** Choose **Controller > Interfaces**.

**Step 2** Click the name of the desired interface. The Interfaces > Edit page for that interface appears.

**Figure 7-13** *Interfaces > Edit Page*

The screenshot displays the Cisco Wireless LAN Controller configuration interface. The top navigation bar includes links for MONITOR, WLANs, CONTROLLER (selected), WIRELESS, SECURITY, MANAGEMENT, COMMANDS, and HELP. The left sidebar shows a tree view with categories like General, Inventory, Interfaces (selected), Multicast, Network Routes, Internal DHCP Server, Mobility Management, Ports, NTP, CDP, and Advanced. The main content area is titled 'Interfaces > Edit' and contains several sections:
 

- General Information:** Interface Name (vlan 101), MAC Address (00:0b:85:40:90:c0).
- Configuration:** Guest Lan (checkbox), Quarantine (checkbox), Quarantine Vlan Id (0).
- Physical Information:** Port Number (0), Backup Port (0), Active Port (0), Enable Dynamic AP Management (checkbox).
- Interface Address:** VLAN Identifier (101).
- DHCP Information:** Primary DHCP Server, Secondary DHCP Server.
- Access Control List:** ACL Name (none).

 At the bottom, a note states: 'Note: Changing the Interface parameters causes the WLANs to be temporarily disabled and thus may result in loss of connectivity for some clients.'

**Step 3** From the ACL Name drop-down list, choose the desired ACL and click **Apply**. The default is None.

**Note**

Only IPv4 ACL are supported as interface ACL, see [Chapter 4, “Configuring Ports and Interfaces,”](#) for more information on configuring controller interfaces.

- Step 4** Click **Save Configuration** to save your changes.

## Applying an Access Control List to the Controller CPU

- Step 1** Choose **Security > Access Control Lists > CPU Access Control Lists** to open the CPU Access Control Lists page.
- Step 2** Select the **Enable CPU ACL** check box to enable a designated ACL to control the traffic to the controller CPU or unselect the check box to disable the CPU ACL feature and remove any ACL that had been applied to the CPU. The default value is unselected.
- Step 3** From the ACL Name drop-down list, choose the ACL that will control the traffic to the controller CPU. None is the default value when the CPU ACL feature is disabled. If you choose None while the CPU ACL Enable check box is selected, an error message appears indicating that you must choose an ACL.

**Note**

This parameter is available only if you have selected the CPU ACL Enable check box.

**Note**

When CPU ACL is enabled, it is applicable to both wireless and wired traffic. Only IPv4 ACL are supported as CPU ACL.

- Step 4** Click **Apply** to commit your changes.
- Step 5** Click **Save Configuration** to save your changes.

## Applying an Access Control List to a WLAN

- Step 1** Choose **WLANs** to open the WLANs page.
- Step 2** Click the ID number of the desired WLAN to open the WLANs > Edit page.
- Step 3** Choose the **Advanced** tab to open the WLANs > Edit (Advanced) page.

Figure 7-14 WLANs &gt; Edit (Advanced) Page

- Step 4** From the Override Interface ACL drop-down list, choose the IPv4 or IPv6 ACL that you want to apply to this WLAN. The ACL that you choose overrides any ACL that is configured for the interface. None is the default value.

**Note**

To support centralized access control through an AAA server such as ISE or ACS, you must configure the IPv4 and IPv6 ACL on the controller and the WLAN must be configured with AAA override enabled feature.

**Note**

See [Chapter 8, “Working with WLANs,”](#) for more information on configuring WLANs.

- Step 5** Click **Apply** to commit your changes.
- Step 6** Click **Save Configuration** to save your changes.

## Applying a Preauthentication Access Control List to a WLAN

- Step 1** Choose **WLANs** to open the WLANs page.
- Step 2** Click the ID number of the desired WLAN to open the WLANs > Edit page.

**Step 3** Choose the **Security** and **Layer 3** tabs to open the WLANs > Edit (Security > Layer 3) page.

**Figure 7-15** WLANs > Edit (Security > Layer 3) Page

**Step 4** Select the **Web Policy** check box.

**Step 5** From the Preauthentication ACL drop-down list, choose the desired ACL and click **Apply**. None is the default value.

**Note** See [Chapter 8, “Working with WLANs,”](#) for more information on configuring WLANs.

**Step 6** Click **Save Configuration** to save your changes.

## Configuring and Applying Access Control Lists (CLI)

### Configuring Access Control Lists

**Step 1** See all of the ACLs that are configured on the controller by entering this command:

**show acl summary**

Information similar to the following appears:

```
ACL Counter Status      Enabled
-----
ACL Name                Applied
-----
acl1                    Yes
acl2                    Yes
acl3                    Yes
```

**Step 2** See all of the IPv6 ACLs that are configured on the controller by entering this command:

**show ipv6 acl summary**

**Step 3** See detailed information for a particular ACL by entering this command:

**show [ipv6] acl detailed *acl\_name***

Information similar to the following appears:

		Source	Destination	Source Port	Dest Port					
I	Dir	IP Address/Netmask	IP Address/Netmask	Prot	Range	Range	DSCP	Action	Counter	
1	Any	0.0.0.0/0.0.0.0	0.0.0.0/0.0.0.0	Any	0-65535	0-65535	0	Deny	0	
2	In	0.0.0.0/0.0.0.0	200.200.200.0/ 255.255.255.0	6	80-80	0-65535	Any	Permit	0	

DenyCounter : 0

The Counter text box increments each time a packet matches an ACL rule, and the DenyCounter text box increments each time a packet does not match any of the rules.

**Note**

If a traffic/request is allowed from the controller by a permit rule, then the response to the traffic/request in the opposite direction also is allowed and cannot be blocked by a deny rule in the ACL.

**Step 4** Enable or disable ACL counters for your controller by entering this command:

```
config acl counter {start | stop}
```

**Note**

If you want to clear the current counters for an ACL, enter the **clear acl counters *acl\_name*** command.

**Note**

ACL counters are available only on the Cisco 5500 Series Controller, Cisco 4400 Series Controller, Cisco WiSM, and Catalyst 3750G Integrated Wireless LAN Controller Switch.

**Step 5** Add a new ACL by entering this command:

```
config [ipv6] acl create acl_name
```

You can enter up to 32 alphanumeric characters for the *acl\_name* parameter.

**Note**

When you try to create an interface name with space, the controller CLI does not create an interface. For example, if you want to create an interface name *int 3*, the CLI will not create this since there is a space between *int* and *3*. If you want to use *int 3* as the interface name, you need to enclose within single quotes like '*int 3*'.

**Step 6** Add a rule for an ACL by entering this command:

```
config [ipv6] acl rule add acl_name rule_index
```

**Step 7** Configure an ACL rule by entering this command:

```
config [ipv6] acl rule
```

```
action acl_name rule_index {permit | deny} |
```

```
change index acl_name old_index new_index |
```

```
destination address acl_name rule_index ip_address netmask |
```

```
destination port range acl_name rule_index start_port end_port |
```

```
direction acl_name rule_index {in | out | any} |
```

```
dscp acl_name rule_index dscp |
```

```
protocol acl_name rule_index protocol |
```

```

source address acl_name rule_index ip_address netmask |
source address [ipv6] acl_name rule_index prefix |
swap index acl_name index_1 index_2

```

See [Step 8](#) of the “Configuring and Applying Access Control Lists (GUI)” section on page 7-57 for explanations of the rule parameters.

**Step 8** Save your settings by entering this command:

```
save config
```

**Note** To delete an ACL, enter the **config [ipv6] acl delete *acl\_name*** command. To delete an ACL rule, enter the **config [ipv6] acl rule delete *acl\_name rule\_index*** command.

## Applying Access Control Lists

**Step 1** Perform any of the following:

- To apply an ACL to a management, AP-manager, or dynamic interface, enter this command:

```
config interface acl {management | ap-manager | dynamic_interface_name} acl_name
```

**Note** To see the ACL that is applied to an interface, enter the **show interface detailed {management | ap-manager | dynamic\_interface\_name}** command. To remove an ACL that is applied to an interface, enter the **config interface acl {management | ap-manager | dynamic\_interface\_name} none** command.

See [Chapter 4](#), “Configuring Ports and Interfaces,” for more information on configuring controller interfaces.

- To apply an ACL to the data path, enter this command:

```
config acl apply acl_name
```

- To apply an ACL to the controller CPU to restrict the type of traffic (wired, wireless, or both) reaching the CPU, enter this command:

```
config acl cpu acl_name {wired | wireless | both}
```

**Note** To see the ACL that is applied to the controller CPU, enter the **show acl cpu** command. To remove the ACL that is applied to the controller CPU, enter the **config acl cpu none** command.

- To apply an ACL to a WLAN, enter this command:

```
config wlan acl wlan_id acl_name
```

**Note** To see the ACL that is applied to a WLAN, enter the **show wlan *wlan\_id*** command. To remove the ACL that is applied to a WLAN, enter the **config wlan acl *wlan\_id* none** command.

- To apply a preauthentication ACL to a WLAN, enter this command:

```
config wlan security web-auth acl wlan_id acl_name
```

See [Chapter 8, “Working with WLANs,”](#) for more information on configuring WLANs.

**Step 2** Save your changes by entering this command:

```
save config
```

---

## Configuring Management Frame Protection

This chapter contains the following topics:

- [Information About Management Frame Protection, page 7-66](#)
- [Guidelines and Limitations, page 7-67](#)
- [Configuring Management Frame Protection \(GUI\), page 7-68](#)
- [Viewing the Management Frame Protection Settings \(GUI\), page 7-69](#)
- [Configuring Management Frame Protection \(CLI\), page 7-70](#)
- [Viewing the Management Frame Protection Settings \(CLI\), page 7-70](#)
- [Debugging Management Frame Protection Issues \(CLI\), page 7-72](#)

## Information About Management Frame Protection

Management frame protection (MFP) provides security for the otherwise unprotected and unencrypted 802.11 management messages passed between access points and clients. MFP provides both infrastructure and client support.

- **Infrastructure MFP**—Protects management frames by detecting adversaries that are invoking denial-of-service attacks, flooding the network with associations and probes, interjecting as rogue access points, and affecting network performance by attacking the QoS and radio measurement frames. It also provides a quick and effective means to detect and report phishing incidents.

Specifically, infrastructure MFP protects 802.11 session management functions by adding message integrity check information elements (MIC IEs) to the management frames emitted by access points (and not those emitted by clients), which are then validated by other access points in the network. Infrastructure MFP is passive. It can detect and report intrusions but has no means to stop them.

- **Client MFP**—Shields authenticated clients from spoofed frames, preventing many of the common attacks against wireless LANs from becoming effective. Most attacks, such as deauthentication attacks, revert to simply degrading performance by contending with valid clients.

Specifically, client MFP encrypts management frames sent between access points and CCXv5 clients so that both the access points and clients can take preventative action by dropping spoofed class 3 management frames (that is, management frames passed between an access point and a client that is authenticated and associated). Client MFP leverages the security mechanisms defined by IEEE 802.11i to protect the following types of class 3 unicast management frames: disassociation, deauthentication, and QoS (WMM) action. Client MFP protects a client-access point session from the most common type of denial-of-service attack. It protects class 3 management frames by using the same encryption method used for the session’s data frames. If a frame received by the access point or client fails decryption, it is dropped, and the event is reported to the controller.

To use client MFP, clients must support CCXv5 MFP and must negotiate WPA2 using either TKIP or AES-CCMP. EAP or PSK may be used to obtain the PMK. CCKM and controller mobility management are used to distribute session keys between access points for Layer 2 and Layer 3 fast roaming.

**Note**

To prevent attacks using broadcast frames, access points supporting CCXv5 will not emit any broadcast class 3 management frames (such as disassociation, deauthentication, or action). CCXv5 clients and access points must discard broadcast class 3 management frames.

Client MFP supplements infrastructure MFP rather than replaces it because infrastructure MFP continues to detect and report invalid unicast frames sent to clients that are not client-MFP capable as well as invalid class 1 and 2 management frames. Infrastructure MFP is applied only to management frames that are not protected by client MFP.

Infrastructure MFP consists of three main components:

- Management frame protection—The access point protects the management frames it transmits by adding a MIC IE to each frame. Any attempt to copy, alter, or replay the frame invalidates the MIC, causing any receiving access point configured to detect MFP frames to report the discrepancy.
- Management frame validation—In infrastructure MFP, the access point validates every management frame that it receives from other access points in the network. It ensures that the MIC IE is present (when the originator is configured to transmit MFP frames) and matches the content of the management frame. If it receives any frame that does not contain a valid MIC IE from a BSSID belonging to an access point that is configured to transmit MFP frames, it reports the discrepancy to the network management system. In order for the timestamps to operate properly, all controllers must be Network Transfer Protocol (NTP) synchronized.
- Event reporting—The access point notifies the controller when it detects an anomaly, and the controller aggregates the received anomaly events and can report the results through SNMP traps to the network management system.

**Note**

Client MFP uses the same event reporting mechanisms as infrastructure MFP.

Infrastructure MFP is enabled by default and can be disabled globally. When you upgrade from a previous software release, infrastructure MFP is disabled globally if access point authentication is enabled because the two features are mutually exclusive. Once infrastructure MFP is enabled globally, signature generation (adding MICs to outbound frames) can be disabled for selected WLANs, and validation can be disabled for selected access points.

Client MFP is enabled by default on WLANs that are configured for WPA2. It can be disabled, or it can be made mandatory (in which case, only clients that negotiate MFP are allowed to associate) on selected WLANs.

## Guidelines and Limitations

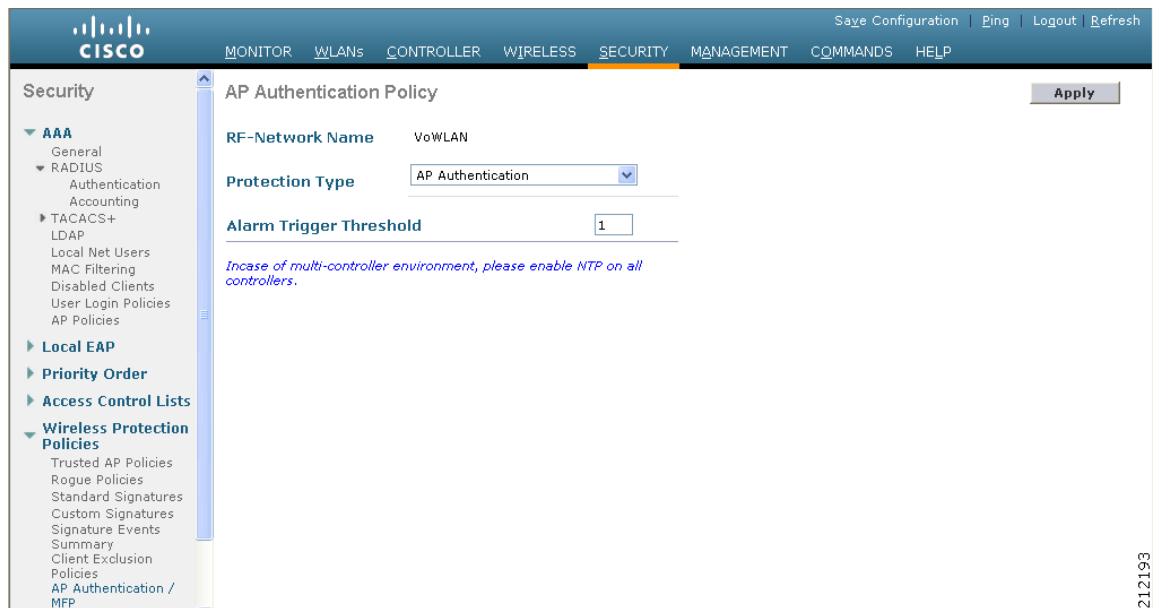

- Infrastructure MFP is a global setting only in the 7.0.98.0 release. In the earlier releases, there was an option for you to enable or disable the MFP infrastructure protection for WLANs and MFP infrastructure validation for APs. These options are no longer available in the GUI or CLI.
- Controller software release 4.1 or later releases support both infrastructure and client MFP while controller software release 4.0 supports only infrastructure MFP.
- MFP is supported for use with Cisco Aironet lightweight access points.

- Lightweight access points support infrastructure MFP in local and monitor modes and in FlexConnect mode when the access point is connected to a controller. They support client MFP in local, FlexConnect, and bridge modes.
- OEAP 600 Series Access points do not support MFP.
- Client MFP is supported for use only with CCXv5 clients using WPA2 with TKIP or AES-CCMP.
- Non-CCXv5 clients may associate to a WLAN if client MFP is disabled or optional.
- Error reports generated on a FlexConnect access point in standalone mode cannot be forwarded to the controller and are dropped.

## Configuring Management Frame Protection (GUI)

- Step 1** Choose **Security > Wireless Protection Policies > AP Authentication/MFP** to open the AP Authentication Policy page.

**Figure 7-16** AP Authentication Policy Page

- Step 2** From the Protection Type drop-down list, enable infrastructure MFP globally for the controller by choosing **Management Frame Protection**.
- Step 3** Click **Apply** to commit your changes.

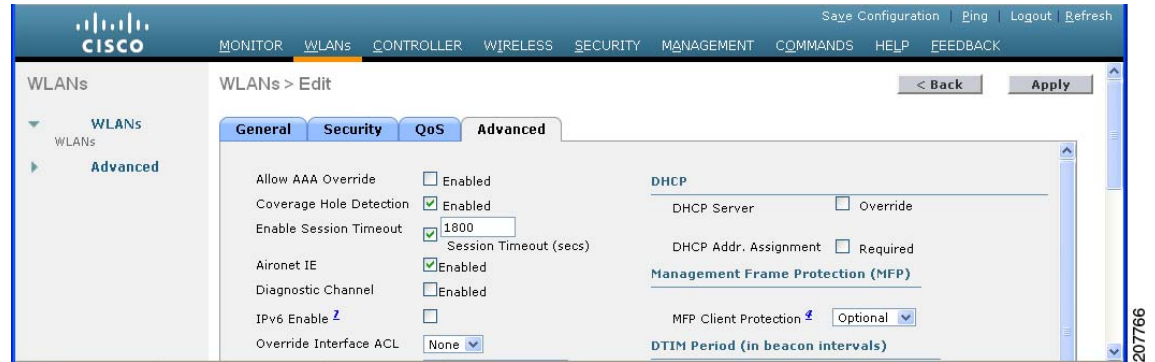

**Note**

If more than one controller is included in the mobility group, you must configure a Network Time Protocol (NTP) server on all controllers in the mobility group that are configured for infrastructure MFP.

- Step 4** Configure client MFP for a particular WLAN after infrastructure MFP has been enabled globally for the controller as follows:
- Choose **WLANs**.

- b. Click the profile name of the desired WLAN. The WLANs > Edit page appears.
- c. Choose **Advanced**. The WLANs > Edit (Advanced) page appears.

**Figure 7-17** WLANs > Edit (Advanced) Page

- d. From the MFP Client Protection drop-down list choose **Disabled**, **Optional**, or **Required**. The default value is Optional. If you choose Required, clients are allowed to associate only if MFP is negotiated (that is, if WPA2 is configured on the controller and the client supports CCXv5 MFP and is also configured for WPA2).

**Note** For Cisco OEAP 600, MFP is not supported. It should either be Disabled or Optional.

- e. Click **Apply** to commit your changes.

**Step 5** Click **Save Configuration** to save your settings.

## Viewing the Management Frame Protection Settings (GUI)

To see the controller's current global MFP settings, choose **Security > Wireless Protection Policies > Management Frame Protection**. The Management Frame Protection Settings page appears.

**Figure 7-18 Management Frame Protection Settings Page**

WLAN-ID	WLAN Name	WLAN Status	Infrastructure Protection	Client Protection
1	default	Enabled	Enabled	Optional

AP Name	Infrastructure Validation	Radio	Operational Status	Infrastructure Protection Capability	Infrastructure Validation Capability
devesh-AP1010	Enabled	a	Up	Full	Full
devesh-AP1010	Enabled	b/g	Up	Full	Full

On this page, you can see the following MFP settings:

- The Management Frame Protection field shows if infrastructure MFP is enabled globally for the controller.
- The Controller Time Source Valid field indicates whether the controller time is set locally (by manually entering the time) or through an external source (such as the NTP server). If the time is set by an external source, the value of this field is “True.” If the time is set locally, the value is “False.” The time source is used for validating the timestamp on management frames between access points of different controllers within a mobility group.
- The Infrastructure Protection field shows if infrastructure MFP is enabled for individual WLANs.
- The Client Protection field shows if client MFP is enabled for individual WLANs and whether it is optional or required.

## Configuring Management Frame Protection (CLI)

- Enable or disable infrastructure MFP globally for the controller by entering this command:  
**config wps mfp infrastructure {enable | disable}**
- Enable or disable client MFP on a specific WLAN by entering this command:  
**config wlan mfp client {enable | disable} wlan\_id [required]**

If you enable client MFP and use the optional **required** parameter, clients are allowed to associate only if MFP is negotiated.

## Viewing the Management Frame Protection Settings (CLI)

- See the controller’s current MFP settings by entering this command:

```
show wps mfp summary
```

Information similar to the following appears:

```
Global Infrastructure MFP state.... Enabled
Controller Time Source Valid..... False
```

```

              WLAN      Infra.      Client
WLAN ID  WLAN Name  Status      Protection  Protection
-----  -

```

1	test1	Enabled	Disabled	Disabled
2	open	Enabled	Enabled	Required
3	testpsk	Enabled	*Enabled	Optional but inactive (WPA2 not configured)

AP Name	Infra. Validation	Radio	Operational State	--Infra. Capability-- Protection	Validation
mapAP	Disabled	a	Up	Full	Full
		b/g	Up	Full	Full
rootAP2	Enabled	a	Up	Full	Full
		b/g	Up	Full	Full
FlexConnect	*Enabled	b/g	Up	Full	Full
		a	Down	Full	Full

- See the current MFP configuration for a particular WLAN by entering this command:

**show wlan** *wlan\_id*

Information similar to the following appears:

```

WLAN Identifier..... 1
Profile Name..... test1
Network Name (SSID)..... test1
Status..... Enabled
MAC Filtering..... Disabled
Broadcast SSID..... Enabled
...
Local EAP Authentication..... Enabled (Profile 'test')
Diagnostics Channel..... Disabled
Security

    802.11 Authentication:..... Open System
    Static WEP Keys..... Disabled
    802.1X..... Enabled
        Encryption:..... 104-bit WEP
    Wi-Fi Protected Access (WPA/WPA2)..... Disabled
    CKIP ..... Disabled
    IP Security..... Disabled
    IP Security Passthru..... Disabled
    Web Based Authentication..... Disabled

				Client	Not encrypted	174	Assoc Resp Probe Resp

## Debugging Management Frame Protection Issues (CLI)

Use this command if you experience any problems with MFP:

- debug wps mfp ? {enable | disable}**

where ? is one of the following:

**client**—Configures debugging for client MFP messages.

**capwap**—Configures debugging for MFP messages between the controller and access points.

**detail**—Configures detailed debugging for MFP messages.

**report**—Configures debugging for MFP reporting.

**mm**—Configures debugging for MFP mobility (inter-controller) messages.

## Configuring Client Exclusion Policies

This section contains the following topics:

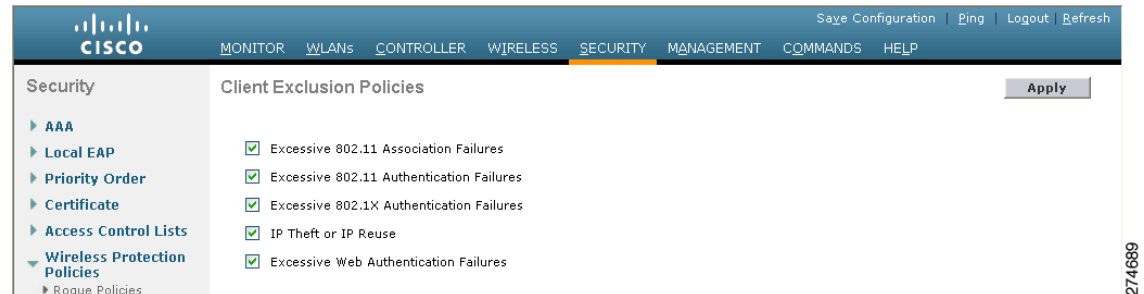

- [Configuring Client Exclusion Policies \(GUI\), page 7-73](#)
- [Configuring Client Exclusion Policies \(CLI\), page 7-73](#)

## Configuring Client Exclusion Policies (GUI)

- Step 1** Choose **Security > Wireless Protection Policies > Client Exclusion Policies** to open the Client Exclusion Policies page.

**Figure 7-19** *Client Exclusion Policies Page*

- Step 2** Select any of these check boxes if you want the controller to exclude clients for the condition specified. The default value for each exclusion policy is enabled.
- **Excessive 802.11 Association Failures**—Clients are excluded on the sixth 802.11 association attempt, after five consecutive failures.
  - **Excessive 802.11 Authentication Failures**—Clients are excluded on the sixth 802.11 authentication attempt, after five consecutive failures.
  - **Excessive 802.1X Authentication Failures**—Clients are excluded on the fourth 802.1X authentication attempt, after three consecutive failures.
  - **IP Theft or IP Reuse**—Clients are excluded if the IP address is already assigned to another device.
  - **Excessive Web Authentication Failures**—Clients are excluded on the fourth web authentication attempt, after three consecutive failures.
- Step 3** Click **Apply** to commit your changes.
- Step 4** Click **Save Configuration** to save your changes.

## Configuring Client Exclusion Policies (CLI)

- Step 1** Enable or disable the controller to exclude clients on the sixth 802.11 association attempt, after five consecutive failures by entering this command:
- ```
config wps client-exclusion 802.11-assoc {enable | disable}
```
- Step 2** Enable or disable the controller to exclude clients on the sixth 802.11 authentication attempt, after five consecutive failures by entering this command:
- ```
config wps client-exclusion 802.11-auth {enable | disable}
```
- Step 3** Enable or disable the controller to exclude clients on the fourth 802.1X authentication attempt, after three consecutive failures by entering this command:
- ```
config wps client-exclusion 802.1x-auth {enable | disable}
```

- Step 4** Enable or disable the controller to exclude clients if the IP address is already assigned to another device by entering this command:

```
config wps client-exclusion ip-theft {enable | disable}
```

- Step 5** Enable or disable the controller to exclude clients on the fourth web authentication attempt, after three consecutive failures by entering this command:

```
config wps client-exclusion web-auth {enable | disable}
```

- Step 6** Enable or disable the controller to exclude clients for all of the above reasons by entering this command:

```
config wps client-exclusion all {enable | disable}
```

- Step 7** Use the following command to add or delete client exclusion entries.

```
config exclusionlist {add MAC [description] | delete MAC | description MAC [description]}
```

- Step 8** Save your changes by entering this command:

```
save config
```

- Step 9** See a list of clients that have been dynamically excluded, by entering this command:

```
show exclusionlist
```

Information similar to the following appears:

Dynamically Disabled Clients

| MAC Address       | Exclusion Reason | Time Remaining (in secs) |
|-------------------|------------------|--------------------------|
| 00:40:96:b4:82:55 | 802.1X Failure   | 51                       |

- Step 10** See the client exclusion policy configuration settings by entering this command:

```
show wps summary
```

Information similar to the following appears:

```
Auto-Immune
  Auto-Immune..... Disabled

Client Exclusion Policy
  Excessive 802.11-association failures..... Enabled
  Excessive 802.11-authentication failures..... Enabled
  Excessive 802.1x-authentication..... Enabled
  IP-theft..... Enabled
  Excessive Web authentication failure..... Enabled

Signature Policy
  Signature Processing..... Enabled
```

# Configuring Identity Networking

## Information About Identity Networking

In most wireless LAN systems, each WLAN has a static policy that applies to all clients associated with an SSID. Although powerful, this method has limitations because it requires clients to associate with different SSIDs to inherit different QoS and security policies.

However, the Cisco Wireless LAN solution supports identity networking, which allows the network to advertise a single SSID but allows specific users to inherit different QoS or security policies based on their user profiles. The specific policies that you can control using identity networking are as follows:

- **Quality of service**—When present in a RADIUS Access Accept, the QoS Level value overrides the QoS value specified in the WLAN profile.
- **ACL**—When the ACL attribute is present in the RADIUS Access Accept, the system applies the ACL name to the client station after it authenticates, which overrides any ACLs that are assigned to the interface.
- **VLAN**—When a VLAN Interface-name or VLAN tag is present in a RADIUS Access Accept, the system places the client on a specific interface.

---

**Note** The VLAN feature only supports MAC filtering, 802.1X, and WPA. The VLAN feature does not support web authentication or IPsec.

---

- **Tunnel Attributes.**

---

**Note** When any of the other RADIUS attributes (QoS-Level, ACL-Name, Interface-Name, or VLAN-Tag), which are described later in this section, are returned, the Tunnel Attributes must also be returned.

---

The operating system's local MAC filter database has been extended to include the interface name, allowing local MAC filters to specify to which interface the client should be assigned. A separate RADIUS server can also be used, but the RADIUS server must be defined using the Security menus.

## RADIUS Attributes Used in Identity Networking

This section explains the RADIUS attributes used in identity networking. This section contains the following topics:

- [QoS-Level, page 7-76](#)
- [ACL-Name, page 7-76](#)
- [Interface-Name, page 7-76](#)
- [VLAN-Tag, page 7-77](#)
- [Tunnel Attributes, page 7-78](#)

## QoS-Level

This attribute indicates the QoS level to be applied to the mobile client's traffic within the switching fabric, as well as over the air. This example shows a summary of the QoS-Level Attribute format. The text boxes are transmitted from left to right.

```

0                               1                               2                               3
0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
|   Type   |   Length   |   Vendor-Id   |
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
| Vendor-Id (cont.) | Vendor type | Vendor length |
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
|                               QoS Level                               |
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+

```

- Type – 26 for Vendor-Specific
- Length – 10
- Vendor-Id – 14179
- Vendor type – 2
- Vendor length – 4
- Value – Three octets:
  - 0 – Bronze (Background)
  - 1 – Silver (Best Effort)
  - 2 – Gold (Video)
  - 3 – Platinum (Voice)

## ACL-Name

This attribute indicates the ACL name to be applied to the client. A summary of the ACL-Name Attribute format is shown below. The text boxes are transmitted from left to right.

```

0                               1                               2                               3
0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
|   Type   |   Length   |   Vendor-Id   |
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
| Vendor-Id (cont.) | Vendor type | Vendor length |
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
|           ACL Name...           |
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+

```

- Type – 26 for Vendor-Specific
- Length – >7
- Vendor-Id – 14179
- Vendor type – 6
- Vendor length – >0
- Value – A string that includes the name of the ACL to use for the client

## Interface-Name

This attribute indicates the VLAN Interface a client is to be associated to. A summary of the Interface-Name Attribute format is shown below. The text boxes are transmitted from left to right.

- Type – 26 for Vendor-Specific
- Length – >7
- Vendor-Id – 14179
- Vendor type – 5
- Vendor length – >0
- Value – A string that includes the name of the interface the client is to be assigned to.

**Note** This Attribute only works when MAC filtering is enabled or if 802.1X or WPA is used as the security policy.

## VLAN-Tag

This attribute indicates the group ID for a particular tunneled session and is also known as the Tunnel-Private-Group-ID attribute.

This attribute might be included in the Access-Request packet if the tunnel initiator can predetermine the group resulting from a particular connection and should be included in the Access-Accept packet if this tunnel session is to be treated as belonging to a particular private group. Private groups may be used to associate a tunneled session with a particular group of users. For example, it may be used to facilitate routing of unregistered IP addresses through a particular interface. It should be included in Accounting-Request packets which contain Acct-Status-Type attributes with values of either Start or Stop and which pertain to a tunneled session.

A summary of the Tunnel-Private-Group-ID Attribute format is shown below. The text boxes are transmitted from left to right.

- Type – 81 for Tunnel-Private-Group-ID.
- Length – >= 3
- Tag – The Tag text box is one octet in length and is intended to provide a means of grouping attributes in the same packet which refer to the same tunnel. If the value of the Tag text box is greater than 0x00 and less than or equal to 0x1F, it should be interpreted as indicating which tunnel (of several alternatives) this attribute pertains. If the Tag text box is greater than 0x1F, it should be interpreted as the first byte of the following String text box.
- String – This text box must be present. The group is represented by the String text box. There is no restriction on the format of group IDs.

## Tunnel Attributes

**Note**

When any of the other RADIUS attributes (QoS-Level, ACL-Name, Interface-Name, or VLAN-Tag) are returned, the Tunnel Attributes must also be returned.

RFC 2868 defines RADIUS tunnel attributes used for authentication and authorization, and RFC2867 defines tunnel attributes used for accounting. Where the IEEE 802.1X authenticator supports tunneling, a compulsory tunnel may be set up for the Supplicant as a result of the authentication.

In particular, it may be desirable to allow a port to be placed into a particular VLAN, defined in IEEE 8021Q, based on the result of the authentication. This configuration can be used, for example, to allow a wireless host to remain on the same VLAN as it moves within a campus network.

The RADIUS server typically indicates the desired VLAN by including tunnel attributes within the Access-Accept. However, the IEEE 802.1X authenticator may also provide a hint as to the VLAN to be assigned to the Supplicant by including Tunnel attributes within the AccessRequest.

For use in VLAN assignment, the following tunnel attributes are used:

- Tunnel-Type=VLAN (13)
- Tunnel-Medium-Type=802
- Tunnel-Private-Group-ID=VLANID

The VLAN ID is 12 bits, with a value between 1 and 4094, inclusive. Because the Tunnel-Private-Group-ID is of type String as defined in RFC 2868, for use with IEEE 802.1X, the VLANID integer value is encoded as a string.

When Tunnel attributes are sent, it is necessary to fill in the Tag text box. As noted in RFC 2868, section 3.1:

- The Tag text box is one octet in length and is intended to provide a means of grouping attributes in the same packet that refer to the same tunnel. Valid values for this text box are 0x01 through 0x1F, inclusive. If the Tag text box is unused, it must be zero (0x00).
- For use with Tunnel-Client-Endpoint, Tunnel-Server-Endpoint, Tunnel-Private-Group-ID, Tunnel-Assignment-ID, Tunnel-Client-Auth-ID or Tunnel-Server-Auth-ID attributes (but not Tunnel-Type, Tunnel-Medium-Type, Tunnel-Password, or Tunnel-Preference), a tag text box of greater than 0x1F is interpreted as the first octet of the following text box.
- Unless alternative tunnel types are provided, (e.g. for IEEE 802.1X authenticators that may support tunneling but not VLANs), it is only necessary for tunnel attributes to specify a single tunnel. As a result, where it is only desired to specify the VLANID, the tag text box should be set to zero (0x00) in all tunnel attributes. Where alternative tunnel types are to be provided, tag values between 0x01 and 0x1F should be chosen.

# Configuring AAA Override

This section contains the following topics:

- [Information About AAA Override, page 7-79](#)
- [Guidelines and Limitations, page 7-79](#)
- [Updating the RADIUS Server Dictionary File for Proper QoS Values, page 7-79](#)
- [Configuring AAA Override \(GUI\), page 7-80](#)

- [Configure AAA Override \(CLI\), page 7-81](#)

## Information About AAA Override

The Allow AAA Override option of a WLAN enables you to configure the WLAN for identity networking. It enables you to apply VLAN tagging, QoS, and ACLs to individual clients based on the returned RADIUS attributes from the AAA server.

## Guidelines and Limitations

- If a client moves to a new interface due to the AAA override and then you apply an ACL to that interface, the ACL does not take effect until the client reauthenticates. To work around this issue, apply the ACL and then enable the WLAN so that all clients connect to the ACL that is already configured on the interface, or disable and then reenables the WLAN after you apply the interface so that the clients can reauthenticate.
- When the interface group is mapped to a WLAN and clients connect to the WLAN, the client does not get the IP address in a round robin fashion.
- Most of the configuration for allowing AAA override is done at the RADIUS server, where you should configure the Access Control Server (ACS) with the override properties you would like it to return to the controller (for example, Interface-Name, QoS-Level, and VLAN-Tag).
- On the controller, enable the Allow AAA Override configuration parameter using the GUI or CLI. Enabling this parameter allows the controller to accept the attributes returned by the RADIUS server. The controller then applies these attributes to its clients.

## Updating the RADIUS Server Dictionary File for Proper QoS Values

If you are using a Steel-Belted RADIUS (SBR), FreeRadius, or similar RADIUS server, clients may not obtain the correct QoS values after the AAA override feature is enabled. For these servers, which allow you to edit the dictionary file, you need to update the file to reflect the proper QoS values: Silver is 0, Gold is 1, Platinum is 2, and Bronze is 3. To update the RADIUS server dictionary file, follow these steps:

### Note

This issue does not apply to the Cisco Secure Access Control Server (ACS).

To update the RADIUS server dictionary file, follow these steps:

**Step 1** Stop the SBR service (or other RADIUS service).

**Step 2** Save the following text to the Radius\_Install\_Directory\Service folder as ciscowlan.dct:

```
#####
# CiscoWLAN.dct- Cisco Wireless Lan Controllers
#
# (See README.DCT for more details on the format of this file)
#####

# Dictionary - Cisco WLAN Controllers
#
# Start with the standard Radius specification attributes
```

```
#
@radius.dct
#
# Standard attributes supported by Airespace
#
# Define additional vendor specific attributes (VSAs)
#

MACRO Airespace-VSA(t,s) 26 [vid=14179 type1=%t% len1=+2 data=%s%]

ATTRIBUTE   WLAN-Id                Airespace-VSA(1, integer)    cr
ATTRIBUTE   Aire-QoS-Level          Airespace-VSA(2, integer)    r
VALUE Aire-QoS-Level Bronze    3
VALUE Aire-QoS-Level Silver    0
VALUE Aire-QoS-Level Gold      1
VALUE Aire-QoS-Level Platinum  2

ATTRIBUTE   DSCP                    Airespace-VSA(3, integer)    r
ATTRIBUTE   802.1P-Tag              Airespace-VSA(4, integer)    r
ATTRIBUTE   Interface-Name          Airespace-VSA(5, string)     r
ATTRIBUTE   ACL-Name                Airespace-VSA(6, string)     r

# This should be last.

#####
# CiscoWLAN.dct - Cisco WLC dictionary
#####
```

**Step 3** Open the dictiona.dcm file (in the same directory) and add the line “@ciscowlan.dct.”

**Step 4** Save and close the dictiona.dcm file.

**Step 5** Open the vendor.ini file (in the same directory) and add the following text:

```
vendor-product      = Cisco WLAN Controller
dictionary          = ciscowlan
ignore-ports        = no
port-number-usage   = per-port-type
help-id             =
```

**Step 6** Save and close the vendor.ini file.

**Step 7** Start the SBR service (or other RADIUS service).

**Step 8** Launch the SBR Administrator (or other RADIUS Administrator).

**Step 9** Add a RADIUS client (if not already added). Choose **Cisco WLAN Controller** from the Make/Model drop-down list.

## Configuring AAA Override (GUI)

**Step 1** Choose **WLANs** to open the WLANs page.

**Step 2** Click the ID number of the WLAN that you want to configure. The WLANs > Edit page appears.

**Step 3** Choose the **Advanced** tab to open the WLANs > Edit (Advanced) page.

**Figure 7-20** WLANs > Edit (Advanced) Page

The screenshot shows the Cisco WLAN configuration interface. The 'WLANs > Edit' page has four tabs: General, Security, QoS, and Advanced. The 'Advanced' tab is active, displaying various configuration options. On the left, there's a sidebar with 'WLANs' and 'Advanced' selected. The main area contains several settings: 'Allow AAA Override' (unchecked), 'Coverage Hole Detection' (checked), 'Enable Session Timeout' (checked with a value of 1800), 'Aironet IE' (checked), 'Diagnostic Channel' (checked), and 'IPv6 Enable' (unchecked). On the right, there are 'DHCP' settings: 'DHCP Server' (unchecked), 'DHCP Addr. Assignment' (checked), and 'Management Frame Protection (MFP)' (checked with a dropdown set to 'Optional'). At the top right, there are links for 'Save Configuration', 'Ping', 'Logout', and 'Refresh'. At the bottom right, there are '< Back' and 'Apply' buttons.

- Step 4** Select the **Allow AAA Override** check box to enable AAA override or unselect it to disable this feature. The default value is disabled.
- Step 5** Click **Apply** to commit your changes.
- Step 6** Click **Save Configuration** to save your changes.

## Configure AAA Override (CLI)

```
config wlan aaa override {enable | disable} wlan_id
```

For *wlan\_id*, enter an ID from 1 to 16.

## Managing Rogue Devices

This section contains the following topics:

- [Information About Rogue Devices, page 7-81](#)
- [Guidelines and Limitations, page 7-82](#)
- [WCS Interaction and Rogue Detection, page 7-83](#)
- [Configuring Rogue Detection \(GUI\), page 7-83](#)
- [Configuring Rogue Detection \(CLI\), page 7-85](#)

## Information About Rogue Devices

Rogue access points can disrupt wireless LAN operations by hijacking legitimate clients and using plain-text or other denial-of-service or man-in-the-middle attacks. That is, a hacker can use a rogue access point to capture sensitive information, such as usernames and passwords. The hacker can then transmit a series of clear-to-send (CTS) frames. This action mimics an access point informing a particular client to transmit and instructing all others to wait, which results in legitimate clients being unable to access network resources. Wireless LAN service providers have a strong interest in banning rogue access points from the air space.

Because rogue access points are inexpensive and readily available, employees sometimes plug unauthorized rogue access points into existing LANs and build ad-hoc wireless networks without IT department knowledge or consent. These rogue access points can be a serious breach of network security because they can be plugged into a network port behind the corporate firewall. Because employees

generally do not enable any security settings on the rogue access point, it is easy for unauthorized users to use the access point to intercept network traffic and hijack client sessions. Even more alarming, wireless users frequently publish unsecure access point locations, increasing the odds of having enterprise security breached.

## Detecting Rogue Devices

The controller continuously monitors all nearby access points and automatically discovers and collects information on rogue access points and clients. When the controller discovers a rogue access point, it uses the Rogue Location Discovery Protocol (RLDP) to determine if the rogue is attached to your network.

You can configure the controller to use RLDP on all access points or only on access points configured for monitor (listen-only) mode. The latter option facilitates automated rogue access point detection in a crowded RF space, allowing monitoring without creating unnecessary interference and without affecting regular data access point functionality. If you configure the controller to use RLDP on all access points, the controller always chooses the monitor access point for RLDP operation if a monitor access point and a local (data) access point are both nearby. If RLDP determines that the rogue is on your network, you can choose to either manually or automatically contain the detected rogue.

A rogue access point is moved to a contained state either automatically or manually. The controller selects the best available access point for containment and pushes the information to the access point. The access point stores the list of containments per radio. For auto-containment, you can configure the controller to use only monitor mode access point.

The containment operation happens in following two ways:

- The container access point goes through the list of containments periodically and sends unicast containment frames. For rogue access point containment, the frames are sent only if there is a rogue client associated.
- Whenever a contained rogue activity is detected, containment frames are transmitted.

The individual rogue containment involves sending a sequence of unicast disassociation and deauthentication frames.

## Guidelines and Limitations

- Starting in release 7.0.116.0 and later releases, the controller software provides enhanced rogue containment strategies. In previous releases, when a rogue device was detected, the controller sent containment frames at regular intervals to the rogue devices. In release 7.0.116.0 and later, the containment frames are sent immediately after authorization and associations are detected. The enhanced containment algorithm provides more effective containment of ad hoc clients.
- In a dense RF environment where maximum rogue access points are suspected, the chances of detecting rogue access points by a local and FlexConnect mode access point in channel 157 or 161 are less when compared to other channels. To mitigate this problem, we recommended that you use dedicated monitor mode access points.
- The local and FlexConnect mode access points are designed to serve associated clients and these access points spend relatively less time performing off-channel scanning. The access points spend about 50 milliseconds on each channel. If you want to perform high rogue detection, a monitor mode access point must be used. Alternatively, you can reduce the scan intervals from 180 seconds to a

lesser value, for example, 120 or 60 seconds, ensuring that the radio goes off-channel more frequently which improves the chances of rogue detection. However, the access point would still spend about 50 milliseconds on each channel.

- Rogue detection is disabled by default for OfficeExtend access points because these access points, which are deployed in a home environment, are likely to detect a large number of rogue devices.
- Controller software release 5.0 or later releases improve the classification and reporting of rogue access points through the use of rogue states and user-defined classification rules that enable rogues to automatically move between states. In previous releases, the controller listed all rogue access points on one page sorted by MAC address or BSSID.

## WCS Interaction and Rogue Detection

WCS software release 5.0 or later releases also support rule-based classification. WCS uses the classification rules configured on the controller. The controller sends traps to WCS after the following events:

- If an unknown access point moves to Friendly for the first time, the controller sends a trap to WCS only if the rogue state is Alert. It does not send a trap if the rogue state is Internal or External.
- If a rogue entry is removed after the timeout expires, the controller sends a trap to WCS for rogue access points categorized as Malicious (Alert, Threat) or Unclassified (Alert). The controller does not remove rogue entries with the following rogue states: Contained, Contained Pending, Internal, and External.

## Configuring Rogue Detection (GUI)

**Step 1** Make sure that rogue detection is enabled on the desired access points. Rogue detection is enabled by default for all access points joined to the controller (except for OfficeExtend access points). However, in controller software release 6.0 or later releases, you can enable or disable it for individual access points by selecting or unselecting the **Rogue Detection** check box on the All APs > Details for (Advanced) page.

**Step 2** Choose **Security > Wireless Protection Policies > Rogue Policies > General** to open the Rogue Policies page.

**Step 3** From the Rogue Location Discovery Protocol drop-down list, choose one of the following options:

- **Disable**—Disables RLDP on all access points. This is the default value.
- **All APs**—Enables RLDP on all access points.
- **Monitor Mode APs**—Enables RLDP only on access points in monitor mode.

**Step 4** In the Expiration Timeout for Rogue AP and Rogue Client Entries text box, enter the number of seconds after which the rogue access point and client entries expire and are removed from the list. The valid range is 240 to 3600 seconds, and the default value is 1200 seconds.

**Note** If a rogue access point or client entry times out, it is removed from the controller only if its rogue state is Alert or Threat for any classification type.

**Step 5** If desired, select the **Validate Rogue Clients Against AAA** check box to use the AAA server or local database to validate if rogue clients are valid clients. The default value is unselected.

**Step 6** If desired, select the **Detect and Report Ad-Hoc Networks** check box to enable ad-hoc rogue detection and reporting. The default value is selected.

**Step 7** In the Rogue Detection Report Interval text box, enter the time interval in seconds at which APs should send rogue detection report to the controller. The valid range is from 10 seconds to 300 seconds, and the default value is 10 seconds.

---

**Note** This feature is applicable to APs that are in monitor mode only.

---

**Step 8** In the Rogue Detection Minimum RSSI text box, enter the minimum RSSI value that a rogue should have for APs to detect and for a rogue entry to be created in the controller. The valid range is from -128 dBm to 0 dBm, and the default value is 0 dBm.

---

**Note** This feature is applicable to all the AP modes.

---

There can be many rogues with very weak RSSI values that do not provide any valuable information in rogue analysis. Therefore, you can use this option to filter rogues by specifying the minimum RSSI value at which APs should detect rogues.

---

**Step 9** In the Rogue Detection Transient Interval text box, enter the time interval at which a rogue has to be scanned for by the AP after the first time that the rogue is scanned. After the rogue is scanned, updates are sent periodically to the controller. The APs filter transient rogues, which are active for a very short period and are then silent. The valid range is from 120 seconds to 1800 seconds, and the default value is 0.

---

**Note** This feature is applicable to APs that are in monitor mode only.

---

This feature has the following advantages:

- Rogue reports from APs to the controller are shorter.
- Transient rogue entries are avoided in the controller.
- Unnecessary memory allocation for transient rogues are avoided.

**Step 10** If you want the controller to automatically contain certain rogue devices, select the following check boxes. Otherwise, leave the check boxes unselected, which is the default value.

**Caution**

---

When you enable any of these parameters, the following warning appears: “Using this feature may have legal consequences. Do you want to continue?” The 2.4- and 5-GHz frequencies in the Industrial, Scientific, and Medical (ISM) band are open to the public and can be used without a license. As such, containing devices on another party’s network could have legal consequences.

---

- **Auto Containment Level**—Set the auto containment level by selecting a value from the drop-down list. The default is 1.
- **Auto Containment only for monitor mode APs**—Enable the check box if you want to use only monitor mode access points for auto-containment.
- **Rogue on Wire**—Automatically contains rogues that are detected on the wired network.

- **Using Our SSID**—Automatically contains rogues that are advertising your network's SSID. If you leave this parameter unselected, the controller only generates an alarm when such a rogue is detected.
- **Valid Client on Rogue AP**—Automatically contains a rogue access point to which trusted clients are associated. If you leave this parameter unselected, the controller only generates an alarm when such a rogue is detected.
- **AdHoc Rogue AP**—Automatically contains ad-hoc networks detected by the controller. If you leave this parameter unselected, the controller only generates an alarm when such a network is detected.

**Step 11** Click **Apply** to commit your changes.

**Step 12** Click **Save Configuration** to save your changes.

## Configuring Rogue Detection (CLI)

**Step 1** Make sure that rogue detection is enabled on the desired access points. Rogue detection is enabled by default for all access points joined to the controller (except for OfficeExtend access points). However, in controller software release 6.0 or later releases, you can enable or disable it for individual access points by entering the **config rogue detection {enable | disable} Cisco\_AP** command.

**Note** To see the current rogue detection configuration for a specific access point, enter the **show ap config general Cisco\_AP** command.

**Note** Rogue detection is disabled by default for OfficeExtend access points because these access points, which are deployed in a home environment, are likely to detect a large number of rogue devices.

**Step 2** Enable, disable, or initiate RLDP by entering these commands:

- **config rogue ap rldp enable alarm-only**—Enables RLDP on all access points.
- **config rogue ap rldp enable alarm-only monitor\_ap\_only**—Enables RLDP only on access points in monitor mode.
- **config rogue ap rldp initiate rogue\_mac\_address**—Initiates RLDP on a specific rogue access point.
- **config rogue ap rldp disable**—Disables RLDP on all access points.

**Step 3** Specify the number of seconds after which the rogue access point and client entries expire and are removed from the list by entering this command:

**config rogue ap timeout seconds**

The valid range for the *seconds* parameter is 240 to 3600 seconds (inclusive), and the default value is 1200 seconds.

**Note** If a rogue access point or client entry times out, it is removed from the controller only if its rogue state is Alert or Threat for any classification type.

**Step 4** Enable or disable ad-hoc rogue detection and reporting by entering this command:

**config rogue adhoc {enable | disable}**

**Step 5** Enable or disable the AAA server or local database to validate if rogue clients are valid clients by entering this command:

**config rogue client aaa {enable | disable}**

**Step 6** Specify the time interval in seconds at which APs should send rogue detection report to the controller by entering the following command:

**config rogue detection monitor-ap report-interval *time in sec***

Valid range for the *time in sec* parameter is 10 seconds to 300 seconds, and the default value is 10 seconds.

**Note**

This feature is applicable to APs that are in monitor mode only.

**Step 7** Specify the minimum RSSI value that rogues should have for APs to detect and for rogue entry to be created in the controller by entering the following command:

**config rogue detection min-rssi *rssi in dBm***

Valid range for the *rssi in dBm* parameter is -128 dBm to 0 dBm, and the default value is 0 dBm.

**Note**

This feature is applicable to all the AP modes.

There can be many rogues with very weak RSSI values that do not provide any valuable information in rogue analysis. Therefore, you can use this option to filter rogues by specifying the minimum RSSI value at which APs should detect rogues.

**Step 8** Specify the time interval at which rogues have to be consistently scanned for by APs after the first time the rogues are scanned for by entering the following command:

**config rogue detection monitor-ap transient-rogue-interval *time in sec***

Valid range for the *time in sec* parameter is 120 seconds to 1800 seconds, and the default value is 0.

**Note**

This feature is applicable to APs that are in monitor mode only

Using the transient interval values, you can control the time interval at which APs should scan for rogues. APs can also filter the rogues based on their transient interval values.

This feature has the following advantages:

- Rogue reports from APs to the controller are shorter.
- Transient rogue entries are avoided in the controller.
- Unnecessary memory allocation for transient rogues are avoided.

**Step 9** If you want the controller to automatically contain certain rogue devices, enter these commands:

**Caution**

When you enter any of these commands, the following warning appears: “Using this feature may have legal consequences. Do you want to continue?” The 2.4- and 5-GHz frequencies in the Industrial, Scientific, and Medical (ISM) band are open to the public and can be used without a license. As such, containing devices on another party’s network could have legal consequences.

- **config rogue ap rldp enable auto-contain**—Automatically contains rogues that are detected on the wired network.
- **config rogue ap ssid auto-contain**—Automatically contains rogues that are advertising your network’s SSID.

**Note**

If you want the controller to only generate an alarm when such a rogue is detected, enter the **config rogue ap ssid alarm** command.

- **config rogue ap valid-client auto-contain**—Automatically contains a rogue access point to which trusted clients are associated.

**Note**

If you want the controller to only generate an alarm when such a rogue is detected, enter the **config rogue ap valid-client alarm** command.

- **config rogue adhoc auto-contain**—Automatically contains adhoc networks detected by the controller.

**Note**

If you want the controller to only generate an alarm when such a network is detected, enter the **config rogue adhoc alert** command.

- **configure rogue auto-containment level {1 - 4}**—Sets the auto containment level when you enter a value between 1 and 4. The default is 1.
- **config rogue auto-contain level 1 monitor\_mode\_ap\_only**—Automatically contains only monitor mode access points.

**Step 10** Configure RLDP scheduling by entering this command:

- **config rogue ap rldp schedule add**—Enables you to schedule RLDP on a particular day of the week. You must enter the day of the week (for example **mon**, **tue**, **wed**, and so on) on which you want to schedule RLDP and the start time and end time in HH:MM:SS format. An example is as follows:

```
config rogue ap rldp schedule add mon 22:00:00 23:00:00
```

**Note**

When you configure RLDP scheduling, it is assumed that the scheduling would occur in the future, that is, after the configuration is saved.

**Step 11** Save your changes by entering this command:

```
save config
```

# Classifying Rogue Access Points

This section contains the following topics:

- [Information About Classifying Rogue Access Points, page 7-88](#)
- [Configuring Rogue Classification Rules \(GUI\), page 7-90](#)
- [Viewing and Classifying Rogue Devices \(GUI\), page 7-93](#)
- [Configuring Rogue Classification Rules \(CLI\), page 7-96](#)
- [Viewing and Classify Rogue Devices \(CLI\), page 7-98](#)

## Information About Classifying Rogue Access Points

The controller software now enables you to create rules that can organize and display rogue access points as Friendly, Malicious, or Unclassified.

By default, none of the classification rules are enabled. Therefore, all unknown access points are categorized as Unclassified. When you create a rule, configure conditions for it, and enable the rule, the unclassified access points are reclassified. Whenever you change a rule, it is applied to all access points (friendly, malicious, and unclassified) in the Alert state only.

**Note**

---

Rule-based rogue classification does not apply to ad-hoc rogues and rogue clients.

---

**Note**

---

You can configure up to 64 rogue classification rules per controller.

---

When the controller receives a rogue report from one of its managed access points, it responds as follows:

1. The controller verifies that the unknown access point is in the friendly MAC address list. If it is, the controller classifies the access point as Friendly.
2. If the unknown access point is not in the friendly MAC address list, the controller starts applying rogue classification rules.
3. If the rogue is already classified as Malicious, Alert or Friendly, Internal or External, the controller does not reclassify it automatically. If the rogue is classified differently, the controller reclassifies it automatically only if the rogue is in the Alert state.
4. The controller applies the first rule based on priority. If the rogue access point matches the criteria specified by the rule, the controller classifies the rogue according to the classification type configured for the rule.
5. If the rogue access point does not match any of the configured rules, the controller classifies the rogue as Unclassified.
6. The controller repeats the previous steps for all rogue access points.
7. If RLDP determines that the rogue access point is on the network, the controller marks the rogue state as Threat and classifies it as Malicious automatically, even if no rules are configured. You can then manually contain the rogue (unless you have configured RLDP to automatically contain the rogue), which would change the rogue state to Contained. If the rogue access point is not on the network, the controller marks the rogue state as Alert, and you can manually contain the rogue.

8. If desired, you can manually move the access point to a different classification type and rogue state.

**Table 7-9**      **Classification Mapping**

| Rule-Based Classification Type | Rogue States                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Friendly                       | <ul style="list-style-type: none"> <li>• Internal—If the unknown access point is inside the network and poses no threat to WLAN security, you would manually configure it as Friendly, Internal. An example is the access points in your lab network.</li> <li>• External—If the unknown access point is outside the network and poses no threat to WLAN security, you would manually configure it as Friendly, External. An example is an access point that belongs to a neighboring coffee shop.</li> <li>• Alert—The unknown access point is moved to Alert if it is not in the neighbor list or in the user-configured friendly MAC list.</li> </ul> |
| Malicious                      | <ul style="list-style-type: none"> <li>• Alert—The unknown access point is moved to Alert if it is not in the neighbor list or in the user-configured friendly MAC list.</li> <li>• Threat—The unknown access point is found to be on the network and poses a threat to WLAN security.</li> <li>• Contained—The unknown access point is contained.</li> <li>• Contained Pending—The unknown access point is marked Contained, but the action is delayed due to unavailable resources.</li> </ul>                                                                                                                                                         |
| Unclassified                   | <ul style="list-style-type: none"> <li>• Pending—On first detection, the unknown access point is put in the Pending state for 3 minutes. During this time, the managed access points determine if the unknown access point is a neighbor access point.</li> <li>• Alert—The unknown access point is moved to Alert if it is not in the neighbor list or in the user-configured friendly MAC list.</li> <li>• Contained—The unknown access point is contained.</li> <li>• Contained Pending—The unknown access point is marked Contained, but the action is delayed due to unavailable resources.</li> </ul>                                              |

If you upgrade to controller software release 5.0 or later releases, the classification and state of the rogue access points are reconfigured as follows:

- From Known to Friendly, Internal
- From Acknowledged to Friendly, External
- From Contained to Malicious, Contained

As mentioned previously, the controller can automatically change the classification type and rogue state of an unknown access point based on user-defined rules, or you can manually move the unknown access point to a different classification type and rogue state.

**Table 7-10 Allowable Classification Type and Rogue State Transitions**

| From                                        | To                            |
|---------------------------------------------|-------------------------------|
| Friendly (Internal, External, Alert)        | Malicious (Alert)             |
| Friendly (Internal, External, Alert)        | Unclassified (Alert)          |
| Friendly (Alert)                            | Friendly (Internal, External) |
| Malicious (Alert, Threat)                   | Friendly (Internal, External) |
| Malicious (Contained, Contained Pending)    | Malicious (Alert)             |
| Unclassified (Alert, Threat)                | Friendly (Internal, External) |
| Unclassified (Contained, Contained Pending) | Unclassified (Alert)          |
| Unclassified (Alert)                        | Malicious (Alert)             |

If the rogue state is Contained, you have to uncontain the rogue access point before you can change the classification type. If you want to move a rogue access point from Malicious to Unclassified, you must delete the access point and allow the controller to reclassify it.

## Configuring Rogue Classification Rules (GUI)

- Step 1** Choose **Security > Wireless Protection Policies > Rogue Policies > Rogue Rules** to open the Rogue Rules page.

**Figure 7-21 Rogue Rules Page**

Any rules that have already been created are listed in priority order. The name, type, and status of each rule is provided.

**Note** If you ever want to delete a rule, hover your cursor over the blue drop-down arrow for that rule and click **Remove**.

**Step 2** Create a new rule as follows:

- a. Click **Add Rule**. An Add Rule section appears at the top of the page.
- b. In the Rule Name text box, enter a name for the new rule. Make sure that the name does not contain any spaces.
- c. From the Rule Type drop-down list, choose **Friendly** or **Malicious** to classify rogue access points matching this rule as friendly or malicious.
- d. Click **Add** to add this rule to the list of existing rules, or click **Cancel** to discard this new rule.

**Step 3** Edit a rule as follows:

- a. Click the name of the rule that you want to edit. The Rogue Rule > Edit page appears.

**Figure 7-22** Rogue Rule > Edit Page

The screenshot shows the Cisco Wireless LAN Controller configuration interface. The top navigation bar includes links for Save Configuration, Ping, Logout, and Refresh. The main menu on the left lists various configuration sections: AAA, Local EAP, Priority Order, Access Control Lists, and Wireless Protection Policies. The 'Rogue Rule > Edit' page is displayed, showing the following fields:

- Rule Name:** Rule1
- Type:** Friendly (dropdown menu)
- Match Operation:** Match All (radio button), Match Any (radio button, selected)
- Enable Rule:** ☐
- Conditions:** A section with an 'Add Condition' button and a dropdown menu showing 'SSID'.

- b. From the Type drop-down list, choose **Friendly** or **Malicious** to classify rogue access points matching this rule as friendly or malicious.
- c. From the Match Operation text box, choose one of the following:
  - **Match All**—If this rule is enabled, a detected rogue access point must meet all of the conditions specified by the rule in order for the rule to be matched and the rogue to adopt the classification type of the rule.
  - **Match Any**—If this rule is enabled, a detected rogue access point must meet any of the conditions specified by the rule in order for the rule to be matched and the rogue to adopt the classification type of the rule. This is the default value.
- d. To enable this rule, select the **Enable Rule** check box. The default value is unselected.
- e. From the Add Condition drop-down list, choose one or more of the following conditions that the rogue access point must meet and click **Add Condition**.
  - **SSID**—Requires that the rogue access point have a specific user-configured SSID. If you choose this option, enter the SSID in the User Configured SSID text box, and click **Add SSID**.

**Note** To delete an SSID, highlight the SSID and click **Remove**.

- **RSSI**—Requires that the rogue access point have a minimum received signal strength indication (RSSI) value. For example, if the rogue access point has an RSSI that is greater than the configured value, then the access point could be classified as malicious. If you choose this option, enter the minimum RSSI value in the Minimum RSSI text box. The valid range is –95 to –50 dBm (inclusive), and the default value is 0 dBm.

- **Duration**—Requires that the rogue access point be detected for a minimum period of time. If you choose this option, enter a value for the minimum detection period in the Time Duration text box. The valid range is 0 to 3600 seconds (inclusive), and the default value is 0 seconds.
- **Client Count**—Requires that a minimum number of clients be associated to the rogue access point. For example, if the number of clients associated to the rogue access point is greater than or equal to the configured value, then the access point could be classified as malicious. If you choose this option, enter the minimum number of clients to be associated to the rogue access point in the Minimum Number of Rogue Clients text box. The valid range is 1 to 10 (inclusive), and the default value is 0.
- **No Encryption**—Requires that the rogue access point's advertised WLAN does not have encryption enabled. If a rogue access point has encryption disabled, it is likely that more clients will try to associate to it. No further configuration is required for this option.

---

**Note** WCS refers to this option as "Open Authentication."

---

- **Managed SSID**—Requires that the rogue access point's managed SSID (the SSID configured for the WLAN) be known to the controller. No further configuration is required for this option.

---

**Note** The SSID and Managed SSID conditions cannot be used with the Match All operation because these two SSID lists are mutually exclusive. If you define a rule with Match All and have these two conditions configured, the rogue access points are never classified as friendly or malicious because one of the conditions can never be met.

---

You can add up to six conditions per rule. When you add a condition, it appears under the Conditions section.

---

**Note** If you ever want to delete a condition from this rule, hover your cursor over the blue drop-down arrow for that condition and click **Remove**.

---

- Click **Apply** to commit your changes.

**Step 4** Click **Save Configuration** to save your changes.

**Step 5** If you want to change the order in which rogue classification rules are applied, follow these steps:

- Click **Back** to return to the Rogue Rules page.
- Click **Change Priority** to access the Rogue Rules > Priority page.  
The rogue rules are listed in priority order in the Change Rules Priority text box.
- Highlight the rule for which you want to change the priority, and click **Up** to raise its priority in the list or **Down** to lower its priority in the list.
- Continue to move the rules up or down until the rules are in the desired order.
- Click **Apply** to commit your changes.

**Step 6** Classify any rogue access points as friendly and add them to the friendly MAC address list as follows:

- Choose **Security > Wireless Protection Policies > Rogue Policies > Friendly Rogue** to open the Friendly Rogue > Create page.
- In the MAC Address text box, enter the MAC address of the friendly rogue access point.
- Click **Apply** to commit your changes.

- d. Click **Save Configuration** to save your changes. This access point is added to the controller's list of friendly access points and should now appear on the Friendly Rogue APs page.

## Viewing and Classifying Rogue Devices (GUI)

### Caution

When you choose to **contain a rogue device**, the following warning appears: “There may be legal issues following this containment. Are you sure you want to continue?” The 2.4- and 5-GHz frequencies in the Industrial, Scientific, and Medical (ISM) band are open to the public and can be used without a license. As such, containing devices on another party's network could have legal consequences.

**Step 1** Choose **Monitor > Rogues**.

**Step 2** Choose the following options to view the different types of rogue access points detected by the controller:

- **Friendly APs**
- **Malicious APs**
- **Unclassified APs**

**Figure 7-23** *Rogue APs Page*

| MAC Address                                | SSID    | Channel | # Detecting Radios | Number of Clients | Status              |
|--------------------------------------------|---------|---------|--------------------|-------------------|---------------------|
| <input type="checkbox"/> 00:17:0f:34:48:ab | Unknown | Unknown | 0                  | 0                 | Containment Pending |
| <input type="checkbox"/> ea:f2:c1:6e:4f:9b | Unknown | Unknown | 0                  | 0                 | Containment Pending |
| <input type="checkbox"/> fc:fb:fb:d9:6c:6f | K2      | 36      | 2                  | 0                 | Contained           |

The Friendly Rogue APs page, Malicious Rogue APs page, and Unclassified Rogue APs page provide the following information: the MAC address and SSID of the rogue access point, Channel Number, the number of clients connected to the rogue access point, the number of radios that detected the rogue access point, and the current status of the rogue access point.

### Note

To remove acknowledged rogues from the database, go to the WLC UI and change the rogue state to Alert Unknown and click Save Configuration. If the rogue is no longer present, it will disappear from the database in 20 minutes.

**Note**

If you ever want to delete a rogue access point from one of these pages, hover your cursor over the blue drop-down arrow and click **Remove**. To delete multiple rogue access points, check the check box corresponding to the row you want to delete and click **Remove Selected**.

- Step 3** Obtain more details about a rogue access point by clicking the MAC address of the access point. The Rogue AP Detail page appears.

This page provides the following information: the MAC address of the rogue device, the type of rogue device (such as an access point), whether the rogue device is on the wired network, the dates and times when the rogue device was first and last reported, and the current status of the device.

The Class Type text box shows the current classification for this rogue access point:

- **Friendly**—An unknown access point that matches the user-defined friendly rules or an existing known and acknowledged rogue access point. Friendly access points cannot be contained.
- **Malicious**—An unknown access point that matches the user-defined malicious rules or is moved manually by the user from the Friendly or Unclassified classification type.

**Note**

Once an access point is classified as Malicious, you cannot apply rules to it in the future, and it cannot be moved to another classification type. If you want to move a malicious access point to the Unclassified classification type, you must delete the access point and allow the controller to reclassify it.

- **Unclassified**—An unknown access point that does not match the user-defined friendly or malicious rules. An unclassified access point can be contained. It can also be moved to the Friendly or Malicious classification type automatically in accordance with user-defined rules or manually by the user.

- Step 4** If you want to change the classification of this device, choose a different classification from the Class Type drop-down list.

**Note**

A rogue access point cannot be moved to another class if its current state is Contain.

- Step 5** From the Update Status drop-down list, choose one of the following options to specify how the controller should respond to this rogue access point:

- **Internal**—The controller trusts this rogue access point. This option is available if the Class Type is set to Friendly.
- **External**—The controller acknowledges the presence of this rogue access point. This option is available if the Class Type is set to Friendly.
- **Contain**—The controller contains the offending device so that its signals no longer interfere with authorized clients. This option is available if the Class Type is set to Malicious or Unclassified.
- **Alert**—The controller forwards an immediate alert to the system administrator for further action. This option is available if the Class Type is set to Malicious or Unclassified.

The bottom of the page provides information on both the access points that detected this rogue access point and any clients that are associated to it. To see more details for any of the clients, click **Edit** to open the Rogue Client Detail page.

- Step 6** Click **Apply** to commit your changes.

- Step 7** Click **Save Configuration** to save your changes.

- Step 8** View any rogue clients that are connected to the controller by choosing **Rogue Clients**. The Rogue Clients page appears. This page shows the following information: the MAC address of the rogue client, the MAC address of the access point to which the rogue client is associated, the SSID of the rogue client, the number of radios that detected the rogue client, the date and time when the rogue client was last reported, and the current status of the rogue client.
- Step 9** Obtain more details about a rogue client by clicking the MAC address of the client. The Rogue Client Detail page appears.
- This page provides the following information: the MAC address of the rogue client, the MAC address of the rogue access point to which this client is associated, the SSID and IP address of the rogue client, the dates and times when the rogue client was first and last reported, and the current status of the rogue client.
- Step 10** From the Update Status drop-down list, choose one of the following options to specify how the controller should respond to this rogue client:
- **Contain**—The controller contains the offending device so that its signals no longer interfere with authorized clients.
  - **Alert**—The controller forwards an immediate alert to the system administrator for further action.
- The bottom of the page provides information on the access points that detected this rogue client.
- Step 11** Click **Apply** to commit your changes.
- Step 12** If desired, you can test the controller's connection to this client by clicking **Ping**.
- Step 13** Click **Save Configuration** to save your changes.
- Step 14** See any ad-hoc rogues detected by the controller by choosing **Adhoc Rogues**. The Adhoc Rogues page appears.
- This page shows the following information: the MAC address, BSSID, and SSID of the ad-hoc rogue, the number of radios that detected the ad-hoc rogue, and the current status of the ad-hoc rogue.
- Step 15** Obtain more details about an ad-hoc rogue by clicking the MAC address of the rogue. The Adhoc Rogue Detail page appears.
- This page provides the following information: the MAC address and BSSID of the ad-hoc rogue, the dates and times when the rogue was first and last reported, and the current status of the rogue.
- Step 16** From the Update Status drop-down list, choose one of the following options to specify how the controller should respond to this ad-hoc rogue:
- **Contain**—The controller contains the offending device so that its signals no longer interfere with authorized clients.
  - **Alert**—The controller forwards an immediate alert to the system administrator for further action.
  - **Internal**—The controller trusts this rogue access point.
  - **External**—The controller acknowledges the presence of this rogue access point.
- Step 17** From the Maximum Number of APs to Contain the Rogue drop-down list, choose one of the following options to specify the maximum number of access points used to contain this ad-hoc rogue: **1**, **2**, **3**, or **4**.
- The bottom of the page provides information on the access points that detected this ad-hoc rogue.
- Step 18** Click **Apply** to commit your changes.
- Step 19** Click **Save Configuration** to save your changes.
- Step 20** View any access points that have been configured to be ignored by choosing **Rogue AP Ignore-List**. The Rogue AP Ignore-List page appears.

This page shows the MAC addresses of any access points that are configured to be ignored. The rogue-ignore list contains a list of any autonomous access points that have been manually added to WCS maps by WCS users. The controller regards these autonomous access points as rogues even though WCS is managing them. The rogue-ignore list allows the controller to ignore these access points. The list is updated as follows:

- When the controller receives a rogue report, it checks to see if the unknown access point is in the rogue-ignore access point list.
- If the unknown access point is in the rogue-ignore list, the controller ignores this access point and continues to process other rogue access points.
- If the unknown access point is not in the rogue-ignore list, the controller sends a trap to WCS. If WCS finds this access point in its autonomous access point list, WCS sends a command to the controller to add this access point to the rogue-ignore list. This access point is then ignored in future rogue reports.
- If a user removes an autonomous access point from WCS, WCS sends a command to the controller to remove this access point from the rogue-ignore list.

## Configuring Rogue Classification Rules (CLI)

**Step 1** Create a rule by entering this command:

```
config rogue rule add ap priority priority classify {friendly | malicious} rule_name
```

**Note** If you later want to change the priority of this rule and shift others in the list accordingly, enter the **config rogue rule priority priority rule\_name command**. If you later want to change the classification of this rule, enter the **config rogue rule classify {friendly | malicious} rule\_name command**.

**Note** If you ever want to delete all of the rogue classification rules or a specific rule, enter the **config rogue rule delete {all | rule\_name} command**.

**Step 2** Disable all rules or a specific rule by entering this command:

```
config rogue rule disable {all | rule_name}
```

**Note** A rule must be disabled before you can modify its attributes.

**Step 3** Add conditions to a rule that the rogue access point must meet by entering this command:

```
config rogue rule condition ap set condition_type condition_value rule_name
```

where *condition\_type* is one of the following:

- **ssid**—Requires that the rogue access point have a specific SSID. You should add SSIDs that are not managed by the controller. If you choose this option, enter the SSID for the *condition\_value parameter*. The SSID is added to the user-configured SSID list.

**Note**

If you ever want to delete all of the SSIDs or a specific SSID from the user-configured SSID list, enter the **config rogue rule condition ap delete ssid {all | ssid} rule\_name** command.

- **rssi**—Requires that the rogue access point have a minimum RSSI value. For example, if the rogue access point has an RSSI that is greater than the configured value, then the access point could be classified as malicious. If you choose this option, enter the minimum RSSI value for the *condition\_value parameter*. The valid range is –95 to –50 dBm (inclusive), and the default value is 0 dBm.
- **duration**—Requires that the rogue access point be detected for a minimum period of time. If you choose this option, enter a value for the minimum detection period for the *condition\_value parameter*. The valid range is 0 to 3600 seconds (inclusive), and the default value is 0 seconds.
- **client-count**—Requires that a minimum number of clients be associated to the rogue access point. For example, if the number of clients associated to the rogue access point is greater than or equal to the configured value, then the access point could be classified as malicious. If you choose this option, enter the minimum number of clients to be associated to the rogue access point for the *condition\_value parameter*. The valid range is 1 to 10 (inclusive), and the default value is 0.
- **no-encryption**—Requires that the rogue access point's advertised WLAN does not have encryption enabled. A *condition\_value parameter* is not required for this option.
- **managed-ssid**—Requires that the rogue access point's SSID be known to the controller. A *condition\_value parameter* is not required for this option.

**Note**

You can add up to six conditions per rule. If you ever want to delete all of the conditions or a specific condition from a rule, enter the **config rogue rule condition ap delete {all | condition\_type} condition\_value rule\_name** command.

- Step 4** Specify whether a detected rogue access point must meet all or any of the conditions specified by the rule in order for the rule to be matched and the rogue access point to adopt the classification type of the rule by entering this command:

```
config rogue rule match {all | any} rule_name
```

- Step 5** Enable all rules or a specific rule by entering this command:

```
config rogue rule enable {all | rule_name}
```

**Note**

For your changes to become effective, you must enable the rule.

- Step 6** Add a new friendly access point entry to the friendly MAC address list or delete an existing friendly access point entry from the list by entering this command:

```
config rogue ap friendly {add | delete} ap_mac_address
```

- Step 7** Save your changes by entering this command:

```
save config
```

- Step 8** View the rogue classification rules that are configured on the controller by entering this command:

```
show rogue rule summary
```

Information similar to the following appears:

```
Priority Rule Name State Type Match Hit Count
-----
```

|   |       |          |           |     |     |
|---|-------|----------|-----------|-----|-----|
| 1 | Rule1 | Disabled | Friendly  | Any | 0   |
| 2 | Rule2 | Enabled  | Malicious | Any | 339 |
| 3 | Rule3 | Disabled | Friendly  | Any | 0   |

**Step 9** View detailed information for a specific rogue classification rule by entering this command:

**show rogue rule detailed *rule\_name***

Information similar to the following appears:

```

Priority..... 2
Rule Name..... Rule2
State..... Enabled
Type..... Malicious
Match Operation..... Any
Hit Count..... 352
Total Conditions..... 6
Condition 1
  type..... Client-count
  value..... 10
Condition 2
  type..... Duration
  value (seconds)..... 2000
Condition 3
  type..... Managed-ssid
  value..... Enabled
Condition 4
  type..... No-encryption
  value..... Enabled
Condition 5
  type..... Rssi
  value (dBm)..... -50
Condition 6
  type..... Ssid
  SSID Count..... 1
  SSID 1..... test

```

## Viewing and Classify Rogue Devices (CLI)

- View a list of all rogue access points detected by the controller by entering this command:

**show rogue ap summary**

Information similar to the following appears:

```

Rogue Location Discovery Protocol..... Enabled
Rogue AP timeout..... 1200

MAC Address      Classification    # APs # Clients Last Heard
-----
00:0a:b8:7f:08:c0 Friendly          0      0      Not Heard
00:0b:85:01:30:3f Malicious         1      0      Fri Nov 30 11:30:59 2007
00:0b:85:63:70:6f Malicious         1      0      Fri Nov 30 11:20:14 2007
00:0b:85:63:cd:bf Malicious         1      0      Fri Nov 30 11:23:12 2007
...

```

- See a list of the friendly rogue access points detected by the controller by entering this command:

**show rogue ap friendly summary**

Information similar to the following appears:

```
Number of APs..... 1
```

| MAC Address       | State    | # APs | # Clients | Last Heard               |
|-------------------|----------|-------|-----------|--------------------------|
| 00:0a:b8:7f:08:c0 | Internal | 1     | 0         | Tue Nov 27 13:52:04 2007 |

- See a list of the malicious rogue access points detected by the controller by entering this command:

#### **show rogue ap malicious summary**

Information similar to the following appears:

```
Number of APs..... 264
```

| MAC Address       | State | # APs | # Clients | Last Heard               |
|-------------------|-------|-------|-----------|--------------------------|
| 00:0b:85:01:30:3f | Alert | 1     | 0         | Fri Nov 30 11:20:01 2007 |
| 00:0b:85:63:70:6f | Alert | 1     | 0         | Fri Nov 30 11:20:14 2007 |
| 00:0b:85:63:cd:bf | Alert | 1     | 0         | Fri Nov 30 11:23:12 2007 |
| 00:0b:85:63:cd:dd | Alert | 1     | 0         | Fri Nov 30 11:27:03 2007 |
| 00:0b:85:63:cd:de | Alert | 1     | 0         | Fri Nov 30 11:26:23 2007 |
| 00:0b:85:63:cd:df | Alert | 1     | 0         | Fri Nov 30 11:26:50 2007 |
| ...               |       |       |           |                          |

- See a list of the unclassified rogue access points detected by the controller by entering this command:

#### **show rogue ap unclassified summary**

Information similar to the following appears:

```
Number of APs..... 164
```

| MAC Address       | State | # APs | # Clients | Last Heard               |
|-------------------|-------|-------|-----------|--------------------------|
| 00:0b:85:63:cd:bd | Alert | 1     | 0         | Fri Nov 30 11:12:52 2007 |
| 00:0b:85:63:cd:e7 | Alert | 1     | 0         | Fri Nov 30 11:29:01 2007 |

    SSID..... rf4k3ap
    Channel..... 3
    RSSI..... -56 dBm
    SNR..... 15 dB
    Encryption..... Disabled
    ShortPreamble..... Disabled
    WPA Support..... Disabled
    Last reported by this AP..... Tue Dec 11 20:45:45 2007
```

- See a list of rogue access points that are configured to be ignore by entering this command:

#### **show rogue ignore-list**

Information similar to the following appears:

```
MAC Address
-----
10:bb:17:cc:01:ef
```

**Note** See [Step 20](#) of the “[Viewing and Classifying Rogue Devices \(GUI\)](#)” section on page 7-93 for more information on the rogue-ignore access point list.

- Classify a rogue access point as friendly by entering this command:

#### **config rogue ap classify friendly state {internal | external} *ap\_mac\_address***

where

- **internal** means that the controller trusts this rogue access point.
- **external** means that the controller acknowledges the presence of this rogue access point.

**Note** A rogue access point cannot be moved to the Friendly class if its current state is Contain.

- Mark a rogue access point as malicious by entering this command:

**config rogue ap classify malicious state {alert | contain} *ap\_mac\_address***

where

- **alert** means that the controller forwards an immediate alert to the system administrator for further action.
- **contain** means that the controller contains the offending device so that its signals no longer interfere with authorized clients.

---

**Note** A rogue access point cannot be moved to the Malicious class if its current state is Contain.

---

- Mark a rogue access point as unclassified by entering this command:

**config rogue ap classify unclassified state {alert | contain} *ap\_mac\_address***

---

**Note** A rogue access point cannot be moved to the Unclassified class if its current state is Contain.

---

- **alert** means that the controller forwards an immediate alert to the system administrator for further action.
  - **contain** means that the controller contains the offending device so that its signals no longer interfere with authorized clients.
  - Specify how the controller should respond to a rogue client by entering one of these commands:
    - **config rogue client alert *client\_mac\_address***—The controller forwards an immediate alert to the system administrator for further action.
    - **config rogue client contain *client\_mac\_address***—The controller contains the offending device so that its signals no longer interfere with authorized clients.
  - Specify how the controller should respond to an ad-hoc rogue by entering one these commands:
    - **config rogue adhoc alert *rogue\_mac\_address***—The controller forwards an immediate alert to the system administrator for further action.
    - **config rogue adhoc contain *rogue\_mac\_address***—The controller contains the offending device so that its signals no longer interfere with authorized clients.
    - **config rogue adhoc external *rogue\_mac\_address***—The controller acknowledges the presence of this ad-hoc rogue.
  - Save your changes by entering this command:  
**save config**
- 

## Configuring Cisco TrustSec SXP

This section contains the following topics:

- [Information About Cisco TrustSec SXP, page 7-103](#)
- [Guidelines and Limitations, page 7-103](#)
- [Configuring Cisco TrustSec SXP \(GUI\), page 7-104](#)

- [Creating a New SXP Connection \(GUI\)](#), page 7-105
- [Configuring Cisco TrustSec SXP \(CLI\)](#), page 7-105

## Information About Cisco TrustSec SXP

Cisco TrustSec (CTS) enables organizations to secure their networks and services through identity-based access control to anyone, anywhere, anytime. The solution also offers data integrity and confidentiality services, policy-based governance, and centralized monitoring, troubleshooting, and reporting services. CTS can be combined with personalized, professional service offerings to simplify solution deployment and management and is a foundational security component to Cisco Borderless Networks.

The CTS architecture establishes domains of trusted network devices. Each device in the domain is authenticated by its peers. Communication on the links between devices in the domain is secured with a combination of encryption, message integrity checks, and data-path replay protection mechanisms. CTS uses the device and user credentials acquired during authentication for classifying the packets by security groups (SGs) as they enter the network. This packet classification is maintained by tagging packets on ingress to the CTS network so that they can be correctly identified to apply security and other policy criteria along the data path. The tag, called the security group tag (SGT), allows the network to enforce the access control policy by enabling the endpoint device to act upon the SGT to filter traffic.

One of the components of the CTS architecture is the security group-based access control. Access policies in the Cisco TrustSec domain are topology-independent, based on the roles (as indicated by security group number) of source and destination devices rather than on network addresses. Individual packets are tagged with the security group number of the source.

Cisco devices use the SGT Exchange Protocol (SXP) to propagate SGTs across network devices that do not have hardware support for Cisco TrustSec. SXP is the software solution to avoid CTS hardware upgrade on all switches. WLC will be supporting SXP as part of the CTS architecture. The SXP sends SGT information to the CTS-enabled switches so that appropriate role-based access control lists (RBACLs) can be activated depending on the role information represented by the SGT. By default, the controller always works in the Speaker mode. To implement the SXP on a network, only the egress distribution switch needs to be CTS-enabled, and all the other switches can be non-CTS-capable switches.

The SXP runs between any access layer and distribution switch or between two distribution switches. The SXP uses TCP as the transport layer. CTS authentication is performed for any host (client) that joins the network on the access layer switch similar to an access switch with CTS-enabled hardware. The access layer switch is not CTS hardware enabled. Data traffic is not encrypted or cryptographically authenticated when it passes through the access layer switch. The SXP is used to pass the IP address of the authenticated device (that is a wireless client) and the corresponding SGT up to the distribution switch. If the distribution switch is CTS-hardware enabled, the switch inserts the SGT into the packet on behalf of the access layer switch. If the distribution switch is not CTS-hardware enabled, the SXP on the distribution switch passes the IP-SGT mapping to all the distribution switches that have CTS hardware. On the egress side, the enforcement of the RBACL occurs at the egress Layer 3 interface on the distribution switch.

For more information about CTS, see <http://www.cisco.com/en/US/netsol/ns1051/index.html>.

## Guidelines and Limitations

- SXP is not supported on FlexConnect access points.
- SXP is supported only in centrally switched networks that have central authentication.

- By default, SXP is supported for APs that work in local mode only.
- The controller always operates in the Speaker mode.
- The configuration of the default password should be consistent for both controller and the switch.
- Fault tolerance is not supported because fault tolerance requires local switching on APs.
- SXP is supported for both IPv4 and IPv6 clients.
- Static IP-SGT mapping for local authentication of users is not supported.
- IP-SGT mapping requires authentication with external ACS servers.
- SXP is supported on the following security policies only:
  - WPA2-dot1x
  - WPA-dot1x
  - 802.1x (Dynamic WEP)
  - MAC Filtering using RADIUS servers
  - Web authentication using RADIUS servers for user authentication

## Configuring Cisco TrustSec SXP (GUI)

**Step 1** Choose **SECURITY > TrustSec SXP** to open the SXP Configuration page.

**Figure 7-24 SXP Configuration Page**

The screenshot shows the Cisco TrustSec SXP Configuration page. The left sidebar lists navigation options: Security, AAA, Local EAP, Priority Order, Certificate, Access Control Lists, Wireless Protection Policies, Web Auth, TrustSec SXP, and Advanced. The main content area is titled 'SXP Configuration' and includes the following fields:

- Total SXP Connections: 0
- SXP State: Disabled (dropdown menu)
- SXP Mode: Speaker
- Default Password: [masked with dots]
- Default Source IP: 9.4.64.8
- Retry Period: 120

Below these fields is a table with the following headers: Peer IP Address, Source IP Address, and Connection Status.

331255

This page lists the following SXP configuration details:

- Total SXP Connections—Number of SXP connections that are configured.
- SXP State—Status of SXP connections as either disabled or enabled.
- SXP Mode—SXP mode of the controller. The controller is always set to Speaker mode for SXP connections.
- Default Password—Password for MD5 authentication of SXP messages. We recommend that the password has a minimum of 6 characters.
- Default Source IP—IP address of the management interface. SXP uses the default source IP address for all new TCP connections.

- **Retry Period**—SXP retry timer. The default value is 120 seconds (2 minutes). The valid range is 0 to 64000 seconds. The SXP retry period determines how often the controller retries for an SXP connection. When an SXP connection is not successfully set up, the controller makes a new attempt to set up the connection after the SXP retry period timer expires. Setting the SXP retry period to 0 seconds disables the timer and retries are not attempted.

This page also displays the following information about SXP connections:

- **Peer IP Address**—The IP address of the next hop switch to which the controller is connected. There is no effect on the existing TCP connections when you configure a new peer connection.
- **Source IP Address**—The management IP address of the controller.
- **Connection Status**—Status of the SXP connection.

- Step 2** To enable CTS SXP, from the SXP State drop-down list, choose **Enabled**.
- Step 3** Enter the default password that should be used to make an SXP connection. We recommend that the password contain a minimum of 6 characters.
- Step 4** In the Retry Period text box, enter the time in seconds that determines how often the Cisco TrustSec software retries for an SXP connection.
- Step 5** Click **Apply** to commit your changes.
- 

## Creating a New SXP Connection (GUI)

- Step 1** Choose **SECURITY > TrustSec SXP** and click **New** to open the SXP Connection > New page.
- Step 2** In the Peer IP Address text box, enter the IP address of the next hop switch to which the controller is connected.
- Step 3** Click **Apply**.
- 

## Configuring Cisco TrustSec SXP (CLI)

- To enable or disable the SXP on the controller, enter this command:  
**config cts sxp {enable | disable}**
- To configure the default password for MD5 Authentication of SXP messages, enter this command:  
**config cts sxp default password *password***
- To configure the SXP retry period, enter the following command:  
**config cts sxp retry period *time-in-seconds***
- To configure the IP address of the next hop switch with which the controller is connected, enter the command:  
**config cts sxp connection peer *ip-address***
- To remove an SXP connection, enter this command:  
**config cts sxp connection delete *ip-address***
- To see a summary of SXP configuration, enter this command:

**show cts sxp summary**

Information similar to the following appears:

```
SXP State..... Enable
SXP Mode..... Speaker
Default Password..... ****
Default Source IP..... 209.165.200.224
Connection retry open period ..... 120
```

- To see the list of SXP connections that are configured, enter the following command:

**show cts sxp connections**

Information similar to the following appears:

```
Total num of SXP Connections..... 1
SXP State..... Enable
Peer IP          Source IP          Connection Status
-----
209.165.200.229  209.165.200.224          On
```

## Configuring Cisco Intrusion Detection System

This section contains the following topics:

- [Information About Cisco Intrusion Detection System, page 7-106](#)
- [Additional Information, page 7-107](#)
- [Configuring IDS Sensors \(GUI\), page 7-107](#)
- [Configuring IDS Sensors \(CLI\), page 7-108](#)
- [Viewing Shunned Clients \(CLI\), page 7-110](#)

## Information About Cisco Intrusion Detection System

The Cisco Intrusion Detection System/Intrusion Prevention System (CIDS/CIPS) instructs controllers to block certain clients from accessing the wireless network when attacks involving these clients are detected at Layer 3 through Layer 7. This system offers significant network protection by helping to detect, classify, and stop threats including worms, spyware/adware, network viruses, and application abuse. Two methods are available to detect potential attacks:

- IDS sensors
- IDS signatures

You can configure IDS sensors to detect various types of IP-level attacks in your network. When the sensors identify an attack, they can alert the controller to shun the offending client. When you add a new IDS sensor, you register the controller with that IDS sensor so that the controller can query the sensor to get the list of shunned clients.

When an IDS sensor detects a suspicious client, it alerts the controller to shun this client. The shun entry is distributed to all controllers within the same mobility group. If the client to be shunned is currently joined to a controller in this mobility group, the anchor controller adds this client to the dynamic exclusion list, and the foreign controller removes the client. The next time that the client tries to connect to a controller, the anchor controller rejects the handoff and informs the foreign controller that the client is being excluded.

## Additional Information

The Cisco wireless intrusion prevention system (wIPS) is also supported on the controller through WCS. See the “[Configuring wIPS](#)” section on page 7-121 for more information.

See [Chapter 15, “Configuring Mobility Groups,”](#) for more information on mobility groups.

## Configuring IDS Sensors (GUI)

**Step 1** Choose **Security > Advanced > CIDs > Sensors** to open the CIDS Sensors List page.

**Figure 7-25** CIDS Sensors List Page

| Index | Server Address  | Port | State   | Query Interval |
|-------|-----------------|------|---------|----------------|
| 1     | 209.165.200.225 | 443  | Enabled | 10             |
| 2     | 209.165.200.225 | 443  | Enabled | 60             |

This page lists all of the IDS sensors that have been configured for this controller.

**Note** If you want to delete an existing sensor, hover your cursor over the blue drop-down arrow for that sensor and choose **Remove**.

**Step 2** Add an IDS sensor to the list by clicking **New**. The CIDS Sensor Add page appears.

**Step 3** The controller supports up to five IDS sensors. From the Index drop-down list, choose a number (between 1 and 5) to determine the sequence in which the controller consults the IDS sensors. For example, if you choose 1, the controller consults this IDS sensor first.

**Step 4** In the Server Address text box, enter the IP address of your IDS server.

**Step 5** The Port text box contains the number of the HTTPS port through which the controller is to communicate with the IDS sensor. We recommend that you set this parameter to 443 because the sensor uses this value to communicate by default.

The default value is 443 and the range is 1 to 65535.

**Step 6** In the Username text box, enter the name that the controller uses to authenticate to the IDS sensor.

**Note** This username must be configured on the IDS sensor and have at least a read-only privilege.

**Step 7** In the Password and Confirm Password text boxes, enter the password that the controller uses to authenticate to the IDS sensor.

**Step 8** In the Query Interval text box, enter the time (in seconds) for how often the controller should query the IDS server for IDS events.

The default is 60 seconds and the range is 10 to 3600 seconds.

- Step 9** Select the **State** check box to register the controller with this IDS sensor or unselected this check box to disable registration. The default value is disabled.
- Step 10** In the Fingerprint text box, enter a 40-hexadecimal-character security key. This key is used to verify the validity of the sensor and is used to prevent security attacks.

**Note** Make sure you include colons that appear between every two bytes within the key. For example, enter AA:BB:CC:DD.

- Step 11** Click **Apply**. Your new IDS sensor appears in the list of sensors on the CIDS Sensors List page.
- Step 12** Click **Save Configuration** to save your changes.

## Viewing Shunned Clients (GUI)

- Step 1** Choose **Security > Advanced > CIDS > Shunned Clients** to open the CIDS Shun List page.

**Figure 7-26 CIDS Shun List Page**

| IP Address      | Last MAC Address  | Expire | Sensor IP / Index |
|-----------------|-------------------|--------|-------------------|
| 209.165.200.225 | 00:00:00:00:00:00 | 60     | 209.165.200.225/1 |
| 209.165.200.225 | 00:00:00:00:00:00 | 59     | 209.165.200.225/1 |

This page shows the IP address and MAC address of each shunned client, the length of time that the client's data packets should be blocked by the controller as requested by the IDS sensor, and the IP address of the IDS sensor that discovered the client.

- Step 2** Click **Re-sync** to purge and reset the list as desired.

## Configuring IDS Sensors (CLI)

- Step 1** Add an IDS sensor by entering this command:
- ```
config wps cids-sensor add index ids_ip_address username password
```

The *index* parameter determines the sequence in which the controller consults the IDS sensors. The controller supports up to five IDS sensors. Enter a number (between 1 and 5) to determine the priority of this sensor. For example, if you enter 1, the controller consults this IDS sensor first.

**Note** The username must be configured on the IDS sensor and have at least a read-only privilege.

- Step 2** (Optional) Specify the number of the HTTPS port through which the controller is to communicate with the IDS sensor by entering this command:

**config wps cids-sensor port** *index port\_number*

For the *port-number* parameter, you can enter a value between 1 and 65535. The default value is 443. This step is optional because we recommend that you use the default value of 443. The sensor uses this value to communicate by default.

- Step 3** Specify how often the controller should query the IDS server for IDS events by entering this command:

**config wps cids-sensor interval** *index interval*

For the *interval* parameter, you can enter a value between 10 and 3600 seconds. The default value is 60 seconds.

- Step 4** Enter a 40-hexadecimal-character security key used to verify the validity of the sensor by entering this command:

**config wps cids-sensor fingerprint** *index sha1 fingerprint*

You can get the value of the fingerprint by entering **show tls fingerprint** on the sensor's console.

**Note** Make sure to include the colons that appear between every two bytes within the key (for example, AA:BB:CC:DD).

- Step 5** Enable or disable this controller's registration with an IDS sensor by entering this command:

**config wps cids-sensor** {**enable** | **disable**} *index*

- Step 6** Enable or disable protection from DoS attacks by entering this command:

**config wps auto-immune** {**enable** | **disable**}

The default value is disabled.

**Note** A potential attacker can use specially crafted packets to mislead the IDS into treating a legitimate client as an attacker. It causes the controller to wrongly disconnect this legitimate client and launches a DoS attack. The auto-immune feature, when enabled, is designed to protect against such attacks. However, conversations using Cisco 792x phones might be interrupted intermittently when the auto-immune feature is enabled. If you experience frequent disruptions when using 792x phones, you might want to disable this feature.

- Step 7** Save your settings by entering this command:

**save config**

- Step 8** See the IDS sensor configuration by entering one of these commands:

- **show wps cids-sensor summary**
- **show wps cids-sensor detail** *index*

The second command provides more information than the first.

- Step 9** See the auto-immune configuration setting by entering this command:

**show wps summary**

Information similar to the following appears:

```
Auto-Immune
  Auto-Immune..... Disabled

Client Exclusion Policy
  Excessive 802.11-association failures..... Enabled
  Excessive 802.11-authentication failures..... Enabled
  Excessive 802.1x-authentication..... Enabled
  IP-theft..... Enabled
  Excessive Web authentication failure..... Enabled
Signature Policy
  Signature Processing..... Enabled
```

- Step 10** Obtain debug information regarding IDS sensor configuration by entering this command:
- debug wps cids enable**

**Note**

If you ever want to delete or change the configuration of a sensor, you must first disable it by entering the **config wps cids-sensor disable *index*** command. To delete the sensor, enter the **config wps cids-sensor delete *index*** command.

## Viewing Shunned Clients (CLI)

- Step 1** View the list of clients to be shunned by entering this command:
- show wps shun-list**
- Step 2** Force the controller to synchronize with other controllers in the mobility group for the shun list by entering this command:
- config wps shun-list re-sync**

## Configuring IDS Signatures

This section contains the following topics:

- [Information About IDS Signatures, page 7-111](#)
- [Configuring IDS Signatures \(GUI\), page 7-113](#)
- [Viewing IDS Signature Events \(GUI\), page 7-116](#)
- [Configure IDS Signatures \(CLI\), page 7-118](#)
- [Viewing IDS Signature Events \(CLI\), page 7-119](#)

## Information About IDS Signatures

You can configure IDS signatures, or bit-pattern matching rules used to identify various types of attacks in incoming 802.11 packets, on the controller. When the signatures are enabled, the access points joined to the controller perform signature analysis on the received 802.11 data or management frames and report any discrepancies to the controller. If an attack is detected, appropriate mitigation is initiated.

Cisco supports 17 standard signatures on the controller as shown on the Standard Signatures page.

**Figure 7-27**      **Standard Signatures Page**

The screenshot displays the 'Standard Signatures' configuration page on a Cisco Wireless LAN Controller. The left sidebar shows the navigation menu with 'Wireless Protection Policies' expanded. The main content area has a 'Global Settings' section with a checked checkbox for 'Enable check for all Standard and Custom Signatures'. Below this is a table listing 17 standard signatures.

Precedence	Name	Frame Type	Action	State	Description
1	Bcast deauth	Management	Report	Enabled	Broadcast Deauthentication Frame
2	NULL probe resp 1	Management	Report	Enabled	NULL Probe Response - Zero length SSID element
3	NULL probe resp 2	Management	Report	Enabled	NULL Probe Response - No SSID element
4	Assoc flood	Management	Report	Enabled	Association Request flood
5	Auth flood	Management	Report	Enabled	Authentication Request flood
6	Reassoc flood	Management	Report	Enabled	Reassociation Request flood
7	Broadcast Probe floo	Management	Report	Enabled	Broadcast Probe Request flood
8	Disassoc flood	Management	Report	Enabled	Disassociation flood
9	Deauth flood	Management	Report	Enabled	Deauthentication flood
10	Reserved mgmt 7	Management	Report	Enabled	Reserved management sub-type 7
11	Reserved mgmt F	Management	Report	Enabled	Reserved management sub-type F
12	EAPOL flood	Data	Report	Enabled	EAPOL Flood Attack
13	NetStumbler 3.2.0	Data	Report	Enabled	NetStumbler 3.2.0
14	NetStumbler 3.2.3	Data	Report	Enabled	NetStumbler 3.2.3
15	NetStumbler 3.3.0	Data	Report	Enabled	NetStumbler 3.3.0
16	NetStumbler generic	Data	Report	Enabled	NetStumbler
17	Wellenreiter	Management	Report	Enabled	Wellenreiter

These signatures are divided into six main groups. The first four groups contain management signatures, and the last two groups contain data signatures.

- **Broadcast deauthentication frame signatures**—During a broadcast deauthentication frame attack, a hacker sends an 802.11 deauthentication frame to the broadcast MAC destination address of another client. This attack causes the destination client to disassociate from the access point and lose its connection. If this action is repeated, the client experiences a denial of service. When the broadcast deauthentication frame signature (precedence 1) is used to detect such an attack, the access point listens for clients transmitting broadcast deauthentication frames that match the characteristics of the signature. If the access point detects such an attack, it alerts the controller. Depending on how your system is configured, the offending device is contained so that its signals no longer interfere with authorized clients, or the controller forwards an immediate alert to the system administrator for further action, or both.

- **NULL probe response signatures**—During a NULL probe response attack, a hacker sends a NULL probe response to a wireless client adapter. As a result, the client adapter locks up. When a NULL probe response signature is used to detect such an attack, the access point identifies the wireless client and alerts the controller. The NULL probe response signatures are as follows:
  - NULL probe resp 1 (precedence 2)
  - NULL probe resp 2 (precedence 3)
- **Management frame flood signatures**—During a management frame flood attack, a hacker floods an access point with 802.11 management frames. The result is a denial of service to all clients associated or attempting to associate to the access point. This attack can be implemented with different types of management frames: association requests, authentication requests, reassociation requests, probe requests, disassociation requests, deauthentication requests, and reserved management subtypes.

When a management frame flood signature is used to detect such an attack, the access point identifies management frames matching the entire characteristic of the signature. If the frequency of these frames is greater than the value of the frequency set in the signature, an access point that hears these frames triggers an alarm. The controller generates a trap and forwards it to WCS.

The management frame flood signatures are as follows:

- Assoc flood (precedence 4)
- Auth flood (precedence 5)
- Reassoc flood (precedence 6)
- Broadcast probe flood (precedence 7)
- Disassoc flood (precedence 8)
- Deauth flood (precedence 9)
- Reserved mgmt 7 (precedence 10)
- Reserved mgmt F (precedence 11)

The reserved management frame signatures 7 and F are reserved for future use.

- **Wellenreiter signature**—Wellenreiter is a wireless LAN scanning and discovery utility that can reveal access point and client information. When the Wellenreiter signature (precedence 17) is used to detect such an attack, the access point identifies the offending device and alerts the controller.
- **EAPOL flood signature**—During an EAPOL flood attack, a hacker floods the air with EAPOL frames that contain 802.1X authentication requests. As a result, the 802.1X authentication server cannot respond to all of the requests and fails to send successful authentication responses to valid clients. The result is a denial of service to all affected clients. When the EAPOL flood signature (precedence 12) is used to detect such an attack, the access point waits until the maximum number of allowed EAPOL packets is exceeded. It then alerts the controller and proceeds with the appropriate mitigation.
- **NetStumbler signatures**—NetStumbler is a wireless LAN scanning utility that reports access point broadcast information (such as operating channel, RSSI information, adapter manufacturer name, SSID, WEP status, and the latitude and longitude of the device running NetStumbler when a GPS is attached). If NetStumbler succeeds in authenticating and associating to an access point, it sends a data frame with the following strings, depending on the NetStumbler version:

Version	String
3.2.0	“Flurble gronk bloopit, bnip Frundletrune”

Version	String
3.2.3	"All your 802.11b are belong to us"
3.3.0	Sends white spaces

When a NetStumbler signature is used to detect such an attack, the access point identifies the offending device and alerts the controller. The NetStumbler signatures are as follows:

- NetStumbler 3.2.0 (precedence 13)
- NetStumbler 3.2.3 (precedence 14)
- NetStumbler 3.3.0 (precedence 15)
- NetStumbler generic (precedence 16)

A standard signature file exists on the controller by default. You can upload this signature file from the controller, or you can create a custom signature file and download it to the controller or modify the standard signature file to create a custom signature.

## Configuring IDS Signatures (GUI)

This section contains the following topics:

- [Uploading or Downloading IDS Signatures, page 7-113](#)
- [Enabling or Disabling IDS Signatures, page 7-115](#)

### Uploading or Downloading IDS Signatures

- 
- Step 1** If desired, create your own custom signature file.
- Step 2** Make sure that you have a Trivial File Transfer Protocol (TFTP) server available. Follow these guidelines when setting up a TFTP server:
- If you are downloading through the service port, the TFTP server must be on the same subnet as the service port because the service port is not routable, or you must create static routes on the controller.
  - If you are downloading through the distribution system network port, the TFTP server can be on the same or a different subnet because the distribution system port is routable.
  - A third-party TFTP server cannot run on the same computer as the Cisco WCS because the WCS built-in TFTP server and the third-party TFTP server require the same communication port.
- Step 3** If you are downloading a custom signature file (\*.sig), copy it to the default directory on your TFTP server.
- Step 4** Choose **Commands** to open the Download File to Controller page.

**Figure 7-28** Download File to Controller Page

**Step 5** Perform one of the following:

- If you want to download a custom signature file to the controller, choose **Signature File** from the File Type drop-down list on the Download File to Controller page.
- If you want to upload a standard signature file from the controller, choose **Upload File** and then **Signature File** from the File Type drop-down list on the Upload File from Controller page.

**Step 6** From the Transfer Mode drop-down list, choose **TFTP** or **FTP**.

**Step 7** In the IP Address text box, enter the IP address of the TFTP or FTP server.

**Step 8** If you are downloading the signature file using a TFTP server, enter the maximum number of times that the controller should attempt to download the signature file in the Maximum retries text box.

The range is 1 to 254 and the default value is 10.

**Step 9** If you are downloading the signature file using a TFTP server, enter the amount of time in seconds before the controller times out while attempting to download the signature file in the Timeout text box.

The range is 1 to 254 seconds and the default is 6 seconds.

**Step 10** In the File Path text box, enter the path of the signature file to be downloaded or uploaded. The default value is “/.”

**Step 11** In the File Name text box, enter the name of the signature file to be downloaded or uploaded.

**Note**

When uploading signatures, the controller uses the filename that you specify as a base name and then adds “\_std.sig” and “\_custom.sig” to it in order to upload *both* standard and custom signature files to the TFTP server. For example, if you upload a signature file called “ids1,” the controller automatically generates and uploads both ids1\_std.sig and ids1\_custom.sig to the TFTP server. If desired, you can then modify ids1\_custom.sig on the TFTP server (making sure to set “Revision = custom”) and download it by itself.

**Step 12** If you are using an FTP server, follow these steps:

- a. In the Server Login Username text box, enter the username to log into the FTP server.
- b. In the Server Login Password text box, enter the password to log into the FTP server.
- c. In the Server Port Number text box, enter the port number on the FTP server through which the download occurs. The default value is 21.

**Step 13** Choose **Download** to download the signature file to the controller or **Upload** to upload the signature file from the controller.

## Enabling or Disabling IDS Signatures

- Step 1** Choose **Security > Wireless Protection Policies > Standard Signatures** or **Custom Signatures** to open the Standard Signatures page or the Custom Signatures page.

**Figure 7-29** *Standard Signatures Page*

Precedence	Name	Frame Type	Action	State	Description
1	Boast deauth	Managemen	Report	Enabled	Broadcast Deauthentication Frame
2	NULL probe resp 1	Managemen	Report	Enabled	NULL Probe Response - Zero length SSID element
3	NULL probe resp 2	Managemen	Report	Enabled	NULL Probe Response - No SSID element
4	Assoc flood	Managemen	Report	Enabled	Association Request flood
5	Reassoc flood	Managemen	Report	Enabled	Reassociation Request flood
6	Broadcast Probe floo	Managemen	Report	Enabled	Broadcast Probe Request flood
7	Disassoc flood	Managemen	Report	Enabled	Disassociation flood
8	Deauth flood	Managemen	Report	Enabled	Deauthentication flood
9	Res mgmt 6 & 7	Managemen	Report	Enabled	Reserved management sub-types 6 and 7
10	Res mgmt D	Managemen	Report	Enabled	Reserved management sub-type D
11	Res mgmt E & F	Managemen	Report	Enabled	Reserved management sub-types E and F
12	EAPOL flood	Data	Report	Enabled	EAPOL Flood Attack
13	NetStumbler 3.2.0	Data	Report	Enabled	NetStumbler 3.2.0
14	NetStumbler 3.2.3	Data	Report	Enabled	NetStumbler 3.2.3
15	NetStumbler 3.3.0	Data	Report	Enabled	NetStumbler 3.3.0
16	NetStumbler generic	Data	Report	Enabled	NetStumbler
17	Wellenreiter	Managemen	Report	Enabled	Wellenreiter

The Standard Signatures page shows the list of Cisco-supplied signatures that are currently on the controller. The Custom Signatures page shows the list of customer-supplied signatures that are currently on the controller. This page shows the following information for each signature:

- The order, or precedence, in which the controller performs the signature checks.
- The name of the signature, which specifies the type of attack that the signature is trying to detect.
- The frame type on which the signature is looking for a security attack. The possible frame types are data and management.
- The action that the controller is directed to take when the signature detects an attack. The possible actions are None and Report.
- The state of the signature, which indicates whether the signature is enabled to detect security attacks.
- A description of the type of attack that the signature is trying to detect.

- Step 2** Perform one of the following:

- If you want to allow all signatures (both standard and custom) whose individual states are set to Enabled to remain enabled, select the **Enable Check for All Standard and Custom Signatures** check box at the top of either the Standard Signatures page or the Custom Signatures page. The

default value is enabled (or selected). When the signatures are enabled, the access points joined to the controller perform signature analysis on the received 802.11 data or management frames and report any discrepancies to the controller.

- If you want to disable all signatures (both standard and custom) on the controller, unselect the **Enable Check for All Standard and Custom Signatures** check box. If you unselected this check box, all signatures are disabled, even the ones whose individual states are set to Enabled.

**Step 3** Click **Apply** to commit your changes.

**Step 4** Click the precedence number of the desired signature to enable or disable an individual signature. The Standard Signature (or Custom Signature) > Detail page appears.

This page shows much of the same information as the Standard Signatures and Custom Signatures pages but provides these additional details:

- The tracking method used by the access points to perform signature analysis and report the results to the controller. The possible values are as follows:
  - Per Signature—Signature analysis and pattern matching are tracked and reported on a per-signature and per-channel basis.
  - Per MAC—Signature analysis and pattern matching are tracked and reported separately for individual client MAC addresses on a per-channel basis.
  - Per Signature and MAC—Signature analysis and pattern matching are tracked and reported on a per-signature and per-channel basis as well as on a per-MAC-address and per-channel basis.
- The pattern that is being used to detect a security attack

**Step 5** In the Measurement Interval text box, enter the number of seconds that must elapse before the signature frequency threshold is reached within the configured interval. The range is 1 to 3600 seconds, and the default value varies per signature.

**Step 6** In the Signature Frequency text box, enter the number of matching packets per interval that must be identified at the individual access point level before an attack is detected. The range is 1 to 32,000 packets per interval, and the default value varies per signature.

**Step 7** In the Signature MAC Frequency text box, enter the number of matching packets per interval that must be identified per client per access point before an attack is detected. The range is 1 to 32,000 packets per interval, and the default value varies per signature.

**Step 8** In the Quiet Time text box, enter the length of time (in seconds) after which no attacks have been detected at the individual access point level and the alarm can stop. The range is 60 to 32,000 seconds, and the default value varies per signature.

**Step 9** Select the **State** check box to enable this signature to detect security attacks or unselect it to disable this signature. The default value is enabled (or selected).

**Step 10** Click **Apply** to commit your changes. The Standard Signatures or Custom Signatures page reflects the signature's updated state.

**Step 11** Click **Save Configuration** to save your changes.

---

## Viewing IDS Signature Events (GUI)

**Step 1** Choose **Security > Wireless Protection Policies > Signature Events Summary** to open the Signature Events Summary page.

**Figure 7-30 Signature Events Summary Page**

Signature Type	Precedence	Signature Name	# Events
<a href="#">Standard</a>	8	Deauth flood	1
<a href="#">Standard</a>	7	Disassoc flood	2
<a href="#">Standard</a>	10	Res mgmt D	1
<a href="#">Standard</a>	11	Res mgmt E & F	1
<a href="#">Standard</a>	2	NULL probe resp 1	1
<a href="#">Standard</a>	5	Reassoc flood	2
<a href="#">Standard</a>	6	Broadcast Probe floo	2

This page shows the number of attacks detected by the enabled signatures.

**Step 2** Click the signature type link for that signature to see more information on the attacks detected by a particular signature. The Signature Events Detail page appears.

This page shows the following information:

- The MAC addresses of the clients identified as attackers
- The method used by the access point to track the attacks
- The number of matching packets per second that were identified before an attack was detected.
- The number of access points on the channel on which the attack was detected
- The day and time when the access point detected the attack

**Step 3** Click the **Detail** link for that attack to see more information for a particular attack. The Signature Events Track Detail page appears.

**Figure 7-31 Signature Events Track Detail Page**

Signature Type	Precedence	Signature Name	Source MAC Address	Track Method	Frequency	# APs
Standard	8	Deauth flood	00:40:96:ac:ab:82	Per Mac	30	1
AP MAC Address	AP Name	Radio Type	Channel	Last reported by this AP		
00:0b:85:7f:20:f0	vinay-AireSpace-1010	802.11a	36			

This page shows the following information:

- The MAC address of the access point that detected the attack
- The name of the access point that detected the attack
- The type of radio (802.11a or 802.11b/g) used by the access point to detect the attack
- The radio channel on which the attack was detected
- The day and time when the access point reported the attack

## Configure IDS Signatures (CLI)

- 
- Step 1** If desired, create your own custom signature file.
- Step 2** Make sure that you have a TFTP server available. See the guidelines for setting up a TFTP server in [Step 2](#) of the “[Uploading or Downloading IDS Signatures](#)” section on [page 7-113](#).
- Step 3** Copy the custom signature file (\*.sig) to the default directory on your TFTP server.
- Step 4** Specify the download or upload mode by entering the **transfer {download | upload} mode tftp** command.
- Step 5** Specify the type of file to be downloaded or uploaded by entering the **transfer {download | upload} datatype signature** command.
- Step 6** Specify the IP address of the TFTP server by entering the **transfer {download | upload} serverip tftp-server-ip-address** command.

**Note**

Some TFTP servers require only a forward slash (/) as the TFTP server IP address, and the TFTP server automatically determines the path to the correct directory.

- Step 7** Specify the download or upload path by entering the **transfer {download | upload} path absolute-tftp-server-path-to-file** command.
- Step 8** Specify the file to be downloaded or uploaded by entering the **transfer {download | upload} filename filename.sig** command.

**Note**

When uploading signatures, the controller uses the filename you specify as a base name and then adds “\_std.sig” and “\_custom.sig” to it in order to upload *both* standard and custom signature files to the TFTP server. For example, if you upload a signature file called “ids1,” the controller automatically generates and uploads both `ids1_std.sig` and `ids1_custom.sig` to the TFTP server. If desired, you can then modify `ids1_custom.sig` on the TFTP server (making sure to set “Revision = custom”) and download it by itself.

- Step 9** Enter the **transfer {download | upload} start** command and answer **y** to the prompt to confirm the current settings and start the download or upload.
- Step 10** Specify the number of seconds that must elapse before the signature frequency threshold is reached within the configured interval by entering this command:
- config wps signature interval *signature\_id interval***
- where *signature\_id* is a number used to uniquely identify a signature. The range is 1 to 3600 seconds, and the default value varies per signature.
- Step 11** Specify the number of matching packets per interval that must be identified at the individual access point level before an attack is detected by entering this command:
- config wps signature frequency *signature\_id frequency***
- The range is 1 to 32,000 packets per interval, and the default value varies per signature.
- Step 12** Specify the number of matching packets per interval that must be identified per client per access point before an attack is detected by entering this command:
- config wps signature mac-frequency *signature\_id mac\_frequency***
- The range is 1 to 32,000 packets per interval, and the default value varies per signature.

- Step 13** Specify the length of time (in seconds) after which no attacks have been detected at the individual access point level and the alarm can stop by entering by entering this command:

**config wps signature quiet-time** *signature\_id* *quiet\_time*

The range is 60 to 32,000 seconds, and the default value varies per signature.

- Step 14** Perform one of the following:

- To enable or disable an individual IDS signature, enter this command:

**config wps signature {standard | custom} state** *signature\_id* {**enable** | **disable**}

- To enable or disable IDS signature processing, which enables or disables the processing of all IDS signatures, enter this command:

**config wps signature {enable | disable}**

**Note** If IDS signature processing is disabled, all signatures are disabled, regardless of the state configured for individual signatures.

- Step 15** Save your changes by entering this command:

**save config**

- Step 16** If desired, you can reset a specific signature or all signatures to default values. To do so, enter this command:

**config wps signature reset** {*signature\_id* | **all**}

**Note** You can reset signatures to default values only through the controller CLI.

## Viewing IDS Signature Events (CLI)

- See whether IDS signature processing is enabled or disabled on the controller by entering this command:

**show wps summary**

Information similar to the following appears:

```
Auto-Immune
  Auto-Immune..... Disabled

Client Exclusion Policy
  Excessive 802.11-association failures..... Enabled
  Excessive 802.11-authentication failures..... Enabled
  Excessive 802.1x-authentication..... Enabled
  IP-theft..... Enabled
  Excessive Web authentication failure..... Enabled

Signature Policy
  Signature Processing..... Enabled
```

**Note** If IDS signature processing is disabled, all signatures are disabled, regardless of the state configured for individual signatures.

- See individual summaries of all of the standard and custom signatures installed on the controller by entering this command:

#### **show wps signature summary**

Information similar to the following appears:

```
Signature-ID..... 1
Precedence..... 1
Signature Name..... Bcast deauth
Type..... standard
FrameType..... management
State..... enabled
Action..... report
Tracking..... per Signature and Mac
Signature Frequency..... 50 pkts/interval
Signature Mac Frequency..... 30 pkts/interval
Interval..... 1 sec
Quiet Time..... 300 sec
Description..... Broadcast Deauthentication Frame
Patterns:
    0 (Header):0x00c0:0x00ff
    4 (Header):0x01:0x01
```

- See the number of attacks detected by the enabled signatures by entering this command:

#### **show wps signature events summary**

Information similar to the following appears:

Precedence	Signature Name	Type	# Events
1	Bcast deauth	Standard	2
2	NULL probe resp 1	Standard	1

- See more information on the attacks detected by a particular standard or custom signature by entering this command:

#### **show wps signature events {standard | custom} precedence# summary**

Information similar to the following appears:

```
Precedence..... 1
Signature Name..... Bcast deauth
Type..... Standard
Number of active events..... 2
```

Source MAC Addr	Track Method	Frequency	No. APs	Last Heard
00:01:02:03:04:01	Per Signature	4	3	Tue Dec 6 00:17:44 2005
00:01:02:03:04:01	Per Mac	6	2	Tue Dec 6 00:30:04 2005

- See information on attacks that are tracked by access points on a per-signature and per-channel basis by entering this command:

#### **show wps signature events {standard | custom} precedence# detailed per-signature source\_mac**

- See information on attacks that are tracked by access points on an individual-client basis (by MAC address) by entering this command:

#### **show wps signature events {standard | custom} precedence# detailed per-mac source\_mac**

Information similar to the following appears:

```
Source MAC..... 00:01:02:03:04:01
Precedence..... 1
Signature Name..... Bcast deauth
Type..... Standard
Track..... Per Mac
Frequency..... 6
Reported By

```

## Configuring wIPS

This section contains the following topics:

- [Information About wIPS, page 7-121](#)
- [Guidelines and Limitations, page 7-126](#)
- [Additional References, page 7-126](#)
- [Configuring wIPS on an Access Point \(GUI\), page 7-126](#)
- [Configuring wIPS on an Access Point \(CLI\), page 7-127](#)
- [Viewing wIPS Information \(CLI\), page 7-128](#)

## Information About wIPS

The Cisco Adaptive wireless intrusion prevention system (wIPS) is an advanced approach to wireless threat detection and performance management. It combines network traffic analysis, network device and topology information, signature-based techniques, and anomaly detection to deliver highly accurate and complete wireless threat prevention. With a fully infrastructure-integrated solution, you can continually monitor wireless traffic on both the wired and wireless networks and use that network intelligence to analyze attacks from many sources to more accurately pinpoint and proactively prevent attacks rather than waiting until damage or exposure has occurred.

The Cisco Adaptive wIPS is enabled by the Cisco 3300 Series Mobility Services Engine (MSE), which centralizes the processing of intelligence collected by the continuous monitoring of Cisco Aironet access points. With Cisco Adaptive wIPS functionalities and WCS integration into the MSE, the wIPS service can configure, monitor, and report wIPS policies and alarms.

### Note

If your wIPS deployment consists of a controller, access point, and MSE, you must set all the three entities to the UTC time zone.

The Cisco Adaptive wIPS is not configured on the controller. Instead, WCS forwards the profile configuration to the wIPS service, which forwards the profile to the controller. The profile is stored in flash memory on the controller and sent to access points when they join the controller. When an access point disassociates and joins another controller, it receives the wIPS profile from the new controller.

Local mode or FlexConnect mode access points with a subset of wIPS capabilities is referred to as Enhanced Local Mode access point or just ELM AP. You can configure an access point to work in wIPS mode if the access point is in any of the following modes:

- Monitor
- Local
- FlexConnect

wIPS ELM has limited capability of detecting off-channel alarms. The access point periodically goes off-channel, and monitors the non-serving channels for a short duration, and triggers alarms if any attack is detected on the channel. But the off-channel alarm detection is best effort and it takes longer time to detect attacks and trigger alarms, which might cause the ELM AP intermittently detect an alarm and clear it because it is not visible. Access points in any of the above modes can periodically send alarms based on the policy profile to the wIPS service through the controller. The wIPS service stores and processes the alarms and generates SNMP traps. WCS configures its IP address as a trap destination to receive SNMP traps from the MSE.

Table 7-11 lists all the SNMP trap controls and their respective traps. When a trap control is enabled, all the traps of the trap control are also enabled.

**Table 7-11**      *SNMP Trap Controls and their respective Traps*

Tab Name	Trap Control	Trap
General	Link (Port) Up/Down	linkUp, linkDown
	Spanning Tree	newRoot, topologyChange, stpInstanceNewRootTrap, stpInstanceTopologyChangeTrap
	Config Save	bsnDot11EssCreated, bsnDot11EssDeleted, bsnConfigSaved, ciscoLwappScheduledResetNotif, ciscoLwappClearResetNotif, ciscoLwappResetFailedNotif, ciscoLwappSysInvalidXmlConfig
AP	AP Register	bsnAPDisassociated, bsnAPAssociated
	Ap Interface Up/Down	bsnAPIfUp, bsnAPIfDown
Client Traps	802.11 Association	bsnDot11StationAssociate
	802.11 Disassociation	bsnDot11StationDisassociate
	802.11 Deauthentication	bsnDot11StationDeauthenticate
	802.11 Failed Authentication	bsnDot11StationAuthenticateFail
	802.11 Failed Association	bsnDot11StationAssociateFail
	Exclusion	bsnDot11StationBlacklisted

**Table 7-11** *SNMP Trap Controls and their respective Traps (continued)*

Tab Name	Trap Control	Trap
Security Traps	User Authentication	bsnTooManyUnsuccessLoginAttempts, cLWAGuestUserLoggedIn, cLWAGuestUserLoggedOut
	RADIUS Servers Not Responding	bsnRADIUSServerNotResponding, ciscoLwappAAARadiusReqTimedOut
	WEP Decrypt Error	bsnWepKeyDecryptError
	Rogue AP	bsnAdhocRogueAutoContained, bsnRogueApAutoContained, bsnTrustedApHasInvalidEncryption, bsnMaxRogueCountExceeded, bsnMaxRogueCountClear, bsnApMaxRogueCountExceeded, bsnApMaxRogueCountClear, bsnTrustedApHasInvalidRadioPolicy, bsnTrustedApHasInvalidSsid, bsnTrustedApIsMissing
	SNMP Authentication	agentSnmpAuthenticationTrapFlag
	Multiple Users	multipleUsersTrap
Auto RF Profile Traps	Load Profile	bsnAPLoadProfileFailed
	Noise Profile	bsnAPNoiseProfileFailed
	Interference Profile	bsnAPInterferenceProfileFailed
	Coverage Profile	bsnAPCoverageProfileFailed
Auto RF Update Traps	Channel Update	bsnAPCurrentChannelChanged
	Tx Power Update	bsnAPCurrentTxPowerChanged
Mesh Traps	Child Excluded Parent	ciscoLwappMeshChildExcludedParent
	Parent Change	ciscoLwappMeshParentChange
	Authfailure Mesh	ciscoLwappMeshAuthorizationFailure
	Child Moved	ciscoLwappMeshChildMoved
	Excessive Parent Change	ciscoLwappMeshExcessiveParentChange
	Excessive Children	ciscoLwappMeshExcessiveChildren
	Poor SNR	ciscoLwappMeshAbateSNR, ciscoLwappMeshOnsetSNR
	Console Login	ciscoLwappMeshConsoleLogin
	Excessive Association	ciscoLwappMeshExcessiveAssociation
	Default Bridge Group Name	ciscoLwappMeshDefaultBridgeGroupName

The following are the trap description for the traps mentioned in the [Table 7-11](#) above:

- General Traps

- SNMP Authentication—The SNMPv2 entity has received a protocol message that is not properly authenticated.

---

**Note** When a user who is configured in SNMP V3 mode tries to access the controller with an incorrect password, the authentication fails and a failure message is displayed. However, no trap logs are generated for the authentication failure.

---

- Link (Port) Up/Down—Link changes status from up or down.
- Multiple Users—Two users login with the same login ID.
- Spanning Tree—Spanning Tree traps. See the STP specifications for descriptions of individual parameters.
- Rogue AP—Whenever a rogue access point is detected this trap will be sent with its MAC Address; When a rogue access point that was detected earlier and it no longer exists this trap is sent.
- Config Save—Notification sent when the controller configuration is modified.
- Cisco AP Traps
  - AP Register—Notification sent when an access point associates or disassociates with the controller.
  - AP Interface Up/Down—Notification sent when access point interface (802.11a or 802.11b/g) status goes up or down.
- Client Related Traps
  - 802.11 Association—The associate notification is sent when the client sends an association frame.
  - 802.11 Disassociation—The disassociate notification is sent when the client sends a disassociation frame.
  - 802.11 Deauthentication—The deauthenticate notification is sent when the client sends a deauthentication frame.
  - 802.11 Failed Authentication—The authenticate failure notification is sent when the client sends an authentication frame with a status code other than 'successful'.
  - 802.11 Failed Association—The associate failure notification is sent when the client sends an association frame with a status code other than 'successful'.
  - Exclusion—The associate failure notification is sent when a client is excluded.
- Security Traps
  - User Auth Failure—This trap is to inform that a client RADIUS Authentication failure has occurred.
  - RADIUS Server No Response—This trap is to indicate that no RADIUS server(s) are responding to authentication requests sent by the RADIUS client.
  - WEP Decrypt Error—Notification sent when the controller detects a WEP decrypting error.
  - Rouge AP—Whenever a rogue access point is detected this trap will be sent with its MAC Address; When a rogue access point that was detected earlier and it no longer exists this trap is sent.

- SNMP Authentication—The SNMPv2 entity has received a protocol message that is not properly authenticated.

**Note**

When a user who is configured in SNMP V3 mode tries to access the controller with an incorrect password, the authentication fails and a failure message is displayed. However, no trap logs are generated for the authentication failure.

- Multiple Users—Two users login with the same login ID.
- Auto RF Profile Traps
  - Load Profile—Notification sent when Load Profile state changes between PASS and FAIL.
  - Noise Profile—Notification sent when Noise Profile state changes between PASS and FAIL.
  - Interference Profile—Notification sent when Interference Profile state changes between PASS and FAIL.
  - Coverage Profile—Notification sent when Coverage Profile state changes between PASS and FAIL.
- Auto RF Update Traps
  - Channel Update—Notification sent when access point dynamic channel algorithm is updated.
  - Tx Power Update—Notification sent when access point dynamic transmit power algorithm is updated.
- Mesh Traps
  - Child Excluded Parent—Notification sent when a defined number of failed association to the controller occurs through a parent mesh node.
  - Notification sent when child mesh node exceeds threshold limit of number of discovery response timeouts. The child mesh node will not try to associate excluded parent mesh node for the interval defined. The child mesh node will remember the excluded parent MAC address and when it joins the network it will inform the controller.
  - Parent Change—Notification is sent by the agent when a child mesh node changes its parent. The Child mesh node remembers its previous parent and it will inform the controller about the change of its parent when it joins back the network.
  - Child Moved—Notification sent when a parent mesh node loses connection with its child mesh node.
  - Excessive Parent Change—Notification sent when child mesh node changes its parent frequently. Each mesh node keeps count of number of parent changes in fixed time. If it exceeds the defined threshold then child mesh node informs the controller.
  - Excessive Children—Notification sent when the child count exceeds for a RAP and MAP.
  - Poor SNR—Notification sent when child mesh node detects lower SNR on backhaul link. For the other trap, a notification is sent to clear a notification when child mesh node detects SNR on backhaul link is higher then the object defined by 'cIMeshSNRThresholdAbate'.
  - Console Login—Notification is sent by the agent when login on MAP console is successful or failure after three attempts.
  - Default Bridge Group Name—Notification sent when MAP mesh node joins parent using 'default' bridge group name.

**Note**

The remaining traps do not have trap controls. These are traps, which are not generated too frequently and thus do not require any trap control. Thus, any other trap generated by the Controller cannot be turned off.

**Note**

In all of the above cases, the controller functions solely as a forwarding device.

**Note**

To download the MIBs, click on <http://www.cisco.com/cisco/software/release.html?mdfid=282600534&flowid=7012&softwareid=280775088&release=7.3&relind=AVAILABLE&rellifecycle=&reltype=latest>.

## Guidelines and Limitations

- Starting in release 7.0.116.0, the regular local mode or FlexConnect mode access point has been extended with a subset of Wireless Intrusion Prevention System (wIPS) capabilities. This feature enables you to deploy your access points to provide protection without needing a separate overlay network.
- wIPS ELM is not supported on 1130 and 1240 access points.

## Additional References

For more information on the Cisco Adaptive wIPS, see the *Cisco Wireless Control System Configuration Guide, Release 7.0.172.0* and the *Cisco 3300 Series Mobility Services Engine Configuration Guide, Release 7.0.201.0*.

## Configuring wIPS on an Access Point (GUI)

- 
- Step 1** Choose **Wireless > Access Points > All APs > *access point name***.
- Step 2** Set the **AP Mode** parameter. To configure an access point for wIPS, you must choose one of the following modes from the AP Mode drop-down list:
- Local
  - FlexConnect
  - Monitor
- Step 3** Set the AP Sub Mode to wIPS by choosing **wIPS** from the AP Sub Mode drop-down list.
- Step 4** Click **Apply**.
-

## Configuring wIPS on an Access Point (CLI)

**Step 1** Configure an access point for monitor mode by entering this command:

**config ap mode {monitor | local | flexconnect} *Cisco\_AP***

**Note** To configure an access point for wIPS, the access point must be in **monitor**, **local**, or **flexconnect** modes.

**Step 2** Enter **Y** when you see the message that the access point will be rebooted if you want to continue.

**Step 3** Save your changes by entering this command:

**save config**

**Step 4** Disable the access point radio by entering this command:

**config {802.11a | 802.11b} disable *Cisco\_AP***

**Step 5** Configure the wIPS submode on the access point by entering this command:

**config ap mode *ap\_mode* submode wips *Cisco\_AP***

**Note** To disable wIPS on the access point, enter the **config ap mode *ap\_mode* submode none *Cisco\_AP*** command.

**Step 6** Enable wIPS optimized channel scanning for the access point by entering this command:

**config ap monitor-mode wips-optimized *Cisco\_AP***

The access point scans each channel for 250 milliseconds. It derives the list of channels to be scanned from the monitor configuration. You can choose one of these options:

- **All**—All channels supported by the access point's radio
- **Country**—Only the channels supported by the access point's country of operation
- **DCA**—Only the channel set used by the dynamic channel assignment (DCA) algorithm, which by default includes all of the nonoverlapping channels allowed in the access point's country of operation

The 802.11a or 802.11b Monitor Channels text box in the output of the **show advanced {802.11a | 802.11b} monitor** command shows the monitor configuration channel set:

```
Default 802.11b AP monitoring
 802.11b Monitor Mode..... enable
 802.11b Monitor Channels..... Country channels
 802.11b AP Coverage Interval..... 180 seconds
 802.11b AP Load Interval..... 60 seconds
 802.11b AP Noise Interval..... 180 seconds
 802.11b AP Signal Strength Interval..... 60 seconds
```

**Step 7** Reenable the access point radio by entering this command:

**config {802.11a | 802.11b} enable *Cisco\_AP***

**Step 8** Save your changes by entering this command:

**save config**

## Viewing wIPS Information (CLI)

### Note

You can also view the access point submode from the controller GUI. To do so, choose **Wireless > Access Points > All APs > the access point name > the Advanced** tab. The AP Sub Mode text box shows *wIPS* if the access point is in monitor mode and the wIPS submode is configured on the access point or *None* if the access point is not in monitor mode or the access point is in monitor mode but the wIPS submode is not configured.

- See the wIPS submode on the access point by entering this command:

**show ap config general Cisco\_AP**

Information similar to the following appears:

```
Cisco AP Identifier..... 3
Cisco AP Name..... AP1131:46f2.98ac
...
AP Mode ..... Monitor
Public Safety ..... Disabled Disabled
AP SubMode ..... WIPS
...
```

- See the wIPS optimized channel scanning configuration on the access point by entering this command:

**show ap monitor-mode summary**

Information similar to the following appears:

AP Name	Ethernet MAC	Status	Scanning Channel List
AP1131:46f2.98ac	00:16:46:f2:98:ac	wIPS	1, 6, NA, NA

- See the wIPS configuration forwarded by WCS to the controller by entering this command:

**show wps wips summary**

Information similar to the following appears:

```
Policy Name..... Default
Policy Version..... 3
```

- See the current state of wIPS operation on the controller by entering this command:

**show wps wips statistics**

Information similar to the following appears:

```
Policy Assignment Requests..... 1
Policy Assignment Responses..... 1
Policy Update Requests..... 0
Policy Update Responses..... 0
Policy Delete Requests..... 0
Policy Delete Responses..... 0
Alarm Updates..... 13572
Device Updates..... 8376
Device Update Requests..... 0
Device Update Responses..... 0
Forensic Updates..... 1001
Invalid WIPS Payloads..... 0
Invalid Messages Received..... 0
NMSP Transmitted Packets..... 22950
```

```
NMSP Transmit Packets Dropped..... 0
NMSP Largest Packet..... 1377
```

- Clear the wIPS statistics on the controller by entering this command:  
**clear stats wps wips**

## Configuring Wi-Fi Direct Client Policy

This section contains the following topics:

- [Information About Wi-Fi Direct Client Policy](#), page 7-129
- [Guidelines and Limitations](#), page 7-129
- [Configuring Wi-Fi Direct Client Policy \(GUI\)](#), page 7-129
- [Configuring Wi-Fi Direct Client Policy \(CLI\)](#), page 7-130
- [Monitoring and Troubleshooting Wi-Fi Direct Client Policy \(CLI\)](#), page 7-130

## Information About Wi-Fi Direct Client Policy

Devices that are Wi-Fi Direct capable can connect directly to each other quickly and conveniently to do tasks such as printing, synchronization, and sharing of data. Wi-Fi Direct devices can associate with multiple peer-to-peer (P2P) devices and with infrastructure wireless LANs (WLANs) concurrently. You can use the controller to configure the Wi-Fi Direct Client Policy, on a per WLAN basis, where you can allow or disallow association of Wi-Fi devices with infrastructure WLANs or disable Wi-Fi Direct Client Policy altogether for WLANs.

## Guidelines and Limitations

Wi-Fi Direct Client Policy is applicable to WLANs that have APs in local mode only.

## Configuring Wi-Fi Direct Client Policy (GUI)

- 
- |               |   |
|---------------|---|
| <b>Step 1</b> | Choose <b>WLANs</b> to open the WLANs page.   |
| <b>Step 2</b> | Click the WLAN ID of the WLAN for which you want to configure the Wi-Fi Direct Client Policy. The WLANs > Edit page appears.  |
| <b>Step 3</b> | Click the <b>Advanced</b> tab.  |
| <b>Step 4</b> | From the Wi-Fi Direct Clients Policy drop-down list, choose one of the following options: <ul style="list-style-type: none"><li>• <b>Disabled</b>—Disables the Wi-Fi Direct Client Policy for the WLAN and deauthenticates all Wi-Fi Direct clients.</li><li>• <b>Allow</b>—Allows Wi-Fi Direct clients to associate with the WLAN.</li><li>• <b>Not-Allow</b>—Disallows the Wi-Fi Direct clients from associating with the WLAN.</li></ul> |
| <b>Step 5</b> | Click <b>Apply</b> to commit your configuration.  |
-

## Configuring Wi-Fi Direct Client Policy (CLI)

**Step 1** To configure the Wi-Fi Direct Client Policy on WLANs, enter this command:

```
config wlan wifidirect { allow | disable | not-allow } wlan-id
```

The syntax of the command is as follows:

- **allow**—Allows Wi-Fi Direct clients to associate with the WLAN.
- **disable**—Disables the Wi-Fi Direct Client Policy for the WLAN and deauthenticates all Wi-Fi Direct clients.
- **not-allow**—Disallows the Wi-Fi Direct clients from associating with the WLAN.
- *wlan-id*—WLAN identifier.

**Step 2** Save your configuration by entering this command:

```
save config
```

## Monitoring and Troubleshooting Wi-Fi Direct Client Policy (CLI)

To monitor and troubleshoot the Wi-Fi Direct Client Policy, enter these commands:

- **show wlan wifidirect** *wlan-id*—Displays the status of Wi-Fi Direct Client Policy on the WLAN.
- **show client wifiDirect-stats**—Displays the total number of clients associated and number of clients rejected if Wi-Fi Direct Client Policy is enabled.

## Configuring Web Auth Proxy

This section contains the following topics:

- [Information About Web Auth Proxy, page 7-130](#)
- [Configuring Web Auth Proxy \(GUI\), page 7-131](#)
- [Configuring Web Auth Proxy \(CLI\), page 7-132](#)

## Information About Web Auth Proxy

This feature enables clients that have a manual web proxy enabled in the browser to facilitate authentication with the controller. If the user's browser is configured with manual proxy settings with a configured port number as 8080 or 3128 and if the client requests any URL, the controller responds with a web page prompting the user to change the Internet proxy settings to automatically detect the proxy settings so that the browser's manual proxy settings information does not get lost. After enabling this settings, the user can get access to the network through the web authentication policy. This functionality is given for port 8080 and 3128 because these are the most commonly used ports for the web proxy server.

**Note**

Webauth proxy redirect ports are not blocked via CPU ACL. If a CPU ACL is configured to block the port 8080, 3128, and one random port as part of webauth proxy configuration, then those ports are not blocked because the webauth rules take higher precedence than the CPU ACL rules, until the client is in webauth\_req state.

A web browser has three types of Internet settings that can be configured by the user:

- Auto detect
- System Proxy
- Manual

In a manual proxy server configuration, the browser uses a proxy server's IP address and a port. If this configuration is enabled on the browser, the wireless client communicates with the destination proxy server's IP on the configured port. In a Web-Auth scenario, the controller does not listen to such proxy ports and the client would not be able to establish a TCP connection with the controller. In effect, the user is unable to get any login page to authentication and get access to the network.

When a wireless client enters a web authenticated WLAN network, it tries to access a URL. If a manual proxy configuration is configured on the client's browser, all web traffic going out from the client will be destined to the proxy IP and port configured on the browser.

- A TCP connection is established between the client and the proxy server IP address that the controller proxies for.
- The client processes the DHCP response and obtains a JavaScript file from the controller. The script disables all proxy configurations on the client for that session.

**Note**

For external clients, the controller sends the login page as is (with or without JavaScript).

- Any requests that bypass the proxy configuration. The controller can then perform web-redirection, login, and authentication.
- When the client goes out of the network, and then back into its own network, a DHCP refresh occurs and the client continues to use the old proxy configuration configured on the browser.
- If the external DHCP server is used with webauth proxy, then DHCP option 252 must be configured on the DHCP server for that scope. The value of option 252 will have the format `http://<virtual ip>/proxy.js`. No extra configuration is needed for internal DHCP servers.

**Note**

When you configure FIPS mode with secure web authentication, we recommend that you use Mozilla Firefox as your browser.

## Configuring Web Auth Proxy (GUI)

- Step 1** Choose **Controller > General** to open the Controller > General page.
- Step 2** From the WebAuth Proxy Redirection Mode, select **Enabled**.
- Step 3** In the WebAuth Proxy Redirection Port text box, enter the port number of the web auth proxy.

This text box consists of the port numbers on which the controller listens to for web authentication proxy redirection. By default, the three ports 80, 8080, and 3128 are assumed. If you configured the web authentication redirection port to any port other than these values, you must specify that value.

**Step 4** Click **Apply**.

## Configuring Web Auth Proxy (CLI)

- Enable web auth proxy redirection by entering the **config network web-auth proxy-redirect {enable | disable}** command.
- Configure the secure web (https) authentication for clients by entering the **config network web-auth secureweb {enable | disable}** command.

The default secure web (https) authentication for clients is enabled.

### Note

If you configure to disallow secure web (https) authentication for clients using the **config network web-auth secureweb disable** command, then you must reboot the Cisco WLC to implement the change.

- Set the web auth port number by entering the **config network web-auth port *port-number*** command.

This parameter specifies the port numbers on which the controller listens to for web authentication proxy redirection. By default, the three ports 80, 8080, and 3128 are assumed. If you configured the web authentication redirection port to any port other than these values, you must specify that value.

- To see the current status of the web auth proxy configuration, enter the **show network summary** or the **show running-config** command.

## Detecting Active Exploits

The controller supports three active exploit alarms that serve as notifications of potential threats. They are enabled by default and therefore require no configuration on the controller.

- ASLEAP detection—The controller raises a trap event if an attacker launches a LEAP crack tool. The trap message is visible in the controller's trap log.
- Fake access point detection—The controller tweaks the fake access point detection logic to avoid false access point alarms in high-density access point environments.
- Honeypot access point detection—The controller raises a trap event if a rogue access point is using managed SSIDs (WLANs configured on the controller). The trap message is visible in the controller's trap log.
