[How to specify a different output filename and path for ODBC debugging](#)

Introduction

This document describes the use of the CIS odbc driver in debug trace mode.

How to specify a different output filename and path for ODBC debugging

In some cases you may not want the odbc debug output to be written to the root of the C:\ drive.

This can be directed from the DSN properties in the C:\ProgramData\composite62_x64.xml file.

You must not only specify the newpath, but also include the actual file that gets produced.

Normally it defaults to a filename in the C:\ path, but if we redirect the file, we must also explicitly provide the new filename too.

Here is an example, where the output to a path of D:\temp is redirected, and wrote out a new file named **odbc_62_system_mynewfile.log**
