

Configuring SMDS

The Switched Multimegabit Data Service (SMDS) is a wide-area networking service offered by some Regional Bell Operating Companies (RBOCs) and by MCI. This chapter describes the configuration tasks for the SMDS packet-switched software.

For a complete description of the commands mentioned in this chapter, refer to the “SMDS Commands” chapter in the *Wide-Area Networking Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

SMDS Hardware Requirements

You need the following hardware, equipment, and special software to configure SMDS:

- CSC-MCI or CSC-SCI serial interface controller card, or a HSSI interface on chassis-based systems, or the serial port on an IGS router

To operate on CSC-SCI or CSC-MCI cards, SMDS requires that the appropriate microcode version be installed. Version numbers are 1.2 (or later) for CSC-SCI and 1.7 (or later) for CSC-MCI.

- EIA/TIA-449 or V.35 applique on chassis-based systems, or EIA/TIA-449 transition cable on an IGS router
- SMDS data service unit (SDSU) device
- Packet-switched software option with the system software

Figure 17 illustrates the connections between the different components.

Figure 17 Typical SMDS Configuration

SMDS Addresses

All addresses for SMDS service are assigned by the service provider and can be assigned to individuals and groups.

You must enter addresses in the Cisco SMDS configuration software using an E prefix for multicast addresses and a C prefix for unicast addresses.

Cisco IOS software expects the addresses to be entered in E.164 format, which is 64 bits (15-digit addressing). The first 4 bits are the address type, and the remaining 60 bits are the address. If the first 4 bits are 1100 (0xC), the address is a unicast SMDS address, which is the address of an individual SMDS host. If the first 4 bits are 1110 (0xE), the address is a multicast SMDS address, which is used to broadcast a packet to multiple end points. The 60 bits of the address are in binary-coded decimal (BCD) format. Each 4 bits of the address field presents a single telephone number digit, allowing for up to 15 digits. At a minimum, you must specify at least 11 digits (44 bits). Unused bits at the end of this field are filled with ones.

Note The `arp smds` command supports 48-bit addresses only (C or E followed by 11 digits). The addresses must be entered in dotted notation—for example, C141.5556.1414.

An example of a 15-digit E.164 address follows:

```
C14155561313FFFF
```

Note Previous versions of Cisco IOS software supported 48-bit SMDS addresses. If, when using the current version of the software, you write the configuration to NVRAM, the full 64-bit SMDS address is written. Previous versions of the software will no longer be able to read the new SMDS configuration from NVRAM. However, the current version of the software can read previous versions of the configuration in NVRAM.

The addresses can be entered with periods in a manner similar to Ethernet-style notation, or simply as a string of digits.

The following is an example of an individual address entered in Ethernet-style notation:

```
C141.5555.1212.FFFF
```

The following is an example of a group address:

```
E180.0999.9999.FFFF
```

For additional technical references about SMDS, see the “References and Recommended Readings” appendix in the *Configuration Fundamentals Command Reference*.

SMDS Configuration Task List

Before you can begin the configuration tasks, you must have already obtained your SMDS addresses from your service provider. You need the following two types of addresses:

- The group address for broadcasts
- The SMDS hardware (individual) address for each router that interfaces directly into the SMDS network (that is, customer premises equipment)

You must perform basic steps to enable SMDS. In addition, you can customize SMDS for your particular network needs and monitor SMDS connections. Perform the tasks in the following sections:

- Enable SMDS on the Interface
- Customize Your SMDS Network
- Monitor the SMDS Connection

See the “SMDS Configuration Examples” section at the end of this chapter for ideas of how to configure SMDS on your network.

Enable SMDS on the Interface

You must perform the tasks in the following sections to enable SMDS:

- Set SMDS Encapsulation
- Specify the SMDS Address
- Establish Address Mapping
- Map a Multicast Address to an SMDS Address
- Enable ARP
- Enable Broadcast ARP Messages
- Enable Dynamic Address Mapping for IPX over SMDS

Set SMDS Encapsulation

To set SMDS encapsulation at the interface level, use the following command in interface configuration mode:

Command	Purpose
<code>encapsulation smds</code>	Enable SMDS on the interface.

For examples of enabling SMDS encapsulation, see the examples in the section “SMDS Configuration Examples” later in this chapter.

Specify the SMDS Address

To specify the SMDS individual address for a particular interface, use the following command in interface configuration mode:

Command	Purpose
smds address <i>smds-address</i>	Enter an individual address provided by the SMDS service provider.

For examples of specifying the SMDS address, see the examples in the section “SMDS Configuration Examples” later in this chapter.

Establish Address Mapping

Routing tables are configured dynamically when DECnet, extended AppleTalk, IP, IPX, and ISO CLNS routing are configured. However, you can configure static mapping for these protocols, if needed. For other protocols, you must configure a static map between an individual SMDS address and a higher-level protocol address.

To establish address mapping, use the following command in interface configuration mode:

Command	Purpose
smds static-map <i>protocol protocol-address smds-address</i> [broadcast]	Define static entries for those routers that are SMDS remote peers.

The supported protocols and the keywords to enable them are as follows:

- AppleTalk—**appletalk**
- Banyan VINES—**vines**
- DECnet—**decnet**
- IP—**ip**
- ISO CLNS—**clns**
- Novell IPX—**ipx**
- XNS—**xns**

For examples of establishing address mapping, see the examples in the section “SMDS Configuration Examples” later in this chapter.

Map a Multicast Address to an SMDS Address

You can map an SMDS group address to a broadcast or multicast address used by a higher-level protocol. If you do so, you need not specify the **broadcast** keyword in the **smds static-map** command, and the Cisco IOS software need not replicate each broadcast address.

To map an SMDS group address to a multicast address, use the following command in interface configuration mode:

Command	Purpose
smds multicast <i>protocol smds-address</i>	Map an SMDS group address to a multicast address used by a higher-level protocol.

The protocols supported and the keywords to enable them are as follows. Note that bridging is not a protocol, but the **bridge** keyword is valid for providing a map to a multicast address.

- AppleTalk—**appletalk**
- AppleTalk ARP address—**aarp**
- Banyan VINES—**vines**
- Bridging—**bridge**
- DECnet—**decnet**
- DECnet multicast address for all Level 1 routers—**decnet_router-L1**
- DECnet multicast address for all Level 2 routers—**decnet_router-L2**
- DECnet multicast address for all end systems—**decnet_node**
- IP—**ip**
- ISO CLNS—**clns**
- Multicast address for all CLNS intermediate systems—**clns_is**
- Multicast address for all CLNS end systems—**clns_es**
- Novell IPX—**ipx**
- XNS—**xns**

For examples of mapping to a multicast address, see the examples in the section “SMDS Configuration Examples” later in this chapter.

Enable ARP

When you enable the Address Resolution Protocol (ARP), you can choose to enable either a dynamic ARP cache or one built statically. To enable ARP, use one of the following commands in the specified configuration mode:

Command	Purpose
smds enable-arp	Enable ARP and dynamic address resolution (interface).
arp ip-address smds-address smds	Enable ARP with a static entry for the remote router (global).

An SMDS network can be thought of in much the same way as an X.25 cloud. The premises equipment (in this case Cisco routers) represents the edge of the cloud. The service provider enables communication across the cloud. However, proper configuration is needed for communication to occur. This configuration will differ between protocol families.

One major difference between protocol families is dynamic versus static routing among the routers (called remote peers) on the periphery of the cloud. For IP, routing across the SMDS cloud is fully dynamic. No action on the user’s part is needed to map higher-level protocol addresses to SMDS addresses. Both IP and ARP can be configured and a dynamic ARP routing table enabled.

Note The **arp smds** command requires 12-digit dotted-notation SMDS addresses—for example, C141.5678.9012.

See the section “Configure Specific Protocols” later in this chapter for more information about configuring higher-level protocols.

Enable Broadcast ARP Messages

When an ARP server is present in the network, you can enable broadcast ARP messages that are sent to all ARP SMDS addresses or to all IP SMDS multicast addresses when ARP addresses are not present.

To enable broadcast ARP messages, use the following commands in interface configuration mode:

Steps	Command	Purpose
1	smds enable-arp	Enable ARP and dynamic address resolution.
2	smds multicast arp <i>smds-address</i> [<i>ip-address mask</i>]	Enable broadcast ARP messages.

For an example of how to enable broadcast ARP messages, see the section “Typical Multiprotocol Configuration Example” later in this chapter.

Enable Dynamic Address Mapping for IPX over SMDS

To enable dynamic address mapping for IPX on an SMDS interface, use the following command in interface configuration mode:

Command	Purpose
smds glean ipx [<i>timeout-value</i>] [broadcast]	Enable dynamic address mapping for IPX.

For an example of how to enable dynamic address mapping for IPX over SMDS, see the section “IPX Dynamic Address Mapping Example” later in this chapter.

Customize Your SMDS Network

Perform the tasks in the following sections, as appropriate, for your network:

- Configure Specific Protocols
- Enable Transparent Bridging over SMDS
- Configure SMDS Subinterfaces for Multiple Logical IP Subnetworks
- Reenable the Data Exchange Interface Version 3.2 with Heartbeat Support
- Configure Pseudobroadcasting
- Enable Fast Switching

Configure Specific Protocols

Some protocol families are dynamically routed. For IP and CLNS, routing is fully dynamic, and no action on your part is needed to map higher-level protocol addresses to SMDS addresses. But for the other supported protocols, you must make a static entry for each router to communicate with all other peer routers. The static entries need to be made only for those routers that are SMDS remote peers. Nothing additional needs to be done to assure communication with other nodes behind the peer routers.

For an example of how to configure specific protocols, see the section “Typical Multiprotocol Configuration Example” later in this chapter.

Table 4 lists protocol families and the multicasts that are needed.

Table 4 Protocol Families and Types of Multicasts Needed

Protocol Family	Multicasts Needed
IP	IP
DECnet	DECNET, DECNET_NODE, DECNET_ROUTER-L1, DECNET_ROUTER-L2
CLNS	CLNS, CLNS_ES, CLNS_IS
Novell IPX	IPX
XNS	XNS
AppleTalk	APPLETALK, AARP
Banyan VINES	VINES

Configure ARP and IP

For both IP and ARP, the multicast address must be configured and ARP must be enabled. ARP multicast is required only for ARP servers; the IP multicast is used for ARP and routing updates.

Configure DECnet

Static maps must be configured for DECnet. In addition, a separate **smds multicast** command is needed for DECNET, DECNET_NODE, DECNET_ROUTER-L1, and DECNET_ROUTER-L2.

Configure CLNS

Multicasts must be configured for CLNS_ES and CLNS_IS. No static maps are necessary. End system hello (ESH), intermediate system hello (ISH), and router hello packets are sent to the multicast address, and neighbor entries are created automatically.

Configure IPX

For Novell IPX, the multicast address must be configured. A static map entry can be made for each remote peer, or you can use the **smds glean** command to dynamically map addresses. Static map entries override any dynamic map entries.

Routing Information Protocol (RIP) routing packets, Service Advertisement Protocol (SAP) packets, NetBIOS Name Lookups, directed broadcasts, and traffic to the helper addresses (if that helper address is a broadcast address) are sent to the SMDS IPX multicast address.

Configure XNS

For XNS, the multicast address must be configured, and a static map entry must be made for each remote peer. Only RIP, directed broadcasts, and helper traffic are sent to the XNS multicast address.

Configure AppleTalk

The SMDS cloud must be treated by all AppleTalk routers connected to it as either extended or nonextended. The network types cannot be mixed on the same SMDS cloud. Instead, all AppleTalk routers on an SMDS cloud must agree about the network type: extended or nonextended.

If any router in the SMDS cloud uses Cisco IOS Release 10.3(3) (or earlier), use a nonextended AppleTalk configuration for the SMDS cloud. To use nonextended AppleTalk, use the **appletalk address** command and configure static maps.

If all routers in the SMDS cloud use Cisco IOS Release 10.3(4) (or later), you can use extended AppleTalk to support dynamic AARP for SMDS addresses. To use extended AppleTalk, use the **appletalk cable-range** command.

For information on the **appletalk address** and **appletalk cable-range** commands, refer to the *Network Protocols Command Reference, Part 2*.

For an example of how to configure AppleTalk, see the section “AppleTalk Configuration Examples” later in this chapter.

Configure Banyan VINES

For Banyan VINES, the multicast address must be configured. Also note that VINES works only with static maps.

Enable Transparent Bridging over SMDS

You can enable transparent bridging for SMDS encapsulated serial and HSSI interfaces. Cisco’s implementation of IEEE 802.6i transparent bridging for SMDS supports 802.3, 802.5, and FDDI frame formats. The router can accept frames with or without frame check sequence (FCS).

Fast-switched transparent bridging is the default and is not configurable. If a packet cannot be fast switched, it will be process switched.

To enable transparent bridging, use the following commands beginning in global configuration mode:

Step	Command	Purpose
1	interface <i>type number</i>	Specify a serial or HSSI interface.
2	encapsulation smds	Configure SMDS encapsulation on the serial interface.
3	bridge-group <i>bridge-group</i>	Associate the interface with a bridge group.
4	smds multicast bridge <i>smds-address</i>	Configure bridging across SMDS.

For more information about bridge groups and the **bridge-group** command, see the “Configuring Transparent Bridging” chapter in the *Bridging and IBM Networking Configuration Guide*.

Configure SMDS Subinterfaces for Multiple Logical IP Subnetworks

Multiple logical IP subnetworks are supported as defined by RFC 1209. This RFC explains routing IP over an SMDS cloud where each connection is considered a host on one specific private network, and describes cases where traffic must transit from network to network.

This solution allows a single SMDS interface to be treated as multiple logical IP subnetworks and to support routing of packets from one network to the next without using intervening routers. When multiple logical IP subnetworks are enabled, the router performs routing between the subnetworks using IP addresses on an SMDS interface. Each supported subnetwork has an IP address, a unicast SMDS E.164 address, and a multicast SMDS E.164 address configured on the SMDS interface. Broadcast packets are duplicated and transmitted to all IP networks on the specified SMDS interface and use the associated multicast SMDS address for the network.

Only routers that require knowledge of multiple IP networks need to be configured with multipoint subinterfaces that correspond to different networks.

To configure the Cisco IOS software to have multipoint subinterfaces for multiple logical IP subnetworks, use the following commands in interface configuration mode:

Step	Command	Purpose
1	interface serial <i>interface.subinterface</i> multipoint interface serial <i>slot/port.subinterface</i> multipoint (for Cisco 7000 series routers ¹)	Define a logical subinterface for each IP network.
2	ip address <i>ip-address mask</i>	Configure the subinterface as an IP network.
3	smds address <i>smds-address</i>	Assign a unicast SMDS E.164 address to the subinterface.
4	smds multicast <i>protocol smds-address</i>	Assign a multicast SMDS E.164 address for each protocol supported on the subinterface.
5	smds enable-arp	Enable ARP on the subinterface, if required by the protocol.

¹ Beginning in Cisco IOS Release 11.3, all commands supported on the Cisco 7500 series are also supported on the Cisco 7000 series.

For an example of how to configure multiple logical IP subnetworks, see the “Multiple Logical IP Subnetworks over SMDS Example” section later in this chapter.

Reenable the Data Exchange Interface Version 3.2 with Heartbeat Support

By default, SMDS provides the Data Exchange Interface (DXI) Version 3.2 *heartbeat* process as specified in the SIG-TS-001/1991 standard. The DXI mechanism encapsulates SMDS packets in a DXI frame before they are transmitted. The heartbeat mechanism automatically generates a heartbeat poll frame every 10 seconds. The Interim Local Management Interface (ILMI) is not supported. See the *Wide-Area Networking Command Reference* for more information about DXI 3.2.

Note If you are running serial lines back-to-back, disable keepalive on SMDS interfaces. Otherwise, DXI declares the link down.

If you find you must reenable the DXI heartbeat, use the following command in interface configuration mode:

Command	Purpose
smds dxi	Enable DXI 3.2.

Configure Pseudobroadcasting

Some hosts do not support multicast E.164 addresses. This is a problem in IP where frequent broadcast packets are sent because routing updates are generally broadcast. IP and ARP depend on the use of multicast addresses to determine a route to a destination IP address. A mechanism was needed to artificially support the use of broadcast where multicast E.164 addresses do not exist; the result is *pseudobroadcasting*. If a multicast address is not available to a destination, pseudobroadcasting can be enabled to broadcast packets to those destinations using a unicast address.

To configure pseudobroadcasting, use the following command in interface configuration mode:

Command	Purpose
<code>smds static-map protocol protocol-address smds-address broadcast</code>	Configure pseudobroadcasting.

For an example of how to configure pseudobroadcasting, see the “Pseudobroadcasting Example” section later in this chapter.

Enable Fast Switching

SMDS fast switching of IP, IPX, and AppleTalk packets provides faster packet transfer on serial links with speeds above 56 kbps. Use fast switching if you use high-speed, packet-switched, datagram-based WAN technologies such as Frame Relay offered by service providers.

By default, SMDS fast switching is enabled.

To re-enable fast switching, use the following commands beginning in interface configuration mode:

Step	Command	Purpose
1	<code>interface type number</code>	Define the type and unit number of the interface, and enter interface configuration mode.
2	<code>encapsulation smds</code>	Set SMDS encapsulation.
3	<code>ip route-cache</code>	Enable the interface for IP fast switching.
4	<code>ipx route-cache</code>	Enable the interface for IPX fast switching.
5	<code>appletalk route-cache</code>	Enable the interface for AppleTalk fast switching.

Monitor the SMDS Connection

To monitor the SMDS connection, use one or more of the following commands in EXEC mode:

Command	Purpose
<code>show arp</code>	Monitor ARP activity.
<code>show smds addresses</code>	Display the individual addresses and the interface with which they are associated.
<code>show smds map</code>	Display all SMDS addresses that are mapped to higher-level protocol addresses.
<code>show smds traffic</code>	Display packet traffic activity.

SMDS Configuration Examples

The following section provides typical configuration file examples you can use as models for your network configurations:

- Typical Multiprotocol Configuration Example
- Remote Peer on the Same Network Example
- IPX Dynamic Address Mapping Example
- AppleTalk Configuration Examples
- Multiple Logical IP Subnetworks over SMDS Example
- Pseudobroadcasting Example

Typical Multiprotocol Configuration Example

The following example is a typical interface configured for IP, DECnet, ISO CLNS, Novell IPX, XNS, and AppleTalk. DECnet needs to be configured globally and at the interface level.

```
interface serial 4
 ip address 1.1.1.2 255.0.0.0
 decnet cost 4
 appletalk address 92.1
 appletalk zone smds
 clns router igrp FOO
 ipx net 1a
 xns net 17
 encapsulation SMDS
 ! SMDS configuration follows
 smds address c120.1580.4721
 smds static-map APPLETALK 92.2 c120.1580.4592
 smds static-map APPLETALK 92.3 c120.1580.4593
 smds static-map APPLETALK 92.4 c120.1580.4594
 smds static-map NOVELL 1a.0c00.0102.23ca c120.1580.4792
 smds static-map XNS 17.0c00.0102.23ca c120.1580.4792
 smds static-map NOVELL 1a.0c00.0102.23dd c120.1580.4728
 smds static-map XNS 17.0c00.0102.23aa c120.1580.4727
 smds multicast NOVELL e180.0999.9999
 smds multicast XNS e180.0999.9999
 smds multicast ARP e180.0999.9999
 smds multicast IP e180.0999.9999
 smds multicast APPLETALK e180.0999.9999
 smds multicast AARP e180.0999.9999
 smds multicast CLNS_IS e180.0999.9990
 smds multicast CLNS_ES e180.0999.9990
 smds multicast DECNET_ROUTER e180.0999.9992
 smds multicast DECNET_NODE e180.0999.9992
 smds multicast DECNET e180.0999.9992
 smds enable-arp
```

Remote Peer on the Same Network Example

The following example illustrates a remote peer on the same SMDS network. DECnet needs to be configured globally and at the interface level.

```
interface serial 0
 ip address 1.1.1.1 255.0.0.0
 decnet cost 4
 appletalk address 92.2
 appletalk zone smds
```

```
clns router igrp FOO
ipx net 1a
xns net 17
encapsulation SMDS
! SMDS configuration follows
smds address c120.1580.4792
smds static-map APPLETALK 92.1 c120.1580.4721
smds static-map APPLETALK 92.3 c120.1580.4593
smds static-map APPLETALK 92.4 c120.1580.4594
smds static-map NOVELL 1a.0c00.0102.23cb c120.1580.4721
smds static-map XNS 17.0c00.0102.23cb c120.1580.4721
smds static-map NOVELL 1a.0c00.0102.23dd c120.1580.4728
smds static-map XNS 17.0c00.0102.23aa c120.1580.4727
smds multicast NOVELL e180.0999.9999
smds multicast XNS e180.0999.9999
smds multicast IP e180.0999.9999
smds multicast APPLETALK e180.0999.9999
smds multicast AARP e180.0999.9999
smds multicast CLNS_IS e180.0999.9990
smds multicast CLNS_ES e180.0999.9990
smds multicast DECNET_ROUTER e180.0999.9992
smds multicast DECNET_NODE e180.0999.9992
smds multicast DECNET e180.0999.9992
smds enable-arp
```

IPX Dynamic Address Mapping Example

The following example enables dynamic address mapping for IPX on interface serial 0 and sets the time to live (TTL) to 14 minutes.

```
interface serial 0
encapsulation smds
smds address c141.5797.1313
smds multicast ipx e180.0999.9999
smds glean ipx 14
```

AppleTalk Configuration Examples

The following two sections provide basic examples of configuration for an extended AppleTalk network and for a nonextended AppleTalk network. For more information on AppleTalk commands, refer to the *Network Protocols Command Reference, Part 2*.

Extended AppleTalk Network Example

If all AppleTalk routers on the SMDS cloud are running Cisco IOS software Release 10.3(4) (or later), you can use an AppleTalk extended network. To do so, use the **appletalk cable-range** interface command.

When SMDS is configured for an extended AppleTalk network, SMDS static maps are not required and not used. Dynamic AARP is supported on the multicast channel.

```
interface Serial0
ip address 192.168.200.1 255.255.255.0
encapsulation smds
appletalk cable-range 10-10
appletalk zone SMDS
smds address c151.0988.1923
smds static-map ip 192.168.200.2 c151.0988.8770
smds multicast APPLETALK e151.0988.2232
smds multicast AARP e151.0988.2232
```

```
smds multicast IP e151.0988.2232
smds multicast ARP e151.0988.2232
smds enable-arp
```

Nonextended Appletalk Network Example

The following example configures SMDS for a nonextended AppleTalk network. When SMDS is configured for a nonextended AppleTalk network, SMDS static maps are required and the **appletalk address** command is used. Dynamic AppleTalk Address Resolution Protocol (AARP) is not supported on the multicast channel.

```
interface Serial0
ip address 192.168.200.1 255.255.255.0
encapsulation smds
appletalk address 10.1
appletalk zone SMDS
smds address c151.0988.1923
smds static-map ip 192.168.200.2 c151.0988.8770
smds static-map appletalk 10.2 c151.0988.8770
smds multicast APPLETALK e151.0988.2232
smds multicast IP e151.0988.2232
smds multicast ARP e151.0988.2232
smds enable-arp
```

Multiple Logical IP Subnetworks over SMDS Example

In the following example, Routers A, B, and C are connected to an SMDS cloud by means of two logical subnetworks labelled 1 and 2 as shown in Figure 18.

Router A recognizes two IP networks and can communicate with Routers B and C directly. Router B can communicate with Router A directly, and with Router C via Router A. Router C can communicate with Router A directly and with Router B via Router A.

Notice that a packet destined to Router B from Router C must make two hops on the cloud through the same interface on Router A. Notice also that this configuration is nonstandard. This issue was considered when the multiple logical IP subnetworks proposal was made, and was deemed not to be critical.

Figure 18 Multiple Logical IP Subnetworks Configuration

The following example shows all routers as Cisco 7000 routers, but they can be other platforms.

Note Beginning in Cisco IOS Release 11.3, all commands supported on the Cisco 7500 series are also supported on the Cisco 7000 series

Configuration for Router A

```
interface serial 2/0
 encapsulation smds
!
interface serial 2/0.1 multipoint
 smds addr c111.3333.3333
 ip address 2.2.2.1 255.0.0.0
 smds multicast ip e122.2222.2222
 smds enable-arp
 smds multicast ARP e122.2222.2222
```

Configuration for Router B

```
interface serial 4/0
 encapsulation smds
 smds address c111.2222.2222
 ip address 1.1.1.3 255.0.0.0
 smds multicast ip e180.0999.9999
 smds enable-arp
```

Configuration for Router C

```
interface serial 1/0
 encapsulation smds
 smds address c111.4444.4444
 ip address 2.2.2.2 255.0.0.0
 smds multicast ip e122.2222.2222
 smds enable-arp
```

Pseudobroadcasting Example

In the following example, an ARP broadcast from Router A is sent to multicast address E180.0999.9999.FFFF to Router B and to unicast address C120.1234.5678.FFFF to Router C. The reply from Router C uses the unicast address C120.1111.2222.FFFF for the return reply if it is the target of the ARP request. IGRP broadcast updates follow the same rules.

Configuration for Router A

```
interface s 0
 encapsulation smds
 smds address c120.1111.2222
 ip address 172.20.1.30 255.255.255.0
 smds multicast ip e180.0999.9999
 smds static-map ip 172.20.1.10 c120.1234.5678 broadcast
 smds enable-arp
```

Configuration for Router B

```
interface s 4
  smds address c120.9999.8888
  ip address 172.20.1.20
  smds multicast ip e180.0999.9999
  smds enable-arp
```

Configuration for Router C

```
interface serial 2
  smds address c120.1234.5678
  ip address 172.20.1.10
  smds static-map ip 172.20.1.30 c120.1111.2222 broadcast
  smds enable-arp
```
