- ASBR1 and ASBR2 have three links between them:
  - VRF 1
  - VRF 2
  - MP-BGP session

### Note

The VRFs configured on the ASBRs are called “Option AB VRFs.” The eBGP peers on the ASBRs are called “Option AB Peers.”

**Figure 1** *MPLS VPN Inter-AS Option AB Topology*

136003

## Route Distribution for VPN 1

A route distinguisher (RD) is an identifier attached to a route that identifies which VPN belongs to each route. Each routing instance must have a unique RD autonomous system associated with it. The RD is used to place a boundary around a VPN so that the same IP address prefixes can be used in different VPNs without having these IP address prefixes overlap.

### Note

An RD statement is required if the instance type is a VRF.

The following process describes the route distribution process for VPN 1 in [Figure 1](#). Prefix “N” is used in this process to indicate the IP address of a VPN.

1. CE1 advertises the prefix N to PE1.
2. PE1 advertises a VPN prefix RD 1:N to ASBR1 through MP internal BGP (iBGP).
3. ASBR1 imports the prefix into VPN 1 and creates a prefix RD 5:N.
4. ASBR1 advertises the imported prefix RD 5:N to ASBR2. ASBR1 sets itself as the next hop for prefix RD 5:N and allocates a local label that is signaled with this prefix.
5. ASBR1 advertises the route with the export RT configured on the VRF rather than the originally received RTs. By default, ASBR1 does not advertise the source prefix RD 1:N to ASBR2. This advertisement is suppressed because the prefix is being imported into an Option AB VRF.

### Note

In an Option 10B connection, the source prefix can be advertised to another ASBR on which ASBR1 has an Option 10B connection. An ASBR with an Option 10B connection maintains all VPNv4 routes in its BGP table.

6. ASBR2 receives the prefix RD 5:N and imports it into VPN 1 as RD 7:N.
7. ASBR2 advertises the route with the export RT configured on the VRF rather than the originally received RTs.
8. While importing the prefix, ASBR2 sets the next hop of RD 7:N to the ASBR1 interface IP address in VRF 1. The next hop table ID is also set to VRF 1. When installing the MPLS forwarding entry for RD 7:N, the outgoing label is not installed in forwarding by default. This enables the traffic between the ASBRs to be IP.
9. ASBR2 advertises the imported prefix RD 7:N to PE2. It sets itself as the next hop for this prefix and also allocates a local label that is signaled with the prefix. By default, ASBR2 does not advertise the source prefix RD 5:N to PE2. This advertisement is suppressed because the prefix is being imported into an Option AB VRF.
10. PE2 imports the RD 7:N into VRF 1 as RD 3:N.

## Packet Forwarding for VPN 1

The following packet forwarding process works the same as it does in an Option A scenario. The ASBR acts like the PE by terminating the VPN and then forwards its traffic as standard IP packets with no VPN label to the next PE, which in turn repeats the VPN process. Each PE router, therefore, treats the adjacent PE router as a CE router, and the standard Layer 3 MPLS VPN mechanisms are used for route redistribution with each autonomous system; that is, the PEs use external BGP (eBGP) to distribute unlabeled IPv4 addresses to each other.

**Note**

Prefix “N” is used in this process to indicate the IP address of a VPN.

1. CE3 sends a packet destined for N to PE2.
2. PE2 encapsulates the packet with the VPN label allocated by ASBR2 and the IGP label needed to tunnel the packet to ASBR2.
3. The packet arrives on ASBR2 with the VPN label. ASBR2 removes the VPN label and sends the packet as IP to ASBR1 on the VRF 1 interface.
4. The IP packet arrives at ASBR1 on the VRF 1 interface. ASBR1 then encapsulates the packet with the VPN label allocated by PE1 and the IGP label needed to tunnel the packet to PE1.
5. The packet arrives on PE1 with the VPN label. PE1 disposes the VPN label and forwards the IP packet to CE1.

## Route Distribution for VPN 2

The following information describes the route distribution process for VPN 2 in [Figure 1](#):

1. CE2 advertises prefix N to PE1, where N is the VPN IP address.
2. PE1 advertises a VPN prefix RD 2:N to ASBR1 through MP-iBGP.
3. ASBR1 imports the prefix into VPN 2 and creates a prefix RD 6:N.
4. ASBR1 advertises the imported prefix RD 6:N to ASBR2. It sets itself as the next hop for this prefix and also allocates a local label that is signaled with the prefix. By default, ASBR1 does not advertise the source prefix RD 2:N to ASBR2. This advertisement is suppressed as the prefix is being imported into an Option AB VRF.

**Note**

In the case of an Option 10B connection, the source prefix can be advertised to another ASBR on which ASBR1 has an Option 10B connection. An ASBR with an Option 10B connection maintains all VPNv4 routes in its BGP table.

5. ASBR2 receives the prefix RD 6:N and imports it into VPN 2 as RD 8:N.
6. While importing the prefix, ASBR2 sets the next hop of RD 8:N to ASBR1's interface address in VRF 2. The next hop table ID is also set to that of VRF 2. While installing the MPLS forwarding entry for RD 8:N, by default the outgoing label is not installed in forwarding. This enables traffic between the ASBRs to be IP.
7. ASBR2 advertises the imported prefix RD 8:N to PE2. It sets itself as the next hop for this prefix and also allocates a local label that is signaled with the prefix. By default, ASBR2 does not advertise the source prefix RD 6:N to PE2. This advertisement is suppressed because the prefix is being imported into an Option AB VRF.
8. PE2 imports the RD 8:N into VRF 2 as RD 4:N.

## MPLS VPN—Inter-AS Option AB Route Distribution and Packet Forwarding for CSC

The following sections describe MPLS VPN—Inter-AS Option AB operation for a CSC scenario for VPN 1. These sections are similar to those found in [“MPLS VPN—Inter-AS Option AB Route Distribution and Packet Forwarding in Non-CSC Networks”](#) section on page 4 for VPN 1, except for the method in which MPLS labels are handled between the two ASBRs.

- [Route Distribution for VPN 1, page 5](#)
- [Packet Forwarding for VPN 1, page 5](#)

**Note**

VPN 2 is not shown or discussed in this section.

[Figure 2](#) shows how VPN 1 provides VPN service to a small customer carrier that in turn provides a VPN service to its customer. This configuration implies that VPN 1 is used to provide a Label Switched Path (LSP) between the PE (PE 3 and PE 4) loopback interfaces of the small customer carrier.

**Figure 2** *MPLS VPN Inter-AS Option AB CSC Topology*

**Note**

The RD, RT, VRF, and Link provisioning in this section is the same as in the [“MPLS VPN—Inter-AS Option AB Route Distribution and Packet Forwarding in Non-CSC Networks”](#) section on page 4 example for VPN 1.

### Route Distribution for VPN 1

The following information describe the route distribution process for VPN 1 in [Figure 1](#). Prefix “N” is used in these steps to indicate the IP address of a VPN.

1. CE1 advertises PE 3 loopback N to PE1.
2. PE1 advertises a VPN prefix RD 1:N to ASBR1 through MP-iBGP.
3. ASBR1 imports the prefix into VPN 1 and creates a prefix RD 5:N.
4. ASBR1 advertises the imported prefix RD 5:N to ASBR2. It sets itself as the next hop for this prefix and also allocates a local label that is signaled with the prefix.
5. ASBR1 advertises the route with the export RT configured on the VRF rather than the originally received RTs. By default, ASBR1 does not advertise the source prefix RD 1:N to ASBR2. This advertisement is suppressed as the prefix is being imported into an Option AB VRF.

**Note**

In an Option 10B connection, the source prefix can be advertised to another ASBR on which ASBR1 has an Option 10B connection. An ASBR with an Option 10B connection maintains all VPNv4 routes in its BGP table.

6. ASBR2 receives the prefix RD 5:N and imports it into VPN 1 as RD 7:N.
7. ASBR2 advertises the route with the export RT configured on the VRF rather than the originally received RTs.
8. While importing the prefix, ASBR2 sets the next hop of RD 7:N to ASBR1 interface address in VRF 1. The next hop table ID is also set to that of VRF 1.

**Note**

In a CSC scenario, an outgoing MPLS label can be installed in forwarding by making a configuration change. See [“How to Configure Inter-AS Option AB” section on page 9](#).

9. While installing the MPLS forwarding entry for RD 7:N, the outgoing label is installed during the forwarding process, which enables the traffic between the ASBRs to be MPLS traffic.
10. ASBR2 advertises the imported prefix RD 7:N to PE2. It sets itself as the next hop for this prefix and also allocates a local label that is signaled with the prefix. By default, ASBR2 does not advertise the source prefix RD 5:N to PE2. This advertisement is suppressed as the prefix is being imported into an Option AB VRF.
11. PE2 imports the RD 7:N into VRF 1 as RD 3:N.

## Packet Forwarding for VPN 1

The packet forwarding process shown below works the same as it does in an Option A scenario. See [“MPLS VPN—Inter-AS Option AB Route Distribution and Packet Forwarding in Non-CSC Networks” section on page 4](#) for more information about Option A.

1. PE 4 sends an MPLS packet destined for N to CE2.
2. CE2 swaps the MPLS label and sends a packet destined for N to PE2.
3. PE2 encapsulates the packet with the VPN label allocated by ASBR2 and the IGP label needed to tunnel the packet to ASBR2.
4. The packet arrives on ASBR2 with the VPN label. ASBR2 swaps the received VPN label with the outgoing label received from ASBR1 and sends the MPLS packet on to the VRF 1 interface.
5. The MPLS packet arrives at ASBR1 on the VRF 1 interface. ASBR1 then swaps the received MPLS label with a label stack consisting of the VPN label allocated by PE1 and the IGP label needed to tunnel the packet to PE1.
6. The packet arrives on PE1 with the VPN label. PE1 disposes the VPN label and forwards the MPLS packet to CE1. CE1 in turn swaps the label and forwards the labeled packet to PE 3.

# How to Configure Inter-AS Option AB

The following sections describe how to configure the Inter-AS Option AB feature on an ASBR for either an MPLS VPN or an MPLS VPN that supports CSC:

- [Configuring an Inter-AS Option AB Connection, page 9](#)
- [Changing an Inter-AS Option A Deployment to an Option AB Deployment, page 15](#)

## Configuring an Inter-AS Option AB Connection

The following sections are required and describe how to configure an Inter-AS Option AB connection on an ASBR:

- [Configuring the VRFs on the ASBR Interface for Each VPN Customer, page 9](#)
- [Configuring the MP-BGP Session Between ASBR Peers, page 11](#)
- [Configuring the Routing Policy for VPNs that Need Inter-AS Connections, page 13](#)

**Note**

See the [Configuring MPLS Layer 3 VPNs](#) feature module for more information on configuring PE and CE routers in an MPLS VPN.

## Configuring the VRFs on the ASBR Interface for Each VPN Customer

Use the following steps to configure the VRFs on the ASBR interface for each VPN customer so that these VPNs have connectivity over the MPLS VPN—Inter-AS Option AB network.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **ip vrf forwarding** *vrf-name*
5. **mpls bgp forwarding** (Optional)
6. **end**

**Note**

The **mpls bgp forwarding** command is used only on the ASBR interface for VRFs that support CSC.

Use all of the steps in the following procedure to configure additional VRFs that need to be configured on the ASBR interface and the VRFs that need to be configured on the peer ASBR interface.

## DETAILED STEPS

|        | Command or Action                                                                                            | Purpose                                                                                                                                                                                                                                                                                                 |
|--------|--------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                       | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                        |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                               | Enters global configuration mode.                                                                                                                                                                                                                                                                       |
| Step 3 | <b>interface</b> <i>type number</i><br><br><b>Example:</b><br>Router(config)# interface Ethernet 5/0         | Specifies the interface to configure and enters interface configuration mode. <ul style="list-style-type: none"> <li>The <i>type</i> argument specifies the type of interface to be configured.</li> <li>The <i>number</i> argument specifies the port, connector, or interface card number.</li> </ul> |
| Step 4 | <b>ip vrf forwarding</b> <i>vrf-name</i><br><br><b>Example:</b><br>Router(config-if)# ip vrf forwarding vpn1 | Associates a VRF with the specified interface or subinterface. <ul style="list-style-type: none"> <li>The <i>vrf-name</i> argument is the name assigned to a VRF.</li> </ul>                                                                                                                            |
| Step 5 | <b>mpls bgp forwarding</b><br><br><b>Example:</b><br>Router(config-if)# mpls bgp forwarding                  | (Optional) This step applies to a CSC network only. Configures BGP to enable MPLS forwarding on connecting interfaces for VRFs that must support MPLS traffic.                                                                                                                                          |
| Step 6 | <b>end</b><br><br><b>Example:</b><br>Router(config-if)# end                                                  | (Optional) Exits to privileged EXEC mode.                                                                                                                                                                                                                                                               |

## Configuring the MP-BGP Session Between ASBR Peers

BGP propagates reachability information for VPN-IPv4 prefixes among PE routers by means of the BGP multiprotocol extensions (see RFC 2283, *Multiprotocol Extensions for BGP-4*), which define support for address families other than IPv4. Using the extensions ensures that the routes for a given VPN are learned only by other members of that VPN, enabling members of the VPN to communicate with each other.

Follow the steps in this section to configure the MP-BGP session on the ASBR.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **router bgp** *as-number*
4. **neighbor** {*ip-address* | *peer-group-name*} **remote-as** *as-number*
5. **address-family vpnv4** [**unicast**]
6. **neighbor** {*ip-address* | *peer-group-name*} **activate**
7. **neighbor** {*ip-address* | *peer-group-name*} **inter-as-hybrid**
8. **exit-address-family**
9. **end**

Use all of the steps in the following procedure to configure the MP BGP session on the peer ASBR.

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                     | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                            |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                             | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                           |
| Step 3 | <b>router bgp</b> <i>as-number</i><br><br><b>Example:</b><br>Router(config)# router bgp 100                                                                                                | Configures a BGP routing process and places the router in router configuration mode.<br><br>The <i>as-number</i> argument indicates the number of an autonomous system that identifies the router to other BGP routers and tags the routing information passed along. Valid numbers are from 0 to 65535. Private autonomous system numbers that can be used in internal networks range from 64512 to 65535. |
| Step 4 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>remote-as</b> <i>as-number</i><br><br><b>Example:</b><br>Router(config-router)# neighbor 192.168.0.1<br>remote-as 200 | Adds an entry to the BGP or multiprotocol BGP neighbor table. <ul style="list-style-type: none"> <li>The <i>ip-address</i> argument specifies the IP address of the neighbor.</li> <li>The <i>peer-group-name</i> argument specifies the name of a BGP peer group.</li> <li>The <i>as-number</i> argument specifies the autonomous system to which the neighbor belongs.</li> </ul>                         |
| Step 5 | <b>address-family</b> <b>vpn4</b> [ <b>unicast</b> ]<br><br><b>Example:</b><br>Router(config-router)# address-family vpn4                                                                  | Enters address family configuration mode for configuring routing sessions, such as BGP, that use standard VPNv4 address prefixes. <ul style="list-style-type: none"> <li>The <b>unicast</b> keyword specifies IPv4 unicast address prefixes.</li> </ul>                                                                                                                                                     |
| Step 6 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>activate</b><br><br><b>Example:</b><br>Router(config-router-af)# neighbor 192.168.0.1<br>activate                     | Enables the exchange of information with a neighboring router. <ul style="list-style-type: none"> <li>The <i>ip-address</i> argument specifies the IP address of the neighbor.</li> <li>The <i>peer-group-name</i> argument specifies the name of a BGP peer group.</li> </ul>                                                                                                                              |

|        | Command or Action                                                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 7 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>inter-as-hybrid</b><br><br><b>Example:</b><br>Router(config-router-af)# neighbor 192.168.0.1<br>inter-as-hybrid | Configures eBGP peer router (ASBR) as an Inter-AS Option AB peer. <ul style="list-style-type: none"> <li>The <i>ip-address</i> argument specifies the IP address of the neighbor.</li> <li>The <i>peer-group-name</i> argument specifies the name of a BGP peer group.</li> <li>If any prefixes are imported into Option AB VRFs, then the imported paths are advertised to this peer.</li> <li>If any prefixes are received from this peer and are imported into Option AB VRFs, then the imported paths are advertised to iBGP peers.</li> </ul> <b>Note</b> Advertised routes have RTs that are configured on the VRF. Advertised routes do not have their original RTs. |
| Step 8 | <b>exit-address-family</b><br><br><b>Example:</b><br>Router(config-router-af)# exit-address-family                                                                                   | Exits from the address family configuration submode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Step 9 | <b>end</b><br><br><b>Example:</b><br>Router(config-router-af)# end                                                                                                                   | (Optional) Exits to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Configuring the Routing Policy for VPNs that Need Inter-AS Connections

Use the steps in this section to configure VRFs for the VPNs that need Inter-AS connections between ASBR peers, by configuring the appropriate routing policy and Option AB configuration.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **vrf definition** *vrf-name*
4. **rd** *route-distinguisher*
5. **address-family** **ipv4**
6. **route-target** {**import** | **export** | **both**} *route-target-ext-community*
7. **inter-as-hybrid** [**csc**]
8. **inter-as-hybrid** [**csc**] **next-hop** *ip-address*
9. **exit**

Use all of the steps in the following procedure to configure additional VPNs that need Inter-AS Option AB connectivity on this ASBR and the peer ASBR.

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                              | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                      | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Step 3 | <b>vrf definition</b> <i>vrf-name</i><br><br><b>Example:</b><br>Router(config)# vrf definition vpn1                                                                                 | Defines the VPN routing instance by assigning a VRF name and enters VRF configuration mode. <ul style="list-style-type: none"> <li>The <i>vrf-name</i> argument is the name assigned to a VRF.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Step 4 | <b>rd</b> <i>route-distinguisher</i><br><br><b>Example:</b><br>Router(config-vrf)# rd 100:1                                                                                         | Creates routing and forwarding tables. <ul style="list-style-type: none"> <li>The <i>route-distinguisher</i> argument adds an 8-byte value to an IPv4 prefix to create a VPN IPv4 prefix. You can enter an RD in either of these formats: <ul style="list-style-type: none"> <li>16-bit autonomous system number: your 32-bit number, for example, 101:3</li> <li>32-bit IP address: your 16-bit number, for example, 192.168.122.15:1</li> </ul> </li> </ul>                                                                                                                                                                                                   |
| Step 5 | <b>address-family</b> <i>ipv4</i><br><br><b>Example:</b><br>Router(config-vrf)# address-family ipv4                                                                                 | Enters VRF address family configuration mode to specify an address family for a VRF. <ul style="list-style-type: none"> <li>The <b>ipv4</b> keyword specifies an IPv4 address family for a VRF.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Step 6 | <b>route-target</b> { <b>import</b>   <b>export</b>   <b>both</b> }<br><i>route-target-ext-community</i><br><br><b>Example:</b><br>Router(config-vrf-af)# route-target import 100:1 | Creates a route-target extended community for a VRF. <ul style="list-style-type: none"> <li>The <b>import</b> keyword imports routing information from the target VPN extended community.</li> <li>The <b>export</b> keyword exports routing information to the target VPN extended community.</li> <li>The <b>both</b> keyword imports routing information from and exports routing information to the target VPN extended community.</li> <li>The <i>route-target-ext-community</i> argument adds the route-target extended community attributes to the VRF list of import, export, or both (import and export) route-target extended communities.</li> </ul> |

|               | Command or Action                                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 7</b> | <b>inter-as-hybrid</b> [ <i>csc</i> ]<br><br><b>Example:</b><br>Router(config-vrf-af)# <b>inter-as-hybrid</b>                                                        | Specifies the VRF as an Option AB VRF, which has the following effects: <ul style="list-style-type: none"> <li>• Routes imported to this VRF can be advertised to Option AB peers and VPNv4 iBGP peers.</li> <li>• When routes received from Option AB peers and are imported into the VRF, the next hop table ID of the route is set to the table ID of the VRF.</li> <li>• If the <b>csc</b> keyword is not used, a per-VRF label is allocated for imported routes.</li> <li>• When routes are received from Option AB peers and are imported next into the VRF, the learned out label can only be installed in forwarding when the <b>csc</b> keyword is used.</li> </ul> The <b>csc</b> keyword implies the following: <ul style="list-style-type: none"> <li>• A per-prefix label is allocated for imported routes.</li> <li>• For routes received from Option AB peers that are imported into the VRF, the learned out label is installed in forwarding.</li> </ul> |
| <b>Step 8</b> | <b>inter-as-hybrid</b> [ <i>csc</i> ] <b>next-hop</b> <i>ip-address</i><br><br><b>Example:</b><br>Router(config-vrf-af)# <b>inter-as-hybrid next-hop</b> 192.168.1.0 | (Optional) Specifies the next hop IP address to be set on paths that are imported into the VRF and that are received from an Option AB peer. The next hop context is also set to the VRF, which imports these paths.<br><br>The <b>csc</b> keyword implies the following: <ul style="list-style-type: none"> <li>• A per-prefix label is allocated for imported routes.</li> <li>• For routes received from Option AB peers that are imported into the VRF, the learned outlabel is installed in forwarding.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Step 9</b> | <b>exit</b><br><br><b>Example:</b><br>Router(config-vrf-af)# <b>exit</b>                                                                                             | Exits to global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Changing an Inter-AS Option A Deployment to an Option AB Deployment

In an Option A deployment, the VRF instances are back-to-back between the ASBR routers and there is direct connectivity between PE routers of different autonomous systems. The PE routers are attached by multiple physical or logical interfaces, each of which is associated with a given VPN (through a VRF instance).

In the Option AB deployment, the different autonomous systems interconnect by using a single MP-BGP session in the global routing table to carry control plane traffic.

Use the following steps to change an MPLS VPN Inter-AS Option A deployment to an Option AB deployment.

1. Configure the MP-BGP session on the ASBR. BGP multiprotocol extensions are used to define support for address families other than IPv4 so that the routes for a given VPN are learned only by other members of that VPN, enabling members of the VPN to communicate with each other. See [“Configuring the MP-BGP Session Between ASBR Peers” section on page 11](#) for detailed configuration information.
2. Identify the VRFs that need an upgrade from Option A and configure them for Option AB by using the **inter-as-hybrid** command. See [“Configuring the Routing Policy for VPNs that Need Inter-AS Connections” section on page 13](#) for detailed configuration information.
3. Use the following steps in this section to remove the configuration for the eBGP (peer ASBR) neighbor.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **router bgp** *as-number*
4. **address-family ipv4 vrf** *vrf-name*
5. **no neighbor** {*ip-address* | *peer-group-name*}
6. **exit-address-family**
7. **end**

Repeat all the steps in the following procedure to remove the configuration for additional eBGP (peer ASBR) neighbors.

## DETAILED STEPS

|        | Command or Action                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------|---------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                      | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                                                                                                                                                                                                                                                                                                                       |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal              | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 3 | <b>router bgp</b> <i>as-number</i><br><br><b>Example:</b><br>Router(config)# router bgp 100 | Configures a BGP routing process and places the router in router configuration mode.<br><ul style="list-style-type: none"><li>• The <i>as-number</i> argument indicates the number of an autonomous system that identifies the router to other BGP routers and tags the routing information passed along. Valid numbers are from 0 to 65535. Private autonomous system numbers that can be used in internal networks range from 64512 to 65535.</li></ul> |

|        | Command or Action                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                            |
|--------|-------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 4 | <b>address-family ipv4 vrf vrf-name</b><br><br><b>Example:</b><br>Router(config-router)# address-family ipv4 vrf vpn4         | Configures each VRF that is identified in the MP-BGP session on the ASBR so that the routes for a given VPN are learned only by other members of that VPN, enabling members of the VPN to communicate with each other. Enters address family configuration mode to specify an address family for a VRF.            |
| Step 5 | <b>no neighbor {ip-address   peer-group-name}</b><br><br><b>Example:</b><br>Router(config-router-af)# no neighbor 192.168.0.1 | Removes the configuration for the exchange of information with the neighboring eBGP (ASBR) router. <ul style="list-style-type: none"> <li>The <i>ip-address</i> argument specifies the IP address of the neighbor.</li> <li>The <i>peer-group-name</i> argument specifies the name of a BGP peer group.</li> </ul> |
| Step 6 | <b>exit-address-family</b><br><br><b>Example:</b><br>Router(config-router-af)# exit-address-family                            | Exits from address family configuration mode.                                                                                                                                                                                                                                                                      |
| Step 7 | <b>end</b><br><br><b>Example:</b><br>Router(config-router-af)# end                                                            | (Optional) Exits to privileged EXEC mode.                                                                                                                                                                                                                                                                          |

# Configuration Examples for MPLS VPN—Inter-AS Option AB

The following sections describe standard and CSC MPLS VPN configurations between two ASBR peers that use the Inter-AS AB feature:

- [Inter-AS AB Network Configuration: Examples, page 18](#)
- [Inter-AS AB CSC Configuration: Examples, page 27](#)

## Inter-AS AB Network Configuration: Examples

The following examples show the configuration of an inter-AS option AB network that uses non overlapping IP addresses:

- [CE1: Example, page 18](#)
- [CE2: Example, page 19](#)
- [PE1: Example, page 19](#)
- [Route Reflector 1: Example, page 20](#)
- [ASBR1: Example, page 21](#)
- [ASBR 3: Example, page 23](#)
- [PE2: Example, page 24](#)
- [CE3: Example, page 26](#)
- [CE 4: Example, page 26](#)

### CE1: Example

```
!
ip cef distributed
!
interface lo0
 ip address 192.168.13.13 255.255.255.255
 no shutdown
!
interface et4/0
 ip address 192.168.36.1 255.255.255.0
 no shutdown
!
router ospf 300
 nsf enforce global
 redistribute connected subnets

# Feature Information for MPLS VPN—Inter-AS Option AB

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

**Note**

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1** Feature Information for MPLS VPN—Inter-AS Option AB

| Feature Name                | Release     | Feature Information                                                                                                                                                                                                                                                          |

# Glossary

**autonomous system**—A collection of networks under a common administration sharing a common routing strategy.

**BGP**—Border Gateway Protocol. An interdomain routing protocol that exchanges network reachability information with other BGP systems (which may be within the same autonomous system or between multiple autonomous systems).

**CE router**—customer edge router. A router that is part of a customer network and that interfaces to a provider edge (PE) router. CE routers do not recognize associated MPLS VPNs.

**CSC**—Carrier Supporting Carrier. A hierarchical VPN model that allows small Service Providers, or customer carriers, to interconnect their IP or MPLS networks over an MPLS backbone. This eliminates the need for customer carriers to build and maintain their own MPLS backbone.

**eBGP**—external Border Gateway Protocol. A BGP between routers located within different autonomous systems. When two routers, located in different autonomous systems, are more than one hop away from one another, the eBGP session between the two routers is considered a multihop BGP.

**iBGP**—internal Border Gateway Protocol. A BGP between routers within the same autonomous system.

**IGP**—Interior Gateway Protocol. Internet protocol used to exchange routing information within a single autonomous system. Examples of common Internet IGP protocols include IGRP, OSPF, IS-IS, and RIP.

**IP**—Internet Protocol. Network layer protocol in the TCP/IP stack offering a connectionless internetwork service. IP provides features for addressing, type-of-service specification, fragmentation and reassembly, and security. Defined in RFC 791.

**LFIB**—Label Forwarding Information Base. Data structure used in MPLS to hold information about incoming and outgoing labels and associated Forwarding Equivalence Class (FEC) packets.

**MP-BGP**—Multiprotocol BGP.

**MPLS**—Multiprotocol Label Switching. The name of the IETF working group responsible for label switching, and the name of the label switching approach it has standardized.

**NLRI**—Network Layer Reachability Information. The BGP sends routing update messages containing NLRI to describe a route and how to get there. In this context, an NLRI is a prefix. A BGP update message carries one or more NLRI prefixes and the attributes of a route for the NLRI prefixes; the route attributes include a BGP next hop gateway address and extended community values.

**NSF**—Nonstop forwarding enables routers to continuously forward IP packets following a Route Processor takeover or switchover to another Route Processor. NSF maintains and updates Layer 3 routing and forwarding information in the backup Route Processor to ensure that IP packets and routing protocol information are forwarded continuously during the switchover and route convergence process.

**PE router**—provider edge router. A router that is part of a service provider's network. It is connected to a customer edge (CE) router. All MPLS VPN processing occurs in the PE router.

**QoS**—quality of service. Measure of performance for a transmission system that indicates its transmission quality and service availability.

**RD**—route distinguisher. An 8-byte value that is concatenated with an IPv4 prefix to create a unique VPN-IPv4 prefix.

**RT**—route target. Extended community attribute used to identify the VRF routing table into which a prefix is imported.

**SLA**—Service Level Agreement given to VPN subscribers.

**VPN**—Virtual Private Network. A secure MPLS-based network that shares resources on one or more physical networks (typically implemented by one or more service providers). A VPN contains geographically dispersed sites that can communicate securely over a shared backbone network.

**VRF**—VPN routing and forwarding instance. Routing information that defines a VPN site that is attached to a PE router. A VRF consists of an IP routing table, a derived forwarding table, a set of interfaces that use the forwarding table, and a set of rules and routing protocols that determine what goes into the forwarding table.

## **MPLS Embedded Management and MIBs**

## MPLS EM—MPLS LSP Multipath Tree Trace

---

**First Published: December 4, 2006**

**Last Updated: February 27, 2009**

The MPLS EM—MPLS LSP Multipath Tree Trace feature provides the means to discover all possible equal-cost multipath (ECMP) routing paths of a label switched path (LSP) between an egress and ingress router. Once discovered, these paths can be retested on a periodic basis using Multiprotocol Label Switching (MPLS) LSP ping or traceroute. This feature is an extension to the MPLS LSP traceroute functionality for the tracing of IPv4 LSPs.

You can use the MPLS EM—MPLS LSP Multipath Tree Trace feature to discover all paths for an IPv4 LSP.

This implementation of the MPLS EM—MPLS LSP Multipath Tree Trace feature is based on RFC 4379, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*.

For information on the use of MPLS LSP ping and traceroute, see the [MPLS Embedded Management—LSP Ping/Traceroute and AToM VCCV](#) feature module.

Cisco IOS MPLS Embedded Management (EM) is a set of standards and value-added services that facilitate the deployment, operation, administration, and management of MPLS-based networks according to the fault, configuration, accounting, performance, and security (FCAPS) model.

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the [“Feature Information for MPLS EM—MPLS LSP Multipath Tree Trace”](#) section on [page 33](#).

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

# Contents

- [Prerequisites for MPLS EM—MPLS LSP Multipath Tree Trace, page 2](#)
- [Restrictions for MPLS EM—MPLS LSP Multipath Tree Trace, page 2](#)
- [Information About MPLS EM—MPLS LSP Multipath Tree Trace, page 3](#)
- [How to Configure MPLS EM—MPLS LSP Multipath Tree Trace, page 4](#)
- [Configuration Examples for MPLS EM—MPLS LSP Multipath Tree Trace, page 22](#)
- [Additional References, page 31](#)
- [Command Reference, page 32](#)
- [Feature Information for MPLS EM—MPLS LSP Multipath Tree Trace, page 33](#)
- [Glossary, page 35](#)

## Prerequisites for MPLS EM—MPLS LSP Multipath Tree Trace

The following are prerequisites for using the MPLS EM—MPLS LSP Multipath Tree Trace feature:

- You must understand the concepts and know how to use MPLS LSP ping or traceroute as described in the *MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV* document.
- The routers in your network must be using an implementation based on RFC 4379, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*.
- You should know the following about your MPLS network:
  - The topology
  - The number of links in your network
  - The expected number of LSPs, and how many LSPs
- Understand label switching, forwarding, and load balancing.

## Restrictions for MPLS EM—MPLS LSP Multipath Tree Trace

- All restrictions that apply to the MPLS LSP Ping and LSP Traceroute features also apply to the MPLS EM—MPLS LSP Multipath Tree Trace feature:
  - You cannot use the MPLS LSP Multipath Tree Trace feature to trace the path taken by AToM packets. The MPLS LSP Multipath Tree Trace feature is not supported for AToM. (MPLS LSP Ping is supported for AToM.) However, you can use the MPLS LSP Multipath Tree Trace feature to troubleshoot the Interior Gateway Protocol (IGP) LSP that is used by AToM.
  - You cannot use the MPLS LSP Multipath Tree Trace feature to validate or trace MPLS Virtual Private Networks (VPNs). Multiple LSP paths are not discovered unless all routers in the MPLS core support an RFC 4379 implementation of *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*.
- MPLS LSP multipath tree trace is not expected to operate in networks that support time-to-live (TTL) hiding.

# Information About MPLS EM—MPLS LSP Multipath Tree Trace

Before using the MPLS EM—MPLS LSP Multipath Tree Trace feature, you need an understanding of the following concepts:

- [Overview of MPLS LSP Multipath Tree Trace, page 3](#)
- [Discovery of IPv4 Load Balancing Paths by MPLS LSP Multipath Tree Trace, page 3](#)
- [Echo Reply Return Codes Sent by the Router Processing Multipath LSP Tree Trace, page 4](#)

## Overview of MPLS LSP Multipath Tree Trace

As the number of MPLS deployments increases, the number of traffic types the MPLS networks carry could increase. In addition, load balancing on label switch routers (LSRs) in the MPLS network provides alternate paths for carrying MPLS traffic to a target router. The ability of service providers to monitor LSPs and quickly isolate MPLS forwarding problems is critical to their ability to offer services.

Prior to the release of the MPLS EM—MPLS LSP Multipath Tree Trace feature no automated way existed to discover all paths between provider edge (PE) routers. Troubleshooting forwarding problems between PEs was cumbersome.

The release of the MPLS EM—MPLS LSP Multipath Tree Trace feature provides an automated way to discover all paths from the ingress PE router to the egress PE router in multivendor networks that use IPv4 load balancing at the transit routers. Once the PE-to-PE paths are discovered, use MPLS LSP ping and MPLS LSP traceroute to periodically test them.

The MPLS EM—MPLS LSP Multipath Tree Trace feature requires the Cisco RFC-compliant implementation that is based on RFC 4379. If you do not have a Cisco IOS release that supports RFC 379, MPLS LSP multipath tree trace does not operate to discover all PE-to-PE paths.

## Discovery of IPv4 Load Balancing Paths by MPLS LSP Multipath Tree Trace

IPv4 load balancing at a transit router is based on the incoming label stack and the source and destination addresses in the IP header. The outgoing label stack and IP header source address remain constant for each branch being traced.

When you execute MPLS LSP multipath tree trace on the source LSR, the router needs to find the set of IP header destination addresses to use all possible output paths. The source LSR starts path discovery by sending a transit router a bitmap in an MPLS echo request. The transit router returns information in an MPLS echo request that contains subsets of the bitmap in a downstream map (DS Map) in an echo reply. The source router can then use the information in the echo reply to interrogate the next router. The source router interrogates each successive router until it finds one bitmap setting that is common to all routers along the path. The router uses TTL expiry to interrogate the routers to find the common bits.

For example, you could start path discovery by entering the following command at the source router:

```
Router# trace mpls multipath ipv4 10.131.101.129/32 hashkey ipv4 bitmap 16
```

This command sets the IP address of the target router as 10.131.101.192 255.255.255.255 and configures:

- The default hash key type to 8, which requests that an IPv4 address prefix and bit mask address set be returned in the DS Map in the echo reply.

- The bitmap size to 16. This means that MPLS LSP multipath tree trace uses 16 addresses (starting with 127.0.0.1) in the discovery of all paths of an LSP between the source router and the target router.

If you enter the **trace mpls multipath ipv4 10.131.101.129/32** command, MPLS LSP multipath tree trace uses the default hash type of 8 or IPv4 and a default bitmap size of 32. Your choice of a bitmap size depends on the number of routes in your network. If you have a large number of routes, you might need to use a larger bitmap size.

## Echo Reply Return Codes Sent by the Router Processing Multipath LSP Tree Trace

[Table 1](#) describes the characters that the router processing a multipath LSP tree trace packet returns to the sender about the failure or success of the request.

**Table 1** *Echo Reply Return Codes*

| Output Code | Echo Return Code | Meaning                                                  |
|-------------|------------------|----------------------------------------------------------|
| Period “.”  | —                | A timeout occurred before the target router could reply. |
| x           | 0                | No return code.                                          |
| M           | 1                | Malformed request.                                       |
| m           | 2                | Unsupported type, length, values (TLVs).                 |
| !           | 3                | Success.                                                 |
| F           | 4                | No Forwarding Equivalence Class (FEC) mapping.           |
| D           | 5                | DS Map mismatch.                                         |
| R           | 6                | Downstream router but not target.                        |
| U           | 7                | Reserved.                                                |
| L           | 8                | Labeled output interface.                                |
| B           | 9                | Unlabeled output interface.                              |
| f           | 10               | FEC mismatch.                                            |
| N           | 11               | No label entry.                                          |

- [Using DSCP to Request a Specific Class of Service in an Echo Reply, page 13 \(optional\)](#)
- [Controlling How a Responding Router Replies to an MPLS Echo Request, page 14 \(optional\)](#)
- [Specifying the Output Interface for Echo Packets Leaving a Router for MPLS LSP Multipath Tree Trace, page 16 \(optional\)](#)
- [Setting the Pace of MPLS Echo Request Packet Transmission for MPLS LSP Multipath Tree Trace, page 17 \(optional\)](#)
- [Enabling MPLS LSP Multipath Tree Trace to Detect LSP Breakages Caused by an Interface That Lacks an MPLS Configuration, page 18 \(optional\)](#)
- [Requesting That a Transit Router Validate the Target FEC Stack for MPLS LSP Multipath Tree Trace, page 19 \(optional\)](#)
- [Setting the Number of Timeout Attempts for MPLS LSP Multipath Tree Trace, page 21 \(optional\)](#)

## Customizing the Default Behavior of MPLS Echo Packets

Perform the following task to customize the default behavior of MPLS echo packets. You might need to customize the default echo packet encoding and decoding behavior to allow later implementations of the *Detecting MPLS Data Plane Failures* (RFC 4379) to be deployed in networks running earlier versions of the draft.

### MPLS Embedded Management Configuration

Before using the **ping mpls**, **trace mpls**, or **trace mpls multipath** command, you should consider ensuring that the router is configured to encode and decode MPLS echo packets in a format that all receiving routers in the network can understand.

LSP ping drafts after Version 3 (draft-ietf-mpls-ping-03) have undergone numerous TLV format changes, but the implementations based on different drafts might not interoperate properly.

To allow later Cisco implementations to interoperate with draft Version 3 Cisco and non-Cisco implementations, a global configuration mode (MPLS OAM configuration) allows you to encode and decode echo packets in formats specified by draft Version 3 implementations.

Unless configured otherwise, a Cisco implementation encodes and decodes echo requests assuming the version on which the Internet Engineering Task Force (IETF) implementation is based.

To allow for seamless interoperability with earlier Revision 1 and 3 images, you can use MPLS Operation, Administration, and Maintenance (OAM) configuration mode parameters to force the default behavior of the Revision 4 images to be compliant or compatible in networks with Revision 1 or Revision 3 images.

To prevent failures reported by the replying router due to TLV version issues, you should configure all routers in the core. Encode and decode MPLS echo packets in the same draft version. For example, if the network is running RFC 4379 (Cisco Revision 4) implementations but one router is capable of only Version 3 (Cisco Revision 3), configure all routers in the network to operate in Revision 3 mode.

Cisco Revision 4 is the default version. The default version is the latest LSP Ping version supported by the image on the router.

## Prerequisites

MPLS LSP Multipath Tree Trace requires RFC 4379 (Revision 4).

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls oam**
4. **echo revision {3 | 4}**
5. **[no] echo vendor-extension**
6. **end**

## DETAILED STEPS

|               | Command or Action                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|---------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                      | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                                                                                                                                                                                                                                                                                    |
| <b>Step 2</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal              | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                      |

| Step 6 | <pre>end</pre> <p><b>Example:</b><br/> <pre>Router(config-mpls)# end</pre></p>                                          | <p>Exits to privileged EXEC mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                           |

## Configuring MPLS LSP Multipath Tree Trace

Perform the following task to configure MPLS multipath LSP traceroute. This task helps discover all LSPs from an egress router to an ingress router.

### Prerequisites

Cisco LSP ping or traceroute implementations based on draft-ietf-mpls-lsp-ping-11 are capable in some cases of detecting the formatting of the sender of an MPLS echo request. However, certain cases exist in which an echo request or echo reply might not contain the Cisco extension TLV. To avoid complications due to certain cases where the echo packets are decoded assuming the wrong TLV formats, configure all routers in the network to operate in the same mode.

For an MPLS LSP multipath tree trace to be successful, the implementation in your routers must support RFC 4379 on all core routers.

If all routers in the network support RFC-4379 and another vendor's implementation exists that is not capable of properly handling Cisco's vendor TLV, the routers supporting the RFC-compliant or later configuration must include commands to disable the Cisco vendor TLV extensions.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls oam**
4. **echo revision 4**
5. **[no] echo vendor-extension**
6. **end**
7. **trace mpls multipath ipv4** *destination-ip-address/destination-mask-length*
8. **debug mpls lspv multipath**

## DETAILED STEPS

| Step 8 | <b>debug mpls lspv multipath</b><br><br><b>Example:</b><br>Router# debug mpls lspv multipath                                                                               | Displays multipath information related to the MPLS LSP Multipath Tree Trace feature.                                                                                                                                                                                                                                                                                                                                                                                        |

## Discovering IPv4 Load Balancing Paths Using MPLS LSP Multipath Tree Trace

Perform the following task to discover IPv4 load balancing paths using MPLS LSP multipath tree trace.

### MPLS Multipath LSP Traceroute Path Discovery

A Cisco router load balances MPLS packets based on the incoming label stack and the source and destination addresses in the IP header. The outgoing label stack and IP header source address remain constant for each path being traced. The router needs to find the set of IP header destination addresses to use all possible output paths. This might require exhaustive searching of the 127.x.y.z/8 address space. Once you discover all paths from the source LSR to the target or destination LSR with MPLS LSP multipath tree trace, you can use MPLS LSP traceroute to monitor these paths.

Figure 1 shows how MPLS LSP multipath tree trace discovers LSP paths in a sample network. In Figure 1, the bitmap size is 16 and the numbers 0 to 15 represent the bitmapped addresses that MPLS LSP multipath tree trace uses to discover all the paths from the source LSR R-101 to the target LSR R-150. Figure 1 illustrates how the **trace mpls multipath** command discovers all LSP paths in the sample network.

**Figure 1** MPLS LSP Multipath Tree Trace Path Discovery in a Sample Network

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls oam**
4. **echo revision 4**
5. **end**
6. **trace mpls multipath ipv4 destination-ip-address/destination-mask-length hashkey ipv4 bitmap bitmap-size**

## DETAILED STEPS

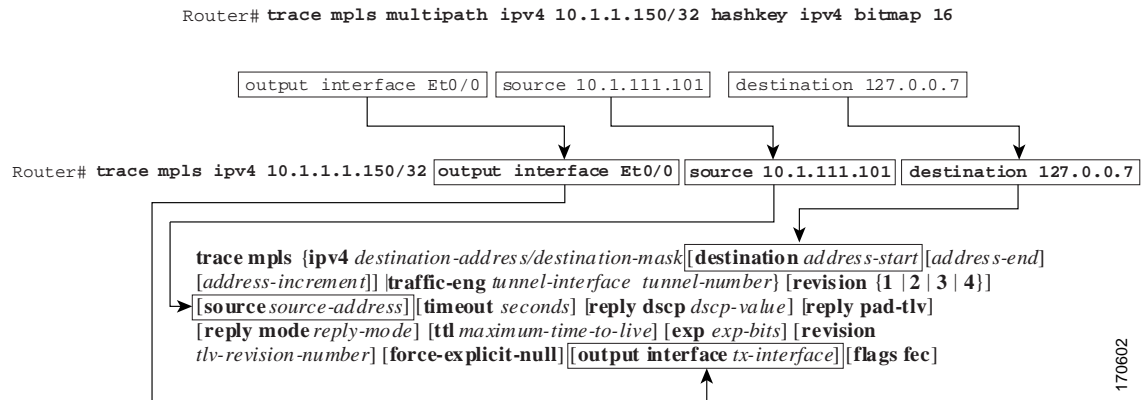

|        | Command or Action                                                                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

The <i>/</i> keyword before this argument is required.</li><li>The <b>hashkey ipv4</b> keywords set the hashkey type to IPv4 addresses.</li><li>The <b>bitmap bitmap-size</b> keyword and arguments set the bitmap size for multipath discovery.</li></ul> |

## Monitoring LSP Paths Discovered by MPLS LSP Multipath Tree Trace Using MPLS LSP Traceroute

Perform the following task to monitor LSP paths discovered by MPLS LSP multipath tree trace using MPLS LSP traceroute. You can take output directly from the **trace mpls multipath** command and add it to a **trace mpls** command periodically to verify that the path is still operating.

Figure 2 shows the mapping of the output of a **trace mpls multipath** command to a **trace mpls** command.

**Figure 2 Mapping of trace mpls multipath Command Output to a trace mpls Command**

Each path you discover with MPLS LSP Multipath Tree Trace can be tested in this manner periodically to monitor the LSP paths in your network.

## SUMMARY STEPS

1. **enable**
2. **trace mpls multipath ipv4** *destination-address/destination-mask-length* **hashkey** **ipv4** **bitmap** *bitmap-size*
3. **trace mpls ipv4** *destination-address/destination-mask-length* [**output interface** *tx-interface*] [**source** *source-address*] [**destination** *address-start*]
4. **exit**

## DETAILED STEPS

### Step 1 enable

Use this command to enable privileged EXEC mode. Enter your password if prompted. For example:

```
Router> enable
Router#
```

### Step 2 trace mpls multipath ipv4 destination-address/destination-mask-length hashkey ipv4 bitmap bitmap-size

Use this command to discover all MPLS LSPs from an egress router to an ingress router. For example:

```
Router# trace mpls multipath ipv4 10.1.1.150/32 hashkey ipv4 bitmap 16
```

Starting LSP Multipath Traceroute for 10.1.1.150/32

Codes: '!' - success, 'Q' - request not sent, '.' - timeout,  
 'L' - labeled output interface, 'B' - unlabeled output interface,  
 'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,  
 'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,  
 'P' - no rx intf label prot, 'p' - premature termination of LSP,

```

'R' - transit router, 'I' - unknown upstream index,
'X' - unknown return code, 'x' - return code 0

Type escape sequence to abort.
LLLL!

Total Time Elapsed 468 ms

```

The output of the **trace mpls multipath** command in the example shows the result of path discovery with MPLS LSP multipath tree trace. In this example, the command sets the bitmap size to 16. Path discovery starts by MPLS LSP multipath tree trace using 16 bitmapped addresses as it locates LSP paths from the source router to the target router with prefix and mask 10.1.1.150/32. MPLS LSP multipath tree trace starts using the 127.x.y.z/8 address space with 127.0.0.1.

**Step 3** **trace mpls ipv4** *destination-address/destination-mask-length* [**output interface** *tx-interface*] [**source** *source-address*] [**destination** *address-start*]

Use this command to verify that the paths discovered when you entered a **trace mpls multipath** command are still operating. For example, the output for Path 0 in the previous **trace mpls multipath** command in [Step 2](#) is:

```
output interface Et0/0 source 10.1.111.101 destination 127.0.0.0
```

If you put the output for path 0 in the **trace mpls** command, you see the following results:

```
Router# trace mpls ipv4 10.1.1.150/32 output interface Et0/0 source 10.1.111.101
destination 127.0.0.0
```

```
Tracing MPLS Label Switched Path to 10.1.1.150/32, timeout is 2 seconds
```

```

Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'I' - unknown upstream index,
'X' - unknown return code, 'x' - return code 0

```

```

Type escape sequence to abort.
 0 10.1.111.101 MRU 1500 [Labels: 33 Exp: 0]
L 1 10.1.111.111 MRU 1500 [Labels: 34 Exp: 0] 40 ms
L 2 10.2.121.121 MRU 1500 [Labels: 34 Exp: 0] 32 ms
L 3 10.3.132.132 MRU 1500 [Labels: 32 Exp: 0] 16 ms
L 4 10.4.140.240 MRU 1504 [Labels: implicit-null Exp: 0] 20 ms
! 5 10.5.150.50 20 ms

```

You can take output directly from the **trace mpls multipath** command and add it to a **trace mpls** command periodically to verify that the path is still operating (see [Figure 2](#)).

**Step 4    exit**

Use this command to exit to user EXEC mode. for example:

```
Router# exit
Router>
```

---

## Using DSCP to Request a Specific Class of Service in an Echo Reply

For Cisco IOS Release 12.2(27)SXE, Cisco added a reply differentiated services code point (DSCP) option that lets you request a specific class of service (CoS) in an echo reply.

The reply DSCP option is supported in the experimental mode for IETF draft-ietf-mpls-lsp-ping-03.txt. Cisco implemented a vendor-specific extension for the reply DSCP option rather than using a Reply TOS TLV. A Reply TOS TLV serves the same purpose as the **reply dscp** command in IETF draft-ietf-mpls-lsp-ping-11.txt. This draft provides a standardized method of controlling the reply DSCP.

**Note**

Before RFC 4379, Cisco implemented the Reply DSCP option as an experimental capability using a Cisco vendor extension TLV. If a router is configured to encode MPLS echo packets for draft Version 3 implementations, a Cisco vendor extension TLV is used instead of the = Reply TOS TLV that was defined in draft Version 8.

To use DSCP to request a specific CoS in an echo reply, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **trace mpls multipath ipv4** *destination-address/destination-mask-length* [**reply dscp** *dscp-value*]
3. **exit**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                           | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Step 2 | <b>trace mpls multipath ipv4 destination-address/destination-mask-length [reply dscp dscp-value]</b><br><br><b>Example:</b><br>Router# trace mpls multipath ipv4 10.131.191.252/32 reply dscp 50 | Discovers all MPLS LSPs from an ingress router to an egress router and controls the DSCP value of an echo reply. <ul style="list-style-type: none"> <li>The <b>ipv4</b> keyword specifies the destination type as an LDP IPv4 address.</li> <li>The <i>destination-address</i> argument is the address prefix of the target to be tested.</li> <li>The <i>destination-mask-length</i> argument is the number of bits in the network mask of the target address. The <b>/</b> keyword before this argument is required.</li> <li>The <b>reply dscp dscp-value</b> keywords and argument are the DSCP value of an echo reply. A Reply TOS TLV serves the same purpose as the <b>reply dscp</b> command in IETF draft-ietf-mpls-lsp-ping-11.txt.</li> </ul> <b>Note</b> To specify a DSCP value, you must enter the <b>reply dscp dscp-value</b> keywords and argument. |
| Step 3 | <b>exit</b><br><br><b>Example:</b><br>Router# exit                                                                                                                                               | Returns to user EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Controlling How a Responding Router Replies to an MPLS Echo Request

This section contains information about and instructions for controlling how a responding router replies to an MPLS echo request. You should understand the following information before you configure a reply mode for the echo request response:

- [Reply Modes for an MPLS LSP Multipath Tree Trace Echo Request Response, page 14](#)

### Reply Modes for an MPLS LSP Multipath Tree Trace Echo Request Response

The reply mode controls how a responding router replies to an MPLS echo request sent by a **trace mpls multipath** command. There are two reply modes for an echo request packet:

- ipv4—Reply with an IPv4 User Datagram Protocol (UDP) packet (default)
- router-alert—Reply with an IPv4 UDP packet with router alert

**Note**

Use the ipv4 and router-alert reply modes with each other to prevent false negatives. If you do not receive a reply via the ipv4 mode, send a test with the router-alert reply mode. If both fail, something is wrong in the return path. The problem might be due to an incorrect ToS setting.

## IPv4 UDP Reply Mode

The IPv4 UDP reply mode is the most common reply mode used with a **trace mpls multipath** command when you want to periodically poll the integrity of an LSP. With this option, you do not have explicit control over whether the packet traverses IP or MPLS hops to reach the originator of the MPLS echo request. If the originating (headend) router fails to receive a reply to an MPLS echo request when you use the **reply mode ipv4** keywords, use the **reply mode router-alert** keywords.

## Router-alert Reply Mode

The router-alert reply mode adds the router alert option to the IP header. When an IP packet that contains an IP router alert option in its IP header or an MPLS packet with a router alert label as its outermost label arrives at a router, the router punts (redirects) the packet to the Route Processor (RP) process level for handling. This forces the RP of each intermediate router to specifically handle the packet at each intermediate hop as it moves back to the destination. Hardware and line-card forwarding inconsistencies are thus bypassed. Router-alert reply mode is slower than IPv4 mode because the reply requires process-level RP handling at each hop.

Table 2 describes how an incoming IP packet with an IP router alert is handled by the router switching path processes when the outgoing packet is an IP packet or an MPLS packet. It also describes how an MPLS packet with a router alert option is handled by the router switching path processes when the outgoing packet is an IP packet or an MPLS packet.

**Table 2** Path Process Handling of IP and MPLS Router Alert Packets

| Incoming Packet                                     | Outgoing Packet                                     | Normal Switching Action                                                                                            | Process Switching Action                                                         |
|-----------------------------------------------------|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| IP packet—Router alert option in IP header          | IP packet—Router alert option in IP header          | Router alert option in IP header causes the packet to be punted to the process switching path.                     | Forwards the packet as is                                                        |
|                                                     | MPLS packet                                         |                                                                                                                    | Forwards the packet as is                                                        |
| MPLS packet—Outermost label contains a router alert | IP packet—Router alert option in IP header          | If the router alert label is the outermost label, it causes the packet to be punted to the process switching path. | Removes the outermost router alert label and forwards the packet as an IP packet |
|                                                     | MPLS packet—Outermost label contains a router alert |                                                                                                                    | Preserves the outermost router alert label and forwards the MPLS packet          |

## SUMMARY STEPS

1. **enable**
2. **trace mpls multipath ipv4** *destination-address/destination-mask-length* **reply mode** {**ipv4** | **router-alert**}
3. **exit**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                              | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Step 2 | <b>trace mpls multipath ipv4 destination-address/destination-mask-length reply mode {ipv4   router-alert}</b><br><br><b>Example:</b><br>Router# trace mpls multipath ipv4 10.131.191.252/32 reply mode router-alert | Discovers all MPLS LSPs from an ingress router to an egress router and specifies the reply mode. <ul style="list-style-type: none"> <li>The <b>ipv4</b> keyword specifies the destination type as an LDP IPv4 address.</li> <li>The <i>destination-address</i> argument is the address prefix of the target to be tested.</li> <li>The <i>destination-mask-length</i> argument is the number of bits in the network mask of the target address. The / keyword before this argument is required.</li> <li>The <b>reply mode</b> keyword requires that you enter one of the following keywords to specify the reply mode: <ul style="list-style-type: none"> <li>The <b>ipv4</b> keyword—Reply with an IPv4 UDP packet (default).</li> <li>The <b>router-alert</b> keyword—Reply with an IPv4 UDP packet with router alert.</li> </ul> </li> </ul> <p><b>Note</b> To specify the reply mode, you must enter the <b>reply mode</b> keyword with the <b>ipv4</b> or <b>router-alert</b> keyword.</p> |
| Step 3 | <b>exit</b><br><br><b>Example:</b><br>Router# exit                                                                                                                                                                  | Returns to user EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Specifying the Output Interface for Echo Packets Leaving a Router for MPLS LSP Multipath Tree Trace

Perform the following task to specify the output interface for echo packets leaving a router for the MPLS LSP Multipath Tree Trace feature. You can use this task to test the LSPs reachable through a given interface.

### Echo Request Output Interface Control

You can control the interface through which packets leave a router. Path output information is used as input to LSP ping and traceroute.

The echo request output interface control feature allows you to force echo packets through the paths that perform detailed debugging or characterizing of the LSP. This feature is useful if a PE router connects to an MPLS cloud and there are broken links. You can direct traffic through a certain link. The feature also is helpful for troubleshooting network problems.

## SUMMARY STEPS

1. **enable**
2. **trace mpls multipath ipv4** *destination-address/destination-mask-length* [**output interface** *tx-interface*]
3. **exit**

## Setting the Pace of MPLS Echo Request Packet Transmission for MPLS LSP Multipath Tree Trace

Perform the following task to set the pace of MPLS echo request packet transmission for the MPLS LSP Multipath Tree Trace feature. Echo request traffic pacing allows you to set the pace of the transmission of packets so that the receiving router does not drop packets. If you have a large amount of traffic on your network you might increase the size of the interval to help ensure that the receiving router does not drop packets.

## SUMMARY STEPS

1. **enable**
2. **trace mpls multipath ipv4** *destination-address/destination-mask-length* [**interval** *milliseconds*]

## 3. exit

## Enabling MPLS LSP Multipath Tree Trace to Detect LSP Breakages Caused by an Interface That Lacks an MPLS Configuration

Perform the following task to enable MPLS LSP multipath tree trace to detect LSP breakages caused by an interface that lacks an MPLS configuration. If an interface is not configured for MPLS, then it cannot forward MPLS packets.

### Explicit Null Label Shimming Tests LSP Ability to Carry MPLS Traffic

For an MPLS LSP multipath tree trace of LSPs carrying IPv4 FECs, you can force an explicit null label to be added to the MPLS label stack even though the label was unsolicited. This allows MPLS LSP multipath tree trace to detect LSP breakages caused by an interface that is not configured for MPLS. MPLS LSP multipath tree trace does not report that an LSP is functioning when it is unable to send MPLS traffic.

An explicit null label is added to an MPLS label stack if MPLS echo request packets are forwarded from an interface not configured for MPLS that is directly connected to the destination of the MPLS LSP multipath tree trace or if the IP TTL value for the MPLS echo request packets is set to 1.

When you enter a **trace mpls multipath** command, you are looking for all MPLS LSP paths from an egress router to an ingress router. Failure at output interfaces that are not configured for MPLS at the penultimate hop are not detected. Explicit-null shimming allows you to test an LSP's ability to carry MPLS traffic.

## SUMMARY STEPS

1. **enable**
2. **trace mpls multipath ipv4 destination-address/destination-mask-length force-explicit-null**
3. **exit**

## DETAILED STEP

## Requesting That a Transit Router Validate the Target FEC Stack for MPLS LSP Multipath Tree Trace

Perform the following task to request that a transit router validate the target FEC stack for the MPLS LSP Multipath Tree Trace feature.

An MPLS echo request tests a particular LSP. The LSP to be tested is identified by the FEC stack.

During an MPLS LSP multipath tree trace, the echo packet validation rules do not require that a transit router validate the target FEC stack TLV. A downstream map TLV containing the correct received labels must be present in the echo request for target FEC stack checking to be performed.

To request that a transit router validate the target FEC stack, set the V flag from the source router by entering the **flags fec** keywords in the **trace mpls multipath** command. The default is that echo request packets are sent with the V flag set to 0.

## SUMMARY STEPS

1. **enable**
2. **trace mpls multipath ipv4** *destination-address/destination-mask-length* [**flags fec**] [**ttl** *maximum-time-to-live*]
3. **exit**

|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                                                               | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 2 | <b>trace mpls multipath ipv4</b> <i>destination-address/destination-mask-length</i> [ <b>flags fec</b> ] [ <b>ttl</b> <i>maximum-time-to-live</i> ]<br><br><b>Example:</b><br>Router# trace mpls multipath ipv4<br>10.131.159.252/32 flags fec ttl 5 | Discovers all MPLS LSPs from an egress router to an ingress router and requests validation of the target FEC stack by a transit router. <ul style="list-style-type: none"> <li>• The <b>ipv4</b> keyword specifies the destination type as an LDP IPv4 address.</li> <li>• The <i>destination-address</i> argument is the address prefix of the target to be tested.</li> <li>• The <i>destination-mask-length</i> argument is the number of bits in the network mask of the target address. The / keyword before this argument is required.</li> <li>• The <b>flags fec</b> keywords requests that target FEC stack validation be done at a transit router.</li> <li>• The <b>ttl</b> <i>maximum-time-to-live</i> keyword and argument pair specify a maximum hop count.</li> </ul> <p><b>Note</b> For a transit router to validate the target FEC stack, you must enter the <b>flags fec</b> and <b>ttl</b> keywords.</p> |
| Step 3 | <b>exit</b><br><br><b>Example:</b><br>Router# exit                                                                                                                                                                                                   | Returns to user EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Setting the Number of Timeout Attempts for MPLS LSP Multipath Tree Trace

Perform the following task to set the number of timeout attempts for the MPLS LSP Multipath Tree Trace feature.

A retry is attempted if an outstanding echo request times out waiting for the corresponding echo reply.

### SUMMARY STEPS

1. **enable**
2. **trace mpls multipath ipv4** *destination-address/destination-mask-length* [**retry-count** *retry-count-value*]
3. **exit**

| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                                          | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Step 2 | <b>trace mpls multipath ipv4</b> <i>destination-address/destination-mask-length</i> [ <b>retry-count</b> <i>retry-count-value</i> ]<br><br><b>Example:</b><br>Router# trace mpls multipath ipv4 10.131.159.252/32 retry-count 4 | Sets the number of retry attempts during an MPLS LSP multipath tree trace. <ul style="list-style-type: none"> <li>• The <b>ipv4</b> keyword specifies the destination type as an LDP IPv4 address.</li> <li>• The <i>destination-address</i> argument is the address prefix of the target to be tested.</li> <li>• The <i>destination-mask-length</i> argument is the number of bits in the network mask of the target address. The / keyword before this argument is required.</li> <li>• The <b>retry-count</b> <i>retry-count-value</i> keyword and argument sets the number of retry attempts after a timeout occurs.</li> </ul> <p>A rertry-count value of “0” means infinite retries. A retry-count value from 0 to10 is suggested. You might want to increase the retry value to greater than 10, if 10 is too small a value. The default retry-count value is 3.</p> <p><b>Note</b> To set the number of retries after a timeout, you must enter the <b>retry-count</b> keyword.</p> |
| Step 3 | <b>exit</b><br><br><b>Example:</b><br>Router# exit                                                                                                                                                                              | Returns to user EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

# Configuration Examples for MPLS EM—MPLS LSP Multipath Tree Trace

This section includes the following configuration examples for the MPLS EM—MPLS LSP Multipath Tree Trace feature:

- [Customizing the Default Behavior of MPLS Echo Packets: Example, page 22](#)
- [Configuring MPLS LSP Multipath Tree Trace: Example, page 22](#)
- [Using DSCP to Request a Specific Class of Service in an Echo Reply: Example, page 24](#)
- [Controlling How a Responding Router Replies to an MPLS Echo Request: Example, page 25](#)
- [Specifying the Output Interface for Echo Packets Leaving a Router for MPLS LSP Multipath Tree Trace: Example, page 25](#)
- [Setting the Pace of MPLS Echo Request Packet Transmission for MPLS LSP Multipath Tree Trace: Example, page 26](#)
- [Enabling MPLS LSP Multipath Tree Trace to Detect LSP Breakages Caused by an Interface That Lacks an MPLS Configuration: Example, page 27](#)
- [Requesting That a Transit Router Validate the Target FEC Stack for MPLS LSP Multipath Tree Trace: Example, page 29](#)
- [Setting the Number of Timeout Attempts for MPLS LSP Multipath Tree Trace: Example, page 29](#)

## Customizing the Default Behavior of MPLS Echo Packets: Example

The following example shows how to customize the behavior of MPLS echo packets so that the MPLS LSP Multipath Tree Trace feature interoperates with a vendor implementation that does not interpret RFC 4379 as Cisco does:

```
configure terminal
!
mpls oam
 echo revision 4
no echo vendor-extension
end
```

The **echo revision** command is included in this example for completeness. The default echo revision number is 4, which corresponds to RFC 4379.

## Configuring MPLS LSP Multipath Tree Trace: Example

The following example shows how to configure the MPLS LSP Multipath Tree Trace feature to interoperate with a vendor implementation that does not interpret RFC 4379 as Cisco does:

```
configure terminal
!
mpls oam
 echo revision 4
no echo vendor-extension
end
!
trace mpls multipath ipv4 10.131.161.151/32
```

The **echo revision** command is included in this example for completeness. The default echo revision number is 4, which corresponds to the RFC 4379.

## Discovering IPv4 Load Balancing Paths Using MPLS LSP Multipath Tree Trace: Example

The following example shows how to use the MPLS LSP Multipath Tree Trace feature to discover IPv4 load balancing paths. The example is based on the sample network shown in [Figure 3](#). In this example, the bitmap size is set to 16. Therefore, path discovery starts by the MPLS LSP Multipath Tree Trace feature using 16 bitmapped addresses as it locates LSP paths from the source router R-101 to the target router R-150 with prefix and mask 10.1.1.150/32. The MPLS LSP Multipath Tree Trace feature starts using the 127.x.y.z/8 address space with 127.0.0.0.

```
Router# trace mpls multipath ipv4 10.1.1.150/32 hashkey ipv4 bitmap 16
```

```
Starting LSP Multipath Traceroute for 10.1.1.150/32
```

```
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
        'L' - labeled output interface, 'B' - unlabeled output interface,
        'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
        'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
        'P' - no rx intf label prot, 'p' - premature termination of LSP,
        'R' - transit router, 'I' - unknown upstream index,
        'X' - unknown return code, 'x' - return code 0
```

```
Type escape sequence to abort.
```

```
LLLL!
```

```
Path 0 found,
```

## Controlling How a Responding Router Replies to an MPLS Echo Request: Example

The following example shows how to control how a responding router replies to an MPLS echo request:

```
Router# trace mpls multipath ipv4 10.1.1.150/32 reply mode router-alert
```

```
Starting LSP Multipath Traceroute for 10.1.1.150/32
```

```
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
        'L' - labeled output interface, 'B' - unlabeled output interface,
        'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
        'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
        'P' - no rx intf label prot, 'p' - premature termination of LSP,

## Specifying the Output Interface for Echo Packets Leaving a Router for MPLS LSP Multipath Tree Trace: Example

The following example shows how to specify the output interface for echo packets leaving a router for the MPLS LSP Multipath Tree Trace feature:

```
Router# trace mpls multipath ipv4 10.1.1.150/32 output interface ethernet0/0
```

```
Tracing MPLS Label Switched Path to 10.1.1.150/32, timeout is 2 seconds
```

```
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
        'L' - labeled output interface, 'B' - unlabeled output interface,
        'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
        'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
        'P' - no rx intf label prot, 'p' - premature termination of LSP,
        'R' - transit router, 'I' - unknown upstream index,
        'X' - unknown return code, 'x' - return code 0
```

```
Type escape sequence to abort.

## Setting the Pace of MPLS Echo Request Packet Transmission for MPLS LSP Multipath Tree Trace: Example

The following examples show how set the pace of MPLS echo request packet transmission for the MPLS LSP Multipath Tree Trace feature. The time between successive MPLS echo requests is set to 300 milliseconds in the first example and 400 milliseconds in the second example:

```
Router# trace mpls multipath ipv4 10.131.159.252/32 interval 300
```

```
Starting LSP Multipath Traceroute for 10.131.159.252/32
```

```
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'I' - unknown upstream index,
'X' - unknown return code, 'x' - return code 0

```

```
Type escape sequence to abort.
```

```
LL!
```

```
Path 0 found,
output interface Et1/0 source 10.2.3.2 destination 127.0.0.0

```

```
Paths (found/broken/unexplored) (1/0/0)
Echo Request (sent/fail) (3/0)
Echo Reply (received/timeout) (3/0)
Total Time Elapsed 1604 ms

```

```
Router# trace mpls multipath ipv4 10.131.159.252/32 interval 400
```

```
Starting LSP Multipath Traceroute for 10.131.159.252/32
```

```
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'I' - unknown upstream index,
'X' - unknown return code, 'x' - return code 0

```

```
Type escape sequence to abort.
```

```
LL!
```

```
Path 0 found,
output interface Et1/0 source 10.2.3.2 destination 127.0.0.0

```

```
Paths (found/broken/unexplored) (1/0/0)
Echo Request (sent/fail) (3/0)
Echo Reply (received/timeout) (3/0)
Total Time Elapsed 1856 ms

```

Notice that the elapsed time increases as you increase the interval size.

## Enabling MPLS LSP Multipath Tree Trace to Detect LSP Breakages Caused by an Interface That Lacks an MPLS Configuration: Example

The following examples shows how to enable the MPLS LSP Multipath Tree Trace feature to detect LSP breakages caused by an interface that lacks an MPLS configuration:

```
Router# trace mpls multipath ipv4 10.1.1.150/32 force-explicit-null
```

```
Starting LSP Multipath Traceroute for 10.1.1.150/32
```

```
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'I' - unknown upstream index,
'X' - unknown return code, 'x' - return code 0
```

```
Type escape sequence to abort.
```

```
LLLL!
```

```
Path 0 found,
```

```
  output interface Et0/0 source 10.1.111.101 destination 127.0.0.0
```

```
LLL!
```

```

## Requesting That a Transit Router Validate the Target FEC Stack for MPLS LSP Multipath Tree Trace: Example

The following example shows how to request that a transit router validate the target FEC stack for the MPLS LSP Multipath Tree Trace feature:

```
Router# trace mpls multipath ipv4 10.1.1.150/32 flags fec ttl 5

Starting LSP Multipath Traceroute for 10.1.1.150/32

Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
        'L' - labeled output interface, 'B' - unlabeled output interface,
        'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
        'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
        'P' - no rx intf label prot, 'p' - premature termination of LSP,
        'R' - transit router, 'I' - unknown upstream index,
        'X' - unknown return code, 'x' - return code 0

Type escape sequence to abort.
LLLL!
Path 0 found,
  output interface Et0/0 source 10.1.111.101 destination 127.0.0.0
LLL!
Path 1 found,
  output interface Et0/0 source 10.1.111.101 destination 127.0.0.1
L!
Path 2 found,
  output interface Et0/0 source 10.1.111.101 destination 127.0.0.5
LL!
Path 3 found,
  output interface Et0/0 source 10.1.111.101 destination 127.0.0.7

Paths (found/broken/unexplored) (4/0/0)
Echo Request (sent/fail) (14/0)
Echo Reply (received/timeout) (14/0)
Total Time Elapsed 464 ms
```

Target FEC stack validation is always done at the egress router when the **flags fec** keywords are specified in the **trace mpls multipath** command.

## Setting the Number of Timeout Attempts for MPLS LSP Multipath Tree Trace: Example

The following example sets the number of timeout attempts for the MPLS LSP Multipath Tree Trace feature to four:

```
Router# trace mpls multipath ipv4 10.1.1.150/32 retry-count 4

Starting LSP Multipath Traceroute for 10.1.1.150/32

Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
        'L' - labeled output interface, 'B' - unlabeled output interface,
        'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
        'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
```

```

'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'I' - unknown upstream index,
'X' - unknown return code, 'x' - return code 0

Type escape sequence to abort.
LLL!
Path 0 found,
  output interface Et0/0 source 10.1.111.101 destination 127.0.0.0
LLL!
Path 1 found,
  output interface Et0/0 source 10.1.111.101 destination 127.0.0.1
L!
Path 2 found,
  output interface Et0/0 source 10.1.111.101 destination 127.0.0.5
LL!
Path 3 found,
  output interface Et0/0 source 10.1.111.101 destination 127.0.0.7

Paths (found/broken/unexplored) (4/0/0)
Echo Request (sent/fail) (14/0)
Echo Reply (received/timeout) (14/0)
Total Time Elapsed 460 ms

```

The following output shows a **trace mpls multipath** command that found one unexplored path, one successful path, and one broken path:

```

Router# trace mpls multipath ipv4 10.1.1.150/32 retry-count 4

Starting LSP Multipath Traceroute for 10.1.1.150/32

Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'I' - unknown upstream index,

## Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Multiprotocol Label Switching Command Reference* at [http://www.cisco.com/en/US/docs/ios/mpls/command/reference/mp\\_book.html](http://www.cisco.com/en/US/docs/ios/mpls/command/reference/mp_book.html). For information about all Cisco IOS commands, use the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the *Cisco IOS Master Command List, All Releases*, at [http://www.cisco.com/en/US/docs/ios/mcl/allreleasemcl/all\\_book.html](http://www.cisco.com/en/US/docs/ios/mcl/allreleasemcl/all_book.html).

- **debug mpls lspv**
- **echo**
- **mpls oam**
- **trace mpls**
- **trace mpls multipath**

# Feature Information for MPLS EM—MPLS LSP Multipath Tree Trace

Table 3 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Note

Table 3 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 3** Feature Information for MPLS EM—MPLS LSP Multipath Tree Trace

| Feature Name                          | Releases                                               | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

# Glossary

**ECMP**—equal-cost multipath. Multiple routing paths of equal cost that may be used for packet forwarding.

**FEC**—Forwarding Equivalence Class. A set of packets that can be handled equivalently for forwarding purposes and are thus suitable for binding to a single label. Examples include the set of packets destined for one address prefix and the packets in any flow.

**flow**—A set of packets traveling between a pair of hosts, or between a pair of transport protocol ports on a pair of hosts. For example, packets with the same source address, source port, destination address, and destination port might be considered a flow.

A flow is also a stream of data traveling between two endpoints across a network (for example, from one LAN station to another). Multiple flows can be transmitted on a single circuit.

**localhost**—A name that represents the host router (device). The localhost uses the reserved loopback IP address 127.0.0.1.

**LSP**—label switched path. A connection between two routers in which MPLS forwards the packets.

**LSPV**—Label Switched Path Verification. An LSP ping subprocess. It encodes and decodes MPLS echo requests and replies, and it interfaces with IP, MPLS, and AToM switching for sending and receiving MPLS echo requests and replies. At the MPLS echo request originator router, LSPV maintains a database of outstanding echo requests for which echo responses have not been received.

**MPLS router alert label**—An MPLS label of 1. An MPLS packet with a router alert label is redirected by the router to the Route Processor (RP) processing level for handling. This allows these packets to bypass any forwarding failures in hardware routing tables.

**OAM**—Operation, Administration, and Management.

**punt**—Redirect packets with a router alert from the line card or interface to Route Processor (RP) level processing for handling.

**RP**—Route Processor. The processor module in a Cisco 7000 series router that contains the CPU, system software, and most of the memory components that are used in the router. It is sometimes called a supervisory processor.

**TTL**—time-to-live. A parameter you can set that indicates the maximum number of hops a packet should take to reach its destination.

**TLV**—type, length, values. A block of information included in a Cisco Discovery Protocol address.

**UDP**—User Datagram Protocol. Connectionless transport layer protocol in the TCP/IP protocol stack. UDP is a simple protocol that exchanges datagrams without acknowledgments or guaranteed delivery, so error processing and retransmission must be handled by other protocols. UDP is defined in RFC 768.

**XDR**—eXternal Data Representation. Standard for machine-independent data structures developed by Sun Microsystems. Used to transport messages between the Route Processor (RP) and the line card.

# MPLS Enhancements to Interfaces MIB

---

**First Published: March 15, 2004**

**Last Updated: April 18, 2008**

This document describes the Multiprotocol Label Switching (MPLS) enhancements to the existing Interfaces MIB (RFC 2233) to support an MPLS layer. This layer provides counters and statistics specifically for MPLS.

## History for MPLS Enhancements to Interfaces MIB Feature

| Release     | Modification                                                    |
|-------------|-----------------------------------------------------------------|
| 12.0(23)S   | This feature was introduced.                                    |
| 12.3(8)T    | This feature was integrated into Cisco IOS Release 12.3(8)T.    |
| 12.2(33)SRA | This feature was integrated into Cisco IOS Release 12.2(33)SRA. |
| 12.2(33)SXH | This feature was integrated into Cisco IOS Release 12.2(33)SXH. |
| 12.2(33)SB  | This feature was integrated into Cisco IOS Release 12.2(33)SB.  |

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for MPLS Enhancements to Interfaces MIB

- SNMP must be installed and enabled on the label switching routers (LSRs)
- MPLS must be enabled on the LSRs
- MPLS IP must be enabled on an interface or an MPLS traffic engineering (TE) tunnel enabled on an interface

## Restrictions for MPLS Enhancements to Interfaces MIB

- Link up and link down traps for the MPLS layer are not supported in this release. Link up and link down traps for the MPLS layer are supported in Cisco IOS Releases 12.2(33)SXH, 12.2(33)SB, 12.2(33)SRB and later releases.
- Write capability using the SNMP SET command is not supported for the MPLS layer in this release.
- Some counters, including discard and multicast, increment on the underlying physical layer; therefore, they equal 0 because they never reach the MPLS layer.
- Starting in Cisco IOS Release 12.4, the high-capacity counters for the MPLS layer interfaces of the Interfaces MIB contain 64 bits of counter data. In previous releases, the high capacity counters displayed 32 bits of counter data.

The following MIB objects are affected:

- ifHCInOctets
- ifHCOctets
- ifHCInUcastPkts
- ifHCOctetsUcastPkts

When the 64-bit values are less than the value of 232, the 32-bit and 64-bit values are identical.

After the counter increases to more than 232, the counters are different; the 64-bit value is computed by the following formula:

$$X * (232) + Y$$

where:

- X is the number of times the 32-bit counter has rolled.
- Y is the residual value of the counter after the roll occurred. The Y value equals the 32-bit value.

When the high-capacity counter values are compared to their 32-bit values, there is a period of time that the counter values are not equal. The 64-bit values lag the 32-bit values when the counters poll the 32-bit hardware counters and computing the correct counter value. During the polling and computation interval, the following high-capacity counter values counters might be inconsistent:

- ifInOctets
- ifOutOctets
- ifInUcastPkts
- ifOutUcastPkts

The inconsistent values can occur if traffic is constantly flowing over an interface and a MIB walk is performed. The 32-bit value is correct at that moment. The 64-bit value lags slightly, because of the polling computations needed to generate it. Once traffic stops flowing over the interface, and a polling period has passed, the two counters are identical and correct.

The lag time depends on the following factors:

- The polling interval used by the Interfaces MIB. The less time the polling interval takes, the more accurate the value is.
- The size of the Interfaces MIB. A large MIB takes a long time to walk and might affect the values found at that instant.
- The number of computations needed to generate the 64-bit value. The number of MPLS-enabled interfaces increases the number of 64-bit counter values that need to be computed.

## Information About MPLS Enhancements to Interfaces MIB

To configure the MPLS Enhancements to Interfaces MIB, you need to understand the following concepts:

- [Feature Design of the MPLS Enhancements to Interfaces MIB, page 3](#)
- [Interfaces MIB Scalar Objects, page 5](#)
- [Stacking Relationships for MPLS Layer Interfaces, page 5](#)
- [Stacking Relationships for Traffic Engineering Tunnels, page 6](#)
- [MPLS Label Switching Router MIB Enhancements, page 7](#)
- [Benefits of the MPLS Enhancements to Interfaces MIB, page 8](#)

## Feature Design of the MPLS Enhancements to Interfaces MIB

The Interfaces MIB (IF MIB) provides an SNMP-based method for managing interfaces. Each entry in the IF MIB establishes indexing, statistics, and stacking relationships among underlying physical interfaces, subinterfaces, and Layer 2 protocols that exist within Cisco IOS software.

The enhancements add an MPLS layer to the IF MIB as a Layer 2 protocol to provide statistics for traffic encapsulated as MPLS on an interface. In this structure, MPLS-specific data such as MPLS-encapsulated traffic counters and the MPLS maximum transmission unit (MTU) resides on top of the underlying physical or virtual interface to allow separation from non-MPLS data.

The enhancements also allow you to display indexing, statistics, and stacking relationships using the `ifStackTable`. MPLS layer interfaces are stacked above the underlying physical or virtual interface that is actually forwarding the MPLS traffic. MPLS traffic engineering tunnels are then stacked above those MPLS layers.

The IF MIB supports several types of interfaces. A virtual interface that provides protocol statistics for MPLS-encapsulated traffic has been added. This interface is stacked above real Cisco IOS interfaces or subinterfaces, such as Ethernet (et0) or ATM (at1/1.1).

Cisco IOS software creates a corresponding MPLS layer above each interface capable of supporting MPLS when the MPLS encapsulation is enabled by issuing the **mpls ip** interface configuration command.

You can also create the interface layer if you enable MPLS TE by using the **mpls traffic-eng tunnels** command in interface configuration mode.

**Note**

You must also issue these commands in global configuration mode for MPLS IP or MPLS TE to be enabled.

An IF MIB entry is created when you enable either MPLS IP or MPLS TE tunnels on an interface; the entry is removed when you disable both MPLS IP and MPLS TE.

## ifStackTable Objects

Table 1 defines the ifStackTable objects.

**Table 1** *ifStackTable Objects and Definitions*

| Object             | Definition                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ifStackHigherLayer | <p>The value of ifIndex corresponding to the higher sublayer of the relationship; that is, the sublayer that runs on top of the sublayer identified by the corresponding instance of the ifStackLowerLayer.</p> <p><b>Note</b> Index objects are not accessible in a MIB walk. This value is part of the object identifier (OID) for every object in the ifStackTable.</p> |
| ifStackLowerLayer  | <p>The value of ifIndex corresponding to the lower sublayer of the relationship; that is, the sublayer that runs below the sublayer identified by the corresponding instance of the ifStackHigherLayer.</p> <p><b>Note</b> Index objects are not accessible in a MIB walk. This value is part of the OID for every object in the ifStackTable.</p>                         |
| ifStackStatus      | Used to create and delete rows in the ifStackTable; status is always active(1) for MPLS.                                                                                                                                                                                                                                                                                   |

## ifRcvAddressTable Objects

Table 2 defines the ifRcvAddressTable objects.

**Note**

Entries for the MPLS layer do not appear in the ifRcvAddressTable.

**Table 2** *ifRcvAddressTable Objects and Descriptions*

| Object              | Definition                                                                                                                                                                                                                        |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ifRcvAddressAddress | An address for which the system accepts packets and frames on this entry's interface.<br><br><b>Note</b> Index objects are not accessible in a MIB walk. This value is part of the OID for every object in the ifRcvAddressTable. |
| ifRcvAddressStatus  | Used to create and delete rows in the ifRcvAddressTable.                                                                                                                                                                          |
| ifRcvAddressType    | Type of storage used for each entry in the ifRcvAddressTable.                                                                                                                                                                     |

## Interfaces MIB Scalar Objects

The IF MIB supports the following scalar objects:

- **ifStackLastChange**—The value of sysUpTime at the time of the last change of the entire interface stack. A change of the interface stack is defined to be any creation, deletion, or change in value of any instance of ifStackStatus. If the interface stack has been unchanged since the last reinitialization of the local network management subsystem, then this object contains a zero value.
- **ifTableLastChange**—The value of sysUpTime at the time of the last creation or deletion of an entry in the ifTable. If the number of entries has been unchanged since the last reinitialization of the local network management subsystem, then this object contains a zero value.

## Stacking Relationships for MPLS Layer Interfaces

The ifStackTable within the IF MIB provides a conceptual stacking relationship between the interfaces and subinterfaces represented as entries in the ifTable.

The ifStackTable is indexed like a linked list. Each entry shows a relationship between two interfaces providing the ifIndexes of the upper and the lower interface. The entries chain together to show the entire stacking relationship. Each entry links with one another until the stack terminates with an ifIndex of 0 at the highest and lowest ends of the stack. For example, in [Figure 1](#), the indexes .10.5 show that ifIndex 10 is stacked upon ifIndex 5. There are 0 entries at the highest and lowest ends of the stack; in [Figure 1](#), the indexes .0.15 and .72.0 are the highest and lowest ends of the stack, respectively.

Figure 1 Sample ATM Stacking Relationship in the ifStackTable

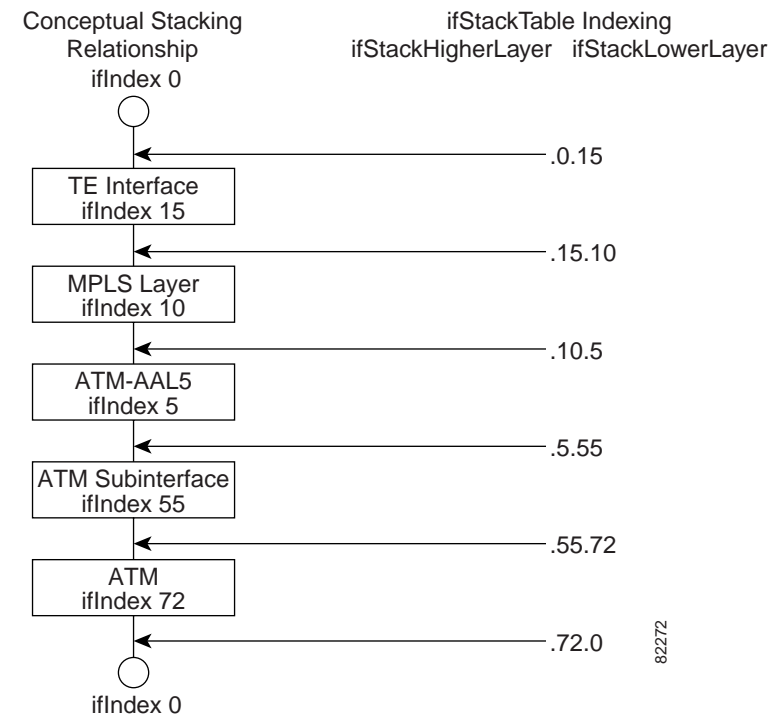

Table 3 describes the indexing of the ifStackTable for the layer relationships shown in Figure 1.

Note

The order of the entries in Table 3 may not be the same as that seen in the MIB walk, which has to follow SNMP ordering rules.

Table 3 Layer Relationships

| Layer Relationship (in Descending Order)     | ifStackHigherLayer/ifStackLowerLayer |
|----------------------------------------------|--------------------------------------|
| TE interface as top layer                    | .0.15                                |
| TE interface stacked upon MPLS layer         | .15.10                               |
| MPLS layer stacked upon ATM-AAL5             | .10.5                                |
| ATM-AAL5 layer stacked upon ATM subinterface | .5.55                                |
| ATM subinterface stacked upon ATM            | .55.72                               |
| ATM as bottom layer                          | .72.0                                |

## Stacking Relationships for Traffic Engineering Tunnels

MPLS TE tunnels are represented in Cisco IOS software and the IF MIB as virtual interfaces. When properly signaled, TE tunnels pass traffic through MPLS over a physical interface. This process dictates that a TE tunnel is to be stacked on an MPLS layer that is stacked on an underlying interface.

TE tunnels can also change paths in response to different error or network conditions. These changes are instigated by using the RSVP-TE signaling protocol. When a change occurs, a tunnel can switch to a different MPLS interface. If no signaling path exists, no paths will be chosen and thus no MPLS interface will be used.

Because a TE tunnel is represented as an IF MIB ifTable entry, the ifStackTable also contains an entry corresponding to the TE tunnel. If the TE tunnel is successfully signaled, the ifStackTable also contains a link between the tunnel interface and one MPLS interface. Note that because it is possible for a TE tunnel to not have a corresponding signaled path, it is thus possible for a TE tunnel's ifStackTable entry to not have a corresponding lower layer. In this case, the lower layer variable contains the value of 0.

Figure 2 shows a TE tunnel before (left) and after (right) being rerouted and the effect on the ifStackTable. When ifIndex 2 fails, the TE tunnel is rerouted through ifIndex 1, the 15.2 entry is removed from the ifStackTable, and the 15.1 entry is added.

**Figure 2** Sample TE Tunnel Stacking Relationship

## MPLS Label Switching Router MIB Enhancements

All of the ifIndex references in the MPLS-LSR-MIB tables have changed from the ifIndex of the underlying physical or virtual interface to the ifIndex of the MPLS layer.

Table 4 shows the specific changes.

**Table 4** MPLS-LSR-MIB ifIndex Objects Enhanced

| Table                                                       | ifIndex                |
|-------------------------------------------------------------|------------------------|
| MPLS interface configuration table (mplsInterfaceConfTable) | mplsInterfaceConfIndex |
| MPLS in-segment table (mplsInSegmentTable)                  | mplsInSegmentIfIndex   |
| MPLS cross-connect table (mplsXCTable)                      | mplsInSegmentIfIndex   |
| MPLS out-segment table (mplsOutSegmentTable)                | mplsOutSegmentIfIndex  |

The following objects from the mplsInterfaceConfTable are affected:

- `mplsInterfaceOutPackets`—Count only MPLS-encapsulated out packets
- `mplsInterfaceInPackets`—Count only MPLS-encapsulated in packets

## Benefits of the MPLS Enhancements to Interfaces MIB

### Improved Accounting Capability

By viewing the MPLS layer, you get MPLS-encapsulated traffic counters that do not include non-MPLS encapsulated traffic (for example, IP packets). Therefore, the counters are more useful for MPLS-related statistics.

### TE Tunnel Interfaces

For TE tunnel interfaces, the stacking relationship reflects the current underlying MPLS interface that is in use and dynamically changes as TE tunnels reoptimize and reroute.

### MPLS-Specific Information

The MPLS layer shows MPLS-specific information including the following:

- If MPLS is enabled
- MPLS counters
- MPLS MTU
- MPLS operational status

## How to Configure MPLS Enhancements to Interfaces MIB

This section contains the following procedures:

- [Enabling the SNMP Agent, page 8](#) (required)
- [Configuration Examples for the MPLS Enhancements to Interfaces MIB, page 10](#) (optional)

## Enabling the SNMP Agent

Perform the following task to enable the SNMP agent.

### SUMMARY STEPS

1. `enable`
2. `show running-config`
3. `configure terminal`
4. `snmp-server community string [view view-name] [ro] [number]`
5. `end`
6. `write memory`

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                |
| Step 2 | <b>show running-config</b><br><br><b>Example:</b><br>Router# show running-config                                                                                                      | Displays the running configuration of the router so that you can determine if an SNMP agent is already running on the device.<br><br>If no SNMP information is displayed, continue with the next step.<br><br>If any SNMP information is displayed, you can modify the information or change it as desired.                                                                                                     |
| Step 3 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                        | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                               |
| Step 4 | <b>snmp-server community</b> <i>string</i> [ <b>view</b> <i>view-name</i> ] [ <b>ro</b> ] [ <i>number</i> ]<br><br><b>Example:</b><br>Router(config)# snmp-server community public ro | Configures read-only (ro) community strings for the MPLS Label Distribution Protocol (LDP) MIB. <ul style="list-style-type: none"> <li>The <i>string</i> argument functions like a password, permitting access to SNMP functionality on label switch routers (LSRs) in an MPLS network.</li> <li>The optional <b>ro</b> keyword configures read-only (ro) access to the objects in the MPLS LDP MIB.</li> </ul> |
| Step 5 | <b>end</b><br><br><b>Example:</b><br>Router(config)# end                                                                                                                              | Exits to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                  |
| Step 6 | <b>write memory</b><br><br><b>Example:</b><br>Router# write memory                                                                                                                    | Writes the modified SNMP configuration into NVRAM of the router, permanently saving the SNMP settings.                                                                                                                                                                                                                                                                                                          |
| Step 7 | <b>show running-config</b><br><br><b>Example:</b><br>Router# show running-config                                                                                                      | Displays the running configuratoin of the router so that you can determine if an SNMP agent is already running on the device.<br><br>If you see any snmp-server statements, SNMP has been enabled on the router.<br><br>If any SNMP information is displayed, you can modify the information or change it as desired.                                                                                           |

# Configuration Examples for the MPLS Enhancements to Interfaces MIB

This section provides the following configuration examples:

- [MPLS Enhancements to Interfaces MIB: Examples, page 10](#)

## MPLS Enhancements to Interfaces MIB: Examples

The following example shows how to enable an SNMP agent:

```
Router# configure terminal  
Router(config)# snmp-server community
```

In the following example, SNMPv1 and SNMPv2C are enabled. The configuration permits any SNMP manager to access all objects with read-only permissions using the community string *public*.

```
Router(config)# snmp-server community public
```

In the following example, read-only access is allowed for all objects to members of access list 4 that specify the comaccess community string. No other SNMP managers have access to any objects.

```
Router(config)# snmp-server community comaccess ro 4
```

## Additional References

The following sections provide references related to the MPLS Enhancements to Interfaces MIB feature.

# Glossary

**ATM**—Asynchronous Transfer Mode. The international standard for cell relay in which multiple service types (such as voice, video, or data) are conveyed in fixed-length (53-byte) cells. Fixed-length cells allow cell processing to occur in hardware, thereby reducing transit delays. ATM is designed to take advantage of high-speed transmission media, such as E3, SONET, and T3.

**ATM-AAL5**—ATM adaptation layer 5. One of four AALs recommended by the ITU-T. AAL5 supports connection-oriented variable bit rate (VBR) services and is used predominantly for the transfer of classical IP over ATM and LAN emulation (LANE) traffic. AAL5 uses simple and efficient AAL (SEAL) and is the least complex of the current AAL recommendations. It offers low bandwidth overhead and simpler processing requirements in exchange for reduced bandwidth capacity and error-recovery capability.

**encapsulation**—Wrapping of data in a particular protocol header. For example, Ethernet data is wrapped in a specific Ethernet header before network transit. Also, when bridging dissimilar networks, the entire frame from one network is simply placed in the header used by the data link layer protocol of the other network.

**IETF**—Internet Engineering Task Force. A task force (consisting of more than 80 working groups) that is developing standards for the Internet and the IP suite of protocols.

**interface**—The boundary between adjacent layers of the ISO model.

**label**—A short, fixed-length identifier that is used to determine the forwarding of a packet.

**label switching**—A term used to describe the forwarding of IP (or other network layer) packets using a label swapping algorithm based on network layer routing algorithms. The forwarding of these packets uses the exact match algorithm and rewrites the label.

**LSR**—label switching router. A device that forwards MPLS packets based on the value of a fixed-length label encapsulated in each packet.

**MIB**—Management Information Base. A database of network management information that is used and maintained by a network management protocol such as SNMP. The value of a MIB object can be changed or retrieved by means of SNMP commands, usually through a network management system. MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

**MPLS**—Multiprotocol Label Switching. A method for forwarding packets (frames) through a network. It enables routers at the edge of a network to apply labels to packets (frames). ATM switches or existing routers in the network core can switch packets according to the labels with minimal lookup overhead.

**MPLS interface**—An interface on which MPLS traffic is enabled.

**MTU**—maximum transmission unit. Maximum packet size, in bytes, that a particular interface can handle.

**NMS**—network management system. System responsible for managing at least part of a network. An NMS is generally a reasonably powerful and well-equipped computer, such as an engineering workstation. NMSs communicate with agents to help keep track of network statistics and resources.

**OID**—object identifier. Values are defined in specific MIB modules. The Event MIB allows you or an NMS to watch over specified objects and to set event triggers based on existence, threshold, and Boolean tests. An event occurs when a trigger is fired; this means that a specified test on an object returns a value of true. To create a trigger, you or an NMS configures a trigger entry in the `mteTriggerTable` of the Event MIB. This trigger entry specifies the OID of the object to be watched. For each trigger entry type, corresponding tables (existence, threshold, and Boolean tables) are populated with the information required for carrying out the test. The MIB can be configured so that when triggers are activated (fired) either an SNMP Set is performed, a notification is sent out to the interested host, or both.

**SNMP**—Simple Network Management Protocol. A management protocol used almost exclusively in TCP/IP networks. SNMP provides a means for monitoring and controlling network devices, and for managing configurations, statistics collection, performance, and security.

**traffic engineering tunnel**—A label-switched tunnel that is used for traffic engineering. Such a tunnel is set up through means other than normal Layer 3 routing; it is used to direct traffic over a path different from the one that Layer 3 routing could cause the tunnel to take.

**trap**—A message sent by an SNMP agent to a network management station, console, or terminal, indicating that a significant event occurred. Traps are less reliable than notification requests, because the receiver does not send an acknowledgment when it receives a trap. The sender cannot determine if the trap was received.

**tunnel**—A secure communication path between two peers, such as routers.

# MPLS Label Switching Router MIB

The MPLS Label Switching Router MIB (MPLS-LSR-MIB) allows you to use the Simple Network Management Protocol (SNMP) to remotely monitor a label switch router (LSR) that is using the Multiprotocol Label Switching (MPLS) technology.

Scalability enhancements provided in the Cisco IOS 12.0(28)S release reduce the size of any MIB walk and improve the usability of the MPLS-LSR-MIB.

ort the Internet Engineering Task Force (IETF) draft Version 8.

**Note** In Cisco IOS Release 12.2(33)SRB and Cisco IOS Release 12.2(33)SB, this MIB has been deprecated and replaced by MPLS-LSR-STD-MIB (RFC 3813). In those two releases and in later images, the entire MIB can be referenced by the name `mplsLsrMIB` for purposes of the SNMP `server excluded/included` command. If other MIB object names need to be referenced on the router, they must be referenced by `MPLS-LSR-MIB::<table_entry_name>`.

## Feature History for MPLS Label Switching Router MIB

| Release     | Modification                                                                                                              |
|-------------|---------------------------------------------------------------------------------------------------------------------------|
| 12.0(14)ST  | This feature was introduced on Cisco IOS Release 12.0(14)ST                                                               |
| 12.2(2)T    | This feature was integrated into Cisco IOS Release 12.2(2)T.                                                              |
| 12.0(22)S   | This feature was implemented on the Cisco 12000 series routers and integrated into Cisco IOS Release 12.0(22)S.           |
| 12.2(14)S   | This feature was integrated into Cisco IOS Release 12.2(14)S and implemented on Cisco 7200 and Cisco 7500 series routers. |
| 12.2(25)S   | This feature was updated to work in the MPLS High Availability environment with the Cisco 7500 series routers.            |
| 12.0(28)S   | This feature was updated to include scalability enhancements in Cisco IOS Release 12.0(28)S.                              |
| 12.2(33)SRB | This MIB has been deprecated and replaced by MPLS-LSR-STD-MIB (RFC 3813).                                                 |
| 12.2(33)SB  | This MIB has been deprecated and replaced by MPLS-LSR-STD-MIB (RFC 3813).                                                 |

## Information About MPLS Label Switching Router MIB

The MPLS-LSR-MIB contains managed objects that support the retrieval of label switching information from a router. The MIB is based on Revision 05 of the IETF MPLS-LSR-MIB. The MPLS-LSR-MIB mirrors a portion of the Cisco MPLS subsystem; specifically, it mirrors the Label Forwarding Information Base (LFIB). This implementation enables a network administrator to get information on the status, character, and performance of the following:

- MPLS-capable interfaces on the LSR
- Incoming MPLS segments (labels) at an LSR and their associated parameters
- Outgoing segments (labels) at an LSR and their associated parameters

In addition, the network administrator can retrieve the status of cross-connect table entries that associate MPLS segments with each other.

[Figure 1](#) shows the association of the cross-connect table with incoming and outgoing segments (labels).

**Figure 1** *Label Forwarding with the Cross-Connect Table*

**Note**

The out-segment table does not display “no label” entries. Labels that are displayed as “POP” are the special MPLS label 3.

The notation used in the MPLS-LSR-MIB follows the conventions defined in Abstract System Notation One (ASN.1). ASN.1 defines an Open System Interconnection (OSI) language used to describe data types apart from particular computer structures and presentation techniques. Each object in the MIB incorporates a DESCRIPTION field that includes an explanation of the object’s meaning and usage, which, together with the other characteristics of the object (SYNTAX, MAX-ACCESS, and INDEX) provides sufficient information for management application development, as well as for documentation and testing.

The MPLS-LSR-MIB represents an ASN.1 notation reflecting an idealized MPLS LSR.

A network administrator can access the entries (objects) in the MPLS-LSR-MIB by means of any SNMP-based network management system (NMS). The network administrator can retrieve information in the MPLS-LSR-MIB using standard SNMP **get** and **getnext** operations.

Typically, SNMP runs as a low-priority process. The response time for the MPLS-LSR-MIB is expected to be similar to that for other MIBs. The size and structure of the MIB and other MIBs in the system influence response time when you retrieve information from the management database. Traffic through the LSR also affects SNMP performance. The busier the switch is with forwarding activities, the greater the possibility of lower SNMP performance.

## MPLS-LSR-MIB Elements

The top-level components of the MPLS-LSR-MIB consist of

- Tables and scalars (mplsLsrObjects)
- Traps (mplsLsrNotifications and mplsLsrNotifyPrefix)
- Conformance (mplsLsrConformance)

This Cisco implementation does not support the notifications defined in the MIB, nor does it support the labelStackTable or the trafficParamTable.

## MPLS-LSR-MIB Tables

The Cisco implementation of the MPLS-LSR-MIB supports four main tables:

- Interface configuration
- In-segment
- Out-segment
- Cross-connect

The MIB contains three supplementary tables to supply performance information. This implementation does not support the label stack and traffic parameter tables.

The following sections list the MPLS-LSR-MIB tables (main and supplementary), their functions, table objects that are supported, and table objects that are *not* supported.

### **MPLS interface configuration table (mplsInterfaceConfTable)**

Provides information for each MPLS-capable interface on an LSR.

Supports:

- A unique interface index or zero
- Minimum and maximum values for an MPLS label received on the interface
- Minimum and maximum values for an MPLS label sent from the interface
- A value for an MPLS label sent from the interface
- Per platform (0) or per interface (1) setting
- The storage type

Does not support:

- The total usable bandwidth on the interface
- The difference between the total usable bandwidth and the bandwidth in use

#### **MPLS interface performance table (mplsInterfacePerfTable)**

Augments the MPLS interface configuration table.

Supports:

- The number of labels in the incoming direction in use
- The number of top-most labels in outgoing label stacks in use

Does not support:

- The number of top-most labels in outgoing label stacks in use
- The number of labeled packets discarded because no cross-connect entries exist
- The number of outgoing MPLS packets requiring fragmentation for transmission

#### **MPLS in-segment table (mplsInSegmentTable)**

Contains a description of incoming segments (labels) at an LSR and their associated parameters.

Administrative and operational status objects for this table control packet transmission. If administrative and operational status objects are down, the LSR does not forward packets. If these status objects are up, the LSR forwards packets.

Supports:

- A unique index identifier
- The incoming label
- The number of labels to pop from the incoming segment
- An address family number from the Internet Assigned Number Authority (IANA)
- A segment cross-connect entry association
- The segment owner
- The storage type
- The administrative status
- The operational status

#### **Note**

The administrative status and operational status are always up for inSegments in the Cisco implementation. Otherwise, these entries do not appear in the table.

Does not support:

- A pointer to a traffic parameter table entry (set to the default 0.0)

#### **MPLS in-segment performance table (mplsInSegmentPerfTable)**

Augments the MPLS in-segment table, providing performance information and counters for incoming segments on an LSR.

Supports:

- The number of 32-bit octets received
- The number of 64-bit octets received
- The time of the last system failure that corresponded to one or more incoming segment discontinuities

#### **Note**

---

The lastFailure parameter is set to zero because it has no meaning in the Cisco implementation.

---

Does not support:

- The total number of packets received
- The number of packets with errors
- The number of labeled packets discarded with no errors

#### **MPLS out-segment table (mplsOutSegmentTable)**

Contains a description of outgoing segments from an LSR and their associated parameters.

Administrative and operational status objects for this table control packet transmission. If administrative and operational status objects are down, the LSR does not forward packets. If these values are up, the LSR forwards packets.

Supports:

- A unique index identifier
- An interface index of the outgoing interface
- An indication of whether or not a top label is pushed onto the outgoing packet's label stack
- The label to push onto the outgoing packet's label stack (if the previous value is true)
- The next hop address type
- The IPv4 address of the next hop
- The segment cross-connect entry association
- The segment owner
- The storage type
- The administrative status
- The operational status

#### **Note**

---

The administrative and operational status entries are always up in the Cisco implementation. Otherwise, the administrative and operational status entries do not appear in the table.

---

Does not support:

- An IPv6 address of the next hop
- A pointer to a traffic parameter table entry (set to the default 0.0)

#### **MPLS out-segment performance table (mplsOutSegmentPerfTable)**

Augments the MPLS out-segment table, providing performance information and counters for outgoing segments on an LSR.

Supports:

- The number of 32-bit octets sent
- The number of 64-bit octets sent
- The time of the last system failure that corresponded to one or more outgoing segment discontinuities

Does not support:

- The number of packets sent
- The number of packets that could not be sent because of errors
- The number of packets discarded with no errors

#### **MPLS cross-connect table (mplsXCTable)**

Associates inSegments (labels) with outSegments (labels) to show the manager how the LSR is currently swapping these labels.

A row in this table consists of one cross-connect entry that is indexed by the cross-connect index, the interface index of the incoming segment, the incoming label, and the out-segment index.

The administrative and operational objects for this table control packet forwarding to and from a cross-connect entry (XCEntry). The administrative status and operational status are always up in the Cisco implementation. Otherwise, the LSR would not forward packets.

Supports:

- A unique index identifier for a group of cross-connect segments
- A label switched path (LSP) to which the cross-connect entry belongs
- An index to the MPLS label stack table that identifies the stack of labels to be pushed under the top label
- An indication whether or not to restore the cross-connect entry after a failure (the default value is false)
- The cross-connect owner
- The storage type
- The administrative status (if up)
- The operational status (if up)

#### **Note**

The administrative status and operational status are always up in the Cisco implementation. Otherwise, these status entries do not appear in the table.

Does not support:

- Tunnel IDs as label switched path (LSP) ID objects

## Information from Scalar Objects

The MPLS-LSR-MIB supports several scalar objects. In the Cisco implementation of the MIB, the following scalar objects are hard-coded to the value indicated and are read-only objects:

- `mplsOutSegmentIndexNext (0)`—The value for the out-segment index when an LSR creates a new entry in the MPLS out-segment table. The 0 indicates that this is not implemented because modifications to this table are not allowed.
- `mplsXCTIndexNext (0)`—The value for the cross-connect index when an LSR creates an entry in the MPLS cross-connect table. The 0 indicates that no unassigned values are available.
- `mplsMaxLabelDepth(2)`—The value for the maximum stack depth.
- `mplsLabelStackIndexNext (0)`—The value for the label stack index when an LSR creates entries in the MPLS label stack table. The 0 indicates that no unassigned values are available.
- `mplsTrafficParamIndexNext (0)`—The value for the traffic parameter index when an LSR creates entries in the MPLS traffic parameter table. The 0 indicates that no unassigned values are available.

The following scalar objects do not contain information for the MPLS-LSR-MIB and are coded as false:

- `mplsInSegmentTrapEnable (false)`—In-segment traps are not sent when this value is false.
- `mplsOutSegmentTrapEnable (false)`—Out-segment traps are not sent when this value is false.
- `mplsXCTrapEnable (false)`—Cross-connect traps are not sent when this value is false.

No trap information exists to support the MIB. Therefore, the following traps are not supported:

- `mplsInSegmentUp`
- `mplsInSegmentDown`
- `mplsOutSegmentUp`
- `mplsOutSegmentDown`
- `mplsXCUp`
- `mplsXCDown`

## Linking Table Elements

In the cross-connect table, cross-connect entries associate incoming segments and interfaces with outgoing segments and interfaces. The following objects index the cross-connect entry:

- **Cross-connect index**—A unique identifier for a group of cross-connect entries in the cross-connect table. In the Cisco implementation, this value is always the same as that for the `outSegmentIndex`, unless there is no label or if the label has been popped.
- **Interface index of the in-segment**—A unique index for an entry in the in-segment table that represents an incoming MPLS interface. The value 0 means platform wide, for any entries that apply to all interfaces.
- **Incoming label**—An entry in the in-segment table that represents the label on the incoming packet.
- **Out-segment index**—A unique identifier for an entry in the out-segment table that contains a top label for the outgoing packet's label stack and an interface index of the outgoing interface.

Figure 2 shows the links between the in-segment and the out-segment in the cross-connect table.

**Figure 2** *Cross-Connect Table Links*

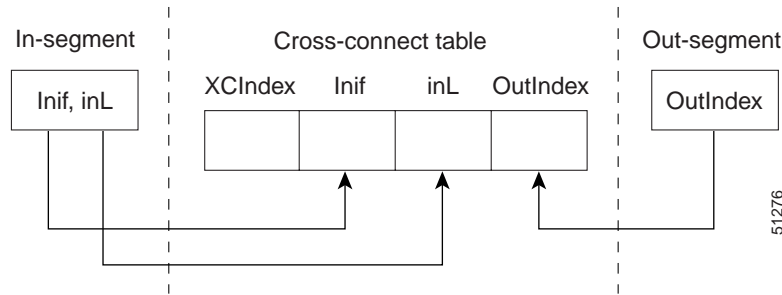

Table 1 shows the cross-connect table links you might see in the output from SNMP **get** operations on the MPLS-LSR-MIB objects that index a cross-connect entry. These objects include

- In-Segment Values—mplsInSegmentIfIndex and mplsInSegmentLabel
- Cross-Connect Entry—mplsXCIndex
- Out-Segment Values—mplsOutSegmentIndex

**Table 1** *MPLS LSR Output Showing Cross-Connect Table Links*

| In-Segment Values     | Cross-Connect Entry                        | Out-Segment Values              |
|-----------------------|--------------------------------------------|---------------------------------|
| 0 <sup>1</sup> , 1000 | 500 <sup>2</sup> , 0, 1000, 0 <sup>2</sup> | —                               |
|                       | 501, 0, 1000, 501                          | 501 = Pop (topLabel), Eth 1/5   |
|                       | 502, 0, 1000, 502                          | 502 = Pop (topLabel), Eth, 1/1) |

1. All MPLS-enabled interfaces can receive incoming labels.
2. For this implementation of the MPLS-LSR-MIB, the cross-connect index and the out-segment index are the same. If there is no outsegment, the value will be zero.

**Note**

The OutSegmentIndex object is not the label. The label can be retrieved from the mplsOutSegmentTopLabel object.

## Interface Configuration Table and Interface MIB Links

The MPLS interface configuration table lists interfaces that support MPLS technology. An LSR creates an entry dynamically in this table for each MPLS-capable interface. An interface becomes MPLS-capable when MPLS is enabled on that interface. A non-zero index for an entry in this table points to the ifIndex for the corresponding interface entry in the ifTable of the Interfaces Group MIB.

The ifTable contains information on each interface in the network. Its definition of an interface includes any sublayers of the internetwork layer of the interface. MPLS interfaces fit into this definition of an interface. Therefore, each MPLS-enabled interface is represented by an entry in the ifTable.

The interrelation of entries in the ifTable is defined by the interfaces stack group of the Interfaces Group MIB. Figure 3 shows how the stack table might appear for MPLS interfaces. The underlying layer refers to any interface that is defined for MPLS internetworking, for example, ATM, Frame Relay, or Ethernet.

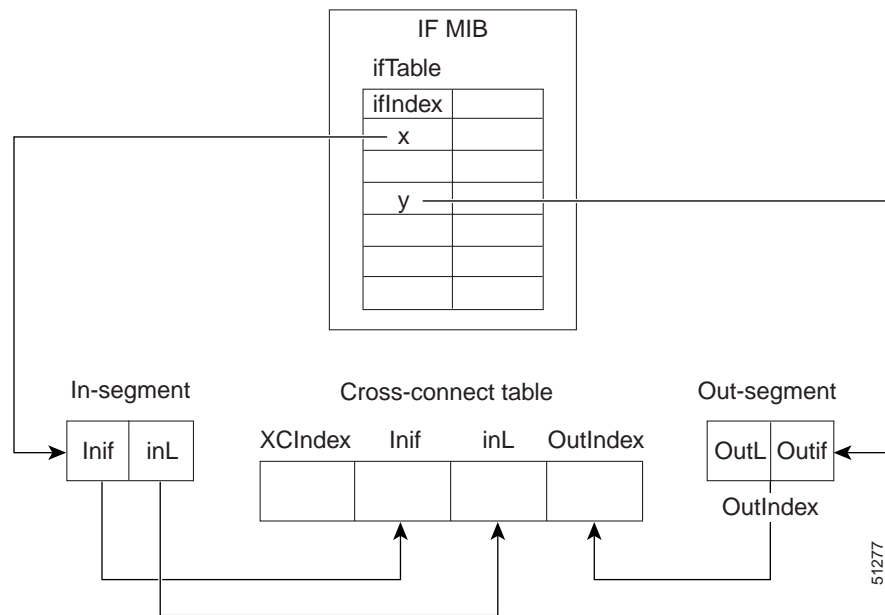

**Figure 3** *Interface Group MIB Stack Table for MPLS Interfaces*

|                                   |       |
|-----------------------------------|-------|
| MPLS-interface ifType = mpls(166) | 51273 |
| Underlying Layer . . .            |       |

**Note**

Tunnel interfaces are included in the MPLS list for the current implementation.

The incoming and outgoing packets include a reference to the interface index for the ifTable of the Interfaces Group MIB. [Figure 4](#) shows the links between MPLS-LSR-MIB objects and the Interfaces Group MIB.

**Figure 4** *MPLS-LSR-MIB and Interfaces Group MIB Links*

- For the Interfaces Group MIB (IF MIB):
  - ifTable represents the MPLS interface table.
  - ifIndex represents the index to an entry in the MPLS interface table.
- For the In-segment:
  - Inif represents the interface on the incoming segment (references an index entry in the ifTable).
  - inL represents the label on the incoming segment.
- For the Out-segment:
  - OutL represents the label on the outgoing segment.
  - Outif represents the interface on the outgoing segment (references an index entry in the ifTable).
- For the Cross-connect table:
  - XCIndex represents the index to an entry in the MPLS cross-connect table.

- Inif represents the interface on the incoming segment.
- inL represents the MPLS label on the incoming segment.
- OutIndex represents an index to an entry in the MPLS out-segment table.

## Using the MPLS-LSR-MIB

The MPLS-LSR-MIB enables you to display the contents of the MPLS Label Forwarding Information Base (LFIB). It gives you the same information that you can obtain using the CLI command **show mpls forwarding-table**.

However, the MPLS-LSR-MIB approach offers these advantages over the CLI command approach:

- A more efficient use of network bandwidth
- Greater interoperability among vendors
- Greater security (SMNP Version 3)

The following paragraphs describe the MPLS-LSR-MIB structure and show, through the use of an example, how the two approaches to the information display compare.

### MPLS-LSR-MIB Structure

MIB structure is represented by a tree hierarchy. Branches along the tree have short text strings and integers to identify them. Text strings describe object names, and integers allow computer software to encode compact representations of the names.

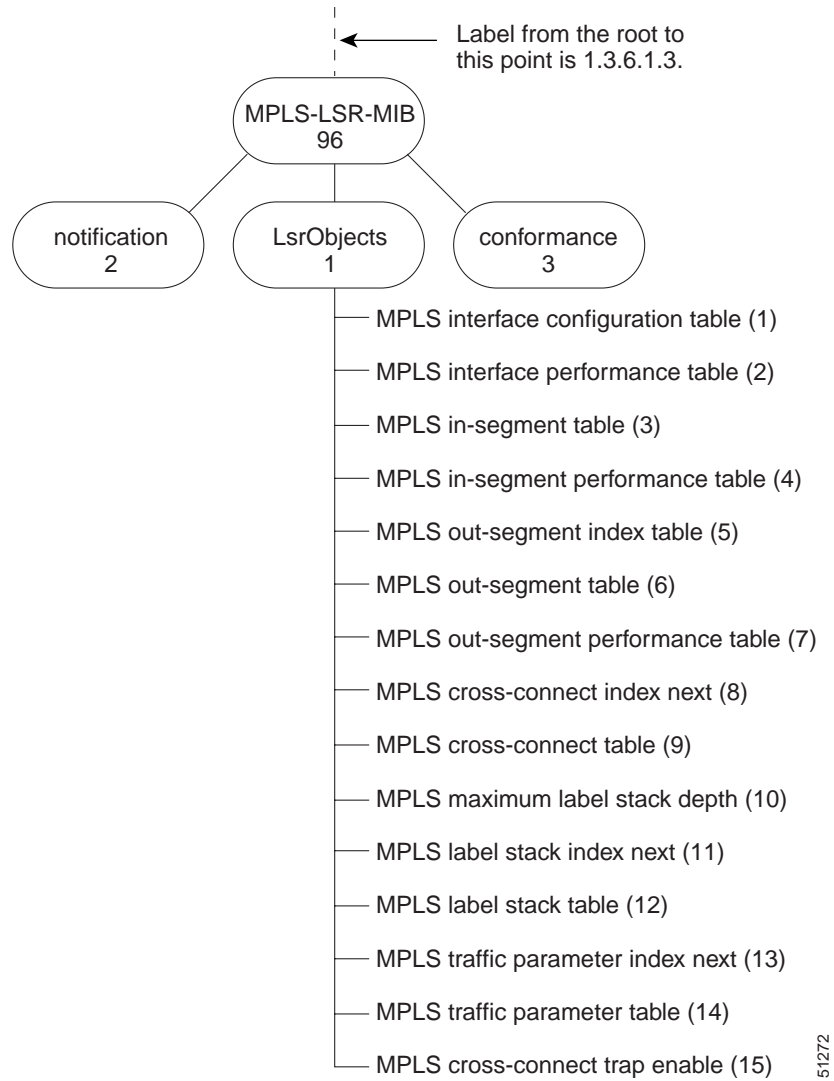

The MPLS-LSR-MIB falls on the experimental branch of the Internet MIB hierarchy. The experimental branch of the Internet MIB hierarchy is represented by the object identifier 1.3.6.1.3. This branch can also be represented by its object name *iso.org.dod.internet.experimental*. The MPLS-LSR-MIB is identified by the object name *mplsLsrMIB*, which is denoted by the number 96. Therefore, objects in the MPLS-LSR-MIB can be identified in either of the following ways:

- The object identifier—1.3.6.1.3.96.[MIB-variable]
- The object name—*iso.org.dod.internet.experimental.mplsLsrMIB.[MIB-variable]*

To display a *MIB-variable*, you enter an SNMP **get** command with an object identifier. Object identifiers are defined by the MPLS-LSR-MIB.

Figure 5 shows the position of the MPLS-LSR-MIB in the Internet MIB hierarchy.

**Figure 5** *MPLS-LSR-MIB in the Internet MIB Hierarchy*

## CLI Commands and the MPLS-LSR-MIB

The MPLS LFIB is the component of the Cisco MPLS subsystem that contains management information for LSRs. You can access this management information by means of either of the following:

- Using the **show mpls forwarding-table** CLI command
- Entering SNMP **get** commands on a network manager

The following examples show how you can gather LSR management information using both methods.

### CLI Command Output

A **show mpls forwarding-table** CLI command allows you to look at label forwarding information for a packet on a specific MPLS LSR.

Router# **show mpls forwarding-table**

| Local Tag | Outgoing Tag or VC | Prefix or Tunnel Id | Bytes Tag Switched | Outgoing interface | Next Hop    |
|-----------|--------------------|---------------------|--------------------|--------------------|-------------|
| 19        | Pop Tag            | 10.3.4.0/24         | 0                  | Et1/4              | 10.22.23.23 |
| 22        | 23                 | 14.14.14.14/32      | 0                  | AT2/0.1            | point2point |
|           | 1/36               | 14.14.14.14/32      | 0                  | AT2/0.2            | point2point |

### MPLS-LSR-MIB Output

SNMP commands on MIB objects also allow you to look at the label forwarding information for a specific MPLS LSR.

You can do a walk-through of the MIB by running a command such as **getmany -v2c public mplsLsrMIB** on a network manager where **getmany** does repeated SNMP **getnext** operations to retrieve the contents of the MPLS-LSR-MIB.

```
mplsXCOperStatus.9729.0.19.9729 = up(1)
mplsXCOperStatus.11265.0.22.11265 = up(1)
mplsXCOperStatus.11266.0.22.11266 = up(1)
```

You can continue to scan the output of the **getmany** command for the following (from the MPLS out-segment table):

- Out-segment's top label objects (mplsOutSegmentTopLabel)

```
mplsOutSegmentTopLabel.9729 = 3
mplsOutSegmentTopLabel.11265 = 23
mplsOutSegmentTopLabel.11266 = 65572
```

#### Note

65572 is 1/36 in label form (1 is the high-order 16 bits. 36 is the low-order 16 bits.)

- Out-segment's interface index (mplsOutSegmentIfIndex)

```
mplsOutSegmentIfIndex.9729 = 7
mplsOutSegmentIfIndex.11265 = 28
mplsOutSegmentIfIndex.11266 = 31
```

## Benefits

The benefits described in the following paragraphs are available to you with the MPLS-LSR-MIB.

### Troubleshooting LSR Problems

By monitoring the cross-connect entries and the associated incoming and outgoing segments, you can see which labels are installed and how they are being swapped. Use the MPLS-LSR-MIB in place of the **show mpls forwarding** CLI command.

### Monitoring of LSR Traffic Loads

By monitoring interface and packet operations on an MPLS LSR, you can identify high- and low-traffic patterns, as well as traffic distributions.

### Improvement of Network Performance

By identifying potentially high-traffic areas, you can set up load sharing to improve network performance.

### Verification of LSR Configuration

By comparing results from SNMP **get** commands and the **show mpls forwarding** CLI command, you can verify your LSR configuration.

### Displaying of Active Label Switched Paths

By monitoring the cross-connect entries and the associated incoming segments and outgoing segments, you can determine the active LSPs.

## How to Configure the MPLS LSR MIB

See the following sections for configuration tasks for the MPLS-LSR-MIB feature. Each task in the list is identified as either optional or required.

- [Enabling the SNMP Agent](#) (required)
- [Verifying That the SNMP Agent Has Been Enabled](#) (optional)

## Prerequisites

The MPLS-LSR-MIB requires the following:

- SNMP installed and enabled on the LSR
- MPLS enabled on the LSR
- 60K of memory

---

**Note** Additional capacity is not required for runtime dynamic random-access memory (DRAM).

---

## Enabling the SNMP Agent

The SNMP agent for the MPLS-LSR-MIB is disabled by default. To enable the SNMP agent, perform the following steps:

### SUMMARY STEPS

1. **enable**
2. **show running-config**
3. **configure terminal**
4. **snmp-server community** *string* [**view** *view-name*] [**ro**] [*number*]
5. **end**
6. **copy running-config startup-config**

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                        |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                                                                             |
| Step 2 | <b>show running-config</b><br><br><b>Example:</b><br>Router# show running-config                                                                                                      | Displays the running configuration of the router to determine if an SNMP agent is already running on the device.<br><br>If no SNMP information is displayed, continue with the next step.<br><br>If any SNMP information is displayed, you can modify the information or change it as desired. |
| Step 3 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                        | Enters global configuration mode.                                                                                                                                                                                                                                                              |
| Step 4 | <b>snmp-server community</b> <i>string</i> [ <b>view</b> <i>view-name</i> ] [ <b>ro</b> ] [ <i>number</i> ]<br><br><b>Example:</b><br>Router(config)# snmp-server community public ro | Configures read-only (ro) SNMP community strings.<br><br>This command enables the SNMP agent and permits any SNMP manager to access all objects with read-only permission using the community string public.                                                                                   |

|        | Command or Action                                                                                                                 | Purpose                                                                                                                                                                                                  |
|--------|-----------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 5 | <code>end</code><br><br><b>Example:</b><br><code>Router(config)# end</code>                                                       | Exits to privileged EXEC mode.                                                                                                                                                                           |
| Step 6 | <code>copy running-config startup-config</code><br><br><b>Example:</b><br><code>Router# copy running-config startup-config</code> | Copies the modified SNMP configuration into router NVRAM, permanently saving the SNMP settings.<br><br>When you are working with Cisco IOS Release 10.3 or earlier, use the <b>write memory</b> command. |

## Verifying That the SNMP Agent Has Been Enabled

To verify that the SNMP agent has been enabled, perform the following steps:

- 
- Step 1** Access the router through a Telnet session:
- ```
Prompt# telnet xxx.xxx.xxx.xxx
```
- where `xxx.xxx.xxx.xxx` represents the IP address of the target device.
- Step 2** Enter privileged mode:
- ```
Router# enable
```
- Step 3** Display the running configuration and look for SNMP information:
- ```
Router# show running-configuration
...
...
snmp-server community public RO
```
- If you see any “snmp-server” statements, SNMP has been enabled on the router.
- 

## Configuration Examples for the MPLS LSR MIB

The following example shows how to enable an SNMP agent.

```
configure terminal
snmp-server community
```

In the following example, SNMPv1 and SNMPv2C are enabled. The configuration permits any SNMP manager to access all objects with read-only permissions using the community string *public*.

```
configure terminal
snmp-server community public
```

In the following example, read-only access is allowed for all objects to members of access list 4 that specify the *comaccess* community string. No other SNMP managers have access to any objects.

```
configure terminal
snmp-server community comaccess ro 4
```

## Glossary

**cross-connect (XC)**—An association of in-segments and incoming Multiprotocol Label Switching (MPLS) interfaces to out-segments and outgoing MPLS interfaces.

**IETF**—Internet Engineering Task Force. A task force (consisting of more than 80 working groups) that is developing standards for the Internet and the IP suite of protocols.

**inSegment**—A label on an incoming packet that is used to determine the forwarding of the packet.

**Internet Engineering Task Force**—See IETF.

**label**—A short, fixed length identifier that is used to determine the forwarding of a packet.

**Label Distribution Protocol**—See LDP.

**label switched path**—See LSP.

**label switching**—Describes the forwarding of IP (or other network layer) packets by a label swapping algorithm based on network layer routing algorithms. The forwarding of these packets uses the exact match algorithm and rewrites the label.

**label switch router**—See LSR.

**LDP**—Label Distribution Protocol. A standard protocol that operates between Multiprotocol Label Switching (MPLS)-enabled routers to negotiate the labels (addresses) used to forward packets. The Cisco proprietary version of this protocol is the Tag Distribution Protocol (TDP).

**LSP**—label switched path. A sequence of hops in which a packet travels from one router to another router by means of label switching mechanisms. A label switched path can be established dynamically, based on normal routing mechanisms, or through configuration.

**LSR**—label switch router. A device that forwards Multiprotocol Label Switching (MPLS) packets based on the value of a fixed-length label encapsulated in each packet.

**Management Information Base**—See MIB.

**MIB**—Management Information Base. A database of network management information that is used and maintained by a network management protocol such as Simple Network Management Protocol (SNMP). The value of a MIB object can be changed or retrieved by means of SNMP commands, usually through a network management system. MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

**MPLS**—Multiprotocol Label Switching. A switching method that forwards IP traffic through use of a label. This label instructs the routers and the switches in the network where to forward the packets. The forwarding of MPLS packets is based on preestablished IP routing information.

**MPLS interface**—An interface on which Multiprotocol Label Switching (MPLS) traffic is enabled.

**Multiprotocol Label Switching**—See MPLS.

**notification request**—A message sent by a Simple Network Management Protocol (SNMP) agent to a network management station, console, or terminal, indicating that a significant event occurred. SNMP notification requests are more reliable than traps, because a notification request from an SNMP agent requires that the SNMP manager acknowledge receipt of the notification request. The manager replies with an SNMP response protocol data unit (PDU). If the manager does not receive a notification message from an SNMP agent, it does not send a response. If the sender (SNMP agent) never receives a response, the notification request can be sent again.

**outSegment**—A label on an outgoing packet.

**Simple Network Management Protocol**—See SNMP.

**SNMP**—Simple Network Management Protocol. A management protocol used almost exclusively in TCP/IP networks. SNMP provides a means for monitoring and controlling network devices, and for managing configurations, statistics collection, performance, and security.

**trap**—A message sent by a Simple Network Management Protocol (SNMP) agent to a network management station, console, or terminal, indicating that a significant event occurred. Traps are less reliable than notification requests, because the receiver does not send an acknowledgment when it receives a trap. The sender cannot determine if the trap was received.

# MPLS Label Distribution Protocol MIB Version 8 Upgrade

**First Published: November 13, 2000**

**Last Updated: March 06, 2009**

The MPLS Label Distribution Protocol (LDP) MIB Version 8 Upgrade feature enhances the LDP MIB to support the Internet Engineering Task Force (IETF) draft Version 8.

**Note**

In Cisco IOS Release 12.2(33)SRB and Cisco IOS Release 12.2(33)SB, this MIB has been deprecated and replaced by MPLS-LDP-STD-MIB (RFC 3815). In those two releases and in later images, the entire MIB can be referenced by the name `mplsLdpMIB` for purposes of the `SNMP server excluded/included` command. If other MIB object names need to be referenced on the router, they must be referenced by `MPLS-LDP-MIB::<table_entry_name>`.

## History for MLPS Label Distribution Protocol MIB Version 8 Update Feature

Release	Modification
12.0(11)ST	This feature was introduced to provide SNMP agent support for the MPLS LDP MIB on Cisco 7200, Cisco 7500, and Cisco 12000 series routers.
12.2(2)T	This feature was added to this release to provide SNMP agent support for the MPLS LDP MIB on Cisco 7200 and Cisco 7500 series routers.
12.0(21)ST	This feature was added to this release to provide SNMP agent and LDP notification support for the MPLS LDP MIB on Cisco 7200, Cisco 7500, and Cisco 12000 series Internet routers.
12.0(22)S	This feature (Version 1) was integrated into Cisco IOS Release 12.0(22)S.
12.0(24)S	This feature was upgraded to Version 8 in Cisco IOS Release 12.0(24)S.
12.0(27)S	Support for the MPLS VPN—VPN Aware LDP MIB feature was added.
12.2(18)S	This feature was integrated into Cisco IOS Release 12.2(18)S.
12.2(33)SRA	This feature was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH	This feature was integrated into Cisco IOS Release 12.2(33)SXH.

**Americas Headquarters:**

**Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA**

- [Additional References, page 39](#)
- [Command Reference, page 41](#)
- [Glossary, page 42](#)

## Prerequisites for MPLS LDP MIB Version 8 Upgrade

- Simple Network Management Protocol (SNMP) must be installed and enabled on the label switch routers (LSRs).
- Multiprotocol Label Switching (MPLS) must be enabled on the LSRs.
- LDP must be enabled on the LSRs.

## Restrictions for MPLS LDP MIB Version 8 Upgrade

This implementation of the MPLS LDP MIB is limited to read-only (RO) permission for MIB objects, except for MIB object *mplsLdpSessionUpDownTrapEnable*, which has been extended to be writable by the SNMP agent.

Setting this object to a value of true enables both the *mplsLdpSessionUp* and *mplsLdpSessionDown* notifications on the LSR; conversely, setting this object to a value of false disables both of these notifications.

For a description of notification events, see the [“Events Generating MPLS LDP MIB Notifications in MPLS LDP MIB Version 8 Upgrade”](#) section on page 9.

Most MPLS LDP MIB objects are set up automatically during the LDP peer discovery (hello) process and the subsequent negotiation of parameters and establishment of LDP sessions between the LDP peers.

The following tables are not implemented in this feature:

- `mplsLdpEntityFrParmsTable`
- `mplsLdpEntityConfFrLRTable`
- `mplsLdpFrameRelaySesTable`
- `mplsFecTable`
- `mplsLdpSesInLabelMapTable`
- `mplsXCsfecsTable`
- `mplsLdpSesPeerAddrTable`

## Information About MPLS LDP MIB Version 8 Upgrade

To configure MPLS LDP MIB Version 8 Upgrade, you need to understand the following concepts:

- [Feature Design of MPLS LDP MIB Version 8 Upgrade, page 3](#)
- [Enhancements in Version 8 of the MPLS LDP MIB, page 5](#)
- [Benefits of MPLS LDP MIB Version 8 Upgrade, page 5](#)

## Feature Design of MPLS LDP MIB Version 8 Upgrade

MPLS is a packet forwarding technology that uses a short, fixed-length value called a label in packets to specify the next hop for packet transport through an MPLS network by means of label switch routers (LSRs).

A fundamental MPLS principle is that LSRs in an MPLS network must agree on the definition of the labels being used for packet forwarding operations. Label agreement is achieved in an MPLS network by means of procedures defined in the LDP.

LDP operations begin with a discovery (hello) process, during which an LDP entity (a local LSR) finds a cooperating LDP peer in the network, and the two negotiate basic operating procedures. The recognition and identification of a peer by means of this discovery process results in a hello adjacency, which represents the context within which label binding information is exchanged between the local LSR and its LDP peer. LDP then creates an active LDP session between the two LSRs to effect the exchange of label binding information. When this process is carried to completion with respect to all of the LSRs in an MPLS network, the result is a label-switched path (LSP), which constitutes an end-to-end packet transmission pathway between the communicating network devices.

By means of LDP, LSRs can collect, distribute, and release label binding information to other LSRs in an MPLS network, thereby enabling the hop-by-hop forwarding of packets in the network along normally routed paths.

The MPLS LDP MIB has been implemented to enable standard, SNMP-based network management of the label switching features in Cisco IOS software. Providing this capability requires SNMP agent code to execute on a designated network management station (NMS) in the network. The NMS serves as the medium for user interaction with the network management objects in the MPLS LDP MIB.

The SNMP agent code has a layered structure that is compatible with Cisco IOS software and presents a network administrative and management interface to the objects in the MPLS LDP MIB and, thence, to the rich set of label switching capabilities supported by Cisco IOS software.

By means of an SNMP agent, you can access MPLS LDP MIB objects using standard SNMP GET operations, and you can use those objects to accomplish a variety of network management tasks. All the objects in the MPLS LDP MIB follow the conventions defined in the IETF draft MIB entitled *draft-ietf-mpls-ldp-mib-08.txt*, which defines network management objects in a structured and standardized manner. This draft MIB is evolving and is soon expected to be a standard. Accordingly, the MPLS LDP MIB will be implemented in such a way that it tracks the evolution of this IETF document.

However, slight differences exist between the IETF draft MIB and the implementation of equivalent Cisco IOS functions. As a result, some minor translations between the MPLS LDP MIB objects and the internal Cisco IOS data structures are needed. Such translations are accomplished by the SNMP agent, which runs in the background on the NMS workstation as a low-priority process.

The extensive Cisco IOS label switching capabilities provide an integrated approach to managing the large volumes of traffic carried by WANs. These capabilities are integrated into the Layer 3 network services, thus optimizing the routing of high-volume traffic through Internet service provider backbones while, at the same time, ensuring the resistance of the network to link or node failures.

Cisco IOS Release 12.0(11)ST and later releases support the following MPLS LDP MIB-related functions:

- Tag Distribution Protocol (TDP)
- Generation and sending of event notification messages that signal changes in the status of LDP sessions
- Enabling and disabling of event notification messages by means of extensions to existing SNMP CLI commands
- Specification of the name or the IP address of an NMS workstation in the operating environment to which Cisco IOS event notification messages are to be sent to serve network administrative and management purposes
- Storage of the configuration pertaining to an event notification message in NVRAM of the NMS

The structure of the MPLS LDP MIB conforms to Abstract Syntax Notation One (ASN.1), so the MIB forms a highly structured and idealized database of network management objects.

Using any standard SNMP application, you can retrieve and display information from the MPLS LDP MIB by means of standard SNMP GET and GETNEXT operations.

#### Note

Because the MPLS LDP MIB was not given an Internet Assigned Numbers Authority (IANA) experimental object identifier (OID) at the time of its implementation, Cisco chose to implement the MIB under the `ciscoExperimental` OID number, as follows:

```
ciscoExperimental
1.3.6.1.4.1.9.10
mplsLdpMIB
1.3.6.1.4.1.9.10.65
```

If the MPLS LDP MIB is assigned an IANA Experimental OID number, Cisco will replace all objects in the MIB under the `ciscoExperimental` OID and reposition the objects under the IANA Experimental OID.

## Enhancements in Version 8 of the MPLS LDP MIB

Version 8 of the MPLS LDP MIB contains the following enhancements:

- TDP support
- Upgraded objects
- New indexing that is no longer based on the number of sessions
- Multiple SNMP context support for Virtual Private Networks (VPNs)

## Benefits of MPLS LDP MIB Version 8 Upgrade

- Supports TDP and LDP
- Establishes LDP sessions between peer devices in an MPLS network
- Retrieves MIB parameters relating to the operation of LDP entities, such as:
  - Well-known LDP discovery port
  - Maximum transmission unit (MTU)
  - Proposed keepalive timer interval
  - Loop detection
  - Session establishment thresholds
  - Range of virtual path identifier/virtual channel identifier (VPI/VCI) pairs to be used in forming labels
- Gathers statistics related to LDP operations, such as error counters ([Table 5](#))
- Monitors the time remaining for hello adjacencies
- Monitors the characteristics and status of LDP peers, such as:
  - Internetwork layer address of LDP peers
  - Loop detection of the LDP peers
  - Default MTU of the LDP peer
  - Number of seconds the LDP peer proposes as the value of the keepalive interval
- Monitors the characteristics and status of LDP sessions, such as:
  - Displaying the error counters ([Table 10](#))
  - Determining the LDP version being used by the LDP session
  - Determining the keepalive hold time remaining for an LDP session
  - Determining the state of an LDP session (whether the session is active or not)
  - Displaying the label ranges ([Table 2](#)) for platform-wide and interface-specific sessions
  - Displaying the ATM parameters ([Table 3](#))

# Description of MPLS LDP MIB Elements for MPLS LDP MIB Version 8 Upgrade

LDP operations related to an MPLS LDP MIB involve the following functional elements:

- LDP entity—Relates to an instance of LDP for purposes of exchanging label spaces; describes a potential session.
- LDP peer—Refers to a remote LDP entity (that is, a nonlocal LSR).
- LDP session—Refers to an active LDP process between a local LSR and a remote LDP peer.
- Hello adjacency—Refers to the result of an LDP discovery process that affirms the state of two LSRs in an MPLS network as being adjacent to each other (that is, as being LDP peers). When the neighbor is discovered, the neighbor becomes a hello adjacency. An LDP session can be established with the hello adjacency. After the session is established, label bindings can be exchanged between the LSRs.

These MPLS LDP MIB elements are briefly described under separate headings below.

In effect, the MPLS LDP MIB provides a network management database that supports real-time access to the various MIB objects in the database. This database reflects the current state of MPLS LDP operations in the network. You can access this network management information database by means of standard SNMP commands issued from an NMS in the MPLS LDP operating environment.

The MPLS LDP MIB supports the following network management and administrative activities:

- Retrieving MPLS LDP MIB parameters pertaining to LDP operations
- Monitoring the characteristics and the status of LDP peers
- Monitoring the status of LDP sessions between LDP peers
- Monitoring hello adjacencies in the network
- Gathering statistics regarding LDP sessions

## LDP Entities

An LDP entity is uniquely identified by an LDP identifier that consists of the `mplsLdpEntityLdpId` and the `mplsLdpEntityIndex` (see [Figure 1](#)).

- The `mplsLdpEntityLdpId` consists of the local LSR ID (four octets) and the label space ID (two octets). The label space ID identifies a specific label space available within the LSR.
- The `mplsLdpEntityIndex` consists of the IP address of the peer active hello adjacency, which is the 32-bit representation of the IP address assigned to the peer LSR.

The `mplsLdpEntityProtocolVersion` is a sample object from the `mplsLdpEntityTable`.

[Figure 1](#) shows the following indexing:

- `mplsLdpEntityLdpId` = 10.10.10.10.0.0
- LSR ID = 10.10.10.10
- Label space ID = 0.0

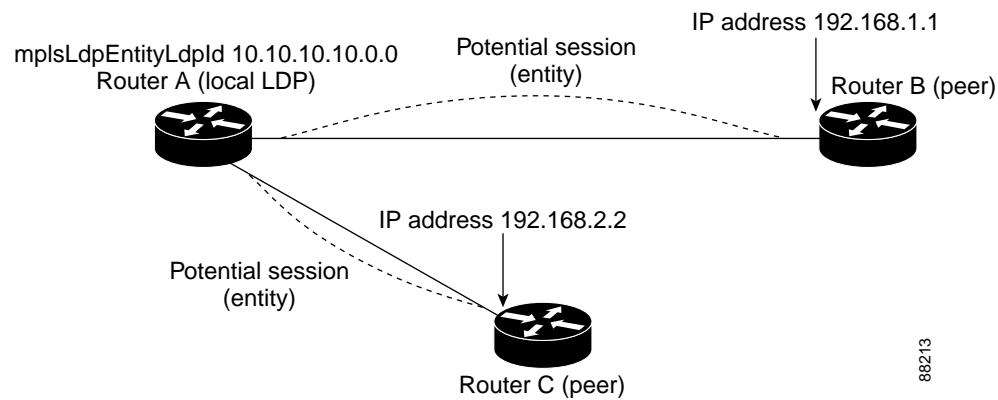

The `mplsLdpEntityLdpId` or the LDP ID consists of the LSR ID and the label space ID.

- The IP address of peer active hello adjacency or the `mplsLdpEntityIndex` = 3232235777, which is the 32-bit representation of the IP address assigned to the peer's active hello adjacency.

**Figure 1 Sample Indexing for an LDP Entity**

An LDP entity represents a label space that has the potential for a session with an LDP peer. An LDP entity is set up when a hello adjacency receives a hello message from an LDP peer.

In [Figure 2](#), Router A has potential sessions with two remote peers, Routers B and C. The mplsLdpEntityLdpId is 10.10.10.10.0.0, and the IP address of the peer active hello adjacency (mplsLdpEntityIndex) is 3232235777, which is the 32-bit representation of the IP address 192.168.1.1 for Router B.

**Figure 2 LDP Entity**

## LDP Sessions and Peers

LDP sessions exist between local entities and remote peers for the purpose of distributing label spaces. There is always a one-to-one correspondence between an LDP peer and an LDP session. A single LDP session is an LDP instance that communicates across one or more network links with a single LDP peer.

LDP supports the following types of sessions:

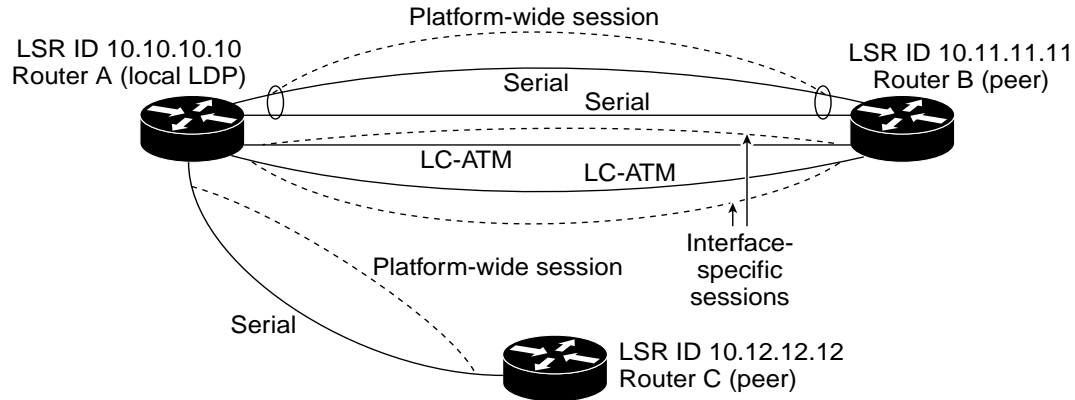

- **Interface-specific**—An interface-specific session uses interface resources for label space distributions. For example, each label-controlled ATM (LC-ATM) interface uses its own VPIs/VCIs for label space distributions. Depending on its configuration, an LDP platform can support zero, one, or more interface-specific sessions. Each LC-ATM interface has its own interface-specific label space and a nonzero label space ID.
- **Platform-wide**—An LDP platform supports a single platform-wide session for use by all interfaces that can share the same global label space. For Cisco platforms, all interface types except LC-ATM use the platform-wide session and have a label space ID of zero.

When a session is established between two peers, entries are created in the mplsLdpPeerTable and the mplsLdpSessionTable because they have the same indexing.

In Figure 3, Router A has two remote peers, Routers B and C. Router A has a single platform-wide session that consists of two serial interfaces with Router B and another platform-wide session with Router C. Router A also has two interface-specific sessions with Router B.

**Figure 3 LDP Sessions**

88215

Figure 4 shows entries that correspond to the `mplsLdpPeerTable` and the `mplsLdpSessionTable` in Figure 3.

In Figure 4, `mplsLdpSesState` is a sample object from the `mplsLdpSessionTable` on Router A. There are four `mplsLdpSesState` sample objects shown (top to bottom). The first object represents a platform-wide session associated with two serial interfaces. The next two objects represent interface-specific sessions for the LC-ATM interfaces on Routers A and B. These interface-specific sessions have nonzero peer label space IDs. The last object represents a platform-wide session for the next peer, Router C.

The indexing is based on the entries in the `mplsLdpEntityTable`. It begins with the indexes of the `mplsLdpEntityTable` and adds the following:

- Peer LDP ID = 10.11.11.11.0.0  
The peer LDP ID consists of the peer LSR ID (four octets) and the peer label space ID (two octets).
- Peer LSR ID = 10.11.11.11
- Peer label space ID = 0.0  
The peer label space ID identifies a specific peer label space available within the LSR.

**Figure 4 Sample Indexing for an LDP Session**

mplsLdpSessionTable		Peer LDP ID	
mplsLdpSesState.10.10.10.10.0.0.3232235777	Indexing of mplsLdpEntityTable	10.11.11.11.0.0	
		Peer LSR ID	Peer label space ID
		mplsLdpSesState.10.10.10.10.0.0.3232236034.10.12.12.12.0.0	
		mplsLdpSesState.10.10.10.10.0.1.3232235778.10.11.11.11.0.1

88216

## LDP Hello Adjacencies

An LDP hello adjacency is a network link between a router and its peers. An LDP hello adjacency enables two adjacent peers to exchange label binding information.

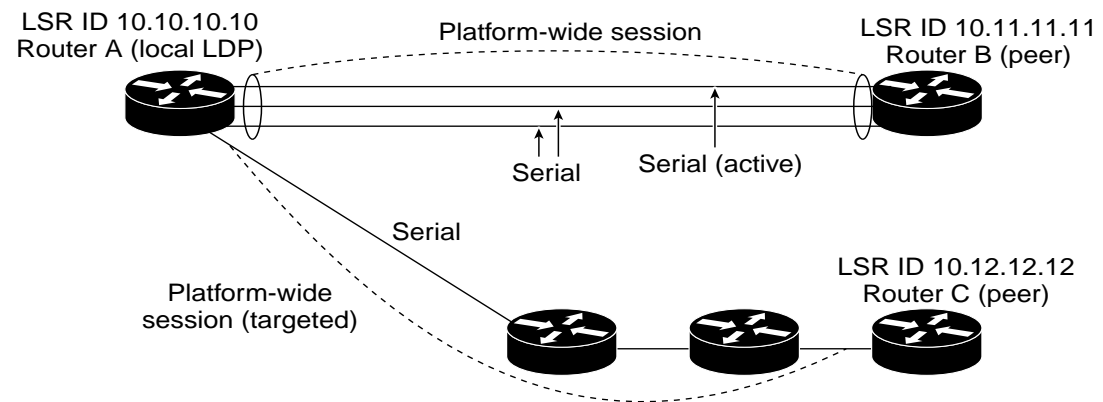

An LDP hello adjacency exists for each link on which LDP runs. Multiple LDP hello adjacencies exist whenever there is more than one link in a session between a router and its peer, such as in a platform-wide session.

A hello adjacency is considered active if it is currently engaged in a session, or nonactive if it is not currently engaged in a session.

A targeted hello adjacency is not directly connected to its peer and has an unlimited number of hops between itself and its peer. A linked hello adjacency is directly connected between two routers.

In [Figure 5](#), Router A has two remote peers, Routers B and C. Router A has a platform-wide session with Router B that consists of three serial interfaces, one of which is active and another platform-wide (targeted) session with Router C.

**Figure 5** Hello Adjacency

88217

[Figure 6](#) shows entries in the `mplsLdpHelloAdjacencyTable`. There are four `mplsLdpHelloAdjHoldTimeRem` sample objects (top to bottom). They represent the two platform-wide sessions and the four serial links shown in [Figure 5](#).

The indexing is based on the `mplsLdpSessionTable`. When the `mplsLdpHelloAdjIndex` enumerates the different links within a single session, the active link is `mplsLdpHelloAdjIndex = 1`.

**Figure 6** Sample Indexing for an LDP Hello Adjacency

```

mplsLdpHelloAdjacencyTable

## Events Generating MPLS LDP MIB Notifications in MPLS LDP MIB Version 8 Upgrade

When you enable MPLS LDP MIB notification functionality by issuing the **snmp-server enable traps mpls ldp** command, notification messages are generated and sent to a designated NMS in the network to signal the occurrence of specific events within Cisco IOS.

The MPLS LDP MIB objects involved in LDP status transitions and event notifications include the following:

- **mplsLdpSessionUp**—This message is generated when an LDP entity (a local LSR) establishes an LDP session with another LDP entity (an adjacent LDP peer in the network).
- **mplsLdpSessionDown**—This message is generated when an LDP session between a local LSR and its adjacent LDP peer is terminated.
- **mplsLdpPathVectorLimitMismatch**—This message is generated when a local LSR establishes an LDP session with its adjacent peer LSR, but the two LSRs have dissimilar path vector limits.

The value of the path vector limit can range from 0 through 255; a value of 0 indicates that loop detection is off; any value other than zero up to 255 indicates that loop detection is on and, in addition, specifies the maximum number of hops through which an LDP message can pass before a loop condition in the network is sensed.

We recommend that all LDP-enabled routers in the network be configured with the same path vector limit. Accordingly, the **mplsLdpPathVectorLimitMismatch** object exists in the MPLS LDP MIB to provide a warning message to the NMS when two routers engaged in LDP operations have different path vector limits.

---

**Note** This notification is generated only if the distribution method is downstream-on-demand.

---

- **mplsLdpFailedInitSessionThresholdExceeded**—This message is generated when a local LSR and an adjacent LDP peer attempt to set up an LDP session between them, but fail to do so after a specified number of attempts. The default number of attempts is 8. This default value is implemented and cannot be changed.

Eight failed attempts to establish an LDP session between a local LSR and an LDP peer, due to any type of incompatibility between the devices, causes this notification message to be generated. Cisco routers support the same features across multiple platforms.

Therefore, the most likely incompatibility to occur between Cisco LSRs is a mismatch of their respective ATM VPI/VCI label ranges.

For example, if you specify a range of valid labels for an LSR that does not overlap the range of its adjacent LDP peer, the routers try eight times to create an LDP session between themselves before the **mplsLdpFailedInitSessionThresholdExceeded** notification is generated and sent to the NMS as an informational message.

The LSRs whose label ranges do not overlap continue their attempt to create an LDP session between themselves after the eight-retry threshold is exceeded.

In such cases, the LDP threshold exceeded notification alerts the network administrator about a condition in the network that might warrant attention.

RFC 3036, *LDP Specification*, details the incompatibilities that can exist between Cisco routers and/or other vendor LSRs in an MPLS network.

Among such incompatibilities, for example, are the following:

- Nonoverlapping ATM VPI/VCI ranges (as noted above) or nonoverlapping Frame-Relay DLCI ranges between LSRs attempting to set up an LDP session
- Unsupported label distribution method
- Dissimilar protocol data unit (PDU) sizes
- Dissimilar types of LDP feature support

# MIB Tables in MPLS LDP MIB Version 8 Upgrade

Version 8 of the MPLS LDP MIB consists of the following tables:

- **mplsLdpEntityTable** ([Table 1](#))—Contains entries for every active LDP hello adjacency. Nonactive hello adjacencies appear in the **mplsLdpHelloAdjacencyTable**, rather than this table. This table is indexed by the local LDP identifier for the interface and the IP address of the peer active hello adjacency. (See [Figure 1](#).)

The advantage of showing the active hello adjacency instead of sessions in this table is that the active hello adjacency can exist even if an LDP session is not active (cannot be established). Previous implementations of the IETF MPLS-LDP MIB used sessions as the entries in this table. This approach was inadequate because as sessions went down, the entries in the entity table would disappear completely because the agent code could no longer access them. This resulted in the MIB failing to provide information about failed LDP sessions.

Directed adjacencies are also shown in this table. These entries, however, are always up administratively (**adminStatus**) and operationally (**operStatus**), because the adjacencies disappear if the directed session fails. Nondirected adjacencies might disappear from the MIB on some occasions, because adjacencies are deleted if the underlying interface becomes operationally down, for example.

- **mplsLdpEntityConfGenLRTTable** ([Table 2](#))—Contains entries for every LDP-enabled interface that is in the global label space. (For Cisco, this applies to all interfaces except LC-ATM. LC-ATM entities are shown in the **mplsLdpEntityConfAtmLRTTable** instead.) Indexing is the same as it is for the **mplsLdpEntityTable**, except two indexes have been added, **mplsLdpEntityConfGenLRMin** and **mplsLdpEntityConfGenLRMax**. These additional indexes allow more than one label range to be defined. However, in the current Cisco IOS implementation, only one global label range is allowed.
- **mplsLdpEntityAtmParmsTable** ([Table 3](#))—Contains entries for every LDP-enabled LC-ATM interface. This table is indexed the same as the **mplsLdpEntityTable** although only LC-ATM interfaces are shown.
- **mplsLdpEntityConfAtmLRTTable** ([Table 4](#))—Contains entries for every LDP-enabled LC-ATM interface. Indexing is the same as it is for the **mplsLdpEntityTable**, except two indexes have been added, **mplsLdpEntityConfAtmLRMinVpi** and **mplsLdpEntityConfAtmLRMinVci**. These additional indexes allow more than one label range to be defined. However, in the current Cisco IOS implementation, only one label range per LC-ATM interface is allowed.
- **mplsLdpEntityStatsTable** ([Table 5](#))—Augments the **mplsLdpEntityTable** and shares the exact same indexing for performing GET and GETNEXT operations. This table shows additional statistics for entities.
- **mplsLdpPeerTable** ([Table 6](#))—Contains entries for all peer sessions. This table is indexed by the local LDP identifier of the session, the IP address of the peer active hello adjacency, and the peer's LDP identifier. (See [Figure 4](#).)
- **mplsLdpHelloAdjacencyTable** ([Table 7](#))—Contains entries for all hello adjacencies. This table is indexed by the local LDP identifier of the associated session, the IP address of the peer active hello adjacency, the LDP identifier for the peer, and an arbitrary index that is set to the list position of the adjacency. (See [Figure 6](#).)
- **mplsLdpSessionTable** ([Table 8](#))—Augments the **mplsLdpPeerTable** and shares the same indexing for performing GET and GETNEXT operations. This table shows all sessions.

- `mplsLdpAtmSesTable` (Table 9)—Contains entries for LC-ATM sessions. Indexing is the same as it is for the `mplsLdpPeerTable`, except two indexes have been added, `mplsLdpSesAtmLRLowerBoundVpi` and `mplsLdpSesAtmLRLowerBoundVci`. These additional indexes allow more than one label range to be defined. However, in the current Cisco IOS implementation, only one label range per LC-ATM interface is allowed.
- `mplsLdpSesStatsTable` (Table 10)—Augments the `mplsLdpPeerTable` and shares the exact same indexing for performing GET and GETNEXT operations. This table shows additional statistics for sessions.

## mplsLdpEntityTable

Table 1 lists the `mplsLdpEntityTable` objects and their descriptions.

**Table 1** *mplsLdpEntityTable Objects and Descriptions*

Object	Description
<code>mplsLdpEntityEntry</code>	Represents an LDP entity, which is a potential session between two peers.
<code>mplsLdpEntityLdpId</code>	The LDP identifier (not accessible) consists of the local LSR ID (four octets) and the label space ID (two octets).
<code>mplsLdpEntityIndex</code>	A secondary index that identifies this row uniquely. It consists of the IP address of the peer active hello adjacency, which is the 32-bit representation of the IP address assigned to the LSR (not accessible).
<code>mplsLdpEntityProtocolVersion</code>	The version number of the LDP protocol to be used in the session initialization message.
<code>mplsLdpEntityAdminStatus</code>	The administrative status of this LDP entity is always up. If the hello adjacency fails, this entity disappears from the <code>mplsLdpEntityTable</code> .
<code>mplsLdpEntityOperStatus</code>	The operational status of this LDP entity. Values are unknown(0), enabled(1), and disabled(2).
<code>mplsLdpEntityTcpDscPort</code>	The TCP discovery port for LDP or TDP. The default value is 646 (LDP).
<code>mplsLdpEntityUdpDscPort</code>	The UDP discovery port for LDP or TDP. The default value is 646 (LDP).
<code>mplsLdpEntityMaxPduLength</code>	The maximum PDU length that is sent in the common session parameters of an initialization message.
<code>mplsLdpEntityKeepAliveHoldTimer</code>	The two-octet value that is the proposed keepalive hold time for this LDP entity.
<code>mplsLdpEntityHelloHoldTimer</code>	The two-octet value that is the proposed hello hold time for this LDP entity.
<code>mplsLdpEntityInitSesThreshold</code>	The threshold for notification when this entity and its peer are engaged in an endless sequence of initialization messages. The default value is 8 and cannot be changed by SNMP or CLI.

**Table 1** *mplsLdpEntityTable Objects and Descriptions (continued)*

Object	Description
mplsLdpEntityLabelDistMethod	The specified method of label distribution for any given LDP session. Values are downstreamOnDemand(1) and downstreamUnsolicited(2).
mplsLdpEntityLabelRetentionMode	Can be configured to use either conservative(1) for LC-ATM or liberal(2) for all other interfaces.
mplsLdpEntityPVLMisTrapEnable	<p>Indicates whether the mplsLdpPVLMismatch trap should be generated.</p> <p>If the value is enabled(1), the trap is generated. If the value is disabled(2), the trap is not generated. The default is disabled(2).</p> <p><b>Note</b> The mplsLdpPVLMismatch trap is generated only if mplsLdpEntityLabelDistMethod is downstreamOnDemand(1).</p>
mplsLdpEntityPVL	<p>If the value of this object is 0, loop detection for path vectors is disabled. Otherwise, if this object has a value greater than zero, loop detection for path vectors is enabled, and the path vector limit is this value.</p> <p><b>Note</b> The mplsLdpEntityPVL object is non-zero only if mplsLdpEntityLabelDistMethod is downstreamOnDemand(1).</p>
mplsLdpEntityHopCountLimit	<p>If the value of this object is 0, loop detection using hop counters is disabled.</p> <p>If the value of this object is greater than 0, loop detection using hop counters is enabled, and this object specifies this entity's maximum allowable value for the hop count.</p> <p><b>Note</b> The mplsLdpEntityHopCountLimit object is non-zero only if mplsLdpEntityLabelDistMethod is downstreamOnDemand(1).</p>
mplsLdpEntityTargPeer	If this LDP entity uses a targeted adjacency, this object is set to true(1). The default value is false(2).
mplsLdpEntityTargPeerAddrType	The type of the internetwork layer address used for the extended discovery. This object indicates how the value of mplsLdpEntityTargPeerAddr is to be interpreted.
mplsLdpEntityTargPeerAddr	The value of the internetwork layer address used for the targeted adjacency.
mplsLdpEntityOptionalParameters	<p>Specifies the optional parameters for the LDP initialization message. If the value is generic(1), no optional parameters are sent in the LDP initialization message associated with this entity.</p> <p>LC-ATM uses atmParameters(2) to specify that a row in the mplsLdpEntityAtmParmsTable corresponds to this entry.</p> <p><b>Note</b> Frame Relay parameters are not supported.</p>

**Table 1** *mplsLdpEntityTable Objects and Descriptions (continued)*

Object	Description
mplsLdpEntityDiscontinuityTime	The value of sysUpTime on the most recent occasion when one or more of this entity's counters suffered a discontinuity. The relevant counters are the specific instances of any Counter32 or Counter64 object contained in the mplsLdpEntityStatsTable that are associated with this entity. If no such discontinuities have occurred since the last reinitialization of the local management subsystem, this object contains a 0 value.
mplsLdpEntityStorType	The storage type for this entry is a read-only implementation that is always volatile.
mplsLdpEntityRowStatus	This object is a read-only implementation that is always active.

## mplsLdpEntityConfGenLRTable

Table 2 lists the mplsLdpEntityConfGenLRTable objects and their descriptions.

**Table 2** *mplsLdpEntityConfGenLRTable Objects and Descriptions*

Object	Description
mplsLdpEntityConfGenLREntry	A row in the LDP Entity Configurable Generic Label Range table. One entry in this table contains information on a single range of labels; the range is defined by an upper boundary (VPI/VCI pair) and a lower boundary (VPI/VCI pair).  The current implementation supports one label range per entity.
mplsLdpEntityConfGenLRMin	The minimum label configured for this range (not accessible).
mplsLdpEntityConfGenLRMax	The maximum label configured for this range (not accessible).
mplsLdpEntityConfGenIfIndxOrZero	This value represents the SNMP IF-MIB index for the platform-wide entity. If the active hello adjacency is targeted, the value is 0.
mplsLdpEntityConfGenLRStorType	The storage type for this entry is a read-only implementation that is always volatile.
mplsLdpEntityConfGenLRRowStatus	This object is a read-only implementation that is always active.

## mplsLdpEntityAtmParmsTable

Table 3 lists the mplsLdpEntityAtmParmsTable objects and their descriptions.

**Table 3** *mplsLdpEntityAtmParmsTable Objects and Descriptions*

Object	Description
mplsLdpEntityAtmParmsEntry	Represents the ATM parameters and ATM information for this LDP entity.
mplsLdpEntityAtmIfIndxOrZero	This value represents the SNMP IF-MIB index for the interface-specific LC-ATM entity.
mplsLdpEntityAtmMergeCap	Denotes the merge capability of this entity.
mplsLdpEntityAtmLRComponents	Number of label range components in the initialization message. This also represents the number of entries in the mplsLdpEntityConfAtmLRTable that correspond to this entry.
mplsLdpEntityAtmVcDirectionality	<p>If the value of this object is <code>bidirectional(0)</code>, a given VCI within a given VPI is used as a label for both directions independently of one another.</p> <p>If the value of this object is <code>unidirectional(1)</code>, a given VCI within a VPI designates one direction.</p>
mplsLdpEntityAtmLsrConnectivity	<p>The peer LSR can be connected indirectly by means of an ATM VP, so that the VPI values can be different on the endpoints. For that reason, the label must be encoded entirely within the VCI field.</p> <p>Values are <code>direct(1)</code>, the default, and <code>indirect(2)</code>.</p>
mplsLdpEntityDefaultControlVpi	The default VPI value for the non-MPLS connection.
mplsLdpEntityDefaultControlVci	The default VCI value for the non-MPLS connection.
mplsLdpEntityUnlabTrafVpi	VPI value of the VCC supporting unlabeled traffic. This non-MPLS connection is used to carry unlabeled (IP) packets.
mplsLdpEntityUnlabTrafVci	VCI value of the VCC supporting unlabeled traffic. This non-MPLS connection is used to carry unlabeled (IP) packets.
mplsLdpEntityAtmStorType	The storage type for this entry is a read-only implementation that is always volatile.
mplsLdpEntityAtmRowStatus	This object is a read-only implementation that is always active.

## mplsLdpEntityConfAtmLRTable

Table 4 lists the mplsLdpEntityConfAtmLRTable objects and their descriptions.

**Table 4** *mplsLdpEntityConfAtmLRTable Objects and Descriptions*

Object	Description
mplsLdpEntityConfAtmLREntry	A row in the LDP Entity Configurable ATM Label Range Table. One entry in this table contains information on a single range of labels; the range is defined by an upper boundary (VPI/VCI pair) and a lower boundary (VPI/VCI pair). This is the same data used in the initialization message. This label range should overlap the label range of the peer.
mplsLdpEntityConfAtmLRMinVpi	The minimum VPI number configured for this range (not accessible).
mplsLdpEntityConfAtmLRMinVci	The minimum VCI number configured for this range (not accessible).
mplsLdpEntityConfAtmLRMaxVpi	The maximum VPI number configured for this range (not accessible).
mplsLdpEntityConfAtmLRMaxVci	The maximum VCI number configured for this range (not accessible).
mplsLdpEntityConfAtmLRStorType	The storage type for this entry is a read-only implementation that is always volatile.
mplsLdpEntityConfAtmLRRowStatus	This object is a read-only implementation that is always active.

## mplsLdpEntityStatsTable

Table 5 lists the mplsLdpEntityStatsTable objects and their descriptions.

**Table 5** *mplsLdpEntityStatsTable Objects and Descriptions*

Object	Description
mplsLdpEntityStatsEntry	These entries augment the mplsLdpEntityTable by providing additional information for each entry.
mplsLdpAttemptedSessions	Not supported in this feature.
mplsLdpSesRejectedNoHelloErrors	A count of the session rejected/no hello error notification messages sent or received by this LDP entity.
mplsLdpSesRejectedAdErrors	A count of the session rejected/parameters advertisement mode error notification messages sent or received by this LDP entity.
mplsLdpSesRejectedMaxPduErrors	A count of the session rejected/parameters max PDU length error notification messages sent or received by this LDP entity.
mplsLdpSesRejectedLRErrors	A count of the session rejected/parameters label range notification messages sent or received by this LDP entity.
mplsLdpBadLdpIdentifierErrors	A count of the number of bad LDP identifier fatal errors detected by the session associated with this LDP entity.

**Table 5** *mplsLdpEntityStatsTable Objects and Descriptions (continued)*

Object	Description
mplsLdpBadPduLengthErrors	A count of the number of bad PDU length fatal errors detected by the session associated with this LDP entity.
mplsLdpBadMessageLengthErrors	A count of the number of bad message length fatal errors detected by the session associated with this LDP entity.
mplsLdpBadTlvLengthErrors	A count of the number of bad Type-Length-Value (TLV) length fatal errors detected by the session associated with this LDP entity.
mplsLdpMalformedTlvValueErrors	A count of the number of malformed TLV value fatal errors detected by the session associated with this LDP entity.
mplsLdpKeepAliveTimerExpErrors	A count of the number of session keepalive timer expired errors detected by the session associated with this LDP entity.
mplsLdpShutdownNotifReceived	A count of the number of shutdown notifications received related to the session associated with this LDP entity.
mplsLdpShutdownNotifSent	A count of the number of shutdown notifications sent related to the session associated with this LDP entity.

## mplsLdpPeerTable

Table 6 lists the mplsLdpPeerTable objects and their descriptions.

**Table 6** *mplsLdpPeerTable Objects and Descriptions*

Object	Description
mplsLdpPeerEntry	Information about a single peer that is related to a session (not accessible). <b>Note</b> This table is augmented by the mplsLdpSessionTable.
mplsLdpPeerLdpId	The LDP identifier of this LDP peer (not accessible) consists of the peer LSR ID (four octets) and the peer label space ID (two octets).
mplsLdpPeerLabelDistMethod	For any given LDP session, the method of label distribution. Values are downstreamOnDemand(1) and downstreamUnsolicited(2).

**Table 6** *mplsLdpPeerTable Objects and Descriptions (continued)*

Object	Description
mplsLdpPeerLoopDetectionForPV	<p>An indication of whether loop detection based on path vectors is disabled or enabled for this peer.</p> <p>For downstream unsolicited distribution (mplsLdpPeerLabelDistMethod is downstreamUnsolicited(2)), this object always has a value of disabled(0) and loop detection is disabled.</p> <p>For downstream-on-demand distribution (mplsLdpPeerLabelDistMethod is downstreamOnDemand(1)), this object has a value of enabled(1), provided that loop detection based on path vectors is enabled.</p>
mplsLdpPeerPVL	<p>If the value of mplsLdpPeerLoopDetectionForPV for this entry is enabled(1), this object represents that path vector limit for this peer.</p> <p>If the value of mplsLdpPeerLoopDetectionForPV for this entry is disabled(0), this value should be 0.</p>

## mplsLdpHelloAdjacencyTable

Table 7 lists the mplsLdpHelloAdjacencyTable objects and their descriptions.

**Table 7** *mplsLdpHelloAdjacencyTable Objects and Descriptions*

Object	Description
mplsLdpHelloAdjacencyEntry	Each row represents a single LDP hello adjacency. An LDP session can have one or more hello adjacencies (not accessible).
mplsLdpHelloAdjIndex	An identifier for this specific adjacency (not accessible). The active hello adjacency has mplsLdpHelloAdjIndex equal to 1.
mplsLdpHelloAdjHoldTimeRem	The time remaining for this hello adjacency. This interval changes when the next hello message, which corresponds to this hello adjacency, is received.
mplsLdpHelloAdjType	This adjacency is the result of a link hello if the value of this object is link(1). Otherwise, this adjacency is a result of a targeted hello and its value is targeted(2).

## mplsLdpSessionTable

Table 8 lists the mplsLdpSessionTable objects and their descriptions.

**Table 8** *mplsLdpSessionTable Objects and Descriptions*

Object	Description
mplsLdpSessionEntry	An entry in this table represents information on a single session between an LDP entity and an LDP peer. The information contained in a row is read-only. This table augments the mplsLdpPeerTable.
mplsLdpSesState	<p>The current state of the session. All of the states are based on the LDP or TDP state machine for session negotiation behavior.</p> <p>The states are as follows:</p> <ul style="list-style-type: none"> <li>• nonexistent(1)</li> <li>• initialized(2)</li> <li>• openrec(3)</li> <li>• opensent(4)</li> <li>• operational(5)</li> </ul>
mplsLdpSesProtocolVersion	The version of the LDP protocol which this session is using. This is the version of the LDP protocol that has been negotiated during session initialization.
mplsLdpSesKeepAliveHoldTimeRem	The keepalive hold time remaining for this session.
mplsLdpSesMaxPduLen	The value of maximum allowable length for LDP PDUs for this session. This value could have been negotiated during the session initialization.
mplsLdpSesDiscontinuityTime	<p>The value of sysUpTime on the most recent occasion when one or more of this session's counters suffered a discontinuity. The relevant counters are the specific instances of any Counter32 or Counter64 object contained in the mplsLdpSesStatsTable associated with this session.</p> <p>The initial value of this object is the value of sysUpTime when the entry was created in this table.</p>

## mplsLdpAtmSesTable

Table 9 lists the mplsLdpAtmSesTable objects and their descriptions.

**Table 9** *mplsLdpAtmSesTable Objects and Descriptions*

Objects	Description
mplsLdpAtmSesEntry	An entry in this table represents information on a single label range intersection between an LDP entity and an LDP peer (not accessible).
mplsLdpAtmSesLRLowerBoundVpi	The minimum VPI number for this range (not accessible).
mplsLdpAtmSesLRLowerBoundVci	The minimum VCI number for this range (not accessible).

**Table 9** *mplsLdpAtmSesTable Objects and Descriptions (continued)*

Objects	Description
mplsLdpAtmSesLRUpperBoundVpi	The maximum VPI number for this range (read-only).
mplsLdpAtmSesLRUpperBoundVci	The maximum VCI number for this range (read-only).

## mplsLdpSesStatsTable

[Table 10](#) lists the mplsLdpSesStatsTable objects and their descriptions.

**Table 10** *mplsLdpSesStatsTable Objects and Descriptions*

Object	Description
mplsLdpSesStatsEntry	An entry in this table represents statistical information on a single session between an LDP entity and an LDP peer. This table augments the mplsLdpPeerTable.
mplsLdpSesStatsUnkMesTypeErrors	This object is the count of the number of unknown message type errors detected during this session.
mplsLdpSesStatsUnkTlvErrors	This object is the count of the number of unknown TLV errors detected during this session.

## VPN Contexts in MPLS LDP MIB Version 8 Upgrade

Within an MPLS Border Gateway Protocol (BGP) 4 Virtual Private Network (VPN) environment, separate LDP processes can be created for each VPN. These processes and their associated data are called LDP contexts. Each context is independent from all others and contains data specific only to that context.

Cisco IOS Release 12.0(11)ST and later releases include the VPN Aware LDP MIB feature that allows the LDP MIB to get VPN context information. The feature adds support for different contexts for different MPLS VPNs. Users of the MIB can view MPLS LDP processes for a given MPLS VPN. The VPN Aware LDP MIB feature does not change the syntax of the IETF MPLS-LDP MIB. It changes the number and types of entries within the tables.

The IETF MPLS-LDP MIB can show information about only one context at a time. You can specify a context, either a global context or an MPLS VPN context, using an SNMP security name.

The following sections describe topics related to the VPN Aware LDP MIB feature:

- [SNMP Contexts, page 21](#)
- [VPN Aware LDP MIB Sessions, page 21](#)
- [VPN Aware LDP MIB Notifications, page 23](#)

## SNMP Contexts

SNMP contexts provide VPN users with a secure way of accessing MIB data. When a VPN is associated with a context, that VPN's specific MIB data exists in that context. Associating a VPN with a context enables service providers to manage networks with multiple VPNs. Creating and associating a context with a VPN enables a provider to prevent the users of one VPN from accessing information about users of other VPNs on the same networking device.

VPN-aware SNMP requires that SNMP manager and agent entities operating in a VPN environment agree on mapping between the SNMP security name and the VPN name. This mapping is created by using different contexts for the SNMP data of different VPNs, which is accomplished through the configuration of the SNMP View-based Access Control Model MIB (SNMP-VACM-MIB). The SNMP-VACM-MIB is configured with views so that a user on a VPN with a security name is allowed access to the restricted object space within the context of only that VPN.

SNMP request messages undergo three phases of security and access control before a response message is sent back with the object values within a VPN context:

- The first security phase is authentication of the username. During this phase, the user is authorized for SNMP access.
- The second phase is access control. During this phase, the user is authorized for SNMP access to the group objects in the requested SNMP context.
- In the third phase, the user can access a particular instance of a table entry. With this third phase, complete retrieval can be based on the SNMP context name.

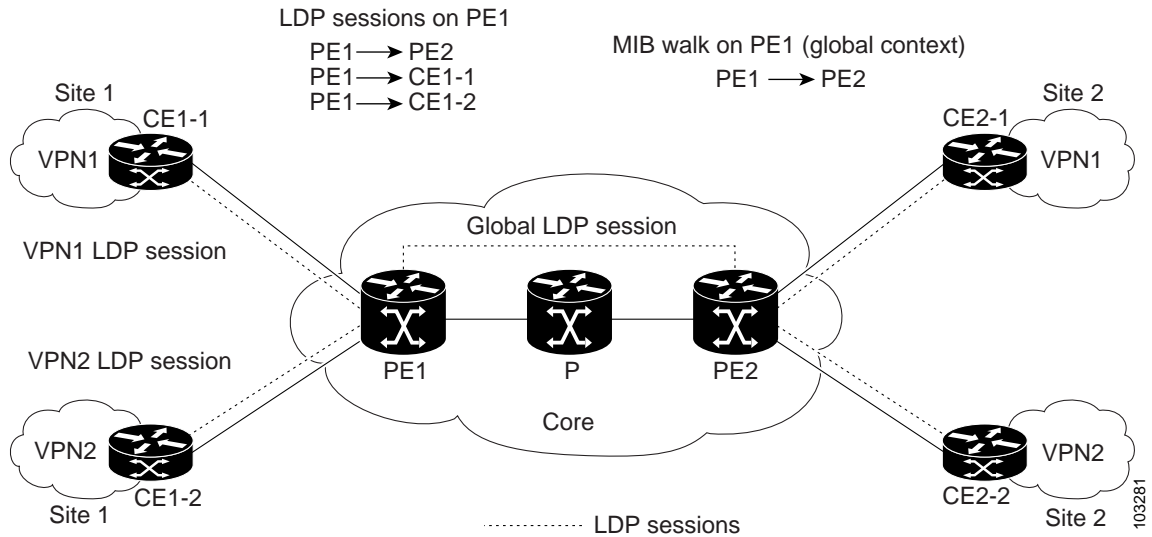

IP access lists can be configured and associated with SNMP community strings. This feature enables you to configure an association between VRF instances and SNMP community strings. When a VRF instance is associated with an SNMP community string, SNMP processes requests coming in for a particular community string only if they are received from the configured VRF. If the community string contained in the incoming packet does not have a VRF associated with it, it is processed only if it came in through a non-VRF interface.

You can also enable or disable authentication traps for SNMP packets dropped due to VRF mismatches. By default, if SNMP authentication traps are enabled, VRF authentication traps are also enabled.

## VPN Aware LDP MIB Sessions

Prior to Cisco IOS Release 12.0(11)ST, an SNMP query to the MPLS LDP MIB returned information about global sessions only. A query did not return information about LDP sessions in a VPN context. The IETF MPLS LDP MIB retrieved information from global routing tables, but did not retrieve information from VPN routing and forwarding instances (VRFs) that store per-VPN routing data. The MPLS LDP MIB looked only at LDP processes in the global context and ignored all other sessions. A query on a VRF returned no information. You can view LDP processes in a VPN context.

[Figure 7](#) shows a sample MPLS VPN network with the MPLS LDP sessions prior to the implementation of the VPN Aware LDP MIB feature.

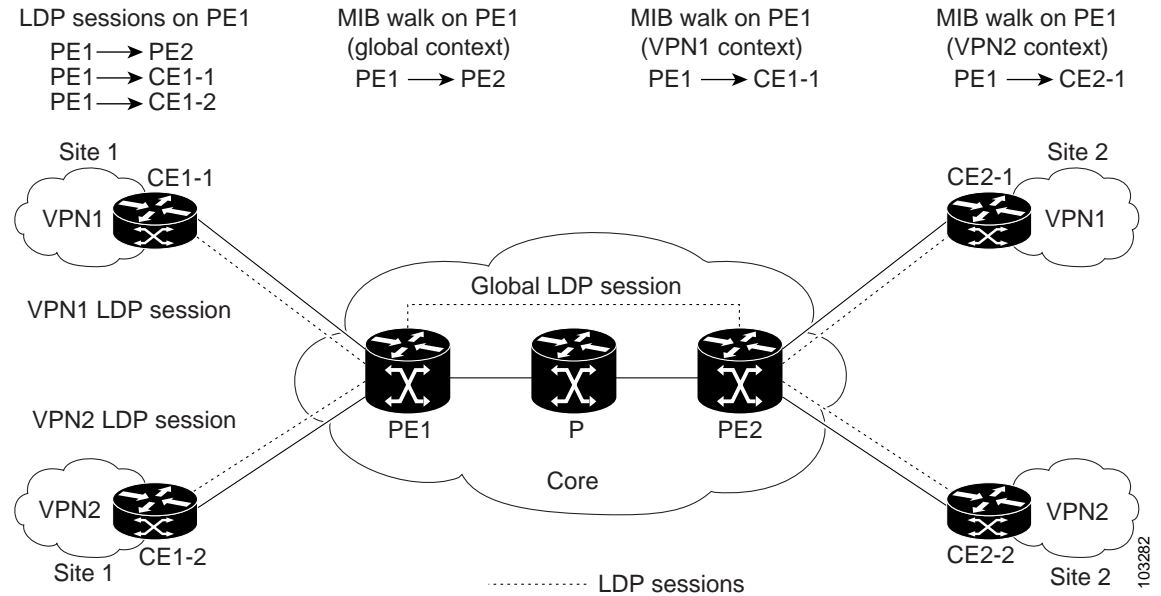

**Figure 7** *MPLS LDP Sessions Setup Before VPN Aware LDP MIB Feature*

A MIB walk prior to this Cisco IOS release displayed only global session information.

With the VPN Aware LDP MIB enhancement in this Cisco IOS release, an SNMP query to the IETF MPLS-LDP-MIB supports both global and VPN contexts. This feature allows you to enter LDP queries on any VRF and on the core (global context). A query can differentiate between LDP sessions from different VPNs. LDP session information for a VPN stays in the context of that VPN. Therefore, the information from one VPN is not available to a user of a different VPN. The VPN Aware update to the LDP MIB also allows you to view LDP processes operating in a Carrier Supporting Carrier (CSC) network.

In an MPLS VPN, a service provider edge router (PE) might contain VRFs for several VPNs as well as a global routing table. To set up separate LDP processes for different VPNs on the same device, you need to configure each VPN with a unique securityName, contextName, and View-based Access Control Model (VACM) view. The VPN securityName must be configured for the IETF MPLS LDP MIB.

Figure 8 shows LDP sessions for a sample MPLS VPN network with the VPN Aware LDP MIB feature.

**Figure 8 MPLS LDP Sessions with the VPN Aware LDP MIB Feature**

With the VPN Aware LDP MIB feature, you can do MIB queries or MIB walks for an MPLS VPN LDP session or a global LDP session.

**Note**

To verify LDP session information for a specific VPN, use the **show mpls ldp neighbor vrf vpn-name detail** command.

## VPN Aware LDP MIB Notifications

Prior to Cisco IOS Release 12.0(11)ST, all notification messages for MPLS LDP sessions were sent to the same designated network management station (NMS) in the network. The notifications were enabled with the **snmp-server enable traps mpls ldp** command.

Figure 9 shows LDP notifications that were sent before the implementation of the VPN Aware LDP MIB feature.

**Figure 9** *LDP Notifications Sent Before the VPN Aware LDP MIB Feature*

The VPN Aware LDP MIB feature supports LDP notifications for multiple LDP contexts for VPNs. LDP notifications can be generated for the core (global context) and for different VPNs. You can cause notifications be sent to different NMS hosts for different LDP contexts. LDP notifications associated with a specific VRF are sent to the NMS designated for that VRF. LDP global notifications are sent to the NMS configured to receive global traps.

To enable LDP context notifications for the VPN Aware LDP MIB feature, use either the SNMP object `mplsLdpSessionsUpDownEnable` (in the global LDP context only) or the following extended global configuration commands.

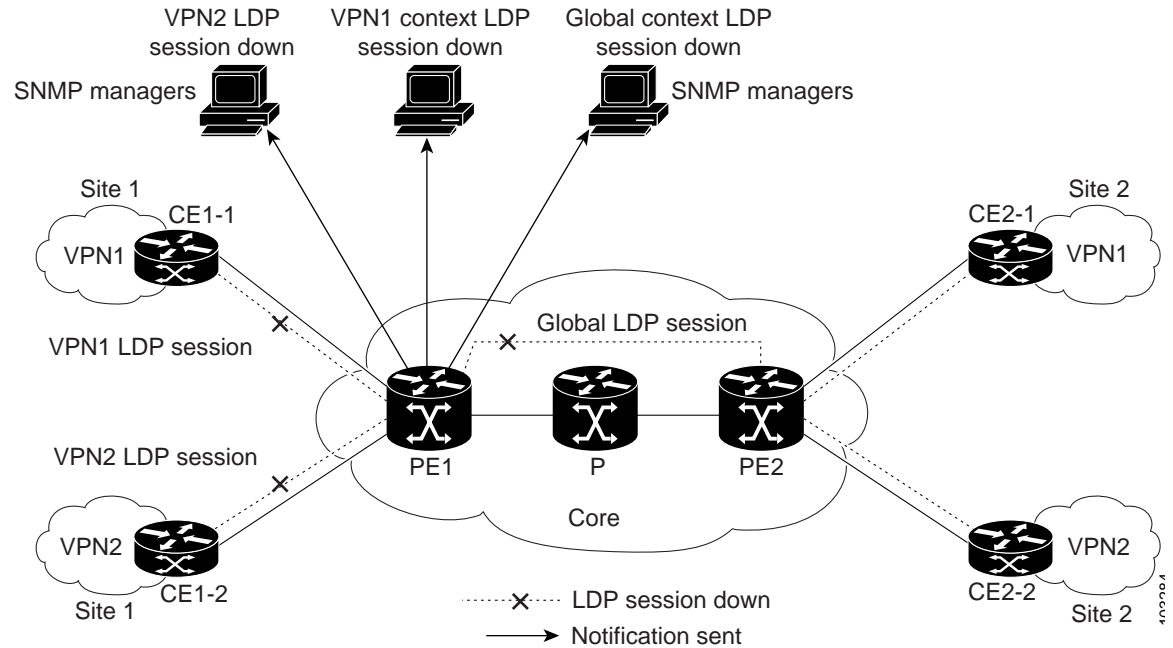

To enable LDP notifications for the global context, use the following commands:

```
PE-Router(config)# snmp-server host host-address traps community mpls-ldp
PE-Router(config)# snmp-server enable traps mpls ldp
```

To enable LDP notifications for a VPN context, use the following commands:

```
PE-Router(config)# snmp-server host host-address vrf vrf-name version {v1|v2c|v3}
community community-string udp-port upd-port mpls-ldp
PE-Router(config)# snmp-server enable traps mpls ldp
```

Figure 10 shows LDP notifications with the VPN Aware LDP MIB feature.

**Figure 10** *LDP Notifications With the VPN Aware LDP MIB Feature*

## How to Configure MPLS LDP MIB Version 8 Upgrade

This section contains the following procedures:

- [Enabling the SNMP Agent, page 25](#) (required)
- [Enabling Cisco Express Forwarding, page 26](#) (required)
- [Enabling MPLS Globally, page 27](#) (required)
- [Enabling LDP Globally, page 28](#) (required)
- [Enabling MPLS on an Interface, page 29](#) (required)
- [Enabling LDP on an Interface, page 30](#) (required)
- [Configuring a VPN Aware LDP MIB, page 31](#) (required)
- [Verifying MPLS LDP MIB Version 8 Upgrade, page 37](#) (optional)

### Enabling the SNMP Agent

Perform this task to enable the SNMP agent.

#### SUMMARY STEPS

1. **enable**
2. **show running-config**
3. **configure terminal**
4. **snmp-server community *string* [view *view-name*] [ro] [number]**

5. **end**
6. **write memory**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>show running-config</b>  <b>Example:</b> Router# show running-config	Displays the running configuration of the router so that you can determine if an SNMP agent is already running on the device.  If no SNMP information is displayed, continue with the next step.  If any SNMP information is displayed, you can modify the information or change it as desired.
Step 3	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 4	<b>snmp-server community string [view view-name] [ro] [number]</b>  <b>Example:</b> Router(config)# snmp-server community public ro	Configures read-only (ro) community strings for the MPLS LDP MIB. <ul style="list-style-type: none"> <li>The <i>string</i> argument functions like a password, permitting access to SNMP functionality on label switch routers (LSRs) in an MPLS network.</li> <li>The optional <b>ro</b> keyword configures read-only (ro) access to the objects in the MPLS LDP MIB.</li> </ul>
Step 5	<b>end</b>  <b>Example:</b> Router(config)# end	Exits to privileged EXEC mode.
Step 6	<b>write memory</b>  <b>Example:</b> Router# write memory	Writes the modified SNMP configuration into NVRAM of the router, permanently saving the SNMP settings.

## Enabling Cisco Express Forwarding

Perform this task to enable Cisco Express Forwarding or distributed Cisco Express Forwarding.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**

3. **ip cef distributed**
4. **end**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>ip cef distributed</b>  <b>Example:</b> Router(config)# ip cef distributed	Enables distributed Cisco Express Forwarding.
Step 4	<b>end</b>  <b>Example:</b> Router(config)# end	Exits to privileged EXEC mode.

## Enabling MPLS Globally

Perform this task to enable MPLS globally.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls ip**
4. **end**

**DETAILED STEPS**

	Command or Action	Purpose
<b>Step 1</b>	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
<b>Step 2</b>	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
<b>Step 3</b>	<b>mpls ip</b>  <b>Example:</b> Router(config)# mpls ip	Enables MPLS forwarding of IPv4 packets along normally routed paths for the platform.
<b>Step 4</b>	<b>end</b>  <b>Example:</b> Router(config)# end	Exits to privileged EXEC mode.

**Enabling LDP Globally**

Perform this task to enable LDP globally.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **mpls label protocol {ldp | tdp}**
4. **end**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>enable</code>	Enables privileged EXEC mode.
	<b>Example:</b> <code>Router&gt; enable</code>	<ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<code>configure terminal</code>	Enters global configuration mode.
	<b>Example:</b> <code>Router# configure terminal</code>	
Step 3	<code>mpls label protocol {ldp   tdp}</code>	Specifies the platform default label distribution protocol.
	<b>Example:</b> <code>Router(config)# mpls label protocol ldp</code>	
Step 4	<code>end</code>	Exits to privileged EXEC mode.
	<b>Example:</b> <code>Router(config)# end</code>	

## Enabling MPLS on an Interface

Perform this task to enable MPLS on an interface.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface [type number]`
4. `mpls ip`
5. `end`

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>interface</b> [ <i>type number</i> ]  <b>Example:</b> Router(config)# interface Ethernet 1	Enters interface configuration mode. <ul style="list-style-type: none"> <li>The <i>type number</i> argument identifies the interface to be configured.</li> </ul>
Step 4	<b>mpls ip</b>  <b>Example:</b> Router(config-if)# mpls ip	Enables MPLS forwarding of IPv4 packets along normally routed paths for a particular interface.
Step 5	<b>end</b>  <b>Example:</b> Router(config-if)# end	Exits to privileged EXEC mode.

## Enabling LDP on an Interface

Perform this task to enable LDP on an interface.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** [*type number*]
4. **mpls label protocol** {ldp | tdp | both}
5. **end**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"><li>Enter your password if prompted.</li></ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>interface</b> [type number]  <b>Example:</b> Router(config)# interface Ethernet 1	Enters interface configuration mode. <ul style="list-style-type: none"><li>The <i>type number</i> argument identifies the interface to be configured.</li></ul>
Step 4	<b>mpls label protocol</b> {ldp   tdp   both}  <b>Example:</b> Router(config-if)# mpls label protocol ldp	Specifies the label distribution protocol to be used on a given interface.
Step 5	<b>end</b>  <b>Example:</b> Router(config-if)# end	Exits to privileged EXEC mode.

## Configuring a VPN Aware LDP MIB

To configure a VPN Aware LDP MIB, perform the following tasks:

- [Configuring SNMP Support for a VPN, page 31](#)
- [Configuring an SNMP Context for a VPN, page 32](#)
- [Associating an SNMP VPN Context with SNMPv1 or SNMPv2, page 34](#)

## Configuring SNMP Support for a VPN

Perform this task to configure SNMP support for a Virtual Private Network (VPN) or a remote VPN.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server host** *host-address* [traps | informs] [version {1 | 2c | 3 [auth | noauth | priv]]  
*community-string* [udp-port *port*] [notification-type] [vrf *vrf-name*]
4. **snmp-server engineID remote** *ip-address* [udp-port *udp-port-number*] [vrf *vrf-name*]  
*engineid-string*
5. **end**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>snmp-server host</b> <i>host-address</i> [ <b>traps</b>   <b>informs</b> ] [ <b>version</b> {1   2c   3 [ <b>auth</b>   <b>noauth</b>   <b>priv</b> ]}] <i>community-string</i> [ <b>udp-port</b> <i>port</i> ] [ <i>notification-type</i> ] [ <b>vrf</b> <i>vrf-name</i> ]  <b>Example:</b> Router(config)# snmp-server host example.com vrf trap-vrf	Specifies the recipient of an SNMP notification operation and specifies the Virtual Private Network (VPN) routing and forwarding (VRF) instance table to be used for the sending of SNMP notifications.
Step 4	<b>snmp-server engineID remote</b> <i>ip-address</i> [ <b>udp-port</b> <i>udp-port-number</i> ] [ <b>vrf</b> <i>vrf-name</i> ] <i>engineid-string</i>  <b>Example:</b> Router(config)# snmp-server engineID remote 172.16.20.3 vrf traps-vrf 80000009030000B064EFE100	Configures a name for the remote SNMP engine on a router.
Step 5	<b>end</b>  <b>Example:</b> Router(config)# end	Exits to privileged EXEC mode.

## What to Do Next

Proceed to the [“Configuring an SNMP Context for a VPN”](#) section on page 32.

## Configuring an SNMP Context for a VPN

Perform this task to configure an SNMP context for a VPN. This sets up a unique SNMP context for a VPN, which allows you to access the VPN’s LDP session information.

## SNMP Context

SNMP contexts provide VPN users with a secure way of accessing MIB data. When a VPN is associated with a context, that VPN’s specific MIB data exists in that context. Associating a VPN with a context enables service providers to manage networks with multiple VPNs. Creating and associating a context with a VPN enables a provider to prevent the users of one VPN from accessing information about users of other VPNs on the same networking device.

## VPN Route Distinguishers

A route distinguisher (RD) creates routing and forwarding tables for a VPN. Cisco IOS adds the RD to the beginning of the customer's IPv4 prefixes to change them into globally unique VPN-IPv4 prefixes.

Either the RD is an autonomous system number (ASN)-relative RD, in which case it is composed of an autonomous system number and an arbitrary number, or it is an IP-address-relative RD, in which case it is composed of an IP address and an arbitrary number. You can enter an RD in either of these formats:

- 16-bit ASN: your 32-bit number, for example, 101:3.
- 32-bit IP address: your 16-bit number, for example, 192.168.122.15:1.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server context** *context-name*
4. **ip vrf** *vrf-name*
5. **rd** *route-distinguisher*
6. **context** *context-name*
7. **route-target** {**import** | **export** | **both**} *route-target-ext-community*
8. **end**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"><li>Enter your password if prompted.</li></ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>snmp-server context context-name</b>  <b>Example:</b> Router(config)# snmp-server context context1	Creates and names an SNMP context.
Step 4	<b>ip vrf vrf-name</b>  <b>Example:</b> Router(config)# ip vrf vrf1	Configures a Virtual Private Network (VPN) routing and forwarding instance (VRF) table and enters VRF configuration mode.
Step 5	<b>rd route-distinguisher</b>  <b>Example:</b> Router(config-vrf)# rd 100:120	Creates a VPN route distinguisher.
Step 6	<b>context context-name</b>  <b>Example:</b> Router(config-vrf)# context context1	Associates an SNMP context with a particular VRF.
Step 7	<b>route-target {import   export   both}</b> <b>route-target-ext-community</b>  <b>Example:</b> Router(config-vrf)# route-target export 100:1000	(Optional) Creates a route-target extended community for a VRF.
Step 8	<b>end</b>  <b>Example:</b> Router(config)# end	Exits to privileged EXEC mode.

## What to Do Next

Proceed to the [“Associating an SNMP VPN Context with SNMPv1 or SNMPv2”](#) section on page 34.

## Associating an SNMP VPN Context with SNMPv1 or SNMPv2

Perform this task to associate an SNMP VPN context with SNMPv1 or SNMPv2. This allows you to access LDP session information for a VPN using SNMPv1 or SNMPv2.

## SNMPv1 or SNMPv2 Security

SNMPv1 and SNMPv2 are not as secure as SNMPv3. SNMP Versions 1 and 2 use plain text communities and do not perform the authentication or security checks that SNMP Version 3 performs.

To configure the VPN Aware LDP MIB feature when using SNMP Version 1 or SNMP Version 2, you need to associate a community name with a VPN. This association causes SNMP to process requests coming in for a particular community string only if they come in from the configured VRF. If the community string contained in the incoming packet does not have an associated VRF, the packet is processed only if it came in through a non-VRF interface. This process prevents users outside the VPN from using a clear text community string to query the VPN data. However, this is not as secure as using SNMPv3.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server user** *username group-name* [**remote host** [**udp-port port**]] {**v1** | **v2c** | **v3** [**encrypted**] [**auth** {**md5** | **sha**} *auth-password*]} [**access access-list**]
4. **snmp-server group** *group-name* {**v1** | **v2c** | **v3** {**auth** | **noauth** | **priv**}} [**context context-name**] [**read readview**] [**write writeview**] [**notify notifyview**] [**access access-list**]
5. **snmp-server view** *view-name oid-tree* {**included** | **excluded**}
6. **snmp-server enable traps** [*notification-type*]
7. **snmp-server host** *host-address* [**traps** | **informs**] [**version** {**1** | **2c** | **3** [**auth** | **noauth** | **priv**]}] [*community-string*] [**udp-port port**] [**notification-type**] [**vrf vrf-name**]
8. **snmp mib community-map** *community-name* [**context context-name**] [**engineid engine-id**] [**security-name security-name**] **target-list** *vpn-list-name*
9. **snmp mib target list** *vpn-list-name* {**vrf vrf-name** | **host ip-address**}
10. **no snmp-server trap authentication vrf**
11. **exit**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>snmp-server user username group-name [remote host [udp-port port]] {v1   v2c   v3 [encrypted] [auth {md5   sha} auth-password]} [access access-list]</b>  <b>Example:</b> Router(config)# snmp-server user customer1 group1 v1	Configures a new user to an SNMP group.
Step 4	<b>snmp-server group group-name {v1   v2c   v3 {auth   noauth   priv}} [context context-name] [read readview] [write writeview] [notify notifyview] [access access-list]</b>  <b>Example:</b> Router(config)# snmp-server group group1 v1 context context1 read view1 write view1 notify view1	Configures a new SNMP group or a table that maps SNMP users to SNMP views. <ul style="list-style-type: none"> <li>Use the <b>context context-name</b> keyword and argument to associate the specified SNMP group with a configured SNMP context.</li> </ul>
Step 5	<b>snmp-server view view-name oid-tree {included   excluded}</b>  <b>Example:</b> Router(config)# snmp-server view view1 ipForward included	Creates or updates a view entry.
Step 6	<b>snmp-server enable traps [notification-type]</b>  <b>Example:</b> Router(config)# snmp-server enable traps	Enables all SNMP notifications (traps or informs) available on your system.
Step 7	<b>snmp-server host host-address [traps   informs] [version {1   2c   3 [auth   noauth   priv]] [community-string [udp-port port] [notification-type] [vrf vrf-name]</b>  <b>Example:</b> Router(config)# snmp-server host 10.0.0.1 vrf customer1 public udp-port 7002	Specifies the recipient of an SNMP notification operation.

	Command or Action	Purpose
Step 8	<pre>snmp mib community-map community-name [context context-name] [engineid engine-id] [security-name security-name] target-list vpn-list-name</pre> <p><b>Example:</b> Router(config)# snmp mib community-maps community1 context context1 target-list commAVpn</p>	Associates an SNMP community with an SNMP context, Engine ID, or security name.
Step 9	<pre>snmp mib target list vpn-list-name {vrf vrf-name   host ip-address}</pre> <p><b>Example:</b> Router(config)# snmp mib target list commAVpn vrf vrfl</p>	Creates a list of target VRFs and hosts to associate with an SNMP community.
Step 10	<pre>no snmp-server trap authentication vrf</pre> <p><b>Example:</b> Router(config)# no snmp-server trap authentication vrf</p>	<p>(Optional) Disables all SNMP authentication notifications (traps and informs) generated for packets received on VRF interfaces.</p> <ul style="list-style-type: none"> <li>Use this command to disable authentication traps only for those packets on VRF interfaces with incorrect community associations.</li> </ul>
Step 11	<pre>exit</pre> <p><b>Example:</b> Router(config) exit</p>	Exits to privileged EXEC mode.

## Verifying MPLS LDP MIB Version 8 Upgrade

Perform a MIB walk using your SNMP management tool to verify that the MPLS LDP MIB Version 8 Upgrade feature is functioning.

## Configuration Examples for MPLS LDP MIB Version 8 Upgrade

This section provides the following configuration examples:

- [MPLS LDP MIB Version 8 Upgrade Examples, page 37](#)
- [Configuring a VPN Aware SNMP Context for SNMPv1 or SNMPv2: Example, page 38](#)

## MPLS LDP MIB Version 8 Upgrade Examples

The following example shows how to enable an SNMP agent on the host NMS:

```
Router# configure terminal
```

Enter configuration commands, one per line. End with CNTL/Z.

```
Router(config)# snmp-server community
```

The following example shows how to enable SNMPv1 and SNMPv2C on the host NMS. The configuration permits any SNMP agent to access all MPLS LDP MIB objects that have read-only permission using the community string public.

```
Router(config)# snmp-server community public
```

The following example shows how to allow read-only access to all MPLS LDP MIB objects relating to members of access list 4 that specify the comaccess community string. No other SNMP agents will have access to any of the MPLS LDP MIB objects.

```
Router(config)# snmp-server community comaccess ro 4
```

The following example shows how to enable LDP globally and then on an interface:

```
Router# configure terminal
```

Enter configuration commands, one per line. End with CNTL/Z.

```
Router(config)# mpls label protocol ldp
```

```
Router(config)# interface Ethernet1
```

```
Router(config-if)# mpls label protocol ldp
```

```
Router(config-if)# end
```

## Configuring a VPN Aware SNMP Context for SNMPv1 or SNMPv2: Example

The following configuration example shows how to configure a VPN Aware SNMP context for the MPLS LDP MIB Version 8 with SNMPv1 or SNMPv2:

```
snmp-server context A
snmp-server context B

ip vrf CustomerA
 rd 100:110
 context A
 route-target export 100:1000
 route-target import 100:1000
!

ip vrf CustomerB
 rd 100:120
 context B
 route-target export 100:2000
 route-target import 100:2000
!

interface Ethernet3/1
 description Belongs to VPN A
 ip vrf forwarding CustomerA
 ip address 10.0.0.0 255.255.0.0

interface Ethernet3/2
 description Belongs to VPN B
 ip vrf forwarding CustomerB
 ip address 10.0.0.1 255.255.0.0
```

```
snmp-server user commA grp1A v1
snmp-server user commA grp2A v2c
snmp-server user commB grp1B v1
snmp-server user commB grp2B v2c

snmp-server group grp1A v1 context A read viewA write viewA notify viewA
snmp-server group grp1B v1 context B read viewB write viewB notify viewB

snmp-server view viewA ipForward included
snmp-server view viewA ciscoPingMIB included
snmp-server view viewB ipForward included
snmp-server view viewB ciscoPingMIB included

snmp-server enable traps
snmp-server host 10.0.0.3 vrf CustomerA commA udp-port 7002
snmp-server host 10.0.0.4 vrf CustomerB commB udp-port 7002

snmp mib community-map commA context A target-list commAvpn
! Configures source address validation
snmp mib community-map commB context B target-list commBvpn
! Configures source address validation
snmp mib target list commAvpn vrf CustomerA
! Configures a list of VRFs or from which community commA is valid
snmp mib target list commBvpn vrf CustomerB
! Configures a list of VRFs or from which community commB is valid
```

# Glossary

**ATM**—Asynchronous Transfer Mode. The international standard for cell relay in which multiple service types (such as voice, video, or data) are conveyed in fixed-length (53-byte) cells. Fixed-length cells allow cell processing to occur in hardware, thereby reducing transit delays. ATM is designed to take advantage of high-speed transmission media, such as E3, SONET, and T3.

**downstream-on-demand distribution**—A label distribution method in which a downstream label switch router (LSR) sends a binding upstream only if the upstream LSR requests it.

**downstream unsolicited distribution**—A label distribution method in which labels are dispersed if a downstream label switch router (LSR) needs to establish a new binding with its neighboring upstream LSR. For example, an edge LSR might enable a new interface with another subnet. The LSR then announces to the upstream router a binding to reach this network.

**informs**—A type of notification message that is more reliable than a conventional trap notification message, because the informs message notification requires acknowledgment, but a trap notification does not.

**label**—A short, fixed-length data identifier that tells switching nodes how to forward data (packets or cells).

**label distribution**—The techniques and processes that are used by label switch routers (LSRs) to exchange label binding information for supporting hop-by-hop forwarding along normally routed paths.

**LDP**—Label Distribution Protocol. The protocol that supports MPLS hop-by-hop forwarding and the distribution of bindings between labels and network prefixes. The Cisco proprietary version of this protocol is the Tag Distribution Protocol (TDP).

**LSP**—label-switched path. A configured connection between two label switch routers (LSRs) in which label-switching techniques are used for packet forwarding; also a specific path through an MPLS network.

**LSR**—label switch router. A Multiprotocol Label Switching (MPLS) node that can forward native Layer 3 packets. The LSR forwards a packet based on the value of a label attached to the packet.

**MIB**—Management Information Base. A database of network management information that is used and maintained by a network management protocol such as Simple Network Management Protocol (SNMP). The value of a MIB object can be changed or retrieved by the use of SNMP commands, usually through a network management system. MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

**MPLS**—Multiprotocol Label Switching. A switching method for the forwarding of IP traffic through the use of a label. This label instructs the routers and the switches in the network where to forward the packets based on preestablished IP routing information.

**MPLS label distribution**—A constraint-based routing algorithm for routing label-switched path (LSP) tunnels.

**NMS**—network management station. A powerful, well-equipped computer (typically an engineering workstation) that is used by a network administrator to communicate with other devices in the network. An NMS is typically used to manage network resources, gather statistics, and perform a variety of network administration and configuration tasks. In the context of SNMP, an NMS is a device that performs SNMP queries to the SNMP agent of a managed device to retrieve or modify information.

**notification**—A message sent by a Simple Network Management Protocol (SNMP) agent to a network management station, console, or terminal to indicate that a significant network event has occurred. *See also* trap.

**RSVP**—Resource Reservation Protocol. A protocol that supports the reservation of resources across an IP network. Applications running on IP end systems can use RSVP to indicate to other nodes the nature of the packet streams they want to receive by specifying such items as bandwidth, jitter, and maximum burst.

**RTR**—Response Time Reporter. A tool that allows you to monitor network performance, network resources, and applications by measuring response times and availability.

**SNMP**—Simple Network Management Protocol. A network management protocol used almost exclusively in TCP/IP networks. SNMP enables a user to monitor and control network devices, manage configurations, collect statistics, monitor performance, and ensure network security.

**SNMP communities**—Authentication scheme that enables an intelligent network device to validate SNMP requests.

**SNMPv2c**—Version 2c of the Simple Network Management Protocol. SNMPv2c supports centralized as well as distributed network management strategies and includes improvements in the Structure of Management Information (SMI), protocol operations, management architecture, and security.

**SNMPv3**—Version 3 of the Simple Network Management Protocol. Interoperable standards-based protocol for network management. SNMPv3 provides secure access to devices by a combination of authenticating and encrypting packets over the network.

**TDP**—Tag Distribution Protocol. A standard protocol used by MPLS-enabled routers to negotiate the tags (addresses) used for forwarding packets. *See also* LDP.

**TLV**—Type-Length-Value. A mechanism used by several routing protocols to carry a variety of attributes. Cisco Discovery Protocol (CDP), Label Discovery Protocol (LDP), and Border Gateway Protocol (BGP) are examples of protocols that use TLVs. BGP uses TLVs to carry attributes such as Network Layer Reachability Information (NLRI), Multiple Exit Discriminator (MED), and local preference.

**trap**—A message sent by an SNMP agent to a network management station, console, or terminal to indicate that a significant network event has occurred. Traps (notifications) are less reliable than inform requests, because the receiver of the trap does not send an acknowledgment of receipt; furthermore, the sender of the trap cannot determine if the trap was received. *See also* notification.

**VCC**—virtual channel connection. A logical circuit, made up of virtual channel links (VCLs), that carries data between two endpoints in an ATM network. Sometimes called a *virtual circuit connection*.

**VCI**—virtual channel identifier. A 16-bit field in the header of an ATM cell. The VCI, together with the virtual path identifier (VPI), is used to identify the next network virtual channel link (VCL) as the cell passes through a series of ATM switches on its way to its final destination.

**VCL**—virtual channel link. The logical connection that exists between two adjacent switches in an ATM network.

**VPI**—virtual path identifier. An 8-bit field in the header of an ATM cell. The VPI, together with the virtual channel identifier (VCI), is used to identify the next network virtual channel link (VCL) as the cell passes through a series of ATM switches on its way to its final destination.

**VPN**—Virtual Private Network. A network that enables IP traffic to use tunneling to travel securely over a public TCP/IP network.

**VRF**—VPN routing and forwarding instance. A VRF consists of an IP routing table, a derived forwarding table, a set of interfaces that use the forwarding table, and a set of rules and routing protocols that determine what goes into the forwarding table. In general, a VRF includes the routing information that defines a customer VPN site that is attached to a PE router.

# MPLS Traffic Engineering MIB

---

**First Published: May 22, 2001**

**Last Updated: February 18, 2009**

The MPLS Traffic Engineering MIB enables Simple Network Management Protocol (SNMP) agent support in Cisco IOS software for Multiprotocol Label Switching (MPLS) traffic engineering (TE) management, as implemented in the MPLS Traffic Engineering MIB (MPLS TE MIB). The SNMP agent code operating in conjunction with the MPLS TE MIB enables a standardized, SNMP-based approach to be used in managing the MPLS TE features in Cisco IOS software.

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the [“Feature Information for the MPLS Traffic Engineering MIB”](#) section on page 16.

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

# Restrictions for the MPLS Traffic Engineering MIB

The following restrictions apply to the MPLS TE MIB for Cisco IOS releases:

- Supports read-only (RO) permission for MIB objects.
- Contains no configuration support by means of SET functions, except for the `mplsTunnelTrapEnable` object (which has been made writable). Accordingly, the MPLS TE MIB contains indexing support for the Interfaces MIB.
- Supports only SNMP GET, GETNEXT, and GETBULK retrieval functions, except in the case of the `mplsTunnelTrapEnable` object (which has been made writable by means of SET functions).
- Contains no support for Guaranteed Bandwidth Traffic Engineering (GBTE) or Auto Bandwidth features.

## Information About the MPLS Traffic Engineering MIB

This section describes the following:

- [Supported Objects in the MPLS Traffic Engineering MIB, page 5](#)
- [CLI Access to MPLS Traffic Engineering MIB Information, page 9](#)

## MPLS Traffic Engineering MIB Cisco Implementation

The MPLS TE MIB is based on the Internet Engineering Task Force (IETF) draft MIB entitled *draft-ietf-mpls-te-mib-05.txt* which includes objects describing features that support MPLS TE.

Slight differences between the IETF draft MIB and the implementation of the TE capabilities within Cisco IOS software require some minor translations between the MPLS TE MIB and the internal data structures of Cisco IOS software. These translations are made by the SNMP agent code that is installed and operating on various hosts within the network. This SNMP agent code, running in the background as a low priority process, provides a management interface to Cisco IOS software.

The SNMP objects defined in the MPLS TE MIB can be displayed by any standard SNMP utility. All MPLS TE MIB objects are based on the IETF draft MIB; thus, no specific Cisco SNMP application is required to support the functions and operations pertaining to the MPLS TE MIB.

## MPLS Traffic Engineering Overview

MPLS TE capabilities in Cisco IOS software enable an MPLS backbone to replicate and expand upon the TE capabilities of Layer 2 ATM and Frame Relay networks.

TE capabilities are essential to effective management of service provider and Internet service provider (ISP) backbones. Such backbones must support high transmission capacities, and the networks incorporating backbones must be extremely resilient to link or node failures.

The MPLS TE facilities built into Cisco IOS software provide a feature-rich, integrated approach to managing the large volumes of traffic that typically flow through WANs. The MPLS TE facilities are integrated into Layer 3 network services, thereby optimizing the routing of IP traffic in the face of constraints imposed by existing backbone transmission capacities and network topologies.

## Capabilities Supported by the MPLS Traffic Engineering MIB

The following functionality is supported in the MPLS Traffic Engineering MIB:

- The ability to generate and queue notification messages that signal changes in the operational status of MPLS TE tunnels.
- Extensions to existing SNMP commands that provide the ability to enable, disable, and configure notification messages for MPLS TE tunnels.
- The ability to specify the name or the IP address of a network management station (NMS) in the operating environment to which notification messages are to be sent.
- The ability to write notification configurations into nonvolatile memory.

## Notification Generation Events

When MPLS TE notifications are enabled (see the **snmp-server enable traps mpls traffic-eng** command), notification messages relating to specific events within Cisco IOS software are generated and sent to a specified NMS in the network.

For example, an `mplsTunnelUp` notification is sent to an NMS when an MPLS TE tunnel is configured and the tunnel transitions from an operationally “down” state to an “up” state.

Conversely, an `mplsTunnelDown` notification is generated and sent to an NMS when an MPLS TE tunnel transitions from an operationally “up” state to a “down” state.

An `mplstunnelRerouted` notification is sent to the NMS under the following conditions:

- The signaling path of an existing MPLS TE tunnel fails for some reason and a new path option is signaled and placed into effect (that is, the tunnel is rerouted).
- The signaling path of an existing MPLS TE tunnel is fully operational, but a better path option can be signaled and placed into effect (that is, the tunnel can be reoptimized). This reoptimization can be triggered by:
  - A timer
  - The issuance of an **mpls traffic-eng reoptimize** command
  - A configuration change that requires the resignaling of a tunnel

The `mplsTunnelReoptimized` notification is not generated when an MPLS traffic engineering tunnel is reoptimized. However, an `mplsTunnelReroute` notification is generated. Thus, at the NMS, you cannot distinguish between a tunnel reoptimization event and tunnel reroute event.

Path options are configurable parameters that you can use to specify the order of priority for establishing a new tunnel path. For example, you can create a tunnel head configuration and define any one of many path options numbered 1 through  $n$ , with “1” being the highest priority option and “ $n$ ” being an unlimited number of lower priority path options. Thus, there is no limit to the number of path options that you can specify in this manner.

## Notification Implementation

When an MPLS TE tunnel interface (or any other device interface, such as an Ethernet or Packet over SONET (POS) interface) transitions between an up and down state, an Interfaces MIB (ifMIB) link notification is generated. When such a notification occurs in an MPLS TE MIB environment, the interface is checked by software to determine if the notification is associated with an MPLS TE tunnel. If so, the interfaces MIB link notification is interlinked with the appropriate `mplsTunnelUp` or `mplsTunnelDown` notification to provide notification to the NMS regarding the operational event occurring on the tunnel interface. Hence, the generation of an Interfaces MIB link notification pertaining to an MPLS traffic engineering tunnel interface begets an appropriate `mplsTunnelUp` or `mplsTunnelDown` notification that is transmitted to the specified NMS.

An `mplsTunnelRerouted` notification is generated whenever the signaling path for an MPLS TE tunnel changes. However, software intelligence in the MPLS TE MIB prevents the reroute notification from being sent to the NMS when a TE tunnel transitions between an up or down state during an administrative or operational status check of the tunnel. Either an up or down notification or a reroute notification can be sent in this instance, but not both. This action prevents unnecessary traffic on the network.

## Benefits of MPLS Traffic Engineering MIB

The MPLS Traffic Engineering MIB provides the following benefits:

- Provides a standards-based SNMP interface for retrieving information about MPLS TE.
- Provides information about the traffic flows on MPLS TE tunnels.
- Presents MPLS TE tunnel routes, including the configured route, the Interior Gateway Protocol (IGP) calculated route, and the actual route traversed.
- Provides information, in conjunction with the Interfaces MIB, about how a tunnel was rerouted in the event of a link failure.
- Provides information about the configured resources used for an MPLS TE tunnel.
- Supports the generation and queueing of notifications that call attention to major changes in the operational status of MPLS TE tunnels;
- Forwards notification messages to a designated NMS for evaluation or action by network administrators.

## MPLS Traffic Engineering MIB Layer Structure

The SNMP agent code supporting the MPLS TE MIB follows the existing model for such code in Cisco IOS software and is, in part, generated by the Cisco IOS tool set, based on the MIB source code.

The SNMP agent code, which has a layered structure similar to that of the MIB support code in Cisco IOS software, consists of four layers:

- Platform independent layer—This layer is generated primarily by the Cisco IOS MIB development tool set and incorporates platform and implementation independent functions. The Cisco IOS MIB development tool set creates a standard set of files associated with a MIB.
- Application interface layer—The functions, names, and template code for MIB objects in this layer are also generated by the Cisco IOS MIB development tool set.
- Application specific layer—This layer provides an interface between the application interface layer and the application program interface (API) and data structures layer and performs tasks needed to retrieve required information from Cisco IOS software, such as searching through data structures.
- API and data structures layer—This layer contains the data structures or APIs within Cisco IOS software that are retrieved or called in order to set or retrieve SNMP management information.

## Features and Technologies Related to MPLS Traffic Engineering MIB

The MPLS TE MIB feature is used in conjunction with the following features and technologies:

- Standards-based SNMP network management application
- MPLS
- MPLS TE
- MPLS label switching router MIB (MPLS-LSR-MIB)

## Supported Objects in the MPLS Traffic Engineering MIB

The MPLS TE MIB contains numerous tables and object definitions that provide read-only SNMP management support for the MPLS TE features in Cisco IOS software. The MPLS TE MIB conforms to Abstract Syntax Notation One (ASN.1), thus reflecting an idealized MPLS TE database.

Using any standard SNMP network management application, you can retrieve and display information from the MPLS TE MIB by using GET operations; similarly, you can traverse information in the MIB database for display by using GETNEXT operations.

The MPLS TE MIB tables and objects supported in Cisco IOS releases follow. Important MIB tables (those highlighted in bold type) are described briefly in accompanying text.

- **mplsTunnelConfigured**—Total number of tunnel configurations that are defined on this node.
- **mplsTunnelActive**—Total number of label switched paths (LSPs) that are defined on this node.
- **mplsTunnelTEDistProto**—The IGP distribution protocol in use.
- **mplsTunnelMaxHops**—The maximum number of hops any given tunnel can utilize.
- **mplsTunnelIndexNext**—Unsupported; set to 0.
- **mplsTunnelTable**—Entries in this table with an instance of 0 and a source address of 0 represent tunnel head configurations. All other entries in this table represent instances of LSPs, both signaled and standby. If a tunnel instance is signaled, its operating status (operStatus) is set to “up” (1) and its instance corresponds to an active LSP.

Tunnel configurations exist only on the tunnel head where the tunnel interface is defined. LSPs traverse the network and involve tunnel heads, tunnel midpoints, and tunnel tails.

Pointers in the tunnel table refer to corresponding entries in other MIB tables. By using these pointers, you can find an entry in the `mplsTunnelTable` and follow a pointer to other tables for additional information. The pointers are the following: *mplsTunnelResourcePointer*, *mplsTunnelHopTableIndex*, *mplsTunnelARHopTableIndex*, and *mplsTunnelCHopTableIndex*.

The tunnel table is indexed by tunnel ID, tunnel instance, tunnel source address, and tunnel destination address. The description of each entry has an alphabetic suffix (a), (b), or (c), if appropriate, to indicate the applicability of the entry:

- a. For tunnel head configurations only
- b. For LSPs only
- c. For both tunnel head configurations and LSPs

Following is a list and description of each entry.

- `mplsTunnelIndex`—Same as tunnel ID (c).
- `mplsTunnelInstance`—Tunnel instance of the LSP; 0 for head configurations (b).
- `mplsTunnelIngressLSRId`—Source IP address of the LSP; 0 for head configurations (b).
- `mplsTunnelEgressLSRId`—Destination IP address of the tunnel (c).
- `mplsTunnelName`—Command name for the tunnel interfaces (a).
- `mplsTunnelDescr`—Descriptive name for tunnel configurations and LSPs (c).
- `mplsTunnelIsIf`—Indicator of whether the entry represents an interface (c).
- `mplsTunnelIfIndex`—Index of the tunnel interface within the `ifMIB` (a).
- `mplsTunnelXCPointer`—(For midpoints only – no tails) Pointer for the LSP within the `mplsXCTable` of the MPLS LSR MIB (b).
- `mplsTunnelSignallingProto`—Signaling protocol used by tunnels (c).
- `mplsTunnelSetupPrio`—Setup priority of the tunnel (c).
- `mplsTunnelHoldingPrio`—Holding priority of the tunnel (c).
- `mplsTunnelSessionAttributes`—Session attributes (c).
- `mplsTunnelOwner`—Tunnel owner (c).
- `mplsTunnelLocalProtectInUse`—Not implemented (c).
- `mplsTunnelResourcePointer`—Pointer into the Resource Table (b).
- `mplsTunnelInstancePriority`—Not implemented (b).
- `mplsTunnelHopTableIndex`—Index into the Hop Table (a).
- `mplsTunnelARHopTableIndex`—Index into the AR Hop Table (b).
- `mplsTunnelCHopTableIndex`—Index into the C Hop Table (b).
- `mplsTunnelPrimaryTimeUp`—Amount of time, in seconds, that the current path has been up (a).
- `mplsTunnelPathChanges`—Number of times a tunnel has been ressignaled (a).
- `mplsTunnelLastPathChange`—Amount of time, in seconds, since the last path ressignaling occurred (a).
- `mplsTunnelCreationTime`—Time stamp when the tunnel was created (a).
- `mplsTunnelStateTransitions`—Number of times the tunnel has changed state (a).
- `mplsTunnelIncludeAnyAffinity`—Not implemented (a).

- `mplsTunnelIncludeAllAffinity`—Attribute bits that must be set for the tunnel to traverse a link (a).
- `mplsTunnelExcludeAllAffinity`—Attribute bits that must *not* be set for the tunnel to traverse a link (a).
- `mplsTunnelPathInUse`—Path option number being used for the tunnel’s path. If no path option is active, this object will be 0 (a).
- `mplsTunnelRole`—Role of the tunnel on the router; that is, head, midpoint, or tail (c).
- `mplsTunnelTotalUptime`—Amount of time, in seconds, that the tunnel has been operationally up (a).
- `mplsTunnelInstanceUptime`—Not implemented (b).
- `mplsTunnelAdminStatus`—Administrative status of a tunnel (c).
- `mplsTunnelOperStatus`—Actual operating status of a tunnel (c).
- `mplsTunnelRowStatus`—This object is used in conjunction with configuring a new tunnel. This object will always be seen as “active” (a).
- `mplsTunnelStorageType`—Storage type of a tunnel entry (c).
- `mplsTunnelHopListIndexNext`—Next valid index to use as an index in the `mplsTunnelHopTable`.
- **`mplsTunnelHopTable`**—Entries in this table exist only for tunnel configurations and correspond to the path options defined for the tunnel. Two types of path options exist: *explicit* and *dynamic*. This table shows all hops listed in the explicit path options, while showing only the destination hop for dynamic path options. The tunnel hop table is indexed by tunnel ID, path option, and hop number.

Following is a list and description of each table entry.

- `mplsTunnelHopListIndex`—Primary index into the table.
- `mplsTunnelHopIndex`—Secondary index into the table.
- `mplsTunnelHopAddrType`—Indicates if the address of this hop is the type IPv4 or IPv6.
- `mplsTunnelHopIpv4Addr`—The IPv4 address of this hop.
- `mplsTunnelHopIpv4PrefixLen`—The prefix length of the IPv4 address.
- `mplsTunnelHopIpv6Addr`—The IPv6 address of this hop.
- `mplsTunnelHopIpv6PrefixLen`—The prefix length of the IPv6 address.
- `mplsTunnelHopAsNumber`—This object will contain 0 or the autonomous system number of the hop, depending on the value of `mplsTunnelHopAddrType`.
- `mplsTunnelHopLspId`—This object will contain 0 or the LSPID of the tunnel, depending on the value of `mplsTunnelHopAddrType`.
- `mplsTunnelHopType`—Denotes whether this tunnel hop is routed in a strict or loose fashion.
- `mplsTunnelHopRowStatus`—This object is used in conjunction with the configuring of a new row in the table.
- `mplsTunnelHopStorageType`—The storage type of this MIB object.
- `mplsTunnelResourceIndexNext`—This object contains the next appropriate value to be used for `mplsTunnelResourceIndex` when creating entries in the `mplsTunnelResourceTable`.
- **`mplsTunnelResourceTable`**—Entries in this table correspond to the “Tspec” information displayed when you execute the **`show mpls traffic-eng tunnels`** command. These entries exist only for LSPs.

The tunnel resource table is indexed by address and hop number. Following the *mplsTunnelResourcePointer* pointer from the tunnel table is the best way to retrieve information from this table.

Following is a list and description of each table entry.

- *mplsTunnelResourceIndex*—The primary index into this table.
- *mplsTunnelResourceMaxRate*—The maximum rate, in bits per second, supported by this tunnel.
- *mplsTunnelResourceMeanRate*—The mean rate, in bits per second, supported by this tunnel.
- *mplsTunnelResourceMaxBurstSize*—The maximum burst size, in bytes, allowed by this tunnel.
- *mplsTunnelResourceRowStatus*—This object is used in conjunction with the configuration of a new row in the table.
- *mplsTunnelResourceStorageType*—The storage type of this MIB object.
- **mplsTunnelARHopTable**—Entries in this table correspond to the actual route taken by the tunnel, and whose route was successfully signaled by the network. The hops present in this table correspond to those present in the record route object (RRO) in Resource Reservation Protocol (RSVP). You can also display the information in this table by executing the **show mpls traffic-eng tunnels** command.

The actual route hop table is indexed by address and hop number. Following the *mplsTunnelARHopTableIndex* pointer from the tunnel table is the best way to retrieve information from this table.

Following is a list and description of each table entry:

- *mplsTunnelARHopListIndex*—The primary index into this table.
- *mplsTunnelARHopIndex*—The secondary index into this table.
- *mplsTunnelARHopIpv4Addr*—The IPv4 address of this hop.
- *mplsTunnelARHopIpv4PrefixLen*—The prefix length of the IPv4 address.
- *mplsTunnelARHopIpv6Addr*—The IPv6 address of this hop.
- *mplsTunnelARHopIpv6PrefixLen*—The prefix length of the IPv6 address.
- *mplsTunnelARHopAsNumber*—This object will contain 0 or the AS number of the hop, depending on the value of *mplsTunnelARHopAddrType*.
- *mplsTunnelARHopAddrType*—The type of address for this MIB entry, either IPv4 or IPv6.
- *mplsTunnelARHopType*—Denotes whether this tunnel hop is routed in a strict or loose manner.
- **mplsTunnelCHopTable**—Entries in this table correspond to the explicit route object (ERO) in RSVP, which is used to signal the LSP. The list of hops in this table will contain those hops that are computed by the constraint-based shortest path first (SPF) algorithm. In those cases where “loose” hops are specified for the tunnel, this table will contain the hops that are “filled-in” between the loose hops to complete the path. If you specify a complete explicit path, the computed hop table matches your specified path.

The computed hop table is indexed by address and hop number. Following the *mplsTunnelCHopTableIndex* pointer from the tunnel table is the best way to retrieve information from this table.

Following is a list and description of each table entry:

- *mplsTunnelCHopListIndex*—The primary index into this table.
- *mplsTunnelCHopIndex*—The secondary index into this table.
- *mplsTunnelCHopAddrType*—Indicates if the address of this hop is the type IPv4 or IPv6.

- `mplsTunnelCHopIpv4Addr`—The IPv4 address of this hop.
- `mplsTunnelCHopIpv4PrefixLen`—The prefix length of the IPv4 address.
- `mplsTunnelCHopIpv6Addr`—The IPv6 address of this hop.
- `mplsTunnelCHopIpv6PrefixLen`—The prefix length of the IPv6 address.
- `mplsTunnelCHopAsNumber`—This object will contain 0 or the autonomous system number of the hop, depending on the value of `mplsTunnelHopAddrType`.
- `mplsTunnelCHopType`—Denotes whether this tunnel hop is routed in a strict or loose way.
- **`mplsTunnelPerfTable`**—The tunnel performance table, which augments the **`mplsTunnelTable`**, provides packet and byte counters for each tunnel. This table contains the following packet and byte counters:
  - `mplsTunnelPerfPackets`—This packet counter works only for tunnel heads.
  - `mplsTunnelPerfHCPackets`—This packet counter works only for tunnel heads.
  - `mplsTunnelPerfErrors`—This packet counter works only for tunnel heads.
  - `mplsTunnelPerfBytes`—This byte counter works for tunnel heads and tunnel midpoints, but not for tunnel tails.
  - `mplsTunnelPerfHCBytes`—This byte counter works for tunnel heads and tunnel midpoints, but not for tunnel tails.
- `mplsTunnelTrapEnable`—The object type *mplsTunnelTrapEnable* is enhanced to be writable. Accordingly, if this object type is set to “TRUE,” the following notifications are enabled, thus giving you the ability to monitor changes in the operational status of MPLS TE tunnels:
  - `mplsTunnelUp`
  - `mplsTunnelDown`
  - `mplsTunnelRerouted`

If the *mplsTunnelTrapEnable* object is set to “FALSE,” such operational status notifications are not generated. These notification functions are based on the definitions (`mplsTeNotifications`) contained in the IETF draft document entitled *draft-ietf-mpls-te-mib-05.txt*.

## CLI Access to MPLS Traffic Engineering MIB Information

Figure 1 shows commands that you can use to retrieve information from specific tables in the MPLS TE MIB. As noted in this figure, some information in the MPLS TE MIB is not retrievable by commands.

**Figure 1**      **Commands for Retrieving MPLS TE MIB Information**

		show mpls traffic-eng tunnels	show mpls traffic-eng summary	show ip explicit-paths	show interfaces	Not available in command

## Retrieving Information from the MPLS Traffic Engineering MIB

This section describes how to efficiently retrieve information about TE tunnels. Such information can be useful in large networks that contain many TE tunnels.

Traverse across a single column of the *mplsTunnelTable*, such as *mplsTunnelName*. This action provides the indexes of every tunnel configuration, and any LSPs involving the host router. Using these indexes, you can perform a GET operation to retrieve information from any column and row of the *mplsTunnelTable*.

The *mplsTunnelTable* provides pointers to other tables for each tunnel. The column *mplsTunnelResourcePointer*, for example, provides an object ID (OID) that you can use to access resource allocation information in the *mplsTunnelResourceTable*. The columns *mplsTunnelHopTableIndex*, *mplsTunnelARHopTableIndex*, and *mplsTunnelCHopTableIndex* provide the primary index into the *mplsTunnelHopTable*, *mplsTunnelARHopTable*, and *mplsTunnelCHopTable*, respectively. By traversing the MPLS TE MIB in this manner using a hop table column and primary index, you can retrieve information pertaining to the hops of that tunnel configuration.

Because tunnels are treated as interfaces, the tunnel table column (*mplsTunnelIfIndex*) provides an index into the Interfaces MIB that you can use to retrieve interface-specific information about a tunnel.

## How to Configure the MPLS Traffic Engineering MIB

This section contains the following tasks:

- [Enabling the SNMP Agent to Help Manage Various MPLS TE Tunnel Characteristics of Tunnels on the Local Router, page 11](#) (required)

- [Verifying the Status of the SNMP Agent, page 12](#) (optional)

## Enabling the SNMP Agent to Help Manage Various MPLS TE Tunnel Characteristics of Tunnels on the Local Router

The SNMP agent for the MPLS TE MIB is disabled by default. To enable the SNMP agent for the MPLS TE MIB, perform the following steps.

### SUMMARY STEPS

1. `telnet host`
2. `enable`
3. `show running-config`
4. `configure terminal`
5. `snmp-server community string [view view-name] [ro | rw] [ipv6 nacl] [access-list-number]`
6. `snmp-server enable traps [identification-type] [notification-option]`
7. `exit`
8. `write memory`

### DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>telnet host</code>  <b>Example:</b> Router> telnet 192.172.172.172	Telnets to the router identified by the specified IP address (represented as xxx.xxx.xxx.xxx).
Step 2	<code>enable</code>  <b>Example:</b> Router# enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
Step 3	<code>show running-config</code>  <b>Example:</b> Router# show running-config	Displays the running configuration to determine if an SNMP agent is already running. <ul style="list-style-type: none"> <li>• If no SNMP information is displayed, go to <a href="#">Step 4</a>. If any SNMP information is displayed, you can modify the information or change it as needed.</li> </ul>
Step 4	<code>configure terminal</code>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
<b>Step 5</b>	<b>snmp-server community</b> <i>string</i> [ <b>view</b> <i>view-name</i> ] [ <b>ro</b>   <b>rw</b> ] [ <b>ipv6</b> <i>nacl</i> ] [ <i>access-list-number</i> ]  <b>Example:</b> Router(config)# snmp-server community comaccess ro 4	Enables the read-only (RO) community string.
<b>Step 6</b>	<b>snmp-server enable traps</b> [ <i>identification-type</i> ] [ <i>notification-option</i> ]  <b>Example:</b> Router(config)# snmp-server enable traps	Enables an LSR to send SNMP notifications or informs to an SNMP host.  <b>Note</b> This command is optional. After SNMP is enabled, all MIBs (not just the TE MIB) are available for the user to query.
<b>Step 7</b>	<b>exit</b>  <b>Example:</b> Router(config)# exit	Exits global configuration mode and returns to privileged EXEC mode.
<b>Step 8</b>	<b>write memory</b>  <b>Example:</b> Router# write memory	Writes the modified configuration to NVRAM, permanently saving the settings.

## Verifying the Status of the SNMP Agent

To verify that the SNMP agent has been enabled on a host network device, perform the following steps.

### SUMMARY STEPS

1. **telnet** *host*
2. **enable**
3. **show running-config**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>telnet</b> <i>host</i>  <b>Example:</b> Router# telnet 192.172.172.172	Telnet to the target device identified by the specified IP address (represented as <i>xxx.xxx.xxx.xxx</i> ).
Step 2	<b>enable</b>  <b>Example:</b> Router# enable	Enables SNMP on the target device.
Step 3	<b>show running-config</b>  <b>Example:</b> Router# show running-config	Displays the running configuration on the target device and is used to examine the output for displayed SNMP information.

## Examples

The following example displays the running configuration on the target device and its SNMP information.

```
Router# show running-config
.
.
.
snmp-server community public ro
snmp-server community private ro
```

Any **snmp-server** statement that appears in the output and takes the form shown here verifies that SNMP has been enabled on that device.

## Configuration Examples for the MPLS Traffic Engineering MIB

This section contains the following configuration examples:

- [Enabling the SNMP Agent to Help Manage Various MPLS TE Tunnel Characteristics of Tunnels on the Local Router: Example, page 13](#)

### Enabling the SNMP Agent to Help Manage Various MPLS TE Tunnel Characteristics of Tunnels on the Local Router: Example

The following example shows how to enable an SNMP agent on a host network device:

```
Router# configure terminal
Router(config)# snmp-server community private
```

The following example shows how to enable SNMPv1 and SNMPv2C. The configuration permits any SNMP agent to access all MPLS TE MIB objects with read-only permissions using the community string *public*.

```
Router(config)# snmp-server community public
```

The following example shows how to allow read-only access to all MPLS TE MIB objects relating to members of access list 4 that specify the *comaccess* community string. No other SNMP agents will have access to any MPLS TE MIB objects.

```
Router(config)# snmp-server community comaccess ro 4
```

## Additional References

The following sections provide references related to the MPLS Traffic Engineering MIB.

## Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Multiprotocol Label Switching Command Reference* at [http://www.cisco.com/en/US/docs/ios/mpls/command/reference/mp\\_book.html](http://www.cisco.com/en/US/docs/ios/mpls/command/reference/mp_book.html). For information about all Cisco IOS commands, go to the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup>.

- **snmp-server community**
- **snmp-server enable traps mpls traffic-eng**
- **snmp-server host**

# Feature Information for the MPLS Traffic Engineering MIB

Table 1 lists the release history for this MIB.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1** Feature Information for the MPLS Traffic Engineering MIB

Feature Name	Releases	Feature Information
MPLS Traffic Engineering MIB	12.0(17)S 12.0(17)ST 12.2(8)T 12.2(14)S 12.2(28)SB 12.2(31)SB2	<p>The MPLS Traffic Engineering MIB feature enables the SNMP agent support in Cisco IOS software for MPLS TE management, as implemented in the MPLS TE MIB.</p> <p>In 12.0(17)S, this feature provided the ability to generate and queue SNMP notification messages that signal changes in the operational status of MPLS TE tunnels when you are using the MPLS TE MIB on Cisco 7500 series routers and Cisco 12000 series Internet routers.</p> <p>In 12.0(17)ST, support for SNMP traffic engineering notifications was extended to include Cisco 7500 series routers and Cisco 12000 series Internet routers.</p> <p>In 12.2(8)T, support for SNMP TE notifications was extended to include Cisco 7500 series routers. The <b>snmp-server host</b> command was modified.</p> <p>In 12.2(14)S, this feature was integrated.</p> <p>In 12.2(28)SB, this feature was integrated.</p> <p>In 12.2(31)SB2, this feature was integrated.</p> <p>The following commands were introduced or modified: <b>snmp-server community</b>, <b>snmp-server enable traps mpls traffic-eng</b>, <b>snmp-server host</b>.</p>

# Glossary

**affinity bits**—An MPLS traffic engineering tunnel’s requirements on the attributes of the links it will cross. The tunnel’s affinity bits and affinity mask must match with the attributes of the various links carrying the tunnel.

**call admission precedence**—An MPLS traffic engineering tunnel with a higher priority will, if necessary, preempt an MPLS traffic engineering tunnel with a lower priority. An expected use is that tunnels that are more difficult to route will have a higher priority, and can preempt tunnels that are less difficult to route, on the assumption that those lower priority tunnels can find another path.

**constraint-based routing**—Procedures and protocols used to determine a route across a backbone taking into account resource requirements and resource availability, instead of simply using the shortest path.

**flow**—A traffic load entering the backbone at one point—point of presence (POP)—and leaving it from another that must be traffic engineered across the backbone. The traffic load will be carried across one or more LSP tunnels running from the entry POP to the exit POP.

**headend**—The LSR at which the tunnel originates. The tunnel’s “head” or tunnel interface will reside at this LSR as well.

**informs**—A type of notification message that is more reliable than a conventional trap notification message because an informs message requires acknowledgment.

**label**—A short, fixed-length data construct that tells switching nodes how to forward data (packets or cells).

**label switched path (LSP) tunnel**—A configured connection between two routers, using label switching to carry the packets.

**LSP**—label switched path. A path that is followed by a labeled packet over several hops, starting at an ingress LSR and ending at an egress LSR.

**LSR**—label switch router. A Layer 3 router that forwards a packet based on the value of a label encapsulated in the packet.

**MIB**—Management Information Base. A database of network management information (consisting of MIB objects) that is used and maintained by a network management protocol such as SNMP. The value of a MIB object can be changed or retrieved using SNMP commands, usually by a GUI-based network management system. MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

**MPLS**—Multiprotocol Label Switching. Switching method that forwards IP traffic using a label. This label instructs the routers and the switches in the network where to forward the packets based on preestablished IP routing information.

**NMS**—network management station. An NMS is a powerful, well-equipped computer (typically an engineering workstation) that is used by a network administrator to communicate with other devices in the network. An NMS is typically used to manage network resources, gather statistics, and perform a variety of network administration and configuration tasks.

**notification**—A message sent by an SNMP agent to a network management station, console, or terminal to indicate that a significant event within Cisco IOS software has occurred (see traps).

**OSPF**—Open Shortest Path First. A link-state routing protocol used for routing IP.

**RSVP**—Resource Reservation Protocol. Protocol for reserving network resources to provide quality of service (QoS) guarantees to application flows.

**SNMP**—Simple Network Management Protocol. A network management protocol used almost exclusively in TCP/IP networks. SNMP provides a means to monitor and control network devices, manage configurations, collect statistics, monitor performance, and ensure network security.

**tailend**—The downstream, receive end of a tunnel.

**traffic engineering**—Techniques and processes that cause routed traffic to travel through the network on a path other than the one that would have been chosen if standard routing methods were used.

**trap**—A message sent by an SNMP agent to a network management station, console, or terminal to indicate that a significant event within Cisco IOS software has occurred. Traps (notifications) are less reliable than inform requests, because the receiver of the trap does not send an acknowledgment of receipt; furthermore, the sender of the trap cannot determine if the trap was received (see notification).

**VCC**—virtual channel connection. A VCC is a logical circuit consisting of VCLs that carries data between two endpoints in an ATM network. Sometimes called a virtual circuit connection.

**VCI**—virtual channel identifier. A 16-bit field in the header of an ATM cell. The VCI, together with the VPI, is used to identify the next network VCL as the cell passes through a series of ATM switches on its way to its final destination.

**VCL**—virtual channel link. A VCL is the logical connection that exists between two adjacent switches in an ATM network.

**VPI**—virtual path identifier. An 8-bit field in the header of an ATM cell. The VPI, together with the VCI, is used to identify the next network VCL as the cell passes through a series of ATM switches on its way to its final destination.

# MPLS Traffic Engineering—Fast Reroute MIB

---

**First Published: March 30, 2001**

**Last Updated: February 27, 2009**

The MPLS Traffic Engineering—Fast Reroute MIB provides Simple Network Management Protocol (SNMP)-based network management of the Multiprotocol Label Switching (MPLS) Fast Reroute (FRR) feature in Cisco IOS software.

The Fast Reroute MIB has the following features:

- Notifications can be created and queued.
- Command-line interface (CLI) commands enable notifications, and specify the IP address to where the notifications will be sent.
- The configuration of the notifications can be written into nonvolatile memory.

The MIB includes objects describing features within MPLS FRR, and it includes the following tables:

- cmplsFrrConstTable
- cmplsFrrLogTable
- cmplsFrrFacRouteDBTable

The MIB also includes scalar objects (that is, objects that are not in a table). For more information, see the [“FRR MIB Scalar Objects” section on page 4](#).

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the [“Feature Information for MPLS Traffic Engineering—Fast Reroute MIB” section on page 17](#).

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

---

**Americas Headquarters:**

**Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA**

# Contents

- [Prerequisites for the MPLS Traffic Engineering—Fast Reroute MIB, page 2](#)
- [Restrictions for the MPLS Traffic Engineering—Fast Reroute MIB, page 3](#)
- [Information About the MPLS Traffic Engineering—Fast Reroute MIB, page 3](#)
- [How to Configure the MPLS Traffic Engineering—Fast Reroute MIB, page 8](#)
- [Configuration Examples for the MPLS Traffic Engineering—Fast Reroute MIB, page 14](#)
- [Additional References, page 15](#)
- [Feature Information for MPLS Traffic Engineering—Fast Reroute MIB, page 17](#)
- [Glossary, page 18](#)

## Prerequisites for the MPLS Traffic Engineering—Fast Reroute MIB

- The network must support the Intermediate System-to-Intermediate System (IS-IS) or Open Shortest Path First (OSPF) protocol.
- The SNMP is installed and enabled on the label switch routers (LSRs).
- MPLS is enabled globally on each LSR.
- Cisco Express Forwarding is enabled on the LSRs.
- Traffic engineering (TE) tunnels are enabled.
- MPLS FRR is enabled on one of the TE tunnels.
- The Resource Reservation Protocol (RSVP) is enabled.

## Restrictions for the MPLS Traffic Engineering—Fast Reroute MIB

- The implementation of the FRR MIB is limited to read-only (RO) permission for MIB objects.
- Configuration of the FRR MIB using the SNMP SET command is not supported in Cisco IOS Release 12.2(33)SRA or in prior releases.
- The following tables are not implemented in the specified releases:
  - mplsFrrOne2OnePlrTable—Not implemented in Cisco IOS software.
  - mplsFrrDetourTable—Not implemented in Cisco IOS software.
  - cmplsFrrLogTable—Implemented only in Cisco IOS 12.0S-based releases.

# Information About the MPLS Traffic Engineering—Fast Reroute MIB

To use the MPLS Traffic Engineering—Fast Reroute MIB, you need to understand the following concepts:

- [Feature Design of the MPLS Traffic Engineering—Fast Reroute MIB, page 3](#)
- [Functional Structure of the MPLS Traffic Engineering—Fast Reroute MIB, page 3](#)
- [System Flow of SNMP Protocol Requests and Response Messages, page 4](#)
- [FRR MIB Scalar Objects, page 4](#)
- [FRR MIB Notifications, page 5](#)
- [MIB Tables in the MPLS Traffic Engineering—Fast Reroute MIB, page 6](#)

## Feature Design of the MPLS Traffic Engineering—Fast Reroute MIB

The FRR MIB enables standard, SNMP-based network management of FRR in Cisco IOS software. This capability requires that SNMP agent code executes on a designated network management station (NMS) in the network. The NMS serves as the medium for user interaction with the network management objects in the MIB.

The FRR MIB is based on the Internet Engineering Task Force (IETF) draft MIB specification *draft-ietf-mpls-fastreroute-mib-02.txt*. The IETF draft MIB, which undergoes revisions periodically, is evolving toward becoming a standard. The Cisco implementation of the FRR MIB is expected to track the evolution of the IETF draft MIB, and may change accordingly.

Slight differences between the IETF draft MIB and the implementation of FRR within Cisco IOS software require some minor translations between the FRR MIB objects and the internal data structures of Cisco IOS software. These translations are accomplished by the SNMP agent, which runs in the background on the NMS workstation as a low priority process and provides a management interface to Cisco IOS software.

You can use an SNMP agent to access FRR MIB objects using standard SNMP GET operations. All the objects in the FRR MIB follow the conventions defined in the IETF draft MIB.

## Functional Structure of the MPLS Traffic Engineering—Fast Reroute MIB

The SNMP agent code supporting the FRR MIB follows the existing model for such code in Cisco IOS software and is, in part, generated by the Cisco IOS tool set, based on the MIB source code. The basis for the generated code is the Cisco version of the FRR MIB CISC0-ietf-frr-mib.

The SNMP agent code, which has a layered structure that is common to MIB support code in Cisco IOS software, consists of the following layers:

- **Platform-independent layer**—This layer is generated primarily by the MIB development Cisco IOS tool set and incorporates platform- and implementation-independent functions. These functions handle SNMP standard functionality in the context of the specific MIB. This layer handles indexes and range or enumeration value checks for GET, GET-NEXT, and SET SNMP operations. A function is generated for each SNMP table or group of objects. This layer calls into the next layer.
- **Application interface layer**—The Cisco IOS tool set generates the function names and template code for MIB objects.

- Application-specific layer—This layer provides the mechanism for retrieving relevant data from the managed application layer. It includes an entry point function for each table. This function calls two other functions; one that searches the TE tunnel database that RSVP maintains for the relevant data according to the indexes, and another function that fills the data into the structure.
- Managed application layer—This layer includes all the structures and mechanisms, and is managed by the MIB.

## System Flow of SNMP Protocol Requests and Response Messages

All SNMP protocol requests and response messages are ultimately handled by the SNMP master agent. When such a message is received on a router, the master agent parses the requests and identifies the MIB to which the request refers. The master agent then queries the subagent responsible for the MIB with a GET, GET-NEXT, or SET request. The FRR MIB subagent retrieves the appropriate data, and returns it to the master agent. The master agent is then responsible for returning an SNMP response to the NMS. All queries occur within the IP SNMP Cisco IOS process, which runs as a low priority task.

## FRR MIB Scalar Objects

Scalar objects are objects that are not in tables. A scalar object has one instance (that is, one occurrence).

[Table 1](#) describes the FRR MIB scalar objects.

**Table 1**      *Scalar Objects*

MIB Object	Function
cmplsFrrDetourIncoming	Number of detour link-state packets (LSPs) entering the device. This object returns 0 because cmplsFrrConstProtectionMethod is set to facilityBackup(1).
cmplsFrrDetourOutgoing	Number of detour LSPs leaving the device. This object returns 0 because cmplsFrrConstProtectionMethod is set to facilityBackup(1).
cmplsFrrDetourOriginating	Number of detour LSPs originating from the device. This object returns 0 because cmplsFrrConstProtectionMethod is set to facilityBackup(1).
cmplsFrrSwitchover	Number of tunnels that are being backed up because cmplsFrrConstProtectionMethod is set to facilityBackup(1).
cmplsFrrNumOfConfIfs	Number of MPLS interfaces FRR configured for protection; 0 indicates that LSPs traversing any interface can be protected.
cmplsFrrActProtectedIfs	Number of interfaces FRR is protecting because cmplsFrrConstProtectionMethod is set to facilityBackup(1).
cmplsFrrConfProtectingTuns	Number of backup Fast Reroute-protected tunnels configured because cmplsFrrConstProtectionMethod is set to facilityBackup(1).
cmplsFrrActProtectedTuns	Number of tunnels protected by the Fast Reroute feature. This object returns 0 because cmplsFrrConstProtectionMethod is set to facilityBackup(1).
cmplsFrrActProtectedLSPs	Number of LSPs that FRR is protecting. If cmplsFrrConstProtectionMethod is set to facilityBackup(1), this object returns 0.
cmplsFrrConstProtectionMethod	This object always returns facilityBackup(1) because Cisco supports only the facility backup protection method.

**Table 1**      *Scalar Objects (continued)*

MIB Object	Function
cmplsFrrNotifsEnabled	A value that indicates whether FRR notifications defined in this MIB are enabled or disabled. This object returns True(1) for enabled, or False(2) for disabled. The default is that notifications are disabled.
cmplsFrrLogTableMaxEntries	Maximum number of entries allowed in the FRR log table. In Cisco IOS 12.0S-based releases, this object always returns 32.
cmplsFrrLogTableCurrEntries	Current number of entries in the FRR log table. Except in Cisco IOS-based releases, this object always returns 0.
cmplsFrrNotifMaxRate	Maximum interval rate between FRR MIB notifications. This object always returns 0.

## FRR MIB Notifications

Notifications are issued after particular FRR events occur. This section provides the following information about FRR MIB notifications supported in Cisco IOS Release 12.0(26)S and in prior releases, Cisco IOS Release 12.2(33)SRA, Cisco IOS Release 12.2(33)SXH, and Cisco IOS Release 12.4(20)T:

- [Notification Generation Events, page 5](#)
- [Notification Specification, page 5](#)
- [Notification Monitoring, page 6](#)

### Notification Generation Events

When you enable FRR MIB notification functionality by issuing the **snmp-server enable traps mpls fast-reroute** command, FRR events generate notification messages that are sent to a designated NMS in the network to signal the occurrence of specific events in Cisco IOS software.

The FRR MIB objects involved in FRR status transitions and event notifications include cmplsFrrProtected. This message is sent to an NMS if there is a major TE tunnel change (that is, fast rerouting of TE tunnels).

### Notification Specification

Each FRR notification has a generic type identifier and an enterprise-specific type identifier for identifying the notification type. The generic type for all FRR notifications is “enterprise Specific” because this is not one of the generic notification types defined for SNMP. The enterprise-specific type is 1 for cmplsFrrProtected.

Each notification contains the following objects from the FRR MIB so that the FRR tunnel can be easily identified:

- cmplsFrrConstNumProtectingTunOnIf
- cmplsFrrConstNumProtectedTunOnIf
- cmplsFrrConstBandwidth

Upon being invoked, the appropriate FRR interface indexes have already been retrieved by existing FRR code. The FRR interfaces are then used to fill in data for the three objects included in the notification.

## Notification Monitoring

When FRR MIB notifications are enabled (see the **snmp-server enable traps** command), notification messages relating to specific FRR events within Cisco IOS software are generated and sent to a specified NMS in the network. Any utility that supports SNMPv1 or SNMPv2 notifications can receive notification messages.

To monitor FRR MIB notifications, log in to an NMS that supports a utility that displays SNMP notifications, and start the display utility.

## MIB Tables in the MPLS Traffic Engineering—Fast Reroute MIB

The FRR MIB consists of the following tables:

- [cmplsFrrConstTable](#), page 6
- [cmplsFrrLogTable](#), page 7
- [cmplsFrrFacRouteDBTable](#), page 7

The tables access various data structures to obtain information regarding detours, the FRR database, and logging.

### cmplsFrrConstTable

cmplsFrrConstTable displays the configuration of an FRR-enabled tunnel and the characteristics of its accompanying backup tunnels. For each protected tunnel, there can be multiple backup tunnels.

The table is indexed by the following:

- cmplsFrrConstIfIndex
- cmplsFrrConstTunnelIndex
- cmplsFrrConstTunnelInstance

[Table 2](#) describes the MIB objects for cmplsFrrConstTable.

**Table 2** *cmplsFrrConstTable Objects*

MIB Object	Function
cmplsFrrConstIfIndex	Uniquely identifies an interface on which FRR is configured. If an index has a value of 0, the configuration applies to all interfaces on the device on which the FRR feature can operate.
cmplsFrrConstTunnelIndex	Tunnel for which FRR is requested.
cmplsFrrConstTunnelInstance	Tunnel for which FRR is requested. The value always is 0 because only tunnel heads are represented, and tunnel heads have an instance value of 0.
cmplsFrrConstSetupPrio	Setup priority of the backup tunnel.
cmplsFrrConstHoldingPrio	Holding priority of the backup tunnel.
cmplsFrrConstInclAnyAffinity	Attribute bits that must be set for the tunnel to traverse a link.
cmplsFrrConstInclAllAffinity	Attribute bits that must not be set for the tunnel to traverse a link.
cmplsFrrConstExclAllAffinity	A link satisfies the exclude-all constraint only if the link contains none of the administrative groups specified in the constraint.

**Table 2** *cmplsFrrConstTable Objects (continued)*

MIB Object	Function
cmplsFrrConstHopLimit	The maximum number of hops that the backup tunnel can traverse.
cmplsFrrConstBandwidth	The bandwidth of the backup tunnels for this tunnel, in thousands of bits per second (kbps).
cmplsFrrConstRowStatus	Creates, modifies, and deletes a row in this table.

## cmplsFrrLogTable

### Note

cmplsFrrLogTable and the **show mpls traffic-eng fast-reroute log reroutes** command are supported only in Cisco IOS 12.0S-based releases.

cmplsFrrLogTable is indexed by the object cmplsFrrLogIndex. The index corresponds to a log entry in the FRR feature's **show mpls traffic-eng fast-reroute log reroutes** command. That **show** command stores up to 32 entries at a time. If entries are added, the oldest entry is overwritten with new log information.

cmplsFrrLogTable can store up to 32 entries at a time, overwriting older entries as newer ones are added. The index cmplsFrrLogIndex is incremented to give each log table entry of the MIB a unique index value. Therefore, it is possible to have indexes greater than 32 even though only 32 entries are displaying.

[Table 3](#) describes the MIB objects for cmplsFrrLogTable.

**Table 3** *cmplsFrrLogTable Objects*

MIB Object	Function
cmplsFrrLogIndex	Number of the FRR event.
cmplsFrrLogEventTime	Number of milliseconds that elapsed from bootstrap time to the time that the event occurred.
cmplsFrrLogInterface	Identifies the interface that was affected by this FRR event. The value can be set to 0 if mplsFrrConstProtectionMethod is set to oneToOneBackup(0).
cmplsFrrLogEventType	The type of FRR event that occurred. The object returns Protected or Other.
cmplsFrrLogEventDuration	Duration of the event, in milliseconds.
cmplsFrrLogEventReasonString	Implementation-specific explanation of the event. The object returns interface down event or interface other event.

## cmplsFrrFacRouteDBTable

The following indexes specify which interface and tunnel are being protected by the FRR feature:

- cmplsFrrFacRouteProtectedIfIndex
- cmplsFrrFacRouteProtectedTunIndex

The following indexes specify the backup tunnel that provides protection to the protected tunnel:

- `cmplsFrrFacRouteProtectedIfIndex`
- `cmplsFrrFacRouteProtectingTunIndex`
- `cmplsFrrFacRouteProtectedTunIndex`
- `cmplsFrrFacRouteProtectedTunInstance`
- `cmplsFrrFacRouteProtectedTunIngressLSRId`
- `cmplsFrrFacRouteProtectedTunEgressLSRId`

This version of the MIB will attempt to leverage the work already done for the MPLS TE MIB because it contains similar lookup functions for TE tunnels.

[Table 4](#) describes the MIB objects for `cmplsFrrFacRouteDBTable`.

**Table 4** *cmplsFrrFacRouteDBTable Objects*

MIB Object	Function
<code>cmplsFrrFacRouteProtectedIfIndex</code>	Interface configured for FRR protection.
<code>cmplsFrrFacRouteProtectingTunIndex</code>	The tunnel number of the protecting (backup) tunnel.
<code>cmplsFrrFacRouteProtectedTunIndex</code>	The <code>mplsTunnelEntry</code> primary index for the tunnel head interface designated to protect the interface specified in <code>mplsFrrFacRouteIfProtIdx</code> (and all the tunnels using this interface).
<code>cmplsFrrFacRouteProtectedTunInstance</code>	An <code>mplsTunnelEntry</code> that is being protected by FRR. An instance uniquely identifies a tunnel.
<code>cmplsFrrFacRouteProtectedTunIngressLSRId</code>	Inbound label for the backup LSR.
<code>cmplsFrrFacRouteProtectedTunEgressLSRId</code>	Outbound label for the backup LSR.
<code>cmplsFrrFacRouteProtectedTunStatus</code>	State of the protected tunnel. Valid values are: <ul style="list-style-type: none"> <li>• <code>active</code>—Tunnel label has been placed in the Label Forwarding Information Base (LFIB) and is ready to be applied to incoming packets.</li> <li>• <code>ready</code>—Tunnel's label entry has been created, but is not in the LFIB.</li> <li>• <code>partial</code>—Tunnel's label entry has not been fully created.</li> </ul>
<code>cmplsFrrFacRouteProtectingTunResvBw</code>	Amount of bandwidth, in megabytes per second, that is reserved by the backup tunnel.
<code>cmplsFrrFacRouteProtectingTunProtectionType</code>	Type of protection: 0 designates link protection; 1 designates node protection.

## How to Configure the MPLS Traffic Engineering—Fast Reroute MIB

This section contains the following tasks:

- [Enabling the SNMP Agent for FRR MIB Notifications, page 9](#) (required)
- [Enabling Cisco Express Forwarding, page 10](#) (required)

- [Enabling TE Tunnels, page 11](#) (required)
- [Enabling MPLS FRR on Each TE Tunnel, page 12](#) (required)
- [Enabling a Backup Tunnel on an Interface, page 13](#) (required)

## Enabling the SNMP Agent for FRR MIB Notifications

To enable the SNMP agent for FRR MIB notifications, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **show running-config**
3. **configure terminal**
4. **snmp-server community *string* [view *view-name*] [ro] [*access-list-number*]**
5. **snmp-server enable traps mpls fast-reroute protected**
6. **end**
7. **write memory**

### DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
Step 2	<b>show running-config</b>  <b>Example:</b> Router# show running-config	Displays the running configuration of the router to determine if an SNMP agent is already running on the device.  If no SNMP information is displayed, continue with the next step.  If any SNMP information is displayed, you can modify or change the information.
Step 3	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 4	<b>snmp-server community <i>string</i> [view <i>view-name</i>] [ro] [<i>access-list-number</i>]</b>  <b>Example:</b> Router(config)# snmp-server community public ro	Configures read-only (ro) SNMP community strings for the FRR MIB.

	Command or Action	Purpose
Step 5	<b>snmp-server enable traps mpls fast-reroute protected</b>  <b>Example:</b> Router(config)# snmp-server enable traps mpls fast-reroute protected	Enables Fast Reroute traps.
Step 6	<b>end</b>  <b>Example:</b> Router(config)# end	Exits to privileged EXEC mode.
Step 7	<b>write memory</b>  <b>Example:</b> Router# write memory	Writes the modified SNMP configuration into NVRAM of the router, permanently saving the SNMP settings.

## Enabling Cisco Express Forwarding

To enable Cisco Express Forwarding, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef distributed**
4. **end**

### DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	<code>ip cef distributed</code>  <b>Example:</b> Router(config)# ip cef distributed	Enables distributed Cisco Express Forwarding.
Step 4	<code>end</code>  <b>Example:</b> Router(config)# end	Exits to privileged EXEC mode.

## Enabling TE Tunnels

To enable TE tunnels, perform the following steps.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip cef`
4. `mpls traffic-eng tunnels`
5. `interface typeslot/port`
6. `mpls traffic-eng tunnels`
7. `end`

### DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>enable</code>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
Step 2	<code>configure terminal</code>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<code>ip cef</code>  <b>Example:</b> Router(config)# ip cef	Enables standard Cisco Express Forwarding operations.
Step 4	<code>mpls traffic-eng tunnels</code>  <b>Example:</b> Router(config)# mpls traffic-eng tunnels	Enables the MPLS TE tunnel feature on a device.

	Command or Action	Purpose
Step 5	<code>interface typeslot/port</code>  <b>Example:</b> Router(config)# interface POS1/0	Specifies the interface and enters interface configuration mode.
Step 6	<code>mpls traffic-eng tunnels</code>  <b>Example:</b> Router(config-if)# mpls traffic-eng tunnels	Enables the MPLS TE tunnel feature on an interface.
Step 7	<code>end</code>  <b>Example:</b> Router(config-if)# end	Returns to privileged EXEC mode.

## Enabling MPLS FRR on Each TE Tunnel

To enable MPLS FRR on each TE tunnel, perform the following steps.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface typeslot/port`
4. `tunnel mode mpls traffic-eng`
5. `tunnel mpls traffic-eng fast-reroute`
6. `end`

### DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>enable</code>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
Step 2	<code>configure terminal</code>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<code>interface typeslot/port</code>  <b>Example:</b> Router(config)# interface POS1/0	Specifies the interface and enters interface configuration mode.

	Command or Action	Purpose
Step 4	<code>tunnel mode mpls traffic-eng</code>  <b>Example:</b> Router(config-if)# tunnel mode mpls traffic-eng	Sets the mode of a tunnel to MPLS for traffic engineering.
Step 5	<code>tunnel mpls traffic-eng fast-reroute</code>  <b>Example:</b> Router(config-if)# tunnel mpls traffic-eng fast-reroute	Enables Fast Reroute on the TE tunnel being protected.
Step 6	<code>end</code>  <b>Example:</b> Router(config-if)# end	Exits to privileged EXEC mode.

## Enabling a Backup Tunnel on an Interface

To enable a backup tunnel on an interface, perform the following steps.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface typeslot/port`
4. `mpls traffic-eng backup-path tunnel interface`
5. `end`

### DETAILED STEPS

Step 1	<code>enable</code>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
Step 2	<code>configure terminal</code>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<code>interface typeslot/port</code>  <b>Example:</b> Router(config)# interface POS1/0	Specifies the interface and enters interface configuration mode.

	Command or Action	Purpose
Step 4	<code>mpls traffic-eng backup-path tunnel interface</code>  <b>Example:</b> Router(config-if)# mpls traffic-eng backup-path tunnel1	Enables a backup tunnel on a specified interface.
Step 5	<code>end</code>  <b>Example:</b> Router(config-if)# end	Exits to privileged EXEC mode.

## Configuration Examples for the MPLS Traffic Engineering—Fast Reroute MIB

- [Enabling an SNMP Agent on a Host NMS: Example, page 14](#)
- [Enabling Cisco Express Forwarding: Example, page 14](#)
- [Enabling TE Tunnels: Example, page 14](#)
- [Enabling MPLS FRR on Each TE Tunnel: Example, page 15](#)
- [Enabling a Backup Tunnel on an Interface: Example, page 15](#)

### Enabling an SNMP Agent on a Host NMS: Example

The following example shows how to enable an SNMP agent on the host NMS:

```
enable
show running-config
configure terminal
snmp-server community public ro
snmp-server enable traps mpls fast-reroute protected
end
write memory
```

### Enabling Cisco Express Forwarding: Example

The following example shows how to enable Cisco Express Forwarding:

```
enable
configure terminal
ip cef distributed
end
```

### Enabling TE Tunnels: Example

The following example shows how to enable traffic engineering tunnels:

```
enable
configure terminal
```

```
ip cef
mpls traffic-eng tunnels
interface Ethernet1/0
mpls traffic-eng tunnels
end
```

## Enabling MPLS FRR on Each TE Tunnel: Example

The following example shows how to enable MPLS Fast Reroute on each TE tunnel:

```
enable
configure terminal
interface POS1/0
tunnel mode mpls traffic-eng
tunnel mpls traffic-eng fast-reroute
end
```

## Enabling a Backup Tunnel on an Interface: Example

The following example shows how to enable a backup tunnel on an interface:

```
enable
configure terminal
interface POS1/0
mpls traffic-eng backup-path tunnel1
end
```

# Feature Information for MPLS Traffic Engineering—Fast Reroute MIB

Table 5 lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Release 12.0(10)ST or Cisco IOS Release 12.0(16)ST or 12.4(20)T or a later release appear in the table.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

**Table 5** Feature Information for MPLS Traffic Engineering—Fast Reroute MIB

Feature Name	Releases	Feature Information
MPLS Traffic Engineering—Fast Reroute MIB	12.0(10)ST 12.0(16)ST 12.0(22)S 12.0(26)S 12.2(33)SRA 12.2(33)SXH 12.4(20)T	<p>The MPLS Traffic Engineering—Fast Reroute MIB provides SNMP-based network management of the Multiprotocol Label Switching (MPLS) Fast Reroute (FRR) feature in Cisco IOS software.</p> <p>In 12.0(10)ST, the Fast Reroute link protection feature was introduced.</p> <p>In 12.0(16)ST, link protection for Cisco series 7200 and 7500 platforms was added.</p> <p>In 12.0(22)S, Fast Reroute enhancements, including node protection, were added.</p> <p>In 12.0(26)S, support for the IETF MIB <i>draft-ietf-mpls-fastreroute-mib-02.txt</i>, which provides network management for the FRR feature, was added.</p> <p>In 12.2(33)SRA, support for <code>cmplsFrrLogTableCurrEntries</code> and <code>cmplsFrrNotifMaxRate</code> was added. The <code>cmplsFrrLogTable</code> is not supported.</p> <p>In 12.2(33)SXH, support was added.</p> <p>In 12.4(20)T, support was added.</p>

# Glossary

**Cisco Express Forwarding**—An advanced Layer 3 IP switching technology. Cisco Express Forwarding optimizes network performance and scalability for networks with large and dynamic traffic patterns.

**index**—A method of uniquely identifying a tunnel.

**instance**—An occurrence. An object can have one or more instances.

**IS-IS**—Intermediate System-to-Intermediate System. IS-IS is an OSI link-state hierarchical routing protocol based on DECnet Phase V routing where intermediate system (IS) routers exchange routing information based on a single metric to determine network topology.

**label**—A short, fixed-length data construct that tells switching nodes how to forward data (packets or cells).

**LFIB**—Label Forwarding Information Base. The data structure for storing information about incoming and outgoing tags (labels) and associated equivalent packets suitable for labeling.

**LSR**—label switching router. A device that forwards MPLS packets based on the value of a fixed-length label encapsulated in each packet.

**MIB**—Management Information Base. A database of network management information that is used and maintained by a network management protocol such as Simple Network Management Protocol (SNMP). The value of a MIB object can be changed or retrieved by using SNMP commands, usually through a network management system. MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

**NMS**—network management station. A powerful, well-equipped computer (typically an engineering workstation) that is used by a network administrator to communicate with other devices in the network. An NMS is typically used to manage network resources, gather statistics, and perform a variety of network administration and configuration tasks.

**notification**—A message sent by a Simple Network Management Protocol (SNMP) agent to a network management station, console, or terminal to indicate that a significant event within Cisco IOS software has occurred.

**object**—A variable that has a specific instance associated with it.

**OSPF**—Open Shortest Path First. Link-state, hierarchical Interior Gateway Protocol (IGP) routing algorithm proposed as a successor to Routing Information Protocol (RIP) in the Internet community. OSPF features include least-cost routing, multipath routing, and load balancing.

**RSVP**—Resource Reservation Protocol. Protocol for reserving network resources to provide quality of service (QoS) guarantees to application flows.

**scalar object**—Objects that are not instances. A scalar object has one instance.

**SNMP**—Simple Network Management Protocol. A network management protocol used almost exclusively in TCP/IP networks. SNMP provides a means to monitor and control network devices, manage configurations, collect statistics, monitor performance, and ensure network security.

**SNMP agent**—A managed node or device. The router that has the MIB implementation on it.

# MPLS VPN—MIB Support

---

**First Published: March 18, 2002**

**Last Updated: August 26, 2008**

This document describes the Simple Network Management Protocol (SNMP) agent support in Cisco IOS software for Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) management, as implemented in the draft *MPLS/BGP Virtual Private Network Management Information Base Using SMIv2* (*draft-ietf-ppvpn-mpls-vpn-mib-05.txt*). This document also describes the cMplsNumVrfRouteMaxThreshCleared notification, which is implemented as part of the proprietary MIB CISCO-IETF-PPVNP-MPLS-VPN-MIB.

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the “[Feature Information for MPLS VPN—MIB Support](#)” section on page 30.

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

- [Glossary, page 32](#)

## Prerequisites for MPLS VPN—MIB Support

The MPLS VPN MIB agent requires the following:

- SNMP is installed and enabled on the label switching routers.
- MPLS is enabled on the label switching routers.
- Multiprotocol Border Gateway Protocol (BGP) is enabled on the label switching routers.
- Cisco Express Forwarding is enabled on the label switching routers.

## Restrictions for MPLS VPN—MIB Support

The following restrictions apply to the PPVPN-MPLS-VPN MIB:

- Configuration of the MIB using the SNMP SET command is not supported, except for trap-related objects, such as `mplsVpnNotificationEnable` and `mplsVpnVrfSecIllegalLabelRcvThresh`.
- The `mplsVpnVrfBgpNbrPrefixTable` is not supported.

## Information About MPLS VPN—MIB Support

This section contains the following topics:

- [MPLS VPN Overview, page 2](#)
- [MPLS VPN MIB Overview, page 3](#)
- [MPLS VPN MIB and the IETF, page 3](#)
- [Capabilities Supported by PPVPN-MPLS-VPN MIB, page 3](#)
- [Functional Structure of the PPVPN-MPLS-VPN MIB, page 4](#)
- [Supported Objects in PPVPN-MPLS-VPN MIB, page 4](#)
- [Unsupported Objects in PPVPN-MPLS-VPN MIB, page 19](#)

## MPLS VPN Overview

The MPLS VPN technology allows service providers to offer intranet and extranet VPN services that directly connect their customers' remote offices to a public network with the same security and service levels that a private network offers. Each VPN is associated with one or more VPN routing and forwarding (VRF) instances. A VRF is created for each VPN defined on a router and contains most of the information needed to manage and monitor MPLS VPNs: an IP routing table, a derived Cisco Express Forwarding table, a set of interfaces that use this forwarding table, and a set of rules and routing protocol parameters that control the information that is included in the routing table.

## MPLS VPN MIB Overview

The Provider-Provisioned VPN (PPVPN)-MPLS-VPN MIB provides access to MPLS VRF information, and interfaces included in the VRF, and other configuration and monitoring information.

The PPVPN-MPLS-VPN MIB provides the following benefits:

- A standards-based SNMP interface for retrieving information about critical MPLS VPN events.
- VRF information to assist in the management and monitoring of MPLS VPNs.
- Information, in conjunction with the Interfaces MIB, about interfaces assigned to VRFs.
- Performance statistics for all VRFs on a router.
- The generation and queueing of notifications that call attention to major changes in the operational status of MPLS VPN enabled interfaces; the forwarding of notification messages to a designated network management system (NMS) for evaluation and action by network administrators.
- Advanced warning when VPN routing tables are approaching or exceed their capacity.
- Warnings about the reception of illegal labels on a VRF-enabled interface. Such receptions may indicate misconfiguration or an attempt to violate security.

This document also describes the CISCO-IETF-PPVPN-MPLS-VPN-MIB, which contains the cMplsNumVrfRouteMaxThreshCleared notification.

## MPLS VPN MIB and the IETF

SNMP agent code operating with the PPVPN-MPLS-VPN MIB enables a standardized, SNMP-based approach to managing MPLS VPNs in Cisco IOS software.

The PPVPN-MPLS-VPN MIB is based on the Internet Engineering Task Force draft MIB specification *draft-ietf-ppvpn-mpls-vpn-mib-05.txt*, which includes objects describing features that support MPLS VPN events. This IETF draft MIB, which undergoes revisions from time to time, is becoming a standard. Accordingly, the Cisco implementation of the PPVPN-MPLS-VPN MIB is expected to track the evolution of the IETF draft MIB, and may change accordingly.

Some slight differences between the IETF draft MIB and the actual implementation of MPLS VPNs within Cisco IOS software require some minor translations between the PPVPN-MPLS-VPN MIB and the internal data structures of Cisco IOS software. These translations are accomplished by means of the SNMP agent code. Also, while running as a low priority process, the SNMP agent provides a management interface to Cisco IOS software. SNMP adds little overhead on the normal functions of the device.

The SNMP objects defined in the PPVPN-MPLS-VPN MIB can be viewed by any standard SNMP utility. The network administrator can retrieve information in the PPVPN-MPLS-VPN MIB using standard SNMP get and getnext operations for SNMP v1, v2, and v3.

All PPVPN-MPLS-VPN MIB objects are based on the IETF draft MIB; thus, no Cisco-specific SNMP application is required to support the functions and operations pertaining to the PPVPN-MPLS-VPN MIB features.

## Capabilities Supported by PPVPN-MPLS-VPN MIB

The PPVPN-MPLS-VPN MIB provides you with the ability to do the following:

- Gather routing and forwarding information for MPLS VPNs on a router.

- Expose information in the VRF routing table.
- Gather information on BGP configuration related to VPNs and VRF interfaces and statistics.
- Emit notification messages that signal changes when critical MPLS VPN events occur.
- Enable, disable, and configure notification messages for MPLS VPN events by using extensions to existing SNMP command-line interface (CLI) commands.
- Specify the IP address of NMS in the operating environment to which notification messages are sent.
- Write notification configurations into nonvolatile memory.

## Functional Structure of the PPVPN-MPLS-VPN MIB

The SNMP agent code supporting the PPVPN-MPLS-VPN MIB follows the existing model for such code in Cisco IOS software and is, in part, generated by the Cisco IOS software tool set, based on the MIB source code.

The SNMP agent code, which has a layered structure that is common to MIB support code in Cisco IOS software, consists of four layers:

- Platform-independent layer—This layer is generated primarily by the MIB development Cisco IOS software tool set and incorporates platform- and implementation-independent functions. The Cisco IOS MIB development tool set creates a standard set of files associated with a MIB.
- Application interface layer—The functions, names, and template code for MIB objects in this layer are also generated by the MIB development Cisco IOS software tool set.
- Application-specific layer—This layer provides an interface between the application interface layer and the API and data structures layer below and performs tasks needed to retrieve required information from Cisco IOS software, such as searching through data structures.
- API and data structures layer—This layer contains the data structures or APIs within Cisco IOS software that are retrieved or called in order to set or retrieve SNMP management information.

## Supported Objects in PPVPN-MPLS-VPN MIB

The PPVPN-MPLS-VPN MIB contains numerous tables and object definitions that provide read-only SNMP management support for the MPLS VPN feature in Cisco IOS software. The PPVPN-MPLS-VPN MIB conforms to Abstract Syntax Notation One (ASN.1), thus reflecting an idealized MPLS VPN database.

Using any standard SNMP network management application, you can retrieve and display information from the PPVPN-MPLS-VPN MIB using GET operations; similarly, you can traverse information in the MIB database for display using GETNEXT operations.

The PPVPN-MPLS-VPN MIB tables and objects are described briefly in the following sections:

- [Scalar Objects, page 6](#)
- [MIB Tables, page 6](#)
- [Notifications, page 16](#)

Objects that are not supported are listed in the [“Unsupported Objects in PPVPN-MPLS-VPN MIB” section on page 19](#).

Figure 1 shows a simple MPLS VPN configuration. This configuration includes two customer MPLS VPNs, labeled VPN1 and VPN2, and a simple provider network that consists of two provider edge (PE) routers, labeled PE1 and PE2, and a provider core router labeled P. Figure 1 shows the following sample configuration:

- VRF names—VPN1 and VPN2
- Interfaces associated with VRFs—Et1, Et2, and At3/0
- Routing protocols—Open Shortest Path First. Link-state (OSPF), Routing Information Protocol (RIP), and internal Border Gateway Protocol (IBGP)
- Routes associated with VPN1—10.1.0.0, 10.2.0.0, and 10.3.0.0
- Routes associated with VPN2—172.16.1.0 and 172.16.2.0
- Routes associated with the provider network—192.168.1.0, 192.168.2.0, and 192.168.3.0

This configuration is used in this document to explain MPLS VPN events that are monitored and managed by the PPVPN-MPLS-VPN MIB.

**Figure 1**      **Sample MPLS VPN Configuration**

## Scalar Objects

Table 1 shows the supported PPVPN-MPLS-VPN MIB scalar objects.

**Table 1** *PPVPN-MPLS-VPN MIB Scalar Objects*

MIB Object	Function
<code>mplsVpnConfiguredVrfs</code>	The number of VRFs configured on the router, including VRFs recently deleted.
<code>mplsVpnActiveVrfs</code>	The number of VRFs that are active on the router. An active VRF is assigned to at least one interface that is in the operationally up state.
<code>mplsVpnConnectedInterfaces</code>	The total number of interfaces assigned to any VRF.
<code>mplsVpnNotificationEnable</code>	<p>A value that indicates whether all the PPVPN-MPLS-VPN MIB notifications are enabled:</p> <ul style="list-style-type: none"> <li>Setting this object to true enables all notifications defined in the PPVPN-MPLS-VPN MIB.</li> <li>Setting this object to false disables all notifications defined in the MIB.</li> </ul> <p>This is one of the few objects that is writable.</p>
<code>mplsVpnVrfConfMaxPossibleRoutes</code>	A number that indicates the amount of routes that this router is capable of storing. This value cannot be determined because it is based on the amount of available memory in the system. Therefore, this object is set to zero (0).

## MIB Tables

The PPVPN-MPLS-VPN MIB implementation supports the following tables described in this section:

- [mplsVpnVrfTable](#), page 6
- [mplsVpnInterfaceConfTable](#), page 8
- [mplsVpnVrfRouteTargetTable](#), page 10
- [mplsVpnVrfBgpNbrAddrTable](#), page 12
- [mplsVpnVrfSecTable](#), page 13
- [mplsVpnVrfPerfTable](#), page 13
- [mplsVpnVrfRouteTable](#), page 13

### **mplsVpnVrfTable**

Entries in the VRF configuration table (`mplsVpnVrfTable`) represent the VRFs that are defined on the router. This includes recently deleted VRFs. The information in this table is also displayed with the **show ip vrf** command.

Each VRF is referenced by its VRF name (`mplsVpnVrfName`).

Table 2 lists the MIB objects and their functions for this table.

**Table 2** *PPVPN-MPLS-VPN MIB Objects for the mplsVpnVrfTable*

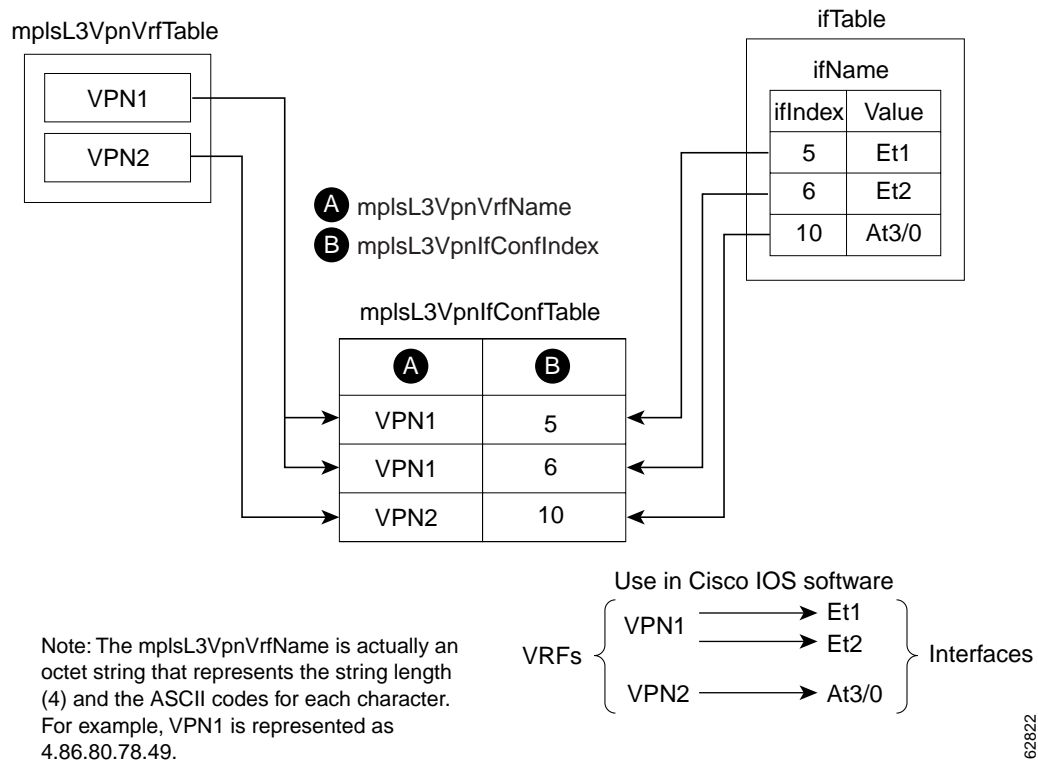

MIB Object	Function
mplsVpnVrfName	The name associated with this VRF. When this object is used as an index to a table, the first octet is the string length, and subsequent octets are the ASCII codes of each character. For example, “vpn1” is represented as 4.118.112.110.49.
mplsVpnVrfDescription	The description of the VRF. This is specified with the following configuration command:  Router(config)# <b>ip vrf</b> <i>vrf-name</i>  Router(config-vrf)# <b>description</b> <i>vrf-description</i>
mplsVpnVrfRouteDistinguisher	The route distinguisher for this VRF. This is specified with the following configuration command:  Router(config)# <b>ip vrf</b> <i>vrf-name</i>  Router(config-vrf)# <b>rd</b> <i>route-distinguisher</i>
mplsVpnVrfCreationTime	The value of the sysUpTime when this VRF entry was created.
mplsVpnVrfOperStatus	The operational status of this VRF. A VRF is up (1) when at least one interface associated with the VRF is up. A VRF is down (2) when: <ul style="list-style-type: none"> <li>No interfaces exist whose ifOperStatus = up (1).</li> <li>No interfaces are associated with this VRF.</li> </ul>
mplsVpnVrfActiveInterfaces	The number of interfaces assigned to this VRF that are operationally up.
mplsVpnVrfAssociatedInterfaces	The number of interfaces assigned to this VRF, independent of the operational status.
mplsVpnVrfConfMidRouteThreshold	The middle route threshold. If the amount of routes in the VRF crosses this threshold, an mplsNumVrfRouteMidThreshExceeded notification is sent (if notifications are enabled and configured). You can set this value in configuration mode as a percentage of the maximum with the <b>maximum routes limit</b> { <i>warn-threshold</i>   <b>warn-only</b> } command, as follows:  Router(config)# <b>ip vrf</b> <i>vpn1</i>  Router(config-vrf)# <b>maximum routes</b> 1000 50  The middle or warn threshold is set for VRF vpn1 as 50 percent of the maximum route threshold.  The following command sets a middle threshold of 1000 routes. An mplsNumVrfRouteMidThreshExceeded notification is sent when this threshold is exceeded. However, additional routes are still allowed because a maximum route threshold is not set with this command.  Router(config-vrf)# <b>maximum routes</b> 1000 <b>warn-only</b>

**Table 2** *PPVPN-MPLS-VPN MIB Objects for the mplsVpnVrfTable (continued)*

MIB Object	Function
mplsVpnVrfConfHighRouteThreshold	<p>The maximum route threshold. If the number of routes in the VRF crosses this threshold, an mplsNumVrfRouteMaxThreshExceeded notification is sent (if notifications are enabled and configured). You can set this value in configuration mode with the <b>maximum routes limit</b> {<i>warn-threshold</i>   <b>warn-only</b>} command as follows:</p> <pre>Router(config)# ip vrf vpn2</pre> <pre>Router(config-vrf)# maximum routes 1000 75</pre> <p>The maximum route threshold is set for 1000 routes for VRF vpn2 with a middle or warn threshold of 75 percent of this threshold.</p>
mplsVpnVrfConfMaxRoutes	This value is the same as the mplsVpnVrfConfHighRouteThreshold.
mplsVpnVrfConfLastChanged	<p>The value of sysUpTime when the configuration of the VRF changes or interfaces are assigned or unassigned from the VRF.</p> <p><b>Note</b> This object is updated only when values in this table change.</p>
mplsVpnVrfConfRowStatus	Read-only implementation. This object normally reads “active (1),” but may read “notInService (2),” if a VRF was recently deleted.
mplsVpnVrfConfStorageType	Read-only implementation. This object always reads “volatile (2).”

### mplsVpnInterfaceConfTable

In Cisco IOS software, a VRF is associated with one MPLS VPN. Zero or more interfaces can be associated with a VRF. A VRF uses an interface that is defined in the ifTable of the Interfaces Group of MIB II (IFMIB). The IFMIB defines objects for managing interfaces. The ifTable of this MIB contains information on each interface in the network. The mplsVpnInterfaceConfTable associates a VRF from the mplsVpnVrfTable with a forwarding interface from the ifTable. [Figure 2](#) shows the relationship between VRFs and interfaces defined in the ifTable and the mplsVpnInterfaceConfTable.

**Figure 2** VRFs, the Interfaces MIB, and the *mplsVpnInterfaceConfTable*

Entries in the VPN interface configuration table (*mplsVpnInterfaceConfTable*) represent the interfaces that are assigned to each VRF. The information available in this table is also displayed with the **show ip vrf** command.

The *mplsVpnInterfaceConfTable* shows how interfaces are assigned to VRFs. A label switch router (LSR) creates an entry in this table for every interface capable of supporting MPLS VPNs.

The *mplsVpnInterfaceConfTable* is indexed by the following:

- *mplsVpnVrfName*—The VRF name
- *mplsVpnInterfaceConfIndex*—An identifier that is the same as the *ifIndex* from the Interface MIB of the interface assigned to the VRF

Table 3 lists the MIB objects and their functions for this table.

**Table 3** *PPVPN-MPLS-VPN MIB Objects for the mplsVpnInterfaceConfTable*

MIB Object	Function
mplsVpnInterfaceConfIndex	Provides the interface MIB ifIndex of this interface that is assigned to a VRF.
mplsVpnInterfaceLabelEdgeType	Indicates whether the interface is a provider edge interface (1) or a customer edge interface (2).  This value is always providerEdge (1) because in Cisco IOS software, customerEdge interfaces are not assigned to VRFs and do not appear in this table.
mplsVpnInterfaceVpnClassification	Specifies what type of VPN this interface is providing: carrier supporting carrier (CSC) (1), enterprise (2), or InterProvider (3).  This value is set to enterprise (2) if MPLS is not enabled and to carrier supporting carrier (1) if MPLS is enabled on this interface.
mplsVpnInterfaceVpnRouteDistProtocol	Indicates the route distribution protocols that are being used to redistribute routes with BGP on this interface: BGP (2), OSPF (3), or RIP (4).  In Cisco IOS software, router processes are defined and redistributed on a per-VRF basis, not per-interface. Therefore, all interfaces assigned to the same VRF have the same value for this object.
mplsVpnInterfaceConfStorageType	Read-only implementation. This object always reads “volatile (2).”
mplsVpnInterfaceConfRowStatus	Read-only implementation. This object normally reads “active (1),” but may read “notInService (2),” if a VRF was recently deleted.

### mplsVpnVrfRouteTargetTable

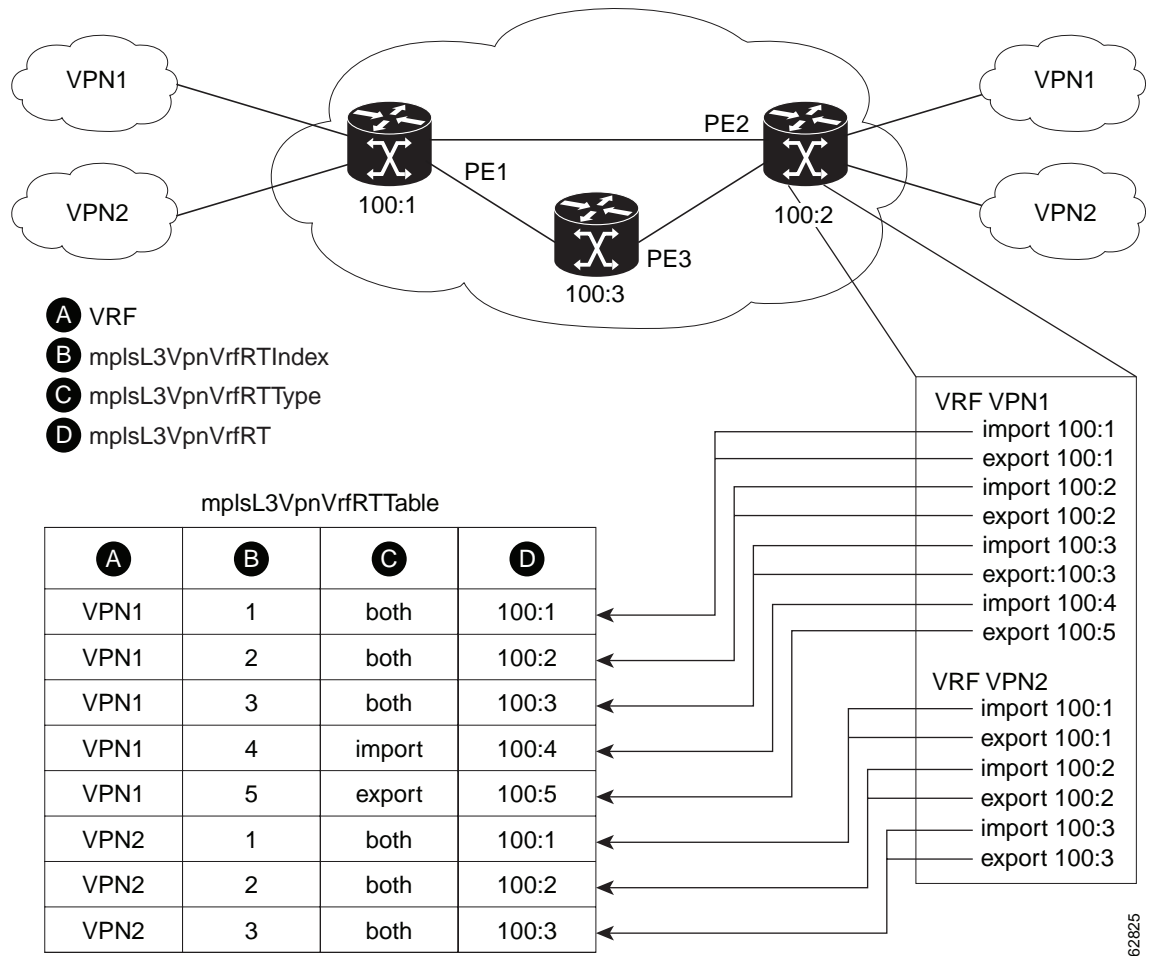

The route target table (mplsVpnVrfRouteTargetTable) describes the route target communities that are defined for a particular VRF. An LSR creates an entry in this table for each target configured for a VRF supporting an MPLS VPN instance.

The distribution of VPN routing information is controlled through the use of VPN route target communities, implemented by BGP extended communities. Distribution of VPN routing information works as follows:

- When a VPN route learned from a customer edge (CE) router is injected into BGP, a list of VPN route target extended community attributes is associated with it. Typically the list of route target community values is set from an export list of route targets associated with the VRF from which the route was learned.
- An import list of route target extended communities is associated with each VRF. The import list defines route target extended community attributes a route must have for the route to be imported into the VRF. For example, if the import list for a particular VRF includes route target communities A, B, and C, then any VPN route that carries any of those route target extended communities—A, B, or C—is imported into the VRF.

Figure 3 shows a sample configuration and its relationship to an mplsVpnVrfRouteTargetTable. A route target table exists on each PE router. Routers with route distinguishers (RDs) 100:1, 100:2, and 100:3 are shown in the sample configuration. Routers with RDs 100:4 and 100:5 are not shown in Figure 3, but are included in the route targets for PE2 and in the mplsVpnVrfRouteTargetTable.

**Figure 3** Sample Configuration and the *mplsVpnVrfRouteTargetTable*

Note: The mplsL3VpnVrfName is actually an octet string that represents the string length (4) and the ASCII codes for each character. For example, VPN1 is represented as 4.86.80.78.49.

The *mplsVpnVrfRouteTargetTable* shows the import and export route targets for each VRF. The table is indexed by the following:

- *mplsVpnVrfName*—The VRF name
- *mplsVpnVrfRouteTargetIndex*—The route target entry identifier
- *mplsVpnVrfRouteTargetType*—A value specifying whether the entry is an import route target, export route target, or is defined as both

Table 4 lists the MIB objects and their functions for this table.

**Table 4** *PPVPN-MPLS-VPN MIB Objects for the mplsVpnVrfRouteTargetTable*

MIB Object	Function
mplsVpnVrfRouteTargetIndex	A value that defines each route target's position in the table.
mplsVpnVrfRouteTargetType	Determines which type of route target the entry represents: import (1), export (2), or both (3).
mplsVpnVrfRouteTarget	Determines the route distinguisher for this target.
mplsVpnVrfRouteTargetDescr	Description of the route target. This object is not supported. Therefore, the object is the same as mplsVpnVrfRouteTarget.
mplsVpnVrfRouteTargetRowStatus	Read-only implementation. This object normally reads "active (1)," but may read "notInService (2)," if a VRF was recently deleted.

### mplsVpnVrfBgpNbrAddrTable

The BGP neighbor address table (mplsVpnVrfBgpNbrAddrTable) represents the MPLS external Border Gateway Protocol (eBGP) neighbors that are defined for a particular VRF. An LSR creates an entry for every BGP neighbor that is defined in the VRF's address-family.

The mplsVpnVrfBgpNbrAddrTable is indexed by the following:

- mplsVpnVrfName—The VRF name
- mplsVpnInterfaceConfIndex—An identifier that is the same as the ifIndex from the Interface MIB of the interface assigned to the VRF
- mplsVpnVrfBgpNbrIndex—The IP address of the neighbor

Table 5 lists the MIB objects and their functions for this table.

**Table 5** *PPVPN-MPLS-VPN MIB Objects for the mplsVpnVrfBgpNbrAddrTable*

MIB Object	Function
mplsVpnVrfBgpNbrIndex	The IPv4 address of the eBGP neighbor.
mplsVpnVrfBgpNbrRole	The role of this eBGP neighbor: customer edge (1) or provider edge (2). If the object mplsVpnInterfaceVpnClassification is CSC, then this value is provider edge (2); otherwise, this value is customer edge (1).
mplsVpnVrfBgpNbrType	Address type of this eBGP neighbor. The MIB supports only IPv4 (1). Therefore, this object returns "ipv4 (1)."
mplsVpnVrfBgpNbrAddr	IP address of the eBGP neighbor.
mplsVpnVrfBgpNbrRowStatus	Read-only implementation. This object normally reads "active (1)," but may read "notInService (2)" if a VRF was recently deleted.
mplsVpnVrfBgpNbrStorageType	Read-only implementation. This object always reads "volatile (2)."

## mplsVpnVrfSecTable

The VRF security table (mplsVpnVrfSecTable) provides information about security for each VRF. An LSR creates an entry in this table for every VRF capable of supporting MPLS VPN.

The mplsVpnVrfSecTable *augments* the mplsVpnVrfTable and has the same indexing.

Table 6 lists the MIB objects and their functions for this table.

**Table 6** PPVPN-MPLS-VPN MIB Objects for the mplsVpnVrfSecTable

MIB Object	Function
mplsVpnVrfSecIllegalLabelViolations	<p>The number of illegally received labels on a VRF interface. Only illegal labels are counted by this object, therefore the object only applies to a VRF interface that is MPLS enabled (CSC situation).</p> <p>This counter is incremented whenever a label is received that is above or below the valid label range, not in the global label forwarding table, or is received on the wrong VRF (that is, table IDs for the receiving interface and appropriate VRF label forwarding table do not match).</p>
mplsVpnVrfSecIllegalLabelRcvThresh	<p>Notification threshold for illegal labels received on this VRF. When the number of illegal labels received on this interface crosses this threshold, an mplsNumVrfSecIllegalLabelThreshExceeded notification is sent (if the notification is enabled and configured).</p> <p>This object is one of the few in this MIB agent that supports the SNMP SET operation, which allows you to change this value.</p>

## mplsVpnVrfPerfTable

The VRF performance table (mplsVpnVrfPerfTable) provides statistical performance information for each VRF. An LSR creates an entry in this table for every VRF capable of supporting MPLS VPN.

The mplsVpnVrfPerfTable *augments* the mplsVpnVrfTable and has the same indexing.

Table 7 lists the MIB objects and their functions for this table.

**Table 7** PPVPN-MPLS-VPN MIB Objects for the mplsVpnVrfPerfTable

MIB Objects	Functions
mplsVpnVrfPerfRoutesAdded	The number of routes added to this VRF over the course of its lifetime.
mplsVpnVrfPerfRoutesDeleted	The number of routes removed from this VRF.
mplsVpnVrfPerfCurrNumRoutes	The number of routes currently defined within this VRF.

## mplsVpnVrfRouteTable

The VRF routing table (mplsVpnVrfRouteTable) provides the IP routing table information for each VRF. The information available in this table can also be accessed with the **show ip route vrf vrf-name** command. For example, for PE1 in Figure 1:

- With the **show ip route vrf vpn1** command, you would see results like the following:

```
Router# show ip route vrf vpn1
```

```
Codes: C - connected, S - static, I - IGRP, R - RIP, M - mobile, B - BGP
D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
```

```

N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default, U - per-user static route, o - ODR
P - periodic downloaded static route
!
Gateway of last resort is not set
!
    10.0.0.0/32 is subnetted, 3 subnets
B       10.3.0.0 [200/0] via 192.168.2.1, 04:36:33
C       10.1.0.0/16 is directly connected, Ethernet1
C       10.2.0.0/16 [200/0] directly connected Ethernet2, 04:36:33

```

- With the **show ip route vrf vpn2** command, you would see results like the following:

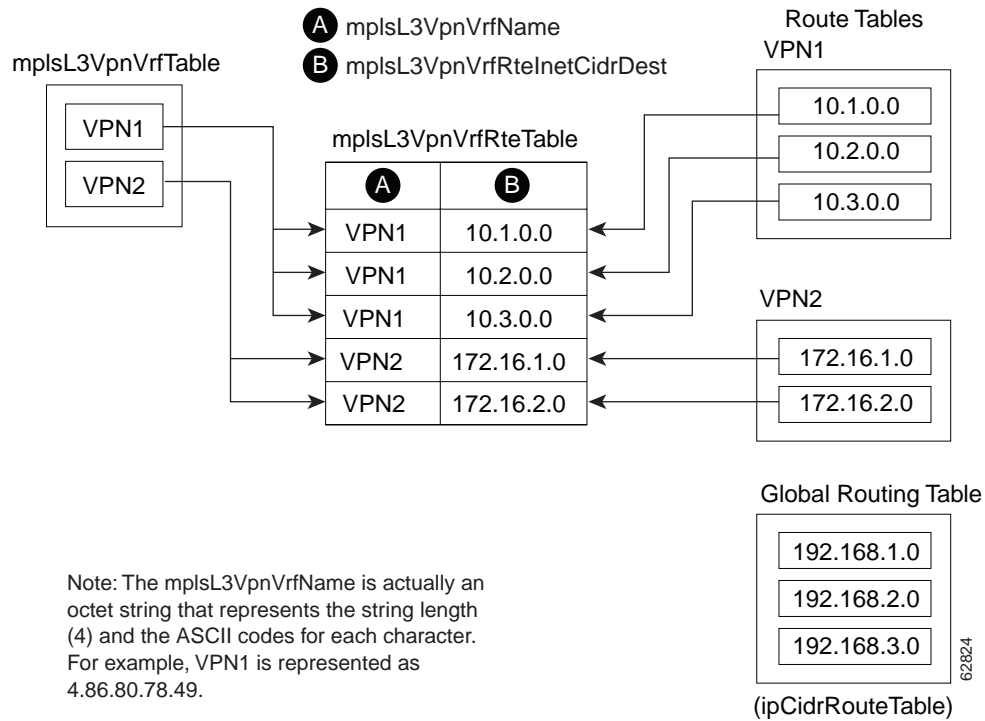

```

Router# show ip route vrf vpn2

Codes: C - connected, S - static, I - IGRP, R - RIP, M - mobile, B - BGP
D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default, U - per-user static route, o - ODR
P - periodic downloaded static route
!
Gateway of last resort is not set
!
    172.16.0.0/32 is subnetted, 2 subnets
B       172.16.2.0 [200/0] via 192.168.2.1, 04:36:33
C       172.16.1.0 is directly connected, ATM 3/0

```

Figure 4 shows the relationship of the routing tables, the VRFs, and the `mplsVpnVrfRouteTable`. You can display information about the VPN1 and VPN2 route tables using the **show ip route vrf vrf-name** command. The global route table is the same as `ipCidrRouteTable` in the IP-FORWARD-MIB. You can display information about the global route table with the **show ip route** command.

**Figure 4**      **Route Table, VRFs, and the mplsVpnVrfRouteTable**

An LSR creates an entry in this table for every route that is configured, either dynamically or statically, within the context of a specific VRF capable of supporting MPLS VPN.

The `mplsVpnVrfRouteTable` is indexed by the following:

- `mplsVpnVrfName`—The VRF name, which provides the VRF routing context
- `mplsVpnVrfRouteDest`—The IP destination address
- `mplsVpnVrfRouteMask`—The IP destination mask
- `mplsVpnVrfRouteTos`—The IP header ToS bits
- `mplsVpnVrfRouteNextHop`—The IP address of the next hop for each route entry

#### Note

The ToS bits are not supported and, therefore, are always 0.

Table 8 lists the MIB objects and their functions for the mplsVpnVrfRouteTable. This table represents VRF-specific routes. The global routing table is the ipCidrRouteTable in the IP-FORWARD-MIB.

**Table 8** *PPVPN-MPLS-VPN MIB Objects for the mplsVpnVrfRouteTable*

MIB Object	Function
mplsVpnVrfRouteDest	The destination IP address defined for this route.
mplsVpnVrfRouteDestAddrType	The address type of the IP destination address (mplsVpnVrfRouteDest). This MIB implementation supports only IPv4 (1). Therefore, this object has a value of “ipv4 (1).”
mplsVpnVrfRouteMask	The destination IP address mask defined for this route.
mplsVpnVrfRouteMaskAddrType	The address type of the destination IP address mask. This MIB implementation supports only IPv4 (1). Therefore, this object has a value of “ipv4 (1).”
mplsVpnVrfRouteTos	The ToS bits from the IP header for this route. Cisco IOS software supports only ToS bits of zero. Therefore, the object is always 0.
mplsVpnVrfRouteNextHop	The next hop IP address defined for this route.
mplsVpnVrfRouteNextHopAddrType	The address type of the next hop IP address. This MIB implementation only supports only IPv4 (1). Therefore, this object has a value of “ipv4 (1).”
mplsVpnVrfRouteIfIndex	The interface MIB ifIndex for the interface through which this route is forwarded. The object is 0 if no interface is defined for the route.
mplsVpnVrfRouteType	Defines if this route is a local or remotely defined route.
mplsVpnVrfRouteProto	The routing protocol that was responsible for adding this route to the VRF.
mplsVpnVrfRouteAge	The number of seconds since this route was last updated.
mplsVpnVrfRouteInfo	A pointer to more information from other MIBs. This object is not supported and always returns “nulloid (0.0).”
mplsVpnVrfRouteNextHopAS	The autonomous system number of the next hop for this route. This object is not supported and is always 0.
mplsVpnVrfRouteMetric1	The primary routing metric used for this route.
mplsVpnVrfRouteMetric2 mplsVpnVrfRouteMetric3 mplsVpnVrfRouteMetric4 mplsVpnVrfRouteMetric5	Alternate routing metrics used for this route. These objects are supported only for Cisco Interior Gateway Routing Protocol (IGRP) and Cisco Enhanced Interior Gateway Routing Protocol (EIGRP). These objects display the bandwidth metrics used for the route. Otherwise, these values are set to –1.
mplsVpnVrfRouteRowStatus	Read-only implementation. This object normally reads “active (1),” but may read “notInService (2),” if a VRF was recently deleted.
mplsVpnVrfRouteStorageType	Read-only implementation. This object always reads “volatile (2).”

## Notifications

This section provides the following information about supported PPVPN-MPLS-VPN MIB notifications:

- [PPVPN-MPLS-VPN MIB Notification Events, page 17](#)
- [Notification Specification, page 18](#)
- [Monitoring the PPVPN-MPLS-VPN MIB Notifications, page 19](#)

## PPVPN-MPLS-VPN MIB Notification Events

The following notifications of the PPVPN-MPLS-VPN MIB are supported:

- **mplsVrfIfUp**—Sent to an NMS when an interface comes up and is assigned a VRF instance.
- **mplsVrfIfDown**—Generated and sent to the NMS when a VRF is removed from an interface or the interface transitions from an operationally “up” state to a “down” state.
- **mplsNumVrfRouteMidThreshExceeded**—Generated and sent when the middle (warning) threshold is crossed. You can configure this threshold in the CLI by using the following commands:

```
Router(config)# ip vrf vrf-name
```

```
Router(config-vrf)# maximum routes limit warn-threshold (% of max)
```

The *warn-threshold* argument is a percentage of the maximum routes specified by the *limit* argument. You can also configure a middle threshold with the following command, in which the *limit* argument represents the warning threshold:

```
Router(config-vrf)# maximum routes limit warn-only
```

This notification is sent to the NMS only at the time the threshold is exceeded. (See [Figure 5](#) for a comparison of the warning and maximum thresholds.) Whenever the number of routes falls below this threshold and exceeds the threshold again, a notification is sent to the NMS.

- **MplsNumVrfRouteMaxThreshExceeded**—Generated and sent when you attempt to create a route on a VRF that already contains the maximum number of routes as defined by the *limit* argument of the **maximum routes** commands:

```
Router(config)# ip vrf vrf-name
```

```
Router(config-vrf)# maximum routes limit warn-threshold (% of max)
```

A trap notification is sent to the NMS when you attempt to exceed the maximum threshold. Another **MplsNumVrfRouteMaxThreshExceeded** notification is not sent until the number of routes falls below the maximum threshold and reaches the maximum threshold again. (See [Figure 5](#) for an example of how this notification works and for a comparison of the maximum and warning thresholds.)

### Note

The **maximum routes** command sets the number of routes for a VRF. You *cannot* exceed the number of routes in the VRF that you set with the **maximum routes limit warn-threshold** command.

Prior to implementation of the PPVPN-MPLS-VPN MIB, you were not notified when this threshold (or the warning threshold) was reached.

- **mplsNumVrfSecIllegalLabelThreshExceeded**—Generated and sent when the number of illegal labels received on a VRF interface exceeds the threshold *mplsVpnVrfSecIllegalLabelRcvThresh*. This threshold is defined with a value of 0. Therefore, a notification is sent when the first illegal label is received on a VRF. Labels are considered illegal if they are outside of the valid label range, do not have a Label Forwarding Information Base (LFIB) entry, or the table ID of the message does not match the table ID for the label in the LFIB.

## CISCO-IETF-PPVPN-MPLS-VPN MIB Notification Events

The following notification of the CISCO-IETF-PPVPN-MPLS-VPN MIB is supported in Cisco IOS 12.0S releases beginning with Release 12.0(30)S, and in Cisco IOS 12.2S releases beginning with Release 12.2(28)S:

- **cMplsNumVrfRouteMaxThreshCleared**—Generated and sent when the number of routes on a VRF attempts to exceed the maximum number of routes and then drops below the maximum number of routes. **If you attempt to create a route on a VRF that already contains the maximum number of routes, the mplsNumVrfRouteMaxThreshExceeded notification is sent (if enabled). When you remove routes from the VRF so that the number of routes falls below the set limit, the cMplsNumVrfRouteMaxThreshCleared notification is sent.** You can clear all routes from the VRF by using the **clear ip route vrf** command. (See [Figure 5](#) to see when the cMplsNumVrfRouteMaxThreshCleared notification is sent.)

**Figure 5** Comparison of Warning and Maximum Thresholds

For information on the Cisco IOS CLI commands for configuring PPVPN-MPLS-VPN MIB notifications that are to be sent to an NMS, see the [“How to Configure MPLS VPN—MIB Support” section on page 20](#) and the [“Command Reference” section on page 29](#).

## Notification Specification

In an SNMPv1 notification, each VPN notification has a generic type identifier and an enterprise-specific type identifier for identifying the notification type.

- The generic type for all VPN notifications is “enterpriseSpecific” because this is not one of the generic notification types defined for SNMP.

- The enterprise-specific type is identified as follows:
  - 1 for *mplsVrflfUp*
  - 2 for *mplsVrflfDown*
  - 3 for *mplsNumVrfRouteMidThreshExceeded*
  - 4 for *mplsNumVrfRouteMaxThreshExceeded*
  - 5 for *mplsNumVrfSecIllegalLabelThreshExceeded*
  - 6 for *cMplsNumVrfRouteMaxThreshCleared*

In SNMPv2, the notification type is identified by an *SnmpTrapOID* varbind (variable binding consisting of an object identifier [OID] type and value) included within the notification message.

Each notification also contains two additional objects from the PPVPN-MPLS-VPN MIB. These objects provide additional information about the event, as follows:

- The VRF interface up/down notifications provide additional variables—*mplsVpnInterfaceConfIndex* and *mplsVpnVrfName*—in the notification. These variables describe the SNMP interface index and the VRF name, respectively.
- The mid and max threshold notifications include the *mplsVpnVrfName* variable (VRF name) and the *mplsVpnVrfPerfCurrNumRoutes* variable that indicates the current number of routes within the VRF.
- The illegal label notification includes the *mplsVpnVrfName* variable (VRF name) and the *mplsVpnVrfSecIllegalLabelViolations* variable that maintains the current count of illegal labels on a VPN.

### Monitoring the PPVPN-MPLS-VPN MIB Notifications

When PPVPN-MPLS-VPN MIB notifications are enabled (see the [snmp-server enable traps mpls vpn](#) command), notification messages relating to specific MPLS VPN events within Cisco IOS software are generated and sent to a specified NMS in the network. Any utility that supports SNMPv1 or SNMPv2 notifications can receive notification messages.

To monitor PPVPN-MPLS-VPN MIB notification messages, log in to an NMS that supports a utility that displays SNMP notifications, and start the display utility.

## Unsupported Objects in PPVPN-MPLS-VPN MIB

The following objects from the *mplsVpnVrfBgpPathAttrTable* are not supported with SNMP management for MPLS VPN features in Cisco IOS software:

- *mplsVpnVrfBgpPathAttrPeer*
- *mplsVpnVrfBgpPathAttrIpAddrPrefixLen*
- *mplsVpnVrfBgpPathAttrIpAddrPrefix*
- *mplsVpnVrfBgpPathAttrOrigin*
- *mplsVpnVrfBgpPathAttrASPathSegment*
- *mplsVpnVrfBgpPathAttrNextHop*
- *mplsVpnVrfBgpPathAttrMultiExitDisc*
- *mplsVpnVrfBgpPathAttrLocalPref*

- `mplsVpnVrfBgpPathAttrAtomicAggregate`
- `mplsVpnVrfBgpPathAttrAggregatorAS`
- `mplsVpnVrfBgpPathAttrAggregatorAddr`
- `mplsVpnVrfBgpPathAttrCalcLocalPref`
- `mplsVpnVrfBgpPathAttrBest`
- `mplsVpnVrfBgpPathAttrUnknown`

## How to Configure MPLS VPN—MIB Support

This section describes configuration tasks for the MPLS VPN—MIB Support feature. Each task in the list is identified as either required or optional.

- [Configuring the SNMP Community, page 20](#) (required)
- [Configuring the Router to Send SNMP Traps, page 22](#) (required)
- [Configuring Threshold Values for MPLS VPN—SNMP Notifications, page 24](#) (required)

The MPLS VPN notifications are enabled or disabled using the extended CLI commands (see the [“Command Reference” section on page 29](#)).

### Configuring the SNMP Community

An SNMP community string defines the relationship between the SNMP manager and the agent. The community string acts like a password to regulate access to the agent on the router.

Perform this task to configure an SNMP community.

#### SUMMARY STEPS

1. **enable**
2. **show running-config** [*options*]
3. **configure terminal**
4. **snmp-server community** *string* [*view view-name*] [*ro* | *rw*] [*acl-number*]
5. **do copy running-config startup-config**
6. **exit**
7. **show-running config** [*interface* | *map-class*]

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>show running-config</b> [ <i>options</i> ]  <b>Example:</b> Router# show running-config	Displays the running configuration to determine if an SNMP agent is already running. <ul style="list-style-type: none"> <li>If no SNMP information is displayed, continue with the next step. If any SNMP information is displayed, you can modify the information or change it as needed.</li> </ul>
Step 3	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 4	<b>snmp-server community</b> <i>string</i> [ <b>view</b> <i>view-name</i> ] [ <b>ro</b>   <b>rw</b> ] [ <i>acl-number</i> ]  <b>Example:</b> Router(config)# snmp-server community comaccess ro	Sets up the community access string to permit access to the SNMP protocol. <ul style="list-style-type: none"> <li>The <i>string</i> argument acts like a password and permits access to the SNMP protocol.</li> <li>The <b>view</b> <i>view-name</i> keyword argument pair specifies the name of a previously defined view. The view defines the objects available to the community.</li> <li>The <b>ro</b> keyword specifies read-only access. Authorized management stations are only able to retrieve MIB objects.</li> <li>The <b>rw</b> keyword specifies read/write access. Authorized management stations are able to both retrieve and modify MIB objects.</li> <li>The <i>acl-number</i> argument is an integer from 1 to 99 that specifies an access list of IP addresses that are allowed to use the community string to gain access to the SNMP agent.</li> </ul>
Step 5	<b>do copy running-config startup-config</b>  <b>Example:</b> Router(config)# do copy running-config startup-config	Saves the modified configuration to NVRAM as the startup configuration file. <ul style="list-style-type: none"> <li>The <b>do</b> command allows you to perform EXEC level commands in configuration mode.</li> </ul>

	Command or Action	Purpose
Step 6	<code>exit</code>	Returns to privileged EXEC mode.
	<b>Example:</b> <code>Router(config)# exit</code>	
Step 7	<code>show running-config [options]</code>	(Optional) Displays the configuration information currently on the router, the configuration for a specific interface, or map-class information.
	<b>Example:</b> <code>Router# show-running config   include snmp-server</code>	<ul style="list-style-type: none"> <li>Use the <b>show running-config</b> command to check that the <b>snmp-server</b> statements appear in the output.</li> </ul>

## Configuring the Router to Send SNMP Traps

Perform this task to configure the router to sendm SNMP traps to a host.

The **snmp-server host** command specifies which hosts receive traps. The **snmp-server enable traps** command globally enables the trap production mechanism for the specified traps.

For a host to receive a trap, an **snmp-server host** command must be configured for that host, and, generally, the trap must be enabled globally through the **snmp-server enable traps** command.

### Note

Although you can set the *community-string* argument using the **snmp-server host** command by itself, we recommend you define this string using the **snmp-server community** command before using the **snmp-server host** command.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server host** *host-addr* [**traps** | **informs**] [**version** {**1** | **2c** | **3** [**auth** | **noauth** | **priv**]}] *community-string* [**udp-port** *port*] [*notification-type*] [**vrf** *vrf-name*]
4. **snmp-server enable traps mpls vpn** [**illegal-label**] [**max-thresh-cleared**] [**max-threshold**] [**mid-threshold**] [**vrf-down**] [**vrf-up**]
5. **end**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
	<b>Example:</b> <code>Router&gt; enable</code>	
Step 2	<code>configure terminal</code>	Enters global configuration mode.
	<b>Example:</b> <code>Router# configure terminal</code>	

	Command or Action	Purpose
Step 3	<pre>snmp-server host <i>host-addr</i> [<b>traps</b>   <b>informs</b>] [<b>version</b> {1   2c   3 [<b>auth</b>   <b>noauth</b>   <b>priv</b>]}] <i>community-string</i> [<b>udp-port</b> <i>port</i>] [<i>notification-type</i>] [<b>vrf</b> <i>vrf-name</i>]</pre> <p><b>Example:</b></p> <pre>Router(config)# snmp-server host 172.20.2.160 traps comaccess mpls-vpn</pre>	<p>Specifies the recipient of an SNMP notification operation.</p> <ul style="list-style-type: none"> <li>• The <i>host-addr</i> argument specifies the name or Internet address of the host (the targeted recipient).</li> <li>• The <b>traps</b> keyword sends SNMP traps to this host. This is the default.</li> <li>• The <b>informs</b> keyword sends SNMP informs to this host.</li> <li>• The <b>version</b> keyword specifies the version of the SNMP used to send the traps. Version 3 is the most secure model, because it allows packet encryption with the <b>priv</b> keyword. If you use the <b>version</b> keyword, you must specify one of the following: <ul style="list-style-type: none"> <li>– <b>1</b> —SNMPv1. This option is not available with informs.</li> <li>– <b>2c</b> —SNMPv2C.</li> <li>– <b>3</b> —SNMPv3. The following three optional keywords can follow the <b>version 3</b> keyword (<b>auth</b>, <b>noauth</b>, <b>priv</b>).</li> </ul> </li> <li>• The <i>community-string</i> argument is a password-like community string sent with the notification operation.</li> <li>• The <b>udp-port</b> <i>port</i> keyword argument pair names the User Datagram Protocol (UDP) port of the host to use. The default is 162.</li> <li>• The <i>notification-type</i> argument specifies the type of notification to be sent to the host. If no type is specified, all notifications are sent.</li> <li>• The <b>vrf</b> <i>vrf-name</i> keyword argument pair specifies the VRF table that should be used to send SNMP notifications.</li> </ul>

	Command or Action	Purpose
Step 4	<pre>snmp-server enable traps mpls vpn [illegal-label][max-thresh-cleared] [max-threshold][mid-threshold][vrf-down] [vrf-up]</pre> <p><b>Example:</b> Router(config)# snmp-server enable traps mpls vpn vrf-down vrf-up</p>	<p>Enables the router to send MPLS VPN-specific SNMP notifications (traps and informs).</p> <ul style="list-style-type: none"> <li>The <b>illegal-label</b> keyword enables a notification for any illegal labels received on a VRF interface. Labels are illegal if they are outside the legal range, do not have an LFIB entry, or do not match table IDs for the label.</li> <li>The <b>max-thresh-cleared</b> keyword enables a notification when the number of routes falls below the limit after the maximum route limit was attempted.</li> <li>The <b>max-threshold</b> keyword enables a notification that a route creation attempt was unsuccessful because the maximum route limit was reached. Another MplsNumVrfRouteMaxThreshExceeded notification is not sent until the number of routes falls below the maximum threshold and reaches the maximum threshold again. The max-threshold value is determined by the <b>maximum routes</b> command in VRF configuration mode.</li> <li>The <b>mid-threshold</b> keyword enables a notification of a warning that the number of routes created has crossed the warning threshold. This warning is sent only at the time the warning threshold is exceeded.</li> <li>The <b>vrf-down</b> keyword enables a notification for the removal of a VRF from an interface or the transition of an interface to the down state.</li> <li>The <b>vrf-up</b> keyword enables a notification for the assignment VRF to an interface that is operational or for the transition of a VRF interface to the operationally up state.</li> </ul>
Step 5	<pre>end</pre> <p><b>Example:</b> Router(config)# end</p>	<p>(Optional) Exits to privileged EXEC mode.</p>

## Configuring Threshold Values for MPLS VPN—SNMP Notifications

Perform this task to configure the following threshold values for MPLS VPN—SNMP notifications:

- The mplsNumVrfRouteMidThreshExceeded notification event is generated and sent when the middle (warning) threshold is crossed. You can configure this threshold in the CLI by using the **maximum routes** command in VRF configuration mode. This notification is sent to the NMS only at the time the threshold is exceeded. Whenever the number of routes falls below this threshold and exceeds the threshold again, a notification is sent to the NMS.
- The mplsNumVrfRouteMaxThreshExceeded notification event is generated and sent when you attempt to create a route on a VRF that already contains the maximum number of routes as defined by the **maximum routes** command in VRF configuration mode. A trap notification is sent to the

NMS when you attempt to exceed the maximum threshold. Another `MplsNumVrfRouteMaxThreshExceeded` notification is not sent until the number of routes falls below the maximum threshold and reaches the maximum threshold again.

See [Figure 5](#) for an example of how this notification works and for a comparison of the maximum and warning thresholds.

**Note**

The **maximum routes** command sets the number of routes for a VRF. You *cannot* exceed the number of routes in the VRF that you set with the **maximum routes limit warn-threshold** command.

Prior to the implementation of the PPVPN-MPLS-VPN MIB, you were not notified when this threshold (or the warning threshold) was reached.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip vrf vrf-name**
4. **maximum routes limit {warn-threshold | warn-only}**
5. **end**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>ip vrf vrf-name</b>  <b>Example:</b> Router(config)# ip vrf vpn1	Configures a VRF routing table and enters VRF configuration mode. <ul style="list-style-type: none"> <li>The <i>vrf-name</i> argument specifies the name assigned to a VRF.</li> </ul>

	Command or Action	Purpose
Step 4	<pre>maximum routes limit {warn-threshold   warn-only}</pre> <p><b>Example:</b></p> <pre>Router(config-vrf)# maximum routes 10000 80</pre>	<p>Limits the maximum number of routes in a VRF to prevent a PE router from importing too many routes.</p> <ul style="list-style-type: none"> <li>The <i>limit</i> argument specifies the maximum number of routes allowed in a VRF. The range is from 1 to 4,294,967,295.</li> <li>The <i>warn-threshold</i> argument generates a warning when the number of routes set by the <i>warn-threshold</i> argument is reached and rejects routes that exceed the maximum number set in the <i>limit</i> argument. The warning threshold is a percentage from 1 to 100 of the maximum number of routes specified in the <i>limit</i> argument.</li> <li>The <b>warn-only</b> keyword specifies that a system logging error message is issued when the maximum number of routes allowed for a VRF exceeds the limit threshold. However, additional routes are still allowed.</li> </ul>
Step 5	<pre>end</pre> <p><b>Example:</b></p> <pre>Router(config-vrf)# end</pre>	(Optional) Exits to privileged EXEC mode.

## Configuration Examples for MPLS VPN—MIB Support

This section contains the following configuration examples for the MPLS VPN—MIB Support feature:

- [Configuring the SNMP Community: Examples, page 26](#)
- [Configuring the Router to Send SNMP Traps: Example, page 27](#)
- [Configuring Threshold Values for MPLS VPN—SNMP Notifications: Examples, page 27](#)

### Configuring the SNMP Community: Examples

The following example shows enabling a simple SNMP community group. This configuration permits any SNMP client to access all PPVPN-MPLS-VPN MIB objects with read-only access using the community string comaccess.

```
Router# configure terminal
```

```
Router(config)# snmp-server community comaccess ro
```

Verify that the SNMP master agent is enabled for the MPLS VPN—MIB Support feature:

```
Router# show running-config | include snmp-server
```

```
Building configuration...
```

```
.
```

```
snmp-server community comaccess RO
```

#### Note

If you do not see any “snmp-server” statements, SNMP is not enabled on the router.

## Configuring the Router to Send SNMP Traps: Example

The following example shows you how to enable the router to send MPLS VPN notifications to host 172.20.2.160 using the comaccess community string if a VRF transitions from an up or down state:

```
Router# configure terminal

Router(config)# snmp-server host 172.20.2.160 traps comaccess mpls-vpn

Router(config)# snmp-server enable traps mpls vpn vrf-down vrf-up
```

## Configuring Threshold Values for MPLS VPN—SNMP Notifications: Examples

The following example shows how to set a maximum threshold of 10,000 routes and a warning threshold that is 80 percent of the maximum threshold for a VRF named vpn1 on a router:

```
Router(config)# ip vrf vpn1

Router(config-vrf)# maximum routes 10000 80
```

The following example shows how to set a warning threshold of 10,000 routes for a VRF named vpn2 on a router. An error message is generated; however, additional routes are still allowed because a maximum route threshold is not set with this command.

```
Router(config)# ip vrf vpn2

Router(config-vrf)# maximum routes 10000 warn-only
```

## Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Multiprotocol Label Switching Command Reference* at [http://www.cisco.com/en/US/docs/ios/mpls/command/reference/mp\\_book.html](http://www.cisco.com/en/US/docs/ios/mpls/command/reference/mp_book.html). For information about all Cisco IOS commands, use the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the *Cisco IOS Master Command List, All Releases*, at [http://www.cisco.com/en/US/docs/ios/mcl/allreleasemcl/all\\_book.html](http://www.cisco.com/en/US/docs/ios/mcl/allreleasemcl/all_book.html).

- **snmp-server enable traps mpls vpn**

## Feature Information for MPLS VPN—MIB Support

[Table 9](#) lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

**Note**

---

[Table 9](#) lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

---

**Table 9**      **Feature Information for MPLS VPN—MIB Support**

Feature Name	Releases	Feature Information

# Glossary

**autonomous system**—A collection of networks that share the same routing protocol and that are under the same system administration.

**ASN.1**—Abstract Syntax Notation One. The data types independent of particular computer structures and representation techniques. Described by ISO International Standard 8824.

**BGP**—Border Gateway Protocol. The exterior Border Gateway Protocol used to exchange routing information between routers in separate autonomous systems. BGP uses TCP. Because TCP is a reliable protocol, BGP does not experience problems with dropped or fragmented data packets.

**BGP prefixes**—A route announcement using the BGP. A prefix is composed of a path of autonomous system numbers, indicating which networks the packet must pass through, and the IP block that is being routed. A BGP prefix would look something like: 701 1239 42 206.24.14.0/24. (The /24 part is referred to as a CIDR mask.) The /24 indicates that there are 24 ones in the netmask for this block starting from the left side. A /24 corresponds to the natural mask 255.255.255.0.

**Cisco Express Forwarding**—An advanced Layer 3 IP switching technology. Cisco Express Forwarding optimizes network performance and scalability for networks with large and dynamic traffic patterns.

**CE router**—customer edge router. A router on the border between a VPN provider and a VPN customer that belongs to the customer.

**CIDR**—classless interdomain routing. A technique supported by BGP4 and based on route aggregation. CIDR allows routers to group routes to reduce the quantity of routing information carried by the core routers. With CIDR, several IP networks appear to networks outside the group as a single, larger entity. With CIDR, IP addresses and their subnet masks are written as four octets, separated by periods, followed by a forward slash and a two-digit number that represents the subnet mask.

**community**—In SNMP, a logical group of managed devices and NMSs in the same administrative domain.

**community name**—*See* community string.

**community string**—A text string that acts as a password and is used to authenticate messages sent between a managed station and a router containing an SNMP agent. The community string is sent in every packet between the manager and the client. Also called a community name.

**IETF**—Internet Engineering Task Force. A task force consisting of over 80 working groups responsible for developing Internet standards. The IETF operates under the auspices of ISOC. *See also* ISOC.

**informs**—A type of notification message that is more reliable than a conventional trap notification message, because the informs message notification requires acknowledgment, and a trap notification does not.

**ISOC**—Internet Society. An international nonprofit organization, founded in 1992, that coordinates the evolution and use of the Internet. In addition, ISOC delegates authority to other groups related to the Internet, such as the IAB. ISOC is headquartered in Reston, Virginia (United States).

**label**—A short, fixed-length data construct that tells switching nodes how to forward data (packets or cells).

**LDP**—Label Distribution Protocol. A standard protocol between MPLS-enabled routers that is used for the negotiation of the labels (addresses) used to forward packets.

**LFIB**—Label Forwarding Information Base. In the Cisco Label Switching system, the data structure for storing information about incoming and outgoing tags (labels) and associated equivalent packets suitable for labeling.

**LSR**—label switch router. A device that forwards MPLS packets based on the value of a fixed-length label encapsulated in each packet.

**MIB**—Management Information Base. A database of network management information that is used and maintained by a network management protocol such as SNMP or CMIP. The value of a MIB object can be changed or retrieved using SNMP or CMIP commands, usually through a GUI network management system. MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

**MPLS**—Multiprotocol Label Switching. A method for forwarding packets (frames) through a network. It enables routers at the edge of a network to apply labels to packets (frames). ATM switches or existing routers in the network core can switch packets according to the labels with minimal lookup overhead.

**MPLS interface**—An interface on which MPLS traffic is enabled.

**MPLS VPN**—Multiprotocol Label Switching Virtual Private Network. An IP network infrastructure delivering private network services over a public infrastructure using a Layer 3 backbone. Using MPLS VPNs in a Cisco IOS network provides the capability to deploy and administer scalable Layer 3 VPN backbone services including applications, data hosting network commerce, and telephony services to business customers.

For an MPLS VPN solution, an MPLS VPN is a set of provider edge routers that are connected by means of a common “backbone” network to supply private IP interconnectivity between two or more customer sites for a given customer. Each VPN has a set of provisioning templates and policies and can span multiple provider administrative domains (PADs).

**NMS**—network management system. A powerful, well-equipped computer (typically an engineering workstation) that is used by a network administrator to communicate with other devices in the network. An NMS is typically used to manage network resources, gather statistics, and perform a variety of network administration and configuration tasks.

**notification**—A message sent by an SNMP agent to a network management station, console, or terminal to indicate that a significant event within Cisco IOS software has occurred. *See also* trap.

**PE router**—provider edge router. A router on the border between a VPN provider and a VPN customer that belongs to the provider.

**PPVPN**—Provider-Provisioned VPN. The name of the IETF working group that is developing the PPVPN-MPLS-VPN MIB.

**QoS**—quality of service. A measure of performance for a transmission system that reflects its transmission quality and service availability.

**RSVP**—Resource Reservation Protocol. A protocol for reserving network resources to provide quality of service guarantees to application flows.

**RT**—route target. An extended community attribute that identifies a group of routers and, in each router of that group, a subset of forwarding tables maintained by the router that can be populated with a BGP route carrying that extended community attribute. The RT is a 64-bit value by which Cisco IOS discriminates routes for route updates in VRFs.

**SNMP**—Simple Network Management Protocol. The network management protocol used almost exclusively in TCP/IP networks. SNMP provides a means to monitor and control network devices, and to manage configurations, statistics collection, performance, and security. *See also* SNMP2.

**SNMP2**—SNMP Version 2. Version 2 of the popular network management protocol. SNMP2 supports centralized and distributed network management strategies, and includes improvements in the Structure of Management Information (SMI), protocol operations, management architecture, and security. *See also* SNMP.

**traffic engineering**—The techniques and processes used to cause routed traffic to travel through the network on a path other than the one that would have been chosen if standard routing methods had been used.

**trap**—A message sent by an SNMP agent to a network management station, console, or terminal, indicating that a significant event occurred. Traps (notifications) are less reliable than inform requests, because the receiver does not send an acknowledgment when it receives a trap. The sender cannot determine if the trap was received. *See also* notification.

**VPN**—Virtual Private Network. A group of sites that, as the result of a set of administrative policies, are able to communicate with each other over a shared backbone network. A VPN is a secure IP-based network that shares resources on one or more physical networks. A VPN contains geographically dispersed sites that can communicate securely over a shared backbone. *See also* MPLS VPN.

**VPN ID**—A mechanism that identifies a VPN based on RFC 2685. A VPN ID consists of an Organizational Unique Identifier (OUI), a three-octet hex number assigned by the IEEE Registration Authority, and a VPN index, a four-octet hex number, which identifies the VPN within the company.

**VRF**—VPN routing and forwarding instance. A VRF consists of an IP routing table, a derived forwarding table, a set of interfaces that use the forwarding table, and a set of rules and routing protocols that determine what goes into the forwarding table. In general, a VRF includes the routing information that defines a customer VPN site that is attached to a PE router.

# MPLS EM—MPLS LDP MIB—RFC 3815

---

**First Published: February 19, 2007**

**Last Updated: April 23, 2009**

The MPLS EM—MPLS LDP MIB - RFC 3815 feature document describes the MIBs that support the Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) based on RFC 3815, *Definitions of Managed Objects for the Multiprotocol Label Switching (MPLS), Label Distribution Protocol (LDP)*, and describes the differences between RFC 3815 and the MPLS-LDP-MIB based on the Internet Engineering Task Force (IETF) draft Version 8 (draft-ietf-mpls-ldp-08.txt). RFC 3815 and IETF draft Version 8 provide an interface for managing LDP through the use of the Simple Network Management Protocol (SNMP).

In RFC 3815, the content of the MPLS-LDP-MIB is divided into four MIB modules: the MPLS-LDP-STD-MIB, the MPLS-LDP-ATM-STD-MIB, the MPLS-LDP-FRAME-RELAY-STD-MIB, and the MPLS-LDP-GENERIC-STD-MIB.

Cisco IOS MPLS Embedded Management (EM) is a set of standards and value-added services that facilitate the deployment, operation, administration, and management of MPLS-based networks in line with the fault, configuration, accounting, performance, and security (FCAPS) model.

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the “[Feature Information for MPLS EM—MPLS LDP MIB - RFC 3815](#)” section on page 50.

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

# Contents

- [Prerequisites for MPLS EM—MPLS LDP MIB - RFC 3815, page 2](#)
- [Restrictions for MPLS EM—MPLS LDP MIB - RFC 3815, page 2](#)
- [Information About MPLS EM—MPLS LDP MIB - RFC 3815, page 3](#)
- [How to Configure SNMP for MPLS EM—MPLS LDP MIB - RFC 3815, page 31](#)
- [Configuration Examples for MPLS EM—MPLS LDP MIB - RFC 3815, page 45](#)
- [Additional References, page 47](#)
- [Command Reference, page 49](#)
- [Feature Information for MPLS EM—MPLS LDP MIB - RFC 3815, page 50](#)
- [Glossary, page 52](#)

## Prerequisites for MPLS EM—MPLS LDP MIB - RFC 3815

- SNMP must be installed and enabled on the label switch routers (LSRs) or label edge routers (LERs).
- MPLS must be enabled on the LSRs or LERs.
- LDP must be enabled on the LSRs or LERs.
- Cisco Express Forwarding must be enabled on the LSRs or LERs.

For where to find configuration information for MPLS and LDP, see the [“Related Documents” section on page 47](#).

## Restrictions for MPLS EM—MPLS LDP MIB - RFC 3815

The implementation of the MPLS LDP MIB (RFC 3815) for Cisco IOS Release 12.2(33)SRB is limited to read-only (RO) permission for MIB objects.

The following MPLS-LDP-STD-MIB tables are not implemented for Cisco IOS Release 12.2(33)SRB:

- mplsInSegmentLdpLspTable
- mplsOutSegmentLdpLspTable
- mplsFecTable
- mplsLdpLspFecTable
- mplsLdpSessionPeerAddrTable

The following MPLS-LDP-FRAME-RELAY-STD-MIB tables are not implemented for Cisco IOS Release 12.2(33)SRB:

- mplsLdpEntityFrameRelayTable
- mplsLdpEntityFrameRelayLRTTable
- mplsLdpFrameRelaySessionTable

# Information About MPLS EM—MPLS LDP MIB - RFC 3815

Before you configure SNMP for the MPLS EM—MPLS LDP MIB - RFC 3815 feature you should understand the following concepts:

- [Label Distribution Protocol Overview, page 3](#)
- [MPLS EM—MPLS LDP MIB - RFC 3815 Feature Design and Use, page 4](#)

## Label Distribution Protocol Overview

MPLS is a packet forwarding technology that uses a short, fixed-length value called a label in packets to determine the next hop for packet transport through an MPLS network by means of LSRs.

A fundamental MPLS principle is that LSRs in an MPLS network must agree on the definition of the labels being used for packet forwarding operations. Label agreement is achieved in an MPLS network by means of procedures defined in the Label Distribution Protocol (LDP).

LDP operations begin with a discovery (hello) process, during which an LDP entity (a local LSR) finds a cooperating LDP peer in the network and negotiates basic operating procedures between them. The recognition and identification of a peer by means of this discovery process results in a hello adjacency, which represents the context within which label binding information is exchanged between the local LSR and its LDP peer. An LDP function then creates an active LDP session between the two LSRs to effect the exchange of label binding information. The result of this process, when carried to completion with respect to all the LSRs in an MPLS network, is a label switched path (LSP), which constitutes an end-to-end packet transmission pathway between the communicating network devices.

LSRs use LDP to collect, distribute, and label binding information to other LSRs in an MPLS network, thereby enabling the hop-by-hop forwarding of packets in the network along normally routed paths.

## MPLS EM—MPLS LDP MIB - RFC 3815 Feature Design and Use

RFC 3815 defines four MIB modules to support the configuration and monitoring of LDP. The MPLS-LDP-STD-MIB module defines objects that are common to all LDP implementations. To monitor LDP on an LSR or an LER, you need to use this MIB and one of the following Layer 2 MIB modules:

- **MPLS-LDP-GENERIC-STD-MIB**—Use this module and the MPLS-LDP-STD-MIB if the LSR or LER supports LDP that uses the global label space; for example, for Layer 2 Ethernet. This module defines Layer 2 per platform label space objects.
- **MPLS-LDP-ATM-STD-MIB**—Use this module and the MPLS-LDP-STD-MIB if the LSR or LER supports LDP that uses Layer 2 ATM. This module defines Layer 2 ATM objects.
- **MPLS-LDP-FRAME-RELAY-STD-MIB**—Use this module and the MPLS-LDP-STD-MIB if the LSR or LER supports LDP that uses Layer 2 Frame Relay. This module defines Layer 2 Frame Relay objects.

**Note**

The MPLS-LDP-FRAME-RELAY-STD-MIB is not implemented for Cisco IOS Release 12.2(33)SRA.

If the LSR or LER uses LDP that supports Ethernet, ATM, and Frame Relay, then all four MIB modules need to be used by an SNMP agent on the LSR or LER.

The RFC 3815 upgrade to the MPLS-LDP-MIB is implemented to enable standard, SNMP-based network management of the label switching features in Cisco IOS software. Providing this capability requires SNMP agent code to execute on a designated network management station (NMS) in the network. The NMS serves as the medium for user interaction with the network management objects in the MIB.

The SNMP agent is a layered structure that is compatible with Cisco IOS software and presents a network administrative and management interface to the objects in the MPLS LDP MIB and, adds to the rich set of label switching capabilities supported by the Cisco IOS software.

You can use an SNMP agent to access MIB module objects using standard SNMP **get** and **getnext** commands to accomplish a variety of network management tasks. All the objects in the MPLS LDP MIB modules follow the conventions defined in RFC 3815, which defines network management objects in a structured and standardized manner.

Slight differences that exist between the RFC 3815 and the implementation of equivalent functions in the Cisco IOS software require some minor translations between the MPLS LDP MIB objects and the internal data structures of Cisco IOS software. Such translations are accomplished by the SNMP agent, which runs in the background on the NMS workstation as a low priority process.

Cisco IOS Release 12(33)SRB supports the following MPLS LDP MIB-related functions:

- Generating and sending of event notification messages that signal changes in the status of LDP sessions
- Enabling and disabling of event notification messages by means of extensions to existing SNMP command-line interface (CLI) commands
- Specification of the name or the IP address of an NMS workstation in the operating environment to which Cisco IOS event notification messages are to be sent to serve network administrative and management purposes
- Storage of the configuration pertaining to an event notification message in NVRAM of the NMS

The structure of the MPLS LDP MIBs conforms to Abstract Syntax Notation One (ASN.1), thereby forming a highly structured and idealized database of network management objects.

MIB structure is represented by a tree hierarchy. Branches along the tree have short text strings and integers to identify them. Text strings describe object names, and integers allow computer software to encode compact representations of the names.

The MPLS LDP MIB is located on the branch of the Internet MIB hierarchy represented by the object identifier 1.3.6.1.2.1.10.166. This branch can also be represented by its object name `iso.org.dod.internet.mgmt.mib-2.transmission.mplsStdMIB`. The MPLS-LSR-STD-MIB is identified by the object name `mplsLsrStdMIB`, which is denoted by the number 4. Therefore, objects in the MPLS-LDP-STD-MIB can be identified in either of the following ways:

- The object identifier—1.3.6.1.2.1.10.166.4.[MIB-variable]
- The object name—`iso.org.dod.internet.mgmt.mib-2.transmission.mplsStdMIB.mplsLdpStdMIB.[MIB-variable]`

You can use any standard SNMP application to retrieve and display information from the MPLS LDP MIBs by means of standard SNMP GET operations. Similarly, you can traverse and display information in the MIB by means of SNMP GETNEXT operations.

## Benefits of Using the MPLS EM—MPLS LDP MIB - RFC 3815 Feature

The MPLS LDP MIBs (RFC 3815) provide the following benefits:

- Retrieves MIB parameters relating to the operation of LDP entities, such as:
  - Well-known LDP discovery port
  - Maximum transmission unit (MTU)
  - Proposed keepalive timer interval
  - Loop detection
  - Session establishment thresholds
  - Range of Virtual Path Identifier (VPI)-Virtual Channel Identifier (VCI) pairs to be used in forming labels
- Gathers statistics relating to LDP operations, such as:
  - Count of the total established sessions for an LDP entity
  - Count of the total attempted sessions for an LDP entity
- Monitors the time remaining for hello adjacencies
- Monitors the characteristics and status of LDP peers, such as:
  - Internetwork layer address of LDP peers
  - Loop detection of LDP peers
  - Default MTU of the LDP peer
  - Number of seconds the LDP peer proposes as the value of the keepalive interval
- Monitors the characteristics and status of LDP sessions, such as:
  - Displaying the error counters
  - Determining the LDP version being used by the LDP session
  - Determining the keepalive hold time remaining for an LDP session
  - Determining the state of an LDP session (whether the session is active)

- Determining the label ranges for platform-wide and interface-specific sessions
- Determining the ATM parameters

## MPLS LDP MIB (RFC 3815) Elements

The following functional elements of the MPLS LDP MIBs (RFC 3815) are used to perform LDP operations:

- LDP entity—Refers to an instance of LDP for purposes of exchanging label spaces; describes a potential session.
- LDP peer—Refers to a remote LDP entity (that is, a nonlocal LSR).
- LDP session—Refers to an active LDP process between a local LSR and a remote LDP peer.
- Hello adjacency—Refers to the result of an LDP discovery process that affirms the state of two LSRs in an MPLS network as being adjacent to each other (that is, as being LDP peers). When the neighbor is discovered, the neighbor becomes a hello adjacency. An LDP session can be established with the hello adjacency. After the session is established, label bindings can be exchanged between the LSRs.

These MPLS LDP MIB elements are briefly described in the following sections:

- [LDP Entities, page 6](#)
- [LDP Sessions and Peers, page 7](#)
- [LDP Hello Adjacencies, page 9](#)

In effect, the MPLS LDP MIBs provide a network management database that supports real-time access to the various MIB objects within, describing the current state of MPLS LDP operations in the network. This network management information database is accessible by means of standard SNMP commands issued from an NMS in the MPLS LDP operating environment.

The MPLS LDP MIBs support the following network management and administrative activities:

- Retrieving MPLS LDP MIB parameters pertaining to LDP operations
- Monitoring the characteristics and the status of LDP peers
- Monitoring the status of LDP sessions between LDP peers
- Monitoring hello adjacencies in the network
- Gathering statistics regarding LDP sessions

## LDP Entities

An LDP entity is uniquely identified by an LDP identifier that consists of the `mplsLdpEntityLdpId` and the `mplsLdpEntityIndex` (see [Figure 1](#)) objects:

- The `mplsLdpEntityLdpId` consists of the local LSR ID (four octets) and the label space ID (two octets). The label space ID identifies a specific label space available within the LSR.
- The `mplsLdpEntityIndex` consists of the IP address of the peer active hello adjacency, which is the 32-bit representation of the IP address assigned to the peer LSR.

The `mplsLdpEntityProtocolVersion` is a sample object from the `mplsLdpEntityTable`.

Figure 1 shows the following indexing:

- `mplsLdpEntityLdpId` = 10.10.10.10.0.0
- LSR ID = 10.10.10.10
- Label space ID = 0.0

**Note**

The `mplsLdpEntityLdpId` or the LDP ID consists of the LSR ID and the label space ID.

- The IP address of peer active hello adjacency or the `mplsLdpEntityIndex` = 3232235777, which is the 32-bit representation of the IP address assigned to the peer's active hello adjacency.

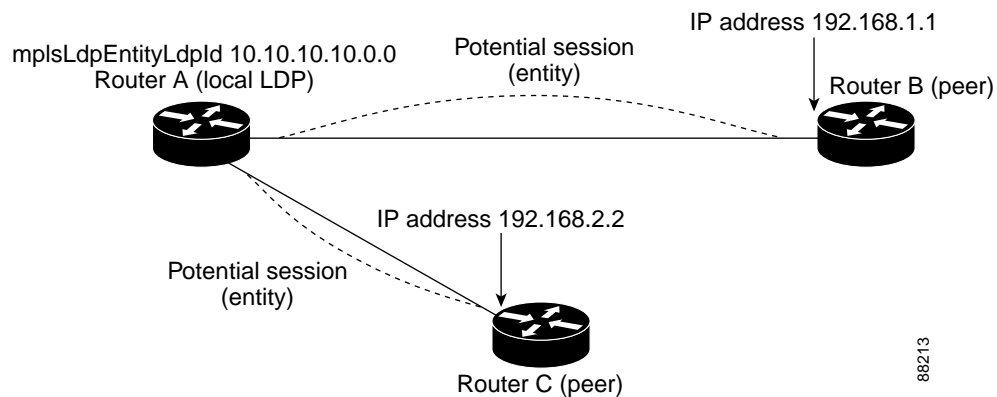

**Figure 1 Sample Indexing for an LDP Entity**

An LDP entity represents a label space that has the potential for a session with an LDP peer. An LDP entity is configured when a hello adjacency receives a hello message from an LDP peer.

In Figure 2, Router A has potential sessions with two remote peers, Routers B and C. The `mplsLdpEntityLdpId` is 10.10.10.10.0.0, and the IP address of the peer active hello adjacency (`mplsLdpEntityIndex`) is 3232235777, which is the 32-bit representation of the IP address 192.168.1.1 for Router B.

**Figure 2 LDP Entity**

## LDP Sessions and Peers

LDP sessions exist between local entities and remote peers for the purpose of distributing label bindings. There is always a one-to-one correspondence between an LDP peer and an LDP session. A single LDP session is an LDP instance that communicates across one or more network links with a single LDP peer.

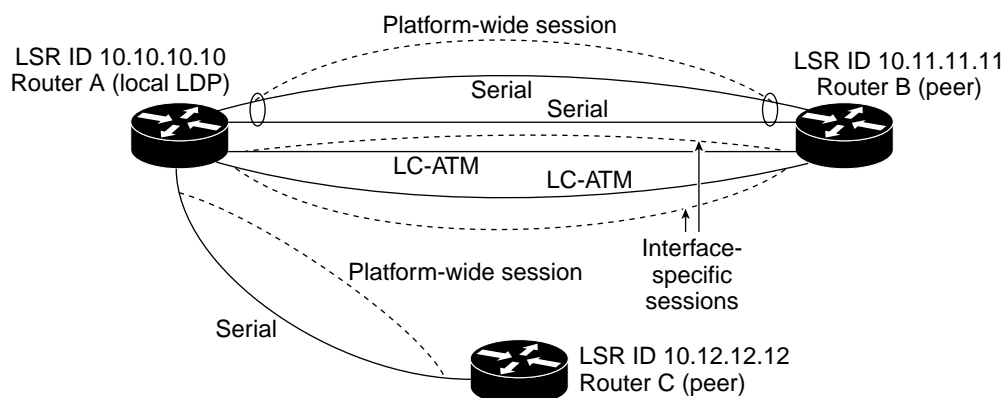

LDP supports the following types of sessions:

- **Interface-specific**—An interface-specific session uses interface resources for label space distributions. For example, each label-controlled ATM (LC-ATM) interface uses its own VPIs and VCIs for label space distributions. Depending on its configuration, an LDP platform can support zero, one, or more interface-specific sessions. Each LC-ATM interface has its own interface-specific label space and a nonzero label space ID.
- **Platform-wide**—An LDP platform supports a single platform-wide session for use by all interfaces that can share the same global label space. For Cisco platforms, all interface types except LC-ATM use the platform-wide session and have a label space ID of zero.

When a session is established between two peers, entries are created in the `mplsLdpPeerTable` and the `mplsLdpSessionTable` because they have the same indexing.

In [Figure 3](#), Router A has two remote peers, Routers B and C. Router A has a single platform-wide session that consists of two serial interfaces with Router B and another platform-wide session with Router C. Router A also has two interface-specific sessions with Router B.

**Figure 3 LDP Sessions**

88215

[Figure 4](#) shows entries that correspond to the `mplsLdpPeerTable` and the `mplsLdpSessionTable` in [Figure 3](#).

In [Figure 4](#), `mplsLdpSesState` is a sample object from the `mplsLdpSessionTable` on Router A. Four `mplsLdpSesState` sample objects are shown (top to bottom). The first object represents a platform-wide session associated with two serial interfaces. The next two objects represent interface-specific sessions for the LC-ATM interfaces on Routers A and B. These interface-specific sessions have nonzero peer label space IDs. The last object represents a platform-wide session for the next peer, Router C.

The indexing is based on the entries in the `mplsLdpEntityTable`. It begins with the indexes of the `mplsLdpEntityTable` and adds the following:

- Peer LDP ID = 10.11.11.11.0.0  
The peer LDP ID consists of the peer LSR ID (four octets) and the peer label space ID (two octets).
- Peer LSR ID = 10.11.11.11
- Peer label space ID = 0.0  
The peer label space ID identifies a specific peer label space available within the LSR.

**Figure 4 Sample Indexing for an LDP Session**

88216

## LDP Hello Adjacencies

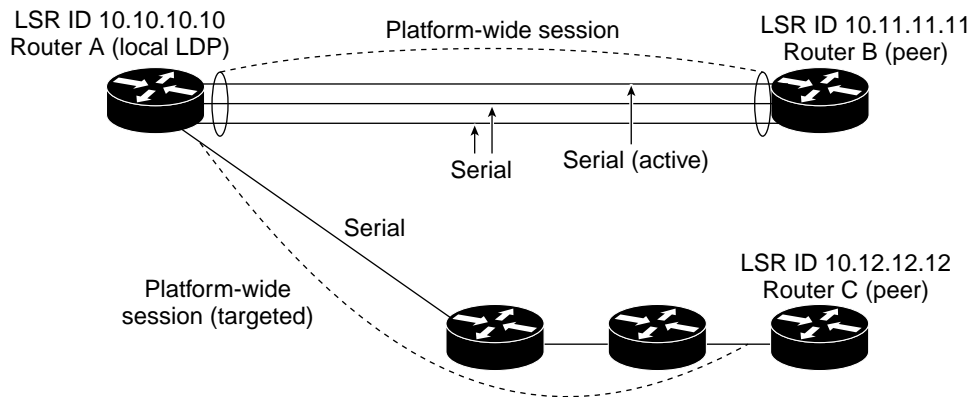

An LDP hello adjacency is an association between a remotely discovered LDP process and a specific network path to reach the remote LDP process. An LDP hello adjacency enables two adjacent peers to exchange label binding information.

An LDP hello adjacency exists for each link on which LDP runs. Multiple LDP hello adjacencies exist whenever there is more than one link in a session between a router and its peer, such as in a platform-wide session.

A hello adjacency is considered active if it is currently engaged in a session, or nonactive if it is not currently engaged in a session.

A targeted hello adjacency is not directly connected to its peer and has an unlimited number of hops between itself and its peer. A linked hello adjacency is directly connected between two routers.

In [Figure 5](#), Router A has two remote peers, Routers B and C. Router A has a platform-wide session with Router B that consists of three serial interfaces, one of which is active and another platform-wide (targeted) session with Router C.

**Figure 5 Hello Adjacency**

88217

[Figure 6](#) shows entries in the mplsLdpHelloAdjacencyTable. There are four mplsLdpHelloAdjHoldTime sample objects (top to bottom). They represent the two platform-wide sessions and the four serial links shown in [Figure 5](#).

The indexing is based on the mplsLdpSessionTable. When the mplsLdpHelloAdjIndex enumerates the different links within a single session, the active link is mplsLdpHelloAdjIndex = 1.

## Events Generating MPLS LDP MIB Notifications

When you enable MPLS LDP MIB notification functionality by issuing the **snmp-server enable traps mpls rfc ldp** command, notification messages are generated and sent to a designated NMS in the network to signal the occurrence of specific events within Cisco IOS software.

The MPLS LDP MIB objects that announce LDP status transitions and event notifications are the following:

- **mplsLdpSessionUp**—This message is generated when an LDP entity (a local LSR) establishes an LDP session with another LDP entity (an adjacent LDP peer in the network). Enable this notification with the **session-up** keyword.
- **mplsLdpSessionDown**—This message is generated when an LDP session between a local LSR and its adjacent LDP peer is terminated. Enable this notification with the **session-down** keyword.

The up and down notifications indicate the last active interface in the LDP session.

- **mplsLdpPathVectorLimitMismatch**—This message is generated when a local LSR establishes an LDP session with its adjacent peer LSR, but the two LSRs have dissimilar path vector limits. Enable this notification with the **pv-limit** keyword.

The value of the path vector limit can range from 0 to 255; a value of 0 indicates that loop detection is off; any value other than 0 up to 255 indicates that loop detection is on and, in addition, specifies the maximum number of hops through which an LDP message can pass before a loop condition in the network is sensed.

We recommend that all LDP-enabled routers in the network be configured with the same path vector limit. Accordingly, the **mplsLdpPathVectorLimitMismatch** object exists in the MPLS LDP MIB to provide a warning message to the NMS when two routers engaged in LDP operations have a dissimilar path vector limits.

**Note** This notification is generated only if the distribution method is downstream-on-demand.

- **mplsLdpFailedInitSessionThresholdExceeded**—This message is generated when a local LSR and an adjacent LDP peer attempt to configure an LDP session between them, but fail to do so after a specified number of attempts. The default number of attempts is eight. This default value is implemented in Cisco IOS software and cannot be changed by either the CLI or an SNMP agent. Enable this notification with the **threshold** keyword.

Eight failed attempts to establish an LDP session between a local LSR and an LDP peer, due to any type of incompatibility between the devices, causes this notification message to be generated.

In general, Cisco routers support the same features across multiple platforms. Therefore, the most likely incompatibility to occur between Cisco LSRs is a mismatch of their respective ATM VPI and VCI label ranges.

For example, if you specify a range of valid labels for an LSR that does not overlap the range of its adjacent LDP peer, the routers try eight times to create an LDP session between themselves before the `mplsLdpFailedInitSessionThresholdExceeded` notification is generated and sent to the NMS as an informational message.

Occasionally, the LSRs whose label ranges do not overlap continue their attempt to create an LDP session between themselves after the eight retry limit is exceeded. In such cases, the LDP threshold exceeded notification alerts the network administrator to the existence of a condition in the network that may warrant attention.

**Note**

An `mplsLdpEntityFailedInitSessionThreshold` trap is supported only on an LC-ATM.

RFC 3036, *LDP Specification*, details the incompatibilities that can exist between Cisco routers or between Cisco routers and other vendor LSRs in an MPLS network. Among such incompatibilities, for example, are the following:

- Nonoverlapping ATM VPI and VCI ranges (as previously noted) or nonoverlapping Frame Relay data-link connection identifiers (DLCI) ranges between LSRs attempting to configure an LDP session
- Unsupported label distribution method
- Dissimilar protocol data unit (PDU) sizes
- Dissimilar LDP feature support

## Scalar Objects in the MPLS LDP MIB Modules (RFC 3815)

The MPLS LDP MIB modules define several scalar objects. [Table 1](#) describes the scalar objects that are implemented for Cisco IOS Release 12.2(33)SRB.

**Table 1** *MPLS LDP MIB Scalar Objects and Descriptions*

Object	Description
<code>mplsLdpLsrId</code>	The LSR's identifier. This is a globally unique value, such as the 32-bit router ID assigned to the LSR.
<code>mplsLdpLsrLoopDetectionCapable</code>	<p>Loop detection capability of the LSR.</p> <p>Loop detection values are: none(1), other(2), hopCount(3), pathVector(4), and hopCountAndPathVector(5).</p> <p>The other(2) value indicates that the LSR supports loop detection, but does not support the three methods associated with values (3), (4), and (5).</p>
<code>mplsLdpEntityLastChange</code>	The value of <code>sysUpTime</code> at the time of the most recent addition or deletion of an entry to or from the <code>mplsLdpEntityTable</code> or <code>mplsLdpEntityStatsTable</code> , or the most recent change in the value of any object in the <code>mplsLdpEntityTable</code> .

**Table 1** *MPLS LDP MIB Scalar Objects and Descriptions*

Object	Description
mplsLdpEntityIndexNext	Value to use for the mplsLdpEntityIndex when the router creates entries in the mplsLdpEntityTable. The value 0 indicates that no unassigned entries are available.
mplsLdpPeerLastChange	The value of sysUpTime at the time of the most recent addition or deletion to or from the mplsLdpPeerTable or mplsLdpSessionTable.

## MIB Tables in the MPLS-LDP-STD-MIB Module (RFC 3815)

The MPLS-LDP-STD-MIB consists of the following tables. These tables define objects that are common to all LDP implementations.

- mplsLdpEntityTable (see [Table 2](#))—Contains entries for every active LDP hello adjacency. Active and nonactive hello adjacencies appear in the mplsLdpHelloAdjacencyTable, rather than this table. This table is indexed by the local LDP identifier for the interface and the IP address of the peer active hello adjacency. (See [Figure 1](#).)

The advantage of showing the active hello adjacency instead of sessions in this table is that the active hello adjacency can exist even if an LDP session is not active (cannot be established).

Directed adjacencies are also shown in this table. Associated adjacencies disappear when the targeted LDP session fails. Nondirected adjacencies might disappear from the mplsLdpEntityTable on some occasions, because adjacencies are deleted if the underlying interface becomes operationally down, for example.

- mplsLdpEntityStatsTable (see [Table 3](#))—Augments the mplsLdpEntityTable and shares the same indexing for performing SNMP GET and GETNEXT operations. This table shows additional statistics for entities.
- mplsLdpPeerTable (see [Table 4](#))—Contains entries for all peer sessions. This table is indexed by the local LDP identifier of the session, the IP address of the peer active hello adjacency, and the peer's LDP identifier. (See [Figure 4](#).)
- mplsLdpSessionTable (see [Table 5](#))—Augments the mplsLdpPeerTable and shares the same indexing for performing GET and GETNEXT operations. This table shows all sessions.
- mplsLdpSessionStatsTable (see [Table 6](#))—Augments the mplsLdpPeerTable and shares the exact same indexing for performing GET and GETNEXT operations. This table shows additional statistics for sessions.
- mplsLdpHelloAdjacencyTable (see [Table 7](#))—Contains entries for active and nonactive hello adjacencies. This table is indexed by the local LDP identifier of the associated session, the IP address of the peer active hello adjacency, the LDP identifier for the peer, and an arbitrary index that is set to the list position of the adjacency. (See [Figure 6](#).)

## MPLS LDP Entity Table (mplsLdpEntityTable) Objects and Descriptions

Table 2 describes the mplsLdpEntityTable objects.

**Table 2** *mplsLdpEntityTable Objects and Descriptions*

Object	Description
mplsLdpEntityEntry	An LDP entity is a potential session between two peers.
mplsLdpEntityLdpId	The LDP identifier (not accessible) consists of the local LSR ID (four octets) and the label space ID (two octets).
mplsLdpEntityIndex	A secondary index that identifies this row uniquely. It consists of the IP address of the peer active hello adjacency, which is the 32-bit representation of the IP address assigned to the LSR (not accessible).
mplsLdpEntityProtocolVersion	The version number of the LDP protocol to be used in the session initialization message.
mplsLdpEntityAdminStatus	This is the administrative status of this LDP entity, which is always up. If the hello adjacency fails, this entity disappears from the mplsLdpEntityTable.
mplsLdpEntityOperStatus	This is the operational status of this LDP entity. Values are unknown(1), enabled(2), and disabled(3).
mplsLdpEntityTcpPort	This is the TCP discovery port for LDP or Tag Distribution Protocol (TDP). The default value is 646 (LDP).
mplsLdpEntityUdpDscPort	This is the User Datagram Protocol (UDP) discovery port for LDP or TDP. The default value is 646 (LDP).
mplsLdpEntityMaxPduLength	This is the maximum PDU length that is sent in the common session parameters of an initialization message.
mplsLdpEntityKeepAliveHoldTimer	The two-octet value that is the proposed keepalive hold time for this LDP entity.
mplsLdpEntityHelloHoldTimer	The two-octet value that is the proposed hello hold time for this LDP entity.
mplsLdpEntityInitSessionThreshold	The threshold for notification when this entity and its peer are engaged in an endless sequence of initialization messages. <ul style="list-style-type: none"> <li>The default value is 8 and cannot be changed by SNMP or the CLI.</li> </ul>
mplsLdpEntityLabelDistMethod	The specified method of label distribution for any given LDP session. Values are downstreamOnDemand(1) and downstreamUnsolicited(2).
mplsLdpEntityLabelRetentionMode	Can be configured to use either conservative(1) for an LC-ATM or liberal(2) for all other interfaces.

**Table 2** *mplsLdpEntityTable Objects and Descriptions (continued)*

Object	Description
mplsLdpEntityPathVectorLimit	<p>If the value of this object is 0, loop detection for path vectors is disabled. Otherwise, if this object has a value greater than zero, loop detection for path vectors is enabled, and the path vector limit is this value.</p> <p><b>Note</b> The mplsLdpEntityPathVectorLimit object is nonzero only if the mplsLdpEntityLabelDistMethod is downstreamOnDemand(1).</p>
mplsLdpEntityHopCountLimit	<p>If the value of this object is 0, loop detection using hop counters is disabled.</p> <ul style="list-style-type: none"> <li>If the value of this object is greater than 0, loop detection using hop counters is enabled, and this object specifies this entity's maximum allowable value for the hop count.</li> </ul> <p><b>Note</b> The mplsLdpEntityHopCountLimit object is nonzero only if the mplsLdpEntityLabelDistMethod is downstreamOnDemand(1).</p>
mplsLdpEntityTransportAddrKind	<p>If this value is interface(1), the IP address of the interface from the hello message is used as the transport address in the hello message.</p> <p>If this value is loopback(2), the IP address of the loopback interface is used as the address in the hello message.</p>
mplsLdpEntityTargetPeer	If this LDP entity uses a targeted adjacency, this object is set to true(1). The default value is false(2).
mplsLdpEntityTargetPeerAddrType	The type of the internetwork layer address used for the extended discovery. This object indicates how the value of mplsLdpEntityTargPeerAddr is to be interpreted, as either IPv4 or IPv6.
mplsLdpEntityTargetPeerAddr	The value of the internetwork layer address used for the targeted adjacency.
mplsLdpEntityLabelType	<p>Specifies the optional parameters for the LDP initialization message. If the value is generic(1), no optional parameters are sent in the LDP initialization message associated with this entity.</p> <ul style="list-style-type: none"> <li>An LC-ATM uses atmParameters(2) to specify that a row in the mplsLdpEntityAtmParmsTable corresponds to this entry.</li> </ul> <p><b>Note</b> Frame Relay parameters are not supported in Cisco IOS Release 12.2(33)SRB.</p>
mplsLdpEntityDiscontinuityTime	The value of sysUpTime on the most recent occasion when one or more of this entity's counters suffered a discontinuity. The relevant counters are the specific instances of any Counter32 or Counter64 object contained in the mplsLdpEntityStatsTable that are associated with this entity. If no such discontinuities have occurred since the last reinitialization of the local management subsystem, this object contains a 0 value.

**Table 2** *mplsLdpEntityTable Objects and Descriptions (continued)*

Object	Description
<code>mplsLdpEntityStorageType</code>	The storage type for this entry is a read-only implementation that is always volatile.
<code>mplsLdpEntityRowStatus</code>	This object is a read-only implementation that is always active.

## MPLS LDP Entity Statistics Table (`mplsLdpEntityStatsTable`) Objects and Descriptions

Table 3 describes the `mplsLdpEntityStatsTable` objects.

**Table 3** *mplsLdpEntityStatsTable Objects and Descriptions*

Object	Description
<code>mplsLdpEntityStatsEntry</code>	These entries augment the <code>mplsLdpEntityTable</code> by providing additional information for each entry.
<code>mplsLdpEntityStatsSessionsAttempts</code>	Not supported in Cisco IOS Release 12.2(33)SRB.
<code>mplsLdpEntityStatsSessionRejectedNoHelloErrors</code>	A count of the session rejected no hello error notification messages sent or received by this LDP entity.
<code>mplsLdpEntityStatsSessionRejectedAdErrors</code>	A count of the session rejected parameters advertisement mode error notification messages sent or received by this LDP entity.
<code>mplsLdpEntityStatsSessionRejectedMaxPduErrors</code>	A count of the session rejected parameters max PDU length error notification messages sent or received by this LDP entity.
<code>mplsLdpEntityStatsSessionRejectedLRErrors</code>	A count of the session rejected parameters label range notification messages sent or received by this LDP entity.
<code>mplsLdpEntityStatsBadLdpIdentifierErrors</code>	A count of the number of bad LDP identifier fatal errors detected by the session associated with this LDP entity.
<code>mplsLdpEntityStatsBadPduLengthErrors</code>	A count of the number of bad PDU length fatal errors detected by the session associated with this LDP entity.
<code>mplsLdpEntityStatsBadMessageLengthErrors</code>	A count of the number of bad message length fatal errors detected by the session associated with this LDP entity.
<code>mplsLdpEntityStatsBadTlvLengthErrors</code>	A count of the number of bad type, length, values (TLVs) length fatal errors detected by the session associated with this LDP entity.
<code>mplsLdpEntityStatsMalformedTlvValueErrors</code>	A count of the number of malformed TLV value fatal errors detected by the session associated with this LDP entity.

**Table 3** *mplsLdpEntityStatsTable Objects and Descriptions (continued)*

Object	Description
mplsLdpEntityStatsKeepAliveTimerExpErrors	A count of the number of session keepalive timer expired errors detected by the session associated with this LDP entity.
mplsLdpEntityStatsShutdownReceivedNotifications	A count of the number of shutdown notifications received related to the session associated with this LDP entity.
mplsLdpEntityStatsShutdownSentNotifications	A count of the number of shutdown notifications sent related to the session associated with this LDP entity.

## MPLS LDP Peer Table (mplsLdpPeerTable) Objects and Descriptions

Table 4 describes the mplsLdpPeerTable objects.

**Table 4** *mplsLdpPeerTable Objects and Descriptions*

Object	Description
mplsLdpPeerEntry	Information about a single peer that is related to a session (not accessible). <b>Note</b> This table is augmented by the mplsLdpSessionTable.
mplsLdpPeerLdpId	The LDP identifier of this LDP peer (not accessible) consists of the peer LSR ID (four octets) and the peer label space ID (two octets).
mplsLdpPeerLabelDistMethod	For any given LDP session, the method of label distribution. Values are downstreamOnDemand(1) and downstreamUnsolicited(2).
mplsLdpPeerPathVectorLimit	If the value of mplsLdpPeerLabelDistMethod is downstreamOnDemand (1), this object represents the path vector limit for this peer. If the value of the mplsLdpPeerLabelDistMethod object is downstreamUnsolicited (2), this value should be 0.
mplsLdpPeerTransportAddrType	Type of Internet address for the mplsLdpPeerTransportAddr object—either the IPv4 transport address or IPv6 transport address used in the opening TCP session or the IPv4 or IPv6 source address for the UDP carrying the hello messages.
mplsLdpPeerTransportAddr	Internet address advertised by the peer in the hello message or the hello source address specified by the mplsLdpPeerTransportAddrType object.

## MPLS LDP Session Table (mplsLdpSessionTable) Objects and Descriptions

Table 5 describes the mplsLdpSessionTable objects.

**Table 5** *mplsLdpSessionTable Objects and Descriptions*

Object	Description
mplsLdpSessionEntry	An entry in this table represents information on a single session between an LDP entity and an LDP peer. The information contained in a row is read-only. This table augments the mplsLdpPeerTable.
mplsLdpSessionStateLastChange	The value of sysUpTime at the time the session entered its state denoted by the mplsLdpSessionState object.
mplsLdpSessionState	<p>The current state of the session. All of the states are based on the LDP or TDP state machine for session negotiation behavior.</p> <p>The states are as follows:</p> <ul style="list-style-type: none"> <li>• nonexistent(1)</li> <li>• initialized(2)</li> <li>• openrec(3)</li> <li>• opensent(4)</li> <li>• operational(5)</li> </ul>
mplsLdpSessionRole	<p>The value of this object indicates whether the LSR or LER takes an active(2) or passive(3) role when a session is established.</p> <p>If the role of the LSR or LER cannot be determined, the value of the object is unknown(1).</p>
mplsLdpSessionProtocolVersion	The version of the LDP protocol that this session is using. This is the version of the LDP protocol that has been negotiated during session initialization.
mplsLdpSessionKeepAliveHoldTimeRem	The keepalive hold time remaining for this session.
mplsLdpSessionKeepAliveTime	The time in seconds between keepalive messages negotiated between a configured value and the peer's proposed keepalive hold timer value. The value is the lower of the two.
mplsLdpSessionMaxPduLen	The value of maximum allowable length for LDP PDUs for this session. This value could have been negotiated during the session initialization.
mplsLdpSessionDiscontinuityTime	<p>The value of sysUpTime on the most recent occasion when one or more of this session's counters suffered a discontinuity. The relevant counters are the specific instances of any Counter32 or Counter64 object contained in the mplsLdpSesStatsTable associated with this session.</p> <p>The initial value of this object is the value of sysUpTime when the entry was created in this table.</p>

## MPLS LDP Session Statistics Table (mplsLdpSessionStatsTable) Objects and Descriptions

Table 6 describes the mplsLdpSessionStatsTable objects.

**Table 6** *mplsLdpSessionStatsTable Objects and Descriptions*

Object	Description
mplsLdpSessionStatsEntry	An entry in this table represents statistical information on a single session between an LDP entity and an LDP peer. This table augments the mplsLdpPeerTable.
mplsLdpSessionStatsUnknownMesTypeErrors	This object is the count of the number of unknown message type errors detected during this session.
mplsLdpSessionStatsUnknownTlvErrors	This object is the count of the number of unknown TLV errors detected during this session.

## MPLS LDP Hello Adjacency Table (mplsLdpHelloAdjacencyTable) Objects and Descriptions

Table 7 describes the mplsLdpHelloAdjacencyTable objects.

**Table 7** *mplsLdpHelloAdjacencyTable Objects and Descriptions*

Object	Description
mplsLdpHelloAdjacencyEntry	Each row represents a single LDP hello adjacency. An LDP session can have one or more hello adjacencies (not accessible).
mplsLdpHelloAdjacencyIndex	An identifier for this specific adjacency (not accessible). The active hello adjacency has the mplsLdpHelloAdjIndex object equal to 1.
mplsLdpHelloAdjacencyHoldTimeRem	The time remaining for this hello adjacency. This interval changes when the next hello message, which corresponds to this hello adjacency, is received.
mplsLdpHelloAdjacencyHoldTime	The hello time negotiated between the LSR or LER and its peer.  If this value is 0, the defaults are used, 15 seconds for link hellos and 45 seconds for targeted hellos.  If this value is 65535, the hold time is infinite.
mplsLdpHelloAdjacencyType	This adjacency is the result of a link hello if the value of this object is link(1). Otherwise, this adjacency is a result of a targeted hello and its value is targeted(2).

## MIB Tables in the MPLS-LDP-ATM-STD-MIB Module (RFC 3815)

The MPLS-LDP-ATM-STD-MIB consists of the following tables. These tables define Layer 2 ATM-related objects for use with the MPLS-LDP-STD-MIB.

- `mplsLdpEntityAtmTable` (see [Table 8](#))—Contains entries for every LDP-enabled LC-ATM interface. This table is indexed in the same way as the `mplsLdpEntityTable` although only LC-ATM interfaces are shown.
- `mplsLdpEntityAtmLRTable` (see [Table 9](#))—Contains entries for every LDP-enabled LC-ATM interface. Indexing is the same as it is for the `mplsLdpEntityTable`, except two indexes have been added, `mplsLdpEntityAtmLRMinVpi` and `mplsLdpEntityAtmLRMinVci`. These additional indexes allow more than one label range to be defined. However, in the Cisco IOS Release 12.2(33)SRB implementation, only one label range per LC-ATM interface is allowed.
- `mplsLdpAtmSessionTable` (see [Table 10](#))—Contains entries for LDP-enabled LC-ATM sessions. Indexing is the same as it is for the `mplsLdpPeerTable`, except two indexes have been added, `mplsLdpAtmSessionLRLowerBoundVpi` and `mplsLdpAtmSessionLRLowerBoundVci`. These additional indexes allow more than one label range to be defined. However, in the Cisco IOS Release 12.2(33)SRB implementation, only one label range per LC-ATM interface is allowed.

### MPLS LDP Entity ATM Table (`mplsLdpEntityAtmTable`) Objects and Descriptions

[Table 8](#) describes the `mplsLdpEntityAtmTable` objects.

**Table 8** *`mplsLdpEntityAtmTable` Objects and Descriptions*

Object	Description
<code>mplsLdpEntityAtmEntry</code>	Represents the ATM parameters and ATM information for this LDP entity.
<code>mplsLdpEntityAtmIfIndxOrZero</code>	This value represents the SNMP IF-MIB index for the interface-specific LC-ATM entity.
<code>mplsLdpEntityAtmMergeCap</code>	Denotes the merge capability of this entity.
<code>mplsLdpEntityAtmLRComponents</code>	Number of label range components in the initialization message. This also represents the number of entries in the <code>mplsLdpEntityConfAtmLRTable</code> that correspond to this entry. <b>Note</b> Cisco IOS software supports only one component.
<code>mplsLdpEntityAtmVcDirectionality</code>	If the value of this object is <code>bidirectional(0)</code> , a given VCI within a given VPI is used as a label for both directions independently of one another. If the value of this object is <code>unidirectional(1)</code> , a given VCI within a VPI designates one direction.
<code>mplsLdpEntityAtmLsrConnectivity</code>	The peer LSR can be connected indirectly by means of an ATM VPI, so that the VPI values can be different on the endpoints. For that reason, the label must be encoded entirely within the VCI field. Values are <code>direct(1)</code> and <code>indirect(2)</code> . The default is <code>direct(1)</code> .
<code>mplsLdpEntityAtmDefaultControlVpi</code>	The default VPI value for the non-MPLS connection.

**Table 8** *mplsLdpEntityAtmTable Objects and Descriptions (continued)*

Object	Description
mplsLdpEntityAtmDefaultControlVci	The default VCI value for the non-MPLS connection.
mplsLdpEntityAtmUnlabTrafVpi	VPI value of the virtual channel connector (VCC) supporting unlabeled traffic. This non-MPLS connection is used to carry unlabeled (IP) packets.
mplsLdpEntityAtmUnlabTrafVci	VCI value of the VCC supporting unlabeled traffic. This non-MPLS connection is used to carry unlabeled (IP) packets.
mplsLdpEntityAtmStorageType	The storage type for this entry is a read-only implementation that is always volatile.
mplsLdpEntityAtmRowStatus	This object is a read-only implementation that is always active.

## MPLS LDP Entity ATM Label Range Table (mplsLdpEntityAtmLRTable) Objects and Descriptions

Table 9 describes the mplsLdpEntityAtmLRTable objects.

**Table 9** *mplsLdpEntityAtmLRTable Objects and Descriptions*

Object	Description
mplsLdpEntityAtmLREntry	A row in the LDP Entity Configurable ATM Label Range Table. One entry in this table contains information on a single range of labels; the range is defined by an upper boundary (VPI/VCI pair) and a lower boundary (VPI/VCI pair). This is the same data used in the initialization message. This label range should overlap the label range of the peer.
mplsLdpEntityAtmLRMinVpi	The minimum VPI number configured for this range (not accessible).
mplsLdpEntityAtmLRMinVci	The minimum VCI number configured for this range (not accessible).
mplsLdpEntityAtmLRMaxVpi	The maximum VPI number configured for this range (not accessible).
mplsLdpEntityAtmLRMaxVci	The maximum VCI number configured for this range (not accessible).
mplsLdpEntityAtmLRStorageType	The storage type for this entry is a read-only implementation that is always volatile.
mplsLdpEntityAtmLRRowStatus	This object is a read-only implementation that is always active.

## MPLS LDP ATM Session Table (mplsLdpAtmSessionTable) Objects and Descriptions

Table 10 describes the mplsLdpAtmSessionTable objects.

**Table 10** *mplsLdpAtmSessionTable Objects and Descriptions*

Objects	Description
mplsLdpAtmSessionEntry	An entry in this table represents information on a single label range intersection between an LDP entity and an LDP peer (not accessible).
mplsLdpAtmSessionLRLowerBoundVpi	The minimum VPI number configured for this range (not accessible).
mplsLdpAtmSessionLRLowerBoundVci	The minimum VCI number configured for this range (not accessible).
mplsLdpAtmSessionLRUpperBoundVpi	The maximum VPI number configured for this range (read-only).
mplsLdpAtmSessionLRUpperBoundVci	The maximum VCI number configured for this range (read-only).

## MIB Table in the MPLS-LDP-GENERIC-STD-MIB Module (RFC 3815)

The MPLS-LDP-GENERIC-STD-MIB contains the following table. This table defines Layer 2 per-platform objects for use with the MPLS-LDP-STD-MIB.

- mplsLdpEntityGenericLRTable (Table 11)—Contains entries for every LDP-enabled interface that is in the global label space. (For Cisco, this applies to all interfaces except LC-ATM. LC-ATM entities are shown in the mplsLdpEntityAtmLRTable instead.) Indexing is the same as it is for the mplsLdpEntityTable, except two indexes have been added, mplsLdpEntityGenericLRMin and mplsLdpEntityGenericLRMax. These additional indexes allow more than one label range to be defined. However, in the Cisco IOS Release 12.2(33)SRB implementation, only one global label range is allowed.

## MPLS LDP Entity Generic Label Range Table (mplsLdpEntityGenericLRTable) Objects and Descriptions

Table 11 describes the mplsLdpEntityGenericLRTable objects.

**Table 11** *mplsLdpEntityGenericLRTable Objects and Descriptions*

Object	Description
mplsLdpEntityGenericLREntry	A row in the LDP Entity Configurable Generic Label Range table. One entry in this table contains information on a single range of labels; the range is defined by an upper boundary and a lower boundary. <ul style="list-style-type: none"> <li>• The current implementation supports one label range per entity.</li> </ul>
mplsLdpEntityGenericLRMin	The minimum label configured for this range (not accessible).

**Table 11** *mplsLdpEntityGenericLRTTable Objects and Descriptions (continued)*

Object	Description
<code>mplsLdpEntityGenericLRMax</code>	The maximum label configured for this range (not accessible).
<code>mplsLdpEntityGenericLabelSpace</code>	This value indicates whether the label space type is perPlatform (1) or perInterface (2).
<code>mplsLdpEntityGenericIfIndxOrZero</code>	This value represents the SNMP IF-MIB index for the platform-wide entity. If the active hello adjacency is targeted, the value is 0.
<code>mplsLdpEntityGenericLRStorageType</code>	The storage type for this entry is a read-only implementation that is always volatile.
<code>mplsLdpEntityGenericLRRowStatus</code>	This object is a read-only implementation that is always active.

## VPN Contexts in the MPLS LDP MIB

Within an MPLS Border Gateway Protocol (BGP) 4 Virtual Private Network (VPN) environment, separate LDP processes can be created for each VPN. These processes and their associated data are called LDP contexts. Each context is independent from all others and contains data specific only to that context.

The VPN Aware LDP MIB feature enables the LDP MIB to get VPN context information. The feature adds support for different contexts for different MPLS VPNs. Users of the MIB can display MPLS LDP processes for a given MPLS VPN. The VPN Aware LDP MIB feature does not change the syntax of the MPLS LDP MIB. It changes the number and types of entries within the tables.

The MPLS LDP MIB can show information about only one context at a time. With Cisco IOS Release 12.2(33)SRB, you can specify a context—either a global context or an MPLS VPN context—using an SNMP security name.

The following sections describe topics related to the VPN Aware LDP MIB feature:

- [SNMP Contexts, page 22](#)
- [VPN Aware LDP MIB Sessions, page 23](#)
- [VPN Aware LDP MIB Notifications, page 24](#)

## SNMP Contexts

SNMP contexts provide VPN users with a secure way of accessing MIB data. When a VPN is associated with a context, that VPN's specific MIB data exists in that context. Associating a VPN with a context enables service providers to manage networks with multiple VPNs. Creating and associating a context with a VPN enables a provider to prevent the users of one VPN from accessing information about users of other VPNs on the same networking device.

VPN-aware SNMP requires that SNMP manager and agent entities operating in a VPN environment agree on mapping between the SNMP security name and the VPN name. This mapping is created by you using different contexts for the SNMP data of different VPNs, which is accomplished through the configuration of the SNMP View-based Access Control Model MIB (SNMP-VACM-MIB). The SNMP-VACM-MIB is configured with views so that a user on a VPN with a security name is allowed access to the restricted object space within the context of only that VPN.

SNMP request messages undergo three phases of security and access control before a response message is sent back with the object values within a VPN context:

- The first security phase is authentication of the username. During this phase, the user is authorized for SNMP access.
- The second phase is access control. During this phase, the user is authorized for SNMP access to the group objects in the requested SNMP context.
- In the third phase, the user can access a particular instance of a table entry. With this third phase, complete retrieval can be based on the SNMP context name.

IP access lists can be configured and associated with SNMP community strings. This feature enables you to configure an association between VPN routing and forwarding (VRF) instances and SNMP community strings. When a VRF instance is associated with an SNMP community string, SNMP processes requests coming in for a particular community string only if they are received from the configured VRF. If the community string contained in the incoming packet does not have a VRF associated with it, it is processed only if it came in through a non-VRF interface.

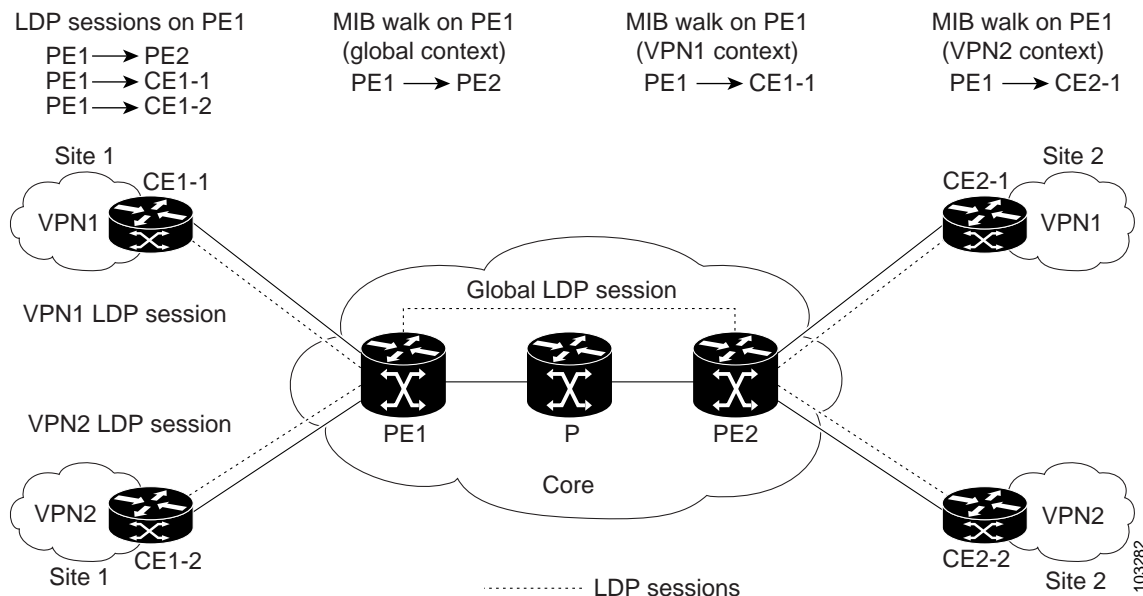

You can also enable or disable authentication traps for SNMP packets dropped due to VRF mismatches. By default, if SNMP authentication traps are enabled, VRF authentication traps are also enabled.

## VPN Aware LDP MIB Sessions

The VPN Aware LDP MIB feature supports an SNMP query to the MPLS LDP MIB for both global and VPN contexts. This feature allows you to enter LDP queries on any VRF and on the core (global context). A query can differentiate between LDP sessions from different VPNs. LDP session information for a VPN stays in the context of that VPN. Therefore, the information from one VPN is not available to a user of a different VPN. The VPN Aware LDP MIB also allows you to display LDP processes operating in a Carrier Supporting Carrier (CSC) network.

In an MPLS VPN, a service provider edge router (PE) might contain VRFs for several VPNs and a global routing table. To set up separate LDP processes for different VPNs on the same device, you need to configure each VPN with a unique `securityName`, `contextName`, and View-based Access Control Model (VACM) view. The VPN `securityName` must be configured for the MPLS LDP MIB.

[Figure 7](#) shows LDP sessions for a sample MPLS VPN with the VPN Aware LDP MIB feature.

**Figure 7 MPLS LDP Sessions with the VPN Aware LDP MIB Feature**

With the VPN Aware LDP MIB feature, you can do MIB queries or MIB walks for an MPLS VPN LDP session or a global LDP session.

**Note**

To verify LDP session information for a specific VPN, use the **show mpls ldp neighbor vrf vpn-name detail** command.

## VPN Aware LDP MIB Notifications

The VPN Aware LDP MIB feature supports LDP notifications for multiple LDP contexts for VPNs. LDP notifications can be generated for the core (global context) and for different VPNs. You can cause notifications be sent to different NMS hosts for different LDP contexts. LDP notifications associated with a specific VRF are sent to the NMS designated for that VRF. LDP global notifications are sent to the NMS configured to receive global traps.

To enable LDP context notifications for the VPN Aware LDP MIB feature, use either the SNMP `mplsLdpSessionsUpDownEnable` object (in the global LDP context only) or the following extended global configuration commands.

To enable LDP notifications for the global context, use the following commands on a provider edge (PE) router:

```
Router(config)# snmp-server host host-address traps community mpls-ldp
```

```
Router(config)# snmp-server enable traps mpls rfc ldp
```

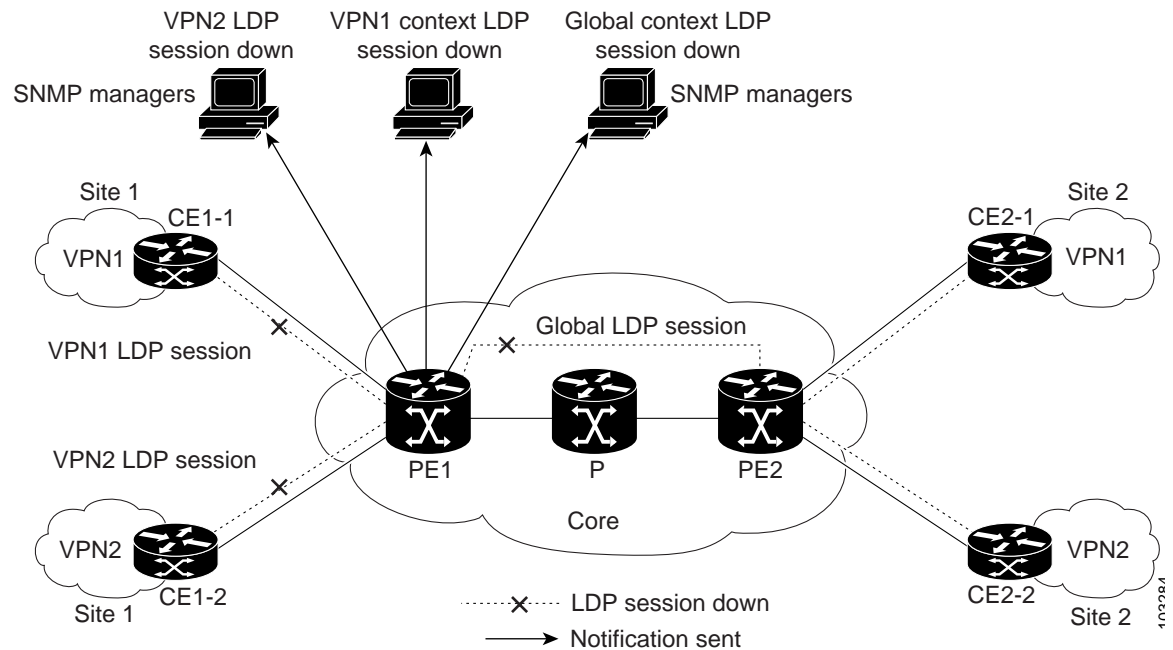

To enable LDP notifications for a VPN context, use the following commands:

```
Router(config)# snmp-server host host-address vrf vrf-name version {v1|v2c|v3}
community community-string udp-port upd-port mpls-ldp
```

```
Router(config)# snmp-server enable traps mpls rfc ldp
```

Figure 8 shows LDP notifications with the VPN Aware LDP MIB feature.

**Figure 8** LDP Notifications with the VPN Aware LDP MIB Feature

## Differences Between the MPLS-LDP-STD-MIB and the MPLS-LDP-MIB

The MPLS-LDP-STD-MIB based on RFC 3815 provides the same basic functionality as the MPLS-LDP-MIB based on the IETF Version 8 draft (draft-ietf-mpls-ldp-08.txt). The module identity was changed from `mplsLdpMIB` to `mplsLdpStdMIB`. Both MIBs provide an interface for managing LDP through the use of SNMP.

After the implementation of the MPLS-LDP-STD-MIB (RFC 3815) in Cisco IOS Release 12.2(33)SRB the MPLS-LDP-MIB will exist for a period of time before support is completely removed. This gives you the chance to migrate to the MPLS-LDP-STD-MIB. Both MIBs can coexist in the same image because the MPLS-LDP-STD-MIB and the MPLS-LDP-MIB have different root object identifiers (OIDs).

The following sections contain information about the major differences between the MPLS-LDP-STD-MIB and the MPLS-LDP-MIB:

- [MPLS-LDP-MIB and MPLS-LDP-STD-MIB Scalar Object Differences, page 25](#)
- [MPLS-LDP-MIB and MPLS-LDP-STD-MIB Table Object Differences, page 26](#)
- [MPLS-LDP-MIB and MPLS-LDP-STD-MIB Notification Changes, page 29](#)

## MPLS-LDP-MIB and MPLS-LDP-STD-MIB Scalar Object Differences

Table 12 shows the difference between the scalar objects in the MPLS-LDP-MIB and the MPLS-LDP-STD-MIB.

**Table 12** *Scalar Objects: MPLS-LDP-MIB and MPLS-LDP-STD-MIB Object Differences*

MPLS-LDP-MIB Object	MPLS-LDP-STD-MIB Object	Difference
—	mplsLdpPeerLastChange	New Object—Indicates the value of the sysUpTime at the time of the most recent addition or deletion to or from the mplsLdpPeerTable or the mplsLdpSessionTable.
mplsLdpSesUpDownTrapEnable	—	Object deleted.
—	mplsFecLastChange <b>Note</b> Not supported in Cisco IOS Releases 12.2(33)SRB and 12.2(33)SB.	New object—Contains the sysUpTime at the time of the most recent change to the mplsLdpFecTable.
—	mplsLdpLspFecLastChange <b>Note</b> Not supported in Cisco IOS Releases 12.2(33)SRB and 12.2(33)SB.	New object—Stores the last change time for the mplsLdpLspFecTable.
—	mplsLdpEntityLastChange	New object—Indicates the last change time for the mplsLdpEntityTable or mplsLdpEntityStatsTable.

## MPLS-LDP-MIB and MPLS-LDP-STD-MIB Table Object Differences

The following tables show the major differences between the MPLS-LDP-MIB and the MPLS-LDP-STD-MIB objects for each table.

### MPLS LDP Entity Table (mplsLdpEntityTable) Differences

[Table 13](#) shows the major differences between MPLS-LDP-MIB and MPLS-LDP-STD-MIB objects for the MPLS LDP entity table.

**Table 13** *MPLS LDP Entity Table: MPLS-LDP-MIB and MPLS-LDP-STD-MIB Object Differences*

MPLS-LDP-MIB Object	MPLS-LDP-STD-MIB Object	Difference
mplsLdpEntityIndexNext	mplsLdpEntityIndexNext	Syntax changed—Unsigned32 to IndexIntegerNextFree.
mplsLdpEntityIndex	mplsLdpEntityIndex	Syntax changed—Unsigned32 to IndexInteger.
mplsLdpEntityProtocolVersion	mplsLdpEntityProtocolVersion	Syntax changed—Unsigned32 to Integer32.
mplsLdpEntityAdminStatus	mplsLdpEntityAdminStatus	Description changed—Modified to suggest that an NMS clean up any related entry in the mplsLdpPeerTable in case this object is changed from enable to disable.

**Table 13** *MPLS LDP Entity Table: MPLS-LDP-MIB and MPLS-LDP-STD-MIB Object Differences (continued)*

MPLS-LDP-MIB Object	MPLS-LDP-STD-MIB Object	Difference
mplsLdpEntityOperStatus	mplsLdpEntityOperStatus	Description changed—Modified to include the value of unknown(1) for a transient condition before the LSR changes the value to enabled(2) or disabled(3).
mplsLdpEntityTcpDscPort	mplsLdpEntityTcpPort	Object name changed.
mplsLdpEntityMaxPduLength	mplsLdpEntityMaxPduLength	Syntax changed—Lower-limit value for this object increased from 0 to 256.  Description changed—Indicates that the receiving LSR should calculate the maximum PDU length for the session by using the smaller of its and its peer's proposal for the Max PDU length.
mplsLdpEntityInitSessionThreshold	mplsLdpEntityInitSessionThreshold	Syntax changed—Maximum value changed from MAXINT to 100.
mplsLdpEntityLabelDistMethod	mplsLdpEntityLabelDistMethod	Syntax changed—INTEGER to MplsLabelDistributionMethod TC.
mplsLdpEntityLabelRetentionMode	mplsLdpEntityLabelRetentionMode	Syntax changed—INTEGER to MplsRetentionMode TC.
mplsLdpEntityPVLmisTrapEnable	—	Notification control object removed.
mplsLdpEntityPVL	mplsLdpEntityPathVectorLimit	Object name changed.
mplsLdpEntityHopCountLimit	mplsLdpEntityHopCountLimit	DEFVAL clause added for a default value = 0.
—	mplsLdpEntityTransportAddrKind	New object—Indicates the address to be used for hello messages (interface and loopback).
mplsLdpEntityTargPeerAddrType	mplsLdpEntityTargPeerAddrType	Syntax changed—To InetAddressType.
mplsLdpEntityTargPeerAddr	mplsLdpEntityTargPeerAddr	Syntax changed—To InetAddress.
mplsLdpEntityOptionalParameters	mplsLdpEntityLabelType	Object name changed.
mplsLdpEntityStorType	mplsLdpEntityStorageType	Object name changed.
mplsLdpEntityRowStatus	mplsLdpEntityRowStatus	Description change—Added recommendation to set the mplsLdpEntityAdminStatus to down, change the objects in this entry, and then set the Admin status to enable.

**MPLS LDP Entity Statistics Table (mplsLdpEntityStatsTable) Differences****Note**

A general paragraph regarding discontinuities is added to all the counter objects in MPLS LDP entity statistics table: “Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of mplsLdpEntityDiscontinuityTime.”

Table 14 shows the difference between MPLS-LDP-MIB and MPLS-LDP-STD-MIB objects for the MPLS LDP entity statistics table.

**Table 14 MPLS LDP Entity Statistics Table: MPLS-LDP-MIB and MPLS-LDP-STD-MIB Object Differences**

MPLS-LDP-MIB Object	MPLS-LDP-STD-MIB Object	Difference
mplsLdpAttemptedSessions	mplsLdpEntityStatsSessionAttempts	Object name changed.
mplsLdpSesRejectedNoHelloErrors	mplsLdpEntityStatsSessionRejectedNoHelloErrors	Object name changed.
mplsLdpSesRejectedAdErrors	mplsLdpEntityStatsSessionRejectedAdErrors	Object name changed.
mplsLdpSesRejectedMaxPduErrors	mplsLdpEntityStatsSessionRejectedMaxPduErrors	Object name changed.
mplsLdpSesRejectedLRErrors	mplsLdpEntityStatsSessionRejectedLRErrors	Object name changed.
mplsLdpBadLdpIdentifierErrors	mplsLdpEntityStatsBadLdpIdentifierErrors	Object name changed.
mplsLdpBadPduLengthErrors	mplsLdpEntityStatsBadPduLengthErrors	Object name changed.
mplsLdpBadMessageLengthErrors	mplsLdpEntityStatsBadMessageLengthErrors	Object name changed.
mplsLdpBadTlvLengthErrors	mplsLdpEntityStatsBadTlvLengthErrors	Object name changed.
mplsLdpMalformedTlvValueErrors	mplsLdpEntityStatsMalformedTlvValueErrors	Object name changed.
mplsLdpKeepAliveTimerExpErrors	mplsLdpEntityStatsKeepAliveTimerExpErrors	Object name changed.
mplsLdpShutdownNotifReceived	mplsLdpEntityStatsShutdownReceivedNotifications	Object name changed.
mplsLdpShutdownNotifSent	mplsLdpEntityStatsShutdownSentNotifications	Object name changed.

### MPLS LDP Peer Table (mplsLdpPeerTable) Differences

Table 15 shows the difference between MPLS-LDP-MIB and MPLS-LDP-STD-MIB objects for the MPLS LDP peer table.

**Table 15 MPLS LDP Peer Table: MPLS-LDP-MIB and MPLS-LDP-STD-MIB Object Differences**

MPLS-LDP-MIB Object	MPLS-LDP-STD-MIB Object	Difference
mplsLdpPeerLabelDistMethod	mplsLdpPeerLabelDistMethod	Syntax change—From INTEGER to MplsLabelDistributionMethod
mplsLdpPeerLoopDectionForPV	—	Object deleted.
mplsLdpPeerPVL	mplsLdpPeerPathVectorLimit	Object name changed.
—	mplsLdpPeerTransportAddrType	New object—Internet address type (IPv4 or IPv6) advertised by the peer in the hello message or hello source message.
—	mplsLdpPeerTransportAddr	New object—Internet address (IPv4 or IPv6) advertised by the peer in the hello message or hello source message.

## MPLS LDP Session Table (mplsLdpSessionTable) Differences

Table 16 shows the difference between MPLS-LDP-MIB and MPLS-LDP-STD-MIB objects for the MPLS LDP session table.

**Table 16** *MPLS LDP Session Table: MPLS-LDP-MIB and MPLS-LDP-STD-MIB Object Differences*

MPLS-LDP-MIB Object	MPLS-LDP-STD-MIB Object	Difference
mplsLdpSesState	mplsLdpSessionState	Object name changed.
mplsLdpSesProtocolVersion	mplsLdpSessionProtocolVersion	Object name changed.
—	mplsLdpSessionStateLastChange	New Object—Indicates the last change time for this table.
—	mplsLdpSessionRole	New object—Indicates the LSR state: active, passive, or unknown.
mplsLdpSesKeepAliveHoldTimeRem	mplsLdpSessionKeepAliveHoldTimeRem	Object name changed.
—	mplsLdpSessionKeepAliveTime	New object—Indicates the actual keepalive time negotiated between peers.
mplsLdpSesMaxPduLen	mplsLdpSessionMaxPduLen	Object name changed.
mplsLdpSesDiscontinuityTime	mplsLdpSessionDiscontinuityTime	Object name changed.

## MPLS LDP Hello Adjacency Table (mplsLdpHelloAdjacencyTable) Differences

Table 17 shows the difference between MPLS-LDP-MIB and MPLS-LDP-STD-MIB objects for the MPLS LDP hello adjacency table.

**Table 17** *MPLS LDP Hello Adjacency Table: MPLS-LDP-MIB and MPLS-LDP-STD-MIB Object Differences*

MPLS-LDP-MIB Object	MPLS-LDP-STD-MIB Object	Difference
mplsLdpHelloAdjIndex	mplsLdpHelloAdjacencyIndex	Object name changed.
mplsLdpHelloAdjHoldTimeRem	mplsLdpHelloAdjacencyHoldTimeRem	Object name changed.
—	mplsLdpHelloAdjacencyHoldTime	New object—Indicates the actual negotiated adjacency hold time.
mplsLdpHelloAdjType	mplsLdpHelloAdjacencyType	Object name changed.

## MPLS-LDP-MIB and MPLS-LDP-STD-MIB Notification Changes

All notifications from the MPLS-LDP-MIB are retained in the MPLS-LDP-STD-MIB. The following changes are implemented for the notifications in MPLS-LDP-STD-MIB:

- The mplsLdpPVLMismatch notification is renamed to mplsLdpPathVectorLimitMismatch.
- The mplsLdpEntityPVLMisTrapEnable, notification control object, was removed for the MPLS-LDP-STD-MIB.
- The Cisco IOS command for enabling notifications for the MPLS-LDP-MIB is different from the command for enabling notifications for the MPLS-LSR-STD-MIB.

For the MPLS-LDP-MIB, the command is **snmp-server enable traps mpls ldp**. For the MPLS-LSR-STD-MIB, the command is **snmp-server enable traps mpls rfc ldp**.

## Differences Between the MPLS-LDP-MIB and the MPLS-LDP-ATM-STD-MIB (RFC 3815)

Layer 2 ATM-related objects are removed from the MPLS-LDP-MIB and placed in a new MIB module in RFC 3815. The new MIB module is the MPLS-LDP-ATM-STD-MIB. This action provides modularity and reduces the size of the MPLS LDP MIB.

Table 18 lists the differences between ATM-related objects in the MPLS-LDP-MIB and objects in the MPLS-LDP-ATM-STD-MIB.

**Table 18** *Differences Between MPLS-LDP-MIB and MPLS-LDP-ATM-STD-MIB Objects*

MPLS-LDP-MIB Object	MPLS-LDP-ATM-STD-MIB Object	Difference
mplsLdpEntityAtmParmsTable	mplsLdpEntityAtmTable	Object name changed.
mplsLdpEntityAtmMergeCap	mplsLdpEntityAtmMergeCap	Syntax changed—Added enumerations vpMerge and vpAndVcMerge.
mplsLdpEntityDefaultControlVpi	mplsLdpEntityAtmDefaultControlVpi	Object name changed.
mplsLdpEntityDefaultControlVci	mplsLdpEntityAtmDefaultControlVci	Object name changed.
mplsLdpEntityUnlabTrafVpi	mplsLdpEntityAtmUnlabTrafVpi	Object name changed.
mplsLdpEntityUnlabTrafVci	mplsLdpEntityAtmUnlabTrafVci	Object name changed.
mplsLdpEntityAtmStorType	mplsLdpEntityAtmStorageType	Object name changed.
mplsLdpEntityAtmRowStatus	mplsLdpEntityAtmRowStatus	Description changed—Clarified different row status operations. Added a recommendation that the mplsLdpEntityAdminStatus object be set to down before the LSR changes the objects in this table.
mplsLdpEntityConfAtmLRTable	mplsLdpEntityAtmLRTable	Object name changed.
mplsLdpEntityConfAtmLREntry	mplsLdpEntityAtmLREntry	Object name changed.
mplsLdpEntityConfAtmLRMinVpi	mplsLdpEntityAtmLRMinVpi	Object name changed. Description changed—0 added as a valid value.
mplsLdpEntityConfAtmLRMinVci	mplsLdpEntityAtmLRMinVci	Object name changed.
mplsLdpEntityConfAtmLRMaxVpi	mplsLdpEntityAtmLRMaxVpi	Object name changed.
mplsLdpEntityConfAtmLRMaxVci	mplsLdpEntityAtmLRMaxVci	Object name changed.
mplsLdpEntityConfAtmLRStorType	mplsLdpEntityAtmLRStorageType	Object name changed.
mplsLdpEntityConfAtmLRRowStatus	mplsLdpEntityAtmLRRowStatus	Object name changed.
mplsLdpAtmSesTable	mplsLdpAtmSessionTable	Object name changed.
mplsLdpSesAtmLRLowerBoundVpi	mplsLdpSessionAtmLRLowerBoundVpi	Object name changed.
mplsLdpSesAtmLRLowerBoundVci	mplsLdpSessionAtmLRLowerBoundVci	Object name changed.
mplsLdpSesAtmLRUpperBoundVpi	mplsLdpSessionAtmLRUpperBoundVpi	Object name changed.
mplsLdpSesAtmLRUpperBoundVci	mplsLdpSessionAtmLRUpperBoundVci	Object name changed.

## Differences Between the MPLS-LDP-MIB and the MPLS-LDP-GENERIC-STD-MIB (RFC 3815)

Layer 2 objects for per-platform label spaces are removed from the MPLS-LDP-MIB and placed in a new MIB module in RFC 3815. The new MIB module is the MPLS-LDP-GENERIC-STD-MIB. This action provides modularity and reduces the size of the MPLS LDP MIB.

[Table 19](#) shows the difference between generic label space objects in the MPLS-LDP-MIB and objects in the MPLS-GENERIC-STD-MIB.

**Table 19** *MPLS LDP LSP DEC Table: MPLS-LDP-MIB and MPLS-LDP-GENERIC-STD-MIB Object Differences*

MPLS-LDP-MIB Object	MPLS-LDP-GENERIC-STD-MIB Object	Difference
mplsLdpEntityConfGenLRTable	mplsLdpEntityGenericLRTable	Object name changed.
mplsLdpEntityConfGenLRMin	mplsLdpEntityGenericLRMin	Object name changed.
mplsLdpEntityConfGenLRMax	mplsLdpEntityGenericLRMax	Object name changed.
mplsLdpEntityConfGenIfIndexOrZero	mplsLdpEntityGenericIfIndexOrZero	Object name changed.
mplsLdpEntityConfGenLRStorType	mplsLdpEntityGenericLRStorageType	Object name changed.
mplsLdpEntityConfGenLRRowStatus	mplsLdpEntityGenericRowStatus	Object name changed.
—	mplsLdpEntityGenericLabelSpace	New object—A value of perPlatform(1) indicates the label space type is per platform; a value of perInterface(2) indicates the label space type is per interface.

## How to Configure SNMP for MPLS EM—MPLS LDP MIB - RFC 3815

To configure SNMP for the MPLS EM—MPLS LDP MIB - RFC 3815 feature, perform the following tasks:

- [Configuring Access to an SNMP Agent on a Host NMS Workstation, page 31](#) (required)
- [Configuring the Router to Send SNMP Notifications to a Host for Monitoring LDP, page 33](#) (required)
- [Configuring a VPN-Aware LDP MIB, page 35](#) (optional)

### Configuring Access to an SNMP Agent on a Host NMS Workstation

To configure access to the SNMP agent on a host NMS workstation, perform the following task.

Through the use of an SNMP agent, the MPLS LDP MIBs described in RFC 3815 provide an interface for monitoring and managing LDP.

To use SNMP to manage LDP, you need to configure access to an SNMP agent on a NMS workstation. By default, the SNMP agent for the MPLS LDP MIB is disabled. Step 2 shows you how to determine if an SNMP agent is already configured, and if you need to modify the SNMP information to monitor and manage LDP.

## SUMMARY STEPS

1. **enable**
2. **show running-config**
3. **configure terminal**
4. **snmp-server community** *string* [**view** *view-name*] [**ro** | **rw**] [*acl-number*]
5. **do copy running-config startup-config**
6. **exit**
7. **show-running config**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
Step 2	<b>show running-config</b>  <b>Example:</b> Router# show running-config	Displays the running configuration to determine if an SNMP agent is already running. <ul style="list-style-type: none"> <li>• If no SNMP information is displayed, continue with the next step. If any SNMP information is displayed, you can modify the information or change it as needed.</li> </ul>
Step 3	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 4	<b>snmp-server community</b> <i>string</i> [ <b>view</b> <i>view-name</i> ] [ <b>ro</b>   <b>rw</b> ] [ <i>acl-number</i> ]  <b>Example:</b> Router(config)# snmp-server community comaccess ro	Configures the community access string to permit access to the SNMP protocol. <ul style="list-style-type: none"> <li>• The <i>string</i> argument acts like a password and permits access to the SNMP protocol.</li> <li>• The <b>view</b> <i>view-name</i> keyword argument pair specifies the name of a previously defined view. The view defines the objects available to the community.</li> <li>• The <b>ro</b> keyword specifies read-only access. Authorized management stations are able to only retrieve MIB objects.</li> <li>• The <b>rw</b> keyword specifies read/write access. Authorized management stations are able to both retrieve and modify MIB objects.</li> <li>• The <i>acl-number</i> argument is an integer from 1 to 99 that specifies an access list of IP addresses that are allowed to use the community string to gain access to the SNMP agent.</li> </ul>

	Command or Action	Purpose
Step 5	<code>do copy running-config startup-config</code>  <b>Example:</b> <pre>Router(config)# do copy running-config startup-config</pre>	(Optional) Saves the modified configuration to nonvolatile memory (NVRAM) as the startup configuration file. <ul style="list-style-type: none"> <li>• Use this command if you made changes to the MIB information.</li> <li>• The <b>do</b> command allows you to perform EXEC-level commands in configuration modes.</li> </ul>
Step 6	<code>exit</code>  <b>Example:</b> <pre>Router(config)# exit</pre>	Returns to privileged EXEC mode.
Step 7	<code>show running-config</code>  <b>Example:</b> <pre>Router# show running-config   include snmp-server</pre>	(Optional) Displays the configuration information currently on the router. <ul style="list-style-type: none"> <li>• Use the <b>show running-config</b> command to check that the <b>snmp-server</b> command statements appear in the output.</li> </ul>

## Examples

Use the **show running-config** command to display the running configuration on the host NMS workstation and examine the output for SNMP information. For example:

```
Router# show running-config | include snmp-server

snmp-server community public RO
snmp-server community private RW
```

The presence of any **snmp-server** command statement in the output that takes the form shown in this example verifies that access to the SNMP agent is configured on the host NMS workstation.

## Configuring the Router to Send SNMP Notifications to a Host for Monitoring LDP

To configure the router to send SNMP notifications to a host to monitor LDP, perform the following task. The ability to display SNMP notifications helps in managing LDP sessions. You can determine if an LDP session between peers is up or down, if the path vector limits are the same for both LDP peers, and if the path vector limit threshold between the peers has been exceeded.

The **snmp-server host** command specifies which hosts receive notifications or traps. The **snmp-server enable traps** command globally enables the trap production mechanism for the specified traps.

For a host to receive a trap, an **snmp-server host** command must be configured for that host, and, generally, the trap must be enabled globally through the **snmp-server enable traps** command.

## Prerequisites

Although you can set the *community-string* argument using the **snmp-server host** command by itself, we recommend that you define this string using the **snmp-server community** command prior to using the **snmp-server host** command.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server host** *host-address* [**traps** | **informs**] [**version** {**1** | **2c** | **3** [**auth** | **noauth** | **priv**]}] *community-string* [**udp-port** *port*] [*notification-type*] [**vrf** *vrf-name*]
4. **snmp-server enable traps mpls ldp** [**pv-limit**] [**session-down**] [**session-up**] [**threshold**]
5. **end**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>snmp-server host</b> <i>host-address</i> [ <b>traps</b>   <b>informs</b> ] [ <b>version</b> { <b>1</b>   <b>2c</b>   <b>3</b> [ <b>auth</b>   <b>noauth</b>   <b>priv</b> ]}] <i>community-string</i> [ <b>udp-port</b> <i>port</i> ] [ <i>notification-type</i> ] [ <b>vrf</b> <i>vrf-name</i> ]  <b>Example:</b> Router(config)# snmp-server host 172.20.2.160 traps comaccess mpls-ldp	Specifies the recipient of an SNMP notification operation. <ul style="list-style-type: none"> <li>• The <i>host-address</i> argument specifies the name or Internet address of the host (the targeted recipient).</li> <li>• The <b>traps</b> keyword sends SNMP traps to this host. This is the default.</li> <li>• The <b>informs</b> keyword sends SNMP informs to this host.</li> <li>• The <b>version</b> keyword specifies the version of the SNMP used to send the traps. Version 3 is the most secure model, because it allows packet encryption with the <b>priv</b> keyword. If you use the <b>version</b> keyword, you must specify one of the following: <ul style="list-style-type: none"> <li>– <b>1</b>—SNMPv1. This option is not available with informs.</li> <li>– <b>2c</b>—SNMPv2C.</li> <li>– <b>3</b>—SNMPv3. The following three optional keywords can follow the <b>version 3</b> keyword: <b>auth</b>, <b>noauth</b>, <b>priv</b>.</li> </ul> </li> <li>• The <i>community-string</i> argument is a password-like community string sent with the notification operation.</li> </ul>

Command or Action	Purpose
<p><b>Step 4</b></p> <pre>snmp-server enable traps mpls ldp [pv-limit] [session-down] [session-up] [threshold]</pre> <p><b>Example:</b>  Router(config)# snmp-server enable traps mpls  rfc ldp session-down</p>	<ul style="list-style-type: none"> <li>• The <b>udp-port</b> <i>port</i> keyword argument pair names the UDP port of the host to use. The default is 162.</li> <li>• The <i>notification-type</i> argument specifies the type of notification to be sent to the host. If no type is specified, all notifications are sent.</li> <li>• The <b>vrf</b> <i>vrf-name</i> keyword argument pair specifies the VRF table that should be used to send SNMP notifications.</li> </ul> <p>Enables the router to send MPLS LDP-specific SNMP notifications (traps and informs) defined in RFC 3815.</p> <ul style="list-style-type: none"> <li>• The <b>pv-limit</b> keyword controls (enables or disables) path-vector (PV) limit notifications (mplsLdpPathVectorLimitMismatch). This notification is generated when the router establishes an LDP session with its adjacent peer LSR, but the two LSRs have dissimilar path-vector limits.</li> <li>• The <b>session-down</b> keyword controls (enables or disables) LDP session down notifications (mplsLdpSessionDown). This message is generated when an LDP session between the router and its adjacent LDP peer is terminated.</li> <li>• The <b>session-up</b> keyword controls (enables or disables) LDP session up notifications (mplsLdpSessionUp). This notification is generated when the router establishes an LDP session with another LDP entity (an adjacent LDP peer in the network).</li> <li>• The <b>threshold</b> keyword controls (enables or disables) PV limit notifications (mplsLdpFailedInitSessionThresholdExceeded). This notification is generated after eight failed attempts to establish an LDP session between the router and an LDP peer. The failure can be the result of any type of incompatibility between the devices.</li> </ul>
<p><b>Step 5</b></p> <pre>end</pre> <p><b>Example:</b>  Router(config)# end</p>	<p>(Optional) Exits to privileged EXEC mode.</p>

## Configuring a VPN-Aware LDP MIB

To configure a VPN-aware LDP MIB, perform the following tasks:

- [Configuring SNMP Support for a VPN, page 36](#) (required)
- [Configuring an SNMP Context for a VPN, page 37](#) (required)
- [Configuring a VPN-Aware SNMP Context for SNMPv1 or SNMPv2, page 39](#) (required)

## Configuring SNMP Support for a VPN

To configure SNMP support for a VPN (or a remote VPN), perform the following task.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server host** *host-address* [**vrf** *vrf-name*] [**traps** | **informs**] [**version** {**1** | **2c** | **3** [**auth** | **noauth** | **priv**]}] *community-string* [**udp-port** *port*] [*notification-type*]
4. **snmp-server engineID remote** *ip-address* [**udp-port** *udp-port-number*] [**vrf** *vrf-name*] *engineid-string*
5. **end**

### DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>snmp-server host</b> <i>host-address</i> [ <b>vrf</b> <i>vrf-name</i> ] [ <b>traps</b>   <b>informs</b> ] [ <b>version</b> { <b>1</b>   <b>2c</b>   <b>3</b> [ <b>auth</b>   <b>noauth</b>   <b>priv</b> ]}] <i>community-string</i> [ <b>udp-port</b> <i>port</i> ] [ <i>notification-type</i> ]  <b>Example:</b> Router(config)# snmp-server host example.com vrf trap-vrf	Specifies the recipient of an SNMP notification operation and specifies the VRF instance table to be used for the sending of SNMP notifications. <ul style="list-style-type: none"> <li>• The <i>host-address</i> argument specifies the name or Internet address of the host (the targeted recipient).</li> <li>• The <b>vrf</b> <i>vrf-name</i> keyword argument pair specifies the VRF table that should be used to send SNMP notifications.</li> <li>• The <b>traps</b> keyword sends SNMP traps to this host. This is the default.</li> <li>• The <b>informs</b> keyword sends SNMP informs to this host.</li> <li>• The <b>version</b> keyword specifies the version of the SNMP used to send the traps. Version 3 is the most secure model, because it allows packet encryption with the <b>priv</b> keyword. If you use the <b>version</b> keyword, you must specify one of the following:</li> </ul>

	Command or Action	Purpose
		<ul style="list-style-type: none"> <li>– <b>1</b> —SNMPv1. This option is not available with informs.</li> <li>– <b>2c</b> —SNMPv2C.</li> <li>– <b>3</b> —SNMPv3. The following three optional keywords can follow the <b>version 3</b> keyword: <b>auth</b>, <b>noauth</b>, <b>priv</b>.</li> <li>• The <i>community-string</i> argument is a password-like community string sent with the notification operation.</li> <li>• The <b>udp-port</b> <i>port</i> keyword argument pair names the UDP port of the host to use. The default is 162.</li> <li>• The <i>notification-type</i> argument specifies the type of notification to be sent to the host. If no type is specified, all notifications are sent.</li> </ul>
<b>Step 4</b>	<pre>snmp-server engineID remote ip-address [udp-port udp-port-number] [vrf vrf-name] engineid-string</pre> <p><b>Example:</b></p> <pre>Router(config)# snmp-server engineID remote 172.16.20.3 vrf traps-vrf 80000009030000B064EFE100</pre>	<p>Specifies the SNMP engine ID of a remote SNMP device.</p> <ul style="list-style-type: none"> <li>• The <i>ipv4-address</i> argument is the IPv4 address of the device that contains the remote copy of SNMP.</li> <li>• The <i>ipv6-address</i> argument is the IPv6 address of the device that contains the remote copy of SNMP.</li> <li>• The <b>udp-port</b> keyword specifies a User Datagram Protocol (UDP) port of the host to use.</li> <li>• The <i>udp-port-number</i> argument is the socket number on the remote device that contains the remote copy of SNMP. The default is 161.</li> <li>• The <b>vrf</b> keyword specifies an instance of a routing table.</li> <li>• The <i>vrf-name</i> argument is the name of the VRF table to use for storing data.</li> <li>• The <i>engineid-string</i> is a string of a maximum of 24 characters that identifies the engine ID.</li> </ul>
<b>Step 5</b>	<pre>end</pre> <p><b>Example:</b></p> <pre>Router(config)# end</pre>	<p>Exits to privileged EXEC mode.</p>

## What to Do Next

Proceed to the [“Configuring an SNMP Context for a VPN”](#) section on page 37.

## Configuring an SNMP Context for a VPN

To configure an SNMP context for a VPN, perform the following task. This sets up a unique SNMP context for a VPN, which allows you to access the VPN’s LDP session information.

### SNMP Context

SNMP contexts provide VPN users with a secure way of accessing MIB data. When a VPN is associated with a context, that VPN’s specific MIB data exists in that context. Associating a VPN with a context enables service providers to manage networks with multiple VPNs. Creating and associating a context with a VPN enables a provider to prevent the users of one VPN from accessing information about users of other VPNs on the same networking device.

### VPN Route Distinguishers

A route distinguisher (RD) creates routing and forwarding tables for a VPN. Cisco IOS software adds the RD to the beginning of the customer’s IPv4 prefixes to change them into globally unique VPN-IPv4 prefixes.

Either the RD is an autonomous system number (ASN)-relative RD, in which case it is composed of an autonomous system number and an arbitrary number, or it is an IP-address-relative RD, in which case it is composed of an IP address and an arbitrary number. You can enter an RD in either of these formats:

- 16-bit ASN: your 32-bit number, for example, 101:3.
- 32-bit IP address: your 16-bit number, for example, 192.168.122.15:1.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server context** *context-name*
4. **ip vrf** *vrf-name*
5. **rd** *route-distinguisher*
6. **context** *context-name*
7. **route-target** { **import** | **export** | **both** } *route-target-ext-community*
8. **end**

### DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
	<b>Example:</b> Router> enable	
Step 2	<b>configure terminal</b>	Enters global configuration mode.
	<b>Example:</b> Router# configure terminal	
Step 3	<b>snmp-server context</b> <i>context-name</i>	Creates and names an SNMP context. <ul style="list-style-type: none"> <li>• The <i>context-name</i> argument is the name of the SNMP context being created.</li> </ul>
	<b>Example:</b> Router(config)# snmp-server context context1	

	Command or Action	Purpose
Step 4	<b>ip vrf</b> <i>vrf-name</i>  <b>Example:</b> Router(config)# ip vrf vrf1	Configures a VRF table and enters VRF configuration mode. <ul style="list-style-type: none"> <li>The <i>vrf-name</i> argument is the name assigned to a VRF.</li> </ul>
Step 5	<b>rd</b> <i>route-distinguisher</i>  <b>Example:</b> Router(config-vrf)# rd 100:120	Creates a VPN route distinguisher. <ul style="list-style-type: none"> <li>The <i>route-distinguisher</i> argument specifies to add an 8-byte value to an IPv4 prefix to create a VPN IPv4 prefix. You can enter a route distinguisher in either of these formats: <ul style="list-style-type: none"> <li>16-bit autonomous system number: your 32-bit number For example, 101:3.</li> <li>32-bit IP address: your 16-bit number For example, 192.168.122.15:1.</li> </ul> </li> </ul>
Step 6	<b>context</b> <i>context-name</i>  <b>Example:</b> Router(config-vrf)# context context1	Associates an SNMP context with a particular VRF. <ul style="list-style-type: none"> <li>The <i>context-name</i> argument is the name of the SNMP VPN context, up to 32 characters.</li> </ul>
Step 7	<b>route-target</b> { <b>import</b>   <b>export</b>   <b>both</b> } <i>route-target-ext-community</i>  <b>Example:</b> Router(config-vrf)# route-target export 100:1000	(Optional) Creates a route-target extended community for a VRF. <ul style="list-style-type: none"> <li>The <b>import</b> keyword specifies to import routing information from the target VPN extended community.</li> <li>The <b>export</b> keyword specifies to export routing information to the target VPN extended community.</li> <li>The <b>both</b> keyword specifies to import both import and export routing information to the target VPN extended community.</li> <li>The <i>route-target-ext-community</i> argument adds the route-target extended community attributes to the VRF's list of import, export, or both (import and export) route-target extended communities.</li> </ul>
Step 8	<b>end</b>  <b>Example:</b> Router(config-vrf)# end	Exits to privileged EXEC mode.

## What to Do Next

Proceed to the [“Configuring a VPN-Aware SNMP Context for SNMPv1 or SNMPv2”](#) section on page 39.

## Configuring a VPN-Aware SNMP Context for SNMPv1 or SNMPv2

To configure a VPN-aware SNMP context for SNMPv1 or SNMPv2, perform the following task. This allows you to access LDP session information for a VPN using SNMPv1 or SNMPv2.

## SNMPv1 or SNMPv2 Security

SNMPv1 and SNMPv2 are not as secure as SNMPv3. SNMP Versions 1 and 2 use plain text communities and do not perform the authentication or security checks that SNMP Version 3 performs.

To configure the VPN Aware LDP MIB feature when using SNMP Version 1 or SNMP Version 2, you need to associate a community name with a VPN. This association causes SNMP to process requests coming in for a particular community string only if they come in from the configured VRF. If the community string contained in the incoming packet does not have an associated VRF, the packet is processed only if it came in through a non-VRF interface. This process prevents users outside the VPN from using a clear text community string to query the VPN data. However, this is not as secure as using SNMPv3.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server user** *username group-name* [**remote host** *[udp-port port]*] {**v1** | **v2c** | **v3** [**encrypted**] [**auth** {**md5** | **sha**} *auth-password*]} [**access** *access-list*]
4. **snmp-server group** *group-name* {**v1** | **v2c** | **v3** {**auth** | **noauth** | **priv**}} [**context** *context-name*] [**read** *readview*] [**write** *writeview*] [**notify** *notifyview*] [**access** *access-list*]
5. **snmp-server view** *view-name oid-tree* {**included** | **excluded**}
6. **snmp-server enable traps** [*notification-type*]
7. **snmp-server host** *host-address* [**vrf** *vrf-name*] [**traps** | **informs**] [**version** {**1** | **2c** | **3** [**auth** | **noauth** | **priv**]}] *community-string* [**udp-port** *port*] [**notification-type**]
8. **snmp mib community-map** *community-name* [**context** *context-name*] [**engineid** *engine-id*] [**security-name** *security-name*] **target-list** *vpn-list-name*
9. **snmp mib target list** *vpn-list-name* {**vrf** *vrf-name* | **host** *ip-address*}
10. **no snmp-server trap authentication vrf**
11. **end**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>	Enables privileged EXEC mode.
	<b>Example:</b> Router> enable	<ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>	Enters global configuration mode.
	<b>Example:</b> Router# configure terminal	

	Command or Action	Purpose
<p><b>Step 3</b></p>	<pre>snmp-server user username group-name [<b>remote</b> host [udp-port port]] {v1   v2c   v3 [encrypted] [auth {md5   sha} auth-password]} [access access-list]</pre> <p><b>Example:</b></p> <pre>Router(config)# snmp-server user customer1 group1 v1</pre>	<p>Configures a new user to an SNMP group.</p> <ul style="list-style-type: none"> <li>• The <i>username</i> argument is the name of the user on the host that connects to the agent.</li> <li>• The <i>group-name</i> argument is the name of the group to which the user belongs.</li> <li>• The <b>remote host</b> keyword and argument specify a remote SNMP entity to which the user belongs, and the hostname or IPv6 address or IPv4 IP address of that entity. If both an IPv6 address and IPv4 IP address are being specified, the IPv6 host must be listed first.</li> <li>• The <b>udp-port port</b> keyword and argument specify the UDP port number of the remote host. The default is UDP port 162.</li> <li>• The <b>v1</b> keyword specifies that SNMPv1 should be used.</li> <li>• The <b>v2c</b> keyword specifies that SNMPv2c should be used.</li> <li>• The <b>v3</b> keyword specifies that the SNMPv3 security model should be used. Allows the use of the <b>encrypted</b> and or <b>auth</b> keywords.</li> <li>• The <b>encrypted</b> keyword specifies whether the password appears in encrypted format (a series of digits, masking the true characters of the string).</li> <li>• The <b>auth</b> keyword specifies which authentication level should be used.</li> <li>• The <b>md5</b> keyword is the HMAC-MD5-96 authentication level.</li> <li>• The <b>sha</b> keyword is the HMAC-SHA-96 authentication level.</li> <li>• The <i>auth-password</i> argument is a string (not to exceed 64 characters) that enables the agent to receive packets from the host. The minimum length for a password is one character. The recommended length of a password is at least eight characters, and should include both letters and numbers.</li> <li>• The <b>access access-list</b> keyword and argument specify an access list to be associated with this SNMP user.</li> </ul>

Command or Action	Purpose
<p><b>Step 4</b></p> <pre>snmp-server group group-name {v1   v2c   v3} {auth   noauth   priv} [context context-name] [read readview] [write writeview] [notify notifyview] [access access-list]</pre> <p><b>Example:</b></p> <pre>Router(config)# snmp-server group group1 v1 context context1 read view1 write view1 notify view1</pre>	<p>Configures a new SNMP group or a table that maps SNMP users to SNMP views.</p> <ul style="list-style-type: none"> <li>• The <i>group-name</i> argument is the name of the group.</li> <li>• The <b>v1</b> keyword specifies that SNMPv1 should be used for the group.</li> <li>• The <b>v2c</b> keyword specifies that SNMPv2c should be used for the group. The SNMPv2c security model allows for the transmission of informs, and supports 64-character strings (instead of 32-character strings).</li> <li>• The <b>v3</b> keyword specifies that the SNMPv3 should be used for the group. SMNPv3 is the most secure of the supported security models, because it allows you to explicitly configure the authentication characteristics.</li> <li>• The <b>auth</b> keyword specifies authentication of a packet without encrypting it.</li> <li>• The <b>noauth</b> keyword specifies no authentication of a packet.</li> <li>• The <b>priv</b> keyword specifies authentication of a packet with encryption.</li> <li>• The <b>context</b> <i>context-name</i> keyword and argument associate the specified SNMP group with a configured SNMP context.</li> <li>• The <b>read</b> <i>readview</i> keyword and argument specify a read view for the SNMP group. The <i>readview</i> argument represents a string (not to exceed 64 characters) that is the name of the view that enables you to display only the contents of the agent.</li> <li>• The <b>write</b> <i>writeview</i> keyword and argument specify a write view for the SNMP group. The <i>writeview</i> argument represents a string (not to exceed 64 characters) that is the name of the view that enables you to enter data and configure the contents of the agent.</li> <li>• The <b>notify</b> and <i>notifyview</i> keyword argument specify a notify view for the SNMP group. The <i>writeview</i> argument represents a string (not to exceed 64 characters) that is the name of the view that enables you to specify a notify, inform, or trap.</li> <li>• The <b>access</b> <i>access-list</i> keyword and argument specify a standard access list (a standard ACL) to associate with the group.</li> </ul>

	Command or Action	Purpose
Step 5	<pre>snmp-server view view-name oid-tree {included   excluded}</pre> <p><b>Example:</b></p> <pre>Router(config)# snmp-server view view1 ipForward included</pre>	<p>Creates or updates a view entry.</p> <ul style="list-style-type: none"> <li>The <i>view-name</i> argument is the label for the view record that you are updating or creating. The name is used to reference the record.</li> <li>The <i>oid-tree</i> argument is the object identifier of the ASN.1 subtree to be included or excluded from the view. To identify the subtree, specify a text string consisting of numbers, such as 1.3.6.2.4, or a word, such as system. Replace a single subidentifier with the asterisk (*) wildcard to specify a subtree family; for example 1.3.*.4.</li> <li>The <b>included</b> keyword configures the OID (and subtree OIDs) specified in the <i>oid-tree</i> argument to be included in the SNMP view.</li> <li>The <b>excluded</b> keyword configures the OID (and subtree OIDs) specified in the <i>oid-tree</i> argument to be explicitly excluded from the SNMP view.</li> </ul>
Step 6	<pre>snmp-server enable traps [notification-type]</pre> <p><b>Example:</b></p> <pre>Router(config)# snmp-server enable traps</pre>	<p>Enables all SNMP notifications (traps or informs) available on your system.</p> <ul style="list-style-type: none"> <li>The <i>notification-type</i> argument specifies the particular type of SNMP notification(s) to be enabled on the LSR. If a notification type is not specified, all SNMP notifications applicable to the LSR are enabled and sent to the SNMP host.</li> </ul>
Step 7	<pre>snmp-server host host-address [vrf vrf-name] [traps   informs] [version {1   2c   3 [auth   noauth   priv]] community-string [udp-port port] [notification-type]</pre> <p><b>Example:</b></p> <pre>Router(config)# snmp-server host 10.0.0.1 vrf customer1 public udp-port 7002</pre>	<p>Specifies the recipient of an SNMP notification operation.</p> <ul style="list-style-type: none"> <li>The <i>host-address</i> argument specifies the name or Internet address of the host (the targeted recipient).</li> <li>The <b>vrf</b> <i>vrf-name</i> keyword argument pair specifies the VRF table that should be used to send SNMP notifications.</li> <li>The <b>traps</b> keyword sends SNMP traps to this host. This is the default.</li> <li>The <b>informs</b> keyword sends SNMP informs to this host.</li> <li>The <b>version</b> keyword specifies the version of the SNMP used to send the traps. Version 3 is the most secure model, because it allows packet encryption with the <b>priv</b> keyword. If you use the <b>version</b> keyword, you must specify one of the following: <ul style="list-style-type: none"> <li><b>1</b> —SNMPv1. This option is not available with informs.</li> <li><b>2c</b> —SNMPv2C.</li> <li><b>3</b> —SNMPv3. The following three optional keywords can follow the <b>version 3</b> keyword: <b>auth</b>, <b>noauth</b>, <b>priv</b>.</li> </ul> </li> </ul>

Command or Action	Purpose
	<ul style="list-style-type: none"> <li>The <i>community-string</i> argument is a password-like community string sent with the notification operation.</li> <li>The <b>udp-port</b> <i>port</i> keyword argument pair names the UDP port of the host to use. The default is 162.</li> <li>The <i>notification-type</i> argument specifies the type of notification to be sent to the host. If no type is specified, all notifications are sent.</li> </ul>
<p><b>Step 8</b></p> <pre>snmp mib community-map community-name [context context-name] [engineid engine-id] [security-name security-name] target-list vpn-list-name</pre> <p><b>Example:</b>  Router(config)# snmp mib community-map community1 context context1 target-list commAVpn</p>	<p>Associates an SNMP community with an SNMP context, engine ID, or security name.</p> <ul style="list-style-type: none"> <li>The <i>community-name</i> argument is an SNMP community string.</li> <li>The <b>context</b> <i>context-name</i> keyword and argument specify an SNMP context name to be mapped to the SNMP community.</li> <li>The <b>engineid</b> <i>engine-id</i> keyword and argument specify an SNMP engine ID to be mapped to the SNMP community.</li> <li>The <b>security-name</b> <i>security-name</i> keyword and argument specify the security name to be mapped to the SNMP community.</li> <li>The <b>target-list</b> <i>vpn-list-name</i> keyword and argument specify the VRF list to be mapped to the SNMP community. The list name should correspond to a list name used in the <b>snmp mib target list</b> command.</li> </ul>
<p><b>Step 9</b></p> <pre>snmp mib target list vpn-list-name {vrf vrf-name   host ip-address}</pre> <p><b>Example:</b>  Router(config)# snmp mib target list commAVpn vrf vrf1</p>	<p>Creates a list of target VRFs and hosts to associate with an SNMP community.</p> <ul style="list-style-type: none"> <li>The <i>vpn-list-name</i> argument is the name of the target list.</li> <li>The <b>vrf</b> keyword adds a specified VRF to the target list.</li> <li>The <i>vrf-name</i> argument is the name of a VRF to include in the list.</li> <li>The <b>host</b> keyword adds a specified host to the target list.</li> <li>The <i>ip-address</i> argument is the IP address of the host.</li> </ul>
<p><b>Step 10</b></p> <pre>no snmp-server trap authentication vrf</pre> <p><b>Example:</b>  Router(config)# no snmp-server trap authentication vrf</p>	<p>(Optional) Disables all SNMP authentication notifications (traps and informs) generated for packets received on VRF interfaces.</p> <ul style="list-style-type: none"> <li>Use this command to disable authentication traps only for those packets on VRF interfaces with incorrect community associations.</li> </ul>
<p><b>Step 11</b></p> <pre>end</pre> <p><b>Example:</b>  Router(config) end</p>	<p>Exits to privileged EXEC mode.</p>

# Configuration Examples for MPLS EM—MPLS LDP MIB - RFC 3815

This section contains the following configuration examples for MPLS EM—MPLS LDP MIB-RFC 3815:

- [Configuring Access to an SNMP Agent on a Host NMS Workstation: Example, page 45](#)
- [Configuring the Router to Send SNMP Notifications to a Host for Monitoring LDP: Example, page 45](#)
- [Configuring a VPN-Aware LDP MIB: Example, page 46](#)

## Configuring Access to an SNMP Agent on a Host NMS Workstation: Example

The following example shows how to configure access to an SNMP agent on a host NMS workstation:

```
configure terminal
!
snmp-server community
end
```

The following example shows how to configure access to SNMPv1 and SNMPv2C on the host NMS workstation. The configuration permits any SNMP agent to access all MPLS LDP MIB objects with read-only permission using the community string public.

```
configure terminal
!
snmp-server community public
end
```

The following example shows how to allow read-only access to all MPLS LDP MIB objects relating to members of access list 4 that specify the comaccess community string. No other SNMP agents will have access to any of the MPLS LDP MIB objects.

```
configure terminal
!
snmp-server community comaccess ro 4
end
```

## Configuring the Router to Send SNMP Notifications to a Host for Monitoring LDP: Example

The following example shows how to configure the router to send SNMP notifications to a host for monitoring LDP:

```
config terminal
!
snmp-server host 172.20.2.160 traps comaccess mpls-ldp
snmp-server enable traps mpls rfc ldp session-up
!
snmp-server enable traps mpls rfc ldp session-down
end
```

The session up and session down LDP notifications are configured.

## Configuring a VPN-Aware LDP MIB: Example

This section contains the following examples for configuring a VPN-aware LDP MIB:

- [Configuring SNMP Support for a VPN: Example, page 46](#)
- [Configuring an SNMP Context for a VPN: Example, page 46](#)
- [Configuring a VPN-Aware SNMP Context for SNMPv1 or SNMPv2: Example, page 46](#)

### Configuring SNMP Support for a VPN: Example

The following example shows how to configure SNMP support for a VPN:

```
configure terminal
!
snmp-server host 10.10.10.1 vrf traps-vrf
snmp-server engineID remote 172.16.20.3 vrf traps-vrf 80000009030000B064EFE100
end
```

### Configuring an SNMP Context for a VPN: Example

The following example shows how to configure an SNMP context for a VPN. In this example, the VPN vrf1 is associated with the SNMP context context1.

```
configure terminal
!
snmp-server context context1
ip vrf vrf1
rd 100:120
context context1
route-target export 100:1000
end
```

### Configuring a VPN-Aware SNMP Context for SNMPv1 or SNMPv2: Example

The following configuration example shows how to configure a VPN-aware SNMP context for the MPLS LDP MIB with SNMPv1 or SNMPv2:

```
snmp-server context A
snmp-server context B

ip vrf CustomerA
rd 100:110
context A
route-target export 100:1000
route-target import 100:1000
!

ip vrf CustomerB
rd 100:120
context B
route-target export 100:2000
route-target import 100:2000
!

interface Ethernet3/1
description Belongs to VPN A
ip vrf forwarding CustomerA
ip address 10.0.0.0 255.255.0.0
```

```

interface Ethernet3/2
  description Belongs to VPN B
  ip vrf forwarding CustomerB
  ip address 10.0.0.1 255.255.0.0

snmp-server user commA grp1A v1
snmp-server user commA grp2A v2c
snmp-server user commB grp1B v1
snmp-server user commB grp2B v2c

snmp-server group grp1A v1 context A read viewA write viewA notify viewA
snmp-server group grp1B v1 context B read viewB write viewB notify viewB

snmp-server view viewA ipForward included
snmp-server view viewA ciscoPingMIB included
snmp-server view viewB ipForward included
snmp-server view viewB ciscoPingMIB included

snmp-server enable traps
snmp-server host 10.0.0.3 vrf CustomerA commA udp-port 7002
snmp-server host 10.0.0.4 vrf CustomerB commB udp-port 7002

snmp mib community-map commA context A target-list commAvpn
! Configures source address validation
snmp mib community-map commB context B target-list commBvpn
! Configures source address validation
snmp mib target list commAvpn vrf CustomerA
! Configures a list of VRFs or from which community commA is valid
snmp mib target list commBvpn vrf CustomerB
! Configures a list of VRFs or from which community commB is valid

```

# Glossary

**FPI**—forwarding path identifier. An identifier required to locate Multiprotocol Label Switching (MPLS) forwarding information for a forwarding equivalence class (FEC). Examples of types of FPIs supported by the MPLS Forwarding Infrastructure (MFI) are IPv4, IPv6, LABEL, SSS, and TE.

**LDP**—Label Distribution Protocol. A standard protocol between MPLS-enabled routers that is used for the negotiation of the labels (addresses) used to forward packets.

**LFIB**—Label Forwarding Information Base. A data structure and way of managing forwarding in which destinations and incoming labels are associated with outgoing interfaces and labels.

**LSP**—label switched path. A sequence of hops in which a packet travels from one router to another router by means of label switching mechanisms. A label switched path can be established dynamically, based on normal routing mechanisms, or through configuration.

**LSR**—label switch router. A device that forwards MPLS packets based on the value of a fixed-length label encapsulated in each packet.

**MFI**—MPLS Forwarding Infrastructure. In the Cisco MPLS subsystem, the data structure for storing information about incoming and outgoing labels and associated equivalent packets suitable for labeling.

**MIB**—Management Information Base. Database of network management information that is used and maintained by a network management protocol such as SNMP. The value of a MIB object can be changed or retrieved by means of SNMP commands, usually through a network management system. MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

**MOI**—MPLS output information. The MOI includes the next hop, outgoing interface, and outgoing label.

**MPLS**—Multiprotocol Label Switching. MPLS is a method for forwarding packets (frames) through a network. It enables routers at the edge of a network to apply labels to packets (frames). ATM switches or existing routers in the network core can switch packets according to the labels with minimal lookup overhead.

**NMS**—network management station. A device (usually a workstation) that performs Simple Network Management Protocol (SNMP) queries to the SNMP agent of a managed device to retrieve or modify information.

**notification request**—Message sent by an SNMP agent to a network management station, console, or terminal, indicating that a significant event occurred. SNMP notification requests are more reliable than traps, because a notification request from an SNMP agent requires that the SNMP manager acknowledge receipt of the notification request. The manager replies with an SNMP response protocol data unit (PDU). If the manager does not receive a notification message from an SNMP agent, it does not send a response. If the sender (SNMP agent) never receives a response, the notification request can be sent again. Thus, a notification request is more likely than a trap to reach its intended destination.

**SNMP**—Simple Network Management Protocol. Management protocol used almost exclusively in TCP/IP networks. SNMP provides a means for monitoring and controlling network devices, and for managing configurations, statistics collection, performance, and security.

**trap**—Message sent by an SNMP agent to a network management station, console, or terminal, indicating that a significant event occurred. Traps are less reliable than notification requests, because the receiver does not send an acknowledgment when it receives a trap. The sender cannot determine if the trap was received.

# MPLS EM—MPLS LSR MIB - RFC 3813

---

**First Published: February 19, 2007**

**Last Updated: April 11, 2008**

The MPLS LSR MIB- RFC 3813 (MPLS-LSR-STD-MIB) allows you to use the Simple Network Management Protocol (SNMP) to remotely monitor a label switch router (LSR) that is using the Multiprotocol Label Switching (MPLS) technology.

This document describes the MPLS-LSR-STD-MIB. The document also describes the major differences between the MPLS-LSR-STD-MIB and draft Version 5 of the MPLS-LSR-MIB.

The MPLS EM—MPLS LSR MIB - RFC 3813 feature introduces the MPLS-LSR-STD-MIB, which is an upgrade from draft Version 5 of the MPLS-LSR-MIB to an implementation of the *Multiprotocol Label Switching (MPLS) Label Switching Router (LSR) Management Information Base (MIB)*, RFC 3813. This feature also introduces the VPN Aware LSR MIB feature that enables the MPLS-LSR-STD-MIB to get VPN context information.

Cisco IOS MPLS Embedded Management (EM) is a set of standards and value-added services that facilitate the deployment, operation, administration, and management of MPLS-based networks in line with the fault, configuration, accounting, performance, and security (FCAPS) model.

## **Finding Feature Information in This Module**

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for MPLS EM—MPLS LSR MIB - RFC 3813](#)” section on [page 39](#).

## **Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images**

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for MPLS EM—MPLS LSR MIB - RFC 3813

The MPLS-LSR-STD-MIB requires the following:

- SNMP installed and enabled on the LSR
- MPLS enabled on the LSR
- MPLS Forwarding Infrastructure (MFI)

## Restrictions for MPLS EM—MPLS LSR MIB - RFC 3813

- The implementation of the MPLS-LSR-STD-MIB (RFC 3815) for Cisco IOS Releases 12.2(33)SRB and 12.2(33)SB is limited to read-only (RO) permission for MIB objects.
- The following MIB objects are not supported in Cisco IOS Releases 12.2(33)SRB and 12.2(33)SB:
  - mplsInterfaceTotalBandwidth (MPLS interface table)
  - mplsInterfaceAvailableBandwidth (MPLS interface table)
  - mplsInterfacePerfInLabelLookupFailures (MPLS interface performance table)
  - mplsInterfacePerfOutFragmentedPkts (MPLS interface performance table)
  - mplsInSegmentTrafficParamPtr (MPLS in-segment table)
  - mplsInSegmentPerfDiscards (MPLS in-segment performance table)
- The following notifications are not supported:
  - mplsXCUp
  - mplsXCDown

# Information About MPLS EM—MPLS LSR MIB - RFC 3813

Before you configure SNMP and the MPLS-LSR-STD-MIB to remotely manage an MPLS LSR, you should understand the following concepts:

- [MPLS-LSR-STD-MIB Benefits, page 3](#)
- [Label Switching Information Managed by the MPLS-LSR-STD-MIB, page 4](#)
- [MPLS-LSR-STD-MIB Elements, page 5](#)
- [Brief Description of MPLS-LSR-STD-MIB Tables, page 5](#)
- [MPLS LSR Information Available Through the MPLS-LSR-STD-MIB, page 5](#)
- [Information from MPLS-LSR-STD-MIB Scalar Objects, page 10](#)
- [MPLS-LSR-STD-MIB Indexing—Linking Table Elements, page 11](#)
- [Interface Configuration Table and Interface MIB Links, page 12](#)
- [MPLS-LSR-STD-MIB Structure, page 13](#)
- [CLI Commands and the MPLS-LSR-MIB, page 14](#)
- [VPN Aware LSR MIB, page 16](#)
- [Major Differences Between the MPLS-LSR-STD-MIB and the MPLS-LSR-MIB, page 17](#)

## MPLS-LSR-STD-MIB Benefits

The benefits described in the following paragraphs are available to you with the MPLS-LSR-STD-MIB.

### LSR Problem Troubleshooting

By monitoring the cross-connect entries and the associated incoming and outgoing segments, you can see which labels are installed and how they are being swapped. Use the MPLS-LSR-STD-MIB in place of the **show mpls forwarding** command-line interface (CLI) command.

### LSR Traffic Load Monitoring

By monitoring interface and packet operations on an MPLS LSR, you can identify high- and low-traffic patterns, and traffic distributions.

### Improvement of Network Performance

By identifying potentially high-traffic areas, you can set up load sharing to improve network performance.

### Verification of LSR Configuration

By comparing results from SNMP **get** commands and the **show mpls forwarding** CLI command, you can verify your LSR configuration.

### Active Label Switched Paths Monitoring

By monitoring the cross-connect entries and the associated incoming segments and outgoing segments, you can determine the active LSPs.

## Label Switching Information Managed by the MPLS-LSR-STD-MIB

The MPLS-LSR-STD-MIB contains managed objects that support the retrieval of label switching information from a router. The MIB is based on RFC 3813. This implementation enables a network administrator to get information on the status, character, and performance of the following:

- MPLS-capable interfaces on the LSR
- Incoming MPLS segments (labels) at an LSR and their associated parameters
- Outgoing segments (labels) at an LSR and their associated parameters

In addition, the network administrator can retrieve the status of cross-connect table entries that associate MPLS segments with each other.

Figure 1 shows the association of the cross-connect table with incoming and outgoing segments (labels).

**Figure 1** Label Forwarding with the Cross-Connect Table

### Note

The out-segment table does not display “no label” entries. Labels that are displayed as “POP” are the special MPLS label 3.

The notation used in the MPLS-LSR-STD-MIB follows the conventions defined in Abstract System Notation One (ASN.1). ASN.1 defines an Open Systems Interconnection (OSI) language used to describe data types independently from particular computer structures and presentation techniques. Each object in the MIB incorporates a DESCRIPTION field that includes an explanation of the object’s meaning and usage, which, together with the other characteristics of the object (SYNTAX, MAX-ACCESS, and INDEX) provides sufficient information for management application development, as well as for documentation and testing.

The MPLS-LSR-STD-MIB represents an ASN.1 notation that represents an idealized MPLS LSR.

A network administrator can access the entries (objects) in the MPLS-LSR-STD-MIB by means of any SNMP-based network management system (NMS). The network administrator can retrieve information in the MPLS-LSR-STD-MIB using standard SNMP **get** and **getnext** commands.

Typically, SNMP runs as a low-priority process. The response time for the MPLS-LSR-STD-MIB is expected to be similar to that for other MIBs. The size and structure of the MIB and other MIBs in the system influence response time when you retrieve information from the management database. Traffic through the LSR also affects SNMP performance. The busier the switch is with forwarding activities, the greater the possibility of lower SNMP performance.

## MPLS-LSR-STD-MIB Elements

The top-level components of the MPLS-LSR-STD-MIB are:

- Tables and scalars (mplsLsrObjects)
- Notifications (mplsLsrNotifications)
- Conformance (mplsLsrConformance)

## Brief Description of MPLS-LSR-STD-MIB Tables

This section lists and briefly describes of the main and supplementary tables in the MPLS-LSR-STD-MIB.

The Cisco implementation of the MPLS-LSR-STD-MIB supports four main tables:

- MPLS interface table (mplsInterfaceTable)—Contains entries for all MPLS-capable interfaces on the LSR.
- MPLS in-segment table (mplsInSegmentTable)—Contains a description of incoming labels on the LSR.
- Mpls out-segment table (mplsOutSegmentTable)—Contains a description of outgoing labels on the LSR.
- MPLS cross-connect table (mplsXCTable)—Contains the connections between the in-segments and out-segments on the LSR. A single cross-connect entry is equivalent to a single entry in the Label Forwarding Information Base (LFIB), showing an in-label being switched to an out-label. A cross-connect entry can exist where no corresponding in-segment exists. For example, only the outgoing label exists at the head end of a traffic engineering (TE) tunnel.

Three tables manage labels, the MPLS in-segment table, the MPLS out-segment table, and the MPLS cross-connect tables.

The MIB contains three supplementary tables to supply performance information:

- MPLS interface performance table (mplsInterfacePerfTable)—Augments the MPLS interface table. Provides objects to measure performance for MPLS-capable interfaces on the LSR.
- MPLS in-segment performance table (mplsInSegmentPerfTable)—Augments the MPLS in-segment table. Provides performance information and counters for incoming segments on the LSR.
- MPLS out-segment performance table (mplsOutSegmentPerfTable)—Augments the MPLS out-segment table. Provides performance information and counters for outgoing segments on the LSR.

## MPLS LSR Information Available Through the MPLS-LSR-STD-MIB

You can use SNMP **get** and **getnext** commands to gather label switching information for an MPLS LSR available through the MPLS-LSR-STD-MIB tables. This section describes the MPLS LSR information available from each table:

- [MPLS Interface Table \(mplsInterfaceTable\)](#), page 6
- [MPLS Interface Performance Table \(mplsInterfacePerfTable\)](#), page 6
- [MPLS In-Segment Table \(mplsInSegmentTable\)](#), page 7
- [MPLS In-Segment Performance Table \(mplsInSegmentPerfTable\)](#), page 7

- [MPLS Out-Segment Table \(mplsOutSegmentTable\)](#), page 8
- [MPLS Out-Segment Performance Table \(mplsOutSegmentPerfTable\)](#), page 9
- [MPLS Cross-Connect Table \(mplsXCTable\)](#), page 9
- [MPLS Label Stack Table \(mplsLabelStackTable\)](#), page 10
- [MPLS In-Segment Map Table \(mplsInSegmentMapTable\)](#), page 10

## MPLS Interface Table (mplsInterfaceTable)

[Table 1](#) lists the MPLS LSR information and associated MIB objects provided by the MPLS interface table (mplsInterfaceTable).

**Table 1** *MPLS Interface Table—MPLS LSR Information and Associated MIB Object*

MPLS LSR Information	MIB Object
Minimum value for an MPLS label that can be received on the interface	<code>mplsInterfaceLabelMinIn</code>
Maximum value for an MPLS label that can be received on the interface	<code>mplsInterfaceLabelMaxIn</code>
A unique MPLS-enabled interface index or 0	<code>mplsInterfaceIndex</code>
Minimum value for an MPLS label that the LSR can send from the interface	<code>mplsInterfaceLabelMinOut</code>
Maximum value for an MPLS label that the LSR can send from the interface	<code>mplsInterfaceLabelMaxOut</code>
Per platform (0) or per interface (1) setting	<code>mplsInterfaceLabelParticipationType</code>

The following MIB objects and associated MPLS LSR information from the MPLS interface table are not supported:

- `mplsInterfaceTotalBandwidth`—The total usable bandwidth on the interface.
- `mplsInterfaceAvailableBandwidth`—The difference between the total usable bandwidth and the bandwidth in use.

## MPLS Interface Performance Table (mplsInterfacePerfTable)

[Table 2](#) lists the MPLS LSR information and associated MIB objects provided by the MPLS interface performance table (mplsInterfacePerfTable).

**Table 2** *MPLS Interface Performance Table—MPLS LSR Information and Associated MIB Object*

MPLS LSR Information	MIB Object
Number of labels in the incoming direction in use	<code>mplsInterfacePerfInLabelsInUse</code>
Number of top-most labels in outgoing label stacks in use	<code>mplsInterfacePerfOutLabelsInUse</code>

The following MIB objects and associated MPLS LSR information from the MPLS interface performance table are not supported:

- `mplsInterfacePerfInLabelLookupFailures`—The number of labeled packets discarded because no cross-connect entries exist.
- `mplsInterfacePerfOutFragmentedPkts`—The number of outgoing MPLS packets requiring fragmentation for transmission.

## MPLS In-Segment Table (`mplsInSegmentTable`)

Table 3 lists the MPLS LSR information and associated MIB objects provided by the MPLS in-segment table (`mplsInSegmentTable`).

**Table 3** *MPLS In-Segment Table—MPLS LSR Information and Associated MIB Object*

MPLS LSR Information	MIB Object
Unique index identifier	<code>mplsInSegmentIndex</code>
Interface index for the incoming MPLS interface	<code>mplsInSegmentInterface</code>
Incoming label	<code>mplsInSegmentLabel</code>
Pointer to an external table containing the label, if not represented fully in the <code>mplsInSegmentLabel</code> object	<code>mplsInSegmentLabelPtr</code>
Number of labels to pop (remove) from the incoming segment	<code>mplsInSegmentNPop</code>
An address family number from the Internet Assigned Number Authority (IANA)	<code>mplsInSegmentAddrFamily</code>
Segment cross-connect entry association	<code>mplsInSegmentXCIndex</code>
Segment owner	<code>mplsInSegmentOwner</code>
Status of the table row	<code>mplsInSegmentRowStatus</code>
Storage type	<code>mplsInSegmentStorageType</code>

The following MIB object and associated MPLS LSR information from the MPLS in-segment table is not supported:

- `mplsInSegmentTrafficParamPtr`—A pointer to a traffic parameter table entry (set to the default 0.0).

## MPLS In-Segment Performance Table (`mplsInSegmentPerfTable`)

Table 4 lists the MPLS LSR information and associated MIB objects provided by the MPLS in-segment performance table (`mplsInSegmentPerfTable`).

**Table 4** *MPLS In-Segment Performance Table—MPLS LSR Information and Associated MIB Object*

MPLS LSR Information	MIB Object
Number of 32-bit octets received	<code>mplsInSegmentPerfOctets</code>
Number of 64-bit octets received	<code>mplsInSegmentPerfHOctets</code>
Total number of packets received	<code>mplsInSegmentPerfPackets</code>

**Table 4** *MPLS In-Segment Performance Table—MPLS LSR Information and Associated MIB Object (continued)*

MPLS LSR Information	MIB Object
Number of packets with errors	mplsInSdegmentPerfErrors
Time of the last system failure that corresponded to one or more incoming segment discontinuities	mplsInSegmentPerfDiscontinuityTime

The following MIB object and associated MPLS LSR information from the MPLS in-segment performance table is not supported:

- mplsInSegmentPerfDiscards—The number of labeled packets discarded with no errors.

## MPLS Out-Segment Table (mplsOutSegmentTable)

Table 5 lists the MPLS LSR information and associated MIB objects provided by the MPLS out-segment table (mplsOutSegmentTable).

**Table 5** *MPLS Out-Segment Table—MPLS LSR Information and Associated MIB Object*

MPLS LSR Information	MIB Object
Unique index identifier	mplsOutSegmentIndex
Interface index of the outgoing interface	mplsOutSegmentInterface
Indication of whether a top label is pushed onto the outgoing packet's label stack	mplsOutSegmentPushToptLabel
Label to push onto the outgoing packet's label stack (if the mplsOutSegmentPushToptLabel is true)	mplsOutSegmentToptLabel
Pointer to an external table containing the label, if not represented fully in the mplsOutSegmentTopLabel object (set to the default 0.0)	mplsOutSegmentTopLabelPtr
Next-hop Internet address type (unknown [0], ipv4 [1], ipv6 [2])	mplsOutSegmentNextHopAddrType
Internet address of the next hop	mplsOutSegmentNextHopAddr
Segment cross-connect entry association	mplsOutSegmentXCIndex
Segment owner	mplsOutSegmentOwner
Status of the table row	mplsOutSegmentRowStatus
Storage type	mplsOutSegmentStorageType

The following MIB object and associated MPLS LSR information from the8—A pointer to a traffic parameter table entry (set to the default 0.0).

## MPLS Out-Segment Performance Table (mplsOutSegmentPerfTable)

Table 6 lists the MPLS LSR information and associated MIB objects provided by the MPLS out-segment performance table (mplsOutSegmentPerfTable).

**Table 6** *MPLS Out-Segment Performance Table—MPLS LSR Information and Associated MIB Object*

MPLS LSR Information	MIB Object
Number of 32-bit octets sent	mplsOutSegmentPerfOctets
Total number of packets sent	mplsOutSegmentPerfPackets
Number of packets that could not be sent because of errors	mplsOutSegmentPerfErrors
Number of 64-bit octets sent	mplsOutSegmentPerfHOctets
The time of the last system failure that corresponded to one or more outgoing segment discontinuities	mplsOutSegmentPerfDiscontinuityTime

The following MIB object and associated MPLS LSR information from the MPLS out-segment performance table is not supported:

- mplsOutSegmentPerfDiscards—The number of packets discarded with no errors.

## MPLS Cross-Connect Table (mplsXCTable)

Table 7 lists the MPLS LSR information and associated MIB objects provided by the MPLS cross-connect table (mplsXCTable).

**Table 7** *MPLS Cross-Connect Table—MPLS LSR Information and Associated MIB Object*

MPLS LSR Information	MIB Object
Unique index identifier for a group of cross-connect segments	mplsXCIndex
In-segment label index	mplsXCInSegmentIndex
Out-segment index	mplsXCOutSegmentIndex
Label switched path (LSP) to which the cross-connect entry belongs	mplsXCLspId
Index to the MPLS label stack table that identifies the stack of labels to be pushed under the top label	mplsXCLabelStackIndex
Cross-connect owner	mplsXCOwner
Status of table row	mplsXCRowStatus
Storage type	mplsXCStorageType
Administrative status (if up)	mplsXCAdminStatus
Operational status (if up)	mplsXCOperStatus

**Note**

The administrative status and operational status are always up in the Cisco implementation. Otherwise, these status entries do not appear in the table.

## MPLS Label Stack Table (mplsLabelStackTable)

Table 8 lists the MPLS LSR information and associated MIB objects provided by the MPLS label stack table (mplsLabelStackTable).

**Table 8** *MPLS Label Stack Table—MPLS LSR Information and Associated MIB Object*

MPLS LSR Information	MIB Object
Primary index for a stack of labels to be pushed on an outgoing packet	mplsLabelStackIndex
Secondary index identifying one label of the stack	mplsLabelStackLabelIndex
Label to be pushed	mplsLabelStackLabel
Pointer to an external table containing the label, if not represented fully in the mplsLabelStackLabel object	mplsLabelStackLabelPtr
Status of the table row	mplsLabelStackRowStatus
Storage type	mplsLabelStackStorageType

## MPLS In-Segment Map Table (mplsInSegmentMapTable)

Table 9 lists the MPLS LSR information and associated MIB objects provided by the MPLS in-segment map table.

**Table 9** *MPLS In-Segment Map Table—MPLS LSR Information and Associated MIB Object*

MPLS LSR Information	MIB Object
Index containing the same value as the mplsInSegmentInterface in the MPLS in-segment table	mplsInSegmentMapInterface
Index containing the same value as the mplsInSegmentLabel in the MPLS in-segment table	mplsInSegmentMapLabel
Pointer to an external table containing the label, if the label for the in-segment cannot be represented fully in the mplsInSegmentLabel object	mplsInSegmentMapLabelPtrIndex
The mplsInSegmentIndex that corresponds to the mplsInSegmentInterface and mplsInSegmentLabel objects or the mplsInSegmentInterface and mplsInSegmentLabelPtr objects	mplsInSegmentMapIndex

## Information from MPLS-LSR-STD-MIB Scalar Objects

The MPLS-LSR-STD-MIB supports several scalar objects. In the Cisco implementation of the MIB for Cisco IOS Releases 12.2(33)SRB and 12.2(33)SB, the following scalar objects are hard-coded to the value indicated and are read-only objects. This symbol (“ ”) indicates an empty string.

- `mplsInSegmentIndexNext` (“ ”)—The value for the in-segment index when the LSR creates an entry in the MPLS in-segment table. The “ ” indicates that this is not implemented because modifications to this table are not allowed.
- `mplsOutSegmentIndexNext` (“ ”)—The value for the out-segment index when an LSR creates a new entry in the MPLS out-segment table. The “ ” indicates that this is not implemented because modifications to this table are not allowed.
- `mplsXCIndexNext` (“ ”)—The value for the cross-connect index when an LSR creates an entry in the MPLS cross-connect table. The “ ” indicates that no unassigned values are available.
- `mplsMaxLabelStackDepth` (6)—The value for the maximum stack depth.
- `mplsLabelStackIndexNext` (“ ”)—The value for the label stack index when an LSR creates entries in the MPLS label stack table. The “ ” indicates that no unassigned values are available.
- `mplsXCNotificationEnable` (false)—Cross-connect notifications are not sent when this value is false.

The following notifications are not supported:

- `mplsXCUp`
- `mplsXCDown`

## MPLS-LSR-STD-MIB Indexing—Linking Table Elements

In the MPLS cross-connect table, cross-connect entries associate incoming segments with outgoing segments. The following objects index the cross-connect entry:

- Cross-connect index (`mplsXCIndex`)—A unique identifier for a group of cross-connect entries in the cross-connect table.
- In-segment index (`mplsXCInSegmentIndex`)—The value of this object is the same value as for the `mplsInSegmentIndex` in the in-segment table.

The in-segment table (`mplsInSegmentTable`) is indexed by the incoming label. The `mplsInSegmentIndex` is a 4-byte octet string containing the local label.

- Out-segment index (`mplsXCOutSegmentIndex`)—The value of this object is the same value as for the `mplsOutSegmentIndex` in the out-segment table.

The following figure shows the relationship among the indexes of the `mplsInSegmentTable`, the `mplsXCTable`, and the `mplsOutSegmentTable`.

**Figure 2** *MPLS-LSR-STD-MIB Indexing*

The `mplsInSegmentIndex`, `mplsXCIndex`, and `mplsOutSegmentIndex` values are defined as an `MplsIndexType`, which is a variable-length octet string that can be used to specify an interface index, a physical card or device, or an application ID.

**MPLS In-Segment Table Index**

The `mplsInSegmentIndex` is a 4-byte octet string containing the local label.

**MPLS Cross-Connect Table Index**

The `mplsXCIndex` is a variable-length octet string, the size of which depends on the application type that is represented and the amount of information needed to represent the label for that application type. The application type is based on a forwarding path identifier (FPI) type that is supported by the MFI. The Cisco implementation of the MPLS-LSR-STD-MIB for Cisco IOS Release xx.x(x)X supports the following FPI types: LABEL, TE, and IPv4.

Figure 3 shows how the MPLS-LSR-STD-MIB represents the application types for the cross-connect `mplsXCIndex` object.

**Figure 3** MPLS-LSR-STD-MIB Application Type Representation for `mplsXCIndex` Object

**Legend:**

□ = 1 Byte

FPI - refers to the forwarding path identifier type

LABEL (Length = 5 Bytes) (FPI = 0):

<-FPI-><-----Label----->

TE (Length = 5 Bytes) (FPI = 1):

<-FPI-><-----TE id ----->

IPv4 (Length = 6 Bytes) (FPI = 2):

<-FPI-><-----Prefix-----><mask->

230237

**MPLS Out-Segment Table Index**

The `mplsOutSegmentIndex` is a variable-length octet string. The description of this index is identical to that of the `mplsXCIndex` except the `mplsOutSegmentIndex` is two bytes longer in length. The last two bytes in the out-segment index contains the MPLS output information (MOI) list index.

## Interface Configuration Table and Interface MIB Links

The MPLS interface configuration table lists interfaces that support MPLS technology. An LSR creates an entry dynamically in this table for each MPLS-capable interface. An interface becomes MPLS-capable when MPLS is enabled on that interface. A nonzero index for an entry in this table points to the `ifIndex` for the corresponding interface entry in the MPLS-layer in the `ifTable` of the Interfaces Group MIB.

The `ifTable` contains information on each interface in the network. Its definition of an interface includes any sublayers of the internetwork layer of the interface. MPLS interfaces fit into this definition of an interface. Therefore, each MPLS-enabled interface is represented by an entry in the `ifTable`.

The interrelation of entries in the ifTable is defined by the interfaces stack group of the Interfaces Group MIB. [Figure 4](#) shows how the stack table might appear for MPLS interfaces. The underlying layer refers to any interface that is defined for MPLS internetworking, for example, ATM, Frame Relay, or Ethernet.

**Figure 4** Interface Group MIB Stack Table for MPLS Interfaces

MPLS-interface ifType = mpls(166)	51273
Underlying Layer . . .	

**Note**

Tunnel interfaces are included in the MPLS list for the current implementation.

## MPLS-LSR-STD-MIB Structure

MIB structure is represented by a tree hierarchy. Branches along the tree have short text strings and integers to identify them. Text strings describe object names, and integers allow computer software to encode compact representations of the names.

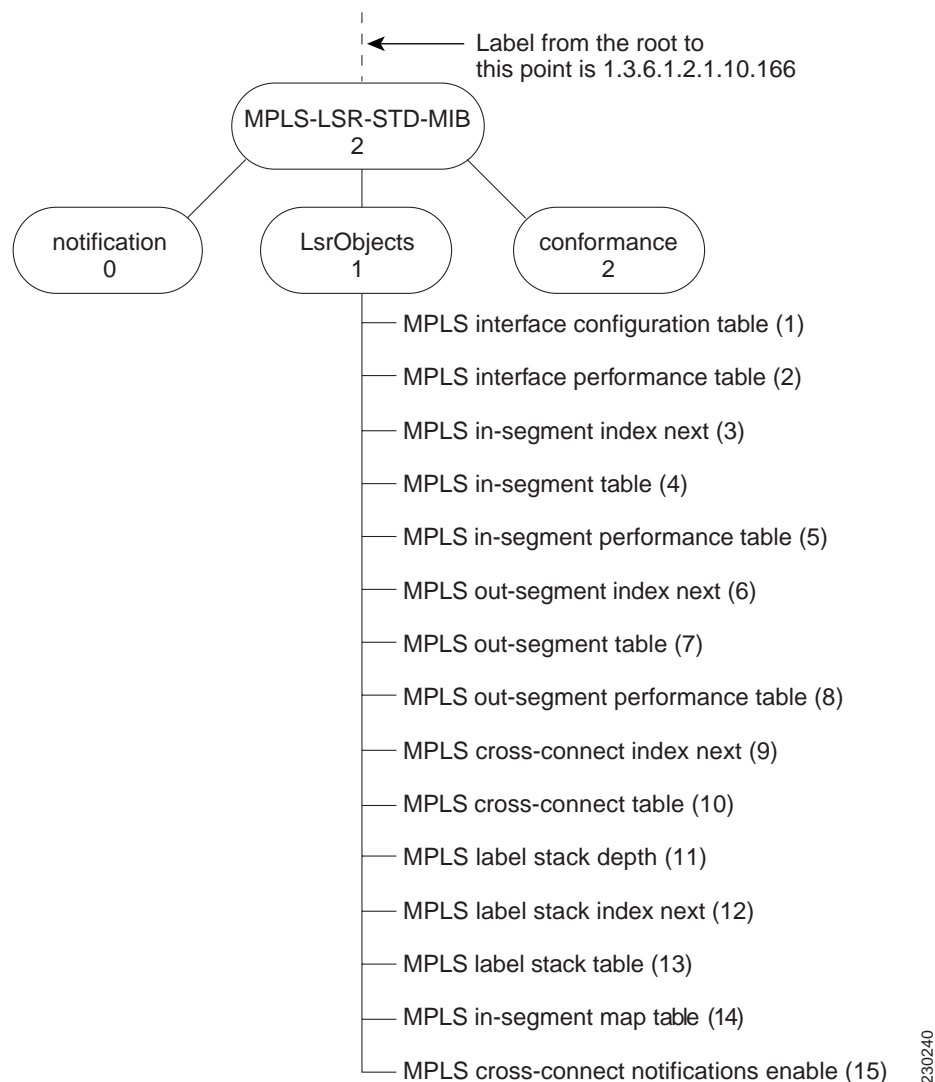

The MPLS-LSR-STD-MIB falls on the branch of the Internet MIB hierarchy represented by the object identifier 1.3.6.1.2.1.10.166. This branch can also be represented by its object name iso.org.dod.internet.mgmt.mib-2.transmission.mplsStdMIB. The MPLS-LSR-STD-MIB is identified by the object name mplsLsrStdMIB, which is denoted by the number 2. Therefore, objects in the MPLS-LSR-MIB can be identified in either of the following ways:

- The object identifier—1.3.6.1.2.1.10.166.2.[MIB-variable]
- The object name—  
iso.org.dod.internet.mgmt.mib-2.transmission.mplsStdMIB.mplsLsrStdMIB.[MIB-variable]

To display a MIB-variable, you enter an SNMP **get** command with an object identifier. Object identifiers are defined by the MPLS-LSR-STD-MIB.

[Figure 5](#) shows the position of the MPLS-LSR-STD-MIB in the Internet MIB hierarchy.

**Figure 5** *MPLS-LSR-STD-MIB in the Internet MIB Hierarchy*

## CLI Commands and the MPLS-LSR-MIB

The MPLS LFIB is the component of the Cisco MPLS subsystem that contains management information for LSRs. You can access this management information by means of either of the following:

- Using the **show mpls forwarding-table** CLI command
- Entering SNMP **get** commands on a network manager

The following examples show how you can gather LSR management information using both methods.

### CLI Command Output

A **show mpls forwarding-table** CLI command allows you to display label forwarding information for a packet on a specific MPLS LSR:

Router# **show mpls forwarding-table**

Local Label	Outgoing Label or VC	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
16	Pop Label	IPv4 VRF[V]	1000	aggregate/vpn1	
17	Pop Label	10.0.0.3/32	0	PO7/1/0	point2point
18	Pop Label	10.30.1.0/16	0	PO7/1/0	point2point
19	17	10.0.0.1/32	0	PO7/1/0	point2point
20	No Label	10.9.0.0/16[V]	0	GE3/1	10.30.2.2
21	No Label	10.0.0.7/32[V]	128856	GE3/1	10.30.2.2

### MPLS-LSR-STD-MIB Output

SNMP commands on MIB objects also allow you to display the label forwarding information for a specific MPLS LSR.

You can do a walk-through of the MIB by running a command such as **getmany -v2c public mplsLsrStdMIB** on a network manager where **getmany** does repeated SNMP **getnext** operations to retrieve the contents of the MPLS-LSR-STD-MIB. Figure 6 shows index information for the **mplsXCOperStatus** MPLS-LSR-STD-MIB object and how to read the information in the MIB output that follows.

**Figure 6** Index Information for the **mplsXCOperStatus** MPLS-LSR-STD-MIB Object

```
mplsXCOperStatus.5.0.0.0.0.4.0.0.0.0.7.0.0.0.0.0.1 = up
mplsXCOperStatus.5.0.0.0.0.1.4.0.0.0.1.1.0 = up
mplsXCOperStatus.5.0.0.0.0.2.4.0.0.0.2.7.0.0.0.0.2.0.1 = up
mplsXCOperStatus.5.0.0.0.0.3.4.0.0.0.3.1.0 = up
mplsXCOperStatus.5.0.0.0.0.16.4.0.0.0.16.7.0.0.0.0.16.0.1 = up
mplsXCOperStatus.5.0.0.0.0.17.4.0.0.0.17.7.0.0.0.0.17.0.1 = up
mplsXCOperStatus.5.0.0.0.0.18.4.0.0.0.18.7.0.0.0.0.18.0.1 = up
mplsXCOperStatus.5.0.0.0.0.19.4.0.0.0.19.7.0.0.0.0.19.0.1 = up
mplsXCOperStatus.5.0.0.0.0.20.4.0.0.0.20.1.0 = up
mplsXCOperStatus.5.0.0.0.0.21.4.0.0.0.21.1.0 = up
mplsXCOperStatus.6.2.10.0.0.3.32.1.0.8.2.10.0.0.3.32.0.1 = up
mplsXCOperStatus.6.2.10.30.0.16.1.0.8.2.30.1.0.0.16.0.1 = up
```

You can continue to scan the output of the **getmany** command for the following MIB objects from the MPLS out-segment table:

- Out-segment's top label objects (**mplsOutSegmentTopLabel**)

```
mplsOutSegmentTopLabel.7.0.0.0.0.0.1 = 3
mplsOutSegmentTopLabel.7.0.0.0.0.2.0.1 = 3
```

```

mplsOutSegmentTopLabel.7.0.0.0.0.16.0.1 = 3
mplsOutSegmentTopLabel.7.0.0.0.0.17.0.1 = 3
mplsOutSegmentTopLabel.7.0.0.0.0.18.0.1 = 3
mplsOutSegmentTopLabel.7.0.0.0.0.19.0.1 = 17

```

For more information on how to read the indexing for MPLS-LSR-STD-MIB objects, see [Figure 2](#) and the “[MPLS-LSR-STD-MIB Indexing—Linking Table Elements](#)” section on page 11.

## VPN Aware LSR MIB

Cisco IOS Releases 12.2(33)SRB and 12.2(33)SB include the VPN Aware LSR MIB feature that enables the MPLS-LSR-STD-MIB to get VPN context information. This feature adds support for different contexts for different MPLS VPNs. Users of the MIB can display per-VPN entries in the MPLS-LSR-STD-MIB tables. The VPN Aware LSR MIB feature does not change the syntax of the MPLS-LSR-STD-MIB. It changes the number and types of entries within the tables.

The MPLS-LSR-STD-MIB can show information about only one context at a time. You can specify either a global context or an MPLS VPN context using an SNMP security name. The security name must match the SNMP community name when an SNMP request is performed on a MIB entry.

## SNMP Contexts

SNMP contexts provide VPN users with a secure way of accessing MIB data. When a VPN is associated with a context, that VPN's specific MIB data exists in that context. Associating a VPN with a context enables service providers to manage networks with multiple VPNs. Creating and associating a context with a VPN enables a provider to prevent the users of one VPN from accessing information about users of other VPNs on the same networking device.

VPN-aware SNMP requires that SNMP manager and agent entities operating in a VPN environment agree on mapping between the SNMP security name and the VPN name. This mapping is created by you using different contexts for the SNMP data of different VPNs, which is accomplished through the configuration of the SNMP View-based Access Control Model MIB (SNMP-VACM-MIB). The SNMP-VACM-MIB is configured with views so that a user on a VPN with a security name is allowed access to the restricted object space within the context of only that VPN.

SNMP request messages undergo three phases of security and access control before a response message is sent back with the object values within a VPN context:

- The first security phase is authentication of the username. During this phase, the user is authorized for SNMP access.
- The second phase is access control. During this phase, the user is authorized for SNMP access to the group objects in the requested SNMP context.

- In the third phase, the user can access a particular instance of a table entry. With this third phase, complete retrieval can be based on the SNMP context name.

IP access lists can be configured and associated with SNMP community strings. This feature enables you to configure an association between VRF instances and SNMP community strings. When a VRF instance is associated with an SNMP community string, SNMP processes requests coming in for a particular community string only if they are received from the configured VRF. If the community string contained in the incoming packet has no VRF associated with it, it is processed only if it came in through a non-VRF interface.

## Major Differences Between the MPLS-LSR-STD-MIB and the MPLS-LSR-MIB

The MPLS-LSR-STD-MIB based on RFC 3813 provides the same basic functionality as the MPLS-LSR-MIB based on Version 05 of the IETF MPLS-LSR-MIB. They both provides an interface for managing label switching through the use of SNMP.

After the implementation of the MPLS-LSR-STD-MIB (RFC 3813) in Cisco IOS Releases 12.2(33)SRB and 12.2(33)SRB, the MPLS-LSR-MIB will exist for a period of time before support is completely removed. This gives you the chance to migrate to the MPLS-LSR-STD-MIB. Both MIBs can coexist in the same image because the MPLS-LSR-STD-MIB and the MPLS-LSR-MIB have different root object identifiers (OIDs).

The following sections contain information about the major differences between the MPLS-LSR-STD-MIB and the MPLS-LSR-MIB:

- [MPLS-LSR-MIB and the MPLS-LSR-STD-MIB Scalar Object Differences, page 17](#)
- [MPLS-LSR-MIB and the MPLS-LSR-STD-MIB Table Object Differences, page 18](#)
- [MPLS-LSR-MIB and MPLS-LSR-STD-MIB Notification Differences, page 22](#)
- [MPLS-LSR-MIB and MPLS-LSR-STD-MIB Indexing Differences, page 22](#)

### MPLS-LSR-MIB and the MPLS-LSR-STD-MIB Scalar Object Differences

Table 10 shows the major difference between the MPLS-LSR-MIB objects and the MPLS-LSR-STD-MIB objects for each scalar object.

**Table 10** *Scalar Objects: MPLS-LSR-MIB and MPLS-LSR-STD-MIB Object Differences*

MPLS-LSR-MIB Object	MPLS-LSR-STD-MIB Object	Difference
mplsTrafficParamIndexNext	—	Object deleted.
mplsInSegmentTrapEnable	—	Object deleted.
mplsOutSegmentTrapEnable	—	Object deleted.
—	mplsInSegmentIndexNext	New object.
mplsOutSegmentIndexNext	mplsOutSegmentIndexNext	Syntax change. Formerly integer 32, now is MplsIndexType, which is an octet string.
mplsXCIndexNext	mplsXCIndexNext	Syntax change. Formerly integer 32, now is MplsIndexType, which is an octet string.

## MPLS-LSR-MIB and the MPLS-LSR-STD-MIB Table Object Differences

The following tables show the major differences between the MPLS-LSR-MIB and the MPLS-LSR-STD-MIB for each table.

### MPLS Interface Table (mplsInterfaceTable) Differences

Table 11 shows the difference between MPLS-LSR-MIB and MPLS-LSR-STD-MIB objects for the MPLS interface table (mplsInterfaceTable), formerly called the MPLS interface configuration table (mplsInterfaceConfTable).

**Table 11** *MPLS Interface Table: MPLS-LSR-MIB and MPLS-LSR-STD-MIB Object Differences*

MPLS-LSR-MIB Object	MPLS-LSR-STD-MIB Object	Difference
mplsInterfaceTotalBuffer	—	Object deleted.
mplsInterfaceAvailableBuffer	—	Object deleted.
mplsInterfaceConfStorageType	—	Object deleted.
mplsInterfaceConfIndex	mplsInterfaceIndex	Object name changed.

### MPLS Interface Performance Table (mplsInterfacePerfTable) Differences

Table 12 shows the major difference between MPLS-LSR-MIB and MPLS-LSR-STD-MIB objects for the MPLS interface performance table (mplsInterfacePerfTable).

**Table 12** *MPLS Interface Performance Table: MPLS-LSR-MIB and MPLS-LSR-STD-MIB Object Differences*

MPLS-LSR-MIB Object	MPLS-LSR-STD-MIB Object	Difference
mplsInterfaceInPackets	—	Object deleted.
mplsInterfaceInDiscards	—	Object deleted.
mplsInterfaceInLabelsUsed	mplsInterfacePerfInLabelsInUse	Object name changed.
mplsInterfaceFailedLabelLookup	mplsInterfacePerfInLabelLookupFailures	Object name changed.
mplsInterfaceOutPackets	—	Object deleted.
mplsInterfaceOutDiscard	—	Object deleted.
mplsInterfaceOutLabelsUsed	mplsInterfacePerfOutLabelsInUse	Object name changed.
mplsInterfaceOutFragments	mplsInterfacePerfOutFragmentedPkts	Object name changed.

### MPLS In-Segment Table (mplsInSegmentTable) Differences

Table 13 shows the major difference between MPLS-LSR-MIB and MPLS-LSR-STD-MIB objects for the MPLS in-segment table (mplsInSegmentTable).

**Table 13** *MPLS In-Segment Table: MPLS-LSR-MIB and MPLS-LSR-STD-MIB Object Differences*

MPLS-LSR-MIB Object	MPLS-LSR-STD-MIB Object	Difference
mplsInSegmentAdminStatus	—	Object deleted.
mplsInSegmentOperStatus	—	Object deleted.

**Table 13** *MPLS In-Segment Table: MPLS-LSR-MIB and MPLS-LSR-STD-MIB Object Differences*

MPLS-LSR-MIB Object	MPLS-LSR-STD-MIB Object	Difference
mplsInSegmentIfIndex	mplsInSegmentInterface	Object name changed. Formerly not accessible (was used as index into the table). Now it is an object in the table.
—	mplsInSegmentIndex	New object. Used as an index into the table.
—	mplsInSegmentLabelPtr	New object.
mplsInSegmentLabel	mplsInSegmentLabel	Formerly not accessible (was used as index into the table). Now it is an object in the table.
mplsInSegmentXCIndex	mplsInSegmentXCIndex	Syntax change. Formerly Integer32, now MplsIndexType, which is an Octet String.

MPLS In-Segment Performance Table (mplsInSegmentPerfTable) Differences

Table 14 shows the major difference between MPLS-LSR-MIB and MPLS-LSR-STD-MIB objects for the MPLS in-segment performance table (mplsInSegmentPerfTable).

**Table 14** *MPLS In-Segment Performance Table: MPLS-LSR-MIB and MPLS-LSR-STD-MIB Object Differences*

MPLS-LSR-MIB Object	MPLS-LSR-STD-MIB Object	Difference
mplsInSegmentOctets	mplsInSegmentPerfOctets	Object name changed.
mplsInSegmentPackets	mplsInSegmentPerfPackets	Object name changed.
mplsInSegmentErrors	mplsInSegmentPerfErrors	Object name changed.
mplsInSegmentDiscards	mplsInSegmentPerfDiscards	Object name changed.
mplsInSegmentHCOctets	mplsInSegmentPerfHCOctets	Object name changed.

MPLS Out-Segment Table (mplsOutSegmentTable) Differences

Table 15 shows the major difference between MPLS-LSR-MIB and MPLS-LSR-STD-MIB objects for the MPLS out-segment table (mplsOutSegmentTable).

**Table 15** *MPLS Out-Segment Table: MPLS-LSR-MIB and MPLS-LSR-STD-MIB Object Differences*

MPLS-LSR-MIB Object	MPLS-LSR-STD-MIB Object	Difference
mplsOutSegmentAdminStatus	—	Object deleted.
mplsOutSegmentOperStatus	—	Object deleted.
mplsOutSegmentIndex	mplsOutSegmentIndex	Syntax changed. Formerly Integer32, now MplsIndexType, which is an octet string.
mplsOutSegmentIfIndex	mplsOutSegmentInterface	Object name changed.

**Table 15** *MPLS Out-Segment Table: MPLS-LSR-MIB and MPLS-LSR-STD-MIB Object Differences (continued)*

MPLS-LSR-MIB Object	MPLS-LSR-STD-MIB Object	Difference
—	mplsOutSgementTopLabelPtr	New object.
mplsOutSegmentNextHopIpAddrType	mplsOutSegmentNextHopAddrType	Object name changed.
mplsOutSegmentNextHopIpv4Addr mplsOutSegmentNextHopIpv6Addr	mplsOutSegmentNextHopAddr	Formerly two objects, now one object with the syntax of InetAddress.
mplsOutSegmentXCIndex	mplsOutSegmentXCIndex	Syntax changed. Formerly Integer32, now MplsIndexType, which is an octet string.

MPLS Out-Segment Performance Table (mplsOutSegmentPerfTable) Differences

Table 16 shows the major difference between MPLS-LSR-MIB and MPLS-LSR-STD-MIB objects for the MPLS out-segment performance table (mplsOutSegmentPerfTable).

**Table 16** *MPLS Out-Segment Performance Table: MPLS-LSR-MIB and MPLS-LSR-STD-MIB Object Differences*

MPLS-LSR-MIB Object	MPLS-LSR-STD-MIB Object	Difference
mplsOutSegmentOctets	mplsOutSegmentPerfOctets	Object name changed.
mplsOutSegmentPackets	mplsOutSegmentPerfPackets	Object name changed.
mplsOutSegmentErrors	mplsOutSegmentPerfErrors	Object name changed.
mplsOutSegmentDiscards	mplsOutSegmentPerfDiscards	Object name changed.
mplsOutSegmentHCOctets	mplsOutSegmentPerfHCOctets	Object name changed.

MPLS Cross-Connect Table (mplsXCTable) Differences

Table 17 shows the major difference between MPLS-LSR-MIB and MPLS-LSR-STD-MIB objects for the MPLS cross-connect table (mplsXCTable).

**Table 17** *MPLS Cross-Connect Table: MPLS-LSR-MIB and MPLS-LSR-STD-MIB Object Differences*

MPLS-LSR-MIB Object	MPLS-LSR-STD-MIB Object	Difference
mplsXCIsPersistent	—	Object deleted.
mplsXCIndex	mplsXCIndex	Syntax changed. Formerly Integer32, now MplsIndexType, which is an octet string.
—	mplsXCInSegmentIndex	New object, an index into the mplsXCTable.

**Table 17** *MPLS Cross-Connect Table: MPLS-LSR-MIB and MPLS-LSR-STD-MIB Object Differences (continued)*

MPLS-LSR-MIB Object	MPLS-LSR-STD-MIB Object	Difference
—	mplsXCOutSegmentIndex	New object, an index into the mplsXCTable.
mplsXCLabelStackIndex	mplsXCLabelStackIndex	Syntax changed. Formerly Integer32, now MplsIndexType, which is an octet string.

#### MPLS Label Stack Table (mplsLabelStackTable) Differences

Table 18 shows the major difference between MPLS-LSR-MIB and MPLS-LSR-STD-MIB objects for the MPLS label stack table (mplsLabelStackTable).

**Table 18** *MPLS Label Stack Table: MPLS-LSR-MIB and MPLS-LSR-STD-MIB Object Differences*

MPLS-LSR-MIB Object	MPLS-LSR-STD-MIB Object	Difference
mplsLabelStackIndex	mplsLabelStackIndex	Syntax changed. Formerly Integer32, now MplsIndexType, which is an octet string.
—	mplsLabelStackLabelPtr	New object.

#### MPLS In-Segment Map Table (mplsInSegmentMapTable) Differences

Table 19 shows the major difference between MPLS-LSR-MIB and MPLS-LSR-STD-MIB objects for the MPLS in-segment map table (mplsInSegmentMapTable). The MPLS in-segment map table is a new table introduced with the MPLS-LSR-STD-MIB.

**Table 19** *MPLS In-Segment Map Table: MPLS-LSR-MIB and MPLS-LSR-STD-MIB Object Differences*

MPLS-LSR-MIB Object	MPLS-LSR-STD-MIB Object	Difference
—	mplsInSegmentMapInterface	New object.
—	mplsInSegmentMapLabel	New object.
—	mplsInSegmentMapLabelPtrIndex	New object.
—	mplsInSegmentMapIndex	New object.

#### MPLS Traffic Parameters Table (mplsTrafficParamTable) Differences

The MPLS traffic parameters table was not supported in Cisco IOS implementation of MPLS-LSR-MIB. It has been removed from the MPLS-LSR-STD-MIB.

## MPLS-LSR-MIB and MPLS-LSR-STD-MIB Notification Differences

Table 20 shows the difference between MPLS-LSR-MIB and MPLS-LSR-STD-MIB notifications.

**Table 20** *MPLS-LSR-MIB and MPLS-LSR-STD-MIB Notification Differences*

MPLS-LSR-MIB Notification	MPLS-LSR-STD-MIB Notification	Difference
mplsInSegmentUp	—	Object deleted.
mplsInSegmentDown	—	Object deleted.
mplsOutSegmentUp	—	Object deleted.
mplsOutSegmentDown	—	Object deleted.
mplsXCUp	mplsXCUp	Returned objects changed.
mplsXCDown	mplsXCDown	Returned objects changed.

The following notifications were not supported for MPLS-LSR-MIB and are not supported for the MPLS-LSR-STD-MIB in Cisco IOS Releases 12.2(33)SRB and 12.3(33)SB:

- mplsXCUp
- mplsXCDown

### Note

For scalability reasons, none of the notifications were implemented in the Cisco IOS software from the MPLS-LSR-MIB. For the same reason, the notifications from the MPLS-LSR-STD-MIB are not implemented in Cisco IOS Releases 12.2(33)SRB and 12.2(33)SB.

## MPLS-LSR-MIB and MPLS-LSR-STD-MIB Indexing Differences

One of the major differences between the MPLS-LSR-MIB and the MPLS-LSR-STD-MIB is the indexing used for the three main tables that manage labels for the MPLS LSR in the MPLS-LSR-MIB and the MPLS-LSR-STD-MIB: the MPLS in-segment table (mplsInSegmentTable), the MPLS cross-connect table (mplsXCTable), and the MPLS out-segment table (mplsOutSegmentTable).

All entries in each table are uniquely identified by one or more indexes. The indexes determine the order in which entries are displayed in a MIB walk.

Table 21 compares indexing characteristics of the draft Version 05 MPLS-LSR-MIB implementation with indexing characteristics of the MPLS-LSR-STD-MIB (RFC 3813) implementation.

**Table 21** *Comparison of Indexing Characteristics of the MPLS-LSR-MIB and the MPLS-LSR-STD-MIB*

Object Compared	MPLS-LSR-MIB Draft Version 05 Implementation	MPLS-LSR-STD-MIB RFC 3813 Implementation
Index type definition	A 32-bit integer type is used to define the indexing into the tables that manage label switching in the MPLS LSR.	An octet string is used to define the indexing into the tables that manage label switching in the MPLS LSR.
MPLS in-segment table index	The MPLS in-segment table is indexed by the SNMP interface index (ifIndex) and the incoming label (mplsInSegmentLabel).	The MPLS in-segment table is indexed by the mplsInSegmentIndex. The mplsInSegmentIndex is a 4-byte octet string representing the local label (mplsInSegmentLabel).

**Table 21**      *Comparison of Indexing Characteristics of the MPLS-LSR-MIB and the MPLS-LSR-STD-MIB (continued)*

Object Compared	MPLS-LSR-MIB Draft Version 05 Implementation	MPLS-LSR-STD-MIB RFC 3813 Implementation
MPLS cross-connect table index	The MPLS cross-connect table indexing has four indexes: mplsXCIndex, ifIndex, mplsInSegmentLabel, and mplsOutSegmentIndex. The SNMP interface index and incoming label are identical to the in-segment table. The mplsXCIndex and mplsOutSegmentIndex values are defined as arbitrary unsigned 32-bit quantities.	The MPLS cross-connect table indexing has three indexes: mplsXCIndex, mplsXCInSegmentIndex, and mplsXCOutSegmentIndex. The mplsXCInSegmentIndex is the same as the mplsInSegmentIndex in the in-segment table. The mplsXCOutSegmentIndex is the same as the mplsOutSegmentIndex in the out-segment table.
MPLS out-segment table index	The MPLS out-segment table is indexed by the mplsOutSegmentIndex, which corresponds to the mplsOutSegmentIndex used in the MPLS cross-connect table.	The MPLS out-segment table is indexed by the mplsOutSegmentIndex, which corresponds to the mplsXCIndex with the addition of two bytes that contain an MOI list index.

For more information about the relationship between the indexes for the MPLS-LSR-STD-MIB implementation, see the [“MPLS-LSR-STD-MIB Indexing—Linking Table Elements”](#) section on page 11.

## How to Configure SNMP for the MPLS EM—MPLS LSR MIB - RFC 3813

This section contains tasks to configure the MPLS EM—MPLS LSR MIB (RFC 3813) feature.

The SNMP agent for the MPLS-LSR-STD-MIB is disabled by default and must be enabled for you to use SNMP to monitor and manage the MPLS LSRs on your network. Perform these task to enable the SNMP Agent and verify that it is enabled:

- [Enabling the SNMP Agent, page 24](#) (required)
- [Verifying That the SNMP Agent Is Enabled, page 26](#) (optional)

Perform the following task to configure a VPN context for the MPLS-LSR-STD-MIB:

- [Configuring a VPN-Aware LSR MIB, page 26](#) (optional)

## Prerequisites

The MPLS-LSR-STD-MIB requires the following:

- SNMP installed and enabled on the LSR
- MPLS enabled on the LSR
- MFI

## Enabling the SNMP Agent

To enable the SNMP agent, perform the following task.

The SNMP agent for the MPLS-LSR-STD-MIB is disabled by default.

### SUMMARY STEPS

1. **enable**
2. `show running-config`
3. **configure terminal**
4. **snmp-server community** *string* [**view** *view-name*] [**ro** | **rw**] [**ipv6 nacl**] [*access-list-number*]
5. **end**
6. `save running-config startup-config`

### DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
	<b>Example:</b> <code>Router&gt; enable</code>	
Step 2	<code>show running-config</code>	Displays the running configuration of the router to determine if an SNMP agent is already running on the device.
	<b>Example:</b> <code>Router# show running-config</code>	If no SNMP information is displayed, continue with the next step.  If any SNMP information is displayed, you can modify the information or change it as desired.
Step 3	<code>configure terminal</code>	Enters global configuration mode.
	<b>Example:</b> <code>Router# configure terminal</code>	

	Command or Action	Purpose
Step 4	<pre>snmp-server community string [view view-name] [ro   rw] [ipv6 nacl] [access-list-number]</pre> <p><b>Example:</b></p> <pre>Router(config)# snmp-server community public ro</pre>	<p>Sets up the community access string to permit access to SNMP.</p> <ul style="list-style-type: none"> <li>The <i>string</i> argument is a community string that consists of from 1 to 32 alphanumeric characters and functions much like a password, permitting access to the SNMP protocol. Blank spaces are not permitted in the community string.</li> <li>The <b>view</b> <i>view-name</i> keyword-argument pair is the name of a previously defined view. The view defines the objects available to the SNMP community.</li> <li>The <b>ro</b> keyword specifies read-only access. Authorized management stations can retrieve only MIB objects.</li> <li>The <b>rw</b> keyword specifies read-write access. Authorized management stations can retrieve and modify MIB objects.</li> <li>The <b>ipv6 nacl</b> keywords specify the IPv6 named access list.</li> <li>The <i>access-list-number</i> argument is an integer from 1 to 99. It specifies a standard access list of IP addresses or a string (not to exceed 64 characters) that is the name of a standard access list of IP addresses allowed access to the SNMP agent.</li> </ul> <p>Alternatively, an integer from 1300 to 1999 that specifies a list of IP addresses in the expanded range of standard access list numbers. Devices at these addresses are allowed to use the community string to gain access to the SNMP agent.</p>
Step 5	<pre>end</pre> <p><b>Example:</b></p> <pre>Router(config)# end</pre>	Exits to privileged EXEC mode.
Step 6	<pre>save running-config startup-config</pre> <p><b>Example:</b></p> <pre>Router# save running-config startup-config</pre>	Saves the modified SNMP configuration into NVRAM of the router, permanently saving the SNMP settings.

## Verifying That the SNMP Agent Is Enabled

To verify that the SNMP agent is enabled, perform the following task.

### SUMMARY STEPS

1. **telnet** *device-ip-address*
2. **enable**
3. **show running-config**
4. **exit**

### DETAILED STEPS

---

**Step 1** **telnet** *device-ip-address*

Use this command to access the router through a Telnet session. For example:

```
Prompt> telnet 10.15.230.20
```

where 10.15.20.20 represents the IP address of the target device.

**Step 2** **enable**

Use this command to enable privileged EXEC mode. Enter your password, if prompted. For example:

```
Router> enable
Router#
```

**Step 3** **show running-config**

Use this command to display the running configuration. Look for SNMP information. For example:

```
Router# show running-config
.
.
.
snmp-server community public RO
```

If you see any “snmp-server” statements, SNMP has been enabled on the router.

**Step 4** **exit**

Use this command to exit privileged EXEC mode. For example:

```
Router# exit
Router>
```

---

## Configuring a VPN-Aware LSR MIB

To configure a VPN-aware LSR MIB, perform the following tasks:

- [Configuring SNMP Support for a VPN, page 27](#) (required)
- [Configuring an SNMP Context for a VPN, page 28](#) (required)
- [Configuring a VPN-Aware SNMP Context for SNMPv1 or SNMPv2, page 30](#) (required)

## Configuring SNMP Support for a VPN

To configure SNMP support for a VPN (or a remote VPN), perform the following task. SNMP support for VPNs allows users of the MPLS-LSR-STD-MIB to display per-VPN entries in the MPLS-LSR-STD-MIB tables.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server engineID remote** {*ipv4-address* | *ipv6-address*} [**udp-port** *udp-port-number*] [**vrf** *vrf-name*] *engineid-string*
4. **end**

### DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>snmp-server engineID remote</b> { <i>ipv4-address</i>   <i>ipv6-address</i> } [ <b>udp-port</b> <i>udp-port-number</i> ] [ <b>vrf</b> <i>vrf-name</i> ] <i>engineid-string</i>  <b>Example:</b> Router(config)# snmp-server engineID remote 172.16.20.3 vrf customer1 80000009030000B064EFE100	Specifies the SNMP engine ID of a remote SNMP device. <ul style="list-style-type: none"> <li>• The <i>ipv4-address</i> argument is the IPv4 address of the device that contains the remote copy of SNMP.</li> <li>• The <i>ipv6-address</i> argument is the IPv6 address of the device that contains the remote copy of SNMP.</li> <li>• The <b>udp-port</b> keyword specifies a User Datagram Protocol (UDP) port of the host to use.</li> <li>• The <i>udp-port-number</i> argument is the socket number on the remote device that contains the remote copy of SNMP. The default is 161.</li> <li>• The <b>vrf</b> keyword specifies an instance of a routing table.</li> <li>• The <i>vrf-name</i> argument is the name of the VRF table to use for storing data.</li> <li>• The <i>engineid-string</i> is a string of a maximum of 24 characters that identifies the engine ID.</li> </ul>
Step 4	<b>end</b>  <b>Example:</b> Router(config)# end	Exits to privileged EXEC mode.

## What to Do Next

Proceed to the [““Configuring an SNMP Context for a VPN” section on page 28.](#)

## Configuring an SNMP Context for a VPN

To configure an SNMP context for a VPN, perform the following task. This sets up a unique SNMP context for a VPN that allows you to access the per-VPN entries in the VRF table.

### SNMP Context

SNMP contexts provide VPN users with a secure way of accessing MIB data. When a VPN is associated with a context, that VPN's specific MIB data exists in that context. Associating a VPN with a context enables service providers to manage networks with multiple VPNs. Creating and associating a context with a VPN enables a provider to prevent the users of one VPN from accessing information about users of other VPNs on the same networking device.

### VPN Route Distinguishers

A route distinguisher (RD) creates routing and forwarding tables for a VPN. Cisco IOS software adds the RD to the beginning of the customer's IPv4 prefixes to change them into globally unique VPN-IPv4 prefixes.

Either the RD is an autonomous system number (ASN)-relative RD, in which case it is composed of an autonomous system number and an arbitrary number, or it is an IP-address-relative RD, in which case it is composed of an IP address and an arbitrary number. You can enter an RD in either of these formats:

- 16-bit ASN: your 32-bit number, for example, 101:3.
- 32-bit IP address: your 16-bit number, for example, 192.168.122.15:1.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server context** *context-name*
4. **ip vrf** *vrf-name*
5. **rd** *route-distinguisher*
6. **context** *context-name*
7. **route-target** {**import** | **export** | **both**} *route-target-ext-community*
8. **end**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>snmp-server context context-name</b>  <b>Example:</b> Router(config)# snmp-server context context-vpn1	Creates an SNMP context. <ul style="list-style-type: none"> <li>The <i>context-name</i> argument is the name of the SNMP context being created.</li> </ul>
Step 4	<b>ip vrf vrf-name</b>  <b>Example:</b> Router(config)# ip vrf customer1	Configures a VRF table and enters VRF configuration mode. <ul style="list-style-type: none"> <li>The <i>vrf-name</i> argument is the name assigned to a VRF.</li> </ul>
Step 5	<b>rd route-distinguisher</b>  <b>Example:</b> Router(config-vrf)# rd 100:1	Creates routing and forwarding tables for a VRF. <ul style="list-style-type: none"> <li>The <i>route-distinguisher</i> argument specifies to add an 8-byte value to an IPv4 prefix to create a VPN IPv4 prefix.</li> </ul>
Step 6	<b>context context-name</b>  <b>Example:</b> Router(config-vrf)# context context-vpn1	Associates an SNMP context with a particular VRF. <ul style="list-style-type: none"> <li>The <i>context-name</i> argument is the name of the SNMP VPN context, up to 32 characters.</li> </ul>
Step 7	<b>route-target {import   export   both}</b> <b>route-target-ext-community</b>  <b>Example:</b> Router(config-vrf)# route-target export 100:1	(Optional) Creates a route-target extended community for a VRF. <ul style="list-style-type: none"> <li>The <b>import</b> keyword specifies to import routing information from the target VPN extended community.</li> <li>The <b>export</b> keyword specifies to export routing information to the target VPN extended community.</li> <li>The <b>both</b> keyword specifies to import both import and export routing information to the target VPN extended community.</li> <li>The <i>route-target-ext-community</i> argument adds the route-target extended community attributes to the VRF's list of import, export, or both (import and export) route-target extended communities.</li> </ul>
Step 8	<b>end</b>  <b>Example:</b> Router(config-vrf)# end	Exits to privileged EXEC mode.

## What to Do Next

Proceed to the [“Configuring a VPN-Aware SNMP Context for SNMPv1 or SNMPv2”](#) section on page 30.

## Configuring a VPN-Aware SNMP Context for SNMPv1 or SNMPv2

To configure a VPN-aware SNMP context for SNMPv1 or SNMPv2, perform the following task. This allows you to access per-VPN entries in the MPLS-LSR-STD-MIB tables using SNMPv1 or SNMPv2.

### SNMPv1 or SNMPv2 Security

SNMPv1 and SNMPv2 are not as secure as SNMPv3. SNMP Versions 1 and 2 use plain text communities and do not perform the authentication or security checks that SNMP Version 3 performs.

To configure the VPN Aware LSR MIB feature when using SNMP Version 1 or SNMP Version 2, you need to associate a community name with a VPN. This association causes SNMP to process requests coming in for a particular community string only if they come in from the configured VRF. If the community string contained in the incoming packet does not have an associated VRF, the packet is processed only if it came in through a non-VRF interface. This process prevents users outside the VPN from using a clear text community string to query the VPN data. However, this is not as secure as using SNMPv3.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server user** *username group-name* [**remote host** [**udp-port port**]] {**v1** | **v2c** | **v3** [**encrypted**] [**auth** {**md5** | **sha**} *auth-password*]} [**access access-list**]
4. **snmp-server group** *group-name* {**v1** | **v2c** | **v3** {**auth** | **noauth** | **priv**}} [**context context-name**] [**read readview**] [**write writeview**] [**notify notifyview**] [**access access-list**]
5. **snmp-server view** *view-name oid-tree* {**included** | **excluded**}
6. **snmp mib community-map** *community-name* [**context context-name**] [**engineid engine-id**] [**security-name security-name**] **target-list** *vpn-list-name*
7. **snmp mib target list** *vpn-list-name* {**vrf vrf-name** | **host ip-address**}
8. **end**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>enable</code>  <b>Example:</b> <code>Router&gt; enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>
Step 2	<code>configure terminal</code>  <b>Example:</b> <code>Router# configure terminal</code>	Enters global configuration mode.

Command or Action	Purpose
<p><b>Step 3</b></p> <pre>snmp-server user username group-name [remote host [udp-port port]] {v1   v2c   v3 [encrypted] [auth {md5   sha} auth-password]} [access access-list]</pre> <p><b>Example:</b></p> <pre>Router(config)# snmp-server user vrfcomm-vpn1 group-vpn1 v2c</pre>	<p>Configures a new user to an SNMP group.</p> <ul style="list-style-type: none"> <li>• The <i>username</i> argument is the name of the user on the host that connects to the agent.</li> <li>• The <i>group-name</i> argument is the name of the group to which the user belongs.</li> <li>• The <b>remote</b> <i>host</i> keyword and argument specify a remote SNMP entity to which the user belongs, and the hostname or IPv6 address or IPv4 IP address of that entity. If both an IPv6 address and IPv4 IP address are being specified, the IPv6 host must be listed first.</li> <li>• The <b>udp-port</b> <i>port</i> keyword and argument specify the UDP port number of the remote host. The default is UDP port 162.</li> <li>• The <b>vi</b> keyword specifies that SNMPv1 should be used.</li> <li>• The <b>v2c</b> keyword specifies that SNMPv2c should be used.</li> <li>• The <b>v3</b> keyword specifies that the SNMPv3 security model should be used. Allows the use of the <b>encrypted</b> and or <b>auth</b> keywords.</li> <li>• The <b>encrypted</b> keyword specifies whether the password appears in encrypted format (a series of digits, masking the true characters of the string).</li> <li>• The <b>auth</b> keyword specifies which authentication level should be used.</li> <li>• The <b>md5</b> keyword is the HMAC-MD5-96 authentication level.</li> <li>• The <b>sha</b> keyword is the HMAC-SHA-96 authentication level.</li> <li>• The <i>auth-password</i> argument is a string (not to exceed 64 characters) that enables the agent to receive packets from the host. The minimum length for a password is one character. The recommended length of a password is at least eight characters, and should include both letters and numbers.</li> <li>• The <b>access</b> <i>access-list</i> keyword and argument specify an access list to be associated with this SNMP user.</li> </ul>

	Command or Action	Purpose
<p><b>Step 4</b></p>	<pre>snmp-server group group-name {v1   v2c   v3 {auth   noauth   priv}} [context context-name] [read readview] [write writeview] [notify notifyview] [access access-list]</pre> <p><b>Example:</b></p> <pre>Router(config)# snmp-server group group-vpn1 v2c context context-vpn1 read view-vpn1 write view-vpn1 notify *tv.00000000.00040000.00000000.0 access context-vpn1</pre>	<p>Configures a new SNMP group or a table that maps SNMP users to SNMP views.</p> <ul style="list-style-type: none"> <li>• The <i>group-name</i> argument is the name of the group.</li> <li>• The <b>vi</b> keyword specifies that SNMPv1 should be used for the group.</li> <li>• The <b>v2c</b> keyword specifies that SNMPv2c should be used for the group. The SNMPv2c security model allows for the transmission of informs, and supports 64-character strings (instead of 32-character strings).</li> <li>• The <b>v3</b> keyword specifies that the SNMPv3 should be used for the group. SMNPv3 is the most secure of the supported security models, because it allows you to explicitly configure the authentication characteristics.</li> <li>• The <b>auth</b> keyword specifies authentication of a packet without encrypting it.</li> <li>• The <b>noauth</b> keyword specifies no authentication of a packet.</li> <li>• The <b>priv</b> keyword specifies authentication of a packet with encryption.</li> <li>• The <b>context</b> <i>context-name</i> keyword and argument associate the specified SNMP group with a configured SNMP context.</li> <li>• The <b>read</b> <i>readview</i> keyword and argument specify a read view for the SNMP group. The <i>readview</i> argument represents a string (not to exceed 64 characters) that is the name of the view that enables you to display only the contents of the agent.</li> <li>• The <b>write</b> <i>writeview</i> keyword and argument specify a write view for the SNMP group. The <i>writeview</i> argument represents a string (not to exceed 64 characters) that is the name of the view that enables you to enter data and configure the contents of the agent.</li> <li>• The <b>notify</b> <i>notifyview</i> keyword and argument specify a notify view for the SNMP group. The <i>writeview</i> argument represents a string (not to exceed 64 characters) that is the name of the view that enables you to specify a notify, inform, or trap.</li> <li>• The <b>access</b> <i>access-list</i> keyword and argument specify a standard access list (a standard ACL) to associate with the group.</li> </ul>

	Command or Action	Purpose
Step 5	<p><b>snmp-server view</b> <i>view-name oid-tree</i> {<b>included</b>   <b>excluded</b>}</p> <p><b>Example:</b> Router(config)# snmp-server view view-vpn1 iso included</p>	<p>Creates or updates a view entry.</p> <ul style="list-style-type: none"> <li>The <i>view-name</i> argument is the label for the view record that you are updating or creating. The name is used to reference the record.</li> <li>The <i>oid-tree</i> argument is the object identifier of the ASN.1 subtree to be included or excluded from the view. To identify the subtree, specify a text string consisting of numbers, such as 1.3.6.2.4, or a word, such as system. Replace a single subidentifier with the asterisk (*) wildcard to specify a subtree family; for example 1.3.*.4.</li> <li>The <b>included</b> keyword configures the OID (and subtree OIDs) specified in the <i>oid-tree</i> argument to be included in the SNMP view.</li> <li>The <b>excluded</b> keyword configures the OID (and subtree OIDs) specified in the <i>oid-tree</i> argument to be explicitly excluded from the SNMP view.</li> </ul>
Step 6	<p><b>snmp mib community-map</b> <i>community-name</i> [<b>context</b> <i>context-name</i>] [<b>engineid</b> <i>engine-id</i>] [<b>security-name</b> <i>security-name</i>] <b>target-list</b> <i>vpn-list-name</i></p> <p><b>Example:</b> Router(config)# snmp mib community-map vrfcomm-vpn1 context context-vpn1 target-list targ-vpn1</p>	<p>Associates an SNMP community with an SNMP context, Engine ID, or security name.</p> <ul style="list-style-type: none"> <li>The <i>community-name</i> argument is an SNMP community string.</li> <li>The <b>context</b> <i>context-name</i> keyword and argument specify an SNMP context name to be mapped to the SNMP community.</li> <li>The <b>engineid</b> <i>engine-id</i> keyword and argument specify an SNMP engine ID to be mapped to the SNMP community.</li> <li>The <b>security-name</b> <i>security-name</i> keyword and argument specify the security name to be mapped to the SNMP community.</li> <li>The <b>target-list</b> <i>vpn-list-name</i> keyword and argument specify the VRF list to be mapped to the SNMP community. The list name should correspond to a list name used in the <b>snmp mib target list</b> command.</li> </ul>

	Command or Action	Purpose
Step 7	<pre>snmp mib target list vpn-list-name {vrf vrf-name   host ip-address}</pre> <p><b>Example:</b></p> <pre>Router(config)# snmp mib target list targ-vpn1 vrf customer1</pre>	<p>Creates a list of target VRFs and hosts to associate with an SNMP community.</p> <ul style="list-style-type: none"> <li>• The <i>vpn-list-name</i> argument is the name of the target list.</li> <li>• The <b>vrf</b> keyword adds a specified VRF to the target list.</li> <li>• The <i>vrf-name</i> argument is the name of a VRF to include in the list.</li> <li>• The <b>host</b> keyword adds a specified host to the target list.</li> <li>• The <i>ip-address</i> argument is the IP address of the host.</li> </ul>
Step 8	<pre>end</pre> <p><b>Example:</b></p> <pre>Router(config) end</pre>	<p>Exits to privileged EXEC mode.</p>

## Configuration Examples for the MPLS EM—MPLS LSR MIB - RFC 3813

This section contains the following configuration examples for the MPLS EM—MPLS LSR MIB - RFC 3813 feature:

- [Enabling the SNMP Agent: Examples, page 35](#)
- [Configuring a VPN-Aware LSR MIB: Example, page 36](#)

### Enabling the SNMP Agent: Examples

The following example shows how to enable an SNMP agent.

```
Router# configure terminal
Router(config)# snmp-server community
```

In the following example, SNMPv1 and SNMPv2C are enabled. The configuration permits any SNMP manager to access all objects with read-only permissions using the community string *public*.

```
Router(config)# snmp-server community public
```

In the following example, read-only access is allowed for all objects to members of access list 4 that specify the comaccess community string. No other SNMP managers have access to any objects.

```
Router(config)# snmp-server community comaccess ro 4
```

## Configuring a VPN-Aware LSR MIB: Example

This section contains the following examples for configuring a VPN-aware LSR MIB:

- [Configuring SNMP Support for a VPN: Example, page 36](#)
- [Configuring an SNMP Context for a VPN: Example, page 36](#)
- [Configuring a VPN-Aware SNMP Context for SNMPv1 or SNMPv2: Example, page 36](#)

### Configuring SNMP Support for a VPN: Example

The following example shows how to configure SNMP support for a VPN:

```
configure terminal
!
snmp-server engineID remote 172.16.20.3 vrf vrf customer1 80000009030000B064EFE100
end
```

### Configuring an SNMP Context for a VPN: Example

The following example shows how to configure an SNMP context for a VPN. In this example, the VPN vrf1 is associated with the SNMP context context1.

```
configure terminal
!
snmp-server context context-vpn1
ip vrf customer1
rd 100:1
context context-vpn1
route-target export 100:1
end
```

### Configuring a VPN-Aware SNMP Context for SNMPv1 or SNMPv2: Example

The following configuration example shows how to configure a VPN-aware SNMP context for the MPLS LSR MIB with SNMPv1 or SNMPv2:

```
snmp-server context context-vpn1

ip vrf customer1
rd 100:1
context context-vpn1
route-target export 100:1
route-target import 100:1
!
!
interface Ethernet1/0
ip vrf forwarding customer1
ip address 10.99.99.100 255.0.0.0
mpls label protocol ldp
mpls ip
!
!
interface Serial3/0
ip vrf forwarding customer1
ip address 10.60.1.1 255.0.0.0
mpls label protocol ldp
mpls ip
serial restart-delay 0
```

```

!
ip access-list standard context-vpn1

!
snmp-server group group-vpn1 v2c context context-vpn1 read view-vpn1 notify
*tv.00000000.00040000.00000000.0 access context-vpn1
!
snmp-server view view-vpn1 iso included
!
snmp-server community public RW
snmp-server community vrfcomm-vpn1 RW1
!
snmp-server user vrfcomm-vpn1 vrfcomm-vpn1 v1
snmp-server user vrfcomm-vpn1 group-vpn1 v2c
!

snmp mib community-map vrfcomm-vpn1 context context-vpn1 target-list targ-vpn1
!
snmp mib target list targ-vpn1 host 0.0.0.0
snmp mib target list targ-vpn1 vrf customer1
!

```

# Feature Information for MPLS EM—MPLS LSR MIB - RFC 3813

Table 22 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Note

Table 22 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release. Unless noted otherwise, subsequent releases of that Cisco IOS software release also support that feature.

**Table 22** Feature Information for MPLS EM—MPLS LSR MIB - RFC 3813

Feature Name	Releases	Feature Information
MPLS EM—MPLS LSR MIB - RFC 3813	12.2(33)SRB 12.2(33)SB	<p>The MPLS LSR MIB- RFC 3813 (MPLS-LSR-STD-MIB) allows you to use the Simple Network Management Protocol (SNMP) to remotely monitor a label switch router (LSR) that is using the Multiprotocol Label Switching (MPLS) technology.</p> <p>This document describes the MPLS-LSR-STD-MIB. The document also describes the major differences between the MPLS-LSR-STD-MIB and draft Version 5 of the MPLS-LSR-MIB.</p> <p>The MPLS EM—MPLS LSR MIB - RFC 3813 feature introduces the MPLS-LSR-STD-MIB, which is an upgrade from draft Version 5 of the MPLS-LSR-MIB to an implementation of the <i>Multiprotocol Label Switching (MPLS) Label Switching Router (LSR) Management Information Base (MIB)</i>, RFC 3813. This feature also introduces the VPN Aware LSR MIB feature that enables the MPLS-LSR-STD-MIB to get VPN context information.</p> <p>Cisco IOS MPLS Embedded Management (EM) is a set of standards and value-added services that facilitate the deployment, operation, administration, and management of MPLS-based networks in line with the fault, configuration, accounting, performance, and security (FCAPS) model.</p> <p>In 12.2(33)SRB, this feature was introduced.</p> <p>In 12.2(33)SB, this feature was integrated into a Cisco IOS 12.2SB release.</p>

# Glossary

**cross-connect (XC)**—An association of in-segments and incoming MPLS interfaces to out-segments and outgoing MPLS interfaces.

**FPI**—forwarding path identifier. An identifier required to locate MPLS forwarding information for a FEC. Examples of types of FPIs supported by the MPLS Forwarding Infrastructure (MFI) are IPv4, IPv6, LABEL, SSS, and TE.

**IETF**—Internet Engineering Task Force. A task force (consisting of more than 80 working groups) that is developing standards for the Internet and the IP suite of protocols.

**inSegment**—A label on an incoming packet that is used to determine the forwarding of the packet.

**label**—A short, fixed-length identifier that is used to determine the forwarding of a packet.

**label switching**—A term used to describe the forwarding of IP (or other network layer) packets using a label swapping algorithm based on network layer routing algorithms. The forwarding of these packets uses the exact match algorithm and rewrites the label.

**LDP**—Label Distribution Protocol. A standard protocol between MPLS-enabled routers that is used for the negotiation of the labels (addresses) used to forward packets.

**LFIB**—Label Forwarding Information Base. A data structure and way of managing forwarding in which destinations and incoming labels are associated with outgoing interfaces and labels.

**LSP**—label switched path. A sequence of hops in which a packet travels from one router to another router by means of label switching mechanisms. A label-switched path can be established dynamically, based on normal routing mechanisms, or through configuration.

**LSR**—label switching router. A device that forwards MPLS packets based on the value of a fixed-length label encapsulated in each packet.

**MFI**—MPLS Forwarding Infrastructure. In the Cisco MPLS subsystem, the data structure for storing information about incoming and outgoing labels and associated equivalent packets suitable for labeling.

**MIB**—Management Information Base. Database of network management information that is used and maintained by a network management protocol such as SNMP. The value of a MIB object can be changed or retrieved by means of SNMP commands, usually through a network management system. MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

**MOI**—MPLS output information. The MOI includes the next hop, outgoing interface, and outgoing label.

**MPLS**—Multiprotocol Label Switching. MPLS is a method for forwarding packets (frames) through a network. It enables routers at the edge of a network to apply labels to packets (frames). ATM switches or existing routers in the network core can switch packets according to the labels with minimal lookup overhead.

**MPLS interface**—An interface on which MPLS traffic is enabled.

**NMS**—Network Management Station. A device (usually a workstation) that performs SNMP queries to the SNMP agent of a managed device in order to retrieve or modify information.

**notification request**—Message sent by an SNMP agent to a network management station, console, or terminal, indicating that a significant event occurred. SNMP notification requests are more reliable than traps, because a notification request from an SNMP agent requires that the SNMP manager acknowledge receipt of the notification request. The manager replies with an SNMP response protocol data unit (PDU). If the manager does not receive a notification message from an SNMP agent, it does not send a response. If the sender (SNMP agent) never receives a response, the notification request can be sent again. Thus, a notification request is more likely than a trap to reach its intended destination.

**outSegment**—A label on an outgoing packet.

**SNMP**—Simple Network Management Protocol. Management protocol used almost exclusively in TCP/IP networks. SNMP provides a means for monitoring and controlling network devices, and for managing configurations, statistics collection, performance, and security.

**trap**—Message sent by an SNMP agent to a network management station, console, or terminal, indicating that a significant event occurred. Traps are less reliable than notification requests, because the receiver does not send an acknowledgment when it receives a trap. The sender cannot determine if the trap was received.

# MPLS EM—MPLS VPN MIB RFC 4382 Upgrade

---

**First Published: January 7, 2008**

**Last Updated: April 11, 2008**

The MPLS EM—MPLS VPN MIB RFC 4382 Upgrade feature document describes the MPLS-L3VPN-STD-MIB that supports Multiprotocol Label Switching (MPLS) Layer 3 Virtual Private Networks (VPNs) based on RFC 4382, *MPLS/BGP Layer 3 Virtual Private Network (VPN) Management Information Base*, and describes the major differences between RFC 4382 and MPLS-VPN-MIB, which is based on the Internet Engineering Task Force (IETF) draft Version 3 (draft-ietf-ppvpn-mpls-vpn-mib-03.txt). This document also describes the changes needed to implement MPLS-L3VPN-STD-MIB (RFC 4382). The MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB provide an interface for managing the MPLS VPN feature in Cisco IOS software through the use of the Simple Network Management Protocol (SNMP).

Cisco IOS MPLS Embedded Management (EM) is a set of standards and value-added services that facilitate the deployment, operation, administration, and management of MPLS-based networks according to the fault, configuration, accounting, performance, and security (FCAPS) model.

## Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for MPLS EM—MPLS VPN MIB RFC 4382 Upgrade” section on page 43](#).

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for MPLS EM—MPLS VPN MIB RFC 4382 Upgrade

The MPLS-L3VPN-STD-MIB agent requires the following:

- SNMP is installed and enabled on the label switching routers (LSRs).
- MPLS is enabled on the LSRs.
- Multiprotocol Border Gateway Protocol (BGP) is enabled on the LSRs.
- Cisco Express Forwarding is enabled on the LSRs.
- Label Distribution Protocol (LDP) paths or traffic-engineered tunnels (RFC 3812) are configured between provider edge (PE) routers and customer edge (CE) routers.

## Restrictions for MPLS EM—MPLS VPN MIB RFC 4382 Upgrade

The following is not supported for Cisco IOS Releases 12.2(33)SRC and 12.2(33)SB:

- Configuration of the MIB using the SNMP SET command is not supported, except for the trap-related object, `mplsL3VpnNotificationEnable`.

## Information About MPLS EM—MPLS VPN MIB RFC 4382 Upgrade

This section contains the following topics:

- [MPLS Layer 3 VPN Overview, page 3](#)
- [MPLS-L3VPN-STD-MIB Benefits, page 3](#)
- [Capabilities Supported by the MPLS-L3VPN-STD-MIB, page 3](#)
- [Supported Objects in the MPLS-L3VPN-STD-MIB, page 4](#)
- [MPLS-L3VPN-STD-MIB Scalar Objects, page 5](#)
- [MPLS-L3VPN-STD-MIB MIB Tables, page 6](#)
- [MPLS-L3VPN-STD-MIB Notification Events, page 18](#)
- [MPLS-L3VPN-STD-MIB Support for IPv6 VPNs over MPLS, page 21](#)
- [MPLS-L3VPN-STD-MIB Data Security, page 24](#)
- [Major Differences Between the MPLS-VPN-MIB and the MPLS-L3VPN-STD-MIB, page 25](#)

## MPLS Layer 3 VPN Overview

The MPLS Layer 3 VPN technology allows service providers to offer intranet and extranet VPN services that directly connect their customers' remote offices to a public network with the same security and service levels that a private network offers. Each VPN is associated with one or more VPN routing and forwarding (VRF) instances. A VRF is created for each VPN defined on a router and contains most of the information needed to manage and monitor MPLS Layer 3 VPNs: an IP routing table, a derived Cisco Express Forwarding table, a set of interfaces that use this forwarding table, and a set of rules and routing protocol parameters that control the information that is included in the routing table.

## MPLS-L3VPN-STD-MIB Benefits

The MPLS-L3VPN-STD-MIB provides access to VRF information, and to interfaces included in the VRF, and other configuration and monitoring information.

The MPLS-L3VPN-STD-MIB provides the following benefits:

- A standards-based SNMP interface for retrieving information about critical MPLS VPN events.
- VRF information to assist in the management and monitoring of MPLS VPNs.
- Information, in conjunction with the Interfaces MIB, about interfaces assigned to VRFs.
- Performance statistics for all VRFs on a router.
- The generation and queueing of notifications that call attention to major changes in the operational status of MPLS VPN enabled interfaces and the forwarding of notification messages to a designated network management system (NMS) for evaluation and action by network administrators.
- Warning when VPN routing tables are approaching or exceed their capacity.
- Warnings about the reception of illegal labels on a VRF-enabled interface. Such receptions may indicate misconfiguration or an attempt to violate security.

## Capabilities Supported by the MPLS-L3VPN-STD-MIB

SNMP agent code operating with the MPLS-L3VPN-STD-MIB enables a standardized, SNMP-based approach to managing MPLS VPNs in Cisco IOS software.

The MPLS-L3VPN-STD-MIB is based on RFC 4382, *MPLS/BGP Layer 3 Virtual Private Network (VPN) Management Information Base*, which includes objects describing features that support MPLS VPN events.

The MPLS-L3VPN-STD-MIB provides you with the ability to do the following:

- Gather routing and forwarding information for MPLS VPNs on a router.
- Display information in the VRF routing table.
- Send notification messages that signal changes when critical MPLS VPN events occur.
- Enable, disable, and configure notification messages for MPLS VPN events by using extensions to existing SNMP command-line interface (CLI) commands.
- Specify the IP address of an NMS in the operating environment to which notification messages are sent.
- Write notification configurations into nonvolatile memory.

Some slight differences between RFC 4382 and the actual implementation of MPLS VPNs within Cisco IOS software require some minor translations between the MPLS-L3VPN-STD-MIB and the internal data structures of Cisco IOS software. These translations are accomplished by means of the SNMP agent code. Also, while running as a low priority process, the SNMP agent provides a management interface to Cisco IOS software. SNMP adds minimal overhead on the normal functions of the device.

All MPLS-L3VPN-STD-MIB objects are based on RFC 4382; thus, no Cisco-specific SNMP application is required to support the functions and operations pertaining to the MPLS-L3VPN-STD-MIB features.

## Supported Objects in the MPLS-L3VPN-STD-MIB

The MPLS-L3VPN-STD-MIB contains numerous tables and object definitions that provide read-only SNMP management support for the MPLS VPN feature in Cisco IOS software. The MPLS-L3VPN-STD-MIB conforms to Abstract Syntax Notation One (ASN.1), thus providing an idealized MPLS VPN database.

Using any standard SNMP network management application, you can retrieve and display information from the MPLS-L3VPN-STD-MIB using GET operations; similarly, you can traverse information in the MIB database for display using GETNEXT operations.

The MPLS-L3VPN-STD-MIB tables and objects are described briefly in the following sections:

- [MPLS-L3VPN-STD-MIB Scalar Objects, page 5](#)
- [MPLS-L3VPN-STD-MIB MIB Tables, page 6](#)
- [MPLS-L3VPN-STD-MIB Notification Events, page 18](#)

[Figure 1](#) shows a simple MPLS VPN configuration. This configuration includes two customer MPLS VPNs (labeled VPN1 and VPN2) and a simple provider network that consists of two PE routers (labeled PE1 and PE2) and a provider core router labeled P. [Figure 1](#) shows the following sample configuration:

- VRF names—VPN1 and VPN2
- Interfaces associated with VRFs—Et1, Et2, and At3/0
- Routing protocols—Open Shortest Path First (OSPF), Routing Information Protocol (RIP), and Interior Border Gateway Protocol (IBGP)
- Routes associated with VPN1—10.1.0.0, 10.2.0.0, and 10.3.0.0
- Routes associated with VPN2—172.16.1.0 and 172.16.2.0
- Routes associated with the provider network—192.168.1.0, 192.168.2.0, and 192.168.3.0

This configuration is used to explain MPLS VPN events that are monitored and managed by the MPLS-L3VPN-STD-MIB.

**Figure 1**      **Sample MPLS Layer 3 VPN Configuration**

For information on IPv6 VPN over MPLS (6VPE) configuration, see the “Implementing IPv6 VPN over MPLS (6VPE)” chapter in the *Cisco IOS IPv6 Configuration Guide*.

## MPLS-L3VPN-STD-MIB Scalar Objects

MPLS-L3VPN-STD-MIB defines several scalar objects. [Table 1](#) describes the scalar objects that are implemented for Cisco IOS Release 12.2(33)SRC and Release 12.2(33)SB.

**Table 1**      **MPLS-L3VPN-STD-MIB Scalar Objects**

MIB Object	Description
mplsL3VpnConfiguredVrfs	The number of VRFs configured on the router, including VRFs recently deleted.
mplsL3VpnActiveVrfs	The number of VRFs that are active on the router. An active VRF is assigned to at least one interface that is in the operationally up state.
mplsL3VpnConnectedInterfaces	The total number of interfaces assigned to a VRF.
mplsL3VpnNotificationEnable	<p>An object to enable or disable MPLS-L3VPN-STD-MIB notifications:</p> <ul style="list-style-type: none"> <li>Setting this object to true enables all notifications defined in the MPLS-L3VPN-STD-MIB.</li> <li>Setting this object to false disables all notifications defined in the MIB. This is the default.</li> </ul> <p>This is one of the few objects that is writable.</p>
mplsL3VpnVrfConfMaxPossRts	The number of routes that this router is capable of storing. This value cannot be determined because it is based on the amount of available memory in the system. Therefore, this object is set to zero (0).

**Table 1** *MPLS-L3VPN-STD-MIB Scalar Objects (continued)*

MIB Object	Description
mplsL3VpnVrfConfRteMxThrshTime	<p>An interval in seconds in which repeat mplsL3VpnVrfNumVrfRouteMaxThreshExceeded notifications can be sent if there is an attempt to continuously add routes after the maximum route limit is reached.</p> <p>The default value is 0. When the value is 0, the MIB agent does not send the notification again unless the number of routes drops below the threshold and attempts to exceed the threshold again.</p> <p>You can set the number of seconds after which the maximum threshold notification is sent with the following configuration command:</p> <pre>Router(config)# snmp mib mpls vpn max-threshold seconds</pre>
mplsL3VpnIlIlLblRcvThrsh	<p>A number above which the receipt of an illegal label generates an mplsNumVrfSecIlIlglLblThrshExcd notification. The default value is 0.</p> <p>You can set the number of illegal labels that generate a notification with the following configuration command:</p> <pre>Router(config)# snmp mib mpls vpn illegal-label number</pre>

## MPLS-L3VPN-STD-MIB MIB Tables

The MPLS-L3VPN-STD-MIB implementation supports the tables described in the following sections:

- [VRF Configuration Table \(mplsL3VpnVrfTable\), page 6](#)
- [VPN Interface Configuration Table \(mplsL3VpnIfConfTable\), page 10](#)
- [VRF Route Target Table \(mplsL3VpnVrfRTTable\), page 11](#)
- [VRF Security Table \(mplsL3VpnVrfSecTable\), page 13](#)
- [VRF Performance Table \(mplsL3VpnVrfPerfTable\), page 13](#)
- [VRF Routing Table \(mplsL3VpnVrfRteTable\), page 14](#)

### VRF Configuration Table (mplsL3VpnVrfTable)

Entries in the VRF configuration table (mplsL3VpnVrfTable) represent the VRF instances that are configured on the router. These include recently deleted VRFs. The information in this table is also displayed in the output of the **show vrf detail** command.

Each VRF is referenced by its VRF name (mplsL3VpnVrfName).

[Table 2](#) lists MPLS Layer 3 VPN information and the associated MIB objects supported by the VRF configuration table (mplsL3VpnVrfTable).

**Table 2**      **VRF Configuration Table—MPLS Layer 3 VPN Information and Associated MIB Objects**

MIB Object	MPLS Layer 3 VPN Information
mplsL3VpnVrfName	<p>The name associated with this VRF. When this object is used as an index to a table, the first octet is the string length, and subsequent octets are the ASCII codes of each character. For example, “vpn1” is represented as 4.118.112.110.49.</p> <p>The VRF name can be equivalent to the VPN ID. If the VRF name is equivalent to the VPN ID, the VRF name must be equivalent to the value for the mplsL3VpnVrfVpnId MIB object. We recommend that all sites that support VRFs that are part of the same VPN use the same naming convention for VRFs and use the same VPN ID.</p>
mplsL3VpnVrfVpnId	The VPN identification number based on RFC 2685. If you do not specify a VPN ID, the value is an empty string.
mplsL3VpnVrfDescription	<p>The description of the VRF. This is specified with the <b>description</b> command in VRF configuration mode:</p> <pre>Router(config)# vrf definition vrf-name Router(config-vrf)# description vrf-description</pre> <p><b>Note</b> You can use the <b>vrf definition vrf-name</b> command to configure both IPv6 and IPv4 address-family VRFs. When you use the <b>ip vrf vrf-name</b> command, you can configure only an IPv4 address-family VRF.</p>
mplsL3VpnVrfRD	<p>The route distinguisher for this VRF. This is specified with the <b>rd</b> command in VRF configuration mode:</p> <pre>Router(config)# vrf definition vrf-name Router(config-vrf)# rd route-distinguisher</pre> <p><b>Note</b> You can use the <b>vrf definition vrf-name</b> command to configure both IPv6 and IPv4 address-family VRFs. When you use the <b>ip vrf vrf-name</b> command, you can configure only an IPv4 address-family VRF.</p>
mplsL3VpnVrfCreationTime	The value of the sysUpTime when this VRF entry was created.
mplsL3VpnVrfOperStatus	<p>The operational status of this VRF. A VRF is up (1) when at least one interface associated with the VRF is up. A VRF is down (2) when:</p> <ul style="list-style-type: none"> <li>• No interfaces exist whose ifOperStatus = up (1).</li> <li>• No interfaces are associated with this VRF.</li> </ul>
mplsL3VpnVrfActiveInterfaces	The number of interfaces assigned to this VRF that are operationally up.
mplsL3VpnVrfAssociatedInterfaces	The number of interfaces assigned to this VRF, independent of the operational status.

**Table 2**      **VRF Configuration Table—MPLS Layer 3 VPN Information and Associated MIB Objects (continued)**

MIB Object	MPLS Layer 3 VPN Information
mplsL3VpnVrfConfMidRteThresh	<p>The middle threshold. If the number of routes in the VRF crosses this threshold, an mplsL3VpnVrfRouteMidThreshExceeded notification is sent (if notifications are enabled and configured). You can set this value in VRF address family configuration mode as a percentage of the maximum with the <b>maximum routes limit {warn-threshold   warn-only}</b> command.</p> <p>For example, the following <b>maximum routes</b> command sets the warning threshold for an IPv4 address family in VRF vpn1 as 50 percent of the maximum route threshold:</p> <pre>Router(config)# vrf definition vpn1 Router(config-vrf)# address-family ipv4 Router(config-vrf-af)# maximum routes 1000 50</pre> <p>If vpn1 also has an IPv6 address family configured, the following <b>maximum routes</b> command sets the warning threshold for the IPv6 address family as 50 percent of its maximum route threshold:</p> <pre>Router(config)# vrf definition vpn1 Router(config-vrf)# address-family ipv6 Router(config-vrf-af)# maximum routes 2000 50</pre> <p><b>Note</b>    The <b>vrf definition vrf-name</b> command can configure both IPv6 and IPv4 address-family VRFs. When you use the <b>ip vrf vrf-name</b> command, you can configure only an IPv4 address-family VRF.</p> <p>If both IPv4 and IPv6 address-family configurations are present in the VRF, the threshold is an aggregate of the warning threshold values. In this example, the aggregate warning threshold is 1500 routes [(ipv4 = 500) + (ipv6 = 1000)]. An mplsL3VpnVrfRouteMidThreshExceeded notification is not sent until both address families reach their warning threshold. If only a single address family exists for the VRF, the mplsL3VpnVrfRouteMidThreshExceeded notification is sent when the warning threshold is reached for the single address family.</p> <p>The following command sets a middle threshold of 1000 routes. An mplsL3VrfRouteMidThreshExceeded notification is sent when this threshold is exceeded. However, additional routes are still allowed because a maximum route threshold is not set with this command.</p> <pre>Router(config-vrf-if)# maximum routes 1000 warn-only</pre> <p>See the “<a href="#">MPLS-L3VPN-STD-MIB Notification Events</a>” section on page 18 for more information on the mplsL3VpnVrfRouteMidThreshExceeded notification.</p>

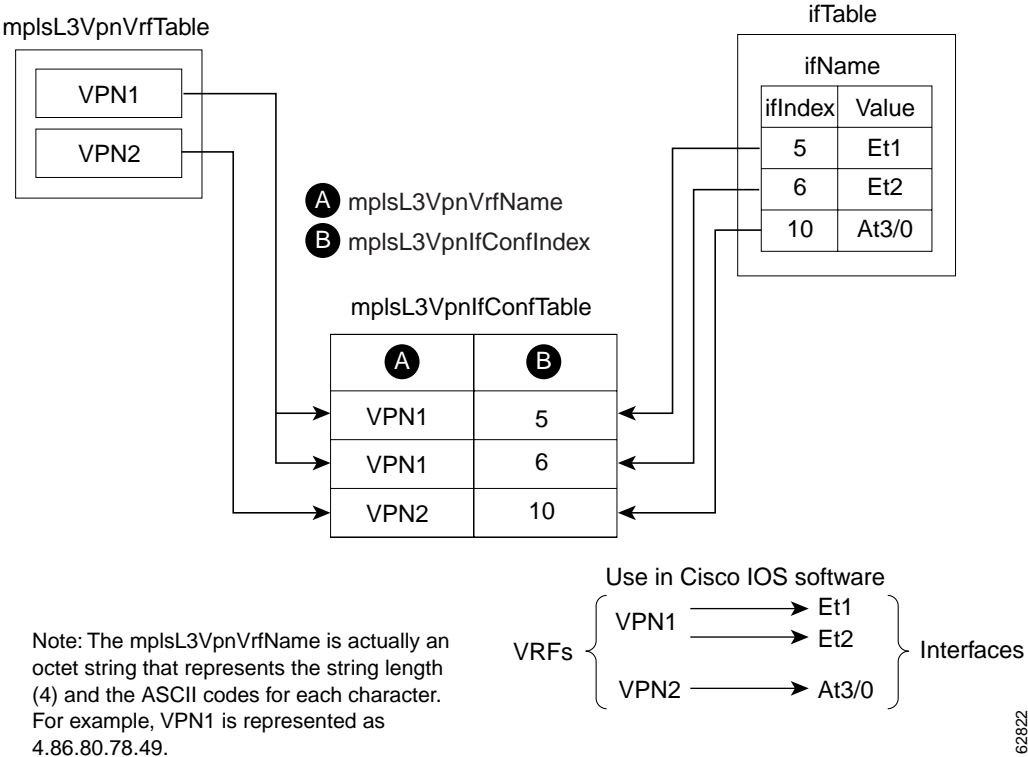

**Table 2** VRF Configuration Table—MPLS Layer 3 VPN Information and Associated MIB Objects (continued)

MIB Object	MPLS Layer 3 VPN Information
mplsL3VpnVrfConfHighRteThresh	<p>The maximum route threshold. If the number of routes in the VRF crosses this threshold, an mplsL3VpnVrfNumVrfRouteMaxThreshExceeded notification is sent (if notifications are enabled and configured). You can set this value in VRF address family configuration mode with the <b>maximum routes limit</b> {<i>warn-threshold</i>   <b>warn-only</b>} command as follows:</p> <pre>Router(config)# vrf definition vpn2 Router(config-vrf)# address-family ipv4 Router(config-vrf-af)# maximum routes 1000 75  Router(config)# vrf definition vpn2 Router(config-vrf)# address-family ipv6 Router(config-vrf-af)# maximum routes 2000 75</pre> <p><b>Note</b> The <b>vrf definition vrf-name</b> command can configure both IPv6 and IPv4 address-family VRFs. When you use the <b>ip vrf vrf-name</b> command, you can configure only an IPv4 address-family VRF.</p> <p>If both IPv4 and IPv6 address-family configurations are present in the VRF, the threshold is an aggregate of the maximum threshold values. In this example, the aggregate maximum route threshold is 3000 [(ipv4 = 1000)+ (ipv6 = 2000)]. An mplsL3VpnVrfNumVrfRouteMaxThreshExceeded notification is not sent until both address families reaches their maximum route threshold. If only a single address family exists for the VRF, the mplsL3VpnVrfRouteMaxThreshExceeded notification is sent when the maximum route threshold is reached for the single address family. Routes are not added to the address-family that has already reached its maximum route threshold.</p> <p>See the “<a href="#">MPLS-L3VPN-STD-MIB Notification Events</a>” section on page 18 for more information on the mplsL3VpnVrfNumVrfRouteMaxThreshExceeded notification.</p>
mplsL3VpnVrfConfMaxRoutes	This value is the same as that for mplsL3VpnVrfConfHighRteThresh.
mplsL3VpnVrfConfLastChanged	<p>The value of sysUpTime when the configuration of the VRF changes or interfaces are assigned or unassigned from the VRF.</p> <p><b>Note</b> This object is updated only when values in this table change.</p>
mplsL3VpnVrfConfRowStatus	The status of a row in the table. This object normally reads “active (1),” but may read “notInService (2)” if a VRF was recently deleted.
mplsL3VpnVrfConfAdminStatus	<p>The operation status of the VRF. The possible values are:</p> <ul style="list-style-type: none"> <li>up (1)—At least one interface is administratively up and the VRF is ready to pass packets.</li> <li>down (2)—All interfaces are administratively down and the VRF cannot pass packets.</li> </ul>
mplsL3VpnVrfConfStorageType	The storage type for the VRF entry. This object always returns a value of “volatile (2).”

VPN Interface Configuration Table (mplsL3VpnIfConfTable)

In Cisco IOS software, a VRF is associated with one MPLS Layer 3 VPN. Zero or more interfaces can be associated with a VRF. A VRF uses an interface that is defined in the ifTable of the Interfaces Group of MIB II (IFMIB). The IFMIB defines objects for managing interfaces. The ifTable of this MIB contains information on each interface in the network. The mplsL3VpnIfConfTable associates a VRF from the mplsL3VpnVrfTable with a forwarding interface from the ifTable. Figure 2 shows the relationship between VRFs and interfaces defined in the ifTable and the mplsL3VpnIfConfTable.

Figure 2 VRFs, the Interfaces MIB, and the mplsL3VpnIfConfTable

Entries in the VPN interface configuration table (mplsL3VpnIfConfTable) represent the interfaces that are assigned to each VRF. The information available in this table is also displayed in the output of the **show vrf** command.

The mplsL3VpnIfConfTable shows how interfaces are assigned to VRFs. An LSR creates an entry in this table for every interface capable of supporting MPLS Layer 3 VPNs.

The mplsL3VpnIfConfTable is indexed by the following:

- mplsL3VpnVrfName—The VRF name
- mplsL3VpnIfConfIndex—An identifier that is the same as the ifIndex from the Interface MIB of the interface assigned to the VRF

Table 3 lists MPLS Layer 3 VPN information and the associated MIB objects supported by the VPN interface configuration table (mplsL3VpnIfConfTable).

62822

**Table 3**      **VPN Interface Configuration Table—MPLS Layer 3 VPN Information and Associated MIB Objects**

MIB Object	MPLS Layer 3 VPN Information
mplsL3VpnIfConfIndex	Provides the interface MIB ifIndex of this interface that is assigned to a VRF.
mplsL3VpnIfVpnClassification	Specifies what type of VPN this interface is providing: carrier supporting carrier (CsC) (1), enterprise (2), or InterProvider (3).  This value is set to enterprise (2) if MPLS is not enabled and to carrier supporting carrier (1) if MPLS is enabled on this interface.
mplsL3VpnIfVpnRouteDistProtocol	Indicates the route distribution protocols that are being used to redistribute routes across the PE-to-CE link on this interface: none (0), BGP (1), OSPF (2), RIP (3), Intermediate System-Intermediate System (IS-IS) (4), static (5), or other (6). More than one protocol can be enabled at the same time.  In Cisco IOS software, router processes are defined and redistributed on a per-VRF basis, not per-interface. Therefore, all interfaces assigned to the same VRF have the same value for this object.
mplsL3VpnIfConfStorageType	Indicates the storage type for the VPN interface entry. The default value for this object is “volatile (2).”
mplsL3VpnIfConfRowStatus	Provides the status of the row in the table that associates the specified interface with the VRF. This object normally reads “active (1),” but may read “notInService (2),” if a VRF was recently deleted.

## VRF Route Target Table (mplsL3VpnVrfRTTable)

The VRF route target table (mplsL3VpnVrfRTTable) describes the route target communities that are defined for a particular VRF. An LSR creates an entry in this table for each target configured for a VRF supporting an MPLS Layer 3 VPN instance.

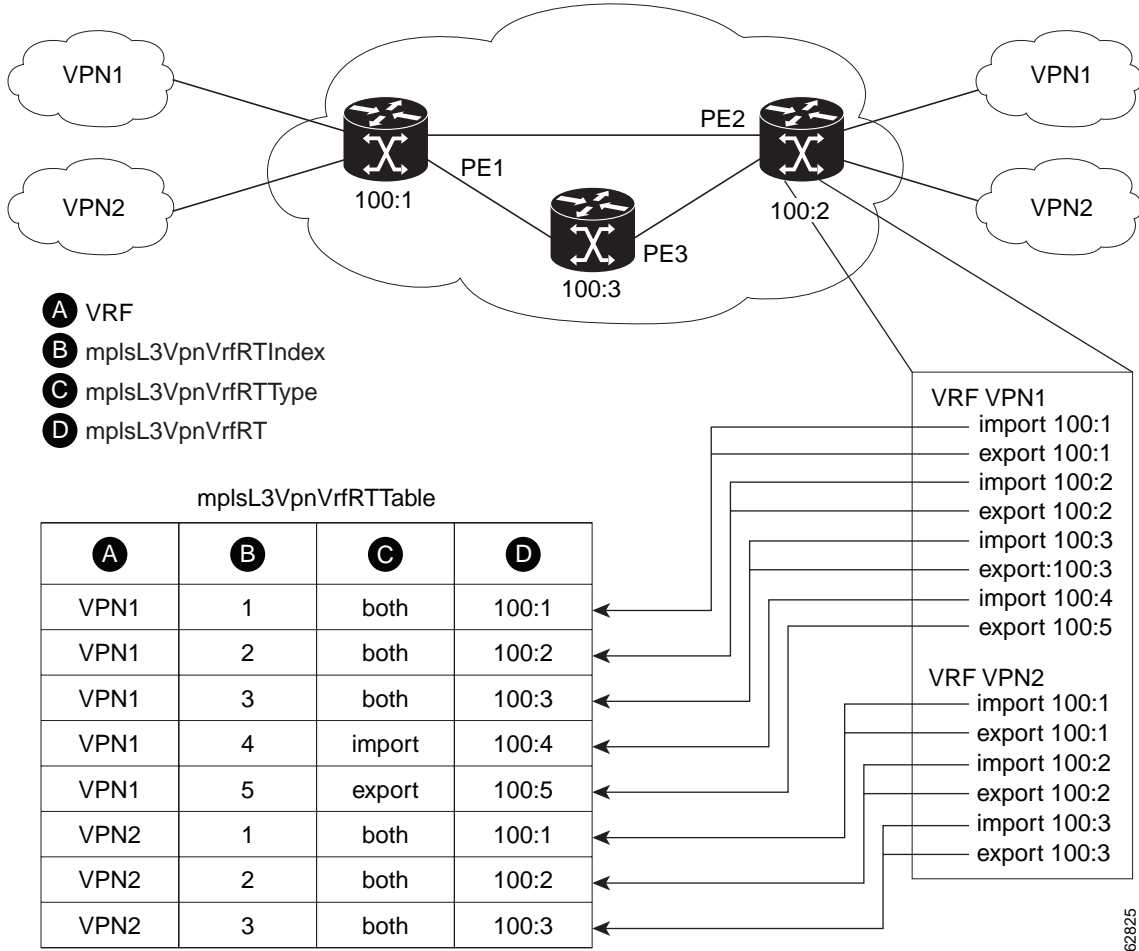

The distribution of VPN routing information is controlled through the use of VPN route target communities, implemented by BGP extended communities. Distribution of VPN routing information works as follows:

- When a VPN route learned from a CE router is injected into BGP, a list of VPN route target extended community attributes is associated with it. Typically the list of route target community values is set from an export list of route targets associated with the VRF from which the route was learned.
- An import list of route target extended communities is associated with each VRF. The import list defines route target extended community attributes a route must have for the route to be imported into the VRF. For example, if the import list for a particular VRF includes route target communities A, B, and C, then any VPN route that carries any of those route target extended communities—A, B, or C—is imported into the VRF.

Figure 3 shows a sample configuration and its relationship to an mplsL3VpnVrfRTTable. A route target table exists on each PE router. Routers with route distinguishers (RDs) 100:1, 100:2, and 100:3 are shown in the sample configuration. Routers with RDs 100:4 and 100:5 are not shown in Figure 3, but are included in the route targets for PE2 and in the mplsL3VpnVrfRTTable.

Figure 3 Sample Configuration and the mplsL3VpnVrfRTTable

Note: The mplsL3VpnVrfName is actually an octet string that represents the string length (4) and the ASCII codes for each character. For example, VPN1 is represented as 4.86.80.78.49.

The mplsL3VpnVrfRTTable shows the import and export route targets for each VRF. The table is indexed by the following:

- mplsL3VpnVrfName—The VRF name
- mplsL3VpnVrfRTIndex—The route target entry identifier
- mplsL3VpnVrfRTType—A value specifying whether the entry is an import route target, is an export route target, or is defined as both

Table 4 lists MPLS Layer 3 VPN information and the associated MIB objects supported by the VRF route target table (mplsL3VpnVrfRTTable).

62825

**Table 4** VRF Route Target Table—MPLS Layer 3 VPN Information and Associated MIB Objects

MIB Object	MPLS Layer 3 VPN Information
mplsL3VpnVrfRTIndex	A value that defines each route target's position in the table.
mplsL3VpnVrfRTType	The route target distribution type: import (1), export (2), or both (3).
mplsL3VpnVrfRT	The route target distribution policy. Determines the route distinguisher for this target.
mplsL3VpnVrfRTDescr	This object contains a string that indicates the address family in which the route target was declared. If the route target was declared in an IPv4 address family, the value of this object is AF_IPv4. If the route target was declared in an IPv6 address family, the value of this object is AF_IPv6.
mplsL3VpnVrfRTRowStatus	The status of the row in the table. This object normally reads "active (1)," but may read "notInService (2)" if a VRF was recently deleted.
mplsL3VpnVrfRTStorageType	The storage type for the VPN route target entry. The default value for this object is "volatile (2)."

## VRF Security Table (mplsL3VpnVrfSecTable)

The VRF security table (mplsL3VpnVrfSecTable) provides information about security for each VRF. An LSR creates an entry in this table for every VRF capable of supporting MPLS Layer 3 VPNs.

The mplsL3VpnVrfSecTable augments the mplsL3VpnVrfTable and has the same indexing.

[Table 5](#) lists MPLS Layer 3 VPN information and the associated MIB objects supported by the VRF security table (mplsL3VpnVrfSecTable).

**Table 5** VRF Security Table—MPLS Layer 3 VPN Information and Associated MIB Objects

MIB Object	MPLS Layer 3 Information
mplsL3VpnVrfSecIllegalLblVltns	<p>The number of illegally received labels on a VRF interface. Only illegal labels are counted by this object, therefore the object applies only to a VRF interface that is MPLS-enabled (carrier supporting carrier [CsC] situation).</p> <p>This counter is incremented whenever a label is received that is above or below the valid label range, is not in the global label forwarding table, or is received on the wrong VRF (that is, table IDs for the receiving interface and appropriate VRF label forwarding table do not match).</p> <p><b>Note</b> Discontinuities can occur at reinitialization of the management system and at other times are indicated by the value of the mplsL3VpnVrfSecDiscontinuityTime object.</p>
mplsL3VpnVrfSecDiscontinuityTime	The value of sysUpTime when any one or more of this entry's counters last had a discontinuity. A switchover would cause a discontinuity. If no discontinuities occurred since the last reinitialization of the local management system, this object contains a value of 0.

## VRF Performance Table (mplsL3VpnVrfPerfTable)

The VRF performance table (mplsL3VpnVrfPerfTable) provides statistical performance information for each VRF. An LSR creates an entry in this table for every VRF capable of supporting MPLS Layer 3 VPNs.

The mplsL3VpnVrfPerfTable augments the mplsL3VpnVrfTable and has the same indexing.

Table 6 lists the MPLS Layer 3 VPN information and the associated MIB objects supported by the VRF performance table (mplsL3VpnVrfPerfTable).

**Table 6 VRF Performance Table—MPLS Layer 3 VPN Information and Associated MIB Objects**

MIB Object	MPLS Layer 3 VPN Information
mplsL3VpnVrfPerfRoutesAdded	<p>The value of this counter is the number of routes added to this VRF since the last discontinuity. Discontinuities can occur at reinitialization of the management system (such as on a switchover) and at other times are indicated by the value of the mplsL3VpnVrfPerfDiscTime object.</p> <p>If both IPv4 and IPv6 address-family configurations are present in the VRF, the value of this counter is the sum of the number of routes from the IPv4 and IPv6 routing tables that are added to the VRF.</p>
mplsL3VpnVrfPerfRoutesDeleted	<p>The value of this counter is the number of routes removed from this VRF.</p> <p><b>Note</b> Discontinuities can occur at reinitialization of the management system and at other times are indicated by the value of the mplsL3VpnVrfPerfDiscTime object.</p> <p>If both IPv4 and IPv6 address-family configurations are present in the VRF, the value of this counter is the sum of the number of routes from the IPv4 and IPv6 routing tables that have been deleted from the VRF.</p>
mplsL3VpnVrfPerfCurrNumRoutes	<p>The number of routes currently defined within this VRF.</p> <p>If both IPv4 and IPv6 address-family configurations are present in the VRF, the number of routes is the sum of the number of routes defined for the IPv4 and IPv6 address families in the VRF.</p>
mplsL3VpnVrfPerfRoutesDropped	This object is not supported. The counter always returns a value of 0.
mplsL3VpnVrfPerfDiscTime	The value of sysUpTime when any one or more of this entry's counters had a discontinuity. A switchover would cause a discontinuity. If no discontinuities occurred since the last reinitialization of the local management subsystem, this object contains a value of 0.

## VRF Routing Table (mplsL3VpnVrfRteTable)

The VRF routing table (mplsL3VpnVrfRteTable) provides per-interface routing table information for each MPLS Layer 3 VPN VRF.

The information available in this table can also be displayed with the **show ip route vrf vrf-name** command for IPv4 routes or the **show ipv6 route vrf vrf-name** command for IPv6 routes.

- For example, for PE1 in Figure 1, with the **show ip route vrf vpn1** command, you would see results like the following:

```
Router# show ip route vrf vpn1
```

```
Codes: C - connected, S - static, I - IGRP, R - RIP, M - mobile, B - BGP
D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
```

```

* - candidate default, U - per-user static route, o - ODR
P - periodic downloaded static route
!
Gateway of last resort is not set
!
      10.0.0.0/32 is subnetted, 3 subnets
B       10.3.0.0 [200/0] via 192.168.2.1, 04:36:33
C       10.1.0.0/16 is directly connected, Ethernet1
C       10.2.0.0/16 [200/0] directly connected Ethernet2, 04:36:33

```

- With the **show ip route vrf vpn2** command, you would see results like the following:

```

Router# show ip route vrf vpn2

Codes: C - connected, S - static, I - IGRP, R - RIP, M - mobile, B - BGP
D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default, U - per-user static route, o - ODR
P - periodic downloaded static route
!
Gateway of last resort is not set
!
      172.16.0.0/32 is subnetted, 2 subnets
B       172.16.2.0 [200/0] via 192.168.2.1, 04:36:33
C       172.16.1.0 is directly connected, ATM 3/0

```

- The following is sample IPv6 output associated with a VRF named vrf3 that you would see with the **show ipv6 route vrf** command:

```

Router# show ipv6 route vrf vrf3

IPv6 Routing Table vrf3 - 6 entries

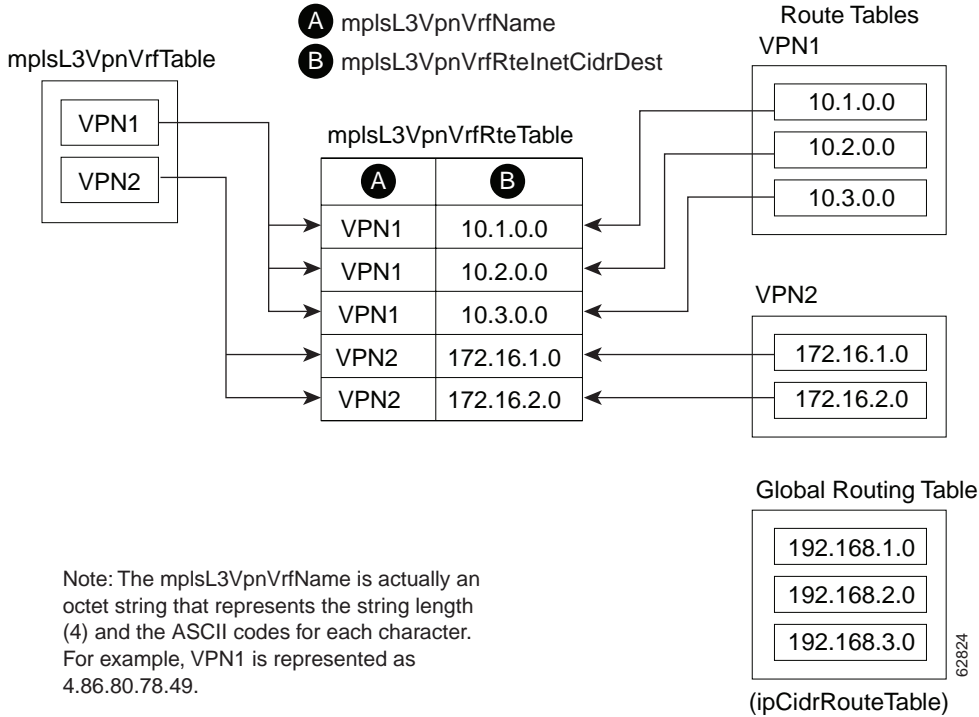

Codes: C - Connected, L - Local, S - Static, R - RIP, B - BGP
       U - Per-user Static route
       I1 - ISIS L1, I2 - ISIS L2, IA - ISIS interarea
       O - OSPF intra, OI - OSPF inter, OE1 - OSPF ext 1, OE2 - OSPF ext 2

C    2001:8::/64 [0/0]
     via ::, FastEthernet0/0
L    2001:8::3/128 [0/0]
     via ::, FastEthernet0/0
B    2002:8::/64 [200/0]
     via ::FFFF:192.168.1.4,
B    2010::/64 [20/1]
     via 2001:8::1,
C    2012::/64 [0/0]
     via ::, Loopback1
L    2012::1/128 [0/0]
     via ::, Loopback1

```

Figure 4 shows the relationship of the routing tables, the VRFs, and the `mplsL3VpnVrfRteTable`. You can display information about the VPN1 and VPN2 route tables using the **show ip route vrf vrf-name** command. The global route table for IPv4 routes is the same as `ipCidrRouteTable` in the IP-FORWARD-MIB. You can display information about the global route table with the **show ip route** command.

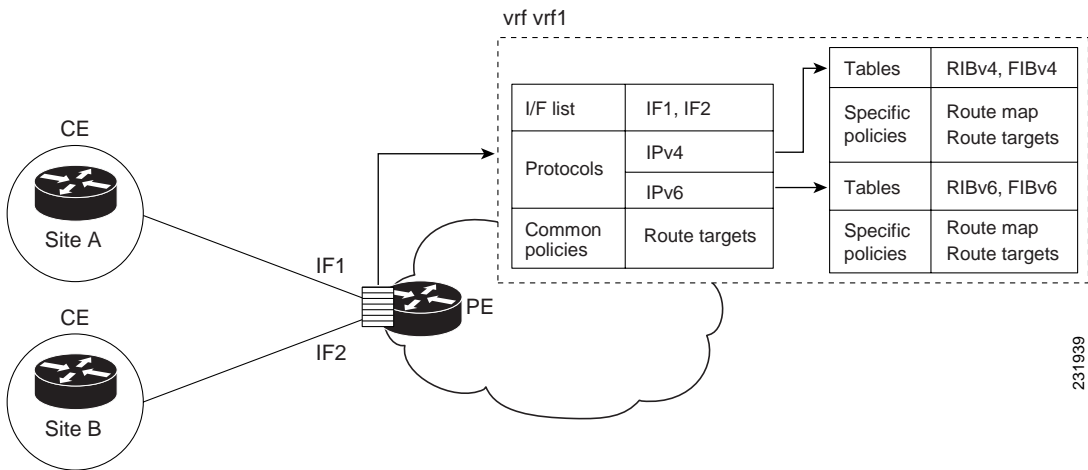

Figure 4 IPv4 Route Table, VRFs, and the mplsL3VpnVrfRteTable

You can display information about IPv6 route tables using the **show ipv6 route vrf {vrf-name | vrf-number}** command. The global route table for IPv6 routes is the same as inetCidrRouteTable in the IP-FORWARD-MIB. You can display information about the global route table with the **show ipv6 route** command.

Figure 5 illustrates a multiprotocol VRF, in which the VRF named vrf1 is enabled for both IPv4 and IPv6 routes and is associated with two interfaces (IF1, IF2), two sets of tables (IPv4 RIB and FIB and IPv6 RIB and FIB), and a set of common or distinct policies.

Figure 5 Multiprotocol VRF

231939

An LSR creates an entry in the `mplsL3VpnVrfRteTable` for every route that is configured, either dynamically or statically, within the context of a specific VRF capable of supporting MPLS Layer 3 VPNs.

The `mplsL3VpnVrfRteTable` is indexed by the following:

- `mplsL3VpnVrfName`—The VRF name, which provides the VRF routing context
- `mplsL3VpnVrfRteInetCidrDestType`—The destination address type (IPv4 or IPv6)
- `mplsL3VpnVrfRteInetCidrDest`—The destination IPv4 or IPv6 address
- `mplsL3VpnVrfRteInetCidrPfxLen`—The length of the prefix for the IP destination address
- `mplsL3VpnVrfRteInetCidrPolicy`—An index that distinguishes between multiple paths to the same destination
- `mplsL3VpnVrfRteInetCidrNHopType`—The address type of the next hop IP address (IPv4 or IPv6)
- `mplsL3VpnVrfRteInetCidrNextHop`—The IP address of the next hop for each route entry

[Table 7](#) lists MPLS Layer 3 VPN information for the MIB objects supported by the VRF routing table (`mplsL3VpnVrfRteTable`). This table represents VRF-specific routes. The global routing table is the `ipCidrRouteTable` (IPv4 routes) or `inetCidrRouteTable` (IPv6 routes) in the IP-FORWARD-MIB.

**Table 7 VRF Routing Table—MPLS Layer 3 VPN Information and Associated MIB Objects**

MIB Object	MPLS LAYER 3 VPN Information
<code>mplsL3VpnVrfRteInetCidrDestType</code>	The address type of the IP destination address. This object has a value of <code>ipv4</code> (1) or <code>ipv6</code> (2).
<code>mplsL3VpnVrfRteInetCidrDest</code>	The destination IP address defined for this route. The type of this address is determined by the value of the <code>mplsL3VpnVrfRteInetCidrDestType</code> object.  The values for the index objects <code>mplsL3VpnVrfRteInetCidrDest</code> and <code>mplsL3VpnVrfRteInetCidrPfxLen</code> must be consistent.
<code>mplsL3VpnVrfRteInetCidrPfxLen</code>	The length of the prefix for the destination address ( <code>mplsL3VpnVrfRteInetCidrDest</code> ).  The values for the index objects <code>mplsL3VpnVrfRteInetCidrDest</code> and <code>mplsL3VpnVrfRteInetCidrPfxLen</code> must be consistent.
<code>mplsL3VpnVrfRteInetCidrPolicy</code>	An index used to distinguish between multiple paths to the same destination. The default value is (0 0).
<code>mplsL3VpnVrfRteInetCidrNHopType</code>	The address type of the next hop IP address. This object has the following values: <code>unknown</code> (0), <code>ipv4</code> (1), <code>ipv6</code> (2), or <code>ipv6z</code> (4). The value should be set to <code>unknown</code> (0) for routes that are not remote.
<code>mplsL3VpnVrfRteInetCidrNextHop</code>	The next hop IP address defined for this route. The type of this address is determined by the <code>mplsL3VpnVrfRteInetCidrNHopType</code> object.
<code>mplsL3VpnVrfRteInetCidrIfIndex</code>	The interface MIB <code>ifIndex</code> for the interface through which this route is forwarded. The object is 0 if no interface is defined for the route.
<code>mplsL3VpnVrfRteInetCidrType</code>	The type of route. The value <code>local</code> (3) indicates a route for which the next hop is the final destination. The value <code>remote</code> (4) is for a route for which the next hop is not the final destination.
<code>mplsL3VpnVrfRteInetCidrProto</code>	The routing protocol that was responsible for adding this route to the VRF.
<code>mplsL3VpnVrfRteInetCidrAge</code>	The number of seconds since this route was last updated.

**Table 7** *VRF Routing Table—MPLS Layer 3 VPN Information and Associated MIB Objects (continued)*

MIB Object	MPLS LAYER 3 VPN Information
mplsL3VpnVrfRteInetCidrNextHopAS	The autonomous system number of the next hop for this route. This object is not supported and is always 0.
mplsL3VpnVrfRteInetCidrMetric1	The primary routing metric used for this route.
mplsL3VpnVrfRteInetCidrMetric2 mplsL3VpnVrfRteInetCidrMetric3 mplsL3VpnVrfRteInetCidrMetric4 mplsL3VpnVrfRteInetCidrMetric5	Alternate routing metrics used for this route. These objects are supported only for Cisco Interior Gateway Routing Protocol (IGRP) and Cisco Enhanced Interior Gateway Routing Protocol (EIGRP) protocols. These objects display the bandwidth metrics used for the route. Otherwise, these values are set to –1.
mplsL3VpnVrfRteXCPointet	This object is not supported. It returns an empty string.  The cross-connect index for the entry associated with the VRF route table entry is in the MPLS Cross-Connect table (mplsXCTable) in the MPLS-LSR-STD-MIB.
mplsL3VpnVrfRteInetCidrStatus	Status of the row. This object normally reads active (1), but may read notInService (2) if a VRF was recently deleted. A row entry cannot be modified when the row status is active (1).

## MPLS-L3VPN-STD-MIB Notification Events

The following notifications of the MPLS-L3VPN-STD-MIB are supported:

- **mplsL3VpnVrfUp**—This notification indicates that the VRF is up. It is generated and sent to an NMS when one interface associated with the VRF is brought up, after previously all interfaces were in the down state.
- **mplsL3VpnVrfDown**—This notification indicates that the VRF is down. It is generated and sent to the NMS when the last interface associated with the VRF is brought down, after all other interfaces associated with the VRF are already in the down state.
- **mplsL3VpnVrfRouteMidThreshExceeded**—This notification is generated and sent when the middle or warning threshold, **mplsL3VpnVrfMidRouteThreshold**, is crossed. You can configure this threshold in the CLI by using the following commands:

```
Router(config)# vrf definition vrf-name
Router(config-vrf)# address-family {ipv4 | ipv6}
Router(config-vrf-af)# maximum routes limit warn-threshold [% of max]
```

The *warn-threshold* argument is a percentage of the maximum routes specified by the *limit* argument. You can also configure a middle threshold with the following command, in which the *limit* argument represents the warning threshold:

```
Router(config-vrf-af)# maximum routes limit warn-only
```

This notification is sent to the NMS only at the time the threshold is exceeded. (See [Figure 6](#) for a comparison of the warning and maximum thresholds.) Whenever the number of routes falls below this threshold and exceeds the threshold again, a notification is sent to the NMS.

If both IPv4 and IPv6 address-family configurations are present in the VRF, the threshold is an aggregate of the warning threshold values. An **mplsL3VpnVrfRouteMidThreshExceeded** notification is not sent until the second address family reaches its warning threshold.

- **mplsL3VpnVrfNumVrfRouteMaxThreshExceeded**—This notification is generated and sent when you attempt to create a route on a VRF that already contains the maximum number of routes indicated by the **mplsL3VpnVrfMaxRouteThreshold** object. The maximum number of routes is defined by the *limit* argument of the **maximum routes** commands:

```
Router(config)# vrf definition vrf-name
Router(config-vrf)# address-family {ipv4 | ipv6}
Router(config-vrf-af)# maximum routes limit warn-threshold [% of max]
```

A trap notification is sent to the NMS when you attempt to exceed the maximum threshold. Another **mplsL3VpnVrfNumVrfRouteMaxThreshExceeded** notification is not sent until the number of routes falls below the maximum threshold and reaches the maximum threshold again or if the time interval is reached when the **mplsL3VpnVrfConfRteMxThreshTime** value is nonzero. (See [Figure 6](#) for an example of how this notification works and for a comparison of the maximum and warning thresholds.)

If an attempt is made to add routes beyond the route limit, SNMP sends a single notification. No other notification is sent until the route count drops below the route limit and another attempt is made to add routes beyond the limit.

However, if you configure the **snmp mib mpls vpn max-threshold time** command with a value other than 0 (0 is the default), SNMP repeats sending of the notification after the time interval passes if an attempt is made to add another route.

If both IPv4 and IPv6 address-family configurations are present in the VRF, the threshold is an aggregate of the maximum threshold values. An **mplsL3VpnVrfNumVrfRouteMaxThreshExceeded** notification is not sent until the second address family reaches its maximum route threshold. Routes are not added to the address family that has already reached its maximum route threshold.

#### Note

If both IPv4 and IPv6 address-family configurations are present in the VRF and one address family does not have a maximum threshold configured, no maximum threshold notification is sent.

- **mplsL3VpnNumVrfSecIlglLblThreshExcd**—This notification is generated and sent when the number of illegal labels received on a VRF interface as indicated by the **mplsL3VpnVrfSecIllegalLblVltns** value has exceeded the **mplsL3VpnIlglLblRcvThresh** value. This threshold is defined with a value of 0. Therefore, a notification is sent when the first illegal label is received on a VRF. Labels are considered illegal if they are outside of the valid label range, do not have a Label Forwarding Information Base (LFIB) entry, or the table ID of the message does not match the table ID for the label in the LFIB.
- **MplsL3VpnNumVrfRouteMaxThreshCleared**—Generated and sent when the number of routes on a VRF attempts to exceed the maximum number of routes and then drops below the maximum number of routes. If you attempt to create a route on a VRF that already contains the maximum number of routes, the **mplsL3VpnVrfNumVrfRouteMaxThreshExceeded** notification is sent (if enabled). When you remove routes from the VRF so that the number of routes falls below the set limit, the **MplsL3VpnNumVrfRouteMaxThreshCleared** notification is sent. You can clear all routes from the VRF by using the **clear ip route vrf** command for IPv4 routes and the **clear ipv6 route vrf** command for IPv6 routes. (See [Figure 6](#) to see when the **MplsL3VpnNumVrfRouteMaxThreshCleared** notification is sent.)

**Figure 6** Comparison of Warning and Maximum Thresholds

For information on the Cisco IOS CLI commands for configuring MPLS-L3VPN-STD-MIB notifications that are sent to an NMS, see the [“How to Configure MPLS EM—MPLS VPN MIB RFC 4382 Upgrade”](#) section on page 30.

## SNMP Notification Specification for the MPLS-L3VPN-STD-MIB

In an SNMPv1 notification, each MPLS Layer 3 VPN notification has a generic type identifier and an enterprise-specific type identifier for identifying the notification type:

- The generic type for all VPN notifications is “enterpriseSpecific” because this is not one of the generic notification types defined for SNMP.
- The enterprise-specific type is identified as follows:
  - 1 for mplsL3VpnVrfUp
  - 2 for mplsL3VpnVrfDown
  - 3 for mplsL3VpnVrfRouteMidThreshExceeded
  - 4 for mplsL3VpnVrfNumVrfRouteMaxThreshExceeded
  - 5 for mplsL3VpnNumVrfSecIllglLblThrshExcd
  - 6 for mplsL3VpnNumVrfRouteMaxThreshCleared

In SNMPv2, the notification type is identified by an SnmpTrapOID varbind (variable binding consisting of an object identifier [OID] type and value) included within the notification message:

- The VRF up and down notifications provide additional variables—mplsL3VpnIfConfRowStatus and mplsL3VpnVrfOperStatus—in the notification. These variables describe the SNMP row status and operational status, respectively.

- The mid threshold notification includes the `mplsL3VpnVrfVConfMidRteThresh` variable and the `mplsL3VpnVrfPerfCurrNumRoutes` variable that indicates the current number of routes within the VRF.
- The max threshold notification includes the `mplsL3VpnVrfVConfHighRteThresh` variable and the `mplsL3VpnVrfPerfCurrNumRoutes` variable that indicates the current number of routes within the VRF.
- The illegal label notification includes the `mplsL3VpnVrfSecIllegalLblVltns` variable that maintains the current count of illegal labels on a VPN.
- The max threshold cleared notification includes the `mplsL3VpnVrfConfHighRteThresh` variable and the `mplsL3VpnVrfPerfCurrNumRoutes` variable that indicates the current number of routes within the VRF.

## MPLS-L3VPN-STD-MIB Notifications Display on Network Management Station

When MPLS-L3VPN-STD-MIB notifications are enabled (see the **snmp-server enable traps mpls rfc vpn** command), notification messages relating to specific MPLS VPN events within Cisco IOS software are generated and sent to a specified NMS in the network. Any utility that supports SNMPv1 or SNMPv2 notifications can receive notification messages.

To monitor MPLS-L3VPN-STD-MIB notification messages, log in to an NMS that supports a utility that displays SNMP notifications, and start the display utility.

## MPLS-L3VPN-STD-MIB Support for IPv6 VPNs over MPLS

The following sections describe how the MPLS-L3VPN-STD-MIB supports IPv6 VPNs over MPLS (6VPE).

- [MPLS-L3VPN-STD-MIB Tables and Objects Support for IPv6 VPNs over MPLS, page 21](#)
- [MPLS-L3VPN-STD-MIB Notifications Support for IPv6 VPNs over MPLS, page 22](#)
- [Information About Setting Maximum Routes for IPv6 Address-Family VRF Route Limits, page 23](#)

## MPLS-L3VPN-STD-MIB Tables and Objects Support for IPv6 VPNs over MPLS

The MPLS-L3VPN-STD-MIB gets some of the information to populate the MIB objects from the RIB routing table. For the MPLS-L3VPN-STD-MIB to support IPv6 routes over MPLS, the MIB needs to access the RIB routing tables for both IPv6 and IPv4 for the VRF.

[Table 8](#) describes how the MPLS-L3VPN-STD-MIB supports the MIB tables and objects that are specified by address families or that require routing table information.

**Table 8** *MPLS-L3VPN-STD-MIB Support of Address Families in MIB Table and Objects*

MIB Tables and Objects	MPLS-L3VPN-STD-MIB Support
VRF route target table ( <code>mplsL3VpnVrfRTTable</code> )	<p>This table lists the route targets specified for the VRF. For IPv6 VPNs over MPLS, route targets can be specified for each address family.</p> <p>The MPLS-L3VPN-STD-MIB retrieves all route targets for IPv4, then retrieves all route targets specified for IPv6.</p> <p>The <code>mplsL3VpnVrfRTDescr</code> object indicates whether a particular route target was defined in an IPv4 or IPv6 address family.</p>

**Table 8** *MPLS-L3VPN-STD-MIB Support of Address Families in MIB Table and Objects (continued)*

MIB Tables and Objects	MPLS-L3VPN-STD-MIB Support
VRF configuration table (mplsL3VpnVrfTable), mplsL3VpnVrfConfMidRteThresh, mplsL3VpnVrfConfHighRteThresh, mplsL3VpnVrfConfMaxRoutes	<p>The Cisco IOS CLI allows the setting of maximum and middle threshold values on a per-address-family basis.</p> <p>When both IPv4 and IPv6 address-family configurations exist, the MPLS-L3VPN-STD-MIB displays the aggregate value of these settings (not to exceed the max int32 value). If the maximum route limit is configured for one address family and not for the other address family, the aggregate value is max int32 (4,294,967,295).</p> <p>When only a single address-family configuration exists for the VRF, the MPLS-L3VPN-STD-MIB displays the value as configured for the single address family. For more information on how the MPLS-L3VPN-STD-MIB supports notifications, see the <a href="#">“MPLS-L3VPN-STD-MIB Notifications Display on Network Management Station”</a> section on page 21 and the <a href="#">“MPLS-L3VPN-STD-MIB Notifications Support for IPv6 VPNs over MPLS”</a> section on page 22.</p>
VRF performance table (mplsL3VpnVrfPerfTable), mplsL3VpnVrfPerfRoutesAdded, mplsL3VpnVrfPerfRoutesDeleted, mplsL3VpnVrfPerfCurrNumRoutes, mplsL3VpnVrfPerfRoutesDropped	The MPLS-L3VPN-STD-MIB gets the routing table information from IPv4 and routing table information from IPv6, adds the values, and give a cumulative count for each of the VRF performance table objects.
VRF routing table (mplsL3VpnVrfRteTable)	<p>This table lists the routes associated with this VRF.</p> <p>The MPLS-L3VPN-STD-MIB needs to get all routes from both the IPv4 route table and IPv6 route table for the VRF.</p>
VPN interface configuration table (mplsL3VpnIfConfTable), mplsL3VpnIfVpnRouteDistProtocol	<p>This is a bit mask that indicates the protocol for the interface on which the VRF is defined. The MPLS-L3VPN-STD-MIB needs to get route table information from both the IPv4 address family and the IPv6 address family to look up the protocol and bits to set.</p> <p>This MPLS-L3VPN-STD-MIB information is a union of the IPv4 and IPv6 configurations in the VRF.</p>

## MPLS-L3VPN-STD-MIB Notifications Support for IPv6 VPNs over MPLS

This section explains how the MPLS-L3VPN-STD-MIB handles the mplsL3VpnVrfRouteMidThreshExceeded, mplsL3VpnVrfNumVrfRouteMaxThreshExceeded, and mplsL3VpnNumVrfRouteMaxThreshCleared notifications.

Notifications for exceeding the route limit for the middle (mplsL3VpnVrfRouteMidThreshExceeded) and maximum (mplsL3VpnVrfNumVrfRouteMaxThreshExceeded) thresholds are triggered by the route table when there is an attempt to add a new route after the number of routes has reached the threshold. With MIB support for both IPv6 and IPv4, two separate route tables could exist for the VRF. When the maximum or middle threshold is exceeded, MPLS-L3VPN-STD-MIB sends notifications to an NMS if you configured these thresholds.

MPLS-L3VPN-STD-MIB manages the maximum and middle thresholds based on an address-family configuration. For Cisco IOS Releases 12.2(33)SRC and 12.2(33)SB, the MPLS-L3VPN-STD-MIB triggers a notification (or trap) based on the aggregate of the IPv4 and IPv6 maximum and middle threshold values.

**Note**

A **maximum** command is introduced in Cisco IOS Release 12.2(33)SRC for the IPv6 address family.

The MPLS-L3VPN-STD-MIB manages the aggregate threshold values as described in the following scenarios:

- Scenario 1: One address family is configured (IPv4 or IPv6); the address family contains maximum and middle threshold configurations:
  - The aggregate max-threshold value is equal to the address family-specific max-route value.
  - The aggregate mid-threshold value is equal to the address family-specific mid-route value.
  - Address family routes stop adding to the routing table when the number of routes reaches the maximum threshold set for the address family. A notification or trap is sent with the next attempt to add a route.
- Scenario 2: Both IPv4 and IPv6 address families are configured; both contain maximum and middle threshold configurations:
  - The aggregate max-threshold value is equal to the sum of the IPv4 and IPv6 max-threshold values (with the upper limit set to a maximum value of 4,294,967,295).
  - The aggregate mid-threshold value is equal to the sum of the IPv4 and IPv6 mid-threshold values. Only when both address families have reached the mid-threshold limit is the notification sent.
  - Address family routes stop adding to the routing table when the number of routes reaches the maximum threshold per address family. A notification or trap is not sent until both IPv4 and IPv6 routes reach the maximum threshold.
- Scenario 3: Both IPv4 and IPv6 address families are configured; only one contains a maximum and middle route threshold configuration:
  - The aggregate max-threshold value is equal to the maximum threshold value (4,294,967,295).
  - The aggregate mid-threshold value is equal to the maximum threshold value (4,294,967,295).
  - Address family routes stop adding to the routing table for the address family that contains the maximum threshold configuration when the number of routes reaches the maximum threshold for the address family. However, no notification or trap is sent.

**Note**

If you configure a single address-family VRF with a maximum and middle threshold (Scenario 1), and later add the other address-family configuration to your VRF without configuring a maximum threshold (Scenario 3), you no longer receive a maximum threshold notification for the original address family when the threshold is reached, but routes would no longer be added to the routing table for this address family.

## Information About Setting Maximum Routes for IPv6 Address-Family VRF Route Limits

You should understand the following before you set maximum routes for the IPv6 address family:

- The **maximum routes** command is entered in address-family configuration mode (the **address-family ipv6** or **address-family ipv4** command) for the specified VRF.
- If you attempt to set the maximum route limit below the current number of routes in the IPv6 routing table for the VRF, the CLI command is rejected. You cannot downsize the IPv6 routing table.

If you configure a warning-only threshold, the command is accepted, but the route limit is not enforced. This statement also applies to IPv4.

- If the routing table has exceeded its route limit, the output from **show ipv6 route vrf** command displays an error message that indicates that the RIB has overflowed.
- If the routing table does not automatically recover from the overflow condition when the number of routes drops below the enforced limit, you would need to enter the **clear ipv6 route vrf** command. This forces the routing table to purge and repopulate.

If the repopulate is successful, then the error condition is cleared. If the automatic or manual purging and repopulate are unsuccessful, the error message in the **show ipv6 route vrf** command output remains.

- For Cisco IOS Releases 12.2(1st)SRC and 12.2(33)SB, the notifications generated in the MPLS-L3VPN-STD-MIB for the route maximum, middle, 3or warnings, and for threshold-cleared objects are an aggregate of the IPv4 and IPv6 route limits and route counts when both routing tables are configured for the VRF.

## MPLS-L3VPN-STD-MIB Data Security

Requirements of the network-facing operator and customers to ensure MPLS-L3VPN-STD-MIB data security are as follows:

- Network-facing operators need to poll all the data in the VRF-aware MPLS-L3VPN-STD-MIB without compromising security. Operators managing the network need to poll all available data in a single SNMP walk.
- Customers managing VRFs from an NMS need to be able to poll data only on VRFs for which they are responsible. Customer VRF information should be visible only to that particular customer. In the configuration example that follows, the customer associated with VRF vrf1 should see only VRF vrf1 information and the customer associated with VRF vrf2 should see only VRF vrf2 information.

Network operators can enter an **snmp-server community** command that contains an access control list (ACL) to make sure that all data is accessible in a single SNMP walk and that customer routers cannot access the data. For example, the operator can enter the following global configuration command: **snmp-server community any-community-name rw access-list acl-number**. The *acl-number* argument can be configured to allow requests from the PE network. This ensures that customer-facing routers cannot access any data using the specified community string.

To ensure that a customer's VRF information is secure, you can configure an SMNP context that is peculiar to the customer's VRF. For example, the following sample configuration ensures that the customer associated with VRF vrf1 and the customer associated with VRF vrf2 both connected to the same PE can access information pertaining only to their own VRF and nothing else:

```
!
vrf definition vrf1
  rd 100:110
  !
  address-family ipv4
    route-target export 100:1000
    route-target import 100:1000
  exit-address-family
!
vrf definition vrf2
  rd 100:120
  !
  address-family ipv4
```

```

route-target export 100:2000
route-target import 100:2000
exit-address-family
!
interface Ethernet3/1
  description Belongs to VPN vrf1
  vrf forwarding vrf1
  ip address 10.20.1.20 255.255.0.0

**Note**

The **snmp-server view** commands include mplsL3VpnMIB with OIDs in this format: **mplsL3VpnMIB.\*.\*.\*.\*.length-of-vrf-name.vrf-name-converted-to-octet-character-representation-of-the-name**. For example:

- VRF vrf1 would be represented as 3.114.101.100.
- VRF vrf2 would be represented as 5.103.114.101.101.110.

**Caution**

You should not enter the **snmp-server community *community-name* rw** command unless a firewall protects SNMP requests entered at the PE router. The community string is unprotected and can be used to poll any data from any network.

## Major Differences Between the MPLS-VPN-MIB and the MPLS-L3VPN-STD-MIB

The MPLS-L3VPN-STD-MIB based on RFC 4382 provides the same basic functionality as the MPLS-VPN-MIB, draft Version 3 (draft-ietf-ppvpn-mpls-vpn-mib-03.txt). They both provide an interface for MPLS Layer 3 VPNs through the use of SNMP.

After the implementation of the MPLS-L3VPN-STD-MIB (RFC 4382) in Cisco IOS Release 12.2(33)SRC, the MPLS-VPN-MIB will exist for a period of time before support is completely removed. This gives you the chance to migrate to the MPLS-L3VPN-STD-MIB. Both MIBs can coexist in the same image because the MPLS-L3VPN-STD-MIB and the MPLS-VPN-MIB have different root OIDs.

The following sections provide information about the major differences between the MPLS-VPN-MIB and the MPLS-L3VPN-STD-MIB:

- [Global Name Changes for the MPLS-L3VPN-STD-MIB Objects, page 26](#)

- [MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB Scalar Object Differences, page 26](#)
- [MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB Table Object Differences, page 26](#)
- [Tables Not Supported in the MPLS-L3VPN-STD-MIB, page 29](#)
- [MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB Notification Differences, page 29](#)

## Global Name Changes for the MPLS-L3VPN-STD-MIB Objects

For the MPLS-L3VPN-STD-MIB, the names of all objects were changed from `mplsVpnname` (MPLS-VPN-MIB object name) to `mplsL3Vpnname`. For example, the VRF configuration table name was changed from `mplsVpnVrfTable` to `mplsL3VpnVrfTable`.

The following sections describe major differences between the MPLS-VPN-MIB and the MPLS-L3VPN-STD-MIB objects where the name change is more significant than the global name change.

## MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB Scalar Object Differences

[Table 9](#) shows the major difference between the MPLS-VPN-MIB objects and the MPLS-L3VPN-STD-MIB objects for each scalar object.

**Table 9** *MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB Scalar Objects*

MPLS-VPN-MIB Object	MPLS-L3VPN-STD-MIB Object	Difference
<code>mplsVpnVrfConfMaxPossibleRoutes</code>	<code>mplsL3VpnVrfConfMaxPossRts</code>	Object name changed.
—	<code>mplsL3VpnVrfConfRteMxThrshTime</code>	New object.
—	<code>mplsL3VpIllLblRcvThrsh</code>	New object.

## MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB Table Object Differences

The following tables show the major differences between the MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB objects for each table.

### VRF Configuration Table (`mplsL3VpnVrfTable`)

[Table 10](#) shows the major differences between the MPLS-VPN-MIB objects and the MPLS-L3VPN-STD-MIB objects for the VRF configuration table (`mplsL3VpnVrfTable`, formerly `mplsVpnVrfTable`).

**Table 10** *VRF Configuration Table: MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB Object Differences*

MPLS-VPN-MIB Object	MPLS-L3VPN-STD-MIB Object	Difference
—	<code>mplsL3VpnVrfVpnId</code>	New object.
<code>mplsVpnVrfRouteDistinguisher</code>	<code>mplsL3VpnVrfRD</code>	Object name changed.
<code>mplsVpnVrfConfMidRouteThreshold</code>	<code>mplsL3VpnVrfConfMidRteThresh</code>	Object name changed.
<code>mplsVpnVrfConfHighRouteThreshold</code>	<code>mplsL3VpnVrfConfHighRteThresh</code>	Object name changed.
—	<code>mplsL3VpnVrfConfAdminStatus</code>	New object.

**VPN Interface Configuration Table (mplsL3VpnIfConfTable)**

Table 11 shows the major differences between the MPLS-VPN-MIB objects and the MPLS-L3VPN-STD-MIB objects for the VPN interface configuration table (mplsL3VpnIfConfTable, formerly mplsVpnInterfaceConfTable).

**Table 11** VPN Interface Configuration Table: MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB Object Differences

MPLS-VPN-MIB Object	MPLS-L3VPN-STD-MIB Object	Difference
mplsVpnInterfaceConfTable	mplsL3VpnIfConfTable	Table name changed.
mplsVpnInterfaceConfIndex	mplsL3VpnIfConfIndex	Object name changed.
mplsVpnInterfaceLabelEdgeType	—	Object deleted.
mplsVpnInterfaceVpnClassification	mplsL3VpnIfVpnClassification	Object name changed.
mplsVpnInterfaceVPNRouteDistProtocol	mplsL3VpnIfVpnRouteDist Protocol	Object name changed.
mplsVpnInterfaceConfStorageType	mplsL3VpnIfConfStorageType	Object name changed.
mplsVpnInterfaceConfRowStatus	mplsL3VpnIfConfRowStatus	Object name changed.

**VRF Route Target Table (mplsL3VpnVrfRTTable)**

Table 12 shows the major differences between the MPLS-VPN-MIB objects and the MPLS-L3VPN-STD-MIB objects for the VRF route target table (mplsL3VpnVrfRTTable, formerly mplsVpnVrfRouteTargetTable).

**Table 12** VRF Route Target Table: MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB Object Differences

MPLS-VPN-MIB Object	MPLS-L3VPN-STD-MIB Object	Difference
mplsVpnVrfRouteTargetTable	mplsL3VpnVrfRTTable	Table named changed.
mplsVpnVrfRouteTargetIndex	mplsL3VpnVrfRTIndex	Object name changed.
mplsVpnVrfRouteTargetType	mplsL3VpnVrfRTType	Object name changed.
mplsVpnVrfRouteTarget	mplsL3VpnVrfRT	Object name changed.
mplsVpnVrfRouteTargetDescr	mplsL3VpnVrfRTDescr	Object name changed.
mplsVpnVrfRouteTargetRowStatus	mplsL3VpnVrfRTRowStatus	Object name changed.
—	mplsL3VpnVrfRTStorageType	New object.

**VRF Security Table (mplsL3VpnVrfSecTable)**

Table 13 shows the major differences between the MPLS-VPN-MIB objects and the MPLS-L3VPN-STD-MIB objects for the VRF security table (mplsL3VpnVrfSecTable, formerly mplsVpnVrfSecTable).

**Table 13** VRF Security Table: MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB Object Differences

MPLS-VPN-MIB Object	MPLS-L3VPN-STD-MIB Object	Difference
mplsVpnVrfSecIllegalLabelViolations	mplsL3VpnVrfSecIllegalLblVtns	Object name changed.
mplsVpnVrfSecIllegalLabelRcvThresh	—	Object deleted.
—	mplsL3VpnVrfSecDiscontinuityTime	New object.

**VRF Performance Table (mplsL3VpnVrfPerfTable)**

Table 14 shows the major differences between the MPLS-VPN-MIB objects and the MPLS-L3VPN-STD-MIB objects for the VRF performance table (mplsL3VpnVrfPerfTable, formerly mplsVpnVrfPerfTable).

**Table 14** VRF Performance Table: MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB Object Differences

MPLS-VPN-MIB Object	MPLS-L3VPN-STD-MIB Object	Difference
—	mplsL3VpnVrfPerfRoutesDropped	New object.
—	mplsL3VpnVrfPerfDiscTime	New object.

**VRF Routing Table (mplsL3VpnVrfRteTable)**

Table 14 shows the major differences between the MPLS-VPN-MIB objects and the MPLS-L3VPN-STD-MIB objects for the VRF routing table (mplsL3VpnVrfRteTable, formerly mplsVpnVrfRouteTable).

The indexing for the VRF routing table has also changed:

- MPLS-VPN-MIB indexing—mplsVpnVrfName, mplsVpnVrfRouteDest, mplsVpnVrfRouteMask, mplsVpnVrfRouteTos, mplsVpnVrfRouteNextHop
- MPLS-L3VPN-STD-MIB indexing—mplsL3VpnVrfName, mplsL3VpnVrfRteInetCidrDestType, mplsL3VpnVrfRteInetCidrDest, mplsL3VpnVrfRteInetCidrPfxLen, mplsL3VpnVrfRteInetCidrPolicy, mplsL3VpnVrfRteInetCidrNHopType, mplsL3VpnVrfRteInetCidrNextHop

**Table 15** VRF Routing Table: MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB Object Differences

MPLS-VPN-MIB Object	MPLS-L3VPN-STD-MIB Object	Difference
mplsVpnVrfRouteTable	mplsL3VpnVrfRteTable	Table name changed.
mplsVpnVrfRouteDest	mplsL3VpnVrfRteInetCidrDest	Object name changed.
mplsVpnVrfRouteDestAddrType	mplsL3VpnVrfRteInetCidrDestType	Object name changed.
mplsVpnVrfRouteMask	—	Object deleted.
mplsVpnVrfRouteMaskAddrType	—	Object deleted.
—	mplsL3VpnVrfRteInetCidrPfxLen	New object.
mplsVpnVrfRouteTos	—	Object deleted.
—	mplsL3VpnVrfRteInetCidrPolicy	New object.
mplsVpnVrfRouteNextHop	mplsL3VpnVrfRteInetCidrNextHop	Object name changed.
mplsVpnVrfRouteNextHopAddrType	mplsL3VpnVrfRteInetCidrNHopType	Object name changed.
mplsVpnVrfRouteIfIndex	mplsL3VpnVrfRteInetCidrIfIndex	Object name changed.
mplsVpnVrfRouteType	mplsL3VpnVrfRteInetCidrType	Object name changed.
mplsVpnVrfRouteProto	mplsL3VpnVrfRteInetCidrProto	Object name changed.
mplsVpnVrfRouteAge	mplsL3VpnVrfRteInetCidrAge	Object name changed.
mplsVpnVrfRouteInfo	—	Object deleted.
mplsVpnVrfRouteNextHopAS	mplsL3VpnVrfRteInetCidrNextHopAS	Object name changed.

**Table 15** VRF Routing Table: MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB Object Differences (continued)

MPLS-VPN-MIB Object	MPLS-L3VPN-STD-MIB Object	Difference
mplsVpnVrfRouteMetric1	mplsL3VpnVrfRteInetCidrMetric1	Object name changed.
mplsVpnVrfRouteMetric2	mplsL3VpnVrfRteInetCidrMetric2	Object name changed.
mplsVpnVrfRouteMetric3	mplsL3VpnVrfRteInetCidrMetric3	Object name changed.
mplsVpnVrfRouteMetric4	mplsL3VpnVrfRteInetCidrMetric4	Object name changed.
mplsVpnVrfRouteMetric5	mplsL3VpnVrfRteInetCidrMetric5	Object name changed.
—	mplsL3VpnVrfRteXCPointer	New object.
mplsVpnVrfRouteStatus	mplsL3VpnVrfRteInetCidrStatus	Object name changed.
mplsVpnVrfRouteStorageType	—	Object deleted.

## Tables Not Supported in the MPLS-L3VPN-STD-MIB

The following tables from the MPLS-VPN-MIB are deleted in the MPLS-L3VPN-STD-MIB (RFC 4382):

- BGP neighbor address table (mplsVpnVrfBgpNbrAddrTable)
- BGP neighbor prefix table (mplsVpnVrfBgpNeighborPrefixTable)

The mplsVpnVrfBgpNeighborPrefixTable was not supported in the Cisco IOS implementation of the MPLS-VPN-MIB.

The Cisco-BGP4-MIB based on *Definitions of Managed Objects for BGP-4* (RFC 4273) provides the information related to BGP.

## MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB Notification Differences

Table 16 shows the major differences between MPLS-VPN-MIB and the MPLS-L3VPN-STD-MIB notifications.

**Table 16** MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB Notification Differences

MPLS-VPN-MIB Notification	MPLS-L3VPN-STD-MIB Notification	Difference
mplsVpnVrfIfUp	—	Notification deleted.
mplsVpnVrfIfDown	—	Notification deleted.
—	mplsL3VpnVrfUp	New notification.
—	mplsL3VpnVrfDown	New notification.
mplsNumVrfRouteMidThreshExceeded	mplsL3VpnVrfRouteMidThreshExceeded	Returned objects changed. Notification name change.
mplsNumVrfRouteMaxThreshExceeded	mplsL3VpnVRFNumVrfRouteMaxThreshExceeded	Returned objects changed. Notification name change.

**Table 16** *MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB Notification Differences (continued)*

MPLS-VPN-MIB Notification	MPLS-L3VPN-STD-MIB Notification	Difference
mplsNumVrfSecIllegalLabelThreshExceeded	mplsL3VpnNumVrfSecIllegalLblThreshExcd	Returned objects changed. Notification name change.
cMplsNumVrfRouteMaxThreshCleared (from the CISCO-IETF-PPVPN-MPLS-VPN-MIB)	mplsL3VpnNumVrfRouteMaxThreshCleared	Notification name changed.

## How to Configure MPLS EM—MPLS VPN MIB RFC 4382 Upgrade

This section contains tasks to configure the MPLS EM—MPLS VPN MIB RFC 4382 Upgrade feature. The MPLS EM—MPLS VPN MIB RFC 4382 Upgrade feature introduces the MPLS-L3VPN-STD-MIB. Perform the following tasks to configure your router to use SNMP to monitor and manage MPLS Layer 3 VPNs:

- [Configuring the SNMP Community, page 30](#) (required)
- [Configuring the Router to Send MPLS Layer 3 VPN SNMP Notifications to a Host, page 32](#) (optional)
- [Configuring Threshold Values for MPLS Layer 3 VPN SNMP Notifications, page 35](#) (optional)
- [Configuring SMNP Controls for MPLS Layer 3 VPN Notification Thresholds: Examples, page 39](#) (optional)

### Configuring the SNMP Community

The SNMP agent for the MPLS-L3VPN-STD-MIB is disabled by default and must be enabled for you to use SNMP for monitoring and managing MPLS Layer 3 VPNs on your network.

An SNMP community string defines the relationship between the SNMP manager and the agent. The community string acts like a password to regulate access to the agent on the router.

Perform this task to configure an SNMP community.

#### SUMMARY STEPS

1. **enable**
2. **show running-config**
3. **configure terminal**
4. **snmp-server community** *string* [**view** *view-name*] [**ro** | **rw**] [*acl-number*]
5. **do copy running-config startup-config**
6. **exit**
7. **show running-config** | **include** *[option]*

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>show running-config</b>  <b>Example:</b> Router# show running-config	Displays the running configuration to determine if an SNMP agent is already running.  If no SNMP information is displayed, continue with the next step.  If any SNMP information is displayed, you can modify the information or change it as needed.
Step 3	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 4	<b>snmp-server community</b> <i>string</i> [ <b>view</b> <i>view-name</i> ] [ <b>ro</b>   <b>rw</b> ] [ <i>acl-number</i> ]  <b>Example:</b> Router(config)# snmp-server community comaccess ro	Configures the community access string to permit access to the SNMP protocol. <ul style="list-style-type: none"> <li>The <i>string</i> argument acts like a password and permits access to the SNMP protocol.</li> <li>The <b>view</b> <i>view-name</i> keyword and argument pair specifies the name of a previously defined view. The view defines the objects available to the community.</li> <li>The <b>ro</b> keyword specifies read-only access. Authorized management stations are able to retrieve only MIB objects.</li> <li>The <b>rw</b> keyword specifies read/write access. Authorized management stations are able to both retrieve and modify MIB objects.</li> <li>The <i>acl-number</i> argument is an integer from 1 to 99 that specifies an access list of IP addresses that are allowed to use the community string to gain access to the SNMP agent.</li> </ul>
Step 5	<b>do copy running-config startup-config</b>  <b>Example:</b> Router(config)# do copy running-config startup-config	Saves the modified configuration to NVRAM as the startup configuration file. <ul style="list-style-type: none"> <li>The <b>do</b> command allows you to perform EXEC-level commands in configuration mode.</li> </ul>

	Command or Action	Purpose
Step 6	<b>exit</b>  <b>Example:</b> Router(config)# exit	Returns to privileged EXEC mode.
Step 7	<b>show running-config   include [option]</b>  <b>Example:</b> Router# show-running config   include snmp-server	(Optional) Displays the configuration information currently on the router, the configuration for a specific interface, or map-class information.  <ul style="list-style-type: none"> <li>Use the <b>show running-config</b> command to confirm that the <b>snmp-server</b> statements appear in the output.</li> </ul>

## Configuring the Router to Send MPLS Layer 3 VPN SNMP Notifications to a Host

Perform this task to configure the router to send MPLS Layer 3 VPN SNMP notifications or traps to a host.

The **snmp-server host** command specifies which hosts receive the notifications. The **snmp-server enable traps** command globally enables the trap production mechanism for the specified notifications.

For a host to receive a notification, an **snmp-server host** command must be configured for that host, and, generally, the notification must be enabled globally through the **snmp-server enable traps** command.

### Note

Although you can set the *community-string* argument using the **snmp-server host** command by itself, we recommend you define this string using the **snmp-server community** command before using the **snmp-server host** command.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server host** *host-addr* [**traps** | **informs**] [**version** {**1** | **2c** | **3** [**auth** | **noauth** | **priv**]}] *community-string* [**udp-port** *port*] [*notification-type*] [**vrf** *vrf-name*]
4. **snmp-server enable traps mpls rfc vpn** [**illegal-label**] [**max-thresh-cleared**] [**max-threshold**] [**mid-threshold**] [**vrf-down**] [**vrf-up**]
5. **end**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><b>enable</b></p> <p><b>Example:</b> Router&gt; enable</p>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<p><b>configure terminal</b></p> <p><b>Example:</b> Router# configure terminal</p>	<p>Enters global configuration mode.</p>
Step 3	<p><b>snmp-server host</b> <i>host-addr</i> [<b>traps</b>   <b>informs</b>] [<b>version</b> {<b>1</b>   <b>2c</b>   <b>3</b> [<b>auth</b>   <b>noauth</b>   <b>priv</b>]}] <i>community-string</i> [<b>udp-port</b> <i>port</i>] [<i>notification-type</i>] [<b>vrf</b> <i>vrf-name</i>]</p> <p><b>Example:</b> Router(config)# snmp-server host 172.20.2.160 traps comaccess mpls-vpn</p>	<p>Specifies the recipient of an SNMP notification operation.</p> <ul style="list-style-type: none"> <li>The <i>host-addr</i> argument specifies the name or Internet address of the host (the targeted recipient).</li> <li>The <b>traps</b> keyword sends SNMP traps to this host. This is the default.</li> <li>The <b>informs</b> keyword sends SNMP informs to this host.</li> <li>The <b>version</b> keyword specifies the version of the SNMP used to send the traps. Version 3 is the most secure model, because it allows packet encryption with the <b>priv</b> keyword. If you use the <b>version</b> keyword, you must specify one of the following: <ul style="list-style-type: none"> <li><b>1</b> —SNMPv1. This option is not available with informs.</li> <li><b>2c</b> —SNMPv2C.</li> <li><b>3</b> —SNMPv3. The following three optional keywords can follow the <b>version 3</b> keyword: <b>auth</b>, <b>noauth</b>, <b>priv</b>.</li> </ul> </li> <li>The <i>community-string</i> argument is a password-like community string sent with the notification operation.</li> <li>The <b>udp-port</b> <i>port</i> keyword and argument pair names the User Datagram Protocol (UDP) port of the host to use. The default is 162.</li> <li>The <i>notification-type</i> argument specifies the type of notification to be sent to the host. If no type is specified, all notifications are sent.</li> <li>The <b>vrf</b> <i>vrf-name</i> keyword and argument pair specifies the VRF table that should be used to send SNMP notifications.</li> </ul>

Command or Action	Purpose
<p><b>Step 4</b></p> <pre>snmp-server enable traps mpls rfc vpn [illegal-label] [max-thresh-cleared] [max-threshold] [mid-threshold] [vrf-down] [vrf-up]</pre> <p><b>Example:</b></p> <pre>Router(config)# snmp-server enable traps mpls rfc vpn vrf-down vrf-up</pre>	<p>Enables the router to send MPLS Layer 3 VPN-specific SNMP notifications (traps and informs).</p> <ul style="list-style-type: none"> <li>The <b>illegal-label</b> keyword enables a notification for any illegal labels received on a VRF interface. Labels are illegal if they are outside the legal range, do not have an LFIB entry, or do not match table IDs for the label.</li> <li>The <b>max-thresh-cleared</b> keyword enables a notification when the number of routes falls below the limit after the maximum route limit was attempted.</li> </ul> <p><b>Note</b> For information on notifications if a VRF has both IPv4 and IPv6 address-family configurations, see the <a href="#">“MPLS-L3VPN-STD-MIB Notifications Support for IPv6 VPNs over MPLS”</a> section on page 22.</p> <ul style="list-style-type: none"> <li>The <b>max-threshold</b> keyword enables a notification that a route creation attempt was unsuccessful because the maximum route limit was reached. Another <code>mplsL3VpnVrfNumVrfRouteMaxThreshExceeded</code> notification is not sent until the number of routes falls below the maximum threshold and reaches the maximum threshold again. The max-threshold value is determined by the <b>maximum routes</b> command in VRF configuration mode.</li> </ul> <p><b>Note</b> For more information on the maximum threshold notification if both IPv4 and IPv6 address family configurations are present in the VRF, see the <a href="#">“MPLS-L3VPN-STD-MIB Notifications Support for IPv6 VPNs over MPLS”</a> section on page 22.</p> <ul style="list-style-type: none"> <li>The <b>mid-threshold</b> keyword enables a notification of a warning that the number of routes created has crossed the warning threshold. This warning is sent only at the time the warning threshold is exceeded.</li> </ul> <p><b>Note</b> For more information on the maximum threshold notification if both IPv4 and IPv6 address family configurations are present in the VRF, see the <a href="#">“MPLS-L3VPN-STD-MIB Notifications Support for IPv6 VPNs over MPLS”</a> section on page 22.</p> <ul style="list-style-type: none"> <li>The <b>vrf-down</b> keyword enables a notification when the last interface in a VRF goes from the up state to the down state.</li> <li>The <b>vrf-up</b> keyword enables a notification when all interfaces in a VRF are previously in a down state and one VRF interface goes to the up state.</li> </ul>

	Command or Action	Purpose
Step 5	<pre>end</pre> <p><b>Example:</b>  <pre>Router(config)# end</pre></p>	(Optional) Exits to privileged EXEC mode.

## Configuring Threshold Values for MPLS Layer 3 VPN SNMP Notifications

Perform this task to configure the following threshold values for MPLS Layer 3 VPN SNMP notifications:

- The `mplsL3VpnVrfRouteMidThreshExceeded` notification event is generated and sent when the middle threshold (warning) is crossed. You can configure this threshold in the CLI by using the **maximum routes** command in VRF configuration mode. This notification is sent to the NMS only at the time the threshold is exceeded. Whenever the number of routes falls below this threshold and exceeds the threshold again, a notification is sent to the NMS.

If both IPv4 and IPv6 address-family configurations are present in the VRF, the threshold is an aggregate of the warning threshold values. An `mplsL3VpnVrfRouteMidThreshExceeded` notification is not sent until the second address family reaches its warning threshold.

- The `mplsL3VpnVrfNumVrfRouteMaxThreshExceeded` notification event is generated and sent when you attempt to create a route on a VRF that already contains the maximum number of routes as defined by the **maximum routes** command in VRF configuration mode. A trap notification is sent to the NMS when you attempt to exceed the maximum threshold. Another `mplsL3VpnVrfNumVrfRouteMaxThreshExceeded` notification is not sent until the number of routes falls below the maximum threshold and reaches the maximum threshold again.

If both IPv4 and IPv6 address-family configurations are present in the VRF, the threshold is an aggregate of the maximum threshold values. An `mplsL3VpnVrfNumVrfRouteMaxThreshExceeded` notification is not sent until the second address family reaches its maximum route threshold. Routes are not added to the address family that has already reached its maximum route threshold.

See [Figure 6](#) for an example of how this notification works and for a comparison of the maximum and warning thresholds.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **vrf definition** *vrf-name*
4. **address-family** {*ipv4* | *ipv6*}
5. **maximum routes** *limit warn-threshold*  
or  
**maximum routes** *limit warn-only*
6. **exit-address-family**
7. **end**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>vrf definition</b> <i>vrf-name</i>  <b>Example:</b> Router(config)# vrf definition vpn1	Configures a VRF routing table and enters VRF configuration mode. <ul style="list-style-type: none"> <li>The <i>vrf-name</i> argument specifies the name assigned to a VRF.</li> </ul>
Step 4	<b>address-family</b> { <i>ipv4</i>   <i>ipv6</i> }  <b>Example:</b> Router(config-vrf) address-family ipv4	Enters VRF address family configuration mode. <ul style="list-style-type: none"> <li>The <b>ipv4</b> keyword specifies an address family for an IPv4 VPN.</li> <li>The <b>ipv6</b> keyword specifies an address family for an IPv6 VPN.</li> </ul>
Step 5	<b>maximum routes</b> <i>limit</i> <i>warn-threshold</i>  <b>Example:</b> Router(config-vrf-af)# maximum routes 10000 80 or <b>maximum routes</b> <i>limit</i> <b>warn-only</b>  <b>Example:</b> Router(config-vrf-af)# maximum routes 10000 warn-only	Limits the maximum number of routes in a VRF to prevent a PE router from importing too many routes. <ul style="list-style-type: none"> <li>The <i>limit</i> argument specifies the maximum number of routes allowed in a VRF. The range is from 1 to 4,294,967,295.</li> <li>The <i>warn-threshold</i> argument generates a warning when the number of routes set by the <i>warn-threshold</i> argument is reached and rejects routes that exceed the maximum number set in the <i>limit</i> argument. The warning threshold is a percentage from 1 to 100 of the maximum number of routes specified in the <i>limit</i> argument.</li> <li>The <b>warn-only</b> keyword specifies that a system message logging (syslog) error message is issued when the maximum number of routes allowed for a VRF exceeds the limit threshold. However, additional routes are still allowed.</li> </ul>
Step 6	<b>exit-address-family</b>  <b>Example:</b> Router(config-vrf-af)# exit-address-family	Exits from VRF address family configuration mode.
Step 7	<b>end</b>  <b>Example:</b> Router(config-vrf)# end	(Optional) Exits to privileged EXEC mode.

## Configuring SNMP Controls for MPLS VPN Notification Thresholds

Perform this task to configure the following SNMP controls for MPLS VPN notification thresholds:

- The `mplsL3VpnVrfConfRteMxThrshTime` is the interval at which the maximum route exceeded notification (`mplsL3VpnVrfNumVrfRouteMaxThreshExceeded`) is reissued after the maximum value is exceeded (or reached) and after the initial notification was sent. You can configure this interval in the CLI by using the **`snmp mib mpls vpn max-threshold`** *seconds* command in global configuration mode. Configure this command if you want to receive more than the initial notification that the maximum route value is exceeded.
- The `mplsL3VpnNumVrfSecIlglLblThrshExcd` notification is generated and sent when the number of illegal label violations on a VRF has exceeded the number indicated by the `mplsL3VpnIlglLblRcvThrsh` scalar. You can configure the number of illegal labels that generate the `mplsL3VpnNumVrfSecIlglLblThrshExcd` notification in the CLI by using the **`snmp mib mpls vpn illegal-label`** *number* command in global configuration mode. Configure this command if you want to allow a certain number of illegal label violations before you receive the `mplsL3VpnNumVrfSecIlglLblThrshExcd` notification.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **`snmp mib mpls vpn max-threshold`** *seconds*
4. **`snmp mib mpls vpn illegal-label`** *number*
5. **end**

### DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>	Enables privileged EXEC mode.
	<b>Example:</b> Router> enable	<ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>	Enters global configuration mode.
	<b>Example:</b> Router# configure terminal	
Step 3	<b><code>snmp mib mpls vpn max-threshold</code></b> <i>seconds</i>	Configures SNMP controls for MPLS VPN notification thresholds.
	<b>Example:</b> Router(config)# snmp mib mpls vpn max-threshold 3600	<ul style="list-style-type: none"> <li>• The <b><code>max-threshold</code></b> keyword controls MPLS VPN maximum threshold exceeded notifications.</li> <li>• The <i>seconds</i> argument is the time in seconds before SNMP resends maximum threshold notifications. The valid range is from 0 to 4,294,967,295. The default is 0.</li> </ul>

	Command or Action	Purpose
Step 4	<pre>snmp mib mpls vpn illegal-label number</pre> <p><b>Example:</b>  Router(config)# snmp mib mpls vpn illegal-label 10</p>	<p>Configures simple SNMP controls for MPLS VPN notification thresholds.</p> <ul style="list-style-type: none"> <li>The <b>illegal-label</b> keyword controls MPLS VPN illegal label threshold exceeded notifications.</li> <li>The <i>number</i> argument is the number of illegal labels allowed before SNMP sends an illegal label threshold notification. The valid range is from 1 to 4,294,967,295. The default is 0.</li> </ul>
Step 5	<pre>end</pre> <p><b>Example:</b>  Router(config)# end</p>	<p>Exits to privileged EXEC mode.</p>

## Configuration Examples for MPLS EM—MPLS VPN MIB RFC 4382 Upgrade

This section contains the following configuration examples for the MPLS EM—MPLS VPN MIB RFC 4382 Upgrade feature:

- [Configuring the SNMP Community: Examples, page 38](#)
- [Configuring the Router to Send MPLS Layer 3 VPN SNMP Traps: Example, page 39](#)
- [Configuring Threshold Values for MPLS Layer 3 VPN SNMP Notifications: Examples, page 39](#)
- [Configuring SMNP Controls for MPLS Layer 3 VPN Notification Thresholds: Examples, page 39](#)

### Configuring the SNMP Community: Examples

The following example shows enabling a simple SNMP community group. This configuration permits any SNMP client to access all MPLS-L3VPN-STD-MIB objects with read-only access using the community string comaccess.

```
configure terminal
!
snmp-server community comaccess ro
```

Use the following command to verify that the SNMP master agent is enabled for the MPLS EM—MPLS VPN MIB RFC 4382 Upgrade feature:

```
Router# show running-config | include snmp-server
```

```
Building configuration...
....
snmp-server community comaccess RO
....
```

#### Note

If you do not see any “snmp-server” statements, SNMP is not enabled on the router.

## Configuring the Router to Send MPLS Layer 3 VPN SNMP Traps: Example

The following example shows you how to enable the router to send MPLS Layer 3 VPN notifications to host 172.20.2.160 using the comaccess community string if a VRF transitions from an up or down state:

```
configure terminal
!
snmp-server host 172.20.2.160 traps comaccess mpls-vpn
snmp-server enable traps mpls rfc vpn vrf-down vrf-up
```

## Configuring Threshold Values for MPLS Layer 3 VPN SNMP Notifications: Examples

The following example shows how to set a maximum threshold of 10,000 routes and a warning threshold that is 80 percent of the maximum threshold for a VRF named vpn1 on a router:

```
configure terminal
!
vrf definition vpn1
 address-family ipv4
  maximum routes 10000 80
 exit address-family
end
```

The following example shows how to set a warning threshold of 10,000 routes for a VRF named vpn2 on a router. An error message is generated; however, additional routes are still allowed because a maximum route threshold is not set with this command.

```
configure terminal
!
vrf definition vpn2
 address-family ipv4
  maximum routes 10000 warn-only
 exit address-family
end
```

## Configuring SNMP Controls for MPLS Layer 3 VPN Notification Thresholds: Examples

The following examples show how to configure SNMP controls for MPLS Layer 3 VPN notification thresholds.

In this example, an interval of 2 hours (7200 seconds) is configured for the resending of maximum threshold exceeded notifications after the first notification was sent and the attempt to add routes continues:

```
configure terminal
!
snmp mib mpls vpn max-threshold 7200
end
```

If you do not configure an interval to resend maximum route exceeded notifications, SNMP sends a single maximum threshold notification at the time that the maximum threshold is exceeded.

In the following example, the number of illegal labels allowed for a VRF is configured as 5 before SNMP sends an illegal label threshold exceeded notification:

## Additional References

```
configure terminal
!
snmp mib mpls vpn illegal-label 5
end
```

If you do not configure an illegal label threshold, then SNMP sends an illegal label notification on the first occurrence of an illegal label.

## Additional References

# Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Multiprotocol Label Switching Command Reference* at [http://www.cisco.com/en/US/docs/ios/mpls/command/reference/mp\\_book.html](http://www.cisco.com/en/US/docs/ios/mpls/command/reference/mp_book.html). For information about all Cisco IOS commands, go to the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or to the *Cisco IOS Master Commands List*.

- **maximum routes**
- **snmp mib mpls vpn**
- **snmp-server enable traps mpls rfc vpn**

# Feature Information for MPLS EM—MPLS VPN MIB RFC 4382 Upgrade

Table 17 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Note

Table 17 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 17** Feature Information for MPLS EM—MPLS VPN MIB RFC 4382 Upgrade

Feature Name	Releases	Feature Information
MPLS EM—MPLS VPN MIB RFC 4382 Upgrade	12.2(33)SRC 12.2(33)SB	<p>The MPLS EM—MPLS VPN MIB RFC 4382 Upgrade feature document describes the MIB that supports Multiprotocol Label Switching (MPLS) Virtual Private Networks (VPNs) based on RFC 4382, <i>MPLS/BGP Virtual Private Network (VPN) Management Information Base</i>. This document also describes the differences between RFC 4382 and the MPLS-VPN-MIB based on the Internet Engineering Task Force (IETF) draft Version 3 (draft-ietf-ppvpn-mpls-vpn-mib-03.txt) and describes the changes needed to implement MPLS-L3VPN-STD-MIB (RFC 4382). The MPLS-VPN-MIB and MPLS-L3VPN-STD-MIB provide an interface for managing the MPLS VPN feature in Cisco IOS software through the use of the Simple Network Management Protocol (SNMP).</p> <p>Cisco IOS MPLS Embedded Management (EM) is a set of standards and value-added services that facilitate the deployment, operation, administration, and management of MPLS-based networks according to the fault, configuration, accounting, performance, and security (FCAPS) model.</p> <p>In 12.2(33)SRC, this feature was introduced on the Cisco 7600 series router.</p> <p>In 12.2(33)SB, the feature was implemented for the Cisco 10000 series router on the Cisco 10000 Performance Routing Engine 2 (PRE-2) and PRE-3.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">MPLS Layer 3 VPN Overview, page 3</a></li> </ul>

# Glossary

**6VPE router**—Provider edge router that provides BGP-MPLS IPv6 VPN service over an IPv4-based MPLS core. It is a IPv6 VPN PE, dual-stack router that implements 6PE concepts on the core-facing interfaces.

**autonomous system**—A collection of networks that share the same routing protocol and that are under the same system administration.

**ASN.1**—Abstract Syntax Notation One. The data types independent of particular computer structures and representation techniques. Described by ISO International Standard 8824.

**BGP**—Border Gateway Protocol. The exterior Border Gateway Protocol used to exchange routing information between routers in separate autonomous systems. BGP uses TCP. Because TCP is a reliable protocol, BGP does not experience problems with dropped or fragmented data packets.

**BGP prefixes**—A route announcement using the BGP. A prefix is composed of a path of autonomous system numbers, indicating which networks the packet must pass through, and the IP block that is being routed. A BGP prefix would look something like: 701 1239 42 206.24.14.0/24. (The /24 part is referred to as a CIDR mask.) The /24 indicates that there are 24 ones in the netmask for this block starting from the left side. A /24 corresponds to the natural mask 255.255.255.0.

**CE router**—customer edge router. A router on the border between a VPN provider and a VPN customer that belongs to the customer.

**CIDR**—classless interdomain routing. A technique supported by BGP4 and based on route aggregation. CIDR allows routers to group routes to reduce the quantity of routing information carried by the core routers. With CIDR, several IP networks appear to networks outside the group as a single, larger entity. With CIDR, IP addresses and their subnet masks are written as four octets, separated by periods, followed by a forward slash and a two-digit number that represents the subnet mask.

**Cisco Express Forwarding**—An advanced Layer 3 IP switching technology. Cisco Express Forwarding optimizes network performance and scalability for networks with large and dynamic traffic patterns.

**community**—In SNMP, a logical group of managed devices and NMSs in the same administrative domain.

**community name**—*See* community string.

**community string**—A text string that acts as a password and is used to authenticate messages sent between a managed station and a router containing an SNMP agent. The community string is sent in every packet between the manager and the client. Also called a community name.

**IETF**—Internet Engineering Task Force. A task force consisting of over 80 working groups responsible for developing Internet standards. The IETF operates under the auspices of ISOC. *See also* ISOC.

**informs**—A type of notification message that is more reliable than a conventional trap notification message, because the informs message notification requires acknowledgment, and a trap notification does not.

**ISOC**—Internet Society. An international nonprofit organization, founded in 1992, that coordinates the evolution and use of the Internet. In addition, ISOC delegates authority to other groups related to the Internet, such as the IAB. ISOC is headquartered in Reston, Virginia (United States).

**label**—A short, fixed-length data construct that tells switching nodes how to forward data (packets or cells).

**LDP**—Label Distribution Protocol. A standard protocol between MPLS-enabled routers that is used for the negotiation of the labels (addresses) used to forward packets.

**LFIB**—Label Forwarding Information Base. In the Cisco Label Switching system, the data structure for storing information about incoming and outgoing tags (labels) and associated equivalent packets suitable for labeling.

**LSR**—label switch router. A device that forwards MPLS packets based on the value of a fixed-length label encapsulated in each packet.

**MIB**—Management Information Base. A database of network management information that is used and maintained by a network management protocol such as SNMP or CMIP. The value of a MIB object can be changed or retrieved using SNMP or CMIP commands, usually through a GUI network management system. MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

**MPLS**—Multiprotocol Label Switching. A method for forwarding packets (frames) through a network. It enables routers at the edge of a network to apply labels to packets (frames). ATM switches or existing routers in the network core can switch packets according to the labels with minimal lookup overhead.

**MPLS interface**—An interface on which MPLS traffic is enabled.

**MPLS VPN**—Multiprotocol Label Switching Virtual Private Network. An IP network infrastructure delivering private network services over a public infrastructure using a Layer 3 backbone. Using MPLS VPNs in a Cisco IOS network provides the capability to deploy and administer scalable Layer 3 VPN backbone services including applications, data hosting network commerce, and telephony services to business customers.

For an MPLS VPN solution, an MPLS VPN is a set of provider edge routers that are connected by means of a common “backbone” network to supply private IP interconnectivity between two or more customer sites for a given customer. Each VPN has a set of provisioning templates and policies and can span multiple provider administrative domains (PADs).

**NMS**—network management system. A powerful, well-equipped computer (typically an engineering workstation) that is used by a network administrator to communicate with other devices in the network. An NMS is typically used to manage network resources, gather statistics, and perform a variety of network administration and configuration tasks.

**notification**—A message sent by an SNMP agent to a network management station, console, or terminal to indicate that a significant event within Cisco IOS software has occurred. *See also* trap.

**PE router**—provider edge router. A router on the border between a VPN provider and a VPN customer that belongs to the provider.

**QoS**—quality of service. A measure of performance for a transmission system that reflects its transmission quality and service availability.

**RIB**—Routing Information Base. Also called the routing table.

**RT**—route target. An extended community attribute that identifies a group of routers and, in each router of that group, a subset of forwarding tables maintained by the router that can be populated with a BGP route carrying that extended community attribute. The RT is a 64-bit value by which Cisco IOS software discriminates routes for route updates in VRFs.

**SNMP**—Simple Network Management Protocol. The network management protocol used almost exclusively in TCP/IP networks. SNMP provides a means to monitor and control network devices, and to manage configurations, statistics collection, performance, and security. *See also* SNMP2.

**SNMP2**—SNMP Version 2. Version 2 of the popular network management protocol. SNMP2 supports centralized and distributed network management strategies, and includes improvements in the Structure of Management Information (SMI), protocol operations, management architecture, and security. *See also* SNMP.

**trap**—A message sent by an SNMP agent to a network management station, console, or terminal, indicating that a significant event occurred. Traps (notifications) are less reliable than inform requests, because the receiver does not send an acknowledgment when it receives a trap. The sender cannot determine if the trap was received. *See also* notification.

**VPN**—Virtual Private Network. A group of sites that, as the result of a set of administrative policies, are able to communicate with each other over a shared backbone network. A VPN is a secure IP-based network that shares resources on one or more physical networks. A VPN contains geographically dispersed sites that can communicate securely over a shared backbone. *See also* MPLS VPN.

**VPN ID**—A mechanism that identifies a VPN based on RFC 2685. A VPN ID consists of an Organizational Unique Identifier (OUI), a three-octet hex number assigned by the IEEE Registration Authority, and a VPN index, a four-octet hex number, which identifies the VPN within the company.

**VRF**—VPN routing and forwarding instance. A VRF consists of an IP routing table, a derived forwarding table, a set of interfaces that use the forwarding table, and a set of rules and routing protocols that determine what goes into the forwarding table. In general, a VRF includes the routing information that defines a customer VPN site that is attached to a PE router.

# Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services

---

**First Published: August 25, 2004**

**Last Updated: February 27, 2009**

The Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services feature provides Simple Network Management Protocol (SNMP) support within an Any Transport over Multiprotocol Label Switching (AToM) infrastructure emulating Ethernet, Frame Relay, and ATM services over packet switched networks (PSNs). The Pseudowire Emulation Edge-to-Edge (PWE3) MIBs are the following:

- CISCO-IETF-PW-MIB (PW-MIB)
- CISCO-IETF-PW-MPLS-MIB (PW-MPLS-MIB)
- CISCO-IETF-PW-ENET-MIB (PW-ENET-MIB)
- CISCO-IETF-PW-FR-MIB (PW-FR-MIB)
- CISCO-IETF-PW-ATM-MIB (PW-ATM-MIB)

Cisco IOS Release 12.2(28)SB introduces support for the CISCO-IETF-PW-ATM-MIB (PW-ATM-MIB), which provides network management information specific to an ATM over pseudowire connection in a Multiprotocol Label Switching (MPLS) AToM or an IP network.

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the [“Feature Information for Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services”](#) section on page 28.

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

- [Information About Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services, page 3](#)
- [How to Configure Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services, page 20](#)
- [Configuration Examples for the Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services, page 24](#)
- [Additional References, page 25](#)
- [Command Reference, page 27](#)
- [Feature Information for Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services, page 28](#)
- [Glossary, page 30](#)

## Prerequisites for Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services

- SNMP must be enabled on the label switch routers (LSRs).
- MPLS must be enabled on the LSRs.
- Pseudowires must be configured with Ethernet, Frame Relay, or ATM access circuits. (For more detailed information, see the [Any Transport over MPLS](#), [Configuring Frame Relay](#), and [Configuring ATM](#) feature modules.

## Restrictions for Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services

The PWE3 MIBs are limited to read-only (RO) permission for MIB objects except for the cpwVcUp and cpwVcDown notification enable object, cpwVcUpDownNotifEnable, which has been extended to be writable by the SNMP agent.

- The following tables in the PW-MIB are not supported:
  - cpwVcPerfCurrentTable
  - cpwVcPerfIntervalTable
- The following objects in the PW-MPLS-MIB are not supported:
  - cpwVcMplsOutboundIndexNext
  - cpwVcMplsInboundIndexNext
- The following tables in the PW-ENET-MIB are not supported:

- cpwVcEnetMplsPriMappingTable
  - cpwVcEnetStatsTable
- The following table in the PW-FR-MIB is not supported:
  - cpwVcFrPMTTable
- The PW-ATM-MIB does not support cell counters on the Cisco 7500 series router. Consequently, an SNMP query for cell counters returns a 0 value.
- The PW-ATM-MIB does not support a high-capacity cell counter per virtual path (VP) or cells per port.
- The PW-ATM-MIB virtual path identifier (VPI)/virtual channel identifier (VCI) value for port mode cell relay is 0.
- The PW-ATM-MIB VP cell relay VCI value is 0.
- The PW-ATM-MIB VP does not support ATM adaptation layer 5 (AAL5); therefore, all packet counters are invalid.

**Note**

This feature is not supported over Ethernet, Frame Relay, and ATM in all releases. See the [“Feature Information for Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services”](#) section on page 28 for more detailed information.

## Information About Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services

To configure the Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services feature, you should understand the following concepts:

- [The Function of a Pseudowire in the PWE3 MIBs, page 4](#)
- [PWE3 MIBs Architecture, page 4](#)
- [Components and Functions of the PWE3 MIBs, page 5](#)
- [Tables in the PW-MIB, page 6](#)
- [Tables in the PW-MPLS-MIB, page 12](#)
- [Tables in the PW-ENET-MIB, page 16](#)
- [Tables in the PW-FR-MIB, page 17](#)
- [Tables in the PW-ATM-MIB, page 17](#)
- [Objects in the PWE3 MIBs, page 19](#)
- [Scalar Objects in the PWE3 MIBs, page 19](#)
- [Notifications in the PWE3 MIBs, page 20](#)
- [Benefits of the PWE3 MIBs, page 20](#)

## The Function of a Pseudowire in the PWE3 MIBs

A pseudowire is a point-to-point connection between pairs of provider edge (PE) routers (as shown in Figure 1). Its primary function is to emulate services like Ethernet over an underlying core MPLS network through encapsulation into a common MPLS format. By encapsulating services into a common MPLS format, a pseudowire allows carriers to converge their services to an MPLS network.

**Figure 1** Sample Pseudowire Topology

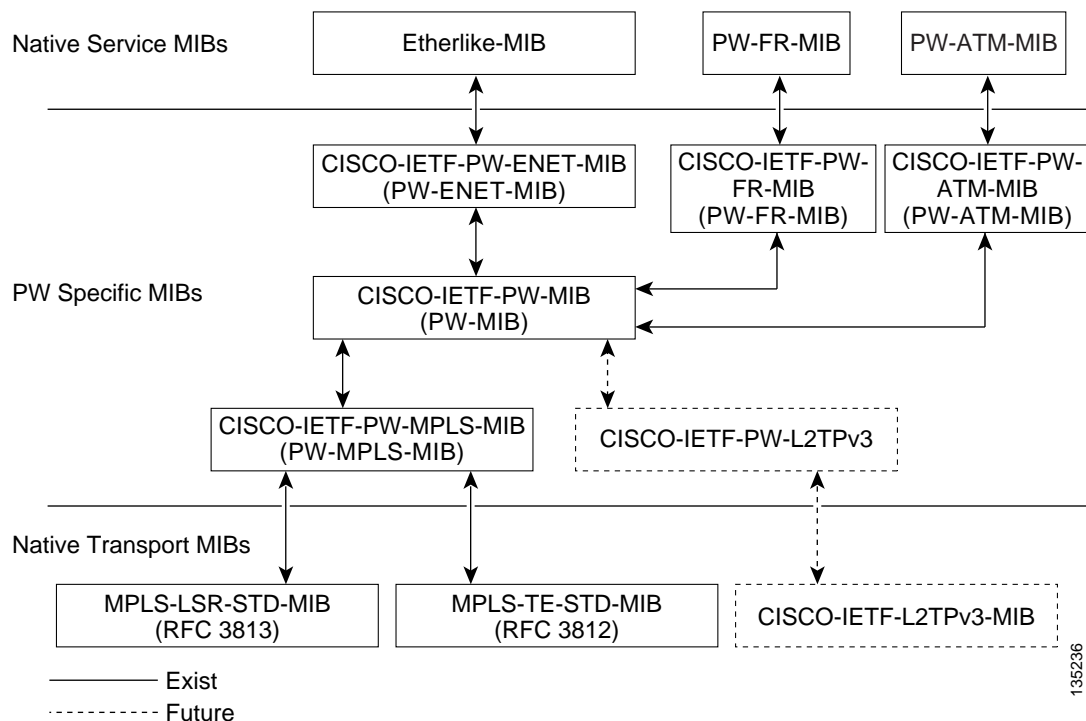

121002

## PWE3 MIBs Architecture

The PWE3 MIBs architecture shown in Figure 2 categorizes three groups of MIBs that, when used together, provide the complete emulated service; the native transport, which carries the service across the core network; and the relationship between the two.

**Figure 2** PWE3 MIBs Architecture

135236

The architecture is modular in that once deployed, new emulated service MIB modules or additional transport MIB modules “plug in” to or extend the existing infrastructure rather than require a new and unique one. This allows you to build management applications without the concern of a new service requiring the deployment of a completely different management strategy. Because the architecture is a generalized association mechanism between existing service and transport MIB modules, native MIB modules work in the absence of the associated PWE3-specific MIBs. The advantage is that if a PWE3-specific MIB has not yet been deployed in Cisco IOS software, which associates a service or transport with pseudowires, these MIB modules can still be queried. However, the only drawback is that the associations with the pseudowires are absent.

## Components and Functions of the PWE3 MIBs

The PWE3 MIBs have the following components and functions:

- PW-MIB (the pseudowire MIB)

This MIB binds the PW-MPLS-MIB and the PW-ENET-MIB together, and provides status of the pseudowire emulation and statistics and configuration information. The PW-MIB also defines the notifications for pseudowire fault and event monitoring.

- PW-MPLS-MIB (the pseudowire MPLS-MIB)

This MIB contains managed objects that can be used by a network manager to monitor pseudowire emulation MPLS services, such as MPLS-traffic engineering (TE)-PSN and MPLS-non-TE-PSN.

This MIB shows the following:

- Cross-connect (XC) indexes for virtual circuits (VCs) that are Label Distribution Protocol (LDP)-signaled and have a preferred path that is not set to an MPLS TE tunnel.
- Tunnel indexes for VCs with a preferred path set to a TE tunnel and an output interface that is a TE tunnel.

- PW-ENET-MIB (the pseudowire Ethernet services MIB)

This MIB contains managed objects that can be used by a network manager to monitor pseudowire emulation Ethernet services.

- PW-FR-MIB (the pseudowire Frame Relay services MIB)

This MIB contains managed objects that can be used by a network manager to monitor pseudowire emulation Frame Relay services.

This MIB uses a Frame Relay over pseudowire (FRoPW) connection that consists of two segments: the Frame Relay segment and the pseudowire segment. The PW-FR-MIB provides hooks to those segments. The PW MIB contains information about the pseudowire segment, and the PW-FR-MIB contains information about the Frame Relay segment.

The PW-FR-MIB is defined at the Pseudowire Service Emulation Layer and resides on top of the generic PW-MIB as shown in [Figure 2](#). Therefore, the PW-FR-MIB is highly dependent on the existence and the service provided by the PW-MIB. In addition, an existing PW-FR connection entry must associate with an existing VC entry in the PW-MIB.

The PW-FR-MIB and the generic PW-MIB are logically tied by the PW VC Index, which is an internal index defined to support the PW-MIB. Each PW VC index uniquely maps into an existing VC entry in the PW-MIB and the PW-FR-MIB.

- PW-ATM-MIB (the pseudowire ATM services MIB)

This MIB contains managed objects that can be used by a network manager to monitor pseudowire emulation ATM services.

This MIB uses an ATM over pseudowire (ATMoPW) connection that consists of two segments: the ATM segment and the pseudowire segment. The PW-ATM-MIB provides hooks to those segments. The PW MIB contains information about the pseudowire segment, and the PW-ATM-MIB contains information about the ATM segment called the attachment circuit.

The PW-ATM-MIB is defined at the Pseudowire Service Emulation Layer and resides on top of the generic PW-MIB as shown in [Figure 2](#). Therefore, the PW-ATM-MIB is highly dependent on the existence and the service provided by the PW-MIB. In addition, an existing PW-ATM connection entry must associate with an existing VC entry in the PW-MIB.

The PW-ATM-MIB and the generic PW-MIB are logically tied by the PW VC Index, which is an internal index defined to support the PW-MIB. Each PW VC index uniquely maps into an existing VC entry in the PW-MIB and the PW-ATM-MIB.

## Tables in the PW-MIB

The PW-MIB consists of the following tables:

- **cpwVcTable** ([Table 1](#))—Contains high-level generic parameters related to VC creation. This table is implemented as read only and is indexed by the `cpwVcIndex`, which uniquely identifies a singular connection. A row in this table represents an emulated virtual connection. This table is used for all VC types.
- **cpwVcPerfTotalTable** ([Table 2](#))—Provides per-VC performance information from the VC start time. This table is indexed by the `cpwVcIndex`.
- **cpwVcIdMappingTable** ([Table 3](#))—Provides reverse mapping of the existing VCs based on VC type and VC ID ordering. This table is typically useful for element manager software (EMS) ordered query of existing VCs. This table is indexed by `cpwVcIdMappingVcType`, `cpwVcIdMappingVcID`, `cpwVcIdMappingPeerAddrType`, and `cpwVcIdMappingPeerAddr`. This table is implemented as read only.
- **cpwVcPeerMappingTable** ([Table 4](#))—Provides reverse mapping of the existing VCs based on VC type and VC ID ordering. This table is typically useful for EMS ordered query of existing VCs. This table is indexed by `cpwVcPeerMappingPeerAddrType`, `cpwVcPeerMappingPeerAddr`, `cpwVcPeerMappingVcType`, and `cpwVcPeerMappingVcID`. This table is implemented as read only.

### cpwVcTable

[Table 1](#) lists the `cpwVcTable` objects and their descriptions.

**Table 1** *cpwVcTable Objects and Descriptions*

Objects	Description
cpwVcType	Indicates the service to be carried over this VC. This is circuit type information.
cpwVcOwner	Set by the operator to indicate the protocol responsible for establishing this VC. Values are the following: <ul style="list-style-type: none"> <li>• manual(1)—Used when no maintenance protocol (PW signaling) is needed to set up the VC, such as configuration of entries in the VC tables including VC labels, and so forth.</li> <li>• maintenanceProtocol(2)—Used for standard signaling of the VC for the specific PSN; for example, LDP for MPLS PSN as specified in <i>draft-martini-l2circuit-trans-mpls</i> or the Layer 2 Tunneling Protocol (L2TP).</li> <li>• other(3)—Used for all other types of signaling.</li> </ul>
cpwVcPsnType	Set by the operator to indicate the PSN type on which this VC is carried. Based on this object, the relevant PSN table entries are created in the PSN-specific MIB modules. For example, if mpls(1) is defined, the agent creates an entry in the cpwVcMplsTable, which further defines the MPLS PSN configuration.
cpwVcSetUpPriority	Defines the relative setup priority of the VC in a lowest-to-highest manner, where 0 is the highest priority. This value is significant if there are competing resources between VCs and the implementation supports this feature. Because this is not implemented in AToM, the value of 0 is used.
cpwVcHoldingPriority	Defines the relative holding priority of the VC in a lowest-to-highest manner, where 0 is the highest priority. This value is significant if there are competing resources between VCs and the implementation supports this feature. Because this is not implemented in AToM, the value of 0 is used.
cpwVcInboundMode	Enables greater security for implementations that use per-platform VC label space. Modes are the following: <ul style="list-style-type: none"> <li>• strict(1)</li> <li>• loose(2)</li> </ul> <p>In strict mode, packets coming from the PSN are accepted only from tunnels that are associated to the same VC via the inbound tunnel table in the case of MPLS, or as identified by the source IP address in the case of L2TP or IP PSN. The entries in the inbound tunnel table are either explicitly configured or implicitly known by the maintenance protocol used for VC setup.</p> <p>If such association is not known, not configured, or not desired, loose mode should be configured, and the node should accept the packet based on the VC label only, regardless of the outer tunnel used to carry the VC.</p>

**Table 1** *cpwVcTable Objects and Descriptions (continued)*

<b>Objects</b>	<b>Description</b>
cpwVcPeerAddrType	Denotes the address type of the peer node maintenance protocol (signaling) address if the PW maintenance protocol is used for the VC creation. It should be set to unknown if the PW maintenance protocol is not used; for example, cpwVcOwner is set to manual.
cpwVcPeerAddr	Contains the value of the peer node address of the PW maintenance protocol entity. This object should contain a value of 0 if not relevant (manual configuration of the VC).
cpwVcID	Use in the outgoing VC ID field within the VC forward equivalence class (FEC) element with LDP signaling or the PW ID attribute-value (AV) pair for the L2TP.
cpwVcLocalGroupID	Use in the Group ID field sent to the peer PW within the maintenance protocol for VC setup; 0 if not used.
cpwVcControlWord	Defines if the control word is sent with each packet by the local node.
cpwVcLocalIfMtu	If not = 0, the optional IfMtu object in the maintenance protocol is sent with this value, representing the locally supported maximum transmission unit (MTU) size over the interface (or the virtual interface) associated with the VC.
cpwVcLocalIfString	Each VC is associated to an interface (or a virtual interface) in the ifTable of the node as part of the service configuration. This object defines if the maintenance protocol sends the interface's name as it appears in the ifTable in the name object as part of the maintenance protocol. If this object is set to false, the optional element is not sent.
cpwVcRemoteGroupID	Obtained from the Group ID field as received via the maintenance protocol used for VC setup; 0 if not used. The value of 0xFFFF is used if the object is not defined by the VC maintenance protocol.
cpwVcRemoteControlWord	If the maintenance protocol is used for VC establishment, this parameter indicates the received status of the control word usage; that is, if packets are received with the control word or not. The value of notYetKnown is used while the maintenance protocol has not yet received the indication from the remote node. In a manual configuration of the VC, this parameter indicates to the local node the expected encapsulation for the received packets.
cpwVcRemoteIfMtu	The remote interface MTU as received from the remote node via the maintenance protocol. This object should be 0 if this parameter is not available or not used.
cpwVcRemoteIfString	Indicates the interface description string as received by the maintenance protocol; it must be a NULL string if not applicable or not known yet.

**Table 1** *cpwVcTable Objects and Descriptions (continued)*

<b>Objects</b>	<b>Description</b>
cpwVcOutboundVcLabel	The VC label used in the outbound direction toward the PSN. This object may be set up manually if the owner is manual; otherwise, it is automatic. Examples; for MPLS PSN, the label represents the 20 bits of the VC tag; for L2TP, it represents the 32 bits of the session ID. If the label is not yet known (signaling in process), the object should return a value of 0xFFFF.
cpwVcInboundVcLabel	The VC label used in the inbound direction for packets received from the PSN. This object may be set up manually if the owner is manual; otherwise, it is automatic. Examples; for MPLS PSN, the label represents the 20 bits of VC tag; for L2TP, the label represents the 32 bits of the session ID. If the label is not yet known (signaling in process), the object should return a value of 0xFFFF.
cpwVcName	The canonical name assigned to the VC.
cpwVcDescr	A textual string containing information about the VC. If there is no description, this object contains a 0 length string.
cpwVcCreateTime	System time when this VC was created.
cpwVcUpTime	Number of consecutive ticks that this VC has been up in both directions together. (Up is observed in cpwVcOperStatus.)
cpwVcAdminStatus	The desired operational status of this VC.
cpwVcOperStatus	Indicates the actual combined operational status of this VC. This object is up if both cpwVcInboundOperStatus and cpwVcOutboundOperStatus are in the up state. For all other values, if the VCs in both directions are of the same value, this object reflects that value; otherwise, it is set to the more severe status of the two. The order of severity from most severe to less severe is as follows: unknown, notPresent, down, lowerLayerDown, dormant, testing, and up. The operator can consult the direction of OperStatus for fault isolation.
cpwVcInboundOperStatus	Indicates the actual operational status of this VC in the inbound direction. Values are the following: <ul style="list-style-type: none"> <li>up—The VC is established and ready to pass packets.</li> <li>down—PW signaling has not yet finished or indications available at the service level show that the VC is not passing packets.</li> <li>testing—AdminStatus at the VC level is set to test.</li> <li>dormant—The VC is not available because the required resources are occupied by higher priority VCs.</li> <li>notPresent—Some component needed for the setup of the VC is missing.</li> <li>lowerLayerDown—The underlying PSN is not in OperStatus up.</li> </ul>

**Table 1** *cpwVcTable Objects and Descriptions (continued)*

Objects	Description
cpwVcOutboundOperStatus	<p>Indicates the actual operational status of this VC in the outbound direction. Values are the following:</p> <ul style="list-style-type: none"> <li>• up—The VC is established and ready to pass packets.</li> <li>• down—PW signaling has not yet finished or indications available at the service level show that the VC is not passing packets.</li> <li>• testing—AdminStatus at the VC level is set to test.</li> <li>• dormant—The VC is not available because the required resources are occupied by higher priority VCs.</li> <li>• notPresent—Some component needed for the setup of the VC is missing.</li> <li>• lowerLayerDown—The underlying PSN is not in OperStatus up.</li> </ul>
cpwVcTimeElapsed	<p>The number of seconds, including partial seconds, that have elapsed since the beginning of the current measurement period. If, for some reason, such as an adjustment in the system's time-of-day clock, and the current interval exceeds the maximum value, the agent returns the maximum value. Because cpwVcPerfIntervalTable is not implemented, this is 0.</p>
cpwVcValidIntervals	<p>The number of previous 15-minute intervals for which data was collected. An agent with PW capability must be capable of supporting at least <math>x</math> intervals. The minimum value of <math>x</math> is 4; the default of <math>x</math> is 32, and the maximum value of <math>x</math> is 96. The value is <math>x</math> unless the measurement was (re)started within the last <math>x \times 15</math> minutes, in which case the value will be the number of complete 15-minute intervals; for example, in the case where the agent is a proxy, some intervals may be unavailable. In this case, this interval is the maximum interval number for which data is available. This interval is set to 0.</p>
cpwVcRowStatus	<p>A read-only implementation that is always active(1). It is used for creating, modifying, and deleting.</p>
cpwVcStorageType	<p>The storage type for this object is a read-only implementation that is always volatile(2).</p>

## cpwVcPerfTotalTable

Table 2 lists the cpwVcPerfTotalTable objects and their descriptions.

**Table 2** *cpwVcPerfTotalTable Objects and Descriptions*

Objects	Description
cpwVcPerfTotalInHCPackets	High-capacity counter for the number of packets received by the VC from the PSN.
cpwVcPerfTotalInHCBytes	High-capacity counter for the number of bytes received by the VC from the PSN.
cpwVcPerfTotalOutHCPackets	High-capacity counter for the number of packets forwarded by the VC to the PSN.
cpwVcPerfTotalOutHCBytes	High-capacity counter for the number of bytes forwarded by the VC (to the PSN).
cpwVcPerfTotalDiscontinuityTime	The value of sysUpTime on the most recent occasion when one or more of this object's counters suffered a discontinuity. The relevant counters are the specific instances of any Counter32 or Counter64. If no such discontinuities have occurred since the last reinitialization of the local management subsystem, this object contains a 0 value.

## cpwVcIdMappingTable

Table 3 lists the cpwVcIdMappingTable objects and their descriptions.

**Table 3** *cpwVcIdMappingTable Objects and Descriptions*

Objects	Description
cpwVcIdMappingVcType	The VC type (indicates the service) of this VC.
cpwVcIdMappingVcID	The VC ID of this VC; 0 if the VC is configured manually.
cpwVcIdMappingPeerAddrType	IP address type of the peer node.
cpwVcIdMappingPeerAddr	IP address of the peer node.
cpwVcIdMappingVcIndex	The value that represents the VC in the cpwVcTable.

## cpwVcPeerMappingTable

Table 4 lists the cpwVcPeerMappingTable objects and their descriptions.

**Table 4** *cpwVcPeerMappingTable Objects and Descriptions*

Objects	Description
cpwVcPeerMappingPeerAddrType	IP address type of the peer node.
cpwVcPeerMappingPeerAddr	IP address of the peer node.
cpwVcPeerMappingVcType	The VC type (indicates the service) of this VC.
cpwVcPeerMappingVcID	The VC ID of this VC; 0 if the VC is configured manually.
cpwVcPeerMappingVcIndex	The value that represents the VC in the cpwVcTable.

## Tables in the PW-MPLS-MIB

The PW-MPLS-MIB consists of the following tables:

- **cpwVcMplsTable** ([Table 5](#))—Specifies information for the VC to be carried over an MPLS PSN. This table is indexed on `cpwVcIndex`.
- **cpwVcMplsOutboundTable** ([Table 6](#))—Associates VCs using an MPLS PSN with the outbound MPLS tunnels toward the PSN or the physical interface in the case of the VC only. A row in this table represents a link between PW VCs that require MPLS tunnels and an MPLS tunnel toward the PSN. This table is indexed by the `cpwVcIndex` and an additional index that is not supported; consequently, its value is 1. The operator creates at least one entry in this table for each PW VC that requires an MPLS PSN. The VC-only case and the `cpwVcMplsOutboundIndex` is not supported.
- **cpwVcMplsInboundTable** ([Table 7](#))—Associates VCs using an MPLS PSN with the inbound MPLS tunnels for packets coming from the PSN, if such association is desired mainly for security reasons. A row in this table represents a link between PW VCs that require MPLS tunnels and an MPLS tunnel for packets arriving from the PSN. This table is indexed by the set of indexes used to identify the VC, `cpwVcIndex`, and an additional index that is not supported; consequently, its value is 1. An entry is created in this table either automatically by the local agent or manually by the operator when strict mode is required. This table points to the appropriate MPLS MIB. For MPLS-TE, the four variables relevant to the indexing of an MPLS TE tunnel are set. The VC-only case and the `cpwVcMplsInboundIndex` are not supported.
- **cpwVcMplsNonTeMappingTable** ([Table 8](#))—Maps an inbound or outbound tunnel to a VC in non-TE applications. A row in this table represents the association between a PW VC and its non-TE MPLS outer tunnel. An application can use this table to retrieve the PW carried over a specific non-TE MPLS outer tunnel quickly. This table is indexed by the `xconnect` index for the MPLS non-TE tunnel and the direction of the VC in the specific entry. The same table is used in both inbound and outbound directions, but in a different row for each direction. If the inbound association is not known, no rows should exist for it. Rows are created by the local agent when all the association data is available for display.
- **cpwVcMplsTeMappingTable** ([Table 9](#))—Maps an inbound or outbound tunnel to a VC in MPLS-TE applications. A row in this table represents the association between a PW VC and its MPLS-TE outer tunnel. An application can use this table to retrieve the PW carried over a specific TE MPLS outer tunnel quickly. This table is indexed by the four indexes of a TE tunnel, the direction of the VC specific entry, and the `VcIndex`. The same table is used in both inbound and outbound directions, but a different row for each direction. If the inbound association is not known, no rows should exist for it. Rows are created by the local agent when all the association data is available for display. This table shows mappings between pseudowires and the `xconnect` index for non-TE outer tunnel or index.

### cpwVcMplsTable

[Table 5](#) lists the `cpwVcMplsTable` objects and their descriptions.

**Table 5** *cpwVcMplsTable Objects and Descriptions*

Objects	Description
cpwVcMplsMplsType	Set by the operator to indicate the outer tunnel types, if they exist. Values are the following: <ul style="list-style-type: none"> <li>mplsTe(0)—Used when the outer tunnel is set up by MPLS-TE.</li> <li>mplsNonTe(1)—Used when the outer tunnel is set up by LDP or manually.</li> </ul>
cpwVcMplsExpBitsMode	Set by the operator to indicate the way the VC shim label EXP bits are to be determined. The value is the following: <ul style="list-style-type: none"> <li>outerTunnel(1)—Used when there is an outer tunnel and cpwVcMplsMplsType is mplsTe or mplsNonTe.</li> </ul>
cpwVcMplsExpBits	Set by the operator to indicate the MPLS EXP bits to be used on the VC shim label if cpwVcMplsExpBitsMode is specified; value = 0.
cpwVcMplsTtl	Set by the operator to indicate the VC time-to-live (TTL) bits to be used on the VC shim label; value = 0.
cpwVcMplsLocalLdpID	The local LDP identifier of the LDP entity creating this VC in the local node. Because the VC labels are always set from the per-platform label space, the last two octets in the LDP ID must be 0s.
cpwVcMplsLocalLdpEntityID	The local LDP entity index of the LDP entity to be used for this VC on the local node; this should be set to all 0s when this object is not used.
cpwVcMplsPeerLdpID	The peer LDP identifier as identified by the LDP session; this should be zero if not relevant or not known yet.
cpwVcMplsStorageType	The storage type for this object is a read-only implementation that is always volatile(2).

## cpwVcMplsOutboundTable

Table 6 lists the cpwVcMplsOutboundTable objects and their descriptions.

**Table 6** *cpwVcMplsOutboundTable Objects and Descriptions*

Objects	Description
cpwVcMplsOutboundIndex	An arbitrary index for enabling multiple rows per VC in this table. The next available free index can be retrieved using cpwVcMplsOutboundIndexNext. The value = 1, because this object is not supported.
cpwVcMplsOutboundLsrXcIndex	Set by the operator. If the outer label is defined in the MPL-LSR-MIB, that is, set by LDP or manually, this object points to the xconnect index of the outer tunnel. Otherwise, this object is set to 0.

**Table 6** *cpwVcMplsOutboundTable Objects and Descriptions (continued)*

Objects	Description
cpwVcMplsOutboundTunnelIndex	Part of the set of indexes for an outbound tunnel, specifically an MPLS-TE outer tunnel; otherwise, this object is set to 0.
cpwVcMplsOutboundTunnelInstance	Part of the set of indexes for an outbound tunnel, specifically an MPLS-TE outer tunnel; otherwise, this object is set to 0.
cpwVcMplsOutboundTunnelLclLSR	Part of the set of indexes for an outbound tunnel, specifically an MPLS-TE outer tunnel; otherwise, this object is set to NULL.
cpwVcMplsOutboundTunnelPeerLSR	Part of the set of indexes for an outbound tunnel, specifically an MPLS-TE outer tunnel; otherwise, this object is set to NULL.
cpwVcMplsOutboundIfIndex	For a VC only with no outer tunnel, this object holds the ifIndex of the outbound port. The value = 0.
cpwVcMplsOutboundRowStatus	A read-only implementation that is always active(1). It is used for creating, modifying, and deleting.
cpwVcMplsOutboundStorageType	The storage type for this object is a read-only implementation that is always volatile(2).

## cpwVcMplsInboundTable

Table 7 lists the cpwVcMplsInboundTable objects and their descriptions.

**Table 7** *cpwVcMplsInboundTable Objects and Descriptions*

Objects	Description
cpwVcMplsInboundIndex	An arbitrary index for enabling multiple rows per VC in this table. The next available free index can be retrieved using cpwVcMplsInboundIndexNext. the value = 1, because this object is not supported.
cpwVcMplsInboundLsrXcIndex	If the outer label is defined in the MPL-LSR-MIB; that is, set by LDP or manually, this object points to the xconnect index of the outer tunnel. The xconnect index represents the pseudowire in the inbound direction retrieving 0 if information for this object is not known.
cpwVcMplsInboundTunnelIndex	Part of the set of indexes for an inbound tunnel, specifically an MPLS-TE outer tunnel; value = 0. This object does not support TE tunnels at the ingress router.
cpwVcMplsInboundTunnelInstance	Part of the set of indexes for an inbound tunnel, specifically an MPLS-TE outer tunnel; value = 0. This object does not support TE tunnels at the ingress router.
cpwVcMplsInboundTunnelLclLSR	Part of the set of indexes for an inbound tunnel, specifically an MPLS-TE outer tunnel; otherwise, set to NULL. This object does not support TE tunnels at the ingress router.

**Table 7** *cpwVcMplsInboundTable Objects and Descriptions (continued)*

Objects	Description
cpwVcMplsInboundTunnelPeerLSR	Part of the set of indexes for an inbound tunnel, specifically an MPLS-TE outer tunnel; otherwise, this object is set to NULL. This object does not support TE tunnels at the ingress router.
cpwVcMplsInboundIfIndex	In the case of a VC only (no outer tunnel), this object holds the ifIndex of the inbound port. The value = 0.
cpwVcMplsInboundRowStatus	A read-only implementation that is always active(1). It is used for creating, modifying, and deleting.
cpwVcMplsInboundStorageType	The storage type for this object is a read-only implementation that is always volatile(2).

## cpwVcMplsNonTeMappingTable

Table 8 lists the cpwVcMplsNonTeMappingTable objects and their descriptions.

**Table 8** *cpwVcMplsNonTeMappingTable Objects and Descriptions*

Objects	Description
cpwVcMplsNonTeMappingTunnelDirection	Identifies if the row represents an outbound or inbound mapping.
cpwVcMplsNonTeMappingXcTunnelIndex	XC index in the MPLS-LSR-MIB of the pseudowire LDP-generated XC entry.
cpwVcMplsNonTeMappingIfIndex	Identifies the port on which the VC is carried for VC only; the value = 0.
cpwVcMplsNonTeMappingVcIndex	Represents the VC in the cpwVcTable.

## cpwVcMplsTeMappingTable

Table 9 lists the cpwVcMplsTeMappingTable objects and their descriptions.

**Table 9** *cpwVcMplsTeMappingTable Objects and Descriptions*

Objects	Description
cpwVcMplsTeMappingTunnelDirection	Identifies if the row represents an outbound mapping.
cpwVcMplsTeMappingTunnelIndex	Index for the conceptual row identifying an MPLS-TE tunnel.
cpwVcMplsTeMappingTunnelInstance	Identifies an instance of an MPLS-TE tunnel.
cpwVcMplsTeMappingTunnelPeerLsrID	Identifies a peer LSR when the outer tunnel is MPLS-TE based.
cpwVcMplsTeMappingTunnelLocalLsrID	Identifies the local LSR.
cpwVcMplsTeMappingVcIndex	Represents the VC in the cpwVcTable.

## Tables in the PW-ENET-MIB

The PW-ENET-MIB consists of the following table:

- **cpwVcEnetTable** ([Table 10](#))—Provides Ethernet port mapping and VLAN configuration for each Ethernet emulated virtual connection. This table is indexed on **cpwVcIndex**, which uniquely identifies a singular connection. The second level index for this table is **cpwVcEnetPwVlan**, which indicates VLANs on this VC. This table is used only for Ethernet VC types—**ethernetVLAN**, **ethernet**, or **ethernet virtual private LAN service (VPLS)**, and is implemented as read-only.

### cpwVcEnetTable

[Table 10](#) lists the **cpwVcEnetTable** objects and their descriptions.

**Table 10** *cpwVcEnetTable Objects and Descriptions*

Objects	Description
<b>cpwVcEnetPwVlan</b>	The VLAN value for frames on a VC. This is one of the indexes to the table so multiple VLAN values can be configured for a PW VC. This value is 4096 to indicate untagged frames; that is, if the <b>cpwVcEnetVlanMode</b> value is <b>removeVlan</b> . This value is the VLAN value of the access circuit if the <b>cpwVcEnetVlanMode</b> value is <b>noChange</b> . The value of 4097 is used if the object is not applicable; for example, when mapping all packets from an Ethernet port to the VC.
<b>cpwVcEnetVlanMode</b>	Indicates the way the VLAN field is handled between the access circuit and the PW VC. The possible values for this field are as follows: <ul style="list-style-type: none"> <li>• <b>noChange</b>—Indicates that the VC contains the original user VLAN, as specified in <b>cpwVcEnetPortVlan</b>.</li> <li>• <b>changeVlan</b>—Indicates that the VLAN field on the VC may be different from the VLAN field on the user's port.</li> <li>• <b>removeVlan</b>—Indicates that the encapsulation on the VC does not include the original VLAN field.</li> </ul>
<b>cpwVcEnetPortVlan</b>	Defines the VLAN value on the physical port (or VPLS virtual port) if a change is required to the VLAN value between the VC and the physical or virtual port. It is equal to <b>cpwVcEnetPwVlan</b> if the <b>cpwVcEnetVlanMode</b> value is <b>noChange</b> . A value of 4096 indicates that no VLAN is associated with the VC; that is, assigning Default VLAN to untagged frames. If all traffic from the VC is being forwarded to the port, then this value is 4097 indicating it is not relevant.
<b>cpwVcEnetPortIfIndex</b>	The <b>ifIndex</b> value of the Ethernet port associated with this PW VC for point-to-point Ethernet service. For VPLS, this value is an <b>ifIndex</b> value for a virtual interface for the VPLS instance.

**Table 10** *cpwVcEnetTable Objects and Descriptions (continued)*

Objects	Description
cpwVcEnetVcIfIndex	Models the VC as a virtual interface in the ifTable. This value is always 0 to indicate no virtual interface is created.
cpwVcEnetRowStatus	A read-only implementation that is always active(1). It is used for creating, modifying, and deleting.
cpwVcEnetStorageType	The storage type for this object is a read-only implementation that is always volatile(2).

## Tables in the PW-FR-MIB

The PW-FR-MIB consists of the following table:

- cpwVcFrTable ([Table 11](#))—Contains entries that represent an FRoPW connection operating in one-to-one mapping mode in which there is a one-to-one correspondence between a Frame Relay VC and a pair of unidirectional pseudowires.

### cpwVcFrTable

[Table 11](#) lists the cpwVcFrTable objects and their descriptions.

**Table 11** *cpwVcFrTable Objects and Descriptions*

Objects	Description
cpwVcFrIfIndex	Returns the interface ifIndex of the Frame Relay (FR) segment of the FRoPW connection.
cpwVcFrDlci	Returns the data-link connection identifier (DLCI) of the Frame Relay segment of an FRoPW connection.
cpwVcFrAdminStatus	Returns the administrative status of an FRoPW connection.
cpwVcFrOperStatus	Returns the combined operational status of an FRoPW connection.
cpwVcFrPw2FrOperStatus	Returns the operational status of the PW-to-FR direction in an FRoPW connection.
cpwVcFrRowStatus	A read-only implementation that is always active(1). It is used for creating, modifying, and deleting.
cpwVcFrStorageType	The storage type for this object is a read-only implementation that is always volatile(2).

## Tables in the PW-ATM-MIB

The PW-ATM-MIB consists of the following tables:

- cpwVcAtmTable ([Table 12](#))—Specifies information for an ATM VC to be carried over the PSN.
- cpwVcAtmPerfTable ([Table 13](#))—Specifies performance-related attributes for an ATM VC.

## cpwVcAtmTable

Table 12 lists the cpwVcAtmTable objects and their descriptions.

**Table 12** *cpwVcAtmTable Objects and Descriptions*

Objects	Description
cpwAtmIf	Specifies the ATM interface that sends and receives cells from the ATM network.
cpwAtmVpi	Specifies the VPI value of the ATM VC.
cpwAtmVci	Specifies the VCI value of the ATM VC.
cpwAtmClpQosMapping	Indicates the presence of cell loss priority (CLP) bits determining the value in quality of service (QoS) fields of the encapsulating protocol. The value could be used only for outbound traffic, which means traffic going out to the PSN.
cpwAtmRowStatus	A read-only implementation that is always active(1). It is used for creating, modifying, and deleting.
cpwAtmOamCellSupported	Indicates whether operation, administration, and maintenance (OAM) cells are transported on this VC.
cpwAtmQosScalingFactor	Represents the scaling factor to be applied to ATM QoS rates when calculating QoS rates for the PSN domain.
cpwAtmCellPacking	Identifies if the VC is configured to do cell packing.
cpwAtmMncp	Identifies the number of cells that need to be packed.
cpwAtmEncap	Provides information on whether MPLS or Layer 2 Tunneling Protocol Version 3 (L2TPv3) is used as the transport.
cpwAtmPeerMncp	Represents the maximum number of cells that can be packed in one packet for a peer interface.
cpwAtmMcptTimeout	Represents the maximum cell packing timeout (MCPT) value used.

## cpwVcAtmPerfTable

Table 13 lists the cpwVcAtmPerfTable objects and their descriptions.

**Table 13** *cpwVcAtmPerfTable Objects and Descriptions*

Objects	Description
cpwAtmCellsReceived	Obtains information on the number of cells that were received and sent to the PSN.
cpwAtmCellsSent	Provides information on the number of cells sent to the ATM network.
cpwAtmCellsRejected	Indicates the number of cells that were rejected by this VC because of policing.
cpwAtmCellsTagged	Indicates the number of cells that were tagged.

**Table 13** *cpwVcAtmPerfTable Objects and Descriptions (continued)*

Objects	Description
cpwAtmHCCellsReceived	Provides the high-capacity counter for the number of cells received by this VC.
cpwAtmHCCellsRejected	Provides the high-capacity counter for the number of cells rejected by this VC.
cpwAtmHCCellsTagged	Provides the high-capacity counter for number of cells that were tagged.
cpwAtmAvgCellsPacked	Provides the average number of cells that were packed.
cpwAtmPktsReceived	Indicates the number of ATM AAL5 packets that are actually sent into the ATM network as packets when the VC is configured to do AAL5 over PW.
cpwAtmPktsSent	Gets the number of packets that are reconstructed from the cells, assigns a VC label, and sends the packets into the PSN.
cpwAtmPktsRejected	Indicates the number of packets that were rejected because of policing.

## Objects in the PWE3 MIBs

The PWE3 MIBs represent an ASN.1 notation reflecting specific components of the pseudowire services. The MIBs enable a network management application using SNMP to get this information for display. The MIBs support the standard GETNEXT and GETBULK functionality, but do not support configuration capabilities (via SET) in the current implementation.

## Scalar Objects in the PWE3 MIBs

The PWE3 MIBs contain the following supported scalar object:

- **cpwVcUpDownNotifEnable**—This object reflects the configuration of the cpwVcUp and cpwVcDown notifications. If either of the notifications is configured via the command-line interface (CLI), then this object has a value of true(1). If this object is set via SNMP to true(1), then it enables the emission of both the cpwVcUp and cpwVcDown notifications; if the object is set via SNMP to false(2), these notifications are not emitted.

### Note

cpwVcUpDownNotifEnable can be set only if RW is configured for the **snmp-server community string [view view-name] [ro | rw] [ipv6 nacl] [access-list-number]** command.

The PWE3 MIBs contain the following unsupported scalar objects:

- **cpwVcIndexNext**—Indicates the next cpwVcIndex value to use when you add rows to the cpwVcTable.
- **cpwVcNotifRate**—Indicates the rate at which cpwVcUp/Down notifications can be issued from the device.
- **cpwVcMplsOutboundIndexNext**—Contains an appropriate value to be used for cpwVcMplsOutboundIndex when you create entries in the cpwVcMplsOutboundTable. The value 0 indicates that no unassigned entries are available. To obtain the cpwVcMplsOutboundIndex value

for a new entry, the manager issues a management protocol retrieval operation to obtain the current value of this object. After each retrieval, the software agent should modify the value to the next unassigned index; however, the software agent *must not* assume such retrieval will be done for each row created.

- **cpwVcMplsInboundIndexNext**—Contains an appropriate value to be used for **cpwVcMplsInboundIndex** when you create entries in the **cpwVcMplsInboundTable**. The value 0 indicates that no unassigned entries are available. To obtain the **cpwVcMplsInboundIndex** value for a new entry, the manager issues a management protocol retrieval operation to obtain the current value of this object. After each retrieval, the software agent should modify the value to the next unassigned index; however, the agent *must not* assume such retrieval will be done for each row created.

## Notifications in the PWE3 MIBs

The **cpwVcUp** and **cpwVcDown** notifications in the PW-MIB indicate when the **operStatus** values for a range of PW VCs have changed state.

The definition of these objects in the PW-MIB indicates that events of the same type, either up or down, must be able to be correlated into ranges. The implementation of these notifications does not do any of this correlation. A notification is generated for each individual VC that has an operational state change if that notification is enabled. A notification does not signal an operational state change for a group of VCs as described in the MIB.

## Benefits of the PWE3 MIBs

The PWE3 MIBs provide the ability to manage pseudowire emulation edge-to-edge by providing MPLS-related information about the service and a mechanism to monitor the Ethernet, Frame Relay, or ATM access circuits.

# How to Configure Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services

This section contains the following procedures:

- [Enabling the SNMP Agent for the PWE3 MIBs, page 20](#) (required)
- [Configuring AToM, Frame Relay, or ATM Circuits Across a Network for the PWE3 MIBs, page 22](#) (required)

## Enabling the SNMP Agent for the PWE3 MIBs

Perform this task to enable the SNMP agent.

### SUMMARY STEPS

1. **enable**
2. **show running-config [interface | map-class]**

3. **configure terminal**
4. **snmp-server community** *string* [**view** *view-name*] [**ro** | **rw**] [**ipv6 nacl**] [*access-list-number*]
5. **end**
6. **write memory**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
	<b>Example:</b> Router> enable	
Step 2	<b>show running-config</b> [interface   map-class]	Displays the running configuration of the router so that you can determine if an SNMP agent is already running on the device.
	<b>Example:</b> Router# show running-config	<p>If no SNMP information is displayed, continue with the next step.</p> <p>If any SNMP information is displayed, you can modify the information or change it as desired.</p> <ul style="list-style-type: none"> <li>The optional <b>interface</b> keyword displays interface-specific configuration information.</li> <li>The optional <b>map-class</b> keyword displays dialer or Frame Relay map-class information.</li> </ul>
Step 3	<b>configure terminal</b>	Enters global configuration mode.
	<b>Example:</b> Router# configure terminal	

	Command or Action	Purpose
Step 4	<pre>snmp-server community <i>string</i> [<i>view view-name</i>] [<i>ro</i>   <i>rw</i>] [<i>ipv6 nacl</i>] [<i>access-list-number</i>]</pre> <p><b>Example:</b> Router(config)# snmp-server community public ro</p>	<p>Sets up the community access string to permit access to SNMP for the MIBs.</p> <ul style="list-style-type: none"> <li>The <i>string</i> argument consists of 1 to 32 alphanumeric characters and functions much like a password, permitting access to SNMP. Blank spaces are not permitted in the community string.</li> <li>The optional <b>view</b> <i>view-name</i> keyword argument combination specifies a previously defined view. The view defines the objects available to the SNMP community.</li> <li>The optional <b>ro</b> keyword configures read-only (ro) access to the objects in the MIBs.</li> <li>The optional <b>rw</b> keyword specifies read-write access. Authorized management stations can both retrieve and modify MIB objects.</li> <li>The optional <b>ipv6</b> <i>nacl</i> keyword argument combination specifies an IPv6 named access list.</li> <li>The optional <i>access-list-number</i> argument is an integer from 1 to 99 that specifies a standard access list of IP addresses or a string (not to exceed 64 characters) that is the name of a standard access list of IP addresses allowed access to the SNMP agent. Alternatively, it is an integer from 1300 to 1999 that specifies a list of IP addresses in the expanded range of standard access list numbers that are allowed to use the community string to gain access to the SNMP agent.</li> </ul>
Step 5	<pre>end</pre> <p><b>Example:</b> Router(config)# end</p>	Exits to privileged EXEC mode.
Step 6	<pre>write memory</pre> <p><b>Example:</b> Router# write memory</p>	Writes the modified SNMP configuration into NVRAM of the router, permanently saving the SNMP settings.

## Configuring AToM, Frame Relay, or ATM Circuits Across a Network for the PWE3 MIBs

This section contains the following procedure:

- [Configuring the Pseudowire Class, page 23](#)

## Configuring the Pseudowire Class

The successful transmission of the Layer 2 frames between PE routers is due to the configuration of the PE routers. You configure the connection, called a pseudowire, between the routers.

**Note**

In simple configurations, this task is optional. You do not need to specify a pseudowire class if you specify the tunneling method as part of the **xconnect** command.

The pseudowire-class configuration group specifies the following characteristics of the tunneling mechanism:

- Encapsulation type
- Control protocol
- Payload-specific options

For more information, see the **pseudowire-class** command in the following feature module:

[Layer 2 Tunnel Protocol Version 3](#)

You must specify the **encapsulation mpls** command as part of the pseudowire class or as part of the **xconnect** command for the AToM VCs to work properly. If you omit the **encapsulation mpls** command as part of the **xconnect** command, you receive the following error:

```
% Incomplete command.
```

Once you specify the **encapsulation mpls** command, you cannot remove it using the **no encapsulation mpls** command. Nor can you change the command's setting using the **encapsulation l2tpv3** command. Those methods result in the following error message:

```
Encapsulation changes are not allowed on an existing pw-class.
```

To remove the command, you must delete the pseudowire with the **no pseudowire-class** command. To change the type of encapsulation, remove the pseudowire with the **no pseudowire-class** command and reestablish the pseudowire and specify the new encapsulation type.

**Note**

There are many options that you can configure. For detailed information, see the [Any Transport over MPLS](#) feature module.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **pseudowire-class** *name*
4. **encapsulation mpls**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>enable</code>  <b>Example:</b> <code>Router&gt; enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none"><li>Enter your password if prompted.</li></ul>
Step 2	<code>configure terminal</code>  <b>Example:</b> <code>Router# configure terminal</code>	Enters global configuration mode.
Step 3	<code>pseudowire-class name</code>  <b>Example:</b> <code>Router(config)# pseudowire-class atom</code>	Establishes a pseudowire class with a name that you specify and enters pseudowire class configuration mode.
Step 4	<code>encapsulation mpls</code>  <b>Example:</b> <code>Router(config-pw)# encapsulation mpls</code>	Specifies the tunneling encapsulation. For AToM, the encapsulation type is <b>mpls</b> .

## What to Do Next

Perform a MIB walk using your SNMP management tool on cpwVcMIB, cpwVcMplsMIB, cpwVcEnetMIB, cpwVcFrMIB, and cpwVcAtmMIB to verify that the PW-MIB, the PW-MPLS-MIB, the PW-ENET-MIB, the PW-FR-MIB, and the PW-ATM-MIB objects, respectively, are populated correctly.

**Note**

SNMPv1 and SNMPv2c are supported.

## Configuration Examples for the Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services

This section provides the following configuration example:

- [PWE3 MIBs: Example, page 24](#)

### PWE3 MIBs: Example

In the following example, the configuration permits any SNMP manager to access all objects with read-only permissions using the community string *public*.

```
Router# configure terminal
```

Enter configuration commands, one per line. End with CNTL/Z.  
Router(config)# **snmp-server community public ro**

**Note**

There is no explicit way to configure the PWE3 MIBs. However, for information on AToM configuration tasks and examples, see the [Any Transport over MPLS](#) feature module.

There are notifications specific to the PWE3 MIBs. For detailed information on the commands used to configure them, see the [“Additional References” section on page 25](#).

## Additional References

## Command Reference

This feature uses no new or modified commands.

## Feature Information for Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services

Table 14 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

**Note**

---

Table 14 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

---

**Table 14**      **Feature Information for Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services**

Feature Name	Releases	Feature Information
Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services	12.0(29)S 12.0(30)S 12.0(31)S 12.2(28)SB 12.2(33)SRA 12.4(11)T 12.2(33)SXH	<p>The Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services feature provides Simple Network Management Protocol (SNMP) support within an Any Transport over Multiprotocol Label Switching (AToM) infrastructure emulating Ethernet, Frame Relay, and ATM services over packet switched networks (PSNs).</p> <p>In Cisco IOS Release 12.0(29)S, this feature was introduced as Pseudowire Emulation Edge-to-Edge MIBs for Ethernet Services.</p> <p>In Cisco IOS Release 12.0(30)S, the title changed to Pseudowire Emulation Edge-to-Edge MIBs for Ethernet and Frame Relay Services because Frame Relay was added as a transport. Support was added for the Cisco 12000 series routers and for the CISCO-IETF-PW-FR-MIB (PW-FR-MIB).</p> <p>In Cisco IOS Release 12.0(31)S, the CISCO-IETF-PW-MPLS-MIB (PW-MPLS-MIB) was modified regarding how cross-connect (XC) and tunnel indexes appear for virtual circuits (VCs).</p> <p>In Cisco IOS Release 12.2(28)SB, the title changed to Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services because ATM was added as a transport. Support was added for the CISCO-IETF-PW-ATM-MIB (PW-ATM-MIB).</p> <p>In Cisco IOS Releases 12.2(33)SRA, 12.4(11)T, and 12.2(33)SXH, this feature was integrated into the releases as the Pseudowire Emulation Edge-to-Edge MIBs for Ethernet and Frame Relay Services feature because ATM is not supported as a transport.</p>

# Glossary

**AAL**—ATM adaptation layer. AAL defines the conversion of user information into cells. AAL1 and AAL2 handle isochronous traffic, such as voice and video; AAL3/4 and AAL5 pertain to data communications through the segmentation and reassembly of packets.

**ATM**—asynchronous transfer mode. A cell-based data transfer technique in which channel demand determines packet allocation. This is an international standard for cell relay in which multiple service types (such as voice, video, or data) are conveyed in fixed-length (53-byte) cells. Fixed-length cells allow cell processing to occur in hardware, thereby reducing transit delays. ATM is designed to take advantage of high-speed transmission media such as E3, SONET, and T3.

**CE router**—customer edge router. A router that is part of a customer network and that interfaces to a provider edge (PE) router.

**DLCI**—data-link connection identifier. A unique number assigned to a PVC endpoint in a Frame Relay network. Identifies a particular PVC endpoint within an access channel in a Frame Relay network and has local significance only to that channel.

**encapsulation**—Wrapping of data in a particular protocol header. For example, Ethernet data is wrapped in a specific Ethernet header before network transit. Also, when bridging occurs in dissimilar networks, the entire frame from one network is simply placed in the header used by the data link layer protocol of the other network.

**EoMPLS**—ethernet over multiprotocol label switching (MPLS). A tunneling mechanism that allows a service provider to tunnel customer Layer 2 traffic through a Layer 3 MPLS network. EoMPLS is a point-to-point solution only. EoMPLS is also known as Layer 2 tunneling.

**Frame Relay**—The industry standard, switched data link layer protocol that handles multiple virtual circuits using High-Level Data Link Control (HDLC) encapsulation between connected devices. Frame Relay is more efficient than X.25, the protocol for which it is generally considered a replacement.

**IETF**—internet engineering task force. A task force (consisting of more than 80 working groups) that is developing standards for the Internet and the IP suite of protocols.

**LDP**—label distribution protocol. The protocol that supports MPLS hop-by-hop forwarding and the distribution of bindings between labels and network prefixes. The Cisco proprietary version of this protocol is the Tag Distribution Protocol (TDP).

**LSP**—label-switched path. A configured connection between two label switch routers (LSRs) in which label-switching techniques are used for packet forwarding; also a specific path through an MPLS network.

**LSR**—label switch router. A Multiprotocol Label Switching (MPLS) node that can forward native Layer 3 packets. The LSR forwards a packet based on the value of a label attached to the packet.

**MIB**—management information base. A database of network management information that is used and maintained by a network management protocol such as simple network management protocol (SNMP). The value of a MIB object can be changed or retrieved by using SNMP commands, usually through a network management system. MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

**MPLS**—multiprotocol label switching. A switching method for the forwarding of IP traffic through the use of a label. This label instructs the routers and the switches in the network where to forward the packets based on preestablished IP routing information.

**MTU**—maximum transmission unit. Maximum packet size, in bytes, that a particular interface can handle.

**NMS**—network management system. System responsible for managing at least part of a network. An NMS is generally a reasonably powerful and well-equipped computer, such as an engineering workstation. An NMS communicates with agents to help keep track of network statistics and resources.

**notification**—A message sent by a Simple Network Management Protocol (SNMP) agent to a network management station, console, or terminal to indicate that a significant network event has occurred. *See also* trap.

**OSPF**—Open Shortest Path First. A link-state hierarchical Interior Gateway Protocol routing algorithm, derived from the IS-IS protocol. OSPF features include least-cost routing, multipath routing, and load balancing.

**PE router**—provider edge router. A router that is part of a service provider's network and is connected to a customer edge (CE) router.

**primary tunnel**—A tunnel whose label-switched path (LSP) may be fast rerouted if there is a failure. Backup tunnels cannot be primary tunnels.

**pseudowire**—PW. A mechanism that carries the elements of an emulated service from one provider edge (PE) to one or more PEs over a packet switched network (PSN).

**SNMP**—simple network management protocol. A management protocol used almost exclusively in TCP/IP networks. SNMP provides a means for monitoring and controlling network devices, and for managing configurations, statistics collection, performance, and security.

**trap**—A message sent by an SNMP agent to a network management station, console, or terminal, indicating that a significant event occurred. Traps are less reliable than notification requests because the receiver does not send an acknowledgment when it receives a trap. The sender cannot determine if the trap was received.

**tunnel**—A secure communication path between two peers, such as routers.

**VC**—virtual circuit. A logical circuit created to ensure reliable communication between two network devices. A virtual circuit can be either permanent (PVC) or switched (SVC).

# MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV

---

**First Published: January 26, 2004**

**Last Updated: February 27, 2009**

The MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV feature helps service providers monitor label switched paths (LSPs) and quickly isolate Multiprotocol Label Switching (MPLS) forwarding problems.

The feature provides the following capabilities:

- MPLS LSP ping to test LSP connectivity for IPv4 Label Distribution Protocol (LDP) prefixes, Resource Reservation Protocol (RSVP) traffic engineering (TE), and Any Transport over MPLS (AToM) forwarding equivalence classes (FECs).
- MPLS LSP traceroute to trace the LSPs for IPv4 LDP prefixes and RSVP TE prefixes.

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the [“Feature Information for MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV” section on page 60](#).

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Contents

- [Prerequisites for MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV, page 2](#)
- [Restrictions for MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV, page 2](#)

---

**Americas Headquarters:**

**Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA**

- [Information About MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV, page 3](#)
- [How to Configure MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV, page 10](#)
- [Configuration Examples for MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV, page 30](#)

- [Glossary, page 62](#)

## Prerequisites for MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV

Before you use the MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV feature, you should:

- Determine the baseline behavior of your MPLS network. For example:
  - Expected MPLS experimental (EXP) treatment.
  - Expected maximum size packet or maximum transmission unit (MTU) of the LSP.
  - The topology, expected label switched path, and number of links in the LSP. Trace the paths of the label switched packets including the paths for load balancing.
- Understand how to use MPLS and MPLS applications. You need to:
  - Know how LDP is configured.
  - Understand AToM concepts.
- Understand label switching, forwarding, and load balancing.

Before using the **ping mpls** or **trace mpls** command, you must ensure that the router is configured to encode and decode MPLS echo packets in a format that all receiving routers in the network can understand.

## Restrictions for MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV

- You cannot use MPLS LSP traceroute to trace the path taken by AToM packets. MPLS LSP traceroute is not supported for AToM. (MPLS LSP ping is supported for AToM.) However, you can use MPLS LSP traceroute to troubleshoot the Interior Gateway Protocol (IGP) LSP that is used by AToM.
- You cannot use MPLS LSP ping to validate or trace MPLS Virtual Private Networks (VPNs).
- You cannot use MPLS LSP traceroute to troubleshoot LSPs that employ time-to-live (TTL) hiding.
- MPLS supports per-destination and per-packet (round robin) load balancing. If per-packet load balancing is in effect, you should not use MPLS LSP traceroute because LSP traceroute at a transit router consistency checks the information supplied in the previous echo response from the directly connected upstream router. When round robin is employed, the path that an echo request packet

takes cannot be controlled in a way that allows a packet to be directed to TTL expire at a given router. Without that ability, the consistency checking may fail during an LSP traceroute. A consistency check failure return code may be returned.

- A platform must support LSP ping and traceroute in order to respond to an MPLS echo request packet.
- Unless the MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV feature is enabled along the entire path, you cannot get a reply if the request fails along the path at any node.
- There are certain limitations when a mixture of draft versions are implemented within a network. The version of the draft must be compatible with Cisco's implementation. Due to the way the LSP Ping draft was written, earlier versions may not be compatible with later versions because of changes to type, length, values (TLVs) formats without sufficient versioning information. Cisco attempts to compensate for this in its implementations by allowing the sending and responding routers to be configured to encode and decode echo packets assuming a certain version.
- If you want to use MPLS LSP traceroute, the network should not use TTL hiding.

## Information About MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV

Before using the MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV feature, you should understand the following concepts:

- [MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV Functionality, page 3](#)
- [MPLS LSP Ping Operation, page 4](#)
- [MPLS LSP Traceroute Operation, page 5](#)
- [MPLS Network Management with MPLS LSP Ping and MPLS LSP Traceroute, page 7](#)
- [Any Transport over MPLS Virtual Circuit Connection, page 7](#)
- [IP Does Not Forward MPLS Echo Request Packets, page 9](#)

## MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV Functionality

Internet Control Message Protocol (ICMP) ping and traceroute are often used to help diagnose the root cause when a forwarding failure occurs. However, they are not well suited for identifying LSP failures because an ICMP packet can be forwarded via IP to the destination when an LSP breakage occurs.

The MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV feature is well suited for identifying LSP breakages for the following reasons:

- An MPLS echo request packet cannot be forwarded via IP because IP TTL is set to 1 and the IP destination address field is set to a 127/8 address.
- The FEC being checked is not stored in the IP destination address field (as is the case of ICMP).

MPLS echo request and reply packets test LSPs. There are two methods by which a downstream router can receive packets:

- The Cisco implementation of MPLS echo request and echo reply that was previously based on the Internet Engineering Task Force (IETF) Internet Draft *Detecting MPLS Data Plane Failures* (draft-ietf-mpls-lsp-ping-03.txt).

- Features described in this document that are based on the IETF RFC 4379 *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*:
  - Echo request output interface control
  - Echo request traffic pacing
  - Echo request end-of-stack explicit-null label shimming
  - Echo request request-dsmap capability
  - Request-fec checking
  - Depth limit reporting

## MPLS LSP Ping Operation

MPLS LSP ping uses MPLS echo request and reply packets to validate an LSP. You can use MPLS LSP ping to validate IPv4 LDP, AToM, and IPv4 RSVP FECs by using appropriate keywords and arguments with the **ping mpls** command.

The MPLS echo request packet is sent to a target router through the use of the appropriate label stack associated with the LSP to be validated. Use of the label stack causes the packet to be forwarded over the LSP itself.

The destination IP address of the MPLS echo request packet is different from the address used to select the label stack. The destination IP address is defined as a 127.x.y.z/8 address. The 127.x.y.z/8 address prevents the IP packet from being IP switched to its destination if the LSP is broken.

An MPLS echo reply is sent in response to an MPLS echo request. The reply is sent as an IP packet and it is forwarded using IP, MPLS, or a combination of both types of switching. The source address of the MPLS echo reply packet is an address obtained from the router generating the echo reply. The destination address is the source address of the router that originated the MPLS echo request packet.

The MPLS echo reply destination port is set to the echo request source port.

Figure 1 shows MPLS LSP ping echo request and echo reply paths.

**Figure 1** MPLS LSP Ping Echo Request and Echo Reply Paths

If you initiate an MPLS LSP ping request at LSR1 to a FEC at LSR6, you get the results shown in Table 1.

**Table 1**      **MPLS LSP Ping Example from Figure 1**

Step	Router	Action
1.	LSR1	Initiates an MPLS LSP ping request for an FEC at the target router LSR6 and sends an MPLS echo request to LSR2.
2.	LSR2	Receives the MPLS echo request packet and forwards it through transit routers LSR3 and LSR4 to the penultimate router LSR5.
3.	LSR5	Receives the MPLS echo request, pops the MPLS label, and forwards the packet to LSR6 as an IP packet.
4.	LSR6	Receives the IP packet, processes the MPLS echo request, and sends an MPLS echo reply to LSR1 through an alternate route.
5.	LSR7 to LSR10	Receives the MPLS echo reply and forwards it back toward LSR1, the originating router.
6.	LSR1	Receives the MPLS echo reply in response to its MPLS echo request.

## MPLS LSP Traceroute Operation

MPLS LSP traceroute uses MPLS echo request and reply packets to validate an LSP. You can use MPLS LSP traceroute to validate IPv4 LDP and IPv4 RSVP FECs by using appropriate keywords and arguments with the **trace mpls** command.

The MPLS LSP Traceroute feature uses TTL settings to force expiration of the TTL along an LSP. MPLS LSP Traceroute incrementally increases the TTL value in its MPLS echo requests (TTL = 1, 2, 3, 4) to discover the downstream mapping of each successive hop. The success of the LSP traceroute depends on the transit router processing the MPLS echo request when it receives a labeled packet with a TTL = 1. On Cisco routers, when the TTL expires, the packet is sent to the Route Processor (RP) for processing. The transit router returns an MPLS echo reply containing information about the transit hop in response to the TTL-expired MPLS packet.

The MPLS echo reply destination port is set to the echo request source port.

### Note

When a router traces an IPV4 FEC that goes over a traffic engineering tunnel, intermediate routers may return U (unreachable) if LDP is not running in those intermediate routers.

Figure 2 shows an MPLS LSP traceroute example with an LSP from LSR1 to LSR4.

**Figure 2** *MPLS LSP Traceroute Example*

If you enter an LSP traceroute to an FEC at LSR4 from LSR1, you get the results shown in [Table 2](#).

**Table 2** *MPLS LSP Traceroute Example Based on [Figure 2](#)*

Step	Router	MPLS Packet Type and Description	Router Action (Receive or Send)
1.	LSR1	MPLS echo request—With a target FEC pointing to LSR4 and to a downstream mapping	<ul style="list-style-type: none"> <li>Sets the TTL of the label stack to 1</li> <li>Sends the request to LSR2</li> </ul>
2.	LSR2	MPLS echo reply	<ul style="list-style-type: none"> <li>Receives the packet with a TTL = 1</li> <li>Processes the User Datagram Protocol (UDP) packet as an MPLS echo request</li> <li>Finds a downstream mapping and replies to LSR1 with its own downstream mapping, based on the incoming label</li> </ul>
3.	LSR1	MPLS echo request—With the same target FEC and the downstream mapping received in the echo reply from LSR2	<ul style="list-style-type: none"> <li>Sets the TTL of the label stack to 2</li> <li>Sends the request to LSR2</li> </ul>
4.	LSR2	MPLS echo request	<ul style="list-style-type: none"> <li>Receives the packet with a TTL = 2</li> <li>Decrements the TTL</li> <li>Forwards the echo request to LSR3</li> </ul>
5.	LSR3	MPLS reply packet	<ul style="list-style-type: none"> <li>Receives the packet with a TTL = 1</li> <li>Processes the UDP packet as an MPLS echo request</li> <li>Finds a downstream mapping and replies to LSR1 with its own downstream mapping based on the incoming label</li> </ul>
6.	LSR1	MPLS echo request—With the same target FEC and the downstream mapping received in the echo reply from LSR3	<ul style="list-style-type: none"> <li>Sets the TTL of the packet to 3</li> <li>Sends the request to LSR2</li> </ul>

103388

**Table 2** *MPLS LSP Traceroute Example Based on Figure 2 (continued)*

Step	Router	MPLS Packet Type and Description	Router Action (Receive or Send)
7.	LSR2	MPLS echo request	<ul style="list-style-type: none"> <li>Receives the packet with a TTL = 3</li> <li>Decrements the TTL</li> <li>Forwards the echo request to LSR3</li> </ul>
8.	LSR3	MPLS echo request	<ul style="list-style-type: none"> <li>Receives the packet with a TTL = 2</li> <li>Decrements the TTL</li> <li>Forwards the echo request to LSR4</li> </ul>
9.	LSR4	MPLS echo reply	<ul style="list-style-type: none"> <li>Receives the packet with a TTL = 1</li> <li>Processes the UDP packet as an MPLS echo request</li> <li>Finds a downstream mapping and also finds that the router is the egress router for the target FEC</li> <li>Replies to LSR1</li> </ul>

## MPLS Network Management with MPLS LSP Ping and MPLS LSP Traceroute

To manage an MPLS network, you must have the ability to monitor LSPs and quickly isolate MPLS forwarding problems. You need ways to characterize the liveness of an LSP and reliably detect when an LSP fails to deliver user traffic.

You can use MPLS LSP ping to verify the LSP that is used to transport packets destined for IPv4 LDP prefixes, and AToM PW FECs. You can use MPLS LSP traceroute to trace LSPs that are used to carry packets destined for IPv4 LDP prefixes.

An MPLS echo request is sent through an LSP to validate it. A TTL expiration or LSP breakage causes the transit router to process the echo request before it gets to the intended destination. The router returns an MPLS echo reply that contains an explanatory reply code to the originator of the echo request.

The successful echo request is processed at the egress of the LSP. The echo reply is sent via an IP path, an MPLS path, or a combination of both back to the originator of the echo request.

## Any Transport over MPLS Virtual Circuit Connection

AToM Virtual Circuit Connection Verification (VCCV) allows you to send control packets inband of an AToM PW from the originating provider edge (PE) router. The transmission is intercepted at the destination PE router, instead of being forwarded to the customer edge (CE) router. This capability allows you to use MPLS LSP ping to test the PW section of AToM virtual circuits (VCs).

LSP ping allows verification of AToM VC setup by FEC 128 or FEC 129. FEC 128-based AToM VCs can be set up by using LDP for signaling or by using a static pseudowire configuration without using any signaling component on the two endpoints. Cisco IOS does not distinguish between FEC 128 and FEC 129 static pseudowires while issuing MPLS ping; the same commands are used.

AToM VCCV consists of the following:

- A signaled component in which the AToM VCCV capabilities are advertised during VC label signaling
- A switching component that causes the AToM VC payload to be treated as a control packet

## AToM VCCV Signaling

One of the steps involved in AToM VC setup is the signaling or communication of VC labels and AToM VCCV capabilities between AToM VC endpoints. To communicate the AToM VCCV disposition capabilities of each endpoint, the router uses an optional parameter, defined in the IETF Internet Draft *Pseudo Wire (PW) Virtual Circuit Connection Verification (VCCV)* (draft-ietf-pwe3-vccv-01).

The AToM VCCV disposition capabilities are categorized as follows:

- Applications—MPLS LSP ping and ICMP ping are applications that AToM VCCV supports to send packets inband of an AToM PW for control purposes.
- Switching modes—Type 1 and Type 2 are switching modes that AToM VCCV uses for differentiating between control and data traffic.

Table 3 describes AToM VCCV Type 1 and Type 2 switching modes.

**Table 3**      **Type 1 and Type 2 AToM VCCV Switching Modes**

Switching Mode	Description
Type 1	Uses a Protocol ID (PID) field in the AToM control word to identify an AToM VCCV packet
Type 2	Uses an MPLS Router Alert Label above the VC label to identify an AToM VCCV packet

## Selection of AToM VCCV Switching Types

Cisco routers always use Type 1 switching, if available, when they send MPLS LSP ping packets over an AToM VC control channel. Type 2 switching accommodates those VC types and implementations that do not support or interpret the AToM control word.

Table 4 shows the AToM VCCV switching mode advertised and the switching mode selected by the AToM VC.

**Table 4**      **AToM VCCV Switching Mode Advertised and Selected by AToM VC**

Type Advertised	Type Selected
AToM VCCV not supported	—
Type 1 AToM VCCV switching	Type 1 AToM VCCV switching
Type 2 AToM VCCV switching	Type 2 AToM VCCV switching
Type 1 and Type 2 AToM VCCV switching	Type 1 AToM VCCV switching

An AToM VC advertises its AToM VCCV disposition capabilities in both directions: that is, from the originating router (PE1) to the destination router (PE2), and from PE2 to PE1.

In some instances, AToM VCs might use different switching types if the two endpoints have different AToM VCCV capabilities. If PE1 supports Type 1 and Type 2 AToM VCCV switching and PE2 supports only Type 2 AToM VCCV switching, there are two consequences:

- LSP ping packets sent from PE1 to PE2 are encapsulated with Type 2 switching.
- LSP ping packets sent from PE2 to PE1 use Type 1 switching.

You can determine the AToM VCCV capabilities advertised to and received from the peer by entering the **show mpls l2transport binding** command at the PE router.

## Information Provided by the Router Processing LSP Ping or LSP Traceroute

Table 5 describes the characters that the router processing an LSP ping or LSP traceroute packet returns to the sender about the failure or success of the request.

You can also display the return code for an MPLS LSP Ping operation if you enter the **verbose** keyword in the **ping mpls** command.

**Table 5** *Echo Reply Return Codes*

Output Code	Echo Return Code	Meaning
x	0	No return code.
M	1	Malformed echo request.
m	2	Unsupported TLVs.
!	3	Success.
F	4	No FEC mapping.
D	5	DS Map mismatch.
I	6	Unknown Upstream Interface index.
U	7	Reserved.
L	8	Labeled output interface.
B	9	Unlabeled output interface.
f	10	FEC mismatch.
N	11	No label entry.
P	12	No receive interface label protocol.
p	13	Premature termination of the LSP.
X	unknown	Undefined return code.

**Note**

Echo return codes 6 and 7 are accepted only for Version 3 (draft-ietf-mpls-ping-03).

## IP Does Not Forward MPLS Echo Request Packets

MPLS echo request packets sent during an LSP ping are never forwarded by IP. The IP header destination address field in an MPLS echo request packet is a 127.x.y.z/8 address. Routers should not forward packets using a 127.x.y.z/8 address. The 127.x.y.z/8 address corresponds to an address for the local host.

Use of a 127.x.y.z address as the destination address of the UDP packet is significant because the MPLS echo request packet fails to make it to the target router if a transit router does not label switch the LSP. The use of the 127.x.y.z address allows for the detection of LSP breakages. The following occurs at the transit router:

- If an LSP breakage occurs at a transit router, the MPLS echo packet is not forwarded; it is consumed by the router.
- If the LSP is intact, the MPLS echo packet reaches the target router and is processed by the terminal point of the LSP.

Figure 3 shows the path of the MPLS echo request and reply when a transit router fails to label switch a packet in an LSP.

**Figure 3** Path when Transit Router Fails to Label Switch a Packet

**Note**

An AToM payload does not contain usable forwarding information at a transit router because the payload may not be an IP packet. An MPLS VPN packet, although an IP packet, does not contain usable forwarding information at a transit router because the destination IP address is significant only to the virtual routing and forwarding (VRF) instances at the endpoints of the MPLS network.

## How to Configure MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV

This section contains the following tasks:

- [Enabling Compatibility Between the MPLS LSP and Ping or Traceroute Implementation, page 11](#) (required)
- [Validating an FEC by Using MPLS LSP Ping and MPLS LSP Traceroute, page 12](#) (required)
- [Using DSCP to Request a Specific Class of Service in an Echo Reply, page 14](#) (optional)
- [Controlling How a Responding Router Replies to an MPLS Echo Request, page 15](#) (optional)
- [Preventing Loops when Using MPLS LSP Ping and LSP Traceroute Command Options, page 17](#) (optional)
- [Detecting LSP Breaks, page 19](#) (optional)

## Enabling Compatibility Between the MPLS LSP and Ping or Traceroute Implementation

LSP ping drafts after Version 3 (draft-ietf-mpls-ping-03) have undergone numerous TLV format changes, but the versions of the draft do not always interoperate.

To allow later Cisco implementations to interoperate with draft Version 3 Cisco and non-Cisco implementations, use a global configuration mode to decode echo packets in formats understood by draft Version 3 implementations.

Unless configured otherwise, a Cisco implementation encodes and decodes echo requests assuming the version on which the IETF implementations is based.

To prevent failures reported by the replying router due to TLV version issues, you should configure all routers in the core. Encode and decode MPLS echo packets in the same draft version. For example, if the network is running RFC 4379 (Cisco Version 4) implementations but one router is capable of only Version 3 (Cisco Revision 3), configure all routers in the network to operate in Revision 3 mode.

The Cisco implementation of MPLS echo request and echo reply is based on the IETF RFC 4379. IETF drafts subsequent to this RFC (drafts 3, 4, 5, 6, and 7) introduced TLV format differences. These differences could not be identified because the echo packet had no way to differentiate between one TLV format and another TLV format. This introduced limited compatibility between the MPLS LSP Ping/Traceroute implementations in the Cisco IOS 12.0(27)S1 and 12.0(27)S2 releases and the MPLS ping or traceroute implementation in later Cisco IOS releases. To allow interoperability between these releases, a **revision** keyword was added for the **ping mpls** and **trace mpls** commands. The **revision** keyword enables Cisco IOS releases to support the existing draft changes and any changes from future versions of the IETF LSP Ping draft.

**Note**

We recommend that you use the **mpls oam** global configuration command instead of the revision option.

**Note**

No images are available on cisco.com to support Revision 2. It is recommended that you use only images supporting Version 3 and later when configuring TLV encode and decode modes. MPLS Multipath LSP traceroute requires Cisco Revision 4 or later.

### Cisco Vendor Extensions

In Cisco's Version 3 (draft-ietf-mpls-ping-03.txt) implementations, Cisco defined a vendor extension TLV in the ignore-if-not-understood TLV space. It is used for the following purposes:

- Provide an ability to track TLV versions.
- Provide an experimental Reply TOS capability.

The first capability was defined before the existence of the global configuration command for setting the echo packet encode and decode behavior. TLV version information in an echo packet overrides the configured decoding behavior. Using this TLV for TLV versions is no longer required since the introduction of the global configuration capability.

The second capability controls the reply DSCP. Draft Version 8 defines a Reply TOS TLV, so the use of the reply DSCP is no longer required.

To enable compatibility between the MPLS LSP and ping or traceroute implementation by customizing the default behavior of echo packets, perform the following steps.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls oam**
4. **echo revision {3 | 4}**
5. **echo vendor-extension**
6. **exit**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"><li>Enter your password if prompted.</li></ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>mpls oam</b>  <b>Example:</b> Router(config)# mpls oam	Enters MPLS OAM configuration mode for customizing the default behavior of echo packets.
Step 4	<b>echo revision {3   4}</b>  <b>Example:</b> Router(config-mpls)# echo revision 4	Specifies the revision number of the echo packet's default values. <ul style="list-style-type: none"><li>3—draft-ietf-mpls-ping-03 (Revision 2).</li><li>4—RFC 4379 compliant (default).</li></ul>
Step 5	<b>echo vendor-extension</b>  <b>Example:</b> Router(config-mpls)# echo vendor-extension	Sends the Cisco-specific extension of TLVs with echo packets.
Step 6	<b>exit</b>  <b>Example:</b> Router(config-mpls)# exit	Returns to global configuration mode.

## Validating an FEC by Using MPLS LSP Ping and MPLS LSP Traceroute

An LSP is formed by labels. Routers learn labels through LDP, AToM, or some other MPLS applications. You can use MPLS LSP ping or traceroute to validate an LSP used for forwarding traffic for a given FEC.

This section describes the following tasks:

- [Validating an LDP IPv4 FEC by Using MPLS LSP Ping and MPLS LSP Traceroute, page 13](#)

- [Validating a Layer 2 FEC by Using MPLS LSP Ping and MPLS LSP Traceroute, page 14](#)

## Validating an LDP IPv4 FEC by Using MPLS LSP Ping and MPLS LSP Traceroute

To ensure that the router will be able to forward MPLS packets for IPv4 FEC prefixes advertised by LDP, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **ping mpls ipv4** *destination-address/destination-mask-length* [**repeat** *count*] [**exp** *exp-bits*] [**verbose**]  
or  
**trace mpls ipv4** *destination-address/destination-mask-length*
3. **exit**

### DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
Step 2	<b>ping mpls ipv4</b> <i>destination-address/destination-mask-length</i> [ <b>repeat</b> <i>count</i> ] [ <b>exp</b> <i>exp-bits</i> ] [ <b>verbose</b> ]  or  <b>trace mpls ipv4</b> <i>destination-address/destination-mask-length</i>  <b>Example:</b> Router# ping mpls ipv4 10.131.191.252/32 exp 5 repeat 5 verbose  or  <b>Example:</b> Router# trace mpls ipv4 10.131.191.252/32	Selects an LDP IPv4 prefix FEC for validation.
Step 3	<b>exit</b>  <b>Example:</b> Router# exit	Returns to user EXEC mode.

## Validating a Layer 2 FEC by Using MPLS LSP Ping and MPLS LSP Traceroute

To ensure that the router will be able to forward MPLS packets for Layer 2 FEC prefixes advertised by LDP, perform the following steps.

### SUMMARY STEPS

- `enable`
- `ping mpls pseudowire ipv4-address vc-id vc-id`
- `exit`

### DETAILED STEPS

Step 1	<code>enable</code>  <b>Example:</b> Router> <code>enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<code>ping mpls pseudowire ipv4-address vc-id vc-id</code>  <b>Example:</b> Router# <code>ping mpls pseudowire 10.131.191.252 vc-id 333</code>	Selects a Layer 2 FEC for validation.
Step 3	<code>exit</code>  <b>Example:</b> Router# <code>exit</code>	Returns to user EXEC mode.

## Using DSCP to Request a Specific Class of Service in an Echo Reply

For Cisco IOS Release 12.2(27)SXE, Cisco added a reply differentiated services code point (DSCP) option that lets you request a specific class of service (CoS) in an echo reply.

The reply DSCP option is supported in the experimental mode for IETF draft-ietf-mpls-lsp-ping-03.txt. Cisco implemented a vendor-specific extension for the reply DSCP option rather than using a Reply TOS TLV. A Reply TOS TLV serves the same purpose as the **reply dscp** command in RFC 4379. This draft provides a standardized method of controlling the reply DSCP.

#### Note

Before draft Version 8, Cisco implemented the Reply DSCP option as an experimental capability using a Cisco vendor extension TLV. If a router is configured to encode MPLS echo packets for draft Version 3 implementations, a Cisco vendor extension TLV is used instead of the Reply TOS TLV that was defined in draft Version 8.

To use DSCP to request a specific CoS in an echo reply, perform the following steps.

### SUMMARY STEPS

- `enable`

2. **ping mpls** {**ipv4** *destination-address/destination-mask-length* | **pseudowire** *ipv4-address vc-id vc-id* } [**reply dscp** *dscp-value*]  
or  
**trace mpls ipv4** *destination-address/destination-mask-length* [**reply dscp** *dscp-value*]
3. **exit**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>ping mpls</b> { <b>ipv4</b> <i>destination-address/destination-mask-length</i>   <b>pseudowire</b> <i>ipv4-address vc-id vc-id</i> } [ <b>reply dscp</b> <i>dscp-value</i> ]  or <b>trace mpls ipv4</b> <i>destination-address/destination-mask-length</i> [ <b>reply dscp</b> <i>dscp-value</i> ]  <b>Example:</b> Router# ping mpls ipv4 10.131.191.252/32 reply dscp 50  or <b>Example:</b> Router# trace mpls ipv4 10.131.191.252/32 reply dscp 50	Controls the DSCP value of an echo reply.
Step 3	<b>exit</b>  <b>Example:</b> Router# exit	Returns to user EXEC mode.

## Controlling How a Responding Router Replies to an MPLS Echo Request

To control how a responding router replies to an MPLS echo request, see the [“Reply Modes for an MPLS LSP Ping and LSP Traceroute Echo Request Response”](#) section.

### Reply Modes for an MPLS LSP Ping and LSP Traceroute Echo Request Response

The reply mode controls how a responding router replies to an MPLS echo request sent by a **ping mpls** or **trace mpls** command. There are two reply modes for an echo request packet:

- ipv4—Reply with an IPv4 UDP packet (default)

- router-alert—Reply with an IPv4 UDP packet with router alert

**Note**

It is useful to use `ipv4` and `router-alert` reply modes in conjunction with each other to prevent false negatives. If you do not receive a reply via the `ipv4` mode, it is useful to send a test with the `router-alert` reply mode. If both fail, something is wrong in the return path. The problem may be only that the Reply TOS is not set correctly.

**ipv4 Reply Mode**

IPv4 packet is the most common reply mode used with a **ping mpls** or **trace mpls** command when you want to periodically poll the integrity of an LSP. With this option, you do not have explicit control over whether the packet traverses IP or MPLS hops to reach the originator of the MPLS echo request. If the originating (headend) router fails to receive a reply to an MPLS echo request when you use the **reply mode ipv4** keywords, use the **reply mode router-alert** keywords.

**Router-alert Reply Mode**

The router-alert reply mode adds the router alert option to the IP header. When an IP packet that contains an IP router alert option in its IP header or an MPLS packet with a router alert label as its outermost label arrives at a router, the router punts (redirects) the packet to the Route Processor (RP) level for handling. This forces the Cisco router to handle the packet at each intermediate hop as it moves back to the destination. Hardware and line-card forwarding inconsistencies are bypassed. Router-alert reply mode is more expensive than IPv4 mode because the reply goes hop-by-hop. It also is slower, so the sender receives a reply in a relatively longer period of time.

Table 6 describes how IP and MPLS packets with an IP router alert option are handled by the router switching path processes.

**Table 6** Path Process Handling of IP and MPLS Router Alert Packets

Incoming Packet	Normal Switching Action	Process Switching Action	Outgoing Packet
IP packet—Router alert option in IP header	Router alert option in IP header causes the packet to be punted to the process switching path.	Forwards the packet as is	IP packet—Router alert option in IP header
		Forwards the packet as is	MPLS packet
MPLS packet—Outermost label contains a router alert	If the router alert label is the outermost label, it causes the packet to be punted to the process switching path.	Removes the outermost router alert label and forwards the packet as an IP packet	IP packet—Router alert option in IP header
		Preserves the outermost router alert label and forwards the MPLS packet	MPLS packet—Outermost label contains a router alert.

**SUMMARY STEPS**

1. **enable**
  2. **ping mpls** {**ipv4** *destination-address/destination-mask-length* | **pseudowire** *ipv4-address vc-id vc-id*} **reply mode** {**ipv4** | **router-alert**}
- or

```
trace mpls ipv4 destination-address/destination-mask reply mode {ipv4 | router-alert}
```

### 3. exit

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<pre>enable</pre> <p><b>Example:</b> Router&gt; enable</p>	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<pre>ping mpls {ipv4 destination-address /destination-mask-length   pseudowire ipv4-address vc-id vc-id} reply mode {ipv4   router-alert}</pre> <p>or</p> <pre>trace mpls ipv4 destination-address /destination-mask reply mode {ipv4   router-alert}</pre> <p><b>Example:</b> Router# ping mpls ipv4 10.131.191.252/32 reply mode ipv4</p> <p>or</p> <pre>Router# trace mpls ipv4 10.131.191.252/32 reply mode router-alert</pre>	Checks MPLS LSP connectivity. or Discovers MPLS LSP routes that packets actually take when traveling to their destinations.  <b>Note</b> To specify the reply mode, you must enter the <b>reply mode</b> keyword with the <b>ipv4</b> or <b>router-alert</b> keyword.
Step 3	<pre>exit</pre> <p><b>Example:</b> Router# exit</p>	Returns to user EXEC mode.

## Preventing Loops when Using MPLS LSP Ping and LSP Traceroute Command Options

The interaction of the MPLS Embedded Management—LSP Ping for LDP feature options can cause loops. See the following sections for a description of the loops you may encounter with the **ping mpls** and **trace mpls** commands:

- [Using MPLS LSP Ping to Discover Possible Loops, page 17](#)
- [Using MPLS LSP Traceroute to Discover Possible Loops, page 18](#)

## Using MPLS LSP Ping to Discover Possible Loops

With the MPLS LSP Ping feature, loops can occur if you use the UDP destination address range, repeat option, or sweep option.

To use MPLS LSP ping to discover possible loops, perform the following steps.

## SUMMARY STEPS

1. **enable**
2. **ping mpls** {**ipv4** *destination-address/destination-mask* [**destination** *address-start address-end increment*] | [**pseudowire** *ipv4-address vc-id vc-id address-end increment*] } [**repeat** *count*] [**sweep** *minimum maximum size-increment*]
3. **exit**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
Step 2	<b>ping mpls</b> { <b>ipv4</b> <i>destination-address /destination-mask</i> [ <b>destination</b> <i>address-start address-end increment</i> ]   [ <b>pseudowire</b> <i>ipv4-address vc-id vc-id address-end increment</i> ]} [ <b>repeat</b> <i>count</i> ] [ <b>sweep</b> <i>minimum maximum size-increment</i> ]  <b>Example:</b> Router# ping mpls ipv4 10.131.159.251/32 destination 127.0.0.1 127.0.0.2 1 repeat 2 sweep 1450 1475 25	Checks MPLS LSP connectivity.
Step 3	<b>exit</b>  <b>Example:</b> Router# exit	Returns to user EXEC mode.

## Using MPLS LSP Traceroute to Discover Possible Loops

With the MPLS LSP Traceroute feature, loops can occur if you use the UDP destination address range option and the time-to-live option.

By default, the maximum TTL is set to 30. Therefore, the traceroute output may contain 30 lines if the target of the traceroute is not reached, which can happen when an LSP problem exists. If an LSP problem occurs, there may be duplicate entries. The router address of the last point that the trace reaches is repeated until the output is 30 lines. You can ignore the duplicate entries.

## SUMMARY STEPS

1. **enable**
2. **trace mpls ipv4** *destination-address/destination-mask* [**destination** *address-start address-end address-increment*] [**ttl** *maximum-time-to-live*]
3. **exit**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>trace mpls ipv4 destination-address /destination-mask [destination address-start address-end address increment] [ttl maximum-time-to-live]</b>  <b>Example:</b> Router# trace mpls ipv4 10.131.159.251/32 destination 127.0.0.1 127.0.0.3 1 ttl 5	Discovers MPLS LSP routes that packets take when traveling to their destinations. The example shows how a loop can occur.
Step 3	<b>exit</b>  <b>Example:</b> Router# exit	Returns to user EXEC mode.

## Detecting LSP Breaks

If there is a problem forwarding MPLS packets in your network, you can determine where there are LSP breaks. This section describes MTU discovery in an LSP.

Untagged output interfaces at a penultimate hop do not impact the forwarding of IP packets through an LSP because the forwarding decision is made at the penultimate hop through use of the incoming label. However, untagged output interfaces cause AToM and MPLS VPN traffic to be dropped at the penultimate hop.

During an MPLS LSP ping, MPLS echo request packets are sent with the IP packet attribute set to “do not fragment.” That is, the Don’t Fragment (DF) bit is set in the IP header of the packet. This allows you to use the MPLS echo request to test for the MTU that can be supported for the packet through the LSP without fragmentation.

Figure 4 shows a sample network with a single LSP from PE1 to PE2 formed with labels advertised by the LDP.

**Figure 4** Sample Network with LSP—Labels Advertised by LDP

You can determine the maximum receive unit (MRU) at each hop by using the MPLS Traceroute feature to trace the LSP. The MRU is the maximum size of a labeled packet that can be forwarded through an LSP.

This section contains the following tasks:

- [Tracking Packets Tagged as Implicit Null, page 20](#)
- [Tracking Untagged Packets, page 21](#)
- [Determining Why a Packet Could Not Be Sent, page 21](#)
- [Detecting LSP Breaks when Load Balancing Is Enabled for IPv4 LDP LSPs, page 22](#)
- [Specifying the Interface Through Which Echo Packets Leave a Router, page 23](#)
- [Pacing the Transmission of Packets, page 24](#)
- [Interrogating the Transit Router for Its Downstream Information by Using Echo Request request-dsmap, page 25](#)
- [Interrogating a Router for Its DSMAP, page 26](#)
- [Requesting that a Transit Router Validate the Target FEC Stack, page 27](#)
- [Enabling LSP Ping to Detect LSP Breakages Caused by Untagged Interfaces, page 28](#)
- [Viewing the AToM VCCV Capabilities Advertised to and Received from the Peer, page 29](#)

## Tracking Packets Tagged as Implicit Null

To track packets tagged as implicit null, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **trace mpls ipv4** *destination-address* /*destination-mask*
3. **exit**

### DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
Step 2	<b>trace mpls ipv4</b> <i>destination-address</i> / <i>destination-mask</i>  <b>Example:</b> Router# trace mpls ipv4 10.131.159.252/32	Discovers MPLS LSP routes that packets actually take when traveling to their destinations.
Step 3	<b>exit</b>  <b>Example:</b> Router# exit	Returns to user EXEC mode.

## Tracking Untagged Packets

To track untagged packets, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **show mpls forwarding-table** *destination-address/destination-mask*
3. **show mpls ldp discovery**
4. **exit**

### DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>show mpls forwarding-table</b> <i>destination-address/destination-mask</i>  <b>Example:</b> Router# show mpls forwarding-table 10.131.159.252/32	Displays the content of the MPLS Label Forwarding Information Base (LFIB) and displays whether the LDP is properly configured.
Step 3	<b>show mpls ldp discovery</b>  <b>Example:</b> Router# show mpls ldp discovery	Displays the status of the LDP discovery process and displays whether the LDP is properly configured.
Step 4	<b>exit</b>  <b>Example:</b> Router# exit	Returns to user EXEC mode.

## Determining Why a Packet Could Not Be Sent

The Q return code means that the packet could not be sent. The problem can be caused by insufficient processing memory, but it probably results because an LSP could not be found that matches the FEC information that was entered on the command line.

You need to determine the reason why the packet was not forwarded so that you can fix the problem in the path of the LSP. To do so, look at the Routing Information Base (RIB), the Forwarding Information Base (FIB), the Label Information Base (LIB), and the MPLS LFIB. If there is no entry for the FEC in any of these routing or forwarding bases, there is a Q return code.

To determine why a packet could not be transmitted, perform the following steps.

### SUMMARY STEPS

1. **enable**

2. **show ip route** [*ip-address* [**mask**]]
3. **show mpls forwarding-table** [*network* {*mask* | *length*} | **labels** *label* [- *label*] | **interface** *interface* | **next-hop** *address* | **lsp-tunnel** [*tunnel-id*]]
4. **exit**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>show ip route</b> [ <i>ip-address</i> [ <b>mask</b> ]]  <b>Example:</b> Router# show ip route 10.0.0.1	Displays the current state of the routing table.  When the MPLS echo reply returns a Q, troubleshooting occurs on the routing information database.
Step 3	<b>show mpls forwarding-table</b> [ <i>network</i> { <i>mask</i>   <i>length</i> }   <b>labels</b> <i>label</i> [- <i>label</i> ]   <b>interface</b> <i>interface</i>   <b>next-hop</b> <i>address</i>   <b>lsp-tunnel</b> [ <i>tunnel-id</i> ]]  <b>Example:</b> Router# show mpls forwarding-table 10.0.0.1/32	Displays the content of the MPLS LFIB. When the MPLS echo reply returns a Q, troubleshooting occurs on a label information database and an MPLS forwarding information database.
Step 4	<b>exit</b>  <b>Example:</b> Router# exit	Returns to user EXEC mode.

## Detecting LSP Breaks when Load Balancing Is Enabled for IPv4 LDP LSPs

An ICMP ping or trace follows one path from the originating router to the target router. Round robin load balancing of IP packets from a source router discovers the various output paths to the target IP address.

For MPLS ping and traceroute, Cisco routers use the source and destination addresses in the IP header for load balancing when multiple paths exist through the network to a target router. The Cisco implementation of MPLS may check the destination address of an IP payload to accomplish load balancing (the type of checking depends on the platform).

To detect LSP breaks when load balancing is enabled for IPv4 LDP LSPs, perform the following steps.

## SUMMARY STEPS

1. **enable**
2. **ping mpls ipv4** *destination-address/destination-mask-length* [**destination** *address-start* *address-end* *increment*]
3. **exit**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> <b>enable</b>	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>ping mpls ipv4 destination-address /destination-mask-length [destination address-start address-end increment]</b>  <b>Example:</b> Router# <b>ping mpls ipv4 10.131.159.251/32 destination 127.0.0.1/8</b>	Checks for load balancing paths.  Enter the 127.z.y.x/8 destination address.
Step 3	<b>exit</b>  <b>Example:</b> Router# <b>exit</b>	Returns to user EXEC mode.

## Specifying the Interface Through Which Echo Packets Leave a Router

To specify the interface through which echo packets leave a router, perform the following steps.

### Echo Request Output Interface Control

You can control the interface through which packets leave a router. Path output information is used as input to LSP ping and traceroute.

The echo request output interface control feature allows you to force echo packets through the paths that perform detailed debugging or characterizing of the LSP. This feature is useful if a PE router connects to an MPLS cloud and there are broken links. You can direct traffic through a certain link. The feature also is helpful for troubleshooting network problems.

To specify the output interface for echo requests, perform the following steps.

## SUMMARY STEPS

- enable**
- ping mpls {ipv4 destination-address/destination-mask | pseudowire ipv4-address vc-id vc-id} [output interface tx-interface]**  
or  
**trace mpls ipv4 destination-address/destination-mask [output interface tx-interface]**
- exit**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>ping mpls</b> { <b>ipv4</b> <i>destination-address</i> / <i>destination-mask</i>   <b>pseudowire</b> <i>ipv4-address</i> <b>vc-id</b> <i>vc-id</i> } [ <b>output interface</b> <i>tx-interface</i> ]  or  <b>trace mpls ipv4</b> <i>destination-address/destination-mask</i> [ <b>output interface</b> <i>tx-interface</i> ]  <b>Example:</b> Router# ping mpls ipv4 10.131.159.251/32 output interface ethernet0/0  or  Router# trace mpls ipv4 10.131.159.251/32 output interface ethernet0/0	Checks MPLS LSP connectivity.  or  Discovers MPLS LSP routes that packets actually take when traveling to their destinations.  <b>Note</b> For this task, you must specify the <b>output interface</b> keyword.
Step 3	<b>exit</b>  <b>Example:</b> Router# exit	Returns to user EXEC mode.

## Pacing the Transmission of Packets

Echo request traffic pacing allows you to pace the transmission of packets so that the receiving router does not drop packets. To perform echo request traffic pacing, perform the following steps.

## SUMMARY STEPS

- enable**
- ping mpls** {**ipv4** *destination-address/destination-mask* | **pseudowire** *ipv4-address* **vc-id** *vc-id*} [**interval** *ms*]  
  
or  
  
**trace mpls ipv4** *destination-address/destination-mask*
- exit**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>ping mpls</b> { <b>ipv4 destination-address</b> / <b>destination-mask</b>   <b>pseudowire ipv4-address vc-id vc-id</b> } [ <b>interval ms</b> ]  or  <b>trace mpls ipv4 destination-address</b> / <b>destination-mask</b>  <b>Example:</b> Router# ping mpls ipv4 10.131.159.251/32 interval 2  or  <b>Example:</b> Router# trace mpls ipv4 10.131.159.251/32	Checks MPLS LSP connectivity.  or  Discovers MPLS LSP routes that packets take when traveling to their destinations.  <b>Note</b> In this task, if you use the <b>ping mpls</b> command you must specify the <b>interval</b> keyword.
Step 3	<b>exit</b>  <b>Example:</b> Router# exit	Returns to user EXEC mode.

## Interrogating the Transit Router for Its Downstream Information by Using Echo Request request-dsmap

The echo request request-dsmap capability troubleshooting feature, used in conjunction with the TTL flag, allows you to selectively interrogate a transit router. If there is a failure, you do not have to enter an **lsp traceroute** command for each previous failure; you can focus just on the failed hop.

A request-dsmap flag in the downstream mapping flags field, and procedures that specify how to trace noncompliant routers allow you to arbitrarily time-to-live (TTL) expire MPLS echo request packets with a wildcard downstream map (DSMAP).

Echo request DSMAPs received without labels indicate that the sender did not have any DSMAPs to validate. If the downstream router ID field of the DSMAP TLV in an echo request is set to the ALLROUTERS address (224.0.0.2) and there are no labels, the source router can arbitrarily query a transit router for its DSMAP information.

The **ping mpls** command allows an MPLS echo request to be TTL-expired at a transit router with a wildcard DSMAP for the explicit purpose of troubleshooting and querying the downstream router for its DSMAPs. The default is that the DSMAP has an IPv4 bitmap hashkey. You also can select hashkey 0 (none). The purpose of the **ping mpls** command is to allow the source router to selectively TTL expire an echo request at a transit router to interrogate the transit router for its downstream information. The ability to also select a multipath (hashkey) type allows the transmitting router to interrogate a transit router for load-balancing information as is done with multipath LSP traceroute, but without having to

interrogate all subsequent nodes traversed between the source router and the router on which each echo request TTL expires. Use an echo request in conjunction with the TTL setting because if an echo request arrives at the egress of the LSP with an echo request, the responding routers never return DSMAPs.

To interrogate the transit router for its downstream information so that you can focus just on the failed hop if there is a failure, perform the following steps.

## SUMMARY STEPS

1. **enable**
2. **ping mpls** {**ipv4** *destination-address/destination-mask* | **pseudowire** *ipv4-address vc-id vc-id*} [**dsmap** [**hashkey** {**none** | **ipv4** *bitmap bitmap-size*}]]
3. **exit**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
Step 2	<b>ping mpls</b> { <b>ipv4</b> <i>destination-address /destination-mask</i>   <b>pseudowire</b> <i>ipv4-address vc-id vc-id</i> } [ <b>dsmap</b> [ <b>hashkey</b> { <b>none</b>   <b>ipv4</b> <i>bitmap bitmap-size</i> }]]  <b>Example:</b> Router# ping mpls ipv4 10.161.251/32 dsmap hashkey ipv4 bitmap 16	Checks MPLS LSP connectivity.  <b>Note</b> In this task, you must specify the <b>dsmap</b> and <b>hashkey</b> keywords.
Step 3	<b>exit</b>  <b>Example:</b> Router# exit	Returns to user EXEC mode.

## Interrogating a Router for Its DSMAP

The router can interrogate the software or hardware forwarding layer for the depth limit that needs to be returned in the DSMAP TLV. If forwarding does not provide a value, the default is 255.

To determine the depth limit, specify the **dsmap** and **ttl** keywords in the **ping mpls** command. The transit router will be interrogated for its DSMAP. The depth limit is returned with the echo reply DSMAP. A value of 0 means that the IP header is used for load balancing. Another value indicates that the IP header load balances up to the specified number of labels.

To interrogate a router for its DSMAP, perform the following steps.

## SUMMARY STEPS

1. **enable**

2. **ping mpls** {**ipv4** *destination-address/destination-mask* | **pseudowire** *ipv4-address vc-id vc-id*} **ttl** *time-to-live* **dsmap**
3. **exit**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>ping mpls</b> { <b>ipv4</b> <i>destination-address /destination-mask</i>   <b>pseudowire</b> <i>ipv4-address vc-id vc-id</i> } <b>ttl</b> <i>time-to-live</i> <b>dsmap</b>  <b>Example:</b> Router# ping mpls ipv4 10.131.159.252/32 ttl 1 dsmap	Checks MPLS LSP connectivity.  <b>Note</b> You must specify the <b>ttl</b> and <b>dsmap</b> keywords.
Step 3	<b>exit</b>  <b>Example:</b> Router# exit	Returns to user EXEC mode.

## Requesting that a Transit Router Validate the Target FEC Stack

An MPLS echo request tests a particular LSP. The LSP to be tested is identified by the FEC stack.

To request that a transit router validate the target FEC stack, set the V flag from the source router by entering the **flags fec** keyword in the **ping mpls** and **trace mpls** commands. The default is that echo request packets are sent with the V flag set to 0.

To request that a transit router validate the target FEC stack, perform the following steps.

## SUMMARY STEPS

1. **enable**
2. **ping mpls** {**ipv4** *destination-address/destination-mask* | **pseudowire** *ipv4-address vc-id vc-id*} **flags fec**  
or  
**trace mpls** **ipv4** *destination-address/destination-mask* **flags fec**
3. **exit**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>ping mpls {ipv4 destination-address /destination-mask   pseudowire ipv4-address vc-id vc-id} flags fec</b>  or  <b>trace mpls ipv4 destination-address /destination-mask flags fec</b>  <b>Example:</b> Router# ping mpls ipv4 10.131.159.252/32 flags fec  or  <b>Example:</b> Router# trace mpls ipv4 10.131.159.252/32 flags fec	Checks MPLS LSP connectivity.  or  Discovers MPLS LSP routes that packets actually take when traveling to their destinations.  <b>Note</b> You must enter the <b>flags fec</b> keyword.
Step 3	<b>exit</b>  <b>Example:</b> Router# exit	Returns to user EXEC mode.

## Enabling LSP Ping to Detect LSP Breakages Caused by Untagged Interfaces

For MPLS LSP ping and traceroute of LSPs carrying IPv4 FECs, you can force an explicit null label to be added to the MPLS label stack even though the label was unsolicited. This allows LSP ping to detect LSP breakages caused by untagged interfaces. LSP ping does not report that an LSP is operational when it is unable to send MPLS traffic.

An explicit null label is added to an MPLS label stack if MPLS echo request packets are forwarded from untagged interfaces that are directly connected to the destination of the LSP ping or if the IP TTL value for the MPLS echo request packets is set to 1.

When you enter an **lsp ping** command, you are testing the LSP's ability to carry IP traffic. Failure at untagged output interfaces at the penultimate hop are not detected. Explicit-null shimming allows you to test an LSP's ability to carry MPLS traffic.

To enable LSP ping to detect LSP breakages caused by untagged interfaces, specify the **force-explicit-null** keyword in the **ping mpls** or **trace mpls** commands as shown in the following steps.

## SUMMARY STEPS

1. **enable**

2. **ping mpls {ipv4 destination-address/destination-mask | pseudowire ipv4-address vc-id vc-id} force-explicit-null**  
or  
**trace mpls ipv4 destination-address/destination-mask force-explicit-null**
3. **exit**

## DETAILED STEP

<b>Step 1</b>	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
<b>Step 2</b>	<b>ping mpls {ipv4 destination-address /destination-mask   pseudowire ipv4-address vc-id vc-id} force-explicit-null</b>  or <b>trace mpls ipv4 destination-address /destination-mask force-explicit-null</b>  <b>Example:</b> Router# ping mpls ipv4 10.131.191.252/32 force-explicit null  or  <b>Example:</b> Router# trace mpls ipv4 10.131.191.252/32 force-explicit-null	Checks MPLS LSP connectivity.  or Discovers MPLS LSP routes that packets actually take when traveling to their destinations.  <b>Note</b> You must enter the <b>force-explicit-null</b> keyword.
<b>Step 3</b>	<b>exit</b>  <b>Example:</b> Router# exit	Returns to user EXEC mode.

## Viewing the AToM VCCV Capabilities Advertised to and Received from the Peer

To view the AToM VCCV capabilities advertised to and received from the peer, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **show mpls l2transport binding**
3. **exit**

## DETAILED STEPS

<b>Step 1</b>	<pre>enable</pre> <p><b>Example:</b> Router&gt; enable</p>	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
<b>Step 2</b>	<pre>show mpls l2transport binding</pre> <p><b>Example:</b> Router# show mpls l2transport binding</p>	Displays VC label binding information.
<b>Step 3</b>	<pre>exit</pre> <p><b>Example:</b> Router# exit</p>	Returns to user EXEC mode.

## Configuration Examples for MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV

Examples for the MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV feature are based on the sample topology shown in [Figure 5](#).

**Figure 5** Sample Topology for Configuration Examples

This section contains the following configuration examples:

- [Enabling Compatibility Between the MPLS LSP and Ping or Traceroute Implementation: Example, page 31](#)
- [Validating an FEC by Using MPLS LSP Ping and LSP Traceroute: Example, page 31](#)
- [Using DSCP to Request a Specific Class of Service in an Echo Reply: Example, page 32](#)
- [Controlling How a Responding Router Replies to an MPLS Echo Request: Example, page 32](#)
- [Preventing Loops when Using MPLS LSP Ping and LSP Traceroute Command Options: Example, page 32](#)
- [Detecting LSP Breaks: Example, page 36](#)
- [Viewing the AToM VCCV Capabilities Advertised to and Received from the Peer: Example, page 57](#)

## Enabling Compatibility Between the MPLS LSP and Ping or Traceroute Implementation: Example

The following example shows how to configure MPLS multipath LSP traceroute to interoperate with a vendor implementation that does not interpret RFC 4379 as Cisco does:

```
configure terminal
!
mpls oam
  echo revision 4
  no echo vendor-extension
exit
```

The default echo revision number is 4, which corresponds to the IEFT draft 11.

## Validating an FEC by Using MPLS LSP Ping and LSP Traceroute: Example

This section describes the following procedures:

- [Validating an LDP IPv4 FEC by Using MPLS LSP Ping and MPLS LSP Traceroute: Example, page 31](#)
- [Validating a Layer 2 FEC by Using MPLS LSP Ping: Example, page 31](#)

### Validating an LDP IPv4 FEC by Using MPLS LSP Ping and MPLS LSP Traceroute: Example

The following example shows how to use the **ping mpls** command to test connectivity of an IPv4 LDP LSP:

```
Router# ping mpls ipv4 10.131.191.252/32 repeat 5 exp 5 verbose
```

Sending 5, 100-byte MPLS Echos to 10.131.191.252, timeout is 2 seconds:

Codes:

```
'!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'X' - unknown return code, 'x' - return code 0
```

Type escape sequence to abort.

```
! 10.131.191.230, return code 3
! 10.131.191.230, return code 3
! 10.131.191.230, return code 3
! 10.131.191.230, return code 3
! 10.131.191.230, return code 3
```

Success rate is 100 percent (5/5), round-trip min/avg/max = 100/10

### Validating a Layer 2 FEC by Using MPLS LSP Ping: Example

The following example validates a Layer 2 FEC:

```
Router# ping mpls pseudowire 10.10.10.15 108 vc-id 333
```

Sending 5, 100-byte MPLS Echos to 10.10.10.15,  
timeout is 2 seconds, send interval is 0 msec:

```

Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
       'L' - labeled output interface, 'B' - unlabeled output interface,
       'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
       'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
       'P' - no rx intf label prot, 'p' - premature termination of LSP,
       'R' - transit router, 'I' - unknown upstream index,
       'X' - unknown return code, 'x' - return code 0

Type escape sequence to abort.
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 28/32/40 ms PE-802#

```

## Using DSCP to Request a Specific Class of Service in an Echo Reply: Example

The following example shows how to use DSCP to request a specific CoS in an echo reply:

```
Router# ping mpls ipv4 10.131.159.252/32 reply dscp 50
```

```

<0-63> Differentiated services codepoint value
af11    Match packets with AF11 dscp (001010)
af12    Match packets with AF12 dscp (001100)
af13    Match packets with AF13 dscp (001110)
af21    Match packets with AF21 dscp (010010)

```

## Controlling How a Responding Router Replies to an MPLS Echo Request: Example

The following example checks MPLS LSP connectivity by using ipv4 reply mode:

```
Router# ping mpls ipv4 10.131.191.252/32 reply mode ipv4
```

## Preventing Loops when Using MPLS LSP Ping and LSP Traceroute Command Options: Example

This section contains the following examples:

- [Possible Loops with MPLS LSP Ping: Example, page 33](#)
- [Possible Loop with MPLS LSP Traceroute: Example, page 34](#)

## Possible Loops with MPLS LSP Ping: Example

The following example shows how a loop operates if you use the following **ping mpls** command:

```
Router# ping mpls ipv4 10.131.159.251/32 destination 127.0.0.1 127.0.0.2 1 repeat 2
sweep 1450 1475 25
```

Sending 2, [1450..1500]-byte MPLS Echos to 10.131.159.251/32,  
timeout is 2 seconds, send interval is 0 msec:

Codes:

```
'!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'X' - unknown return code, 'x' - return code 0
```

Type escape sequence to abort.

Destination address 127.0.0.1

!  
!

Destination address 127.0.0.2

!  
!

Destination address 127.0.0.1

!  
!

Destination address 127.0.0.2

!  
!

A **ping mpls** command is sent for each packet size range for each destination address until the end address is reached. For this example, the loop continues in the same manner until the destination address, 127.0.0.5, is reached. The sequence continues until the number is reached that you specified with the **repeat count** keyword and argument. For this example, the repeat count is 2. The MPLS LSP ping loop sequence is as follows:

```
repeat = 1
  destination address 1 (address-start)
    for (size from sweep minimum to maximum, counting by size-increment)
      send an lsp ping

  destination address 2 (address-start + address-increment)
    for (size from sweep minimum to maximum, counting by size-increment)
      send an lsp ping

  destination address 3 (address-start + address-increment + address-increment)
    for (size from sweep minimum to maximum, counting by size-increment)
      send an lsp ping
```

```

.
.
.
until destination address = address-end

.
.
.
until repeat = count 2

```

## Possible Loop with MPLS LSP Traceroute: Example

The following example shows how a loop occurs if you use the following **trace mpls** command:

```
Router# trace mpls ipv4 10.131.159.251/32 destination 127.0.0.1 127.0.0.3 1 ttl 5
```

Tracing MPLS Label Switched Path to 10.131.159.251/32, timeout is 2 seconds

Codes:

```

'!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'X' - unknown return code, 'x' - return code 0

```

Type escape sequence to abort.

```

Destination address 127.0.0.1
  0 10.131.191.230 MRU 1500 [Labels: 19 Exp: 0]
R 1 10.131.159.226 MRU 1504 [implicit-null] 40 ms
! 2 10.131.159.225 40 ms
Destination address 127.0.0.2
  0 10.131.191.230 MRU 1500 [Labels: 19 Exp: 0]
R 1 10.131.159.226 MRU 1504 [implicit-null] 40 ms
! 2 10.131.159.225 40 ms
Destination address 127.0.0.3
  0 10.131.191.230 MRU 1500 [Labels: 19 Exp: 0]
R 1 10.131.159.226 MRU 1504 [implicit-null] 40 ms
! 2 10.131.159.225 48 ms

```

An **mpls trace** command is sent for each TTL from 1 to the maximum TTL (**ttl maximum-time-to-live** keyword and argument) for each destination address until the address specified with the destination *end-address* argument is reached. In this example, the maximum TTL is 5 and the end destination address is 127.0.0.3. The MPLS LSP traceroute loop sequence is as follows:

```

destination address 1 (address-start)
  for (ttl from 1 to maximum-time-to-live)
    send an lsp trace

destination address 2 (address-start + address-increment)
  for (ttl from 1 to 5)
    send an lsp trace

destination address 3 (address-start + address-increment + address-increment)
  for (ttl from 1 to maximum-time-to-live)
    send an lsp trace
.
.
.
until destination address = 4

```

The following example shows that the trace encountered an LSP problem at the router that has an IP address of 10.6.1.6:

```
Router# traceroute mpls ipv4 10.6.7.4/32
```

```
Tracing MPLS Label Switched Path to 10.6.7.4/32, timeout is 2 seconds
```

```
Codes:
```

```
'!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'X' - unknown return code, 'x' - return code 0
```

```
Type escape sequence to abort.
```

```
0 10.6.1.14 MRU 4470 [Labels: 22 Exp: 0]
R 1 10.6.1.5 MRU 4470 [Labels: 21 Exp: 0] 2 ms

R 3 10.6.1.6 1 ms
R 4 10.6.1.6 1 ms
R 5 10.6.1.6 3 ms
R 6 10.6.1.6 4 ms
R 7 10.6.1.6 1 ms
R 8 10.6.1.6 2 ms
R 9 10.6.1.6 3 ms
R 10 10.6.1.6 4 ms
R 11 10.6.1.6 1 ms
R 12 10.6.1.6 2 ms
R 13 10.6.1.6 4 ms
R 14 10.6.1.6 5 ms
R 15 10.6.1.6 2 ms
R 16 10.6.1.6 3 ms
R 17 10.6.1.6 4 ms
R 18 10.6.1.6 2 ms
R 19 10.6.1.6 3 ms
R 20 10.6.1.6 4 ms
R 21 10.6.1.6 1 ms
R 22 10.6.1.6 2 ms
R 23 10.6.1.6 3 ms
R 24 10.6.1.6 4 ms
R 25 10.6.1.6 1 ms
R 26 10.6.1.6 3 ms
R 27 10.6.1.6 4 ms
R 28 10.6.1.6 1 ms
R 29 10.6.1.6 2 ms
R 30 10.6.1.6 3 ms                      <----- TTL 30.
```

If you know the maximum number of hops in your network, you can set the TTL to a lower value with the **trace mpls ttl maximum-time-to-live** command. The following example shows the same **traceroute** command as the previous example, except that this time the TTL is set to 5:

```
Router# traceroute mpls ipv4 10.6.7.4/32 ttl 5
```

```
Tracing MPLS Label Switched Path to 10.6.7.4/32, timeout is 2 seconds
```

```
Codes:
```

```
'!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'X' - unknown return code, 'x' - return code 0
```

```

Type escape sequence to abort.
 0 10.6.1.14 MRU 4470 [Labels: 22 Exp: 0]
R 1 10.6.1.5 MRU 4474 [No Label] 3 ms

R 3 10.6.1.6 1 ms
R 4 10.6.1.6 3 ms
R 5 10.6.1.6 4 ms

```

## Detecting LSP Breaks: Example

This section contains the following examples:

- [Troubleshooting with LSP Ping or Traceroute: Example, page 36](#)
- [MTU Discovery in an LSP: Example, page 46](#)
- [Tracking Packets Tagged as Implicit Null: Example, page 48](#)
- [Tracking Untagged Packets: Example, page 48](#)
- [Determining Why a Packet Could Not Be Sent: Example, page 49](#)
- [Detecting LSP Breaks when Load Balancing Is Enabled for IPv4 LSPs: Example, page 50](#)
- [Specifying the Interface Through Which Echo Packets Leave a Router: Example, page 52](#)
- [Pacing the Transmission of Packets: Example, page 53](#)
- [Interrogating the Transit Router for Its Downstream Information: Example, page 53](#)
- [Interrogating a Router for Its DSMAP: Example, page 55](#)
- [Requesting that a Transit Router Validate the Target FEC Stack: Example, page 56](#)
- [Enabling LSP Ping to Detect LSP Breakages Caused by Untagged Interfaces: Example, page 56](#)

## Troubleshooting with LSP Ping or Traceroute: Example

ICMP **ping** and **trace** commands are often used to help diagnose the root cause of a failure. When an LSP is broken, the packet may reach the target router by IP forwarding, thus making the ICMP ping and traceroute features unreliable for detecting MPLS forwarding problems. The MPLS LSP ping or traceroute and AToM VCCV features extend this diagnostic and troubleshooting ability to the MPLS network and handle inconsistencies (if any) between the IP and MPLS forwarding tables, inconsistencies in the MPLS control and data plane, and problems with the reply path.

Figure 6 shows a sample topology with an LDP LSP.

**Figure 6** Sample Topology with LDP LSP

This section contains the following subsections:

- [Configuration for Sample Topology, page 37](#)
- [Verification That the LSP Is Configured Correctly, page 43](#)
- [Discovery of LSP Breaks, page 44](#)

## Configuration for Sample Topology

These are sample topology configurations for the troubleshooting examples in the following sections (see [Figure 6](#)). There are the six sample router configurations.

### Router CE1 Configuration

Following is the configuration for the CE1 router:

```
!  
version 12.4  
service timestamps debug datetime msec  
service timestamps log datetime msec  
no service password-encryption  
!  
hostname CE1

## Verification That the LSP Is Configured Correctly

Use the output from the **show** commands in this section to verify that the LSP is configured correctly.

A **show mpls forwarding-table** command shows that tunnel 1 is in the MPLS forwarding table.

```
PE1# show mpls forwarding-table 10.131.159.252
```

Local tag	Outgoing tag or VC	Prefix or Tunnel Id	Bytes tag switched	Outgoing interface	Next Hop
22	18 [T]	10.131.159.252/32 0	Tu1	point2point	

```
[T] Forwarding through a TSP tunnel.
View additional tagging info with the 'detail' option
```

A **trace mpls** command issued at PE1 verifies that packets with 16 as the outermost label and 18 as the end-of-stack label are forwarded from PE1 to PE2.

```
PE1# trace mpls ipv4 10.131.159.252/32
```

Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds

Codes:

```
'!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'X' - unknown return code, 'x' - return code 0
```

Type escape sequence to abort.

```
0 10.131.191.252 MRU 1496 [Labels: 16/18 Exp: 0/0] L 1 10.131.191.229
MRU 1508 [Labels: 18 Exp: 0] 0 ms L 2 10.131.159.225
MRU 1504 [Labels: implicit-null Exp: 0] 0 ms ! 3 10.131.159.234 20 ms
PE1#
```

The MPLS LSP Traceroute to PE2 is successful, as indicated by the exclamation point (!).

## Discovery of LSP Breaks

Use the output of the commands in this section to discover LSP breaks.

An LDP target session is established between routers PE1 and P2, as shown in the output of the following **show mpls ldp discovery** command:

PE1# **show mpls ldp discovery**

```
Local LDP Identifier:
 10.131.191.252:0
Discovery Sources:
Interfaces:
  Ethernet0/0 (ldp): xmit/recv
    LDP Id: 10.131.191.251:0
  Tunnel1 (ldp): Targeted -> 10.131.159.251
Targeted Hellos:
 10.131.191.252 -> 10.131.159.252 (ldp): active/passive, xmit/recv
    LDP Id: 10.131.159.252:0
 10.131.191.252 -> 10.131.159.251 (ldp): active, xmit/recv
    LDP Id: 10.131.159.251:0
```

Enter the following command on the P2 router in global configuration mode:

P2(config)# **no mpls ldp discovery targeted-hello accept**

The LDP configuration change causes the targeted LDP session between the headend and tailend of the TE tunnel to go down. Labels for IPv4 prefixes learned by P2 are not advertised to PE1. Thus, all IP prefixes reachable by P2 are reachable by PE1 only through IP (not MPLS). In other words, packets destined for those prefixes through Tunnel 1 at PE1 will be IP switched at P2 (which is undesirable).

The following **show mpls ldp discovery** command shows that the LDP targeted session is down:

PE1# **show mpls ldp discovery**

```
Local LDP Identifier:
 10.131.191.252:0
Discovery Sources:
Interfaces:
  Ethernet0/0 (ldp): xmit/recv
    LDP Id: 10.131.191.251:0
  Tunnel1 (ldp): Targeted -> 10.131.159.251
Targeted Hellos:
 10.131.191.252 -> 10.131.159.252 (ldp): active/passive, xmit/recv
    LDP Id: 10.131.159.252:0
 10.131.191.252 -> 10.131.159.251 (ldp): active, xmit
```

Enter the **show mpls forwarding-table** command at the PE1 router. The display shows that the outgoing packets are untagged as a result of the LDP configuration changes.

```
PE1# show mpls forwarding-table 10.131.159.252
```

Local tag	Outgoing tag or VC	Prefix or Tunnel Id	Bytes tag switched	Outgoing interface	Next Hop
22	Untagged[T]	10.131.159.252/32	0	Tu1	point2point

```
[T] Forwarding through a TSP tunnel.
View additional tagging info with the 'detail' option
```

A **ping mpls** command entered at the PE1 router displays the following:

```
PE1# ping mpls ipv4 10.131.159.252/32 repeat 1
```

```
Sending 1, 100-byte MPLS Echos to 10.131.159.252/32,
timeout is 2 seconds, send interval is 0 msec:
```

```
Codes:
```

```
'!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'X' - unknown return code, 'x' - return code 0
```

```
Type escape sequence to abort.
```

```
R
```

```
Success rate is 0 percent (0/1)
```

The **ping mpls** command fails. The R indicates that the sender of the MPLS echo reply had a routing entry but no MPLS FEC. Entering the **verbose** keyword with the **ping mpls** command displays the MPLS LSP echo reply sender address and the return code. You should be able to determine where the breakage occurred by telnetting to the replying router and inspecting its forwarding and label tables. You might need to look at the neighboring upstream router as well, because the breakage might be on the upstream router.

```
PE1# ping mpls ipv4 10.131.159.252/32 repeat 1 verbose
```

```
Sending 1, 100-byte MPLS Echos to 10.131.159.252/32,
timeout is 2 seconds, send interval is 0 msec:
```

```
Codes:
```

```
'!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'X' - unknown return code, 'x' - return code 0
```

```
Type escape sequence to abort.
```

```
R 10.131.159.225, return code 6
```

```
Success rate is 0 percent (0/1)
```

Alternatively, use the **LSP traceroute** command to figure out which router caused the breakage. In the following example, for subsequent values of TTL greater than 2, the same router keeps responding (10.131.159.225). This suggests that the MPLS echo request keeps getting processed by the router regardless of the TTL. Inspection of the label stack shows that P1 pops the last label and forwards the

packet to P2 as an IP packet. This explains why the packet keeps getting processed by P2. MPLS echo request packets cannot be forwarded by use of the destination address in the IP header because the address is set to a 127/8 address.

```
PE1# trace mpls ipv4 10.131.159.252/32 ttl 5
```

Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds

Codes:

```
'!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'X' - unknown return code, 'x' - return code 0
```

Type escape sequence to abort.

```
0 10.131.191.230 MRU 1496 [Labels: 22/19 Exp: 0/0]
R 1 10.131.159.226 MRU 1500 [Labels: 19 Exp: 0] 40 ms
R 2 10.131.159.229 MRU 1504 [implicit-null] 28 ms
! 3 10.131.159.230 40 ms
pe1#
```

## MTU Discovery in an LSP: Example

The following example shows the results of a **trace mpls** command when the LSP is formed with labels created by LDP:

```
PE1# trace mpls ipv4 10.131.159.252/32
```

Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds

Codes:

```
'!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'X' - unknown return code, 'x' - return code 0
```

Type escape sequence to abort.

```
0 10.131.191.230 MRU 1496 [Labels: 22/19 Exp: 0/0]
R 1 10.131.159.226 MRU 1500 [Labels: 19 Exp: 0] 40 ms
R 2 10.131.159.229 MRU 1504 [implicit-null] 28 ms
! 3 10.131.159.230 40 ms
pe1#
```

You can determine the MRU for the LSP at each hop through the use of the **show mpls forwarding detail** command:

```
PE1# show mpls forwarding 10.131.159.252 detail
```

Local tag	Outgoing tag or VC	Prefix or Tunnel Id	Bytes tag switched	Outgoing interface	Next Hop
22	19	10.131.159.252/32	0	Tul	point2point
MAC/Encaps=14/22, MRU=1496, Tag Stack{22 19}, via Et0/0					
AABBCC009700AABBCC0098008847 0001600000013000					
No output feature configured					

To determine how large an echo request will fit on the LSP, first calculate the size of the IP MTU by using the **show interface interface-name** command:

```
PE1# show interface e0/0
```

```

Ethernet0/0 is up, line protocol is up
  Hardware is Lance, address is aabb.cc00.9800 (bia aabb.cc00.9800)
  Internet address is 10.131.191.230/30
  MTU 1500 bytes, BW 10000 Kbit, DLY 1000 usec, rely 255/255, load 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:01, output 00:00:01, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
    377795 packets input, 33969220 bytes, 0 no buffer
    Received 231137 broadcasts, 0 runts, 0 giants, 0 throttles
    0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
    0 input packets with dribble condition detected
    441772 packets output, 40401350 bytes, 0 underruns
    0 output errors, 0 collisions, 10 interface resets
    0 babbles, 0 late collision, 0 deferred
    0 lost carrier, 0 no carrier
    0 output buffer failures, 0 output buffers swapped out

```

The IP MTU in the **show interface interface-name** example is 1500 bytes. Subtract the number of bytes corresponding to the label stack from the MTU number. The output of the **show mpls forwarding** command indicates that the Tag stack consists of one label (21). Therefore, the largest MPLS echo request packet that can be sent in the LSP is  $1500 - (2 \times 4) = 1492$ .

You can validate this by using the following **mpls ping** command:

```
PE1# ping mpls ipv4 10.131.159.252/32 sweep 1492 1500 1 repeat 1
```

```

Sending 1, [1492..1500]-byte MPLS Echos to 10.131.159.252/32,
  timeout is 2 seconds, send interval is 0 msec:

```

Codes:

```

'!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'X' - unknown return code, 'x' - return code 0

```

Type escape sequence to abort.

```
!QQQQQQQ
```

```
Success rate is 11 percent (1/9), round-trip min/avg/max = 40/40/40 ms
```

In this command, echo packets that have a range in size from 1492 to 1500 bytes are sent to the destination address. Only packets of 1492 bytes are sent successfully, as indicated by the exclamation point (!). Packets of byte sizes 1493 to 1500 are source-quenched, as indicated by the Qs.

You can pad an MPLS echo request so that a payload of a given size can be tested. The pad TLV is useful when you use the MPLS echo request to discover the MTU that is supportable by an LSP. MTU discovery is extremely important for applications like AToM that contain non-IP payloads that cannot be fragmented.

## Tracking Packets Tagged as Implicit Null: Example

In the following example, Tunnel 1 is shut down, and only an LSP formed with LDP labels is established. An implicit null is advertised between the P2 and PE2 routers. Entering an MPLS LSP traceroute command at the PE1 router results in the following output that shows that packets are forwarded from P2 to PE2 with an implicit-null label. Address 10.131.159.229 is configured for the P2 Ethernet 0/0 out interface for the PE2 router.

```
PE1# trace mpls ipv4 10.131.159.252/32
```

```
Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds
```

```
Codes:
```

```
'!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'X' - unknown return code, 'x' - return code 0
```

```
Type escape sequence to abort.
```

```
0 10.131.191.230 MRU 1496 [Labels: 22/19 Exp: 0/0]
R 1 10.131.159.226 MRU 1500 [Labels: 19 Exp: 0] 40 ms
R 2 10.131.159.229 MRU 1504 [implicit-null] 28 ms
! 3 10.131.159.230 40 ms
pe1#
```

## Tracking Untagged Packets: Example

Untagged cases are valid configurations for IGP LSPs that could cause problems for MPLS VPNs.

A **show mpls forwarding-table** command and a **show mpls ldp discovery** command issued at the P2 router show that LDP is properly configured:

```
P2# show mpls forwarding-table 10.131.159.252
```

Local tag	Outgoing tag or VC	Prefix or Tunnel Id	Bytes tag switched	Outgoing interface	Next Hop
19	Pop tag	10.131.159.252/32	0	Et0/0	10.131.159.230

```
P2# show mpls ldp discovery
```

```
Local LDP Identifier:
 10.131.159.251:0
Discovery Sources:
Interfaces:
 Ethernet0/0 (ldp): xmit/recvd
   LDP Id: 10.131.159.252:0
 Ethernet1/0 (ldp): xmit/recvd
   LDP Id: 10.131.191.251:0
```

The **show mpls ldp discovery** command output shows that Ethernet interface 0/0, which connects PE2 to P2, is sending and receiving packets.

If a **no mpls ip** command is entered on Ethernet interface 0/0, this could prevent an LDP session between the P2 and PE2 routers from being established. A **show mpls ldp discovery** command entered on the PE router shows that the MPLS LDP session with the PE2 router is down.

```
P2# show mpls ldp discovery
```

```
Local LDP Identifier:
 10.131.159.251:0
```

```

Discovery Sources:
Interfaces:
  Ethernet0/0 (ldp): xmit
  Ethernet1/0 (ldp): xmit/recv
  LDP Id: 10.131.191.251:0

```

If the MPLS LDP session to PE2 goes down, the LSP to 10.131.159.252 becomes untagged, as shown by the **show mpls forwarding-table** command:

```
P2# show mpls forwarding-table 10.131.159.252/32
```

Local tag	Outgoing tag or VC	Prefix or Tunnel Id	Bytes tag switched	Outgoing interface	Next Hop
19	Untagged	10.131.159.252/32	864	Et0/0	10.131.159.230

Untagged cases would provide an MPLS LSP traceroute reply with packets tagged with No Label, as shown in the following display. You may need to reestablish an MPLS LSP session from interface P2 to PE2 by entering an **mpls ip** command on the output interface from P2 to PE2, which is Ethernet 0/0 in this example:

```
PE1# trace mpls ipv4 10.131.159.252/32
```

```
Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds
```

```
Codes:
```

```

'!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'X' - unknown return code, 'x' - return code 0

```

```
Type escape sequence to abort.
```

```

0 10.131.191.230 MRU 1500 [Labels: 20 Exp: 0]
R 1 10.131.159.226 MRU 1500 [Labels: 19 Exp: 0] 80 ms
R 2 10.131.159.229 MRU 1504 [No Label] 28 ms      <---No MPLS session from P2 to PE2.
! 3 10.131.159.230 40 ms

```

## Determining Why a Packet Could Not Be Sent: Example

The following example shows a **ping mpls** command when an MPLS echo request is not sent. The transmission failure is shown by the returned Qs.

```
PE1# ping mpls ipv4 10.0.0.1/32
```

```

Sending 5, 100-byte MPLS Echos to 10.0.0.1/32,
  timeout is 2 seconds, send interval is 0 msec:

```

```
Codes:
```

```

'!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'X' - unknown return code, 'x' - return code 0

```

```
Type escape sequence to abort.
```

```
QQQQQ
```

```
Success rate is 0 percent (0/5)
```

The following **show mpls forwarding-table** command and **show ip route** command demonstrate that the IPv4 address (10.0.0.1) address is not in the LFIB or RIB routing table. Therefore, the MPLS echo request is not sent.

```
PE1# show mpls forwarding-table 10.0.0.1

Local  Outgoing  Prefix          Bytes tag  Outgoing     Next Hop
tag    tag or VC   or Tunnel Id    switched   interface

PE1# show ip route 10.0.0.1

% Subnet not in table
```

## Detecting LSP Breaks when Load Balancing Is Enabled for IPv4 LSPs: Example

In the following examples, different paths are followed to the same destination. The output from these examples demonstrates that load balancing occurs between the originating router and the target router.

To ensure that Ethernet interface 1/0 on the PE1 router is operational, enter the following commands on the PE1 router:

```
PE1# configure terminal

Enter configuration commands, one per line.  End with CNTL/Z.

PE1(config)# interface ethernet 1/0

PE1(config-if)# no shutdown

PE1(config-if)# end

*Dec 31 19:14:10.034: %LINK-3-UPDOWN: Interface Ethernet1/0, changed state to up
*Dec 31 19:14:11.054: %LINEPROTO-5-UPDOWN: Line protocol on Interface Ethernet1/0,
changed state to upend
PE1#
*Dec 31 19:14:12.574: %SYS-5-CONFIG_I: Configured from console by console
*Dec 31 19:14:19.334: %OSPF-5-ADJCHG: Process 1, Nbr 10.131.159.252 on Ethernet1/0
from LOADING to FULL, Loading Done
PE1#
```

The following **show mpls forwarding-table** command displays the possible outgoing interfaces and next hops for the prefix 10.131.159.251/32:

```
PE1# show mpls forwarding-table 10.131.159.251/32

Local  Outgoing  Prefix          Bytes tag  Outgoing     Next Hop
tag    tag or VC   or Tunnel Id    switched   interface

21     19         10.131.159.251/32 0           Et0/0       10.131.191.229
20     20         10.131.159.251/32 0           Et1/0       10.131.159.245
```

The following **ping mpls** command to 10.131.159.251/32 with a destination UDP address of 127.0.0.1 shows that the selected path has a path index of 0:

```
Router# ping mpls ipv4 10.131.159.251/32 destination 127.0.0.1/32
```

```
Sending 1, 100-byte MPLS Echos to 10.131.159.251/32,
timeout is 2 seconds, send interval is 0 msec:
```

Codes:

```
'!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
```

'P' - no rx intf label prot, 'p' - premature termination of LSP,  
 'R' - transit router, 'X' - unknown return code, 'x' - return code 0

Type escape sequence to abort.

!

Success rate is 100 percent (1/1), round-trip min/avg/max = 40/40/40 ms

PE1#

To see the actual path chosen, enter the **debug mpls lsvp** command with the **packet** and **data** keywords.

**Note**

The load balancing algorithm attempts to uniformly distribute packets across the available output paths by hashing based on the IP header source and destination addresses. The selection of the *address-start*, *address-end*, and *address-increment* arguments for the **destination** keyword may not provide the expected results.

## Specifying the Interface Through Which Echo Packets Leave a Router: Example

The following example tests load balancing from the upstream router:

```
Router# ping mpls ipv4 10.131.161.251/32 ttl 1 repeat 1 dsmap hashkey ipv4 bitmap 8
```

```
Sending 1, 100-byte MPLS Echos to 10.131.161.251/32,
  timeout is 2 seconds, send interval is 0 msec:
```

```
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'X' - unknown return code, 'x' - return code 0
```

```
Type escape sequence to abort.
```

```

## Pacing the Transmission of Packets: Example

The following example shows the pace of the transmission of packets:

```
Router# ping mpls ipv4 10.5.5.5/32 interval 100
```

```
Sending 5, 100-byte MPLS Echos to 10.5.5.5/32,
timeout is 2 seconds, send interval is 100 msec:
```

```
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'I' - unknown upstream index,
'X' - unknown return code, 'x' - return code 0
```

```
Type escape sequence to abort.
```

```
!!!!
```

```
Success rate is 100 percent (5/5), round-trip min/avg/max = 28/29/36 ms PE-802
```

## Interrogating the Transit Router for Its Downstream Information: Example

The following example shows sample output when a router with two output paths is interrogated:

```
Router# ping mpls ipv4 10.161.251/32 ttl 4 repeat 1 dsmap hashkey ipv4 bitmap 16
```

```
Sending 1, 100-byte MPLS Echos to 10.131.161.251/32,
timeout is 2 seconds, send interval is 0 msec:
```

```
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
```

'L' - labeled output interface, 'B' - unlabeled output interface,  
 'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,  
 'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,  
 'P' - no rx intf label prot, 'p' - premature termination of LSP,  
 'R' - transit router, 'X' - unknown return code, 'x' - return code 0

Type escape sequence to abort.

     127.0.0.7        127.0.0.8        127.0.0.11

Success rate is 0 percent (0/1)

The multipath addresses cause a packet to transit to the router with the output label stack. The **ping mpls** command is useful for determining the number of output paths, but when the router is more than one hop away a router cannot always use those addresses to get the packet to transit through the router being interrogated. This situation exists because the change in the IP header destination address may cause the packet to be load-balanced differently by routers between the source router and the responding router. Load balancing is affected by the source address in the IP header. The following example tests load-balancing reporting from the upstream router:

Router# **ping mpls ipv4 10.131.161.251/32 ttl 1 repeat 1 dsmap hashkey ipv4 bitmap 8**

Sending 1, 100-byte MPLS Echos to 10.131.161.251/32,  
 timeout is 2 seconds, send interval is 0 msec:

Codes: '!' - success, 'Q' - request not sent, '.' - timeout,  
 'L' - labeled output interface, 'B' - unlabeled output interface,

## Enabling LSP Ping to Detect LSP Breakages Caused by Untagged Interfaces: Example

The following example shows the extra label that is added to the end of the label stack when there is explicit-null label shimming:

```
Router# trace mpls ipv4 10.131.159.252/32 force-explicit-null
```

```
Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds
```

Codes:

```

'!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'X' - unknown return code, 'x' - return code 0

```

Type escape sequence to abort.

```
0 10.131.191.252 MRU 1492 [Labels: 16/18/explicit-null Exp: 0/0/0]
L 1 10.131.191.229 MRU 1508 [Labels: 18/explicit-null Exp: 0/0] 0 ms
L 2 10.131.159.225 MRU 1508 [Labels: explicit-null Exp: 0] 0 ms
! 3 10.131.159.234 4 ms
```

The following example shows the command output when there is not explicit-null label shimming:

```
Router# trace mpls ipv4 10.131.159.252/32
```

Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds

```
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'X' - unknown return code, 'x' - return code 0
```

Type escape sequence to abort.

```
0 10.131.191.252 MRU 1496 [Labels: 16/18 Exp: 0/0]
L 1 10.131.191.229 MRU 1508 [Labels: 18 Exp: 0] 4 ms
L 2 10.131.159.225 MRU 1504 [Labels: implicit-null Exp: 0] 4 ms
! 3 10.131.159.234 4 ms
```

## Viewing the AToM VCCV Capabilities Advertised to and Received from the Peer: Example

The following example shows that router PE1 advertises both AToM VCCV Type 1 and Type 2 switching capabilities and that the remote router PE2 advertises only a Type 2 switching capability.

```
Router# show mpls l2transport binding
```

```
Destination Address: 10.131.191.252, VC ID: 333
Local Label: 16
  Cbit: 1, VC Type: Ethernet, GroupID: 0
  MTU: 1500, Interface Desc: n/a
  VCCV Capabilities: Type 1, Type 2 <----- Locally advertised VCCV capabilities
Remote Label: 19
  Cbit: 1, VC Type: Ethernet, GroupID: 0
  MTU: 1500, Interface Desc: n/a
  VCCV Capabilities: Type 2 <-----Remotely advertised VCCV capabilities
```

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Multiprotocol Label Switching Command Reference* at [http://www.cisco.com/en/US/docs/ios/mpls/command/reference/mp\\_book.html](http://www.cisco.com/en/US/docs/ios/mpls/command/reference/mp_book.html). For information about all Cisco IOS commands, use the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup>.

- **debug mpls lspv**
- **echo**
- **mpls oam**
- **ping mpls**
- **show mpls oam echo statistics**
- **trace mpls**

## Feature Information for MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV

Table 7 lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Release 12.0(27)S or Cisco IOS Release 12.4(6)T or 12.3(33)SXI or a later release appear in the table.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

**Note**

Table 7 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 7** *Feature Information for MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV*

Feature Name	Releases	Feature Information
MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV	12.0(27)S 12.2(18)SXE 12.4(6)T 12.2(28)SB 12.0(32)SY 12.4(11)T 12.2(31)SB2 12.2(33)SRB 12.2(33)SXH 12.3(33)SXI	<p>The MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV feature helps service providers monitor label switched paths and quickly isolate MPLS forwarding problems.</p> <p>In Cisco IOS Release 12.0(27)S, this feature was introduced. The <b>show mpls oam echo statistics</b> command was added.</p> <p>The feature was incorporated into Cisco IOS Release 12.4(11)T. AToM Virtual Circuit Connection Verification (VCCV) is supported. The following commands were modified: <b>mpls oam</b>, <b>ping mpls</b>, and <b>trace mpls</b>.</p> <p>The feature was incorporated into Cisco IOS Release 12.2(31)SB2.</p> <p>In Cisco IOS Release 12.2(33)SRB, support for FEC 129 was added.</p> <p>This feature was integrated into Cisco IOS Release 12.2(33)SXH.</p> <p>This feature was integrated into Cisco IOS Release 12.2(33)SXI.</p>

# Glossary

**FEC**—forwarding equivalence class. A set of packets that can be handled equivalently for forwarding purposes and are thus suitable for binding to a single label. Examples include the set of packets destined for one address prefix and the packets in any flow.

**flow**—A set of packets traveling between a pair of hosts, or between a pair of transport protocol ports on a pair of hosts. For example, packets with the same source address, source port, destination address, and destination port might be considered a flow.

A flow is also a stream of data traveling between two endpoints across a network (for example, from one LAN station to another). Multiple flows can be transmitted on a single circuit.

**fragmentation**—The process of breaking a packet into smaller units when they are to be transmitted over a network medium that cannot support the original size of the packet.

**ICMP**—Internet Control Message Protocol. A network layer Internet protocol that reports errors and provides other information relevant to IP packet processing. It is documented in RFC 792.

**LFIB**—Label Forwarding Information Base. A data structure and way of managing forwarding in which destinations and incoming labels are associated with outgoing interfaces and labels.

**localhost**—A name that represents the host router (device). The localhost uses the reserved loopback IP address 127.0.0.1.

**LSP**—label switched path. A connection between two routers in which MPLS forwards the packets.

**LSPV**—Label Switched Path Verification. An LSP Ping subprocess. It encodes and decodes MPLS echo requests and replies, and it interfaces with IP, MPLS, and AToM switching for sending and receiving MPLS echo requests and replies. At the MPLS echo request originator router, LSPV maintains a database of outstanding echo requests for which echo responses have not been received.

**MPLS router alert label**—An MPLS label of 1. An MPLS packet with a router alert label is redirected by the router to the Route Processor (RP) processing level for handling. This allows these packets to bypass any forwarding failures in hardware routing tables.

**MRU**—maximum receive unit. Maximum size, in bytes, of a labeled packet that can be forwarded through an LSP.

**MTU**—maximum transmission unit. Maximum packet size, in bytes, that a particular interface can send or receive.

**punt**—Redirect packets with a router alert from the line card or interface to Route Processor (RP) level processing for handling.

**PW**—pseudowire. A form of tunnel that carries the essential elements of an emulated circuit from one provider edge (PE) router to another PE router over a packet-switched network.

**RP**—Route Processor. The processor module in a Cisco 7000 series router that contains the CPU, system software, and most of the memory components that are used in the router. It is sometimes called a supervisory processor.

**RSVP**—Resource Reservation Protocol. A protocol that supports the reservation of resources across an IP network. Applications running on IP end systems can use RSVP to indicate to other nodes the nature (bandwidth, jitter, maximum burst, and so on) of the packet streams they want to receive. RSVP depends on IPv6. It is also known as Resource Reservation Setup Protocol.

**TLV**—type, length, values. A block of information included in a Cisco Discovery Protocol address.

**TTL hiding**—Time-to-live is a parameter you can set that indicates the maximum number of hops a packet should take to reach its destination.

**UDP**—User Datagram Protocol. Connectionless transport layer protocol in the TCP/IP protocol stack. UDP is a simple protocol that exchanges datagrams without acknowledgments or guaranteed delivery, so error processing and retransmission must be handled by other protocols. UDP is defined in RFC 768.

# MPLS EM - TE MIB RFC 3812

---

**First Published: November 20, 2009**

**Last Updated: November 20, 2009**

The MPLS EM - TE MIB RFC 3812 enables Simple Network Management Protocol (SNMP) agent support in Cisco IOS software for Multiprotocol Label Switching (MPLS) traffic engineering (TE) management, as implemented in the MPLS Traffic Engineering Standard MIB (MPLS TE STD MIB). The SNMP agent code operating in conjunction with the MPLS TE STD MIB enables a standardized, SNMP-based approach to be used in managing the MPLS TE features in Cisco IOS software.

The MPLS EM - TE MIB RFC 3812 feature introduces the MPLS-TE-STD-MIB, which is an upgrade from draft Version 6 of the MPLS-TE-MIB to an implementation of the *Multiprotocol Label Switching (MPLS) Traffic Engineering (TE) Management Information Base (MIB)*, RFC 3812.

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the “[Feature Information for the MPLS EM - TE MIB RFC 3812](#)” section on page 16.

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Restrictions for the MPLS EM - TE MIB RFC 3812

The following restrictions apply to the MPLS TE STD MIB for Cisco IOS releases:

- Supports read-only (RO) permission for MIB objects.
- Contains no configuration support by means of SET functions, except for the `mplsTunnelTrapEnable` object (which has been made writable). Accordingly, the MPLS TE STD MIB contains indexing support for the Interfaces MIB.
- Supports only SNMP GET, GETNEXT, and GETBULK retrieval functions, except in the case of the `mplsTunnelTrapEnable` object (which has been made writable by means of SET functions).
- Contains no support for Guaranteed Bandwidth Traffic Engineering (GBTE) or Auto Bandwidth features.
- The following objects are not supported in Cisco IOS Release 12.2(33)SRE:

## Information About the MPLS EM - TE MIB RFC 3812

## MPLS Traffic Engineering MIB Cisco Implementation

The MPLS TE MIB is based on the Internet Engineering Task Force (IETF) draft MIB entitled *draft-ietf-mpls-te-mib-05.txt* which includes objects describing features that support MPLS TE.

Slight differences between the IETF draft MIB and the implementation of the TE capabilities within Cisco IOS software require some minor translations between the MPLS TE STD MIB and the internal data structures of Cisco IOS software. These translations are made by the SNMP agent code that is installed and operating on various hosts within the network. This SNMP agent code, running in the background as a low priority process, provides a management interface to Cisco IOS software.

The SNMP objects defined in the MPLS TE STD MIB can be displayed by any standard SNMP utility. All MPLS TE STD MIB objects are based on the IETF draft MIB; thus, no specific Cisco SNMP application is required to support the functions and operations pertaining to the MPLS TE STD MIB.

## MPLS Traffic Engineering Overview

MPLS TE capabilities in Cisco IOS software enable an MPLS backbone to replicate and expand upon the TE capabilities of Layer 2 ATM and Frame Relay networks.

TE capabilities are essential to effective management of service provider and Internet service provider (ISP) backbones. Such backbones must support high transmission capacities, and the networks incorporating backbones must be extremely resilient to link or node failures.

The MPLS TE facilities built into Cisco IOS software provide a feature-rich, integrated approach to managing the large volumes of traffic that typically flow through WANs. The MPLS TE facilities are integrated into Layer 3 network services, thereby optimizing the routing of IP traffic in the face of constraints imposed by existing backbone transmission capacities and network topologies.

## Capabilities Supported by the MPLS EM TE MIB RFC 3812

The following functionality is supported in the MPLS EM TE MIB RFC 3812:

- The ability to generate and queue notification messages that signal changes in the operational status of MPLS TE tunnels.
- Extensions to existing SNMP commands that provide the ability to enable, disable, and configure notification messages for MPLS TE tunnels.
- The ability to specify the name or the IP address of a network management station (NMS) in the operating environment to which notification messages are to be sent.
- The ability to write notification configurations into nonvolatile memory.

## Notification Generation Events

When MPLS TE notifications are enabled (see the **snmp-server enable traps mpls traffic-eng** command), notification messages relating to specific events within Cisco IOS software are generated and sent to a specified NMS in the network.

For example, an `mplsTunnelUp` notification is sent to an NMS when an MPLS TE tunnel is configured and the tunnel transitions from an operationally “down” state to an “up” state.

Conversely, an `mplsTunnelDown` notification is generated and sent to an NMS when an MPLS TE tunnel transitions from an operationally “up” state to a “down” state.

An `mplsTunnelRerouted` notification is sent to the NMS when the signaling path of an existing MPLS TE tunnel fails for some reason and a new path option is signaled and placed into effect (that is, the tunnel is rerouted).

An `mplsTunnelReoptimized` notification is sent when the signaling path of an existing MPLS TE tunnel is fully operational, but a better path option can be signaled and placed into effect (that is, the tunnel can be reoptimized). This reoptimization can be triggered by:

- A timer
- The issuance of an **mpls traffic-eng reoptimize** command
- A configuration change that requires the resignaling of a tunnel

Path options are configurable parameters that you can use to specify the order of priority for establishing a new tunnel path. For example, you can create a tunnel head configuration and define any one of many path options numbered 1 through  $n$ , with “1” being the highest priority option and “ $n$ ” being an unlimited number of lower priority path options. Thus, there is no limit to the number of path options that you can specify in this manner.

## Notification Implementation

When an MPLS TE tunnel interface (or any other device interface, such as an Ethernet or Packet over SONET (POS) interface) transitions between an up and down state, an Interfaces MIB (ifMIB) link notification is generated. When such a notification occurs in an MPLS TE STD MIB environment, the interface is checked by software to determine if the notification is associated with an MPLS TE tunnel. If so, the interfaces MIB link notification is interlinked with the appropriate `mplsTunnelUp` or `mplsTunnelDown` notification to provide notification to the NMS regarding the operational event occurring on the tunnel interface. Hence, the generation of an Interfaces MIB link notification pertaining to an MPLS traffic engineering tunnel interface begets an appropriate `mplsTunnelUp` or `mplsTunnelDown` notification that is transmitted to the specified NMS.

An `mplsTunnelRerouted` notification is generated whenever the signaling path for an MPLS TE tunnel changes. However, software intelligence in the MPLS TE STD MIB prevents the reroute notification from being sent to the NMS when a TE tunnel transitions between an up or down state during an administrative or operational status check of the tunnel. Either an up or down notification or a reroute notification can be sent in this instance, but not both. This action prevents unnecessary traffic on the network.

## Benefits of MPLS EM - TE MIB RFC 3812

The MPLS Traffic Engineering MIB provides the following benefits:

- Provides a standards-based SNMP interface for retrieving information about MPLS TE.
- Provides information about the traffic flows on MPLS TE tunnels.
- Presents MPLS TE tunnel routes, including the configured route, the Interior Gateway Protocol (IGP) calculated route, and the actual route traversed.
- Provides information, in conjunction with the Interfaces MIB, about how a tunnel was rerouted in the event of a link failure.
- Provides information about the configured resources used for an MPLS TE tunnel.
- Supports the generation and queueing of notifications that call attention to major changes in the operational status of MPLS TE tunnels;
- Forwards notification messages to a designated NMS for evaluation or action by network administrators.

## MPLS Traffic Engineering MIB Layer Structure

The SNMP agent code supporting the MPLS TE STD MIB follows the existing model for such code in Cisco IOS software and is, in part, generated by the Cisco IOS tool set, based on the MIB source code.

The SNMP agent code, which has a layered structure similar to that of the MIB support code in Cisco IOS software, consists of four layers:

- Platform independent layer—This layer is generated primarily by the Cisco IOS MIB development tool set and incorporates platform and implementation independent functions. The Cisco IOS MIB development tool set creates a standard set of files associated with a MIB.
- Application interface layer—The functions, names, and template code for MIB objects in this layer are also generated by the Cisco IOS MIB development tool set.
- Application specific layer—This layer provides an interface between the application interface layer and the application program interface (API) and data structures layer and performs tasks needed to retrieve required information from Cisco IOS software, such as searching through data structures.
- API and data structures layer—This layer contains the data structures or APIs within Cisco IOS software that are retrieved or called in order to set or retrieve SNMP management information.

## Features and Technologies Related to MPLS EM - TE MIB RFC 3812

The MPLS TE STD MIB feature is used in conjunction with the following features and technologies:

- Standards-based SNMP network management application
- MPLS
- MPLS TE
- MPLS label switching router MIB (MPLS-LSR-MIB)

## Supported Objects in the MPLS EM - TE MIB RFC 3812

The MPLS TE STD MIB contains numerous tables and object definitions that provide read-only SNMP management support for the MPLS TE features in Cisco IOS software. The MPLS TE STD MIB conforms to Abstract Syntax Notation One (ASN.1), thus reflecting an idealized MPLS TE database.

Using any standard SNMP network management application, you can retrieve and display information from the MPLS TE STD MIB by using GET operations; similarly, you can traverse information in the MIB database for display by using GETNEXT operations.

The MPLS TE STD MIB tables and objects supported in Cisco IOS releases follow. Important MIB tables (those highlighted in bold type) are described briefly in accompanying text.

- **mplsTunnelConfigured**—Total number of tunnel configurations that are defined on this node.
- **mplsTunnelActive**—Total number of label switched paths (LSPs) that are defined on this node.
- **mplsTunnelTEDistProto**—The IGP distribution protocol in use.
- **mplsTunnelMaxHops**—The maximum number of hops any given tunnel can utilize.
- **mplsTunnelIndexNext**—Unsupported; set to 0.
- **mplsTunnelTable**—Entries in this table with an instance of 0 and a source address of 0 represent tunnel head configurations. All other entries in this table represent instances of LSPs, both signaled and standby. If a tunnel instance is signaled, its operating status (operStatus) is set to “up” (1) and its instance corresponds to an active LSP.

Tunnel configurations exist only on the tunnel head where the tunnel interface is defined. LSPs traverse the network and involve tunnel heads, tunnel midpoints, and tunnel tails.

Pointers in the tunnel table refer to corresponding entries in other MIB tables. By using these pointers, you can find an entry in the `mplsTunnelTable` and follow a pointer to other tables for additional information. The pointers are the following: *mplsTunnelResourcePointer*, *mplsTunnelHopTableIndex*, *mplsTunnelARHopTableIndex*, and *mplsTunnelCHopTableIndex*.

The tunnel table is indexed by tunnel ID, tunnel instance, tunnel source address, and tunnel destination address. The description of each entry has an alphabetic suffix (a), (b), or (c), if appropriate, to indicate the applicability of the entry:

- a. For tunnel head configurations only
- b. For LSPs only
- c. For both tunnel head configurations and LSPs

Following is a list and description of each entry.

- `mplsTunnelIndex`—Same as tunnel ID (c).
- `mplsTunnelInstance`—Tunnel instance of the LSP; 0 for head configurations (b).
- `mplsTunnelIngressLSRId`—Source IP address of the LSP; 0 for head configurations (b).
- `mplsTunnelEgressLSRId`—Destination IP address of the tunnel (c).
- `mplsTunnelName`—Command name for the tunnel interfaces (a).
- `mplsTunnelDescr`—Descriptive name for tunnel configurations and LSPs (c).
- `mplsTunnelIsIf`—Indicator of whether the entry represents an interface (c).
- `mplsTunnelIfIndex`—Index of the tunnel interface within the `ifMIB` (a).
- `mplsTunnelXCPointer`—(For midpoints only – no tails) Pointer for the LSP within the `mplsXCTable` of the MPLS LSR STD MIB (b).
- `mplsTunnelSignallingProto`—Signaling protocol used by tunnels (c).
- `mplsTunnelSetupPrio`—Setup priority of the tunnel (c).
- `mplsTunnelHoldingPrio`—Holding priority of the tunnel (c).
- `mplsTunnelSessionAttributes`—Session attributes (c).
- `mplsTunnelOwner`—Tunnel owner (c).
- `mplsTunnelLocalProtectInUse`—Not implemented (c).
- `mplsTunnelResourcePointer`—Pointer into the Resource Table (b).
- `mplsTunnelInstancePriority`—Not implemented (b).
- `mplsTunnelHopTableIndex`—Index into the Hop Table (a).
- `mplsTunnelARHopTableIndex`—Index into the AR Hop Table (b).
- `mplsTunnelCHopTableIndex`—Index into the C Hop Table (b).
- `mplsTunnelPrimaryUpTime`—Amount of time, in seconds, that the current path has been up (a).
- `mplsTunnelPathChanges`—Number of times a tunnel has been resignalled (a).
- `mplsTunnelLastPathChange`—Amount of time, in seconds, since the last path resignaling occurred (a).
- `mplsTunnelCreationTime`—Time stamp when the tunnel was created (a).
- `mplsTunnelStateTransitions`—Number of times the tunnel has changed state (a).
- `mplsTunnelIncludeAnyAffinity`—Not implemented (a).

- `mplsTunnelIncludeAllAffinity`—Attribute bits that must be set for the tunnel to traverse a link (a).
- `mplsTunnelExcludeAnyAffinity`—Attribute bits that must *not* be set for the tunnel to traverse a link (a).
- `mplsTunnelPathInUse`—Path option number being used for the tunnel’s path. If no path option is active, this object will be 0 (a).
- `mplsTunnelRole`—Role of the tunnel on the router; that is, head, midpoint, or tail (c).
- `mplsTunnelTotalUpTime`—Amount of time, in seconds, that the tunnel has been operationally up (a).
- `mplsTunnelInstanceUpTime`—Not implemented (b).
- `mplsTunnelAdminStatus`—Administrative status of a tunnel (c).
- `mplsTunnelOperStatus`—Actual operating status of a tunnel (c).
- `mplsTunnelRowStatus`—This object is used in conjunction with configuring a new tunnel. This object will always be seen as “active” (a).
- `mplsTunnelStorageType`—Storage type of a tunnel entry (c).
- `mplsTunnelHopListIndexNext`—Next valid index to use as an index in the `mplsTunnelHopTable`.
- **`mplsTunnelHopTable`**—Entries in this table exist only for tunnel configurations and correspond to the path options defined for the tunnel. Two types of path options exist: *explicit* and *dynamic*. This table shows all hops listed in the explicit path options, while showing only the destination hop for dynamic path options. The tunnel hop table is indexed by tunnel ID, path option, and hop number.

Following is a list and description of each table entry.

- `mplsTunnelHopListIndex`—Primary index into the table.
- `mplsTunnelHopIndex`—Secondary index into the table.
- `mplsTunnelHopAddrType`—Indicates if the address of this hop is the type IPv4 or IPv6.
- `mplsTunnelHopIpAddr`—The IP address of this hop.
- `mplsTunnelHopIpPrefixLen`—The prefix length of the IP address.
- `mplsTunnelHopAsNumber`—This object will contain 0 or the autonomous system number of the hop, depending on the value of `mplsTunnelHopAddrType`.
- `mplsTunnelHopLspId`—This object will contain 0 or the LSPID of the tunnel, depending on the value of `mplsTunnelHopAddrType`.
- `mplsTunnelHopType`—Denotes whether this tunnel hop is routed in a strict or loose fashion.
- `mplsTunnelHopInclude`—Indicates whether this hop must be included in the tunnel.
- `mplsTunnelHopPathOptionName`—Describes a series of hops as they relate to a specified path option.
- `mplsTunnelHopEntryPathComp`—Indicates whether the complete tunnel path should be specified.
- `mplsTunnelHopRowStatus`—This object is used in conjunction with the configuring of a new row in the table.
- `mplsTunnelHopStorageType`—The storage type of this MIB object.
- `mplsTunnelResourceIndexNext`—This object contains the next appropriate value to be used for `mplsTunnelResourceIndex` when creating entries in the `mplsTunnelResourceTable`

- **mplsTunnelResourceTable**—Entries in this table correspond to the “Tspec” information displayed when you execute the **show mpls traffic-eng tunnels** command. These entries exist only for LSPs.

The tunnel resource table is indexed by address and hop number. Following the *mplsTunnelResourcePointer* pointer from the tunnel table is the best way to retrieve information from this table.

Following is a list and description of each table entry.

- *mplsTunnelResourceIndex*—The primary index into this table.
- *mplsTunnelResourceMaxRate*—The maximum rate, in bits per second, supported by this tunnel.
- *mplsTunnelResourceMeanRate*—The mean rate, in bits per second, supported by this tunnel.
- *mplsTunnelResourceMaxBurstSize*—The maximum burst size, in bytes, allowed by this tunnel.
- *mplsTunnelResourceRowStatus*—This object is used in conjunction with the configuration of a new row in the table.
- *mplsTunnelResourceStorageType*—The storage type of this MIB object.
- **mplsTunnelARHopTable**—Entries in this table correspond to the actual route taken by the tunnel, and whose route was successfully signaled by the network. The hops present in this table correspond to those present in the record route object (RRO) in Resource Reservation Protocol (RSVP). You can also display the information in this table by executing the **show mpls traffic-eng tunnels** command.

The actual route hop table is indexed by address and hop number. Following the *mplsTunnelARHopTableIndex* pointer from the tunnel table is the best way to retrieve information from this table.

Following is a list and description of each table entry:

- *mplsTunnelARHopListIndex*—The primary index into this table.
- *mplsTunnelARHopIndex*—The secondary index into this table.
- *mplsTunnelARHopIpAddr*—The IP address of this hop.
- *mplsTunnelARHopIpPrefixLen*—The prefix length of the IP address.
- *mplsTunnelARHopAsNumber*—This object will contain 0 or the AS number of the hop, depending on the value of *mplsTunnelARHopAddrType*.
- *mplsTunnelARHopAddrType*—The type of address for this MIB entry, either IPv4 or IPv6.
- *mplsTunnelARHopType*—Denotes whether this tunnel hop is routed in a strict or loose manner.
- **mplsTunnelCHopTable**—Entries in this table correspond to the explicit route object (ERO) in RSVP, which is used to signal the LSP. The list of hops in this table will contain those hops that are computed by the constraint-based shortest path first (SPF) algorithm. In those cases where “loose” hops are specified for the tunnel, this table will contain the hops that are “filled-in” between the loose hops to complete the path. If you specify a complete explicit path, the computed hop table matches your specified path.

The computed hop table is indexed by address and hop number. Following the *mplsTunnelCHopTableIndex* pointer from the tunnel table is the best way to retrieve information from this table.

Following is a list and description of each table entry:

- *mplsTunnelCHopListIndex*—The primary index into this table.
- *mplsTunnelCHopIndex*—The secondary index into this table.
- *mplsTunnelCHopAddrType*—Indicates if the address of this hop is the type IPv4 or IPv6.

- `mplsTunnelCHopIpAddr`—The IP address of this hop.
- `mplsTunnelCHopIpPrefixLen`—The prefix length of the IP address.
- `mplsTunnelCHopAsNumber`—This object will contain 0 or the autonomous system number of the hop, depending on the value of `mplsTunnelHopAddrType`.
- `mplsTunnelCHopType`—Denotes whether this tunnel hop is routed in a strict or loose way.
- **`mplsTunnelPerfTable`**—The tunnel performance table, which augments the **`mplsTunnelTable`**, provides packet and byte counters for each tunnel. This table contains the following packet and byte counters:
  - `mplsTunnelPerfPackets`—This packet counter works only for tunnel heads.
  - `mplsTunnelPerfHCPackets`—This packet counter works only for tunnel heads.
  - `mplsTunnelPerfErrors`—This packet counter works only for tunnel heads.
  - `mplsTunnelPerfBytes`—This byte counter works for tunnel heads and tunnel midpoints, but not for tunnel tails.
  - `mplsTunnelPerfHCBytes`—This byte counter works for tunnel heads and tunnel midpoints, but not for tunnel tails.
- `mplsTunnelTrapEnable`—The object type *`mplsTunnelTrapEnable`* is enhanced to be writable. Accordingly, if this object type is set to “TRUE,” the following notifications are enabled, thus giving you the ability to monitor changes in the operational status of MPLS TE tunnels:
  - `mplsTunnelUp`
  - `mplsTunnelDown`
  - `mplsTunnelRerouted`
  - `mplsTunnelReoptimized`

If the *`mplsTunnelTrapEnable`* object is set to “FALSE,” such operational status notifications are not generated. These notification functions are based on the definitions (`mplsTeNotifications`) contained in the IETF draft document entitled *`draft-ietf-mpls-te-mib-05.txt`*.

## CLI Access to MPLS EM - TE MIB RFC 3812 Information

Figure 1 shows commands that you can use to retrieve information from specific tables in the MPLS TE MIB. As noted in this figure, some information in the MPLS TE STD MIB is not retrievable by commands.

**Figure 1**      **Commands for Retrieving MPLS TE STD MIB Information**

		show mpls traffic-eng tunnels	show mpls traffic-eng tunnels summary	show ip explicit-paths	show interfaces	Not available in command

## Retrieving Information from the MPLS EM - TE MIB RFC 3812

This section describes how to efficiently retrieve information about TE tunnels. Such information can be useful in large networks that contain many TE tunnels.

Traverse across a single column of the *mplsTunnelTable*, such as *mplsTunnelName*. This action provides the indexes of every tunnel configuration, and any LSPs involving the host router. Using these indexes, you can perform a GET operation to retrieve information from any column and row of the *mplsTunnelTable*.

The *mplsTunnelTable* provides pointers to other tables for each tunnel. The column *mplsTunnelResourcePointer*, for example, provides an object ID (OID) that you can use to access resource allocation information in the *mplsTunnelResourceTable*. The columns *mplsTunnelHopTableIndex*, *mplsTunnelARHopTableIndex*, and *mplsTunnelCHopTableIndex* provide the primary index into the *mplsTunnelHopTable*, *mplsTunnelARHopTable*, and *mplsTunnelCHopTable*, respectively. By traversing the MPLS TE STD MIB in this manner using a hop table column and primary index, you can retrieve information pertaining to the hops of that tunnel configuration.

Because tunnels are treated as interfaces, the tunnel table column (*mplsTunnelIfIndex*) provides an index into the Interfaces MIB that you can use to retrieve interface-specific information about a tunnel.

# How to Configure the MPLS EM - TE MIB RFC 3812

This section contains the following tasks:

- [Enabling the SNMP Agent to Help Manage Various MPLS TE Tunnel Characteristics of Tunnels on the Local Router, page 11](#) (required)
- [Verifying the Status of the SNMP Agent, page 12](#) (optional)

## Enabling the SNMP Agent to Help Manage Various MPLS TE Tunnel Characteristics of Tunnels on the Local Router

The SNMP agent for the MPLS TE STD MIB is disabled by default. To enable the SNMP agent for the MPLS TE STD MIB, perform the following steps.

### SUMMARY STEPS

1. `telnet host`
2. `enable`
3. `show running-config`
4. `configure terminal`
5. `snmp-server community string [view view-name] [ro | rw] [ipv6 nacl] [access-list-number]`
6. `snmp-server enable traps [identification-type] [notification-option]`
7. `exit`
8. `write memory`

### DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>telnet host</code>  <b>Example:</b> Router> telnet 192.172.172.172	Telnets to the router identified by the specified IP address (represented as xxx.xxx.xxx.xxx).
Step 2	<code>enable</code>  <b>Example:</b> Router# enable	Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>
Step 3	<code>show running-config</code>  <b>Example:</b> Router# show running-config	Displays the running configuration to determine if an SNMP agent is already running. <ul style="list-style-type: none"><li>• If no SNMP information is displayed, go to <a href="#">Step 4</a>. If any SNMP information is displayed, you can modify the information or change it as needed.</li></ul>

	Command or Action	Purpose
Step 4	<code>configure terminal</code>  <b>Example:</b> Router# <code>configure terminal</code>	Enters global configuration mode.
Step 5	<code>snmp-server community string [view view-name] [ro   rw] [ipv6 nacl] [access-list-number]</code>  <b>Example:</b> Router(config)# <code>snmp-server community comaccess ro 4</code>	Enables the read-only (RO) community string.
Step 6	<code>snmp-server enable traps [identification-type] [notification-option]</code>  <b>Example:</b> Router(config)# <code>snmp-server enable traps</code>	Enables an LSR to send SNMP notifications or informs to an SNMP host.  <b>Note</b> This command is optional. After SNMP is enabled, all MIBs (not just the TE MIB) are available for the user to query.
Step 7	<code>exit</code>  <b>Example:</b> Router(config)# <code>exit</code>	Exits global configuration mode and returns to privileged EXEC mode.
Step 8	<code>write memory</code>  <b>Example:</b> Router# <code>write memory</code>	Writes the modified configuration to NVRAM, permanently saving the settings.

## Verifying the Status of the SNMP Agent

To verify that the SNMP agent has been enabled on a host network device, perform the following steps.

### SUMMARY STEPS

1. `telnet host`
2. `enable`
3. `show running-config`

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>telnet</b> <i>host</i>  <b>Example:</b> Router# telnet 192.172.172.172	Telnet to the target device identified by the specified IP address (represented as <i>xxx.xxx.xxx.xxx</i> ).
Step 2	<b>enable</b>  <b>Example:</b> Router# enable	Enables SNMP on the target device.
Step 3	<b>show running-config</b>  <b>Example:</b> Router# show running-config	Displays the running configuration on the target device and is used to examine the output for displayed SNMP information.

## Examples

The following example displays the running configuration on the target device and its SNMP information.

```
Router# show running-config
.
.
.
snmp-server community public ro
snmp-server community private ro
```

Any **snmp-server** statement that appears in the output and takes the form shown here verifies that SNMP has been enabled on that device.

# Configuration Examples for the MPLS EM - TE MIB RFC 3812

This section contains the following configuration examples:

- [Enabling the SNMP Agent to Help Manage Various MPLS TE Tunnel Characteristics of Tunnels on the Local Router: Example, page 13](#)

## Enabling the SNMP Agent to Help Manage Various MPLS TE Tunnel Characteristics of Tunnels on the Local Router: Example

The following example shows how to enable an SNMP agent on a host network device:

```
Router# configure terminal
Router(config)# snmp-server community private
```

The following example shows how to enable SNMPv1 and SNMPv2C. The configuration permits any SNMP agent to access all MPLS TE STD MIB objects with read-only permissions using the community string *public*.

```
Router(config)# snmp-server community public
```

The following example shows how to allow read-only access to all MPLS TE STD MIB objects relating to members of access list 4 that specify the *comaccess* community string. No other SNMP agents will have access to any MPLS TE STD MIB objects.

```
Router(config)# snmp-server community comaccess ro 4
```

## Additional References

The following sections provide references related to the MPLS EM - TE MIB RFC 3812.

# Feature Information for the MPLS EM - TE MIB RFC 3812

Table 1 lists the release history for this MIB.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1** Feature Information for the MPLS EM - TE MIB RFC 3812

Feature Name	Releases	Feature Information
MPLS-EN TE MIB RFC 3812	12.2(33)SRE	<p>The MPLS EM - TE MIB RFC 3812 feature enables the SNMP agent support in Cisco IOS software for MPLS TE management, as implemented in the MPLS TE STD MIB.</p> <p>The following commands were introduced or modified:  <b>snmp-server community</b>, <b>snmp-server enable traps mpls rfc</b>, <b>snmp-server enable traps mpls traffic-eng</b>, <b>snmp-server host</b>.</p>

# Glossary

**affinity bits**—An MPLS traffic engineering tunnel’s requirements on the attributes of the links it will cross. The tunnel’s affinity bits and affinity mask must match with the attributes of the various links carrying the tunnel.

**call admission precedence**—An MPLS traffic engineering tunnel with a higher priority will, if necessary, preempt an MPLS traffic engineering tunnel with a lower priority. An expected use is that tunnels that are more difficult to route will have a higher priority, and can preempt tunnels that are less difficult to route, on the assumption that those lower priority tunnels can find another path.

**constraint-based routing**—Procedures and protocols used to determine a route across a backbone taking into account resource requirements and resource availability, instead of simply using the shortest path.

**flow**—A traffic load entering the backbone at one point—point of presence (POP)—and leaving it from another that must be traffic engineered across the backbone. The traffic load will be carried across one or more LSP tunnels running from the entry POP to the exit POP.

**headend**—The LSR at which the tunnel originates. The tunnel’s “head” or tunnel interface will reside at this LSR as well.

**informs**—A type of notification message that is more reliable than a conventional trap notification message because an informs message requires acknowledgment.

**label**—A short, fixed-length data construct that tells switching nodes how to forward data (packets or cells).

**label switched path (LSP) tunnel**—A configured connection between two routers, using label switching to carry the packets.

**LSP**—label switched path. A path that is followed by a labeled packet over several hops, starting at an ingress LSR and ending at an egress LSR.

**LSR**—label switch router. A Layer 3 router that forwards a packet based on the value of a label encapsulated in the packet.

**MIB**—Management Information Base. A database of network management information (consisting of MIB objects) that is used and maintained by a network management protocol such as SNMP. The value of a MIB object can be changed or retrieved using SNMP commands, usually by a GUI-based network management system. MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

**MPLS**—Multiprotocol Label Switching. Switching method that forwards IP traffic using a label. This label instructs the routers and the switches in the network where to forward the packets based on preestablished IP routing information.

**NMS**—network management station. An NMS is a powerful, well-equipped computer (typically an engineering workstation) that is used by a network administrator to communicate with other devices in the network. An NMS is typically used to manage network resources, gather statistics, and perform a variety of network administration and configuration tasks.

**notification**—A message sent by an SNMP agent to a network management station, console, or terminal to indicate that a significant event within Cisco IOS software has occurred (see traps).

**OSPF**—Open Shortest Path First. A link-state routing protocol used for routing IP.

**RSVP**—Resource Reservation Protocol. Protocol for reserving network resources to provide quality of service (QoS) guarantees to application flows.

**SNMP**—Simple Network Management Protocol. A network management protocol used almost exclusively in TCP/IP networks. SNMP provides a means to monitor and control network devices, manage configurations, collect statistics, monitor performance, and ensure network security.

**tailend**—The downstream, receive end of a tunnel.

**traffic engineering**—Techniques and processes that cause routed traffic to travel through the network on a path other than the one that would have been chosen if standard routing methods were used.

**trap**—A message sent by an SNMP agent to a network management station, console, or terminal to indicate that a significant event within Cisco IOS software has occurred. Traps (notifications) are less reliable than inform requests, because the receiver of the trap does not send an acknowledgment of receipt; furthermore, the sender of the trap cannot determine if the trap was received (see notification).

**VCC**—virtual channel connection. A VCC is a logical circuit consisting of VCLs that carries data between two endpoints in an ATM network. Sometimes called a virtual circuit connection.

**VCI**—virtual channel identifier. A 16-bit field in the header of an ATM cell. The VCI, together with the VPI, is used to identify the next network VCL as the cell passes through a series of ATM switches on its way to its final destination.

**VCL**—virtual channel link. A VCL is the logical connection that exists between two adjacent switches in an ATM network.

**VPI**—virtual path identifier. An 8-bit field in the header of an ATM cell. The VPI, together with the VCI, is used to identify the next network VCL as the cell passes through a series of ATM switches on its way to its final destination.

## **MPLS High Availability**

# MPLS High Availability: Overview

---

**First Published: August 11, 2004**

**Last Updated: August 21, 2007**

This document provides an overview of the Multiprotocol Label Switching (MPLS) high availability (HA) features. MPLS HA provides full nonstop forwarding (NSF) and stateful switchover (SSO) capability to the MPLS Label Distribution Protocol (LDP) and MPLS Virtual Private Networks (VPNs) features.

## Finding Feature Information in This Module

*Your Cisco IOS software release may not support all of the features documented in this module.* To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for MPLS High Availability: Overview”](#) section on page 9.

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

# Restrictions for MPLS High Availability

For information about supported hardware, see the following documents:

- For Cisco IOS Release 12.2(25)S, see the [Cross-Platform Release Notes for Cisco IOS Release 12.2S](#).
- For Cisco IOS Release 12.2SB, see the [Cross-Platform Release Notes for Cisco IOS Release 12.2SB](#).
- For Cisco IOS Release 12.2(33)SRA, see the [Release Notes for Cisco IOS Release 12.2SR for the Cisco 7600 Series Routers](#)
- For Cisco IOS Release 12.2(33)SXH, see the [Release Notes for Cisco IOS Release 12.2SX on the Catalyst 6500 Series MSFC](#)

## Information About MPLS High Availability

This section covers the following topics:

- [MPLS High Availability Overview, page 2](#)
- [MPLS High Availability Features, page 3](#)
- [MPLS High Availability Infrastructure Changes, page 4](#)
- [MPLS Applications That Coexist with SSO, page 5](#)

## MPLS High Availability Overview

MPLS HA features provide SSO and NSF capability to the MPLS Label Distribution Protocol (LDP) and MPLS Virtual Private Network (VPN) features. MPLS HA includes the following new features:

- [NSF/SSO—MPLS VPN](#)
- [NSF/SSO—MPLS LDP and LDP Graceful Restart](#)
- [NSF/SSO: Any Transport over MPLS and Graceful Restart](#)

In addition, the MIBs for MPLS VPNs and MPLS LDP have been enhanced to work in the MPLS HA environment.

The following features have been changed or created to work in the MPLS HA environment:

- [MPLS High Availability Infrastructure Changes](#)
- [Cisco Express Forwarding Scalability Enhancements](#)

The following features perform normally in an NSF/SSO environment. They can exist with SSO and NSF but do not have the ability to keep duplicate information in a backup Route Processor (RP) on the Cisco 7500 series router and in a backup Performance Routing Engine2 (PRE2) on the Cisco 10000 series router.

- [MPLS Traffic Engineering](#)
- [MPLS Quality of Service Applications](#)
- [IPv6 over MPLS](#) (not supported on the Cisco 10000 series router)
- [MPLS Label Switching Router MIB](#)
- [MPLS TE MIB](#)

- [MPLS Enhancements to Interfaces MIB](#)

The following sections explain these features in more detail.

## MPLS High Availability Features

The following MPLS HA features have the ability to continue forwarding data following an RP switchover on the Cisco 7500 series router or PRE2 switchover on the Cisco 10000 series router:

- MPLS Label Distribution Protocol (LDP)
- MPLS Virtual Private Networks (VPNs)
- Any Transport over MPLS (AToM)

**Note**

In Cisco IOS Release 12.2(28)SB, AToM is not enabled for high availability on the Cisco 10000 series router. However, AToM coexists with SSO. This means that AToM functions normally in an SSO environment but because state information is not maintained on the standby RP, a switchover can partially disrupt operations

When you enable MPLS HA, you get the benefit of allowing an RP on the Cisco 7500 series router or PRE2 on the Cisco 10000 series router to recover from disruption in service without losing its LDP bindings, MPLS forwarding state, and VPN prefix information.

### NSF/SSO—MPLS VPN

The NSF/SSO—MPLS VPN feature allows a router to recover from a disruption in service without losing its VPN prefix information. The NSF/SSO—MPLS VPN feature works with the BGP Graceful Restart mechanisms defined in the Graceful Restart Internet Engineering Task Force (IETF) specifications and in the [Cisco Nonstop Forwarding](#) feature module. The BGP Graceful Restart feature supports the VPNv4 VRFs, which allows the routers running BGP Graceful Restart to preserve VPN prefix information when a router restarts.

For information about configuring the NSF/SSO—MPLS VPN feature, see the following feature module: [NSF/SSO—MPLS VPN](#).

### NSF/SSO: MPLS VPN MIB

The NSF/SSO—MPLS VPN feature works with the MPLS VPN MIB. For information about configuring the MPLS VPN MIB, see the following feature module: [MPLS VPN: SNMP MIB Support](#).

### NSF/SSO—MPLS LDP and LDP Graceful Restart

MPLS LDP uses SSO, NSF, and Graceful Restart to allow an RP on the Cisco 7500 series router or PRE2 on the Cisco 10000 series router to recover from disruption in the LDP components of the control plane service without losing its MPLS forwarding state. The NSF/SSO—MPLS LDP and LDP Graceful Restart feature works with LDP sessions between directly connected peers as well as with peers that are not directly connected (targeted sessions).

For information about configuring the NSF/SSO—MPLS LDP and LDP Graceful Restart feature, see the following feature module: [NSF/SSO—MPLS LDP and LDP Graceful Restart](#).

## NSF/SSO: MPLS LDP MIB

The MPLS LDP MIB with the IETF Version 8 Upgrade is supported with NSF/SSO—MPLS LDP and LDP Graceful Restart. For information about configuring the MPLS LDP MIB, see the following feature module: [MPLS Label Distribution Protocol MIB Version 8 Upgrade](#).

## NSF/SSO: Any Transport over MPLS and Graceful Restart

AToM uses SSO, NSF, and Graceful Restart to allow an RP to recover from disruption in the LDP components of the control plane service without losing its MPLS forwarding state.

### Note

In Cisco IOS Release 12.2(28)SB, AToM is not enabled for high availability on the Cisco 10000 series router. However, AToM coexists with SSO. This means that AToM functions normally in an SSO environment but because state information is not maintained on the standby RP, a switchover can partially disrupt operations.

For information about configuring AToM NSF/SSO Support and Graceful Restart, see [NSF/SSO: Any Transport over MPLS and Graceful Restart](#).

## MPLS High Availability Infrastructure Changes

The MPLS control plane software has been enhanced to work in an HA environment. The changes made the control plane software more modular, which helps MPLS support newer applications. Some of the control plane software changes made MPLS more scalable and flexible. See the [“Cisco Express Forwarding Scalability Enhancements”](#) section on page 4 for more information.

Changes to the MPLS Forwarding Infrastructure (MFI) and the Cisco Express Forwarding component introduced new commands and changed other existing commands.

MFI replaced the Label Forwarding Information Base (LFIB) and is responsible for managing MPLS data structures used for forwarding. For information about the MPLS command changes related to the MFI, see the following document: [MPLS High Availability: Command Changes](#).

### Note

The MFI and LFIB do not coexist in the same image. Users must use MFI starting with Cisco IOS Release 12.2(25)S and later releases.

MPLS High Availability introduces the MPLS IP Rewrite Manager (IPRM), which manages the interactions between Cisco Express Forwarding, the IP Label Distribution Modules (LDMs), and the MFI. MPLS IPRM is enabled by default. You do not need to configure or customize the IPRM. See the [“Command Reference”](#) section on page 8 for show and debug commands related to IPRM.

## Cisco Express Forwarding Scalability Enhancements

Cisco Express Forwarding provides a forwarding path and maintains a complete forwarding and adjacency table for both the software and hardware forwarding engines.

With MPLS High Availability, Cisco Express Forwarding supports new features and new hardware. The Cisco Express Forwarding improvements enable Cisco Express Forwarding to work with the MPLS HA applications and the MFI infrastructure. Cisco Express Forwarding improvements increase scalability, which are outlined in [Table 1](#).

**Table 1** Cisco Express Forwarding Scalability Enhancements

For the Cisco 7500 Series Router	For the Cisco 10000 Series Router
Up to 512,000 prefixes	Up to 1 million prefixes
Up to 128,000 adjacencies	Up to 1 million adjacencies
4000 VPNs	4000 VPNs
Arbitrary prefix path counts from the Routing Information Base (RIB)	Arbitrary prefix path counts from the RIB
16 paths per prefix for forwarding	8 paths per prefix for forwarding
64 Cisco Express Forwarding instances (such as line cards or redundant RPs)	NA

Cisco Express Forwarding makes the following enhancements:

- Improves memory use
- Reduces large peak memory use
- Reduces route convergence times for the Cisco 7500 series router.

For information about the Cisco Express Forwarding command changes, see [Cisco Express Forwarding: Command Changes](#).

## MPLS Applications That Coexist with SSO

The following sections list the MPLS features that maintain, either partially or completely, undisturbed operation through an RP switchover on the Cisco 7500 series router or PRE2 switchover on the Cisco 10000 series router.

### MPLS Traffic Engineering

The MPLS Traffic Engineering (TE) features work with the new Cisco Express Forwarding and MFI modules. TE is SSO coexistent, which means it maintains, either partially or completely, undisturbed operation through an RP switchover on the Cisco 7500 series router or PRE2 switchover on the Cisco 10000 series router. No additional capabilities have been introduced with MPLS High Availability. The **debug mpls traffic-eng lsd-client** command is introduced with the MPLS High Availability features.

### MPLS Quality of Service Applications

Cisco IOS MPLS supports the IETF DiffServ architecture by enabling the quality of service (QoS) functions listed in [Table 2](#) to act on the MPLS packets.

**Table 2** MPLS QoS Support

Category	Related MPLS QoS Features
Traffic classification	Access Control List matching
Traffic marking	Differentiated services code point (DSCP) MPLS Experimental (EXP) field

**Table 2**      **MPLS QoS Support (continued)**

Category	Related MPLS QoS Features
Congestion management	Low latency queueing (LLQ) Class-based weighted fair queueing (CBWFQ)
Congestion avoidance	Weighted Random Early Detection (WRED)
Traffic conditioning	Shaping and policing

## IPv6 over MPLS

The IPv6 over MPLS application works with the new Cisco Express Forwarding and MFI modules. IPv6 over MPLS is SSO coexistent, which means it maintains, either partially or completely, undisturbed operation through an RP switchover.

### Note

The Cisco 10000 series router does not support the IPv6 over MPLS application.

Command changes are documented in the [Cisco IOS IPv6 Command Reference](#).

## MPLS Label Switching Router MIB

The MPLS Label Switching Router (LSR) MIB works in the MPLS HA environment. Two indexes in the LSR MIB were changed to provide well-defined and ordered values:

- mplsXCIndex
- mplsOutSegmentIndex

This benefits the MPLS LSR MIB in the following ways:

- The MIB walk-through has a consistent and logical order.
- The same index values are maintained after a switchover.

For information about the MPLS LSR MIB, see the [MPLS Label Switching Router MIB](#).

## MPLS TE MIB

The MPLS TE MIB works in the MPLS HA environment. For information about the MPLS TE MIB, see the [MPLS Traffic Engineering \(TE\) MIB](#).

### Note

After an RP switchover on the Cisco 7500 series router or PRE2 switchover on the Cisco 10000 series router, the value of mplsTunnelCreationTime in the TE MIB does not correctly reflect the time when the tunnel was created. After an RP or PRE2 switchover, the tunnel gets a new time stamp.

## MPLS Enhancements to Interfaces MIB

The MPLS Enhancements to Interfaces MIB works in the MPLS HA environment. For information about the MPLS Enhancements to Interfaces MIB, see the [MPLS Enhancements to Interfaces MIB](#).

# Additional References

The following sections provide references related to the MPLS High Availability feature.

## Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Multiprotocol Label Switching Command Reference* at [http://www.cisco.com/en/US/docs/ios/mpls/command/reference/mp\\_book.html](http://www.cisco.com/en/US/docs/ios/mpls/command/reference/mp_book.html). For information about all Cisco IOS commands, go to the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or to the *Cisco IOS Master Commands List*.

- **clear mpls counters**
- **clear mpls ip iprm counters**
- **debug mpls ip iprm**
- **debug mpls ip iprm cef**
- **debug mpls ip iprm events**
- **debug mpls ip iprm ldm**
- **debug mpls ip iprm mfi**
- **debug mpls traffic-eng lsd-client**
- **show mpls ip iprm counters**
- **show mpls ip iprm ldm**

# Feature Information for MPLS High Availability: Overview

Table 3 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Cisco IOS software images are specific to a Cisco IOS software release, a feature set, and a platform. Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

## Note

Table 3 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 3** Feature Information for MPLS High Availability: Overview

Feature Name	Releases	Feature Information
MPLS High Availability: Overview	12.2(25)S 12.2(28)SB 12.2(33)SRA 12.2(33)SXH	This feature provides an overview of the Multiprotocol Label Switching (MPLS) high availability (HA) features.  In 12.2(25)S, this feature was introduced on the Cisco 7500 series router.  In 12.2(28)SB, support was added for the Cisco 10000.  In 12.2(33)SRA, support was added for the Cisco 7600 series routers.  In 12.2(33)SXH, this feature was integrated into Cisco IOS Release 12.2(33)SXH.

# MPLS High Availability: Command Changes

---

**First Published: August 11, 2004**

**Last Updated: August 21, 2007**

This feature module details changes to commands that are required to support updates to the Multiprotocol Label Switching (MPLS) High Availability (HA) feature.

In Cisco IOS Releases 12.2(25)S, 12.2(28)SB, 12.2(33)SRA, and 12.2(33)SXH, the MPLS control plane software is enhanced to work in MPLS HA environments. The changes made the control plane software more modular, which helps MPLS support MPLS HA applications. Some of the control plane software changes also made MPLS more scalable and flexible.

Changes to the MPLS Forwarding Infrastructure (MFI) and the Cisco Express Forwarding component introduced new commands and changed other existing commands. MFI replaced the Label Forwarding Information Base (LFIB) and is responsible for managing MPLS data structures used for forwarding.

## Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for MPLS High Availability: Command Changes”](#) section on page 9.

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Information About MPLS High Availability: Command Changes

Before using MPLS High Availability features, you should understand the following concepts:

- [MPLS Replacement Commands for Tag-Switching Commands, page 2](#)
- [New Command Defaults, page 2](#)
- [MPLS MTU Command Changes, page 2](#)
- [Deleted Commands, page 3](#)
- [Replaced Commands, page 3](#)

## MPLS Replacement Commands for Tag-Switching Commands

Starting with Cisco IOS Releases 12.2(25)S, 12.2(28)SB, 12.2(33)SRA and 12.2(33)SXH, all tag-switching commands are obsoleted and are replaced with MPLS command versions. When you enter an obsolete tag-switching command, such as **tag-switching ip**, you receive the following message:

```
% Command accepted but obsolete, unreleased, or unsupported; see documentation
```

Use the MPLS version of the command instead, such as **mpls ip**.

Support for the tag-switching versions of commands will cease in a future release.

Configuration files that use the tag-switching version of the commands continue to operate. However, running configurations will display the new MPLS versions of the commands.

## New Command Defaults

Starting with Cisco IOS Releases 12.2(25)S, 12.2(28)SB, 12.2(33)SRA and 12.2(33)SXH, Label Distribution Protocol (LDP) is the default protocol. In other releases and trains, the default label distribution protocol is Tag Distribution Protocol (TDP). See the **mpls label protocol** (global configuration) command in the [NSF/SSO—MPLS LDP and MPLS LDP Graceful Restart](#) feature for more information.

## MPLS MTU Command Changes

The **mpls mtu** command has changed over the course of the several releases, starting in Cisco IOS Release 12.2(25)S. This section documents the changes implemented in Cisco IOS Release 12.2(25)S. For information about the changes implemented in Cisco IOS Releases 12.2(27)SBC and later releases, see the [MPLS MTU Command Changes](#) feature.

In Cisco IOS Release 12.2(25)S, if the interface MTU is less than 1524 bytes, you can set the maximum MPLS MTU to 24 bytes more than the interface MTU. For example, if the interface MTU is set to 1510 bytes, then you can set the maximum MPLS MTU to 1534 bytes (1510 + 24).

**Note**

Although you can set the MPLS MTU to a value greater than the interface MTU, it is recommended that you keep the MPLS MTU less than or equal to the interface MTU to prevent the hardware from dropping packets. A best practice is to set the interface MTU of the core-facing interface to a value greater than either the IP MTU or interface MTU of the edge-facing interface.

If the interface MTU is greater than or equal to 1524 bytes, then you can set the maximum MPLS MTU as high as the interface MTU. For example, if the interface MTU is set to 1600 bytes, then you can set the MPLS MTU to a maximum of 1600 bytes. If you set the MPLS MTU higher than the interface MTU, traffic is dropped.

For interfaces that do not allow you to configure the interface MTU value and the interface MTU is 1500 bytes, the MPLS MTU range is 64 to 1524 bytes.

If you upgrade to Cisco IOS Release 12.2(25)S from an earlier release and you have an MPLS MTU setting that does not conform to these guidelines, the MPLS MTU setting is not accepted by the system. If this happens, reconfigure the MPLS MTU setting to conform to the guidelines.

## Deleted Commands

The following commands are no longer available in Cisco IOS Releases 12.2(25)S, 12.2(28)SB, 12.2(33)SRA, and 12.2(33)SXH:

- **debug mpls adjacency**
- **debug mpls lfib cef**
- **debug mpls lfib enc**
- **debug mpls lfib lsp**
- **debug mpls lfib state**
- **debug mpls lfib struct**
- **debug mpls lfib fast-reroute**

## Replaced Commands

[Table 1](#) lists the commands that use the term tag-switching. Starting with Cisco IOS Releases 12.2(25)S, 12.2(28)SB, 12.2(33)SRA, and 12.2(33)SXH, these commands have been updated with MPLS terminology. Although the tag-switching versions of the commands are obsoleted, the tag-switching commands continue to work, but are not documented.

Please use the MPLS versions of the commands. If you issue a tag-switching command, you receive the following error:

```
% Command accepted but obsolete, unreleased, or unsupported; see documentation
```

For information about any of the MPLS commands in [Table 1](#) and [Table 2](#), see the *Cisco IOS Multiprotocol Label Switching Command Reference*.

[Table 1](#) alphabetically lists the MPLS commands used by the Cisco 7500 series routers that replaced the tag-switching commands.

**Table 1** *Cisco 7500 Series—MPLS Commands That Replaced Tag-Switching Commands*

<b>This MPLS Command Replaces</b>	<b>This Tag-Switching Command</b>
debug mpls atm-cos	debug tag-switching atm-cos
debug mpls atm-ldp api	debug tag-switching atm-tdp api

# Feature Information for MPLS High Availability: Command Changes

Table 3 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Cisco IOS software images are specific to a Cisco IOS software release, a feature set, and a platform. Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

## Note

Table 3 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 3** Feature Information for MPLS High Availability: Command Changes

Feature Name	Releases	Feature Information
MPLS High Availability: Command Changes	12.2(25)S 12.2(28)SB 12.2(33)SRA 12.2(33)SXH	This feature explains the MPLS commands that have been modified for the MPLS High Availability feature.  In 12.2(25)S, this feature was introduced on the Cisco 7500 series router.  In 12.2(28)SB, support was added for the Cisco 10000 series router.  In 12.2(33)SRA, support was added for the Cisco 7600 series router.  In 12.2(33)SXH, this feature was integrated into Cisco IOS Release 12.2(33)SXH.

## MPLS LDP Graceful Restart

---

When a router is configured with Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) Graceful Restart (GR), it assists a neighboring router that has MPLS LDP Stateful Switchover/Nonstop Forwarding (SSO/NSF) Support and Graceful Restart to recover gracefully from an interruption in service. In this Cisco IOS release, MPLS LDP GR functions strictly in helper mode, which means it can only help other routers that are enabled with MPLS SSO/NSF and GR to recover. If the router with LDP GR fails, its peer routers cannot help it recover.

### Notes:

- MPLS LDP SSO/NSF Support and Graceful Restart is supported in Cisco IOS Release 12.2(25)S. For brevity, this feature is called LDP SSO/NSF in this document.
- The MPLS LDP GR feature described in this document refers to helper mode.

When you enable MPLS LDP GR on a router that peers with an MPLS LDP SSO/NSF-enabled router, the SSO/NSF-enabled router can maintain its forwarding state when the LDP session between them is interrupted. While the SSO/NSF-enabled router recovers, the peer router forwards packets using stale information. This enables the SSO/NSF-enabled router to become operational more quickly.

### Feature History for MPLS LDP Graceful Restart

Release	Modification
12.0(29)S	The MPLS LDP Graceful Restart feature (in helper mode) was introduced.
12.3(14)T	This feature was integrated into Cisco IOS Release 12.3(14)T.
12.2(33)SRA	This feature was integrated into Cisco IOS Release 12.2(33)SRA.

### Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

# Contents

- [Information About MPLS LDP Graceful Restart, page 2](#)
- [How to Configure MPLS LDP Graceful Restart, page 3](#)
- [Configuration Example for MPLS LDP Graceful Restart, page 6](#)
- [Additional References, page 10](#)
- [Command Reference, page 11](#)

## Information About MPLS LDP Graceful Restart

To configure MPLS LDP GR, you need to understand the following concepts:

- [How MPLS LDP Graceful Restart Works, page 2](#)
- [How a Route Processor Advertises That It Supports MPLS LDP Graceful Restart, page 3](#)
- [What Happens If a Route Processor Does Not Have LDP Graceful Restart, page 3](#)

## How MPLS LDP Graceful Restart Works

MPLS LDP GR works in strict helper mode, which means it helps a neighboring route processor that has MPLS LDP SSO/NSF to recover from disruption in service without losing its MPLS forwarding state. The disruption in service could be the result of a TCP or UDP event or the stateful switchover of a route processor. When the neighboring router establishes a new session, the LDP bindings and MPLS forwarding states are recovered.

In the topology shown in [Figure 1](#), the following elements have been configured:

- LDP sessions are established between Router 1 and Router 2, as well as between Router 2 and Router 3.
- Router 2 has been configured with MPLS LDP SSO/NSF. Routers 1 and 3 have been configured with MPLS LDP GR.
- A label switched path (LSP) has been established between Router 1 and Router 3.

**Figure 1**      *Example of a Network Using LDP Graceful Restart*

The following process shows how Routers 1 and 3, which have been configured with LDP GR help Router 2, which has been configured with LDP SSO/NSF recover from a disruption in service:

1. Router 1 notices an interruption in service with Router 2. (Router 3 also performs the same actions in this process.)
2. Router 1 marks all the label bindings from Router 2 as stale, but it continues to use the bindings for MPLS forwarding.

Router 1 reestablishes an LDP session with Router 2, but keeps its stale label bindings. If you issue a **show mpls ldp neighbor** command with the **graceful-restart** keyword, the command output displays the recovering LDP sessions.

- Both routers readvertise their label binding information. If Router 1 relearns a label from Router 2 after the session has been established, the stale flags are removed. The **show mpls forwarding-table** command displays the information in the MPLS forwarding table, including the local label, outgoing label or VC, prefix, label-switched bytes, outgoing interface, and next hop.

You can set various graceful restart timers. See the following commands for more information:

- mpls ldp graceful-restart timers neighbor-liveness**
- mpls ldp graceful-restart timers max-recovery**

## How a Route Processor Advertises That It Supports MPLS LDP Graceful Restart

A route processor that is configured to perform MPLS LDP GR includes the Fault Tolerant (FT) Type Length Value (TLV) in the LDP initialization message. The route processor sends the LDP initialization message to a neighbor to establish an LDP session.

The FT session TLV includes the following information:

- The Learn from Network (L) flag is set to 1, which indicates that the route processor is configured to perform MPLS LDP GR.
- The Reconnect Timeout field shows the time (in milliseconds) that the neighbor should wait for a reconnection if the LDP session is lost. In this release, the timer is set to 0, which indicates that if the local router fails, its peers should not wait for it to recover. The timer setting indicates that the local router is working in helper mode.
- The Recovery Time field shows the time (in milliseconds) that the neighbor should retain the MPLS forwarding state during a recovery. If a neighbor did not preserve the MPLS forwarding state before the restart of the control plane, the neighbor sets the recovery time to 0.

## What Happens If a Route Processor Does Not Have LDP Graceful Restart

If two route processors establish an LDP session and one route processor is not configured for MPLS LDP GR, the two route processors create a normal LDP session but do not have the ability to perform MPLS LDP GR. Both route processors must be configured for MPLS LDP GR.

## How to Configure MPLS LDP Graceful Restart

This section contains the following procedures:

- [Configuring MPLS LDP Graceful Restart, page 3](#) (required)
- [Verifying the Configuration, page 5](#) (optional)

## Configuring MPLS LDP Graceful Restart

You must enable MPLS LDP GR on all route processors for an LDP session to be preserved during an interruption in service.

MPLS LDP GR is enabled globally. When you enable MPLS LDP GR, it has no effect on existing LDP sessions. New LDP sessions that are established can perform MPLS LDP GR.

## Restrictions

- MPLS LDP GR is supported in strict helper mode.
- Tag Distribution Protocol (TDP) sessions are not supported. Only LDP sessions are supported.
- MPLS LDP GR cannot be configured on label-controlled ATM (LC-ATM) interfaces.
- MPLS LDP SSO/NSF is supported in IOS Release 12.2(25)S. It is not supported in this release.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef [distributed]**
4. **mpls ldp graceful-restart**
5. **interface type slot/port**
6. **mpls ip**
7. **mpls label protocol {ldp | tdp | both}**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>ip cef [distributed]</b>  <b>Example:</b> Router(config)# ip cef distributed	Enables Cisco Express Forwarding (CEF).
Step 4	<b>mpls ldp graceful-restart</b>  <b>Example:</b> Router(config)# mpls ldp graceful-restart	Enables the router to protect the LDP bindings and MPLS forwarding state during a disruption in service.
Step 5	<b>interface type slot/port</b>  <b>Example:</b> Router(config)# interface pos 3/0	Specifies an interface and enters interface configuration mode.

	Command or Action	Purpose
Step 6	<code>mpls ip</code>  <b>Example:</b> Router(config-if)# mpls ip	Configures MPLS hop-by-hop forwarding for an interface.
Step 7	<code>mpls label protocol {ldp   tdp   both}</code>  <b>Example:</b> Router(config-if)# mpls label protocol ldp	Configures the use of LDP for an interface. You must use LDP.

**Note**

You can also issue the **mpls label protocol ldp** command in global configuration mode, which enables LDP on all interfaces configured for MPLS.

## Verifying the Configuration

The following commands help verify that MPLS LDP GR has been configured correctly:

<b>show mpls ldp neighbor with the graceful-restart keyword</b>	Displays the Graceful Restart information for LDP sessions.
<code>show mpls ldp graceful-restart</code>	Displays Graceful Restart sessions and session parameters.

# Configuration Example for MPLS LDP Graceful Restart

Figure 2 shows a configuration where MPLS LDP GR is enabled on Router 1 and MPLS LDP SSO/NSF is enabled on Routers 2 and 3. In this configuration example, Router 1 creates an LDP session with Router 2. Router 1 also creates a targeted session with Router 3 through a traffic engineering tunnel using Router 2.

**Note**

MPLS LDP SSO/NSF is supported in Cisco IOS Release 12.2(25)S. It is not supported in this release.

# NSF/SSO - MPLS LDP and LDP Graceful Restart

---

**First Published: August 16, 2004**

**Last Updated: August 21, 2007**

Cisco Nonstop Forwarding with Stateful Switchover provides continuous packet forwarding, even during a network processor hardware or software failure. In a redundant system, the secondary processor recovers control plane service during a critical failure in the primary processor. SSO synchronizes the network state information between the primary and the secondary processor.

Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) uses SSO, NSF, and graceful restart to allow a Route Processor to recover from disruption in control plane service (specifically, the LDP component) without losing its MPLS forwarding state. LDP NSF works with LDP sessions between directly connected peers and with peers that are not directly connected (targeted sessions).

## Note

---

In this document, the NSF/SSO - MPLS LDP and LDP Graceful Restart feature is called LDP NSF for brevity.

---

## Finding Feature Information in This Module

*Your Cisco IOS software release may not support all of the features documented in this module.* To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for NSF/SSO - MPLS LDP and LDP Graceful Restart](#)” section on [page 16](#).

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

- [Additional References, page 14](#)
- [Command Reference, page 15](#)
- [Feature Information for NSF/SSO - MPLS LDP and LDP Graceful Restart, page 16](#)

## Prerequisites for NSF/SSO - MPLS LDP and LDP Graceful Restart

For information about supported hardware, see the release notes for your platform.

MPLS high availability (HA) requires that neighbor networking devices be NSF-aware.

To perform LDP NSF, Route Processors must be configured for SSO. See the [Stateful Switchover](#) feature module for more information:

You must enable nonstop forwarding on the routing protocols running between the provider (P) routers, provider edge (PE) routers, and customer edge (CE) routers. The routing protocols are:

- Border Gateway Protocol (BGP)
- Open Shortest Path First (OSPF)
- Intermediate System-to-Intermediate System (IS-IS)

See the [Cisco Nonstop Forwarding](#) feature module for more information.

## Restrictions for NSF/SSO - MPLS LDP and LDP Graceful Restart

LDP NSF has the following restrictions:

- Tag Distribution Protocol (TDP) sessions are not supported. Only LDP sessions are supported.
- LDP NSF cannot be configured on label-controlled ATM (LC-ATM) interfaces.

## Information About NSF/SSO - MPLS LDP and LDP Graceful Restart

To configure LDP NSF, you need to understand the following concepts:

- [How NSF/SSO - MPLS LDP and LDP Graceful Restart Works, page 3](#)
- [How a Route Processor Advertises That It Supports NSF/SSO - MPLS LDP and LDP Graceful Restart, page 4](#)
- [Checkpointing, page 5](#)

## How NSF/SSO - MPLS LDP and LDP Graceful Restart Works

LDP NSF allows a Route Processor to recover from disruption in service without losing its MPLS forwarding state. LDP NSF works under the following circumstances:

- **LDP restart**—An LDP Restart occurs after an SSO event interrupts LDP communication with all LDP neighbors. If the Route Processors are configured with LDP NSF, the backup Route Processor retains the MPLS forwarding state and reestablishes communication with the LDP neighbors. Then the Route Processor ensures that the MPLS forwarding state is recovered.
- **LDP session reset**—An LDP session reset occurs after an individual LDP session has been interrupted, but the interruption is not due to an SSO event. The LDP session might have been interrupted due to a TCP or UDP communication problem. If the Route Processor is configured with MPLS LDP NSF support and graceful restart, the Route Processor associates a new session with the previously interrupted session. The LDP bindings and MPLS forwarding states are recovered when the new session is established.

If an SSO event occurs on an LSR, that LSR performs an LDP restart. The adjacent LSRs perform an LDP session reset.

See the following section for more information about LDP restart and reset.

### What Happens During an LDP Restart and an LDP Session Reset

In the topology shown in [Figure 1](#), the following elements have been configured:

- LDP sessions are established between Router 1 and Router 2, as well as between Router 2 and Router 3.
- A label switched path (LSP) has been established between Router 1 and Router 3.
- The routers have been configured with LDP NSF.

**Figure 1** Example of a Network Using LDP Graceful Restart

The following process shows how LDP recovers when one of the routers fails:

1. When a Route Processor fails on Router 2, communications between the routers is interrupted.
2. Router 1 and Router 3 mark all the label bindings from Router 2 as stale, but they continue to use the bindings for MPLS forwarding.
3. Router 1 and Router 3 attempt to reestablish an LDP session with Router 2.
4. Router 2 restarts and marks all of its forwarding entries as stale. If you issue a **show mpls ldp graceful-restart** command, the command output includes the following line:  

```
LDP is restarting gracefully.
```
5. Router 1 and Router 3 reestablish LDP sessions with Router 2, but they keep their stale label bindings. If you issue a **show mpls ldp neighbor** command with the **graceful-restart** keyword, the command output displays the recovering LDP sessions.

6. All three routers readvertise their label binding information. If a label has been relearned after the session has been established, the stale flags are removed. The **show mpls forwarding-table** command displays the information in the MPLS forwarding table, including the local label, outgoing label or VC, prefix, label-switched bytes, outgoing interface, and next hop.

You can set various timers to limit how long the routers wait for an LDP session to be reestablished before restarting the router. See the following commands for more information:

- [mpls ldp graceful-restart timers forwarding-holding](#)
- [mpls ldp graceful-restart timers max-recovery](#)
- [mpls ldp graceful-restart timers neighbor-liveness](#)

## How a Route Processor Advertises That It Supports NSF/SSO - MPLS LDP and LDP Graceful Restart

A Route Processor that is configured to perform LDP NSF includes the Fault Tolerant (FT) Type Length Value (TLV) in the LDP initialization message. The Route Processor sends the LDP initialization message to a neighbor to establish an LDP session.

The FT session TLV includes the following information:

- The Learn from Network (L) flag is set to 1, which indicates that the Route Processor is configured to perform LDP Graceful Restart.
- The Reconnect Timeout field shows the time (in milliseconds) that the neighbor should wait for a reconnection if the LDP session is lost. This field is set to 120 seconds and cannot be configured.
- The Recovery Time field shows the time (in milliseconds) that the neighbor should retain the MPLS forwarding state during a recovery. If a neighbor did not preserve the MPLS forwarding state before the restart of the control plane, the neighbor sets the recovery time to 0.

## What Happens if a Route Processor Does Not Have LDP Graceful Restart

If a Route Processor is not configured for MPLS LDP Graceful Restart and it attempts to establish an LDP session with a Route Processor that is configured with LDP Graceful Restart, the following events occur:

1. The Route Processor that is configured with MPLS LDP Graceful Restart sends an initialization message that includes the FT session TLV value to the Route Processor that is not configured with MPLS LDP Graceful Restart.
2. The Route Processor that is not configured for MPLS LDP Graceful Restart receives the LDP initialization message and discards the FT session TLV.
3. The two Route Processors create a normal LDP session but do not have the ability to perform MPLS LDP Graceful Restart.

You must enable all Route Processors with MPLS LDP Graceful Restart for an LDP session to be preserved during an interruption in service.

## Checkpointing

Checkpointing is a function that copies state information from the active Route Processor to the backup Route Processor, thereby ensuring that the backup Route Processor has the latest information. If the active Route Processor fails, the backup Route Processor can take over.

For the LDP NSF feature, the checkpointing function copies the active Route Processor's LDP local label bindings to the backup Route Processor. The active Route Processor sends updates to the backup Route Processor when local label bindings are modified as a result of routing changes.

**Note**

Local label bindings that are allocated by BGP and null local label bindings are not included in the checkpointing operation.

The checkpointing function is enabled by default.

To display checkpointing data, issue the **show mpls ldp graceful-restart** command on the active Route Processor.

To check that the active and backup Route Processors have identical copies of the local label bindings, you can issue the **show mpls ldp bindings** command with the **detail** keyword on the active and backup Route Processors. This command displays the local label bindings that have been saved. The active Route Processor and the backup Route Processor should have the same local label bindings.

## Troubleshooting Tips

You can use the **debug mpls ldp graceful-restart** command to enable the display of MPLS LDP checkpoint events and errors.

## How to Configure and Use NSF/SSO - MPLS LDP and LDP Graceful Restart

- [Configuring MPLS LDP Graceful Restart, page 5](#) (required)
- [Verifying the Configuration, page 7](#) (optional)

## Configuring MPLS LDP Graceful Restart

MPLS LDP Graceful Restart (GR) is enabled globally. When you enable LDP GR, it has no effect on existing LDP sessions. LDP GR is enabled for new sessions that are established after the feature has been globally enabled.

## Prerequisites

- Route Processors must be configured for SSO. See the [Stateful Switchover](#) feature module for more information:
- You must enable Nonstop Forwarding on the routing protocols running between the P, PE, routers, and CE routers. See the [Cisco Nonstop Forwarding](#) feature module for more information.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef [distributed]**
4. **mpls ldp graceful-restart**
5. **interface type slot/port**
6. **mpls ip**
7. **mpls label protocol {ldp | tdp | both}**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>ip cef [distributed]</b>  <b>Example:</b> Router(config)# ip cef distributed	Enables distributed Cisco Express Forwarding on Cisco 7500 series routers. Distributes Cisco Express Forwarding information to line cards.  <b>Note</b> For the Cisco 10000 series routers, IP Cisco Express Forwarding is on by default and it cannot be disabled.
Step 4	<b>mpls ldp graceful-restart</b>  <b>Example:</b> Router (config)# mpls ldp graceful-restart	Enables the router to protect the LDP bindings and MPLS forwarding state during a disruption in service.
Step 5	<b>interface type slot/port</b>  <b>Example:</b> Router(config)# interface pos 3/0	Specifies an interface and enters interface configuration mode.
Step 6	<b>mpls ip</b>  <b>Example:</b> Router(config-if)# mpls ip	Configures MPLS hop-by-hop forwarding for an interface.
Step 7	<b>mpls label protocol {ldp   tdp   both}</b>  <b>Example:</b> Router(config-if)# mpls label protocol ldp	Configures the use of LDP for an interface. You must use LDP. You can also issue the <b>mpls label protocol ldp</b> command in global configuration mode, which enables LDP on all interfaces configured for MPLS.

## Verifying the Configuration

Use the following procedure to verify that MPLS LDP Graceful Restart has been configured correctly.

### SUMMARY STEPS

1. **show mpls ldp graceful-restart**
2. **show mpls ldp neighbor graceful restart**
3. **show mpls ldp checkpoint**

### DETAILED STEPS

---

**Step 1 show mpls ldp graceful-restart**

The command output displays Graceful Restart sessions and session parameters:

```
Router# show mpls ldp graceful-restart

LDP Graceful Restart is enabled
Neighbor Liveness Timer: 5 seconds
Max Recovery Time: 200 seconds
Down Neighbor Database (0 records):
Graceful Restart-enabled Sessions:
VRF default:

    Peer LDP Ident: 10.18.18.18:0, State: estab
    Peer LDP Ident: 10.17.17.17:0, State: estab
```

**Step 2 show mpls ldp neighbor graceful restart**

The command output displays the Graceful Restart information for LDP sessions:

```
Router# show mpls ldp neighbor graceful-restart

Peer LDP Ident: 10.20.20.20:0; Local LDP Ident 10.17.17.17:0
  TCP connection: 10.20.20.20.16510 - 10.17.17.17.646
  State: Oper; Msgs sent/rcvd: 8/18; Downstream
  Up time: 00:04:39
  Graceful Restart enabled; Peer reconnect time (msecs): 120000
Peer LDP Ident: 10.19.19.19:0; Local LDP Ident 10.17.17.17:0
  TCP connection: 10.19.19.19.11007 - 10.17.17.17.646
  State: Oper; Msgs sent/rcvd: 8/38; Downstream
  Up time: 00:04:30
  Graceful Restart enabled; Peer reconnect time (msecs): 120000
```

**Step 3 show mpls ldp checkpoint**

The command output displays the summary of the checkpoint information:

```
Router# show mpls ldp checkpoint

Checkpoint status: dynamic-sync
Checkpoint resend timer: not running
5 local bindings in add-skipped
9 local bindings in added
1 of 15+ local bindings in none
```

# Configuration Examples for LDP NSF

This section contains the following examples:

- [Configuring NSF/SSO - MPLS LDP and LDP Graceful Restart: Example, page 8](#)

## Configuring NSF/SSO - MPLS LDP and LDP Graceful Restart: Example

The following configuration example shows the LDP NSF feature configured on three routers. (See [Figure 2](#).) In this configuration example, Router 1 creates an LDP session with Router 2. Router 1 also creates a targeted session with Router 3 through a TE tunnel using Router 2.

**Figure 2** MPLS LDP: NSF/SSO Support and Graceful Restart Configuration Example

- **mpls ldp graceful-restart**
- **mpls ldp graceful-restart timers forwarding-holding**
- **mpls ldp graceful-restart timers max-recovery**
- **mpls ldp graceful-restart timers neighbor-liveness**
- **show mpls ip binding**
- **show mpls ldp bindings**
- **show mpls ldp checkpoint**
- **show mpls ldp graceful-restart**
- **show mpls ldp neighbor**

# Feature Information for NSF/SSO - MPLS LDP and LDP Graceful Restart

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1** Feature Information for NSF/SSO - MPLS LDP and LDP Graceful Restart

Feature Name	Releases	Feature Information
NSF/SSO - MPLS LDP and LDP Graceful Restart	12.2(25)S 12.2(28)SB 12.2(33)SRA 12.2(33)SXH	LDP NSF allows a Route Processor to recover from disruption in service without losing its MPLS forwarding state.  In 12.2(25)S, this feature was introduced on Cisco 7500 series routers.  In 12.2(28)SB, this feature was integrated into Cisco IOS Release 12.2(28)SB and implemented on Cisco 10000 series routers.  In 12.2(33)SRA, this feature was integrated into Cisco IOS Release 12.2(33)SRA.  In 12.2(33)SXH, this feature was integrated into Cisco IOS Release 12.2(33)SXH.

# NSF/SSO—MPLS VPN

---

**First Published: August 11, 2004**

**Last Updated: August 21, 2007**

The NSF/SSO—MPLS VPN feature allows a provider edge (PE) router or Autonomous System Border Router (ASBR) (with redundant Route Processors) to preserve data forwarding information in a Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) when the primary Route Processor (RP) restarts. This feature module describes how to enable Nonstop Forwarding in MPLS VPN networks, including the following types of VPNs:

- Basic MPLS VPNs
- MPLS VPN—Carrier Supporting Carrier
- MPLS VPN—Carrier Supporting Carrier—IPv4 BGP Label Distribution
- MPLS VPN—Interautonomous Systems
- MPLS VPN—Inter-AS—IPv4 BGP Label Distribution

## Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for NSF/SSO—MPLS VPN”](#) section on page 51.

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

- [Configuration Examples for NSF/SSO—MPLS VPN](#), page 8
- [Additional References](#), page 49
- [Command Reference](#), page 50
- [Feature Information for NSF/SSO—MPLS VPN](#), page 51

## Prerequisites for NSF/SSO—MPLS VPN

The NSF/SSO—MPLS VPN feature has the following prerequisites:

For information about supported hardware, see the release notes for your platform.

Before enabling Stateful Switchover (SSO), you must enable MPLS Label Distribution Protocol (LDP) Graceful Restart if you use LDP in the core or in the MPLS VPN routing and forwarding instance in an MPLS VPN Carrier Supporting Carrier configuration. See the [NSF/SSO-MPLS LDP and MPLS LDP Graceful Restart](#) feature module for more information.

You must enable NSF on the routing protocols running between the provider (P) routers, PE routers, and customer edge (CE) routers. The routing protocols are:

- Border Gateway Protocol (BGP)
- Open Shortest Path First (OSPF)
- Intermediate System-to-Intermediate System (IS-IS)

Cisco nonstop forwarding support must be configured on the routers for Cisco Express Forwarding. See the [Cisco Nonstop Forwarding](#) feature module for more information.

Before enabling the NSF/SSO—MPLS VPN feature, you must have a supported MPLS VPN network configuration. Configuration information is included in the [Configuring MPLS VPNs](#) feature module.

## Restrictions for NSF/SSO—MPLS VPN

The NSF/SSO—MPLS VPN feature has the following restrictions:

- Tag Distribution Protocol (TDP) sessions are not supported. Only LDP sessions are supported.
- The NSF/SSO—MPLS VPN feature requires that neighbor networking devices be NSF-aware. Peer routers must support the graceful restart of the protocol used to communicate with the NSF/SSO—MPLS VPN-capable router.
- The NSF/SSO—MPLS VPN feature cannot be configured on label-controlled ATM (LC-ATM) interfaces.

## Information About NSF/SSO—MPLS VPN

To configure NSF/SSO—MPLS VPN, you need to understand the following concepts:

- [Elements That Enable NSF/SSO—MPLS VPN to Work](#), page 3
- [How VPN Prefix Information Is Checkpointed to the Backup Route Processor](#), page 3
- [How BGP Graceful Restart Preserves Prefix Information During a Restart](#), page 3
- [What Happens If a Router Does Not Have NSF/SSO—MPLS VPN Enabled](#), page 4

## Elements That Enable NSF/SSO—MPLS VPN to Work

VPN NSF requires several elements to work:

- VPN NSF uses the BGP Graceful Restart mechanisms defined in the Graceful Restart Internet Engineering Task Force (IETF) specifications and in the *Cisco Nonstop Forwarding* feature module. BGP Graceful Restart allows a router to create MPLS forwarding entries for VPNv4 prefixes in NSF mode. The forwarding entries are preserved during a restart. BGP also saves prefix and corresponding label information and recovers the information after a restart.
- The NSF/SSO—MPLS VPN feature also uses NSF for the label distribution protocol in the core network (either MPLS Label Distribution Protocol, traffic engineering, or static labeling).
- The NSF/SSO—MPLS VPN feature uses NSF for the Interior Gateway Protocol (IGP) used in the core (OSPF or IS-IS).
- The NSF/SSO—MPLS VPN feature uses NSF for the routing protocols between the PE and customer CE routers.

## How VPN Prefix Information Is Checkpointed to the Backup Route Processor

When BGP allocates local labels for prefixes, it checkpoints the local label binding in the backup Route Processor. The checkpointing function copies state information from the active Route Processor to the backup Route Processor, thereby ensuring that the backup Route Processor has an identical copy of the latest information. If the active Route Processor fails, the backup Route Processor can take over with no interruption in service. Checkpointing begins when the active Route Processor does a bulk synchronization, which copies all of the local label bindings to the backup Route Processor. After that, the active Route Processor dynamically checkpoints individual prefix label bindings when a label is allocated or freed. This allows forwarding of labeled packets to continue before BGP reconverges.

## How BGP Graceful Restart Preserves Prefix Information During a Restart

When a router that is capable of BGP Graceful Restart loses connectivity, the following happens to the restarting router:

1. The router establishes BGP sessions with other routers and relearns the BGP routes from other routers that are also capable of Graceful Restart. The restarting router waits to receive updates from the neighboring routers. When the neighboring routers send end-of-Routing Information Base (RIB) markers to indicate that they are done sending updates, the restarting router starts sending its own updates.
2. The restarting router accesses the checkpoint database to find the label that was assigned for each prefix. If it finds the label, it advertises it to the neighboring router. If it does not find the label, it allocates a new label and advertises it.
3. The restarting router removes any stale prefixes after a timer for stale entries expires.

When a peer router that is capable of BGP Graceful Restart encounters a restarting router, it does the following:

1. The peer router sends all of the routing updates to the restarting router. When it has finished sending updates, the peer router sends an end-of RIB marker to the restarting router.
2. The peer router does not immediately remove the BGP routes learned from the restarting router from its BGP routing table. As it learns the prefixes from the restarting router, the peer refreshes the stale routes if the new prefix and label information matches the old information.

## What Happens If a Router Does Not Have NSF/SSO—MPLS VPN Enabled

If a router is not configured for the NSF/SSO—MPLS VPN feature and it attempts to establish a BGP session with a router that is configured with the NSF/SSO—MPLS VPN feature, the two routers create a normal BGP session but do not have the ability to perform the NSF/SSO—MPLS VPN feature.

## How to Configure NSF/SSO—MPLS VPN

This section contains the following procedures:

- [Configuring NSF Support for Basic VPNs, page 4](#) (required)
- [Configuring NSF Support for MPLS VPN Interfaces That Use BGP as the Label Distribution Protocol, page 6](#) (required)
- [Verifying the NSF/SSO—MPLS VPN Configuration, page 7](#) (optional)

## Configuring NSF Support for Basic VPNs

Perform this task to configure NSF support for basic VPNs.

### Prerequisites

Route Processors must be configured for SSO. See the [Stateful Switchover](#) feature module for more information.

If you use LDP in the core or in the virtual routing and forwarding (VRF) instances for MPLS VPN Carrier Supporting Carrier configurations, you must enable the MPLS LDP: NSF/SSO Support and Graceful Restart feature. See the [NSF/SSO-MPLS LDP and MPLS LDP Graceful Restart](#) feature module for more information.

You must enable Nonstop Forwarding on the routing protocols running between the P, PE, and CE routers. The routing protocols are OSPF, IS-IS, and BGP. See the [Cisco Nonstop Forwarding](#) feature module for more information.

Before enabling the NSF/SSO—MPLS VPN feature, you must have a supported MPLS VPN network configuration. Configuration information is included in the [Configuring MPLS VPNs](#) feature module.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef [distributed]**
4. **router bgp *as-number***
5. **bgp graceful-restart restart-time *secs***
6. **bgp graceful-restart stalepath-time *secs***
7. **bgp graceful-restart**
8. **end**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>ip cef [distributed]</b>  <b>Example:</b> Router(config)# ip cef distributed	Enables Cisco Express Forwarding <ul style="list-style-type: none"> <li>Use this command if Cisco Express Forwarding is not enabled by default on the router.</li> </ul>
Step 4	<b>router bgp as-number</b>  <b>Example:</b> Router(config)# router bgp 1	Configures a BGP routing process and enters router configuration mode. <ul style="list-style-type: none"> <li>The <i>as-number</i> argument indicates the number of an autonomous system that identifies the router to other BGP routers and tags the routing information passed along.</li> </ul> Valid numbers are from 0 to 65535. Private autonomous system numbers that can be used in internal networks range from 64512 to 65535.
Step 5	<b>bgp graceful-restart restart-time secs</b>  <b>Example:</b> Router(config-router)# bgp graceful-restart restart-time 200	(Optional) Specifies the maximum time to wait for a graceful-restart-capable neighbor to come back up after a restart. The default is 120 seconds. The valid range is from 1 to 3600 seconds.
Step 6	<b>bgp graceful-restart stalepath-time secs</b>  <b>Example:</b> Router(config-router)# bgp graceful-restart stalepath-time 400	(Optional) Specifies the maximum time to hold on to the stale paths of a gracefully restarted peer. All stale paths are deleted after the expiration of this timer. The default is 360 seconds. The valid range is from 1 to 3600 seconds.
Step 7	<b>bgp graceful-restart</b>  <b>Example:</b> Router(config-router)# bgp graceful-restart	Enables BGP Graceful Restart on the router. See <a href="#">Cisco Nonstop Forwarding</a> for more information about the <b>bgp graceful-restart</b> command.
Step 8	<b>end</b>  <b>Example:</b> Router(config-router)# end	(Optional) Exits to privileged EXEC mode.

## Configuring NSF Support for MPLS VPN Interfaces That Use BGP as the Label Distribution Protocol

The following VPN features require special configuration for the NSF/SSO—MPLS VPN feature:

- MPLS VPN—Carrier Supporting Carrier—IPv4 BGP Label Distribution
- MPLS VPN—Inter-AS—IPv4 BGP Label Distribution

You must issue an extra command, **mpls forwarding bgp**, on the interfaces that use BGP to distribute MPLS labels and routes. Use the following procedure to configure the NSF/SSO—MPLS VPN feature in these MPLS VPNs.

### Prerequisites

- Make sure your MPLS VPN is configured for Carrier Supporting Carrier (CSC) or Inter-AS with BGP as the label distribution protocol.
- Configure NSF/SSO—MPLS VPN first, as described in [“Configuring NSF Support for Basic VPNs” section on page 4](#).

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef [distributed]**
4. **interface slot/port**
5. **mpls forwarding bgp**

### DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>	Enables privileged EXEC mode.
	<b>Example:</b> Router> enable	<ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>	Enters global configuration mode.
	<b>Example:</b> Router# configure terminal	
Step 3	<b>ip cef [distributed]</b>	Enables Cisco Express Forwarding.
	<b>Example:</b> Router(config)# ip cef distributed	<ul style="list-style-type: none"> <li>• Use this command if Cisco Express Forwarding is not enabled by default on the router.</li> </ul>

	Command or Action	Purpose
Step 4	<code>interface slot/port</code>  <b>Example:</b> Router(config)# interface POS1/0/0	Defines the interface and enters interface configuration mode.
Step 5	<code>mpls forwarding bgp</code>  <b>Example:</b> Router(config-if)# <code>mpls forwarding bgp</code>	Enables the interface to exchange BGP labels. You need to issue this command on any interface configured to use BGP to forward MPLS labels and routes.

## Verifying the NSF/SSO—MPLS VPN Configuration

This section explains how to verify a configuration that has the NSF/SSO—MPLS VPN feature.

- See the [Cisco Nonstop Forwarding](#) feature module for verification procedures for BGP, OSPF, and IS-IS.
- See the [NSF/SSO-MPLS LDP and MPLS LDP Graceful Restart](#) feature module for verification procedures for the MPLS LDP: NSF/SSO feature
- See the verification information included in the [Configuring MPLS VPNs](#) feature module.

### SUMMARY STEPS

1. `show ip bgp vpnv4 all labels`
2. `show ip bgp vpnv4 all neighbors`
3. `show ip bgp labels`
4. `show ip bgp neighbors`

### DETAILED STEPS

#### Step 1 `show ip bgp vpnv4 all labels`

This command displays incoming and outgoing BGP labels for each route distinguisher. The following is sample output from the command:

```
Router# show ip bgp vpnv4 all labels

Network          Next Hop      In label/Out label
Route Distinguisher: 100:1 (vpn1)
  10.3.0.0/16      10.0.0.5      25/20
                  10.0.0.1      25/23
                  10.0.0.2      25/imp-null
  10.0.0.9/32      10.0.0.1      24/22
                  10.0.0.2      24/imp-null
```

#### Step 2 `show ip bgp vpnv4 all neighbors`

This command displays whether the BGP peers are capable of Graceful Restart. The following is sample output from the command:

```
Router# show ip bgp vpnv4 all neighbors

BGP neighbor is 10.0.0.1, remote AS 100, internal link
```

```

BGP version 4, remote router ID 10.0.0.1
BGP state = Established, up for 02:49:47
Last read 00:00:47, hold time is 180, keepalive interval is 60 seconds
Neighbor capabilities:
  Route refresh: advertised and received(new)
  Address family VPNv4 Unicast: advertised and received
  Graceful Restart Capability: advertised and received
    Remote Restart timer is 120 seconds
  Address families preserved by peer:
    VPNv4 Unicast
    .
    .
    .

```

### Step 3 show ip bgp labels

This command displays information about MPLS labels in the Exterior Border Gateway Protocol (EBGP) route table. The following is sample output from the command:

```
Router# show ip bgp labels
```

Network	Next Hop	In label/Out label
10.3.0.0/16	10.0.0.1	imp-null/imp-null
	0.0.0.0	imp-null/nolabel
10.0.0.9/32	10.0.0.1	21/29
10.0.0.11/32	10.0.0.1	24/38
10.0.0.13/32	0.0.0.0	imp-null/nolabel
10.0.0.15/32	10.0.0.1	29/nolabel
	10.0.0.1	29/21

### Step 4 show ip bgp neighbors

This command displays whether the BGP peers are capable of Graceful Restart. The following is sample output from the command:

```
Router# show ip bgp neighbors
```

```

BGP neighbor is 10.0.0.1, remote AS 100, external link
BGP version 4, remote router ID 10.0.0.5
BGP state = Established, up for 02:54:19
Last read 00:00:18, hold time is 180, keepalive interval is 60 seconds
Neighbor capabilities:
  Route refresh: advertised and received(new)
  Address family IPv4 Unicast: advertised and received
  ipv4 MPLS Label capability: advertised and received
  Graceful Restart Capability: advertised and received
    Remote Restart timer is 120 seconds
  Address families preserved by peer:
    IPv4 Unicast
    .
    .
    .

```

## Configuration Examples for NSF/SSO—MPLS VPN

This section includes six configuration examples. The first configuration example shows the most simple configuration, a basic VPN configuration. The second, third, and fourth examples show different CSC VPN configurations. The fourth example shows a CSC VPN configuration that uses BGP as the MPLS label distribution method and therefore requires the **mpls forwarding bgp** command. The last two examples show Inter-AS configurations.

- [NSF/SSO—MPLS VPN for a Basic MPLS VPN: Example, page 9](#)

- [NSF/SSO—MPLS VPN for a CSC Network with a Customer Carrier Who Is an ISP: Example, page 13](#)
- [NSF/SSO—MPLS VPN for a CSC Network with a Customer Who Is an MPLS VPN Provider: Example, page 18](#)
- [NSF/SSO—MPLS VPN for a CSC Network That Uses BGP to Distribute MPLS Labels: Example, page 26](#)
- [NSF/SSO—MPLS VPN for an Inter-AS Network Using BGP to Distribute Routes and MPLS Labels: Example, page 34](#)
- [NSF/SSO—MPLS VPN for an Inter-AS Network That Uses BGP to Distribute Routes and MPLS Labels over a Non-MPLS VPN Service Provider: Example, page 40](#)

## NSF/SSO—MPLS VPN for a Basic MPLS VPN: Example

In this example, the NSF/SSO—MPLS VPN feature is enabled on the existing MPLS VPN configuration.

### Enabling SSO on a Cisco 7500 Series Router

The following commands are used to enable SSO on the Cisco 7500 series routers:

- `hw-module slot`
- `redundancy`
- `mode sso`

The configuration examples are the same for both platforms with the exception that the following configuration boot commands are seen in the beginning of a Cisco 7500 series router configuration (and not in a Cisco 10000 series router configuration):

```
boot system slot0:rsp-pv-mz
hw-module slot 2 image slot0:rsp-pv-mz
hw-module slot 3 image slot0:rsp-pv-mz
```

### Enabling SSO on a Cisco 10000 Series Router

The SSO mode is enabled by default.

### Enabling NSF on Both the Cisco 7500 Series and Cisco 10000 Series Routers

The following commands are used to enable NSF for the routing protocols, such as BGP and OSPF, and for the label distribution protocols, such as BGP and LDP:

- `bgp graceful-restart restart-time`
- `bgp graceful-restart stalepath-time`
- `bgp graceful-restart`
- `nsf enforce global`

#### Note

In the configuration example, the NSF/SSO commands are bold-faced and any platform-specific commands are highlighted by arrows.

[Figure 1](#) shows the configuration of the NSF/SSO—MPLS VPN feature on the PE and CE routers.

**Figure 1** *MPLS VPN Configuration with MPLS VPN: NSF/SSO***Note**

LDP is the default MPLS label protocol.

The following configuration examples show the configuration of the NSF/SSO—MPLS VPN feature on the CE and PE routers.

## NSF/SSO—MPLS VPN for a CSC Network with a Customer Carrier Who Is an ISP: Example

In this example, MPLS VPN SSO and NSF are configured on the existing MPLS CSC VPN configuration. In the CSC network configuration, the customer carrier is an Internet Service Provider (ISP), as shown in [Figure 2](#).

### Enabling SSO on a Cisco 7500 Series Router

The following commands are used to enable SSO on the Cisco 7500 series routers:

- **hw-module slot**
- **redundancy**
- **mode sso**

The configuration examples are the same for both platforms with the exception that the following configuration boot commands are seen in the beginning of a Cisco 7500 series router configuration (and not in a Cisco 10000 series router configuration):

```
boot system slot0:rsp-pv-mz
hw-module slot 2 image slot0:rsp-pv-mz
hw-module slot 3 image slot0:rsp-pv-mz
```

### Enabling SSO on a Cisco 10000 Series Router

The SSO mode is enabled by default.

### Enabling NSF on Both the Cisco 7500 Series and Cisco 10000 Series Routers

The following commands are used to enable NSF for the routing protocols, such as BGP and OSPF, and for the label distribution protocols, such as BGP and LDP:

- **bgp graceful-restart restart-time**
- **bgp graceful-restart stalepath-time**
- **bgp graceful-restart**
- **nsf enforce global**

#### Note

In the configuration example, the NSF/SSO commands are bold-faced and any platform-specific commands are highlighted by arrows.

**Figure 2** *MPLS VPN CSC Configuration with MPLS VPN: NSF and SSO*

## NSF/SSO—MPLS VPN for a CSC Network with a Customer Who Is an MPLS VPN Provider: Example

In the CSC network configuration shown in [Figure 3](#), the customer carrier is an MPLS VPN provider. The customer carrier has two sites. The backbone carrier and the customer carrier use MPLS. The internal BGP (iBGP) sessions exchange the external routing information of the ISP.

**Figure 3** *MPLS VPN CSC Configuration 2 with MPLS VPN: NSF and SSO*

The following configuration example shows the configuration of each router in the CSC network. OSPF is the protocol used to connect the customer carrier to the backbone carrier. The NSF/SSO—MPLS VPN feature is enabled on the existing MPLS VPN configuration.

### Enabling SSO on a Cisco 7500 Series Router

The following commands are used to enable SSO on the routers:

- `hw-module slot`
- `redundancy`
- `mode sso`

The configuration examples are the same for both platforms with the exception that the following configuration boot commands are seen in the beginning of a Cisco 7500 series router configuration (and not in a Cisco 10000 series router configuration):

```

boot system slot0:rsp-pv-mz
hw-module slot 2 image slot0:rsp-pv-mz

```

```
hw-module slot 3 image slot0:rsp-pv-mz
```

### Enabling SSO on a Cisco 10000 Series Router

The SSO mode is enabled by default.

### Enabling NSF on Both the Cisco 7500 Series and Cisco 10000 Series Routers

The following commands are used to enable NSF for the routing protocols, such as BGP and OSPF, and for the label distribution protocols, such as BGP and LDP:

- `bgp graceful-restart restart-time`
- `bgp graceful-restart stalepath-time`
- `bgp graceful-restart`
- `nsf enforce global`

#### Note

In the configuration examples, the NSF/SSO commands are bold-faced and any platform-specific commands are highlighted with arrows.

## NSF/SSO—MPLS VPN for a CSC Network That Uses BGP to Distribute MPLS Labels: Example

In the following example and in [Figure 4](#), the NSF/SSO—MPLS VPN feature is configured on an existing MPLS VPN.

### Enabling SSO on a Cisco 7500 Series Router

The following commands are used to enable SSO on the routers:

- `hw-module slot`
- `redundancy`
- `mode sso`

The configuration examples are the same for both platforms with the exception that the following configuration boot commands are seen in the beginning of a Cisco 7500 series router configuration (and not in a Cisco 10000 series router configuration):

```
boot system slot0:rsp-pv-mz
hw-module slot 2 image slot0:rsp-pv-mz
hw-module slot 3 image slot0:rsp-pv-mz
```

### Enabling SSO on a Cisco 10000 Series Router

The SSO mode is enabled by default.

### Enabling NSF on Both the Cisco 7500 Series and Cisco 10000 Series Routers

The following commands are used to enable NSF for the routing protocols, such as BGP and OSPF, and for the label distribution protocols, such as BGP and LDP:

- `bgp graceful-restart restart-time`
- `bgp graceful-restart stalepath-time`
- `bgp graceful-restart`
- `nsf enforce global`
- `mpls forwarding bgp`

#### Note

In the configuration examples, the NSF/SSO commands are bold-faced and arrows highlight any platform-specific commands.

This section and [Figure 4](#) provide an example of a backbone carrier and a customer carrier who are both BGP/MPLS VPN service providers. The example shows how BGP is enabled to distribute routes and MPLS labels between PE and CE routers.

**Figure 4** *MPLS VPN CSC Configuration 3 with MPLS VPN: NSF and SSO*

In [Figure 4](#), the subnet mask is 255.255.255.252.

The routers have the following characteristics:

- CE1 and CE2 belong to an end customer. CE1 and CE2 routers exchange routes learned from PE routers. The end customer is purchasing VPN services from a customer carrier.
- PE1 and PE2 are part of a customer carrier network that is configured to provide MPLS VPN services. PE1 and PE2 are peering with a VPNv4 IBGP session to form an MPLS VPN network.
- CSC-CE1 and CSC-CE2 are part of a customer carrier network. CSC-CE1 and CSC-CE2 routers exchange IPv4 BGP updates with MPLS labels and redistribute PE loopback addressees that are sent to and received from the IGP (OSPF in this example). The customer carrier is purchasing Carrier Supporting Carrier VPN services from a backbone carrier.

- CSC-PE1 and CSC-PE2 are part of the backbone carrier's network configured to provide Carrier Supporting Carrier VPN services. CSC-PE1 and CSC-PE2 peer with a VPNv4 IP BGP session to form the MPLS VPN network. In the VRF, CSC-PE1 and CSC-PE2 peer with the CSC-CE routers, which are configured to carry MPLS labels with the routes, within an IPv4 EBGp session.

## NSF/SSO—MPLS VPN for an Inter-AS Network Using BGP to Distribute Routes and MPLS Labels: Example

In [Figure 5](#) and in the following example, the NSF/SSO—MPLS VPN feature is configured on the existing MPLS VPN Inter-AS configuration.

### Enabling SSO on a Cisco 7500 Series Router

The following commands are used to enable SSO on the routers:

- hw-module slot
- redundancy
- mode sso

The configuration examples are the same for both platforms with the exception that the following configuration boot commands are seen in the beginning of a Cisco 7500 series router configuration (and not in a Cisco 10000 series router configuration):

```

boot system slot0:rsp-pv-mz
hw-module slot 2 image slot0:rsp-pv-mz
hw-module slot 3 image slot0:rsp-pv-mz

```

### Enabling SSO on a Cisco 10000 Series Router

The SSO mode is enabled by default.

### Enabling NSF on Both the Cisco 7500 Series and Cisco 10000 Series Routers

The following commands are used to enable NSF for the routing protocols, such as BGP and OSPF, and for the label distribution protocols, such as BGP and LDP:

- `bgp graceful-restart restart-time`
- `bgp graceful-restart stalepath-time`
- `bgp graceful-restart`
- `nsf enforce global`
- `mpls forwarding bgp`

Inter-AS with IPv4 BGP Label Distribution enables you to set up a VPN so that the ASBRs exchange IPv4 routes with MPLS labels of the PE routers. Route reflectors (RRs) exchange VPNv4 routes by using Multihop, Multiprotocol EBGP. This configuration saves the ASBRs from having to store all of the VPNv4 routes. Using the RRs to store the VPNv4 routes and forward them to the PE routers improves scalability.

Figure 5 shows two MPLS VPN service providers. They distribute VPNv4 addresses between the RRs and IPv4 routes and MPLS labels between ASBRs.

**Figure 5** *MPLS VPN Inter-AS Configuration with MPLS VPN: NSF/SSO*

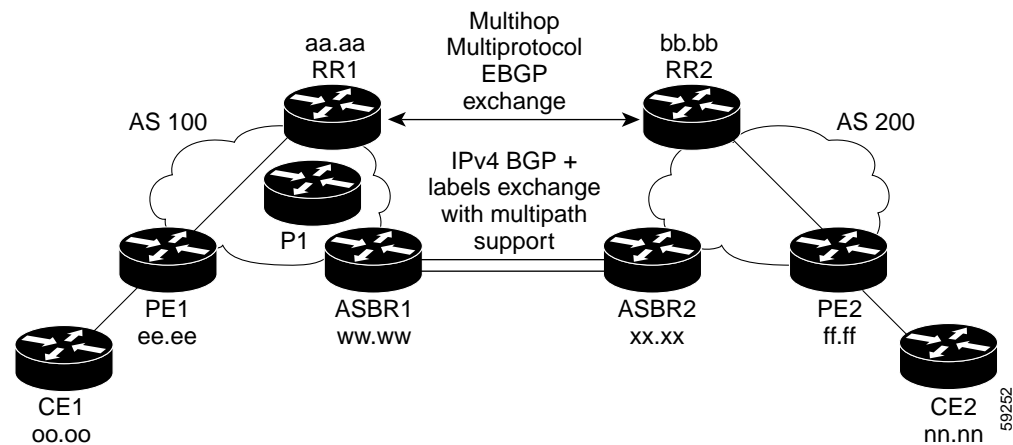

Figure 5 shows the two techniques you can use to distribute the VPNv4 routes and the IPv4 routes and MPLS labels of remote PEs and RRs to local PEs and RRs:

- AS 100 uses the route reflectors to distribute the IPv4 routes and MPLS labels and the VPNv4 routes from the ASBR to the PE.
- In AS 200, the IPv4 routes that ASBR2 learned are redistributed into IGP.

#### Note

In the configuration examples, the NSF/SSO commands are bold-faced and arrows highlight any platform-specific commands.

## RR1 Configuration

The configuration example for RR1 specifies the following:

- RR1 exchanges VPNv4 routes with RR2, using Multihop, Multiprotocol EBGP.

- The VPNv4 next hop information and the VPN label are preserved across the autonomous systems.
- RR1 reflects to PE1 the VPNv4 routes learned from RR2 and the IPv4 routes and MPLS labels learned from ASBR1.

## NSF/SSO—MPLS VPN for an Inter-AS Network That Uses BGP to Distribute Routes and MPLS Labels over a Non-MPLS VPN Service Provider: Example

In this example, the NSF/SSO—MPLS VPN feature is configured on an existing MPLS VPN.

### Enabling SSO on a Cisco 7500 Series Router

The following commands are used to enable SSO on the routers:

- `hw-module slot`
- `redundancy`
- `mode sso`

The configuration examples are the same for both platforms with the exception that the following configuration boot commands are seen in the beginning of a Cisco 7500 series router configuration (and not in a Cisco 10000 series router configuration):

```
boot system slot0:rsp-pv-mz
hw-module slot 2 image slot0:rsp-pv-mz
hw-module slot 3 image slot0:rsp-pv-mz
```

### Enabling SSO on a Cisco 10000 Series Router

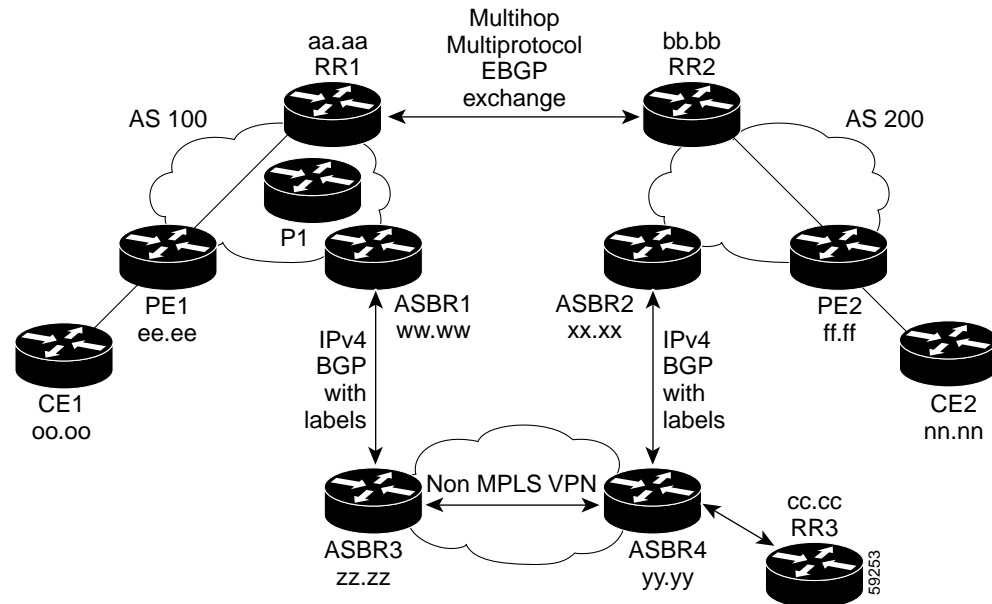

The SSO mode is enabled by default.

### Enabling NSF on Both the Cisco 7500 Series and Cisco 10000 Series Routers

The following commands are used to enable NSF for the routing protocols, such as BGP and OSPF, and for the label distribution protocols, such as BGP and LDP:

- `bgp graceful-restart restart-time`
- `bgp graceful-restart stalepath-time`
- `bgp graceful-restart`
- `nsf enforce global`
- `mpls forwarding bgp`

[Figure 6](#) shows two MPLS VPN service providers that are connected through a non-MPLS VPN service provider. The autonomous system in the middle of the network is configured as a backbone autonomous system that uses LDP to distribute MPLS labels. You can also use traffic engineering tunnels instead of LDP to build the LSP across the non-MPLS VPN service provider.

**Figure 6** *MPLS VPN Inter-AS Configuration 2 with MPLS VPN: NSF/SSO***Note**

In the configuration examples, the NSF/SSO commands are bold-faced and arrows highlight any platform-specific commands.

## RR1 Configuration

The configuration example for RR1 specifies the following:

- RR1 exchanges VPNv4 routes with RR2, using Multihop, Multiprotocol EBGP.
- The VPNv4 next hop information and the VPN label are preserved across the autonomous systems.
- RR1 reflects to PE1 the VPNv4 routes learned from RR2 and the IPv4 routes and MPLS labels learned from ASBR1.

## ASBR2 Configuration

ASBR2 exchanges IPv4 routes and MPLS labels with ASBR1. However, in contrast to ASBR1, ASBR2 does not use the RR to reflect IPv4 routes and MPLS labels to PE2. Instead, ASBR2 redistributes the IPv4 routes and MPLS labels learned from ASBR1 into IGP. PE2 can now reach these prefixes.

```

## ASBR3 Configuration

ASBR3 belongs to a non-MPLS VPN service provider. ASBR3 exchanges IPv4 routes and MPLS labels with ASBR1. ASBR3 also passes the routes learned from ASBR1 to ASBR3 through RR3.

### Note

Do not redistribute EBGP routes learned into internal BGP if you are using IBGP to distribute the routes and labels. This is not a supported configuration.

## Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Multiprotocol Label Switching Command Reference* at [http://www.cisco.com/en/US/docs/ios/mpls/command/reference/mp\\_book.html](http://www.cisco.com/en/US/docs/ios/mpls/command/reference/mp_book.html). For information about all Cisco IOS commands, go to the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or to the *Cisco IOS Master Commands List*.

- **mpls forwarding bgp**
- **show ip bgp labels**
- **show ip bgp vpv4**

# Feature Information for NSF/SSO—MPLS VPN

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Cisco IOS software images are specific to a Cisco IOS software release, a feature set, and a platform. Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

## Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1** Feature Information for NSF/SSO—MPLS VPN

Feature Name	Releases	Feature Information
NSF/SSO—MPLS VPN	12.2(25)S 12.2(28)SB 12.2(33)SRA 12.2(33)SXH	<p>This feature allows a provider edge (PE) router or Autonomous System Border Router (ASBR) (with redundant Route Processors) to preserve data forwarding information in a Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) when the primary Route Processor restarts.</p> <p>In 12.2(25)S, this feature was introduced on the Cisco 7500 series router.</p> <p>In 12.2(28)SB, support was added for the Cisco 10000 series routers.</p> <p>In 12.2(33)SRA, support was added for the Cisco 7600 series routers.</p> <p>In 12.2(33)SXH, this feature was integrated into this release.</p>

# AToM Graceful Restart

---

**First Published: August 9, 2004**

**Last Updated: February 27, 2009**

The AToM Graceful Restart feature assists neighboring routers that have nonstop forwarding (NSF), stateful switchover (SSO) and graceful restart (GR) for Any Transport over MPLS (AToM) to recover gracefully from an interruption in service. AToM GR functions strictly in helper mode, which means it helps other routers that are enabled with the NSF/SSO: Any Transport over MPLS and AToM Graceful Restart feature to recover. If the router with AToM GR fails, its peers cannot help it recover. AToM GR is based on the MPLS Label Distribution Protocol (LDP) Graceful Restart feature.

Keep the following points in mind when reading this document:

- The AToM GR feature described in this document refers to helper mode.
- The NSF/SSO: Any Transport over MPLS and AToM Graceful Restart feature is supported in Cisco IOS Releases 12.2(25)S and 12.2(33)SRA. For brevity, the NSF/SSO: Any Transport over MPLS and AToM Graceful Restart feature is called AToM SSO/NSF in this document.

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the [“Feature Information for AToM Graceful Restart” section on page 8](#).

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Contents

- [Information About AToM Graceful Restart, page 2](#)
- [How to Configure AToM Graceful Restart, page 2](#)

---

**Americas Headquarters:**

**Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA**

- [Configuration Examples for AToM Graceful Restart, page 3](#)
- [Additional References, page 6](#)
- [Command Reference, page 7](#)
- [Feature Information for AToM Graceful Restart, page 8](#)

## Information About AToM Graceful Restart

To configure AToM GR, you should understand the following concepts:

- [How AToM Graceful Restart Works, page 2](#)

## How AToM Graceful Restart Works

AToM GR works in strict helper mode, which means it helps a neighboring route processor that has AToM NSF/SSO to recover from a disruption in service without losing its MPLS forwarding state. The disruption in service could result from a TCP or User Datagram Protocol (UDP) event or the stateful switchover of a route processor. AToM GR is based on the MPLS LDP Graceful Restart feature, which preserves forwarding information for AToM circuits during an LDP session interruption. When the neighboring router establishes a new session, the LDP bindings and MPLS forwarding state are recovered. For more information related to how the LDP Graceful Restart feature works, see the [MPLS LDP Graceful Restart](#) feature module.

## How to Configure AToM Graceful Restart

This section contains the following procedures:

- [Configuring AToM Graceful Restart, page 2](#) (required)

## Configuring AToM Graceful Restart

There is no AToM-specific configuration for AToM GR. You enable LDP GR to assist a neighboring router configured with AToM NSF/SSO to maintain its forwarding state while the LDP session is disrupted.

### Prerequisites

- See the [MPLS LDP Graceful Restart](#) document for information about how LDP GR works and how you can customize it for your network.
- Configure AToM. For information about setting up or configuring AToM, see the [Any Transport over MPLS](#) document.

### Restrictions

- AToM GR is supported in strict helper mode.
- AToM NSF/SSO is supported in Cisco IOS Release 12.2(25)S and 12.2(33)SRA.

- Tag Distribution Protocol (TDP) sessions are not supported. Only LDP sessions are supported.
- MPLS LDP GR cannot be configured on label-controlled ATM (LC-ATM) interfaces.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef [distributed]**
4. **mpls ldp graceful-restart**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>ip cef [distributed]</b>  <b>Example:</b> Router(config)# ip cef distributed	Enables Cisco Express Forwarding.
Step 4	<b>mpls ldp graceful-restart</b>  <b>Example:</b> Router(config)# mpls ldp graceful-restart	Enables the router to protect the LDP bindings and MPLS forwarding state during a disruption in service.  AToM GR is enabled globally. When you enable AToM GR, it has no effect on existing LDP sessions. New LDP sessions that are established can perform AToM GR.

# Configuration Examples for AToM Graceful Restart

This section provides the following configuration examples:

- [AToM Graceful Restart: Configuration Example, page 4](#)
- [AToM Graceful Restart: Recovering from an LDP Session Disruption Example, page 4](#)

## AToM Graceful Restart: Configuration Example

The following example shows an Ethernet VLAN over MPLS configuration. PE1 is configured with AToM Graceful Restart. PE2 is configured with AToM NSF/SSO. The commands for configuring AToM GR and NSF/SSO are shown in bold.

PE1 with AToM GR	PE2 with AToM NSF/SSO

## AToM Graceful Restart: Recovering from an LDP Session Disruption Example

The following examples show the output of the **show mpls l2transport vc** command during normal operation and when an LDP session is recovering from a disruption.

The following example shows the status of the VC on PE1 with AToM GR during normal operation:

Router# **show mpls l2transport vc**

Local intf	Local circuit	Dest address	VC ID	Status
Fa5/1/1.2	Eth VLAN 2	10.2.2.2	1002	UP

The following example shows the status of the VC on PE1 with AToM GR while the VC is recovering from an LDP session disruption. The forwarding state for the circuit remains as it was before the disruption.

Router# **show mpls l2transport vc**

Local intf	Local circuit	Dest address	VC ID	Status
Fa5/1/1.2	Eth VLAN 2	10.2.2.2	1002	RECOVERING

The following example shows the status of the VC on PE1 with AToM GR after the LDP session disruption was cleared. The AToM label bindings were advertised within the allotted time and the status returned to UP.

```
Router# show mpls l2transport vc
```

Local intf	Local circuit	Dest address	VC ID	Status
Fa5/1/1.2	Eth VLAN 2	10.2.2.2	1002	UP

The following example shows the detailed status of the VC on PE1 with AToM GR during normal operation:

```
Router# show mpls l2transport vc detail
```

```
Local interface: Fa5/1/1.2 up, line protocol up, Eth VLAN 2 up
  Destination address: 10.2.2.2, VC ID: 1002, VC status: up
    Preferred path: not configured
    Default path: active
    Tunnel label: imp-null, next hop point2point
    Output interface: Se4/0/3, imposed label stack {16}
  Create time: 1d00h, last status change time: 1d00h
  Signaling protocol: LDP, peer 10.2.2.2:0 up
    MPLS VC labels: local 21, remote 16
    Group ID: local 0, remote 0
    MTU: local 1500, remote 1500
    Remote interface description: "xconnect to PE2"
  Sequencing: receive disabled, send disabled
  VC statistics:
    packet totals: receive 3466, send 12286
    byte totals:   receive 4322368, send 5040220
    packet drops:  receive 0, send 0
```

The following example shows the detailed status of the VC on PE1 with AToM GR while the VC is recovering.

```
Router# show mpls l2transport vc detail
```

```
Local interface: Fa5/1/1.2 up, line protocol up, Eth VLAN 2 up
  Destination address: 10.2.2.2, VC ID: 1002, VC status: recovering
    Preferred path: not configured
    Default path: active
    Tunnel label: imp-null, next hop point2point
    Output interface: Se4/0/3, imposed label stack {16}
  Create time: 1d00h, last status change time: 00:00:03
  Signaling protocol: LDP, peer 10.2.2.2:0 down
    MPLS VC labels: local 21, remote 16
    Group ID: local 0, remote 0
    MTU: local 1500, remote 1500
    Remote interface description: "xconnect to PE2"
  Sequencing: receive disabled, send disabled
  VC statistics:
    packet totals: receive 20040, send 28879
    byte totals:   receive 25073016, send 25992388
    packet drops:  receive 0, send 0
```

<p>The Cisco Support website provides extensive online resources, including documentation and tools for troubleshooting and resolving technical issues with Cisco products and technologies.</p> <p>To receive security and technical information about your products, you can subscribe to various services, such as the Product Alert Tool (accessed from Field Notices), the Cisco Technical Services Newsletter, and Really Simple Syndication (RSS) Feeds.</p> <p>Access to most tools on the Cisco Support website requires a Cisco.com user ID and password.</p>	<p><a href="http://www.cisco.com/techsupport">http://www.cisco.com/techsupport</a></p>

## Command Reference

This feature uses no new or modified commands.

# Feature Information for AToM Graceful Restart

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1** Feature Information for AToM Graceful Restart

Feature Name	Releases	Feature Information
AToM Graceful Restart	12.0(29)S	In 12.0(29)S, this feature was introduced.
	12.2(33)SRA	In 12.2(33)SRA, support was added for the Cisco 7600 series routers.
	12.4(11)T	In 12.4(11)T, this feature was integrated into the release.
	12.2(33)SXH	In 12.2(33)SXH, this feature was integrated into the release.

# NSF/SSO—Any Transport over MPLS and AToM Graceful Restart

---

**First Published: August 11, 2004**

**Last Updated: February 27, 2009**

The NSF/SSO—Any Transport over MPLS and AToM Graceful Restart feature allows Any Transport over MPLS (AToM) to use Cisco nonstop forwarding (NSF), stateful switchover (SSO), and Graceful Restart (GR) to allow a Route Processor (RP) to recover from a disruption in control plane service without losing its Multiprotocol Label Switching (MPLS) forwarding state.

NSF with SSO is effective at increasing availability of network services. Cisco NSF with SSO provides continuous packet forwarding, even during a network processor hardware or software failure. In a redundant system, the secondary processor recovers control plane service during a critical failure in the primary processor. SSO synchronizes the network state information between the primary and the secondary processor.

## Note

In this document, the NSF/SSO—Any Transport over MPLS and AToM Graceful Restart feature is referred to as AToM NSF for brevity.

---

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the [“Feature Information for AToM NSF” section on page 10](#).

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

---

**Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA**

# Contents

- [Prerequisites for AToM NSF, page 2](#)
- [Restrictions for AToM NSF, page 3](#)
- [Information About AToM NSF, page 4](#)
- [Configuration Examples for AToM NSF, page 6](#)
- [Additional References, page 8](#)
- [Command Reference, page 9](#)
- [Feature Information for AToM NSF](#)

## Prerequisites for AToM NSF

Before you can configure AToM NSF, make sure the following tasks have been completed:

- AToM virtual circuits (VCs) have been configured on the router. See the [Any Transport over MPLS](#) feature module for information on configuring AToM. For configuring L2VPN Interworking, see the [L2VPN Interworking](#) feature module.
- SSO has been configured on the Route Processors. See the [Stateful Switchover](#) feature module for configuration information.
- Nonstop forwarding has been configured on the routers. You must enable nonstop forwarding on the routing protocols running between the P routers, PE routers, and CE routers. The routing protocols are Open Shortest Path First (OSPF), Intermediate System-to-Intermediate System (IS-IS), and Border Gateway Protocol (BGP). See the [Cisco Nonstop Forwarding](#) feature module for configuration information.

This section lists the following prerequisites:

- [Supported Hardware, page 2](#)
- [Neighbor Routers in the MPLS HA Environment, page 3](#)
- [Stateful Switchover, page 3](#)
- [Nonstop Forwarding for Routing Protocols, page 3](#)

## Supported Hardware

For hardware requirements for this feature, see the following documents:

- For Cisco IOS Release 12.2(25)S, see the “Supported Hardware” section of the *Cross-Platform Release Notes for Cisco IOS Release 12.2S*.

The URL is:

[http://www.cisco.com/en/US/docs/ios/12\\_2s/release/notes/122Srn.html](http://www.cisco.com/en/US/docs/ios/12_2s/release/notes/122Srn.html)

- For Cisco IOS Release 12.2(28)SB, see the “Supported Hardware” section of the *Cross-Platform Release Notes for Cisco IOS Release 12.2SB*.

The URL is:

[http://www.cisco.com/en/US/docs/ios/12\\_2sb/release/notes/122SB.html](http://www.cisco.com/en/US/docs/ios/12_2sb/release/notes/122SB.html)

- For Cisco IOS Release 12.2(33)SRC, see the “Supported Hardware” section of the *Release Notes for Cisco IOS Release 12.2SR for the Cisco 7600 Series Routers*.

The URL is:

[http://www.cisco.com/en/US/docs/ios/12\\_2sr/release/notes/122SRrn.html](http://www.cisco.com/en/US/docs/ios/12_2sr/release/notes/122SRrn.html)

## Neighbor Routers in the MPLS HA Environment

AToM NSF requires that neighbor networking devices be able to perform AToM GR. In Cisco IOS Releases 12.2(25)S and 12.2(28)SB, the Cisco 7200 and Cisco 7500 routers are capable of supporting AToM GR and can be used as neighbor networking devices.

In Cisco IOS Release 12.2(33)SRC, the Cisco 7600 routers are capable of supporting AToM high availability (HA) and MPLS Label Distribution Protocol (LDP) GR.

## Stateful Switchover

To perform AToM NSF, Route Processors must be configured for SSO and GR. See the *Stateful Switchover* feature module for more information.

## Nonstop Forwarding for Routing Protocols

You must enable NSF on the routing protocols running between the provider (P) routers, provider edge (PE) routers, and customer edge (CE) routers. The routing protocols are the following:

- Border Gateway Protocol (BGP)
- Open Shortest Path First (OSPF)
- Intermediate System-to-Intermediate System (IS-IS)

See the *Cisco Nonstop Forwarding* feature module for more information.

## Restrictions for AToM NSF

AToM NSF includes the following restrictions:

- Tag Distribution Protocol (TDP) sessions are not supported. Only LDP sessions are supported.
- AToM NSF cannot be configured on label-controlled ATM (LC-ATM) interfaces.
- AToM NSF supports AToM Layer 2 Virtual Private Network (L2VPN) Interworking. However, Layer 2 Tunnel Protocol Version 3 (L2TPv3) Interworking is not supported.
- AToM NSF interoperates with Layer 2 local switching. However, AToM NSF has no effect on interfaces configured for local switching.
- To allow distributed Cisco Express Forwarding to work on the interfaces, disable fair queueing on serial interfaces.
- On the Cisco 7500 series routers, distributed Cisco Express Forwarding is needed to support AToM NSF.
- The Cisco 7500 router does not support AToM Ethernet-VLAN interworking IP; however, AToM Ethernet-VLAN interworking Ethernet is supported.

# Information About AToM NSF

To configure AToM NSF, you should understand the following concepts:

- [How AToM NSF Works, page 4](#)
- [AToM Information Checkpointing, page 4](#)
- [ISSU Support, page 5](#)

## How AToM NSF Works

AToM NSF improves the availability of a service provider's network that uses AToM to provide Layer 2 VPN services to its customers. HA provides the ability to detect failures and handle them with minimal disruption to the service being provided. AToM NSF is achieved by SSO and NSF mechanisms. A standby RP provides control-plane redundancy. The control plane state and data plane provisioning information for the attachment circuits (ACs) and AToM pseudowires (PWs) are checkpointed to the standby RP to provide NSF for AToM L2VPNs.

## AToM Information Checkpointing

Checkpointing is a function that copies state information from the active RP to the backup RP, thereby ensuring that the backup RP has the latest information. If the active RP fails, the backup RP can take over.

For the AToM NSF feature, the checkpointing function copies the active RP's information bindings to the backup RP. The active RP sends updates to the backup RP when information is modified.

To display checkpointing data, issue the **show acircuit checkpoint** command on the active and backup RPs. The active and backup RPs have identical copies of the information.

## Checkpointing Troubleshooting Tips

To help troubleshoot checkpointing errors, use the following commands:

- Use the **debug acircuit checkpoint** command to enable checkpointing debug messages for ACs.
- Use the **debug mpls l2transport checkpoint** command to enable checkpointing debug messages for AToM.
- Use the **show acircuit checkpoint** command to display the AC checkpoint information.
- Use the **show mpls l2transport checkpoint** command to display whether checkpointing is allowed, how many AToM VCs were bulk-synchronized (on the active RP), and how many AToM VCs have checkpoint data (on the standby RP).
- Use the **show mpls l2transport vc detail** command to display details of VC checkpointed information.

## ISSU Support

Beginning with Cisco IOS Release 12.2(33)SRC, AToM NSF supports In Service Software Upgrade (ISSU) capability. Virtual Private LAN Services (VPLS) NSF/SSO and HA with ISSU work together to enable upgrades or downgrades of a Cisco IOS image without control and data plane outages. With ISSU, all message data structures that are used for checkpointing and exchanges between the active RP and standby RP are versioned.

## Configuring MPLS LDP Graceful Restart

Before you configure AToM NSF, you need to configure MPLS LDP Graceful Restart.

MPLS LDP GR is enabled globally. When you enable LDP GR, it has no effect on existing LDP sessions. LDP GR is enabled for new sessions that are established after the feature has been globally enabled.

Perform this task to configure MPLS LDP GR.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef [distributed]**
4. **mpls ldp graceful-restart**
5. **interface type slot/port**
6. **mpls ip**
7. **mpls label protocol {ldp | tdp | both}**

### DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>ip cef [distributed]</b>  <b>Example:</b> Router(config)# ip cef distributed	Enables Cisco Express Forwarding.   <b>Note</b> In Cisco ASR 1000 series Aggregation Services Routers, the <b>distributed</b> keyword is mandatory.
Step 4	<b>mpls ldp graceful-restart</b>  <b>Example:</b> Router (config)# mpls ldp graceful-restart	Enables the router to protect the LDP bindings and MPLS forwarding state during a disruption in service.

	Command or Action	Purpose
Step 5	<pre>interface type slot/port</pre> <p><b>Example:</b> Router(config)# interface pos 3/0</p>	Specifies an interface and enters interface configuration mode.
Step 6	<pre>mpls ip</pre> <p><b>Example:</b> Router(config-if)# mpls ip</p>	Configures MPLS hop-by-hop forwarding for an interface.
Step 7	<pre>mpls label protocol {ldp   tdp   both}</pre> <p><b>Example:</b> Router(config-if)# mpls label protocol ldp</p>	Configures the use of LDP for an interface. <ul style="list-style-type: none"> <li>You must use LDP, because TDP sessions are not supported.</li> <li>You can also issue the <b>mpls label protocol ldp</b> command in global configuration mode, which enables LDP on all interfaces configured for MPLS.</li> </ul>

## Configuration Examples for AToM NSF

This section provides the following configuration example:

- [Ethernet to VLAN Interworking with AToM NSF: Example, page 7](#)

## Ethernet to VLAN Interworking with AToM NSF: Example

The following example shows how to configure AToM NSF on two PE routers:

PE1	PE2
<pre> ip cef distributed ! redundancy mode sso ! boot system flash disk2:rsp-pv-mz ! mpls ldp graceful-restart mpls ip mpls label protocol ldp mpls ldp router-id Loopback0 force mpls ldp advertise-labels ! pseudowire-class atom-eth   encapsulation mpls   interworking ethernet ! interface Loopback0   ip address 10.8.8.8 255.255.255.255 ! interface FastEthernet1/1/0   xconnect 10.9.9.9 123 encap mpls pw-class atom-eth  interface POS6/1/0   ip address 10.1.1.1 255.255.255.0   mpls ip   mpls label protocol ldp   clock source internal   crc 32 ! interface Loopback0   ip address 10.8.8.8 255.255.255.255   no shutdown ! router ospf 10   nsf   network 10.8.8.8 0.0.0.0 area 0   network 19.1.1.1 0.0.0.0 area 0 </pre>	<pre> ip cef distributed ! redundancy mode sso ! boot system flash disk2:rsp-pv-mz ! mpls ldp graceful-restart mpls ip mpls label protocol ldp mpls ldp router-id Loopback0 force mpls ldp advertise-labels ! pseudowire-class atom-eth   encapsulation mpls   interworking eth ! interface Loopback0   ip address 10.9.9.9 255.255.255.255 ! interface FastEthernet3/0/0   ip route-cache cef ! interface FastEthernet3/0/0.3   encapsulation dot1Q 10   xconnect 10.8.8.8 123 encap mpls pw-class atom-eth  interface POS1/0/0   ip address 10.1.1.2 255.255.255.0   mpls ip   mpls label protocol ldp   clock source internal   crc 32 ! interface Loopback0   ip address 10.9.9.9 255.255.255.255 ! router ospf 10   nsf   network 10.9.9.9 0.0.0.0 area 0   network 10.1.1.2 0.0.0.0 area 0 </pre>

# NSF/SSO—MPLS TE and RSVP Graceful Restart

---

**First Published: August 2, 2004**

**Last Updated: October 21, 2009**

The NSF/SSO—MPLS TE and RSVP Graceful Restart feature allows a Route Processor (RP) to recover from disruption in control plane service without losing its Multiprotocol Label Switching (MPLS) forwarding state.

Cisco nonstop forwarding (NSF) with stateful switchover (SSO) provides continuous packet forwarding, even during a network processor hardware or software failure. In a redundant system, the secondary processor recovers control plane service during a critical failure in the primary processor. SSO synchronizes the network state information between the primary and the secondary processor.

In Cisco IOS Release 12.2(33)SRE, SSO can co-exist with traffic engineering (TE) primary tunnels, backup tunnels, and automesh tunnels.

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the “[Feature Information for NSF/SSO—MPLS TE and RSVP Graceful Restart](#)” section on [page 14](#).

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

- [Configuration Examples for NSF/SSO—MPLS TE and RSVP Graceful Restart, page 11](#)
- [Additional References, page 12](#)
- [Feature Information for NSF/SSO—MPLS TE and RSVP Graceful Restart, page 14](#)
- [Glossary, page 15](#)

## Prerequisites for NSF/SSO—MPLS TE and RSVP Graceful Restart

- Configure Resource Reservation Protocol (RSVP) graceful restart in full mode.
  - Configure RSVP graceful restart on all interfaces of the neighbor that you want to be restart-capable.
  - Configure the redundancy mode as SSO. See [Stateful Switchover](#).
  - Enable NSF on the routing protocols running among the provider routers (P), provider edge (PE) routers, and customer edge (CE) routers. The routing protocols are as follows:
    - Border Gateway Protocol (BGP)
    - Open Shortest Path First (OSPF)
    - Intermediate System-to-Intermediate System (IS-IS)
- For more information, see [Information about Cisco Nonstop Forwarding](#).
- Enable MPLS.
  - Configure traffic engineering (TE).

## Restrictions for NSF/SSO—MPLS TE and RSVP Graceful Restart

- RSVP graceful restart supports node failure only.
- Unnumbered interfaces are not supported.
- You cannot enable RSVP fast reroute (FRR) hello messages and RSVP graceful restart on the same router.
- Configure this feature on Cisco 7600 series routers with dual RPs only.
- For releases prior to Cisco IOS Release 12.2(33)SRE, you cannot enable primary one-hop autotunnels, backup autotunnels, or autotunnel mesh groups on a router that is also configured with SSO and Route Processor Redundancy Plus (RPR+). This restriction does not prevent an MPLS TE tunnel that is automatically configured by TE autotunnel from being successfully recovered if any midpoint router along the label-switched path (LSP) of the router experiences an SSO. For Cisco IOS Release 12.2(33)SRE, go to the [“MPLS TE Autotunnel and SSO Coexistence” section on page 5](#).
- MPLS TE LSPs that are fast reroutable cannot be successfully recovered if the LSPs are FRR active and the Point of Local Repair (PLR) router experiences an SSO.
- When you configure RSVP graceful restart, you must use the neighbor’s interface IP address.

# Information About NSF/SSO—MPLS TE and RSVP Graceful Restart

To configure the NSF/SSO—MPLS TE and RSVP Graceful Restart feature, you should understand the following concepts:

- [Overview of MPLS TE and RSVP Graceful Restart, page 3](#)
- [MPLS TE Autotunnel and SSO Coexistence, page 5](#)
- [Benefits of MPLS TE and RSVP Graceful Restart, page 5](#)

## Overview of MPLS TE and RSVP Graceful Restart

RSVP graceful restart allows RSVP TE-enabled nodes to recover gracefully following a node failure in the network such that the RSVP state after the failure is restored as quickly as possible. The node failure may be completely transparent to other nodes in the network.

RSVP graceful restart preserves the label values and forwarding information and works with third-party or Cisco routers seamlessly.

RSVP graceful restart depends on RSVP hello messages to detect that a neighbor went down. Hello messages include Hello Request or Hello Acknowledgment (ACK) objects between two neighbors.

A node hello is transmitted when Graceful Restart is globally configured and the first LSP to the neighbor is created.

Interface Hello is an optional configuration. If the Graceful Restart Hello command is configured on an interface, the interface hello is considered to be an additional hello instance with the neighbor.

An interface hello for Graceful Restart is transmitted when all of the following conditions are met:

- Graceful Restart is configured globally.
- Graceful restart is configured on the interface.
- An LSP to the neighbor is created and goes over the interface.

Cisco recommends that you use node hellos if the neighbor supports node hellos, and configure interface hellos only if the neighbor router does not support node hellos.

Interface hellos differ from node hellos, as follows:

- **Interface hello**—The source address in the IP header of the hello message has an IP address that matches the interface that the Hello message sent out. The destination address in the IP header is the interface address of the neighbor on the other side of the link. A TTL of 1 is used for per-interface hellos as it is destined for the directly-connected neighbor.
- **Node hello**—The source address in the IP header of the Hello message includes the TE router ID of the sending router. The destination address of the IP header has the router ID of the neighbor to which this message is sent. A TTL of more than 1 is used.

As shown in [Figure 1](#), the RSVP graceful restart extension to these messages adds an object called Hello Restart\_Cap, which tells neighbors that a node may be capable of recovering if a failure occurs.

**Figure 1** *How RSVP Graceful Restart Works*

The Hello Restart\_Cap object has two values: the restart time, which is the sender's time to restart the RSVP\_TE component and exchange hello messages after a failure; and the recovery time, which is the desired time that the sender wants the receiver to synchronize the RSVP and MPLS databases.

In Figure 1, RSVP graceful restart help neighbor support is enabled on Routers 1 and 3 so that they can help a neighbor recover after a failure, but they cannot perform self recovery. Router 2 has full SSO help support enabled, meaning it can perform self recovery after a failure or help its neighbor to recover. Router 2 has two RPs, one that is active and one that is standby (backup). A TE LSP is signaled from Router 1 to Router 4.

Router 2 performs checkpointing; that is, it copies state information from the active RP to the standby RP, thereby ensuring that the standby RP has the latest information. If an active RP fails, the standby RP can take over.

Routers 2 and 3 exchange periodic graceful restart hello messages every 10,000 milliseconds (ms) (10 seconds), and so do Routers 2 and 1 and Routers 3 and 4. Assume that Router 2 advertises its restart time = 60,000 ms (60 seconds) and its recovery time = 60,000 ms (60 seconds) as shown in the following example:

```
23:33:36: Outgoing Hello:
23:33:36:  version:1 flags:0000 cksum:883C ttl:255 reserved:0 length:32
23:33:36:  HELLO                               type HELLO REQUEST length 12:
23:33:36:    Src_Instance: 0x6EDA8BD7, Dst_Instance: 0x00000000
23:33:36:  RESTART_CAP                               type 1 length 12:
23:33:36:    Restart_Time: 0x0000EA60, Recovery_Time: 0x0000EA60
```

Router 3 records this into its database. Also, both neighbors maintain the neighbor status as UP. However, Router 3's control plane fails at some point (for example, a primary RP failure). As a result, RSVP and TE lose their signaling information and states although data packets continue to be forwarded by the line cards.

When Router 3 declares communication with Router 2 lost, Router 3 starts the restart time to wait for the duration advertised in Router 2's restart time previously recorded (60 seconds). Routers 1 and 2 suppress all RSVP messages to Router 3 except hellos. Router 3 keeps sending the RSVP PATH and RESV refresh messages to Routers 4 and 5 so that they do not expire the state for the LSP; however, Routers 1 and 3 suppress these messages for Router 2.

When Routers 1 and 3 receive the hello message from Router 2, Routers 1 and 3 check the recovery time value in the message. If the recovery time is 0, Router 3 knows that Router 2 was not able to preserve its forwarding information, and Routers 1 and 3 delete all RSVP state that they had with Router 2.

If the recovery time is greater than 0, Router 1 sends Router 2 PATH messages for each LSP that it had previously sent through Router 2. If these messages were previously refreshed in summary messages, they are sent individually during the recovery time. Each of these PATH messages includes a Recovery\_Label object containing the label value received from Router 2 before the failure.

When Router 3 receives a PATH message from Router 2, Router 3 sends a RESV message upstream. However, Router 3 suppresses the RESV message until it receives a PATH message. When Router 2 receives the RESV message, it installs the RSVP state and reprograms the forwarding entry for the LSP.

## MPLS TE Autotunnel and SSO Coexistence

In Cisco IOS 12.2(33)SRE and later releases, MPLS TE primary tunnels, backup tunnels, and automesh tunnels can coexist with SSO; that is, they can be configured together. However, there are the following functional differences:

- Headend autotunnels created on the active RP are not checkpointed and created on the standby RP.
- After the SSO switchover, the new active RP recreates all the headend autotunnels and signals their LSPs. The LSP ID is different from the LSP ID used before the SSO switchover. Tunnel traffic may be dropped during the signaling of new autotunnel LSPs.
- SSO coexistence does not affect TE autotunnels in the midpoint or tailend routers along the LSPs from being checkpointed and recovered.

## Benefits of MPLS TE and RSVP Graceful Restart

### State Information Recovery

RSVP graceful restart allows a node to perform self recovery or to help its neighbor recover state information when there is an RP failure or the device has undergone an SSO.

### Session Information Recovery

RSVP graceful restart allows session information recovery with minimal disruption to the network.

### Increased Availability of Network Services

A node can perform a graceful restart to help itself or a neighbor recover its state by keeping the label bindings and state information, thereby providing a faster recovery of the failed node and not affecting currently forwarded traffic.

## How to Configure NSF/SSO—MPLS TE and RSVP Graceful Restart

This section contains the following procedures:

- [Enabling RSVP Graceful Restart Globally, page 6](#) (required)
- [Enabling RSVP Graceful Restart on an Interface, page 6](#) (required)
- [Setting a DSCP Value, page 7](#) (optional)
- [Setting a Value to Control the Hello Refresh Interval, page 8](#) (optional)
- [Setting a Value to Control the Missed Refresh Limit, page 9](#) (optional)
- [Verifying the RSVP Graceful Restart Configuration, page 10](#) (optional)

## Enabling RSVP Graceful Restart Globally

Perform this task to enable RSVP graceful restart globally.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip rsvp signalling hello graceful-restart mode {help-neighbor | full}**
4. **exit**

### DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>ip rsvp signalling hello graceful-restart mode {help-neighbor   full}</b>  <b>Example:</b> Router(config)# ip rsvp signalling hello graceful-restart mode full	Enables RSVP TE graceful restart capability on an RP. <ul style="list-style-type: none"><li>• Enter the <b>help-neighbor</b> keyword to enable a neighboring router to restart after a failure.</li><li>• Enter the <b>full</b> keyword to enable a router to perform self recovery or to help a neighbor recover after a failure.</li></ul>
Step 4	<b>exit</b>  <b>Example:</b> Router(config)# exit	(Optional) Returns to privileged EXEC mode.

## Enabling RSVP Graceful Restart on an Interface

Perform this task to enable RSVP graceful restart on an interface.

#### Note

You must repeat this procedure for each of the neighbor router's interfaces.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*

4. Repeat Step 3 as needed to configure additional interfaces.
5. **ip rsvp signalling hello graceful-restart neighbor *ip-address***
6. Repeat Step 5 as needed to configure additional IP addresses on a neighbor router's interfaces.
7. **exit**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>interface <i>type number</i></b>  <b>Example:</b> Router(config)# interface POS 1/0/0	Configures the interface type and number and enters interface configuration mode.
Step 4	Repeat Step 3 as needed to configure additional interfaces.	(Optional) Configures additional interfaces.
Step 5	<b>ip rsvp signalling hello graceful-restart neighbor <i>ip-address</i></b>  <b>Example:</b> Router(config-if)# ip rsvp signalling hello graceful-restart neighbor 10.0.0.0	Enables support for RSVP graceful restart on routers helping their neighbors recover TE tunnels following SSO. <p><b>Note</b> The IP address must be that of the neighbor's interface.</p>
Step 6	Repeat Step 5 as needed to configure additional IP addresses on a neighbor router's interfaces.	(Optional) Configures additional IP addresses on a neighbor router's interfaces.
Step 7	<b>exit</b>  <b>Example:</b> Router(config-if)# exit	(Optional) Returns to privileged EXEC mode.

## Setting a DSCP Value

Perform this task to set a differentiated services code point (DSCP) value.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip rsvp signalling hello graceful-restart dscp *num***

4. **exit**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>ip rsvp signalling hello graceful-restart dscp num</b>  <b>Example:</b> Router(config)# ip rsvp signalling hello graceful-restart dscp 30	Sets a DSCP value on a router with RSVP graceful restart enabled.
Step 4	<b>exit</b>  <b>Example:</b> Router(config)# exit	(Optional) Returns to privileged EXEC mode.

## Setting a Value to Control the Hello Refresh Interval

Perform this task to set a value to control the hello refresh interval.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip rsvp signalling hello graceful-restart refresh interval *interval-value***
4. **exit**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>ip rsvp signalling hello graceful-restart refresh interval interval-value</b>  <b>Example:</b> Router(config)# ip rsvp signalling hello graceful-restart refresh interval 5000	Sets the value to control the request interval in graceful restart hello messages. This interval represents the frequency at which RSVP hello messages are sent to a neighbor; for example, one hello message is sent per each interval.  <b>Note</b> If you change the default value for this command and you also changed the RSVP refresh interval using the <b>ip rsvp signalling refresh interval</b> command, ensure that the value for the <b>ip rsvp signalling hello graceful-restart refresh interval</b> command is less than the value for the <b>ip rsvp signalling hello refresh interval</b> command. Otherwise, some or all of the label-switched paths (LSPs) may not be recovered after an SSO has occurred.
Step 4	<b>exit</b>  <b>Example:</b> Router(config)# exit	(Optional) Returns to privileged EXEC mode.

## Setting a Value to Control the Missed Refresh Limit

Perform this task to set a value to control the missed refresh limit.

## SUMMARY STEPS

1. enable
2. configure terminal
3. ip rsvp signalling hello graceful-restart refresh misses *msg-count*
4. exit

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>ip rsvp signalling hello graceful-restart refresh misses msg-count</b>  <b>Example:</b> Router(config)# ip rsvp signalling hello graceful-restart refresh misses 5	Specifies how many sequential RSVP TE graceful restart hello acknowledgments (ACKs) a node can miss before the node considers communication with its neighbor lost.  <b>Note</b> If you change the default value for this command and you are also using the <b>ip rsvp signalling hello refresh misses</b> command, ensure that the value for the <b>ip rsvp signalling hello graceful-restart refresh misses</b> command is less than the value for the <b>ip rsvp signalling hello refresh misses</b> command. Otherwise, some or all of the LSPs may not be recovered after an SSO has occurred.
Step 4	<b>exit</b>  <b>Example:</b> Router(config)# exit	(Optional) Returns to privileged EXEC mode.

## Verifying the RSVP Graceful Restart Configuration

Perform this task to verify the RSVP graceful restart configuration.

## SUMMARY STEPS

1. enable
2. show ip rsvp hello graceful-restart
3. exit

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	(Optional) Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>show ip rsvp hello graceful-restart</b>  <b>Example:</b> Router# show ip rsvp hello graceful-restart	Displays information about the status of RSVP graceful restart and related parameters.
Step 3	<b>exit</b>  <b>Example:</b> Router# exit	(Optional) Returns to user EXEC mode.

## Configuration Examples for NSF/SSO—MPLS TE and RSVP Graceful Restart

This section provides the following configuration examples:

- [Configuring NSF/SSO—MPLS TE and RSVP Graceful Restart: Example, page 11](#)
- [Verifying the NSF/SSO—MPLS TE and RSVP Graceful Restart Configuration: Example, page 12](#)

### Configuring NSF/SSO—MPLS TE and RSVP Graceful Restart: Example

In the following example, RSVP graceful restart is enabled globally and on a neighbor router's interfaces as shown in [Figure 2](#). Related parameters, including a DSCP value, a refresh interval, and a missed refresh limit are set.

**Figure 2**      **Sample Network Configuration**

```

enable
configure terminal
ip rsvp signalling hello graceful-restart mode full
interface POS 1/0/0
 ip rsvp signalling hello graceful-restart neighbor 10.0.0.1
 ip rsvp signalling hello graceful-restart neighbor 10.0.0.2
exit

```

```
ip rsvp signalling hello graceful-restart dscp 30
ip rsvp signalling hello graceful-restart refresh interval 50000
ip rsvp signalling hello graceful-restart refresh misses 5
exit
```

## Verifying the NSF/SSO—MPLS TE and RSVP Graceful Restart Configuration: Example

The following example verifies the status of RSVP graceful restart and the configured parameters:

```
Router# show ip rsvp hello graceful-restart
```

```
Graceful Restart: Enabled (full mode)
Refresh interval: 10000 msecs
Refresh misses: 4
DSCP:0x30
Advertised restart time: 30000 msecs
Advertised recovery time: 120000 msecs
Maximum wait for recovery: 3600000 msecs
```

# Feature Information for NSF/SSO—MPLS TE and RSVP Graceful Restart

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release. Unless noted otherwise, subsequent releases of that Cisco IOS software release also support that feature.

**Table 1** Feature Information for NSF/SSO—MPLS TE and RSVP Graceful Restart

Feature Name	Releases	Feature Information
NSF/SSO—MPLS TE and RSVP Graceful Restart	12.0(29)S 12.2(33)SRA 12.2(33)SRB 12.2(33)SXH 12.2(33)SRE	<p>The NSF/SSO—MPLS TE and RSVP Graceful Restart feature allows an RP or its neighbor to recover from disruption in control plane service without losing its MPLS forwarding state.</p> <p>In Cisco IOS Release 12.0(29)S, this feature was introduced as MPLS Traffic Engineering—RSVP Graceful Restart and allowed a neighboring RP to recover from disruption in control plane service without losing its MPLS forwarding state.</p> <p>In Cisco IOS Release 12.2(33)SRA, this feature was integrated and new commands were added.</p> <p>In Cisco IOS Release 12.2(33)SRB, support was added for ISSU and SSO recovery of LSPs that include loose hops.</p> <p>In Cisco IOS Release 12.2(33)SXH, this feature was integrated.</p> <p>In Cisco IOS Release 12.2(33)SRE, SSO can coexist with primary tunnels, backup tunnels, and mesh tunnels.</p>

# Glossary

**DSCP**—differentiated services code point. Six bits in the IP header, as defined by the IETF. These bits determine the class of service provided to the IP packet.

**Fast Reroute**—A mechanism for protecting MPLS traffic engineering (TE) LSPs from link and node failure by locally repairing the LSPs at the point of failure, allowing data to continue to flow on them while their headend routers attempt to establish end-to-end LSPs to replace them. FRR locally repairs the protected LSPs by rerouting them over backup tunnels that bypass failed links or nodes.

**graceful restart**—A process for helping an RP restart after a node failure has occurred.

**headend**—The router that originates and maintains a given LSP. This is the first router in the LSP's path.

**hello instance**—A mechanism that implements the RSVP hello extensions for a given router interface address and remote IP address. Active hello instances periodically send hello request messages, expecting Hello ACK messages in response. If the expected ACK message is not received, the active hello instance declares that the neighbor (remote IP address) is unreachable (that is, it is lost). This can cause LSPs crossing this neighbor to be fast rerouted.

**IGP**—Interior Gateway Protocol. Internet protocol used to exchange routing information within an autonomous system. Examples of common Internet IGPs include IGRP, OSPF, and RIP.

**ISSU**—In Service Software Upgrade. Software upgrade without service interruption.

**label**—A short, fixed-length data identifier that tells switching nodes how to forward data (packets or cells).

**LSP**—label switched path. A configured connection between two routers, in which MPLS is used to carry packets.

**MPLS**—Multiprotocol Label Switching. A method for forwarding packets (frames) through a network. MPLS enables routers at the edge of a network to apply labels to packets (frames). ATM switches or existing routers in the network core can switch packets according to the labels.

**RSVP**—Resource Reservation Protocol. A protocol that supports the reservation of resources across an IP network. Applications running on IP end systems can use RSVP to indicate to other nodes the nature (bandwidth, jitter, maximum burst, and so on) of the packet streams they want to receive.

**state**—Information that a router must maintain about each LSP. The information is used for rerouting tunnels.

**tailend**—The router upon which an LSP is terminated. This is the last router in the LSP's path.

**TE**—traffic engineering. The techniques and processes used to cause routed traffic to travel through the network on a path other than the one that would have been chosen if standard routing methods had been used.

# NSF/SSO/ISSU Support for VPLS

---

**First Published: January 7, 2008**

**Last Updated: January 7, 2008**

Virtual Private LAN Services (VPLS), with nonstop forwarding (NSF), stateful switchover (SSO), and in service software upgrade (ISSU) support, improves the availability of service provider networks that use VPLS for multipoint Layer 2 virtual private network (VPN) services. Cisco NSF with SSO is effective at increasing availability of network services. Cisco NSF with SSO provides continuous packet forwarding, even during a network processor hardware or software failure. In a redundant system, the secondary processor recovers control plane service in the event of a critical failure in the primary processor, while SSO synchronizes the network state information between the primary and the secondary processor.

In conjunction with VPLS NSF/SSO, VPLS High Availability (HA) features include the ISSU capability. Working together, ISSU and NSF/SSO enable upgrades or downgrades of a Cisco IOS image without control and data plane outages.

## Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [Feature Information for NSF/SSO/ISSU Support for VPLS, page 26](#).

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for NSF/SSO/ISSU Support for VPLS

This section lists the following prerequisites that are required to use the NSF/SSO/ISSU Support for VPLS feature.

You must configure the following features on your network:

- VPLS (see the “Virtual Private LAN Services on the Optical Services Modules” chapter in the *Cisco 7600 Series Router Cisco IOS Software Configuration Guide*, Release 12.2SR)
- VPLS Autodiscovery (see *VPLS Autodiscovery: BGP Based* and *BGP Support for the L2VPN Address Family*)
- NSF/SSO: Any Transport over MPLS (see *NSF/SSO—Any Transport over MPLS and AToM Graceful Restart*)
- NSF/SSO router support on the 7600 router (see the “Configuring NSF with SSO Supervisor Engine Redundancy” chapter in the *Cisco 7600 Series Cisco IOS Software Configuration Guide*, Release 12.2SR)
- ISSU router support on the 7600 router (see the “ISSU and eFSU on Cisco 7600 Series Routers” chapter in the *Cisco 7600 Series Cisco IOS Software Configuration Guide*, Release 12.2SR)

## Restrictions for NSF/SSO/ISSU Support for VPLS

The NSF/SSO/ISSU Support for VPLS feature has the following restrictions:

- NSF/SSO/ISSU support for VPLS does not include support for PWs to auto discovered neighbors via Border Gateway Protocol (BGP). Statically configured neighbors are supported.
- For supported hardware, see the Cisco Release 12.2SR Release Notes.
- NSF/SSO/ISSU support for VPLS does not include support for line cards that do not support Minimal Disruptive Restart (MDR) or pre downloading of firmware or driver code.

## Information About NSF/SSO/ISSU Support for VPLS

To configure the NSF/SSO/ISSU Support for VPLS feature, you should understand the following concepts:

- [How NSF/SSO Works with VPLS, page 3](#)
- [How ISSU Works with VPLS, page 3](#)

## How NSF/SSO Works with VPLS

VPLS with NSF/SSO support improves the availability of service provider networks that use VPLS for multipoint Layer 2 VPN services. HA minimizes service disruptions that can occur if a system failure occurs. To address failures, VPLS HA includes SSO and NSF mechanisms using a standby Route Processor (RP) to provide control-plane redundancy. VPLS NSF is achieved by SSO and NSF mechanisms.

While the standby RP transitions to the active RP, packet forwarding either continues forwarding on line card(s) or packet forwarding is switched over (switchover) to other hardware devices associated with the newly active RP.

## How ISSU Works with VPLS

In conjunction with VPLS NSF/SSO, VPLS HA includes ISSU, a comprehensive in-service upgrade solution for the IP/MPLS edge. ISSU minimizes network downtime due to software upgrades and maintenance activities. ISSU allows upgrades or downgrades to Cisco IOS software images with no effect on the control plane and minimal effect on system packet forwarding. With ISSU, all message data structures used for checkpointing, and exchanges between the active RP and standby RP are versioned.

To perform an in-service upgrade, the standby RP in a dual RP-based platform (such as the Cisco 7600 router) is first loaded with the desired Cisco IOS software release. The standby RP then comes up as a hot-standby RP with an upgraded version of the software, and a switchover is performed to transfer control to the standby RP and run the upgraded image.

During the ISSU procedure, supported SSO protocols and features maintain their session states with no disruption of the Layer 2 protocol sessions. Cisco NSF technology is used to continue packet forwarding during the software upgrade procedure while the routing information is re-created on the newly active RP. The result is a seamless software upgrade for an IP/MPLS provider edge router with no disruptions to Layer 2 protocol sessions and minimal effect on packet forwarding.

### Benefits

Primary benefits for ISSU are:

- Rapid, nondisruptive feature deployment—By preserving user sessions and minimizing packet loss during software upgrades, ISSU helps enable rapid, nondisruptive deployments for new features and services at the IP/MPLS provider edge.
- Comprehensive solution for planned downtime—ISSU addresses the entire spectrum of software upgrade needs, from applying caveat fixes to deploying new features and services, and delivers a comprehensive solution for addressing planned network downtime.
- Increased operational efficiencies—ISSU minimizes and streamlines planned downtime and helps enable operational process changes for software deployment, significantly decreasing planned downtime effort and expenses and increasing operational efficiency.

## How to Configure NSF/SSO/ISSU Support for VPLS

This section contains the following procedures:

- [Configuring VPLS, page 4](#) (required)
- [Configuring NSF/SSO: Any Transport over MPLS, page 4](#) (required)

- [Configuring NSF/SSO Router support, page 4](#) (required)
- [Configuring ISSU Router Support, page 4](#) (required)

## Configuring VPLS

VPLS must be configured on the router. See the “Virtual Private LAN Services on the Optical Services Modules” chapter in the *Cisco 7600 Series Router Cisco IOS Software Configuration Guide*, Release 12.2SR for information on configuring VPLS.

## Configuring NSF/SSO: Any Transport over MPLS

You must configure the NSF/SSO: Any Transport over MPLS feature on the router. See the *NSF/SSO—Any Transport over MPLS and AToM Graceful Restart* feature module for information on configuring the NSF/SSO: Any Transport over MPLS feature.

## Configuring NSF/SSO Router support

You must configure NSF/SSO router support on the Cisco 7600 router. See the “Configuring NSF with SSO Supervisor Engine Redundancy” chapter in the *Cisco 7600 Series Cisco IOS Software Configuration Guide*, Release 12.2SR for information on configuring the NSF with SSO Supervisor Engine Redundancy feature.

## Configuring ISSU Router Support

You must configure ISSU router support on the Cisco 7600 router.

- See the “ISSU and eFSU on Cisco 7600 Series Routers” chapter in the *Cisco 7600 Series Cisco IOS Software Configuration Guide*, Release 12.2SR for information on configuring ISSU and Enhanced Fast Software Upgrade (eFSU) on Cisco 7600 series routers.

## Verifying and Troubleshooting NSF/SSO/ISSU Support for VPLS

To verify the NSF/SSO/ISSU Support for VPLS configuration, use the following show and debug commands:

### DETAILED STEPS

1. **show checkpoint clients**
2. **show vfi [name vfi-name] checkpoint [summary]**
3. **debug cwan atom**
4. **debug cwan ltl**
5. **debug issu client negotiation**
6. **debug issu client registration**

**7. debug issu client transform****8. debug vfi checkpoint****DETAILED STEPS****Step 1 show checkpoint clients**

Use this command to display information about checkpoint clients:

```
Router# show checkpoint clients
```

Check Point List of Clients

CHKPT on ACTIVE server.

Client Name	Client ID	Entity ID	Bundle Mode
-------------	-----------	-----------	-------------

CHKPT Test client	1	--	On
-------------------	---	----	----

Total API Messages Sent:	0
Total IPC Sent:	0
Total Message Len:	0
Total Bytes Allocated:	0
Buffers Held:	0
IPC Frag Count:	0
IPC HW mark:	0
IPC Sends w/Flow Off:	0
Send Errs:	0
Send Peer Errs:	0
Rcv Xform Errs:	0
Xmit Xform Errs:	0
Incompatible Messages:	0

Client Name	Client ID	Entity ID	Bundle Mode
-------------	-----------	-----------	-------------

Network RF Client	3	--	Off
-------------------	---	----	-----

Total API Messages Sent:	10
Total IPC Sent:	10
Total Message Len:	2144
Total Bytes Allocated:	2904
Buffers Held:	0
IPC Frag Count:	0
IPC HW mark:	0
IPC Sends w/Flow Off:	0
Send Errs:	0
Send Peer Errs:	0
Rcv Xform Errs:	0
Xmit Xform Errs:	0
Incompatible Messages:	0

Client Name	Client ID	Entity ID	Bundle Mode
-------------	-----------	-----------	-------------

--More--

.  
.
   
.

**Step 2 show vfi [name vfi-name] checkpoint [summary]**

Use this command to display checkpoint information related to a specific virtual forwarding instance (VFI) named H-VPLS-A-VFI:

```
Router# show vfi name H-VPLS-A-VFI checkpoint
```

```
VFI Active RP
Checkpointing: Allowed
ISSU Client id: 2092, Session id: 65543, Compatible with peer
```

	VFI	VFI AC	VFI PW
Bulk-sync	1	1	3
Checkpoint failures:	0	3	21
Recovered at switchover:	0	0	0
Recovery failures:	0	0	0

Legend: C=Checkpointed

VFI name: H-VPLS-A-VFI, state: up, type: multipoint

VPN ID: 12, Internal ID 1 C

Local attachment circuits:

Vlan200 16387 / 8195 C

Neighbors connected via pseudowires:

Peer ID	VC ID	SSM IDs	
10.0.0.12	12	4096 / 12292	C
10.0.0.15	12	8193 / 16389	C
10.0.0.14	12	12290 / 20486	C

**Step 3 debug cwan atom**

Use this command to enable debugging of Any Transport over MPLS (AToM) platform events.

The following example shows debug message output that appears when debugging is enabled and a PW port is configured and then unconfigured:

```
Router# debug cwan atom
```

ConstWan Generic AToM debugging is on

```
Router# configure terminal
```

Enter configuration commands, one per line. End with CNTL/Z.

```
Router(config)# 12 vfi VPLS-2000 manual
```

```
Router(config-vfi)# vpn id 2000
```

```
Router(config-vfi)# neighbor 10.1.1.1 encapsulation mpls
```

```
Router(config-vfi)#
```

```
01:16:36: cwan_rp_vfi_atom_provision_vlan PROV[VFI-ATOM]: plat_index(0xC7D00084)
vlanid(2000) pseudo_port(0x84) vfi_plat_index(0xC7D00084) seginfo(0x53D38220) segtype(25)
seghandle(0x53AEE074) split-horizon(On) cwan_atom_intf(3) vfi_vcs(3) spoke_vcs(0)
```

```
Router(config-vfi)# end
```

```
Router# debug cwan atom
```

ConstWan Generic AToM debugging is on

```
Router# configure terminal
```

Enter configuration commands, one per line. End with CNTL/Z.

```
Router(config)# 12 vfi VPLS-2000
```

```
Router(config-vfi)# no neighbor 10.1.1.1 encapsulation mpls
```

```
Router(config-vfi)#
```

```
01:27:18: cwan_rp_vfi_atom_unprovision_vlan: UNPROV[VFI-ATOM]: circ_index(0xC7D00084)
is_vfi(1) vlan(2000) vfi_vcs(3) spoke_vcs(0) split_horizon(On)
```

```
01:27:18: cwan_atom_vlan_remove_rp: Vlan2000 ip_iw(0) ip_enabled(0)
```

```
Router(config-vfi)# end
```

**Step 4 debug cwan ltl**

Use this command to enable debugging of Local Target Manager (LTL) debugging events and errors.

The following example shows debug message outputs that appear when debugging is enabled and a PW port is configured and then unconfigured:

```
Router# debug cwan ltl

ConstWan LTL manager debugging is on
Router# configure terminal

Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# 12 vfi VPLS-2000 manual
Router(config-vfi)# vpn id 2000
Router(config-vfi)# neighbor 10.1.1.1 encapsulation mpls
Router(config-vfi)#

01:17:35: CWAN LTL MGR: Port 133 is free to use for VPLS with vlan 2000 - tx_tvc(0x9F404)
Router(config-vfi)# end
Router# debug cwan ltl

ConstWan LTL manager debugging is on
Router# configure terminal

Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# 12 vfi VPLS-2000 manual
Router(config-vfi)# no neighbor 10.1.1.1 encapsulation mpls
Router(config-vfi)#

01:29:05: CWAN LTL MGR: DELETE VPLS PW vlan(2000) pseudo_slotunit(133)
Router(config-vfi)# end
```

**Step 5 debug issu client negotiation**

Use this command to enable debugging of ISSU client negotiation events and errors:

```
Router# debug issu client negotiation

*Jun  5 22:41:47.332: VFI ISSU: Negotiation rc ISSU_RC_NEGO_DONE, compatible

```

## Step 6 debug issu client registration

Use this command to enable debugging of ISSU client registration events and errors.

After the peer router reloads, the following debug messages appear:

```
Router# debug issu client registration
```

```
Router#
```

```

00:42:21: VFI ISSU: Unregistered ISSU session 0, ISSU_RC_OK
00:42:21: %LINK-3-UPDOWN: Interface GigabitEthernet6/2, changed state to down
00:42:21: %LINEPROTO-5-UPDOWN: Line protocol on Interface GigabitEthernet6/2, changed
state to down
00:42:21: %LINK-3-UPDOWN: Interface Vlan2000, changed state to down
00:42:21: %LINK-3-UPDOWN: Interface Vlan2001, changed state to down
00:42:21: %LINK-3-UPDOWN: Interface Vlan2002, changed state to down
Router#
00:42:21: %LINEPROTO-5-UPDOWN: Line protocol on Interface Vlan2000, changed state to down
00:42:21: %LINEPROTO-5-UPDOWN: Line protocol on Interface Vlan2001, changed state to down
00:42:21: %LINEPROTO-5-UPDOWN: Line protocol on Interface Vlan2002, changed state to down
Router#
00:49:01: %LINK-3-UPDOWN: Interface GigabitEthernet6/2, changed state to down
00:49:02: %LINK-3-UPDOWN: Interface GigabitEthernet6/2, changed state to up
PE-3#
00:49:05: %LINEPROTO-5-UPDOWN: Line protocol on Interface GigabitEthernet6/2, changed
state to up
Router#
00:49:35: %LINK-3-UPDOWN: Interface Vlan2000, changed state to up
00:49:35: %LINK-3-UPDOWN: Interface Vlan2001, changed state to up
00:49:35: %LINEPROTO-5-UPDOWN: Line protocol on Interface Vlan2000, changed state to up
00:49:35: %LINEPROTO-5-UPDOWN: Line protocol on Interface Vlan2001, changed state to up
00:49:35: %LINK-3-UPDOWN: Interface Vlan2002, changed state to up
Router#
00:49:35: %LINEPROTO-5-UPDOWN: Line protocol on Interface Vlan2002, changed state to up
Router#
00:49:48: VFI ISSU: Registered session 131171, ISSU_RC_OK
Router#
00:50:08: %HA_CONFIG_SYNC-6-BULK_CFGSYNC_SUCCEED: Bulk Sync succeeded
Router#

```

**Step 7 debug issu client transform [clientID *client-id*]**

Use this command to enable debugging of ISSU client transform events and errors.

The following command example enables debug output for a specific ISSU client (clientID 2092). After the peer router reloads, the following debug messages appear:

```
Router# debug issu client transform clientID 2092

Router#

05:35:15: %LINK-3-UPDOWN: Interface GigabitEthernet6/2, changed state to down
05:35:15: %LINEPROTO-5-UPDOWN: Line protocol on Interface GigabitEthernet6/2, changed
state to down
05:35:15: %LINK-3-UPDOWN: Interface Vlan2000, changed state to down
05:35:15: %LINK-3-UPDOWN: Interface Vlan2001, changed state to down
05:35:15: %LINK-3-UPDOWN: Interface Vlan2002, changed state to down
Router#
05:35:15: %LINEPROTO-5-UPDOWN: Line protocol on Interface Vlan2000, changed state to down
05:35:15: %LINEPROTO-5-UPDOWN: Line protocol on Interface Vlan2001, changed state to down
05:35:15: %LINEPROTO-5-UPDOWN: Line protocol on Interface Vlan2002, changed state to down
Router#
05:41:55: %LINK-3-UPDOWN: Interface GigabitEthernet6/2, changed state to down
05:41:56: %LINK-3-UPDOWN: Interface GigabitEthernet6/2, changed state to up
.
.
.
05:43:02: VFI ISSU: Xmit transform message 5, rc ISSU_RC_OK
05:43:02: ISSU Buffer dump @ 0x0817EC7C
05:43:02:      00 00 00 00
05:43:02: VFI ISSU: Xmit transform message 1, rc ISSU_RC_OK
05:43:02: %HA_CONFIG_SYNC-6-BULK_CFGSYNC_SUCCEED succeeded
Router#
```

**Step 8 debug vfi checkpoint**

Use this command to enable debugging VFI checkpointing events and errors:

```
Router# debug vfi checkpoint

Router# $may24_v1 6 slavedisk0:s72033-adventerprisek9_wan-mz.cflow_may24_v1

Router#

## Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Multiprotocol Label Switching Command Reference* at [http://www.cisco.com/en/US/docs/ios/mps/command/reference/mp\\_book.html](http://www.cisco.com/en/US/docs/ios/mps/command/reference/mp_book.html). For information about all Cisco IOS commands, go to the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or to the *Cisco IOS Master Commands List*.

- **debug cwan atom**
- **debug cwan ltl**
- **debug issu client negotiation**
- **debug issu client registration**
- **debug issu client transform**
- **debug vfi checkpoint**
- **show checkpoint clients**
- **show vfi checkpoint**

# Feature Information for NSF/SSO/ISSU Support for VPLS

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1** Feature Information for NSF/SSO/ISSU Support for VPLS

Feature Name	Releases	Feature Information
NSF/SSO/ISSU Support for VPLS	12.2(33)SRC	Virtual Private LAN Services (VPLS), with NSF/SSO/ISSU support, improves the availability of service provider networks that use VPLS for multipoint Layer 2 VPN services. Cisco nonstop forwarding (NSF) with stateful switchover (SSO) is effective at increasing availability of network services.  In 12.2(33)SRC, this feature was introduced on the Cisco 7600 router.

# NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE

---

**First Published: October 21, 2009**

**Last Updated: November 25, 2009**

This document provides information about configuring nonstop forwarding (NSF), stateful switchover (SSO), and In Service Software Upgrade (ISSU) support for Cisco IOS Virtual Private Network (VPN) IPv6 provider edge router (6VPE) and Cisco IOS IPv6 provider edge router (6PE) over Multiprotocol Label Switching (MPLS).

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the [“Feature Information for NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE”](#) section on [page 17](#).

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE

Ensure that the following are supported for the NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE feature to work:

- IPv6 NSF
- IPv6 Cisco Express Forwarding
- Label Distribution Protocol (LDP) Graceful Restart

LDP Graceful Restart should be enabled if LDP is the protocol used in the MPLS core

You must enable NSF on the following routing protocol that run between the provider (P) routers, PE routers, and the customer edge (CE) routers:

- Border Gateway Protocol (BGP)
- Static routes

Before enabling the NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE feature, you must have a supported MPLS VPN network configuration. See the configuration information included in the following modules: [Configuring MPLS Layer 3 VPNs](#), [Implementing IPv6 over MPLS](#), and [Implementing IPv6 VPN over MPLS](#).

## Restrictions for NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE

The NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE feature has the following restrictions:

- Tag Distribution Protocol (TDP) sessions are not supported. Only LDP sessions are supported.
- MPLS VPN 6VPE and 6PE Carrier Supporting Carrier (CSC) VPNs support only BGP. CSC configurations that use LDP are not supported.
- Only BGP and static routes are supported for 6VPE and 6PE in Cisco IOS Release 12.2(33)SRE.

## Information About NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE

To configure the NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE feature, you need to understand the following concepts:

- [Elements Supporting NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE Features, page 3](#)
- [How BGP Graceful Restart Works for MPLS VPN 6VPE and 6PE, page 3](#)
- [How BGP Graceful Restart Preserves Prefix Information During a Restart, page 3](#)
- [ISSU Support for MPLS VPN 6VPE and 6PE, page 4](#)
- [NSF/SSO Support for MPLS VPN 6VPE and 6PE, page 4](#)
- [BGP Graceful Restart Support for MPLS VPN Configurations, page 5](#)
- [What Happens If a Router Does Not Support NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE, page 5](#)

## Elements Supporting NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE Features

The major elements supporting the functionality of the NSF/SSO and ISSU for Cisco IOS VPN 6vPE and 6PE feature are the following:

- **MPLS VPN**—A supported MPLS VPN network must be configured before you enable the NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE feature
- **BGP Graceful Restart**—The BGP Graceful Restart feature is responsible for negotiating graceful restart capabilities, exchanging forwarding preservation states, and coordinating advertisements after session restarts. MPLS VPNs interact with BGP to exchange Virtual Private Network (VPN) routing and forwarding (VRF) routes and labels.
- **IPv6 NSF**—IPv6 NSF support enables IPv6 cache rebuilds during switchover using checkpointed Cisco Express Forwarding adjacencies.
- **CEF/MFI**—Cisco Express Forwarding and the MPLS Forwarding Infrastructure are responsible for preserving forwarding entries and local labels across Route Processor (RP) switchover.

## How BGP Graceful Restart Works for MPLS VPN 6vPE and 6PE

BGP Graceful Restart behavior for IPv6 and VPNv6 is essentially the same as Graceful Restart behavior for IPv4 and VPNv4; the only difference is the addition of support for IPv6 and VPNv6 address families.

When you configure BGP Graceful Restart, BGP includes the Graceful Restart capability and negotiates the preservation states of address families, that is, IPv4/VPNv4 and IPv6/VPNv6 address families.

Both BGP peers must agree on a Graceful Restart timer, which you can set with the **bgp graceful-restart restart-timer seconds** command. After a BGP session comes up and finishes sending initial updates, each BGP peer sends an end-of-Routing Information Base (RIB) marker.

The NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE feature uses the mechanisms defined in the RFC 4724, *Graceful Restart Mechanism for BGP*, and in the *Cisco Nonstop Forwarding* feature module.

## How BGP Graceful Restart Preserves Prefix Information During a Restart

When a router that is capable of BGP Graceful Restart loses connectivity, the following happens to the restarting router:

1. The router establishes BGP sessions with other routers and relearns the BGP routes from other routers that are also capable of Graceful Restart. The restarting router waits to receive updates from the neighboring routers. When the neighboring routers send end-of-RIB markers to indicate that they are done sending updates, the restarting router starts sending its own updates.
2. The restarting router recovers labels from the MPLS Forwarding Infrastructure (MFI) database for each prefix. If the router finds the label, it advertises the label to the neighboring router. If the router does not find the label, it allocates a new label from the database and advertises it.
3. The restarting router removes any stale prefixes after a timer for stale entries expires.

When a peer router that is capable of BGP Graceful Restart encounters a restarting router, it does the following:

1. The peer router sends all of the routing updates to the restarting router. When it has finished sending updates, the peer router sends an end-of RIB marker to the restarting router.

2. The peer router does not immediately remove the BGP routes learned from the restarting router from its BGP routing table. As it learns the prefixes from the restarting router, the peer refreshes the stale routes if the new prefix and label information matches the old information.

## ISSU Support for MPLS VPN 6vPE and 6PE

In Cisco IOS Release 12.2(33)SRE and future releases, ISSU supports MPLS VPN 6vPE and 6PE. The Cisco IOS ISSU process allows Cisco IOS software to be updated or otherwise modified while packet forwarding continues. In most networks, planned software upgrades are a significant cause of downtime. ISSU allows Cisco IOS software to be modified while packet forwarding continues, which increases network availability and reduces downtime caused by planned software upgrades.

ISSU support for MPLS 6vPE and 6PE relies on 6vPE and 6PE NSF/SSO capability on the platform to minimize disruption on the forwarding plane.

For more information about ISSU, see [Cisco IOS In Service Software Upgrade Process](#).

## NSF/SSO Support for MPLS VPN 6VPE and 6PE

In Cisco IOS Release 12.2(33)SRE and future releases, NSF/SSO supports MPLS VPN 6vPE and 6PE. NSF/SSO for 6VPE and 6PE supports the following configurations:

- NSF/SSO for IPv4 and VPNv4 coexistence
- Basic 6VPE and 6PE over MPLS core technology
- BGP multipath configuration

NSF/SSO for 6VPE supports the following configurations:

- Per-VRF label configuration
- Inter autonomous systems (Inter-AS) topologies, including options B and C
- CSC when IPv6 + labels is configured on the PE-customer edge (CE) link

Because the SSO feature maintains stateful protocol and application information, user session information is maintained during a switchover, and line cards continue to forward network traffic with no loss of sessions, providing improved network availability. SSO initializes and configures the standby RP and synchronizes state information, which can reduce the time required for routing protocols to converge. Network stability may be improved with the reduction in the number of route flaps created when routers in the network failed and lost their routing tables.

When RP switchover happens, forwarding information is preserved by MFI and Cisco Express Forwarding on both line cards and the standby RP. VPNv6 prefix and local label mapping is preserved in the forwarding database. When the standby RP becomes the new active RP, 6PE and 6vPE traffic continues to be forwarded with minimal interruption.

When a BGP session restarts on the new active RP, the new active RP does not have any prior state information about prefixes or labels. The new active RP will have to relearn VPNv6 prefixes from its peers. As the new active RP learns the VPNv6 prefixes, it tries to get new local labels the same way it does when it first comes up. If the MFI database has the preserved copy of the local label for a prefix, the MFI database gives the local label to BGP. Then, BGP maintains the same local label. If the MFI database does not have a preserved local label for the prefix, MFI allocates a new one.

## BGP Graceful Restart Support for MPLS VPN Configurations

The section describes BGP Graceful Restart support for a basic 6VPE setup and for a CSC setup and interautonomous system setup.

- [Graceful Restart Support for a Basic 6VPE Setup, page 5](#)
- [Graceful Restart for 6VPE in Carrier Supporting Carrier and Interautonomous System Setups, page 5](#)

### Graceful Restart Support for a Basic 6VPE Setup

For PE- to-CE external BGP (eBGP), Graceful Restart capability is supported for IPv6 address families. For PE-to-PE interior BGP (iBGP) sessions with or without a route reflector (RR) in the core, BGP Graceful Restart capability supports VPNv6 address families.

When the PE router resets, the connected CE router retains IPv6 prefixes that it received from the PE router and marks the prefixes as stale. If the eBGP session does not reestablish within the specified restart time or the session reestablishes, but does not set the restart or forwarding state bit, the CE router removes the staled IPv6 routes. If the eBGP session reestablishes within the specified restart time and has both the forwarding and restart bits set, the CE router removes the stale state from the IPv6 routes when it receives the updates from PE router. After the CE router receives the end-of-RIB marker, it removes or withdraws the rest of the staled information, if any exists.

The restarting PE router waits for an end-of-RIB marker from all BGP-capable peers including iBGP peers and eBGP peers. Only after receiving an end-of-RIB marker from all BGP capable peers will the PE router start to calculate the best path and send out initial updates.

### Graceful Restart for 6VPE in Carrier Supporting Carrier and Interautonomous System Setups

The same Graceful Restart capabilities for route preservation that apply to a basic 6VPE setup apply to a CSC and Inter-AS setup. IPv6 or VPNv6 routes and labels are preserved during switchover.

In a CSC configuration, when send-labels are configured between a CSC-PE and CSC-CE eBGP connection, labels are preserved along with IPv6 BGP routes when one of the peers restarts.

In Inter-AS option B and options C setups, VPNv6 routes and labels are preserved on an Autonomous System Border Router (ASBR) or route reflector when the VPNv6 peer restarts.

## What Happens If a Router Does Not Support NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE

If a router does not support the NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE feature, prefix and label information is not preserved. After a switchover, BGP has to restart, relearn all routes, and install labels in the forwarding database. This might result in the loss of some network traffic.

# How to Configure NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE

Perform the following tasks to configure NSF/SSO for MPLS 6VPE and 6PE:

- [Configuring NSF/SSO for Basic MPLS 6VPEs and 6PEs, page 6](#) (required)
- [Verifying NSF/SSO and ISSU Support for MPLS VPN 6VPE and 6PE, page 8](#) (optional)

For information on how to configure ISSU, see the [Cisco IOS In Service Software Upgrade Process](#) module.

## Configuring NSF/SSO for Basic MPLS 6VPEs and 6PEs

Perform this task to configure NSF/SSO for basic MPLS 6VPE and 6PEs.

### Note

You can use the **bgp graceful-restart** command to configure BGP Graceful Restart for all available address families.

## Prerequisites

Route Processors must be configured for SSO. See [Stateful Switchover](#) for more information.

If you use LDP in the core, you must enable the MPLS LDP: NSF/SSO Support and Graceful Restart feature. See [NSF/SSO-MPLS LDP and MPLS LDP Graceful Restart](#) for more information.

You must enable nonstop forwarding on the routing protocols running between the P, PE, and CE routers. The routing protocols between the CE router and the PE router are Static and BGP. See [Cisco Nonstop Forwarding](#) for more information.

Before enabling the NSF/SSO—MPLS VPN feature, you must have a supported MPLS VPN network configuration. See configuration information included in the following: [Configuring MPLS Layer 3 VPNs](#), [Implementing IPv6 over MPLS](#), and [Implementing IPv6 VPN over MPLS](#).

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef distributed**
4. **ipv6 unicast-routing**
5. **ipv6 cef distributed**
6. **redundancy**
7. **mode sso**
8. **exit**
9. **router bgp** *autonomous-system-number*
10. **bgp graceful-restart restart-time** *seconds*
11. **bgp graceful-restart stalepath-time** *seconds*
12. **bgp graceful-restart**
13. **end**

## DETAILED STEPS

	Command or Action	Purpose
Step 1	<b>enable</b>  <b>Example:</b> Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>
Step 2	<b>configure terminal</b>  <b>Example:</b> Router# configure terminal	Enters global configuration mode.
Step 3	<b>ip cef distributed</b>  <b>Example:</b> Router(config)# ip cef distributed	Enables distributed Cisco Express Forwarding.
Step 4	<b>ipv6 unicast-routing</b>  <b>Example:</b> Router(config)# ipv6 unicast-routing	Enables the forwarding of IPv6 unicast datagrams.
Step 5	<b>ipv6 cef distributed</b>  <b>Example:</b> Router(config)# ipv6 cef distributed	Enables distributed Cisco Express Forwarding for IPv6.
Step 6	<b>redundancy</b>  <b>Example:</b> Router(config)# redundancy	Enters redundancy configuration mode.
Step 7	<b>mode sso</b>  <b>Example:</b> Router(red-config)# mode sso	Sets the redundancy configuration mode to SSO.
Step 8	<b>exit</b>  <b>Example:</b> Router(red-config)# exit	Exits to global configuration mode.
Step 9	<b>router bgp autonomous-system-number</b>  <b>Example:</b> Router(config)# router bgp 1000	Enters router configuration mode and configures the BGP routing process. <ul style="list-style-type: none"> <li>The <i>autonomous-system-number</i> argument is the number of an autonomous system that identifies the router to other BGP routers and tags the routing information that is passed along. Number is in the range from 1 to 65535.</li> </ul>

	Command or Action	Purpose
Step 10	<b>Command:</b> <code>bgp graceful-restart restart-time seconds</code>  <b>Example:</b> <pre>Router(config-router)# bgp graceful-restart restart-time 180</pre>	Enables the BGP graceful restart timer capability globally for all BGP neighbors. <ul style="list-style-type: none"> <li>The <b>restart-time seconds</b> keyword and argument sets the maximum time period that the local router will wait for a graceful-restart-capable neighbor to return to normal operation after a restart event occurs. The default value for the <i>seconds</i> argument is 120. The configurable range of values is from 1 to 3600.</li> </ul>
Step 11	<b>Command:</b> <code>bgp graceful-restart stalepath-time seconds</code>  <b>Example:</b> <pre>Router(config-router)# bgp graceful-restart stalepath-time 420</pre>	Enables the BGP graceful restart stale path timer capability globally for all BGP neighbors. <ul style="list-style-type: none"> <li>The <b>stalepath-time seconds</b> keyword and argument sets the maximum time period that the local router will hold stale paths for a restarting peer. All stale paths are deleted after this timer expires. The default value for the <i>seconds</i> argument is 360. The configurable range of values is from 1 to 3600.</li> </ul>
Step 12	<b>Command:</b> <code>bgp graceful-restart</code>  <b>Example:</b> <pre>Router(config-router)# bgp graceful-restart</pre>	Enables the BGP graceful restart capability globally for all BGP neighbors.
Step 13	<b>Command:</b> <code>end</code>  <b>Example:</b> <pre>Router(config-router)# end</pre>	Exits to privileged EXEC mode.

## Verifying NSF/SSO and ISSU Support for MPLS VPN 6VPE and 6PE

Perform this task to verify NSF/SSO and ISSU support for 6VPE and 6PE.

### SUMMARY STEPS

1. `enable`
2. `show ip bgp neighbor`
3. `show ip bgp vpnv6 unicast vrf vrf-name`
4. `show ip bgp ipv6 unicast`
5. `show mpls forwarding`
6. `show ipv6 cef vrf-name`

### DETAILED STEPS

- |               |   |
|---------------|---|
| <b>Step 1</b> | <b>enable</b><br><br>Use this command to enable privileged EXEC mode. Enter your password if prompted. For example:<br><br><pre>Router&gt; enable Router#</pre> |
|---------------|---|

**Step 2** **show ip bgp neighbor**

Use this command to verify that the IPv6 address family and VPNv6 address family entries are preserved. For example:

```
Router# show ip bgp neighbor
```

```
BGP neighbor is 10.2.2.2, remote AS 100, internal link
  BGP version 4, remote router ID 10.2.2.2
  BGP state = Established, up for 00:02:42
  Last read 00:00:36, last write 00:00:36, hold time is 180, keepalive
.
.
.
  Neighbor capabilities:
.
.
.
  Graceful Restart Capability: advertised and received
    Remote Restart timer is 120 seconds
  Address families advertised by peer:
    IPv6 Unicast (was preserved), VPNv6 Unicast (was preserved)
```

IPv6 Unicast (was preserved), VPNv6 Unicast (was preserved) is displayed in the Graceful Restart Capability section of the output only after the peer restarts.

**Step 3** **show ip bgp vpnv6 unicast vrf vrf-name**

Use this command to verify that VPNv6 entries are marked as staled during switchover. For example:

```
Router# show ip bgp vpnv6 unicast vrf vpn1
```

```
BGP table version is 10, local router ID is 10.4.4.4
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
               r RIB-failure, S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete

Network          Next Hop          Metric LocPrf Weight Path
Route Distinguisher: 1:1 (default for vrf vpn1)
S>iA::1/128       ::FFFF:10.2.2.2      0      100      0 200 ?
*> A::5/128       A::4:5:5             0              0 200 ?
S>iA::1:2:0/112   ::FFFF:10.2.2.2      0      100      0 ?
* A::4:5:0/112   A::4:5:5             0              0 200 ?
```

**Step 4** **show ip bgp ipv6 unicast**

Use this command to verify that VPNv6 entries are marked as staled during switchover. For example:

```
Router# show ip bgp ipv6 unicast
```

```
BGP table version is 9, local router ID is 10.1.1.1
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
               r RIB-failure, S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete

Network          Next Hop          Metric LocPrf Weight Path
*> A::1/128       ::              0          32768 ?
S A::1:2:0/112   A::1:2:2        0              0 100 ?
*>               ::              0          32768 ?
S> A::4:5:0/112   A::1:2:2        0              0 100 ?
Router#
```

**Step 5 show mpls forwarding**

Use this command to show preserved forwarding entries for IPv6 and VPNv6 prefixes. The sample output is from a PE router in a CSC configuration. Enter the command on the active and the standby router. Compare the sample output from the active router with the sample output from the standby router. Following is sample output from the active router;

Router# **show mpls forwarding**

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Switched	Label	Outgoing interface	Next Hop
18	Pop Label	10.3.3.3/32	0		Et1/0	10.2.3.3
19	Pop Label	10.3.4.0/24	0		Et1/0	10.2.3.3
20	17	10.4.4.4/32	0		Et1/0	10.2.3.3
21	Pop Label	10.1.2.1/32[V]	0		Et0/0	10.1.2.1
22	Pop Label	A::1:2:0/112[V]	0		aggregate/vpn1	
23	Pop Label	A::1:2:1/128[V]	0		Et0/0	A::1:2:1
24	Pop Label	10.1.2.0/24[V]	0		aggregate/vpn1	
25	Pop Label	A::1:2:2/128[V]	0		aggregate/vpn1	
26	18	A::1/128[V]	0		Et0/0	
FE80::A8BB:CCFF:FE03:2101						
27	26	10.4.5.5/32[V]	0		Et1/0	10.2.3.3
28	25	10.4.5.0/24[V]	0		Et1/0	10.2.3.3
29	22	A::4:5:5/128[V]	0		Et1/0	10.2.3.3
30	21	A::4:5:0/112[V]	0		Et1/0	10.2.3.3
31	23	A::4:5:4/128[V]	0		Et1/0	10.2.3.3
32	24	A::5/128[V]	0		Et1/0	10.2.3.3
33	Pop Label	10.1.2.2/32[V]	0		aggregate/vpn1	
34	Pop Label	10.1.1.1/32[V]	0		Et0/0	10.1.2.1
35	27	10.4.5.4/32[V]	0		Et1/0	10.2.3.3
Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Switched	Label	Outgoing interface	Next Hop
36	28	10.5.5.5/32[V]	0		Et1/0	10.2.3.3

Following is sample output from the standby router:

Standby-Router# **show mpls forwarding**

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Switched	Label	Outgoing interface	Next Hop
18	Pop Label	10.3.3.3/32	0		Et1/0	10.2.3.3
19	Pop Label	10.3.4.0/24	0		Et1/0	10.2.3.3

33	Pop Label	10.1.2.2/32[V]	0		aggregate/vpn1	
34	Pop Label	10.1.1.1/32[V]	0		Et0/0	10.1.2.1
35	27	10.4.5.4/32[V]	0		Et1/0	10.2.3.3
Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Switched	Label	Outgoing interface	Next Hop
36	28	10.5.5.5/32[V]	0		Et1/0	10.2.3.3

**Step 6** **show ipv6 cef vrf *vrf-name***

Use this command to show preserved forwarding entries for IPv6 and VPNv6 prefixes. This sample output is also from a PE router in a CSC configuration. Enter the command on the active and the standby router. Compare the sample output from the active router with the sample output from the standby router. Following is the output from the active router:

```
Router# show ipv6 cef vrf vrf1

::/0
  no route
::/127
  discard
A::1/128
  nexthop FE80::A8BB:CCFF:FE03:2101 Ethernet0/0 label 18
A::5/128
  nexthop 10.2.3.3 Ethernet1/0 label 17 24
A::1:2:0/112
  attached to Ethernet0/0
A::1:2:1/128
  attached to Ethernet0/0
A::1:2:2/128
  receive for Ethernet0/0
A::4:5:0/112
  nexthop 10.2.3.3 Ethernet1/0 label 17 21
A::4:5:4/128
  nexthop 10.2.3.3 Ethernet1/0 label 17 23
A::4:5:5/128
  nexthop 10.2.3.3 Ethernet1/0 label 17 22
FE80::/10
```

Following is sample output from the standby router:

```
Standby-Router# show ipv6 cef vrf vrf1

::/0
  no route
::/127
  discard
A::1/128
  nexthop FE80::A8BB:CCFF:FE03:2101 Ethernet0/0 label 18
A::5/128
  nexthop 10.2.3.3 Ethernet1/0 label 17 24
A::1:2:0/112
  attached to Ethernet0/0
A::1:2:1/128
  attached to Ethernet0/0
A::1:2:2/128

# Configuration Examples for Configuring NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE

This section provides the following configuration examples for PE1 Routers.

- [Configuring NSF/SSO for a Basic 6VPE Setup: Example, page 12](#)
- [Configuring NSF/SSO for a Basic 6PE Setup: Example, page 14](#)

## Configuring NSF/SSO for a Basic 6VPE Setup: Example

This section shows the NSF/SSO configuration for a basic 6VPE setup. [Figure 1](#) show a sample basic 6VPE network configuration.

**Figure 1** Sample Basic 6VPE Network Configuration

## PE1 Configuration in a Basic 6VPE Setup

Following is a configuration example for a PE1 router (see [Figure 1](#)) in a basic 6VPE setup that includes VPNv6 and VPNv6 address families:

```

vrf definition vpn1
  rd 1:1
  route-target export 1:1
  route-target import 1:1
  !
  address-family ipv4
  exit-address-family
  !
  address-family ipv6
  exit-address-family
  !
  !
  ip cef distributed
  !
  ipv6 unicast-routing
  ipv6 cef distributed
  mpls ldp graceful-restart ! <==+ Command to configure LDP Graceful Restart
  mpls label protocol ldp
  redundancy
  mode sso
  interface Loopback0
    ip address 10.2.2.2 255.255.255.255
    ipv6 address A::2/128
  !
  interface Ethernet0/0
    vrf forwarding vpn1
    ip address 10.1.2.2 255.255.255.0
    ipv6 address A::1:2:2/112
  
```

```
!interface Ethernet1/0
 ip address 10.2.3.2 255.255.255.0
 mpls label protocol ldp
 mpls ip
!router ospf 10
 log-adjacency-changes
 nsf
 network 0.0.0.0 255.255.255.255 area 0
!
router bgp 100
 no synchronization
 bgp log-neighbor-changes
 bgp graceful-restart restart-time 120      ! <=== This command,
 bgp graceful-restart stalepath-time 360    ! <=== this command, and
 bgp graceful-restart                      ! <=== this command configures NSF/SSO for a 6VPE router.
 neighbor 10.4.4.4 remote-as 100
 neighbor 10.4.4.4 update-source Loopback0
 no auto-summary
!
 address-family vpnv4
  neighbor 10.4.4.4 activate
  neighbor 10.4.4.4 send-community extended
 exit-address-family
!
 address-family vpnv6
  neighbor 10.4.4.4 activate
  neighbor 10.4.4.4 send-community extended
 exit-address-family
!
 address-family ipv4 vrf vpn1
  no synchronization
  redistribute connected
  redistribute static
  neighbor 10.1.2.1 remote-as 200
  neighbor 10.1.2.1 update-source Ethernet0/0
  neighbor 10.1.2.1 activate
 exit-address-family
!
 address-family ipv6 vrf vpn1
  redistribute connected
  redistribute static
  no synchronization
  neighbor A::1:2:1 remote-as 200
  neighbor A::1:2:1 update-source Ethernet0/0
  neighbor A::1:2:1 activate
 exit-address-family
```

## Configuring NSF/SSO for a Basic 6PE Setup: Example

This section shows the NSF/SSO configuration for a basic 6PE setup. [Figure 2](#) shows a sample basic 6PE network configuration.

**Figure 2** Sample Basic 6PE Network Configuration

### PE1 Configuration in a Basic 6PE Setup

Following is a configuration example for the PE1 router (see [Figure 2](#)) in a basic 6PE setup:

```
ip cef distributed
!
ipv6 unicast-routing
ipv6 cef distributed
mpls ldp graceful-restart ! <=== Command to configure LDP Graceful Restart
mpls label protocol ldp
redundancy
mode sso

interface Loopback0
 ip address 10.11.11.1 255.255.255.255
 ipv6 address BEEF:11::1/64
interface Ethernet0/0
 ip address 10.50.1.2 255.255.255.0
 ipv6 address 4000::72B/64
 ipv6 address 8008::72B/64
!
interface Ethernet1/0
 ip address 10.40.1.2 255.255.255.0
 mpls ip
!
router ospf
 nsf
 network 0.0.0.0 0.0.0.0 area 0
!
router bgp 100
 bgp log-neighbor-changes
 bgp graceful-restart restart-time 120 ! <=== This command,
 bgp graceful-restart stalepath-time 360 ! <=== this command, and
 bgp graceful-restart ! <=== this command configures NSF/SSO for a 6PE
router.
 neighbor 8008::72A remote-as 200
 neighbor 10.10.10.1 remote-as 100
 neighbor 10.10.10.1 update-source Loopback0
!
address-family ipv4
 no synchronization
 redistribute connected
 no neighbor 8008::72A activate
 neighbor 10.10.10.1 activate
 no auto-summary
exit-address-family
```

```

!
address-family ipv6
 redistribute connected
 no synchronization
 neighbor 8008::72A activate
 neighbor 10.10.10.1 activate
 neighbor 10.10.10.1 send-label
 exit-address-family

```

# Feature Information for NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE

[Table 1](#) lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Note

[Table 1](#) lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1** Feature Information for NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE

Feature Name	Releases	Feature Information
ISSU—MPLS VPN 6VPE and 6PE ISSU Support	12.2(33)SRE 12.2(33)XNE	<p>This feature provides In Service Software Upgrade (ISSU) support for Cisco IOS Virtual Private Network (VPN) IPv6 provider edge router (6VPE) over Multiprotocol Label Switching (MPLS) and Cisco IOS IPv6 provider edge router (6PE) over MPLS.</p> <p>In 12.2(33)SRE, this feature was introduced on the Cisco 7600 series routers.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li><a href="#">Elements Supporting NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE Features, page 3</a></li> <li><a href="#">ISSU Support for MPLS VPN 6vPE and 6PE, page 4</a></li> </ul> <p>This feature introduced no new or modified commands.</p>

**Table 1**      **Feature Information for NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE (continued)**

Feature Name	Releases	Feature Information
SSO—MPLS VPN 6VPE and 6PE SSO Support	12.2(33)SRE 12.2(33)XNE	<p>This feature provides stateful switchover (SSO) support for Cisco IOS Virtual Private Network (VPN) IPv6 provider edge router (6VPE) over Multiprotocol Label Switching (MPLS) and Cisco IOS IPv6 provider edge router (6PE) over MPLS.</p> <p>In 12.2(33)SRE, this feature was introduced on the Cisco 7600 series routers.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">Elements Supporting NSF/SSO and ISSU—MPLS VPN 6VPE and 6PE Features, page 3</a></li> <li>• <a href="#">How BGP Graceful Restart Works for MPLS VPN 6vPE and 6PE, page 3</a></li> <li>• <a href="#">How BGP Graceful Restart Preserves Prefix Information During a Restart, page 3</a></li> <li>• <a href="#">NSF/SSO Support for MPLS VPN 6VPE and 6PE, page 4</a></li> <li>• <a href="#">BGP Graceful Restart Support for MPLS VPN Configurations, page 5</a></li> </ul> <p>This feature introduced no new or modified commands.</p>

# Glossary

**6PE router**—IPv6 provider edge (PE) router. A router running a Border Gateway Protocol (BGP)-based mechanism to interconnect IPv6 islands over a Multiprotocol Label Switching (MPLS)-enabled IPv4 cloud.

**6VPE router**—Provider edge router providing Border Gateway Protocol (BGP)-Multiprotocol Label Switching (MPLS) IPv6 Virtual Private Network (VPN) service over an IPv4-based MPLS core. It is a IPv6 VPN provider edge (PE), dual-stack router that implements 6PE concepts on the core-facing interfaces.

**BGP**—Border Gateway Protocol. An interdomain routing protocol designed for the global Internet. Exterior Border Gateway Protocols (eBGPs) communicate among different autonomous systems. Interior Border Gateway Protocols (iBGPs) communicate among routers within a single autonomous system.

**CE router**—customer edge router. A router that is part of a customer network and interfaces to a provider edge (PE) router.

**Cisco Express Forwarding**—An advanced Layer 3 IP switching technology. It optimizes network performance and scalability for all kinds of networks.

**eBGP**—external Border Gateway Protocol.

**graceful restart**—A process for helping an RP restart after a node failure has occurred.

**iBGP**—Interior Border Gateway Protocol.

**ISSU**—In Service Software Upgrade. Software upgrade without service interruption.

**LDP**—Label Distribution Protocol. A standard protocol between Multiprotocol Label Switching (MPLS)-enabled routers to negotiate the labels (addresses) used to forward packets.

**MPLS**—Multiprotocol Label Switching. A switching method that forwards IP traffic using a label. This label instructs the routers and switches in the network where to forward the packets based on preestablished IP routing information.

**NSF**—nonstop forwarding. The ability of a router to continue to forward traffic to a router that may be recovering from a failure. Also, the ability of a router recovering from a failure to continue to correctly forward traffic sent to it by a peer.

**PE router**—provider edge router. The PE router is the entry point into the service provider network. The PE router is typically deployed on the edge of the network and is administered by the service provider. The PE router is the redistribution point between EIGRP and BGP in PE to CE networking.

**RIB**—Routing Information Base. Also called the routing table.

**SSO**—stateful switchover. SSO refers to the implementation of Cisco IOS software that allows applications and features to maintain a defined state between an active and standby RP. When a switchover occurs, forwarding and sessions are maintained. Along with NSF, SSO makes an RP failure undetectable to the network.

**VPN**—Virtual Private Network. Enables IP traffic to travel securely over a public TCP/IP network by encrypting traffic from one network to another. A VPN uses tunneling to encrypt all information at the IP level.

**VRF**—Virtual Private Network (VPN) routing and forwarding instance. A VRF consists of an IP routing table, a derived routing table, a set of interfaces that use the forwarding table, and a set of rules and routing information that defines a customer VPN site that is attached to a provider edge (PE) router.
