About Cisco IOS and Cisco IOS XE Software Documentation

Last updated: December 10, 2008

This document describes the objectives, audience, conventions, and organization used in Cisco IOS and Cisco IOS XE software documentation, collectively referred to in this document as Cisco IOS documentation. Also included are resources for obtaining technical assistance, additional documentation, and other information from Cisco. This document is organized into the following sections:

- [Documentation Objectives, page i](#)
- [Audience, page i](#)
- [Documentation Conventions, page ii](#)
- [Documentation Organization, page iii](#)
- [Additional Resources and Documentation Feedback, page xi](#)

Documentation Objectives

Cisco IOS documentation describes the tasks and commands available to configure and maintain Cisco networking devices.

Audience

The Cisco IOS documentation set is intended for users who configure and maintain Cisco networking devices (such as routers and switches) but who may not be familiar with the configuration and maintenance tasks, the relationship among tasks, or the Cisco IOS commands necessary to perform particular tasks. The Cisco IOS documentation set is also intended for those users experienced with Cisco IOS who need to know about new features, new configuration options, and new software characteristics in the current Cisco IOS release.

Documentation Conventions

In Cisco IOS documentation, the term *router* may be used to refer to various Cisco products; for example, routers, access servers, and switches. These and other networking devices that support Cisco IOS software are shown interchangeably in examples and are used only for illustrative purposes. An example that shows one product does not necessarily mean that other products are not supported.

This section includes the following topics:

- [Typographic Conventions, page ii](#)
- [Command Syntax Conventions, page ii](#)
- [Software Conventions, page iii](#)
- [Reader Alert Conventions, page iii](#)

Typographic Conventions

Cisco IOS documentation uses the following typographic conventions:

Convention	Description
[^] or Ctrl	Both the [^] symbol and Ctrl represent the Control (Ctrl) key on a keyboard. For example, the key combination ^D or Ctrl-D means that you hold down the Control key while you press the D key. (Keys are indicated in capital letters but are not case sensitive.)
<i>string</i>	A string is a nonquoted set of characters shown in italics. For example, when setting a Simple Network Management Protocol (SNMP) community string to <i>public</i> , do not use quotation marks around the string; otherwise, the string will include the quotation marks.

Command Syntax Conventions

Cisco IOS documentation uses the following command syntax conventions:

Convention	Description
bold	Bold text indicates commands and keywords that you enter as shown.
<i>italic</i>	Italic text indicates arguments for which you supply values.
[x]	Square brackets enclose an optional keyword or argument.
...	An ellipsis (three consecutive nonbolded periods without spaces) after a syntax element indicates that the element can be repeated.
	A vertical line, called a pipe, indicates a choice within a set of keywords or arguments.
[x y]	Square brackets enclosing keywords or arguments separated by a pipe indicate an optional choice.
{x y}	Braces enclosing keywords or arguments separated by a pipe indicate a required choice.
[x {y z}]	Braces and a pipe within square brackets indicate a required choice within an optional element.

Software Conventions

Cisco IOS uses the following program code conventions:

Convention	Description
Courier font	Courier font is used for information that is displayed on a PC or terminal screen.
Bold Courier font	Bold Courier font indicates text that the user must enter.
< >	Angle brackets enclose text that is not displayed, such as a password. Angle brackets also are used in contexts in which the italic font style is not supported; for example, ASCII text.
!	An exclamation point at the beginning of a line indicates that the text that follows is a comment, not a line of code. An exclamation point is also displayed by Cisco IOS software for certain processes.
[]	Square brackets enclose default responses to system prompts.

Reader Alert Conventions

The Cisco IOS documentation set uses the following conventions for reader alerts:

Caution

Means *reader be careful*. In this situation, you might do something that could result in equipment damage or loss of data.

Note

Means *reader take note*. Notes contain helpful suggestions or references to material not covered in the manual.

Timesaver

Means *the described action saves time*. You can save time by performing the action described in the paragraph.

Documentation Organization

This section describes the Cisco IOS documentation set, how it is organized, and how to access it on Cisco.com. Included are lists of configuration guides, command references, and supplementary references and resources that make up the documentation set. The following topics are included:

- [Cisco IOS Documentation Set, page iv](#)
- [Cisco IOS Documentation on Cisco.com, page iv](#)
- [Configuration Guides, Command References, and Supplementary Resources, page v](#)

Cisco IOS Documentation Set

Cisco IOS documentation consists of the following:

- Release notes and caveats provide information about platform, technology, and feature support for a release and describe severity 1 (catastrophic), severity 2 (severe), and severity 3 (moderate) defects in released Cisco IOS code. Review release notes before other documents to learn whether or not updates have been made to a feature.
- Sets of configuration guides and command references organized by technology and published for each standard Cisco IOS release.
 - Configuration guides—Compilations of documents that provide informational and task-oriented descriptions of Cisco IOS features.
 - Command references—Compilations of command pages that provide detailed information about the commands used in the Cisco IOS features and processes that make up the related configuration guides. For each technology, there is a single command reference that covers all Cisco IOS releases and that is updated at each standard release.
- Lists of all the commands in a specific release and all commands that are new, modified, removed, or replaced in the release.
- Command reference book for **debug** commands. Command pages are listed in alphabetical order.
- Reference book for system messages for all Cisco IOS releases.

Cisco IOS Documentation on Cisco.com

The following sections describe the documentation organization and how to access various document types.

Use Cisco Feature Navigator to find information about platform support and Cisco IOS, Cisco IOS XE, and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

New Features List

The New Features List for each release provides a list of all features in the release with hyperlinks to the feature guides in which they are documented.

Feature Guides

Cisco IOS features are documented in feature guides. Feature guides describe one feature or a group of related features that are supported on many different software releases and platforms. Your Cisco IOS software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in that guide are supported in your software release.

Configuration Guides

Configuration guides are provided by technology and release and comprise a set of individual feature guides relevant to the release and technology.

Command References

Command reference books describe Cisco IOS commands that are supported in many different software releases and on many different platforms. The books are provided by technology. For information about all Cisco IOS commands, use the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the *Cisco IOS Master Command List, All Releases*, at http://www.cisco.com/en/US/docs/ios/mcl/allreleasemcl/all_book.html.

Cisco IOS Supplementary Documents and Resources

Supplementary documents and resources are listed in [Table 2 on page xi](#).

Configuration Guides, Command References, and Supplementary Resources

[Table 1](#) lists, in alphabetical order, Cisco IOS and Cisco IOS XE software configuration guides and command references, including brief descriptions of the contents of the documents. The Cisco IOS command references are comprehensive, meaning that they include commands for both Cisco IOS software and Cisco IOS XE software, for all releases. The configuration guides and command references support many different software releases and platforms. Your Cisco IOS software release or platform may not support all these technologies.

For additional information about configuring and operating specific networking devices, go to the Product Support area of Cisco.com at <http://www.cisco.com/web/psa/products/index.html>.

[Table 2](#) lists documents and resources that supplement the Cisco IOS software configuration guides and command references. These supplementary resources include release notes and caveats; master command lists; new, modified, removed, and replaced command lists; system messages; and the debug command reference.

Table 1 Cisco IOS and Cisco IOS XE Configuration Guides and Command References

Configuration Guide and Command Reference Titles	Features/Protocols/Technologies
<i>Cisco IOS AppleTalk Configuration Guide</i>	AppleTalk protocol.
<i>Cisco IOS XE AppleTalk Configuration Guide</i>	
<i>Cisco IOS AppleTalk Command Reference</i>	
<i>Cisco IOS Asynchronous Transfer Mode Configuration Guide</i>	LAN ATM, multiprotocol over ATM (MPoA), and WAN ATM.
<i>Cisco IOS Asynchronous Transfer Mode Command Reference</i>	

Table 1 Cisco IOS and Cisco IOS XE Configuration Guides and Command References (continued)

Configuration Guide and Command Reference Titles	Features/Protocols/Technologies
<i>Cisco IOS Bridging and IBM Networking Configuration Guide</i> <i>Cisco IOS Bridging Command Reference</i> <i>Cisco IOS IBM Networking Command Reference</i>	- Transparent and source-route transparent (SRT) bridging, source-route bridging (SRB), Token Ring Inter-Switch Link (TRISL), and token ring route switch module (TRRSM). - Data-link switching plus (DLSw+), serial tunnel (STUN), block serial tunnel (BSTUN); logical link control, type 2 (LLC2), synchronous data link control (SDLC); IBM Network Media Translation, including Synchronous Data Logical Link Control (SDLLC) and qualified LLC (QLLC); downstream physical unit (DSPU), Systems Network Architecture (SNA) service point, SNA frame relay access, advanced peer-to-peer networking (APPN), native client interface architecture (NCIA) client/server topologies, and IBM Channel Attach.
<i>Cisco IOS Broadband and DSL Configuration Guide</i> <i>Cisco IOS XE Broadband and DSL Configuration Guide</i> <i>Cisco IOS Broadband and DSL Command Reference</i>	Point-to-Point Protocol (PPP) over ATM (PPPoA) and PPP over Ethernet (PPPoE).
<i>Cisco IOS Carrier Ethernet Configuration Guide</i> <i>Cisco IOS Carrier Ethernet Command Reference</i>	Connectivity fault management (CFM), Ethernet Local Management Interface (ELMI), IEEE 802.3ad link bundling, Link Layer Discovery Protocol (LLDP), media endpoint discovery (MED), and operations, administration, and maintenance (OAM).
<i>Cisco IOS Configuration Fundamentals Configuration Guide</i> <i>Cisco IOS XE Configuration Fundamentals Configuration Guide</i> <i>Cisco IOS Configuration Fundamentals Command Reference</i>	Autoinstall, Setup, Cisco IOS command-line interface (CLI), Cisco IOS file system (IFS), Cisco IOS web browser user interface (UI), basic file transfer services, and file management.
<i>Cisco IOS DECnet Configuration Guide</i> <i>Cisco IOS XE DECnet Configuration Guide</i> <i>Cisco IOS DECnet Command Reference</i>	DECnet protocol.
<i>Cisco IOS Dial Technologies Configuration Guide</i> <i>Cisco IOS XE Dial Technologies Configuration Guide</i> <i>Cisco IOS Dial Technologies Command Reference</i>	Asynchronous communications, dial backup, dialer technology, dial-in terminal services and AppleTalk remote access (ARA), large scale dialout, dial-on-demand routing, dialout, modem and resource pooling, ISDN, multilink PPP (MLP), PPP, virtual private dialup network (VPDN).
<i>Cisco IOS Flexible NetFlow Configuration Guide</i> <i>Cisco IOS Flexible NetFlow Command Reference</i>	Flexible NetFlow.

Table 1 Cisco IOS and Cisco IOS XE Configuration Guides and Command References (continued)

Configuration Guide and Command Reference Titles	Features/Protocols/Technologies
<i>Cisco IOS H.323 Configuration Guide</i>	Gatekeeper enhancements for managed voice services, Gatekeeper Transaction Message Protocol, gateway codec order preservation and shutdown control, H.323 dual tone multifrequency relay, H.323 version 2 enhancements, Network Address Translation (NAT) support of H.323 v2 Registration, Admission, and Status (RAS) protocol, tokenless call authorization, and VoIP gateway trunk and carrier-based routing.
<i>Cisco IOS High Availability Configuration Guide</i> <i>Cisco IOS XE High Availability Configuration Guide</i> <i>Cisco IOS High Availability Command Reference</i>	A variety of High Availability (HA) features and technologies that are available for different network segments (from enterprise access to service provider core) to facilitate creation of end-to-end highly available networks. Cisco IOS HA features and technologies can be categorized in three key areas: system-level resiliency, network-level resiliency, and embedded management for resiliency.
<i>Cisco IOS Integrated Session Border Controller Command Reference</i>	A VoIP-enabled device that is deployed at the edge of networks. An SBC is a toolkit of functions, such as signaling interworking, network hiding, security, and quality of service (QoS).
<i>Cisco IOS Intelligent Services Gateway Configuration Guide</i> <i>Cisco IOS Intelligent Services Gateway Command Reference</i>	Subscriber identification, service and policy determination, session creation, session policy enforcement, session life-cycle management, accounting for access and service usage, session state monitoring.
<i>Cisco IOS Interface and Hardware Component Configuration Guide</i> <i>Cisco IOS XE Interface and Hardware Component Configuration Guide</i> <i>Cisco IOS Interface and Hardware Component Command Reference</i>	LAN interfaces, logical interfaces, serial interfaces, virtual interfaces, and interface configuration.
<i>Cisco IOS IP Addressing Services Configuration Guide</i> <i>Cisco IOS XE Addressing Services Configuration Guide</i> <i>Cisco IOS IP Addressing Services Command Reference</i>	Address Resolution Protocol (ARP), Network Address Translation (NAT), Domain Name System (DNS), Dynamic Host Configuration Protocol (DHCP), and Next Hop Address Resolution Protocol (NHRP).
<i>Cisco IOS IP Application Services Configuration Guide</i> <i>Cisco IOS XE IP Application Services Configuration Guide</i> <i>Cisco IOS IP Application Services Command Reference</i>	Enhanced Object Tracking (EOT), Gateway Load Balancing Protocol (GLBP), Hot Standby Router Protocol (HSRP), IP Services, Server Load Balancing (SLB), Stream Control Transmission Protocol (SCTP), TCP, Web Cache Communication Protocol (WCCP), User Datagram Protocol (UDP), and Virtual Router Redundancy Protocol (VRRP).
<i>Cisco IOS IP Mobility Configuration Guide</i> <i>Cisco IOS IP Mobility Command Reference</i>	Mobile ad hoc networks (MANet) and Cisco mobile networks.
<i>Cisco IOS IP Multicast Configuration Guide</i> <i>Cisco IOS XE IP Multicast Configuration Guide</i> <i>Cisco IOS IP Multicast Command Reference</i>	Protocol Independent Multicast (PIM) sparse mode (PIM-SM), bidirectional PIM (bidir-PIM), Source Specific Multicast (SSM), Multicast Source Discovery Protocol (MSDP), Internet Group Management Protocol (IGMP), and Multicast VPN (MVPN).

Table 1 Cisco IOS and Cisco IOS XE Configuration Guides and Command References (continued)

Configuration Guide and Command Reference Titles	Features/Protocols/Technologies
<i>Cisco IOS IP Routing Protocols Configuration Guide</i> <i>Cisco IOS XE IP Routing Protocols Configuration Guide</i> <i>Cisco IOS IP Routing Protocols Command Reference</i>	Border Gateway Protocol (BGP), multiprotocol BGP, multiprotocol BGP extensions for IP multicast, bidirectional forwarding detection (BFD), Enhanced Interior Gateway Routing Protocol (EIGRP), Interior Gateway Routing Protocol (IGRP), Intermediate System-to-Intermediate System (IS-IS), on-demand routing (ODR), Open Shortest Path First (OSPF), and Routing Information Protocol (RIP).
<i>Cisco IOS IP SLAs Configuration Guide</i> <i>Cisco IOS XE IP SLAs Configuration Guide</i> <i>Cisco IOS IP SLAs Command Reference</i>	Cisco IOS IP Service Level Agreements (IP SLAs).
<i>Cisco IOS IP Switching Configuration Guide</i> <i>Cisco IOS XE IP Switching Configuration Guide</i> <i>Cisco IOS IP Switching Command Reference</i>	Cisco Express Forwarding, fast switching, and Multicast Distributed Switching (MDS).
<i>Cisco IOS IPv6 Configuration Guide</i> <i>Cisco IOS XE IPv6 Configuration Guide</i> <i>Cisco IOS IPv6 Command Reference</i>	For IPv6 features, protocols, and technologies, go to the IPv6 “Start Here” document at the following URL: http://www.cisco.com/en/US/docs/ios/ipv6/configuration/guide/ip6-roadmap.html
<i>Cisco IOS ISO CLNS Configuration Guide</i> <i>Cisco IOS XE ISO CLNS Configuration Guide</i> <i>Cisco IOS ISO CLNS Command Reference</i>	ISO connectionless network service (CLNS).
<i>Cisco IOS LAN Switching Configuration Guide</i> <i>Cisco IOS XE LAN Switching Configuration Guide</i> <i>Cisco IOS LAN Switching Command Reference</i>	VLANs, Inter-Switch Link (ISL) encapsulation, IEEE 802.10 encapsulation, IEEE 802.1Q encapsulation, and multilayer switching (MLS).
<i>Cisco IOS Mobile Wireless Gateway GPRS Support Node Configuration Guide</i> <i>Cisco IOS Mobile Wireless Gateway GPRS Support Node Command Reference</i>	Cisco IOS Gateway GPRS Support Node (GGSN) in a 2.5-generation general packet radio service (GPRS) and 3-generation universal mobile telecommunication system (UMTS) network.
<i>Cisco IOS Mobile Wireless Home Agent Configuration Guide</i> <i>Cisco IOS Mobile Wireless Home Agent Command Reference</i>	Cisco Mobile Wireless Home Agent, an anchor point for mobile terminals for which mobile IP or proxy mobile IP services are provided.
<i>Cisco IOS Mobile Wireless Packet Data Serving Node Configuration Guide</i> <i>Cisco IOS Mobile Wireless Packet Data Serving Node Command Reference</i>	Cisco Packet Data Serving Node (PDSN), a wireless gateway that is between the mobile infrastructure and standard IP networks and that enables packet data services in a code division multiple access (CDMA) environment.
<i>Cisco IOS Mobile Wireless Radio Access Networking Configuration Guide</i> <i>Cisco IOS Mobile Wireless Radio Access Networking Command Reference</i>	Cisco IOS radio access network products.

Table 1 Cisco IOS and Cisco IOS XE Configuration Guides and Command References (continued)

Configuration Guide and Command Reference Titles	Features/Protocols/Technologies
<i>Cisco IOS Multiprotocol Label Switching Configuration Guide</i> <i>Cisco IOS XE Multiprotocol Label Switching Configuration Guide</i> <i>Cisco IOS Multiprotocol Label Switching Command Reference</i>	MPLS Label Distribution Protocol (LDP), MPLS Layer 2 VPNs, MPLS Layer 3 VPNs, MPLS Traffic Engineering (TE), and MPLS Embedded Management (EM) and MIBs.
<i>Cisco IOS Multi-Topology Routing Configuration Guide</i> <i>Cisco IOS Multi-Topology Routing Command Reference</i>	Unicast and multicast topology configurations, traffic classification, routing protocol support, and network management support.
<i>Cisco IOS NetFlow Configuration Guide</i> <i>Cisco IOS XE NetFlow Configuration Guide</i> <i>Cisco IOS NetFlow Command Reference</i>	Network traffic data analysis, aggregation caches, export features.
<i>Cisco IOS Network Management Configuration Guide</i> <i>Cisco IOS XE Network Management Configuration Guide</i> <i>Cisco IOS Network Management Command Reference</i>	Basic system management; system monitoring and logging; troubleshooting, logging, and fault management; Cisco Discovery Protocol; Cisco IOS Scripting with Tool Control Language (Tcl); Cisco networking services (CNS); DistributedDirector; Embedded Event Manager (EEM); Embedded Resource Manager (ERM); Embedded Syslog Manager (ESM); HTTP; Remote Monitoring (RMON); SNMP; and VPN Device Manager Client for Cisco IOS Software (XSM Configuration).
<i>Cisco IOS Novell IPX Configuration Guide</i> <i>Cisco IOS XE Novell IPX Configuration Guide</i> <i>Cisco IOS Novell IPX Command Reference</i>	Novell Internetwork Packet Exchange (IPX) protocol.
<i>Cisco IOS Optimized Edge Routing Configuration Guide</i> <i>Cisco IOS Optimized Edge Routing Command Reference</i>	Optimized edge routing (OER) monitoring, policy configuration, routing control, logging and reporting, and VPN IPsec/generic routing encapsulation (GRE) tunnel interface optimization.
<i>Cisco IOS Quality of Service Solutions Configuration Guide</i> <i>Cisco IOS XE Quality of Service Solutions Configuration Guide</i> <i>Cisco IOS Quality of Service Solutions Command Reference</i>	Class-based weighted fair queuing (CBWFQ), custom queuing, distributed traffic shaping (DTS), generic traffic shaping (GTS), IP- to-ATM class of service (CoS), low latency queuing (LLQ), modular QoS CLI (MQC), Network-Based Application Recognition (NBAR), priority queuing, Security Device Manager (SDM), Multilink PPP (MLPPP) for QoS, header compression, AutoQoS, QoS features for voice, Resource Reservation Protocol (RSVP), weighted fair queuing (WFQ), and weighted random early detection (WRED).
<i>Cisco IOS Security Configuration Guide</i> <i>Cisco IOS XE Security Configuration Guide</i> <i>Cisco IOS Security Command Reference</i>	Access control lists (ACLs), authentication, authorization, and accounting (AAA), firewalls, IP security and encryption, neighbor router authentication, network access security, network data encryption with router authentication, public key infrastructure (PKI), RADIUS, TACACS+, terminal access security, and traffic filters.

Table 1 Cisco IOS and Cisco IOS XE Configuration Guides and Command References (continued)

Configuration Guide and Command Reference Titles	Features/Protocols/Technologies
<i>Cisco IOS Service Selection Gateway Configuration Guide</i> <i>Cisco IOS Service Selection Gateway Command Reference</i>	Subscriber authentication, service access, and accounting.
<i>Cisco IOS Software Activation Configuration Guide</i> <i>Cisco IOS Software Activation Command Reference</i>	An orchestrated collection of processes and components to activate Cisco IOS software feature sets by obtaining and validating Cisco software licenses.
<i>Cisco IOS Software Modularity Installation and Configuration Guide</i> <i>Cisco IOS Software Modularity Command Reference</i>	Installation and basic configuration of software modularity images, including installations on single and dual route processors, installation rollbacks, software modularity binding, software modularity processes and patches.
<i>Cisco IOS Terminal Services Configuration Guide</i> <i>Cisco IOS Terminal Services Command Reference</i> <i>Cisco IOS XE Terminal Services Command Reference</i>	DEC, local-area transport (LAT), and X.25 packet assembler/disassembler (PAD).
<i>Cisco IOS Virtual Switch Command Reference</i>	Virtual switch redundancy, high availability, and packet handling; converting between standalone and virtual switch modes; virtual switch link (VSL); Virtual Switch Link Protocol (VSLP). Note For information about virtual switch configuration, refer to the product-specific software configuration information for the Cisco Catalyst 6500 series switch or for the Metro Ethernet 6500 series switch.
<i>Cisco IOS Voice Configuration Library</i> <i>Cisco IOS Voice Command Reference</i>	Cisco IOS support for voice call control protocols, interoperability, physical and virtual interface management, and troubleshooting. The library includes documentation for IP telephony applications.
<i>Cisco IOS VPDN Configuration Guide</i> <i>Cisco IOS XE VPDN Configuration Guide</i> <i>Cisco IOS VPDN Command Reference</i>	Layer 2 Tunneling Protocol (L2TP) dial-out load balancing and redundancy, L2TP extended failover, L2TP security VPDN, multihop by Dialed Number Identification Service (DNIS), timer and retry enhancements for L2TP and Layer 2 Forwarding (L2F), RADIUS Attribute 82: tunnel assignment ID, shell-based authentication of VPDN users, tunnel authentication via RADIUS on tunnel terminator.
<i>Cisco IOS Wide-Area Networking Configuration Guide</i> <i>Cisco IOS XE Wide-Area Networking Configuration Guide</i> <i>Cisco IOS Wide-Area Networking Command Reference</i>	Frame Relay, Layer 2 Tunneling Protocol Version 3 (L2TPv3), Link Access Procedure, Balanced (LAPB), Switched Multimegabit Data Service (SMDS), and X.25.
<i>Cisco IOS Wireless LAN Configuration Guide</i> <i>Cisco IOS Wireless LAN Command Reference</i>	Broadcast key rotation, IEEE 802.11x support, IEEE 802.1x authenticator, IEEE 802.1x local authentication service for Extensible Authentication Protocol-Flexible Authentication via Secure Tunneling (EAP-FAST), Multiple Basic Service Set ID (BSSID), Wi-Fi Multimedia (WMM) required elements, and Wi-Fi Protected Access (WPA).

Table 2 Cisco IOS Supplementary Documents and Resources

Document Title	Description
<i>Cisco IOS Master Command List, All Releases</i>	Alphabetical list of all the commands documented in all Cisco IOS releases.
<i>Cisco IOS New, Modified, Removed, and Replaced Commands</i>	List of all the new, modified, removed, and replaced commands for a Cisco IOS release.
<i>Cisco IOS Software System Messages</i>	List of Cisco IOS system messages and descriptions. System messages may indicate problems with your system; be informational only; or may help diagnose problems with communications lines, internal hardware, or the system software.
<i>Cisco IOS Debug Command Reference</i>	Alphabetical list of debug commands including brief descriptions of use, command syntax, and usage guidelines.
Release Notes and Caveats	Information about new and changed features, system requirements, and other useful information about specific software releases; information about defects in specific Cisco IOS software releases.
MIBs	Files used for network monitoring. To locate and download MIBs for selected platforms, Cisco IOS releases, and feature sets, use Cisco MIB Locator at the following URL: http://www.cisco.com/go/mibs
RFCs	Standards documents maintained by the Internet Engineering Task Force (IETF) that Cisco IOS documentation references where applicable. The full text of referenced RFCs may be obtained at the following URL: http://www.rfc-editor.org/

Additional Resources and Documentation Feedback

What's New in Cisco Product Documentation is published monthly and describes all new and revised Cisco technical documentation. The *What's New in Cisco Product Documentation* publication also provides information about obtaining the following resources:

- Technical documentation
- Cisco product security overview
- Product alerts and field notices
- Technical assistance

Cisco IOS technical documentation includes embedded feedback forms where you can rate documents and provide suggestions for improvement. Your feedback helps us improve our documentation.

CCDE, CCENT, Cisco Eos, Cisco Lumin, Cisco Nexus, Cisco StadiumVision, Cisco TelePresence, Cisco WebEx, the Cisco logo, DCE, and Welcome to the Human Network are trademarks; Changing the Way We Work, Live, Play, and Learn and Cisco Store are service marks; and Access Registrar, Aironet, AsyncOS, Bringing the Meeting To You, Catalyst, CCDA, CCDP, CCIE, CCIP, CCNA, CCNP, CCSP, CCVP, Cisco, the Cisco Certified Internetwork Expert logo, Cisco IOS, Cisco Press, Cisco Systems, Cisco Systems Capital, the Cisco Systems logo, Cisco Unity, Collaboration Without Limitation, EtherFast, EtherSwitch, Event Center, Fast Step, Follow Me Browsing, FormShare, GigaDrive, HomeLink, Internet Quotient, IOS, iPhone, iQuick Study, IronPort, the IronPort logo, LightStream, Linksys, MediaTone, MeetingPlace, MeetingPlace Chime Sound, MGX, Networkers, Networking Academy, Network Registrar, PCNow, PIX, PowerPanels, ProConnect, ScriptShare, SenderBase, SMARTnet, Spectrum Expert, StackWise, The Fastest Way to Increase Your Internet Quotient, TransPath, WebEx, and the WebEx logo are registered trademarks of Cisco Systems, Inc. and/or its affiliates in the United States and certain other countries.

Using the Command-Line Interface in Cisco IOS and Cisco IOS XE Software

Last updated: December 10, 2008

This document provides basic information about the command-line interface (CLI) in Cisco IOS and Cisco IOS XE software and how you can use some of the CLI features. This document contains the following sections:

- [Initially Configuring a Device, page i](#)
- [Using the CLI, page ii](#)
- [Saving Changes to a Configuration, page xii](#)
- [Additional Information, page xii](#)

For more information about using the CLI, see the “[Using the Cisco IOS Command-Line Interface](#)” section of the *Cisco IOS Configuration Fundamentals Configuration Guide*.

For information about the software documentation set, see the “[About Cisco IOS and Cisco IOS XE Software Documentation](#)” document.

Initially Configuring a Device

Initially configuring a device varies by platform. For information about performing an initial configuration, see the hardware installation documentation that is provided with the original packaging of the product or go to the Product Support area of Cisco.com at <http://www.cisco.com/web/psa/products/index.html>.

After you have performed the initial configuration and connected the device to your network, you can configure the device by using the console port or a remote access method, such as Telnet or Secure Shell (SSH), to access the CLI or by using the configuration method provided on the device, such as Security Device Manager.

Changing the Default Settings for a Console or AUX Port

There are only two changes that you can make to a console port and an AUX port:

- Change the port speed with the **config-register 0x** command. Changing the port speed is not recommended. The well-known default speed is 9600.
- Change the behavior of the port; for example, by adding a password or changing the timeout value.

**Note**

The AUX port on the Route Processor (RP) installed in a Cisco ASR1000 series router does not serve any useful customer purpose and should be accessed only under the advisement of a customer support representative.

Using the CLI

This section describes the following topics:

- [Understanding Command Modes, page ii](#)
- [Using the Interactive Help Feature, page v](#)
- [Understanding Command Syntax, page vi](#)
- [Understanding Enable and Enable Secret Passwords, page viii](#)
- [Using the Command History Feature, page viii](#)
- [Abbreviating Commands, page ix](#)
- [Using Aliases for CLI Commands, page ix](#)
- [Using the no and default Forms of Commands, page x](#)
- [Using the debug Command, page x](#)
- [Filtering Output Using Output Modifiers, page x](#)
- [Understanding CLI Error Messages, page xi](#)

Understanding Command Modes

The CLI command mode structure is hierarchical, and each mode supports a set of specific commands. This section describes the most common of the many modes that exist.

[Table 1](#) lists common command modes with associated CLI prompts, access and exit methods, and a brief description of how each mode is used.

Table 1 *CLI Command Modes*

Command Mode	Access Method	Prompt	Exit Method	Mode Usage
User EXEC	Log in.	Router>	Issue the logout or exit command.	• Change terminal settings. • Perform basic tests. • Display device status.
Privileged EXEC	From user EXEC mode, issue the enable command.	Router#	Issue the disable command or the exit command to return to user EXEC mode.	• Issue show and debug commands. • Copy images to the device. • Reload the device. • Manage device configuration files. • Manage device file systems.
Global configuration	From privileged EXEC mode, issue the configure terminal command.	Router(config)#	Issue the exit command or the end command to return to privileged EXEC mode.	Configure the device.
Interface configuration	From global configuration mode, issue the interface command.	Router(config-if)#	Issue the exit command to return to global configuration mode or the end command to return to privileged EXEC mode.	Configure individual interfaces.
Line configuration	From global configuration mode, issue the line vty or line console command.	Router(config-line)#	Issue the exit command to return to global configuration mode or the end command to return to privileged EXEC mode.	Configure individual terminal lines.

Table 1 CLI Command Modes (continued)

Command Mode	Access Method	Prompt	Exit Method	Mode Usage
ROM monitor	From privileged EXEC mode, issue the reload command. Press the Break key during the first 60 seconds while the system is booting.	rommon # > The # symbol represents the line number and increments at each prompt.	Issue the continue command.	- Run as the default operating mode when a valid image cannot be loaded. - Access the fall-back procedure for loading an image when the device lacks a valid image and cannot be booted. - Perform password recovery when a CTRL-Break sequence is issued within 60 seconds of a power-on or reload event.
Diagnostic (available only on the Cisco ASR1000 series router)	The router boots or enters diagnostic mode in the following scenarios. When a Cisco IOS process or processes fail, in most scenarios the router will reload. - A user-configured access policy was configured using the transport-map command, which directed the user into diagnostic mode. - The router was accessed using an RP auxiliary port. - A break signal (Ctrl-C, Ctrl-Shift-6, or the send break command) was entered, and the router was configured to enter diagnostic mode when the break signal was received.	Router(diag) #	If a Cisco IOS process failure is the reason for entering diagnostic mode, the failure must be resolved and the router must be rebooted to exit diagnostic mode. If the router is in diagnostic mode because of a transport-map configuration, access the router through another port or using a method that is configured to connect to the Cisco IOS CLI. If the RP auxiliary port was used to access the router, use another port for access. Accessing the router through the auxiliary port is not useful for customer purposes.	- Inspect various states on the router, including the Cisco IOS state. - Replace or roll back the configuration. - Provide methods of restarting the Cisco IOS software or other processes. - Reboot hardware, such as the entire router, an RP, an ESP, a SIP, a SPA, or possibly other hardware components. - Transfer files into or off of the router using remote access methods such as FTP, TFTP, and SCP.

EXEC commands are not saved when the software reboots. Commands that you issue in a configuration mode can be saved to the startup configuration. If you save the running configuration to the startup configuration, these commands will execute when the software is rebooted. Global configuration mode is the highest level of configuration mode. From global configuration mode, you can enter a variety of other configuration modes, including protocol-specific modes.

ROM monitor mode is a separate mode that is used when the software cannot load properly. If a valid software image is not found when the software boots or if the configuration file is corrupted at startup, the software might enter ROM monitor mode. Use the question symbol (?) to view the commands that you can use while the device is in ROM monitor mode.

```
rommon 1 > ?
alias                set and display aliases command
boot                 boot up an external process
confreg              configuration register utility
cont                 continue executing a downloaded image
context              display the context of a loaded image
cookie               display contents of cookie PROM in hex
.
.
.
rommon 2 >
```

The following example shows how the command prompt changes to indicate a different command mode:

```
Router> enable
Router# configure terminal
Router(config)# interface ethernet 1/1
Router(config-if)# ethernet
Router(config-line)# exit
Router(config)# end
Router#
```

Note

A keyboard alternative to the **end** command is Ctrl-Z.

Using the Interactive Help Feature

The CLI includes an interactive Help feature. [Table 2](#) describes how to use the Help feature.

Table 2 CLI Interactive Help Commands

Command	Purpose
help	Provides a brief description of the help feature in any command mode.
?	Lists all commands available for a particular command mode.
<i>partial command?</i>	Provides a list of commands that begin with the character string (no space between the command and the question mark).
<i>partial command</i> <Tab>	Completes a partial command name (no space between the command and <Tab>).
<i>command ?</i>	Lists the keywords, arguments, or both associated with the command (space between the command and the question mark).
<i>command keyword ?</i>	Lists the arguments that are associated with the keyword (space between the keyword and the question mark).

The following examples show how to use the help commands:

help

```
Router> help
```

Help may be requested at any point in a command by entering a question mark '?'. If nothing matches, the help list will be empty and you must backup until entering a '?' shows the available options.

Two styles of help are provided:

1. Full help is available when you are ready to enter a command argument (e.g. 'show ?') and describes each possible argument.
2. Partial help is provided when an abbreviated argument is entered and you want to know what arguments match the input (e.g. 'show pr?'.)

?

```
Router# ?
```

Exec commands:

access-enable	Create a temporary access-List entry
access-profile	Apply user-profile to interface
access-template	Create a temporary access-List entry
alps	ALPS exec commands
archive	manage archive files

```
<snip>
```

partial command?

```
Router(config)# zo?
```

```
zone zone-pair
```

partial command<Tab>

```
Router(config)# we<Tab> webvpn
```

command ?

```
Router(config-if)# pppoe ?
```

enable	Enable pppoe
max-sessions	Maximum PPPOE sessions

command keyword ?

```
Router(config-if)# pppoe enable ?
```

```
group attach a BBA group
<cr>
```

Understanding Command Syntax

Command syntax is the format in which a command should be entered in the CLI. Commands include the name of the command, keywords, and arguments. Keywords are alphanumeric strings that are used literally. Arguments are placeholders for values that a user must supply. Keywords and arguments may be required or optional.

Specific conventions convey information about syntax and command elements. [Table 3](#) describes these conventions.

Table 3 *CLI Syntax Conventions*

Symbol/Text	Function	Notes
< > (angle brackets)	Indicate that the option is an argument.	Sometimes arguments are displayed without angle brackets.
A.B.C.D.	Indicates that you must enter a dotted decimal IP address.	Angle brackets (< >) are not always used to indicate that an IP address is an argument.
WORD (all capital letters)	Indicates that you must enter one word.	Angle brackets (< >) are not always used to indicate that a WORD is an argument.
LINE (all capital letters)	Indicates that you must enter more than one word.	Angle brackets (< >) are not always used to indicate that a LINE is an argument.
<cr> (carriage return)	Indicates the end of the list of available keywords and arguments, and also indicates when keywords and arguments are optional. When <cr> is the only option, you have reached the end of the branch or the end of the command if the command has only one branch.	—

The following examples show syntax conventions:

```

Router(config)# ethernet cfm domain ?
WORD    domain name
Router(config)# ethernet cfm domain dname ?
level
Router(config)# ethernet cfm domain dname level ?
<0-7>  maintenance level number
Router(config)# ethernet cfm domain dname level 7 ?
<cr>
Router(config)# snmp-server file-transfer access-group 10 ?
protocol protocol options
<cr>
Router(config)# logging host ?
Hostname or A.B.C.D  IP address of the syslog server
ipv6                 Configure IPv6 syslog server
Router(config)# snmp-server file-transfer access-group 10 ?
protocol protocol options
<cr>

```

Understanding Enable and Enable Secret Passwords

Some privileged EXEC commands are used for actions that impact the system, and it is recommended that you set a password for these commands to prevent unauthorized use. Two types of passwords, enable (not encrypted) and enable secret (encrypted), can be set. The following commands set these passwords and are issued in global configuration mode:

- **enable** *password*
- **enable secret** *password*

Using an enable secret password is recommended because it is encrypted and more secure than the enable password. When you use an enable secret password, text is encrypted (unreadable) before it is written to the config.text file. When you use an enable password, the text is written as entered (readable) to the config.text file.

Each type of password is case sensitive, can contain from 1 to 25 uppercase and lowercase alphanumeric characters, and can start with a number. Spaces are also valid password characters; for example, “two words” is a valid password. Leading spaces are ignored, but trailing spaces are recognized.

Note

Both password commands have numeric keywords that are single integer values. If you choose a number for the first character of your password followed by a space, the system will read the number as if it were the numeric keyword and not as part of your password.

When both passwords are set, the enable secret password takes precedence over the enable password.

To remove a password, use the **no** form of the commands: **no enable** *password* or **no enable secret** *password*.

For more information about password recovery procedures for Cisco products, see http://www.cisco.com/en/US/products/sw/iosswrel/ps1831/products_tech_note09186a00801746e6.shtml.

Using the Command History Feature

The CLI command history feature saves the commands you enter during a session in a command history buffer. The default number of commands saved is 10, but the number is configurable within the range of 0 to 256. This command history feature is particularly useful for recalling long or complex commands.

To change the number of commands saved in the history buffer for a terminal session, issue the **terminal history size** command:

```
Router# terminal history size num
```

A command history buffer is also available in line configuration mode with the same default and configuration options. To set the command history buffer size for a terminal session in line configuration mode, issue the **history** command:

```
Router(config-line)# history [size num]
```

To recall commands from the history buffer, use the following methods:

- Press Ctrl-P or the up arrow key—Recalls commands beginning with the most recent command. Repeat the key sequence to recall successively older commands.

- Press Ctrl-N or the down arrow key—Recalls the most recent commands in the history buffer after they have been recalled using Ctrl-P or the up arrow key. Repeat the key sequence to recall successively more recent commands.

Note The arrow keys function only on ANSI-compatible terminals such as the VT100.

- Issue the **show history** command in user EXEC or privileged EXEC mode—Lists the most recent commands that you entered. The number of commands that are displayed is determined by the setting of the **terminal history size** and **history** commands.

The CLI command history feature is enabled by default. To disable this feature for a terminal session, issue the **terminal no history** command in user EXEC or privileged EXEC mode or the **no history** command in line configuration mode.

Abbreviating Commands

Typing a complete command name is not always required for the command to execute. The CLI recognizes an abbreviated command when the abbreviation contains enough characters to uniquely identify the command. For example, the **show version** command can be abbreviated as **sh ver**. It cannot be abbreviated as **s ver** because **s** could mean **show**, **set**, or **systat**. The **sh v** abbreviation also is not valid because the **show** command has **vrp** as a keyword in addition to **version**. (Command and keyword examples from Cisco IOS Release 12.4(13)T.)

Using Aliases for CLI Commands

To save time and the repetition of entering the same command multiple times, you can use a command alias. An alias can be configured to do anything that can be done at the command line, but an alias cannot move between modes, type in passwords, or perform any interactive functions.

Table 4 shows the default command aliases.

Table 4 Default Command Aliases

Command Alias	Original Command
h	help
lo	logout
p	ping
s	show
u or un	undebug
w	where

To create a command alias, issue the **alias** command in global configuration mode. The syntax of the command is **alias mode command-alias original-command**. Following are some examples:

- Router(config)# **alias exec prt partition**—privileged EXEC mode
- Router(config)# **alias configure sb source-bridge**—global configuration mode
- Router(config)# **alias interface rl rate-limit**—interface configuration mode

To view both default and user-created aliases, issue the **show alias** command.

For more information about the **alias** command, see

http://www.cisco.com/en/US/docs/ios/fundamentals/command/reference/cf_book.html.

Using the no and default Forms of Commands

Most configuration commands have a **no** form that is used to reset a command to its default value or disable a feature or function. For example, the **ip routing** command is enabled by default. To disable this command, you would issue the **no ip routing** command. To re-enable IP routing, you would issue the **ip routing** command.

Configuration commands may also have a **default** form, which returns the command settings to their default values. For commands that are disabled by default, using the **default** form has the same effect as using the **no** form of the command. For commands that are enabled by default and have default settings, the **default** form enables the command and returns the settings to their default values.

The **no** and **default** forms of commands are described in the command pages of command references.

Using the debug Command

A **debug** command produces extensive output that helps you troubleshoot problems in your network. These commands are available for many features and functions within Cisco IOS and Cisco IOS XE software. Some **debug** commands are **debug all**, **debug aaa accounting**, and **debug mpls packets**. To use **debug** commands during a Telnet session with a device, you must first enter the **terminal monitor** command. To turn off debugging completely, you must enter the **undebug all** command.

For more information about **debug** commands, see the *Cisco IOS Debug Command Reference* at

http://www.cisco.com/en/US/docs/ios/debug/command/reference/db_book.html.

Caution

Debugging is a high priority and high CPU utilization process that can render your device unusable. Use **debug** commands only to troubleshoot specific problems. The best times to run debugging are during periods of low network traffic and when few users are interacting with the network. Debugging during these periods decreases the likelihood that the **debug** command processing overhead will affect network performance or user access or response times.

Filtering Output Using Output Modifiers

Many commands produce lengthy output that may use several screens to display. Using output modifiers, you can filter this output to show only the information that you want to see.

Three output modifiers are available and are described as follows:

- **begin** *regular expression*—Displays the first line in which a match of the regular expression is found and all lines that follow.
- **include** *regular expression*—Displays all lines in which a match of the regular expression is found.
- **exclude** *regular expression*—Displays all lines except those in which a match of the regular expression is found.

To use one of these output modifiers, type the command followed by the pipe symbol (|), the modifier, and the regular expression that you want to search for or filter. A regular expression is a case-sensitive alphanumeric pattern. It can be a single character or number, a phrase, or a more complex string.

The following example illustrates how to filter output of the **show interface** command to display only lines that include the expression “protocol.”

```
Router# show interface | include protocol

FastEthernet0/0 is up, line protocol is up
Serial4/0 is up, line protocol is up
Serial4/1 is up, line protocol is up
Serial4/2 is administratively down, line protocol is down
Serial4/3 is administratively down, line protocol is down
```

Understanding CLI Error Messages

You may encounter some error messages while using the CLI. [Table 5](#) shows the common CLI error messages.

Table 5 Common CLI Error Messages

Error Message	Meaning	How to Get Help
% Ambiguous command: “show con”	You did not enter enough characters for the command to be recognized.	Reenter the command followed by a space and a question mark (?). The keywords that you are allowed to enter for the command appear.
% Incomplete command.	You did not enter all the keywords or values required by the command.	Reenter the command followed by a space and a question mark (?). The keywords that you are allowed to enter for the command appear.
% Invalid input detected at “^” marker.	You entered the command incorrectly. The caret (^) marks the point of the error.	Enter a question mark (?) to display all the commands that are available in this command mode. The keywords that you are allowed to enter for the command appear.

For more system error messages, see the following documents:

- [Cisco IOS Release 12.2SR System Message Guide](#)
- [Cisco IOS System Messages, Volume 1 of 2](#) (Cisco IOS Release 12.4)
- [Cisco IOS System Messages, Volume 2 of 2](#) (Cisco IOS Release 12.4)

Saving Changes to a Configuration

To save changes that you made to the configuration of a device, you must issue the **copy running-config startup-config** command or the **copy system:running-config nvram:startup-config** command. When you issue these commands, the configuration changes that you made are saved to the startup configuration and saved when the software reloads or power to the device is turned off or interrupted. The following example shows the syntax of the **copy running-config startup-config** command:

```
Router# copy running-config startup-config
Destination filename [startup-config]?
```

You press Enter to accept the startup-config filename (the default), or type a new filename and then press Enter to accept that name. The following output is displayed indicating that the configuration was saved:

```
Building configuration...
[OK]
Router#
```

On most platforms, the configuration is saved to NVRAM. On platforms with a Class A flash file system, the configuration is saved to the location specified by the CONFIG_FILE environment variable. The CONFIG_FILE variable defaults to NVRAM.

Security Overview

This chapter contains the following sections:

- [About This Guide](#)

Preview the topics in this guide.

- [Creating Effective Security Policies](#)

Learn tips and hints for creating a security policy for your organization. A security policy should be finalized and up to date *before* you configure any security features.

- [Identifying Security Risks and Cisco IOS Solutions](#)

Identify common security risks that might be present in your network, and find the right Cisco IOS security feature to prevent security break-ins.

About This Guide

The *Cisco IOS Security Configuration Guide* describes how to configure Cisco IOS security features for your Cisco networking devices. These security features can protect your network against degradation or failure and also against data loss or compromise resulting from intentional attacks and from unintended but damaging mistakes by well-meaning network users.

This guide is divided into seven parts:

- [Authentication, Authorization, and Accounting \(AAA\)](#)
- [Security Server Protocols](#)
- [Traffic Filtering, Firewalls, and Virus Detection](#)
- [IP Security \(IPSec\) and Internet Key Exchange \(IKE\)](#)
- [Public Key Infrastructure \(PKI\)](#)
- [Other Security Features](#)
- [Cisco IOS Secure Infrastructure](#)

[Appendixes](#) follow the seven main divisions.

The following sections briefly describe each of these sections and the appendixes.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

Authentication, Authorization, and Accounting (AAA)

This part describes how to configure Cisco's authentication, authorization, and accounting (AAA) paradigm. AAA is an architectural framework for configuring a set of three independent security functions in a consistent, modular manner.

- **Authentication**—Provides the method of identifying users, including login and password dialog, challenge and response, messaging support, and, depending on the security protocol you select, encryption. Authentication is the way a user is identified prior to being allowed access to the network and network services. You configure AAA authentication by defining a named list of authentication methods and then applying that list to various interfaces.
- **Authorization**—Provides the method for remote access control, including one-time authorization or authorization for each service, per-user account list and profile, user group support, and support of IP, IPX, ARA, and Telnet.

Remote security servers, such as RADIUS and TACACS+, authorize users for specific rights by associating attribute-value (AV) pairs, which define those rights, with the appropriate user. AAA authorization works by assembling a set of attributes that describe what the user is authorized to perform. These attributes are compared with the information contained in a database for a given user, and the result is returned to AAA to determine the user's actual capabilities and restrictions.

- **Accounting**—Provides the method for collecting and sending security server information used for billing, auditing, and reporting, such as user identities, start and stop times, executed commands (such as PPP), number of packets, and number of bytes. Accounting enables you to track the services users are accessing, as well as the amount of network resources they are consuming.

**Note**

You can configure authentication outside of AAA. However, you must configure AAA if you want to use RADIUS, TACACS+, or Kerberos or if you want to configure a backup authentication method.

Security Server Protocols

In many circumstances, AAA uses security protocols to administer its security functions. If your router or access server is acting as a network access server, AAA is the means through which you establish communication between your network access server and your RADIUS, TACACS+, or Kerberos security server.

The chapters in this part describe how to configure the following security server protocols:

- **RADIUS**—A distributed client/server system implemented through AAA that secures networks against unauthorized access. In the Cisco implementation, RADIUS clients run on Cisco routers and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.
- **TACACS+**—A security application implemented through AAA that provides centralized validation of users attempting to gain access to a router or network access server. TACACS+ services are maintained in a database on a TACACS+ daemon running, typically, on a UNIX or Windows NT workstation. TACACS+ provides for separate and modular authentication, authorization, and accounting facilities.
- **Kerberos**—A secret-key network authentication protocol implemented through AAA that uses the Data Encryption Standard (DES) cryptographic algorithm for encryption and authentication. Kerberos was designed to authenticate requests for network resources. Kerberos is based on the concept of a trusted third party that performs secure verification of users and services. The primary use of Kerberos is to verify that users and the network services they use are really who and what

they claim to be. To accomplish this, a trusted Kerberos server issues tickets to users. These tickets, which have a limited lifespan, are stored in a user's credential cache and can be used in place of the standard username-and-password authentication mechanism.

Traffic Filtering, Firewalls, and Virus Detection

This part describes how to configure your networking devices to filter traffic, function as a firewall, or detect potential viruses.

- Cisco implements traffic filters with access control lists (also called access lists). Access lists determine what traffic is blocked and what traffic is forwarded at router interfaces. Cisco provides both basic and advanced access list capabilities.
 - Basic access lists

An overview of basic access lists is in the chapter “Access Control Lists: Overview and Guidelines.” This chapter describes tips, cautions, considerations, recommendations, and general guidelines for configuring access lists for the various network protocols. You should configure basic access lists for all network protocols that will be routed through your networking device, such as IP, IPX, AppleTalk, and so forth.
 - Advanced access lists

The advanced access list capabilities and configuration are described in the remaining chapters in the “Traffic Filtering, Firewalls, and Virus Detection” part of this document. The advanced access lists provide sophisticated and dynamic traffic filtering capabilities for stronger, more flexible network security.
- Cisco IOS Firewall provides an extensive set of security features, allowing you to configure a simple or elaborate firewall, according to your particular requirements. The following features are key components of Cisco IOS Firewall:
 - Context-based Access Control (CBAC)

CBAC intelligently filters TCP and UDP packets based on application-layer protocol session information. You can configure CBAC to permit specified TCP and UDP traffic through a firewall only when the connection is initiated from within the network you want to protect. CBAC can inspect traffic for sessions that originate from either side of the firewall, and CBAC can be used for intranet, extranet, and Internet perimeters of your network.
 - Cisco IOS Intrusion Prevention System (IPS)

Cisco IOS IPS acts as an in-line intrusion detection sensor, “watching” packets and sessions as they flow through the router and scanning each packet to match any of the Cisco IOS IPS signatures. When Cisco IOS IPS detects suspicious activity, it responds before network security can be compromised and logs the event through Cisco IOS syslog messages or Security Device Event Exchange (SDEE).

Customers can download the Cisco IOS IPS (via a signature detection file [SDF]) to their router from Cisco.com via the VPN and Security Management Solution (VMS) IDS Management Console (MC) 2.3 network management device or via the Cisco Router and Security Device Manager (SDM). Thus VMS IDS MC or SDM can immediately begin scanning for new signatures.
 - Authentication Proxy

The Cisco IOS Firewall authentication proxy feature allows network administrators to apply specific security policies on a per-user basis. Previously, user identity and related authorized access were associated with a user's IP address, or a single security policy had to be applied to

an entire user group or sub network. Now, users can be identified and authorized on the basis of their per-user policy, and access privileges tailored on an individual basis are possible, as opposed to general policy applied across multiple users.

- Port to Application Mapping (PAM)

Port to Application Mapping (PAM) is a feature of Cisco Secure Integrated Software. PAM allows you to customize TCP or UDP port numbers for network services or applications. PAM uses this information to support network environments that run services using ports that are different from the registered or well-known ports associated with an application. For example, the information in the PAM table enables Context-based Access Control (CBAC) supported services to run on non-standard ports.

Firewalls are discussed in the chapters “Cisco IOS Firewall Overview” and “Configuring Context-Based Access Control.”

- Cisco addresses the increased threat and impact of worms and viruses to networked businesses with Cisco Network Admission Control (NAC). NAC enables Cisco routers to enforce access privileges when an endpoint attempts to connect to a network. This access decision is made on the basis of information about the endpoint device, such as its current antivirus state. The antivirus state includes information such as the version of antivirus software, virus definitions, and version of the scan engine.

NAC systems allow noncompliant devices to be denied access, placed in a quarantined area, or given restricted access to computing resources, thus keeping insecure nodes from infecting the network.

IP Security (IPSec) and Internet Key Exchange (IKE)

This section describes how to configure security for VPNs via IPSec and IKE:

- Configuring Security for VPNs with IPSec

This module describes how to configure IPSec. IPSec provides security for transmission of sensitive information over unprotected networks such as the Internet. IPSec provides data authentication and anti-replay services in addition to data confidentiality services.

- Configuring Internet Key Exchange for IPSec VPNs

This module describes how to configure IKE for use with IPSec VPNs. IKE is a key management protocol standard that is used in conjunction with the IPSec standard. IPSec can be configured without IKE, but IKE enhances IPSec by providing additional features, flexibility, and ease of configuration for the IPSec standard.

Public Key Infrastructure (PKI)

This section describes how to implement and manage a Cisco IOS PKI, which provides certificate management to support security protocols such as IPSec, secure shell (SSH), and secure socket layer (SSL). This section is divided into the following modules:

- Cisco IOS PKI Overview: Understanding and Planning a PKI

This module identifies general concepts necessary to understand how a PKI functions.

- Deploying RSA Keys Within a PKI

This module explains how to set up and deploy Rivest, Shamir, and Adelman (RSA) keys within a PKI. An RSA key pair is required before you can obtain a certificate for your router; that is, the end host must generate a pair of RSA keys and exchange the public key with the certification authority (CA) to obtain a certificate and enroll in a PKI.

- **Configuring Revocation and Authorization of Certificates in a PKI**

This module describes how to configure revocation and authorization of certificates in a PKI. After a certificate is validated as a properly signed certificate, it is authorized (via methods such as, certificate maps, PKI-AAA, or a certificate-based ACL) and the revocation status is checked by the issuing CA to ensure that the certificate has not been revoked.

- **Configuring Certificate Enrollment for a PKI**

Certificate enrollment, which is the process of obtaining a certificate from a CA, occurs between the end host requesting the certificate and the CA. Each peer that participates in the PKI must enroll with a CA. This module describes the different methods available for certificate enrollment and describes how to set up each method for a participating PKI peer.

- **Setting Up Secure Device Provisioning (SDP) for Enrollment in a PKI**

This module describes how to use SDP in a PKI. SDP is a web-based certificate enrollment interface that can be used to easily deploy PKI between two end devices, such as a Cisco IOS client and a Cisco IOS certificate server. SDP provides a solution for users deploying a large number of peer devices, including certificates and configurations.

- **Configuring and Managing a Cisco IOS Certificate Server for PKI Deployment**

This module describes how to set up and manage a Cisco IOS Certificate Server (CS) for PKI deployment. A CS embeds a simple certificate server, with limited CA functionality, into the Cisco IOS software.

- **Storing PKI Credentials External to the Router**

This module explains how to store RSA keys on device external to the router via a USB eToken. eTokens provide secure configuration distribution and allow users to store PKI credentials, such as RSA keys, for deployment.

Other Security Features

This section describes six security features in the following chapters:

- **Neighbor Router Authentication: Overview and Guidelines**

This chapter briefly describes the security benefits and operation of neighbor router authentication.

When neighbor authentication is configured on a router, the router authenticates its neighbor router before accepting any route updates from that neighbor. This ensures that a router always receives reliable routing update information from a trusted source.

- **Configuring IP Security Options**

This chapter describes how to configure IP Security Options (IPSO) as described in RFC 1108. IPSO is generally used to comply with the security policy of the U.S. government's Department of Defense.

- **Configuring Unicast Reverse Path Forwarding**

This chapter describes the Unicast Reverse Path Forwarding (Unicast RPF) feature, which helps mitigate problems caused by the introduction of malformed or forged (spoofed) IP source addresses into a network by discarding IP packets that lack a verifiable IP source address. For example, a number of common types of denial-of-service (DoS) attacks, including Smurf and Tribe Flood

Network (TFN), can take advantage of forged or rapidly changing source IP addresses to allow attackers to thwart efforts to locate or filter the attacks. For Internet service providers (ISPs) that provide public access, Unicast RPF deflects such attacks by forwarding only packets that have source addresses that are valid and consistent with the IP routing table. This action protects the network of the ISP, its customer, and the rest of the Internet.

- **Configuring Secure Shell**

This chapter describes the Secure Shell (SSH) feature. SSH is an application and a protocol that provides a secure replacement to a suite of Unix r-commands such as rsh, rlogin and rcp. (Cisco IOS supports rlogin.) The protocol secures the sessions using standard cryptographic mechanisms, and the application can be used similarly to the Berkeley rexec and rsh tools. There are currently two versions of SSH available: SSH Version 1 and SSH Version 2.

- **Configuring 802.1x Authentication Services**

This section describes how to configure local authentication and VPN access via the Institute of Electrical and Electronics Engineers (IEEE) 802.1X protocol framework.

- **WebVPN**

WebVPN provides end users with unrestricted, secure remote access to enterprise sites without having VPN installed on their end devices. Users can access the enterprise sites from anywhere on the Internet and can access enterprise applications such as e-mail and web browsing.

Cisco IOS Secure Infrastructure

- This section contains features that help users secure their network infrastructure. Some of the available features are as follows: Autosecure (which simplifies the security configuration of a router and hardens the router configuration); Image Verification (which enables routers to automatically detect when the integrity of an image is accidentally corrupted as a result of transmission errors or disk corruption); Role-Based CLI Access (which allows network administrators to exercise better control over access to Cisco networking devices), and “Configuring Security with Passwords, Privilege Levels, and Login Usernames for CLI Sessions on Networking Devices” (which is a guide to implementing a baseline level of security for your networking devices).

Appendixes

The appendixes describe the supported RADIUS attributes and TACACS+ attribute-value pairs as follows:

- **RADIUS Attributes**

RADIUS attributes are used to define specific AAA elements in a user profile, which is stored on the RADIUS daemon. This appendix lists the RADIUS attributes currently supported.

- **TACACS+ Attribute-Value Pairs**

TACACS+ attribute-value pairs are used to define specific AAA elements in a user profile, which is stored on the TACACS+ daemon. This appendix lists the TACACS+ attribute-value pairs currently supported.

Creating Effective Security Policies

An effective security policy works to ensure that your organization's network assets are protected from sabotage and from inappropriate access—both intentional and accidental.

All network security features should be configured in compliance with your organization's security policy. If you do not have a security policy, or if your policy is out of date, you should ensure that the policy is created or updated before you decide how to configure security on your Cisco device.

The following sections provide guidelines to help you create an effective security policy:

- [The Nature of Security Policies](#)
- [Two Levels of Security Policies](#)
- [Tips for Developing an Effective Security Policy](#)

The Nature of Security Policies

You should recognize these aspects of security policies:

- Security policies represent trade-offs.

With all security policies, there is some trade-off between user productivity and security measures that can be restrictive and time consuming. The goal of any security design is to provide maximum security with minimum impact on user access and productivity. Some security measures, such as network data encryption, do not restrict access and productivity. On the other hand, cumbersome or unnecessarily redundant verification and authorization systems can frustrate users and even prevent access to critical network resources.

- Security policies should be determined by business needs.

Business needs should dictate the security policy; a security policy should not determine how a business operates.

- Security policies are living documents.

Because organizations are constantly subject to change, security policies must be systematically updated to reflect new business directions, technological changes, and resource allocations.

Two Levels of Security Policies

You can think of a security policy as having two levels: a requirements level and an implementation level.

- At the requirements level, a policy defines the degree to which your network assets must be protected against intrusion or destruction and also estimates the cost (consequences) of a security breach. For example, the policy could state that only human resources personnel should be able to access personnel records, or that only IS personnel should be able to configure the backbone routers. The policy could also address the consequences of a network outage (due to sabotage), and the consequences of inadvertently making sensitive information public.
- At the implementation level, a policy defines guidelines to implement the requirements-level policy, using specific technology in a predefined way. For example, the implementation-level policy could require access lists to be configured so that only traffic from human resources host computers can access the server containing personnel records.

When creating a policy, define security requirements before defining security implementations so that you do not end up merely justifying particular technical solutions that might not actually be required.

Tips for Developing an Effective Security Policy

To develop an effective security policy, consider the recommendations in the following sections:

- [Identifying Your Network Assets to Protect](#)
- [Determining Points of Risk](#)
- [Limiting the Scope of Access](#)
- [Identifying Assumptions](#)
- [Determining the Cost of Security Measures](#)
- [Considering Human Factors](#)
- [Keeping a Limited Number of Secrets](#)
- [Implementing Pervasive and Scalable Security](#)
- [Understanding Typical Network Functions](#)
- [Remembering Physical Security](#)

Identifying Your Network Assets to Protect

The first step to developing a security policy is to understand and identify your organization's network assets. Network assets include the following:

- Networked hosts (such as PCs; includes the hosts' operating systems, applications, and data)
- Networking devices (such as routers)
- Network data (data that travels across the network)

You must both identify your network's assets and determine the degree to which each of these assets must be protected. For example, one subnetwork of hosts might contain extremely sensitive data that should be protected at all costs, while a different subnetwork of hosts might require only modest protection against security risks because there is less cost involved if the subnetwork is compromised.

Determining Points of Risk

You must understand how potential intruders can enter your organization's network or sabotage network operation. Special areas of consideration are network connections, dial-up access points, and misconfigured hosts. Misconfigured hosts, frequently overlooked as points of network entry, can be systems with unprotected login accounts (guest accounts), employ extensive trust in remote commands (such as rlogin and rsh), have illegal modems attached to them, and use easy-to-break passwords.

Limiting the Scope of Access

Organizations can create multiple barriers within networks, so that unlawful entry to one part of the system does not automatically grant entry to the entire infrastructure. Although maintaining a high level of security for the entire network can be prohibitively expensive (in terms of systems and equipment as well as productivity), you can often provide higher levels of security to the more sensitive areas of your network.

Identifying Assumptions

Every security system has underlying assumptions. For example, an organization might assume that its network is not tapped, that intruders are not very knowledgeable, that intruders are using standard software, or that a locked room is safe. It is important to identify, examine, and justify your assumptions: any hidden assumption is a potential security hole.

Determining the Cost of Security Measures

In general, providing security comes at a cost. This cost can be measured in terms of increased connection times or inconveniences to legitimate users accessing the assets, or in terms of increased network management requirements, and sometimes in terms of actual dollars spent on equipment or software upgrades.

Some security measures inevitably inconvenience some sophisticated users. Security can delay work, create expensive administrative and educational overhead, use significant computing resources, and require dedicated hardware.

When you decide which security measures to implement, you must understand their costs and weigh these against potential benefits. If the security costs are out of proportion to the actual dangers, it is a disservice to the organization to implement them.

Considering Human Factors

If security measures interfere with essential uses of the system, users resist these measures and sometimes even circumvent them. Many security procedures fail because their designers do not take this fact into account. For example, because automatically generated “nonsense” passwords can be difficult to remember, users often write them on the undersides of keyboards. A “secure” door that leads to a system’s only tape drive is sometimes propped open. For convenience, unauthorized modems are often connected to a network to avoid cumbersome dial-in security procedures. To ensure compliance with your security measures, users must be able to get their work done as well as understand and accept the need for security.

Any user can compromise system security to some degree. For example, an intruder might learn passwords by simply calling legitimate users on the telephone claiming to be a system administrator and asking for them. If users understand security issues and understand the reasons for them, they are far less likely to compromise security in this way.

Defining such human factors and any corresponding policies needs to be included as a formal part of your complete security policy.

At a minimum, users must be taught never to release passwords or other secrets over unsecured telephone lines (especially through cordless or cellular telephones) or electronic mail. They should be wary of questions asked by people who call them on the telephone. Some companies have implemented formalized network security training for their employees in which employees are not allowed access to the network until they have completed a formal training program.

Keeping a Limited Number of Secrets

Most security is based on secrets; for example, passwords and encryption keys are secrets. But the more secrets there are, the harder it is to keep all of them. It is prudent, therefore, to design a security policy that relies on a limited number of secrets. Ultimately, the most important secret an organization has is the information that can help someone circumvent its security.

Implementing Pervasive and Scalable Security

Use a systematic approach to security that includes multiple, overlapping security methods.

Almost any change that is made to a system can affect security. This is especially true when new services are created. System administrators, programmers, and users need to consider the security implications of every change they make. Understanding the security implications of a change takes practice; it requires lateral thinking and a willingness to explore every way that a service could potentially be manipulated. The goal of any security policy is to create an environment that is not susceptible to every minor change.

Understanding Typical Network Functions

Understand how your network system normally functions, know what is expected and unexpected behavior, and be familiar with how devices are usually used. This kind of awareness helps the organization detect security problems. Noticing unusual events can help catch intruders before they can damage the system. Software auditing tools can help detect, log, and track unusual events. In addition, an organization should know exactly what software it relies on to provide auditing trails, and a security system should not operate on the assumption that all software is bug free.

Remembering Physical Security

The physical security of your network devices and hosts cannot be neglected. For example, many facilities implement physical security by using security guards, closed circuit television, card-key entry systems, or other means to control physical access to network devices and hosts. Physical access to a computer or router usually gives a sophisticated user complete control over that device. Physical access to a network link usually allows a person to tap into that link, jam it, or inject traffic into it. Software security measures can often be circumvented when access to the hardware is not controlled.

Identifying Security Risks and Cisco IOS Solutions

Cisco IOS software provides a comprehensive set of security features to guard against specific security risks. This section describes a few common security risks that might be present in your network, and describes how to use Cisco IOS software to protect against each of these risks:

- [Preventing Unauthorized Access into Networking Devices](#)
- [Preventing Unauthorized Access into Networks](#)
- [Preventing Network Data Interception](#)
- [Preventing Fraudulent Route Updates](#)

Preventing Unauthorized Access into Networking Devices

If someone were to gain console or terminal access into a networking device, such as a router, switch, or network access server, that person could do significant damage to your network—perhaps by reconfiguring the device, or even by simply viewing the device's configuration information.

Typically, you want administrators to have access to your networking device; you do not want other users on your local-area network or those dialing in to the network to have access to the router.

Users can access Cisco networking devices by dialing in from outside the network through an asynchronous port, connecting from outside the network through a serial port, or connecting via a terminal or workstation from within the local network.

To prevent unauthorized access into a networking device, you should configure one or more of the following security features:

- At a minimum, you should configure passwords and privileges at each networking device for all device lines and ports, as described in the module “Configuring Security with Passwords, Privilege Levels, and Login Usernames for CLI Sessions on Networking Devices.” These passwords are stored on the networking device. When users attempt to access the device through a particular line or port, they must enter the password applied to the line or port before they can access the device.
- For an additional layer of security, you can also configure username/password pairs, stored in a database on the networking device, as described in the module “Configuring Security with Passwords, Privilege Levels, and Login Usernames for CLI Sessions on Networking Devices.” These pairs are assigned to lines or interfaces and authenticate each user before that user can access the device. If you have defined privilege levels, you can also assign a specific privilege level (with associated rights and privileges) to each username/password pair.
- If you want to use username/password pairs, but you want to store them centrally instead of locally on each individual networking device, you can store them in a database on a security server. Multiple networking devices can then use the same database to obtain user authentication (and, if necessary, authorization) information. Cisco supports a variety of security server protocols, such as RADIUS, TACACS+, and Kerberos. If you decide to use the database on a security server to store login username/password pairs, you must configure your router or access server to support the applicable protocol; in addition, because most supported security protocols must be administered through the AAA security services, you will probably need to enable AAA. For more information about security protocols and AAA, refer to the chapters in the “Authentication, Authorization, and Accounting (AAA)” part of this document.

Note Cisco recommends that, whenever possible, AAA be used to implement authentication.

- If you want to authorize individual users for specific rights and privileges, you can implement AAA’s authorization feature, using a security protocol such as TACACS+ or RADIUS. For more information about security protocol features and AAA, refer to the chapters in the “Authentication, Authorization, and Accounting (AAA)” part of this document.
- If you want to have a backup authentication method, you must configure AAA. AAA allows you to specify the primary method for authenticating users (for example, a username/password database stored on a TACACS+ server) and then specify backup methods (for example, a locally stored username/password database.) The backup method is used if the primary method’s database cannot be accessed by the networking device. To configure AAA, refer to the chapters in the “Authentication, Authorization, and Accounting (AAA)” part of this document. You can configure up to four sequential backup methods.

Note If you do not have backup methods configured, you will be denied access to the device if the username/password database cannot be accessed for any reason.

- If you want to keep an audit trail of user access, configure AAA accounting as described in the chapter “Configuring Accounting.”

Preventing Unauthorized Access into Networks

If someone were to gain unauthorized access to your organization's internal network, that person could cause damage in many ways, perhaps by accessing sensitive files from a host, by planting a virus, or by hindering network performance by flooding your network with illegitimate packets.

This risk can also apply to a person within your network attempting to access another internal network such as a Research and Development subnetwork with sensitive and critical data. That person could intentionally or inadvertently cause damage; for example, that person might access confidential files or tie up a time-critical printer.

To prevent unauthorized access through a networking device into a network, you should configure one or more of these security features:

- **Traffic Filtering**

Cisco uses access lists to filter traffic at networking devices. Basic access lists allow only specified traffic through the device; other traffic is simply dropped. You can specify individual hosts or subnets that should be allowed into the network, and you can specify what type of traffic should be allowed into the network. Basic access lists generally filter traffic based on source and destination addresses, and protocol type of each packet.

Advanced traffic filtering is also available, providing additional filtering capabilities; for example, the Lock-and-Key Security feature requires each user to be authenticated via a username/password before that user's traffic is allowed onto the network.

All the Cisco IOS traffic filtering capabilities are described in the chapters in the "Traffic Filtering, Firewalls, and Virus Detection" part of this document.

- **Authentication**

You can require users to be authenticated before they gain access into a network. When users attempt to access a service or host (such as a web site or file server) within the protected network, they must first enter certain data such as a username and password, and possibly additional information such as their date of birth or mother's maiden name. After successful authentication (depending on the method of authentication), users will be assigned specific privileges, allowing them to access specific network assets. In most cases, this type of authentication would be facilitated by using CHAP or PAP over a serial PPP connection in conjunction with a specific security protocol, such as TACACS+ or RADIUS.

Just as in preventing unauthorized access to specific network devices, you need to decide whether or not you want the authentication database to reside locally or on a separate security server. In this case, a local security database is useful if you have very few routers providing network access. A local security database does not require a separate (and costly) security server. A remote, centralized security database is convenient when you have a large number of routers providing network access because it prevents you from having to update each router with new or changed username authentication and authorization information for potentially hundreds of thousands of dial-in users. A centralized security database also helps establish consistent remote access policies throughout a corporation.

Cisco IOS software supports a variety of authentication methods. Although AAA is the primary (and recommended) method for access control, Cisco IOS software provides additional features for simple access control that are outside the scope of AAA. For more information, refer to the chapter "Configuring Authentication."

Preventing Network Data Interception

When packets travel across a network, they are susceptible to being read, altered, or “hijacked.” (Hijacking occurs when a hostile party intercepts a network traffic session and poses as one of the session endpoints.)

If the data is traveling across an unsecured network such as the Internet, the data is exposed to a fairly significant risk. Sensitive or confidential data could be exposed, critical data could be modified, and communications could be interrupted if data is altered.

To protect data as it travels across a network, configure network data encryption, as described in the chapter “Configuring IPSec Network Security.”

IPSec provides the following network security services. These services are optional. In general, local security policy will dictate the use of one or more of the following services:

- **Data Confidentiality**—The IPSec sender can encrypt packets before transmitting them across a network.
- **Data Integrity**—The IPSec receiver can authenticate packets sent by the IPSec sender to ensure that the data has not been altered during transmission.
- **Data Origin Authentication**—The IPSec receiver can authenticate the source of the IPSec packets sent. This service is dependent upon the data integrity service.
- **Anti-Replay**—The IPSec receiver can detect and reject replayed packets.

Cisco IPSec prevents routed traffic from being examined or tampered with while it travels across a network. This feature causes IP packets to be encrypted at a Cisco router, routed across a network as encrypted information, and decrypted at the destination Cisco router. In between the two routers, the packets are in encrypted form and therefore the packets’ contents cannot be read or altered. You define what traffic should be encrypted between the two routers, according to what data is more sensitive or critical.

If you want to protect traffic for protocols other than IP, you can encapsulate those other protocols into IP packets using GRE encapsulation, and then encrypt the IP packets.

Typically, you do not use IPSec for traffic that is routed through networks that you consider secure. Consider using IPSec for traffic that is routed across unsecured networks, such as the Internet, if your organization could be damaged if the traffic is examined or tampered with by unauthorized individuals.

Preventing Fraudulent Route Updates

All routing devices determine where to route individual packets by using information stored in route tables. This route table information is created using route updates obtained from neighboring routers.

If a router receives a fraudulent update, the router could be tricked into forwarding traffic to the wrong destination. This could cause sensitive data to be exposed, or could cause network communications to be interrupted.

To ensure that route updates are received only from known, trusted neighbor routers, configure neighbor router authentication as described in the chapter “Neighbor Router Authentication: Overview and Guidelines.”

Authentication, Authorization, and Accounting (AAA)

AAA Overview

Access control is the way you control who is allowed access to the network server and what services they are allowed to use once they have access. Authentication, authorization, and accounting (AAA) network security services provide the primary framework through which you set up access control on your router or access server.

In This Chapter

This chapter includes the following sections:

- [About AAA Security Services](#)
- [Where to Begin](#)
- [What to Do Next](#)

About AAA Security Services

AAA is an architectural framework for configuring a set of three independent security functions in a consistent manner. AAA provides a modular way of performing the following services:

- **Authentication**—Provides the method of identifying users, including login and password dialog, challenge and response, messaging support, and, depending on the security protocol you select, encryption.

Authentication is the way a user is identified prior to being allowed access to the network and network services. You configure AAA authentication by defining a named list of authentication methods, and then applying that list to various interfaces. The method list defines the types of authentication to be performed and the sequence in which they will be performed; it must be applied to a specific interface before any of the defined authentication methods will be performed. The only exception is the default method list (which is named “default”). The default method list is automatically applied to all interfaces if no other method list is defined. A defined method list overrides the default method list.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

All authentication methods, except for local, line password, and enable authentication, must be defined through AAA. For information about configuring all authentication methods, including those implemented outside of the AAA security services, refer to the chapter “Configuring Authentication.”

- **Authorization**—Provides the method for remote access control, including one-time authorization or authorization for each service, per-user account list and profile, user group support, and support of IP, IPX, ARA, and Telnet.

AAA authorization works by assembling a set of attributes that describe what the user is authorized to perform. These attributes are compared to the information contained in a database for a given user and the result is returned to AAA to determine the user’s actual capabilities and restrictions. The database can be located locally on the access server or router or it can be hosted remotely on a RADIUS or TACACS+ security server. Remote security servers, such as RADIUS and TACACS+, authorize users for specific rights by associating attribute-value (AV) pairs, which define those rights with the appropriate user. All authorization methods must be defined through AAA.

As with authentication, you configure AAA authorization by defining a named list of authorization methods, and then applying that list to various interfaces. For information about configuring authorization using AAA, refer to the chapter “Configuring Authorization.”

- **Accounting**—Provides the method for collecting and sending security server information used for billing, auditing, and reporting, such as user identities, start and stop times, executed commands (such as PPP), number of packets, and number of bytes.

Accounting enables you to track the services users are accessing as well as the amount of network resources they are consuming. When AAA accounting is activated, the network access server reports user activity to the RADIUS or TACACS+ security server (depending on which security method you have implemented) in the form of accounting records. Each accounting record is comprised of accounting AV pairs and is stored on the access control server. This data can then be analyzed for network management, client billing, and/or auditing. All accounting methods must be defined through AAA. As with authentication and authorization, you configure AAA accounting by defining a named list of accounting methods, and then applying that list to various interfaces. For information about configuring accounting using AAA, refer to the chapter “Configuring Accounting.”

In many circumstances, AAA uses protocols such as RADIUS, TACACS+, or Kerberos to administer its security functions. If your router or access server is acting as a network access server, AAA is the means through which you establish communication between your network access server and your RADIUS, TACACS+, or Kerberos security server.

Although AAA is the primary (and recommended) method for access control, Cisco IOS software provides additional features for simple access control that are outside the scope of AAA, such as local username authentication, line password authentication, and enable password authentication. However, these features do not provide the same degree of access control that is possible by using AAA.

This section includes the following sections:

- [Benefits of Using AAA](#)
- [AAA Philosophy](#)
- [Method Lists](#)

Benefits of Using AAA

AAA provides the following benefits:

- Increased flexibility and control of access configuration

- Scalability
- Standardized authentication methods, such as RADIUS, TACACS+, and Kerberos
- Multiple backup systems

**Note**

The deprecated protocols, TACACS and extended TACACS, are not compatible with AAA; if you select these security protocols, you will not be able to take advantage of the AAA security services.

AAA Philosophy

AAA is designed to enable you to dynamically configure the type of authentication and authorization you want on a per-line (per-user) or per-service (for example, IP, IPX, or VPDN) basis. You define the type of authentication and authorization you want by creating method lists, then applying those method lists to specific services or interfaces.

For information about applications that use AAA, such as per-user configuration and virtual profiles, refer to the chapters “Configuring Per-User Configuration” and “Configuring Virtual Profiles” in the *Cisco IOS Dial Technologies Configuration Guide*, Release 12.2.

Method Lists

A method list is a sequential list that defines the authentication methods used to authenticate a user. Method lists enable you to designate one or more security protocols to be used for authentication, thus ensuring a backup system for authentication in case the initial method fails. Cisco IOS software uses the first method listed to authenticate users; if that method does not respond, Cisco IOS software selects the next authentication method in the method list. This process continues until there is successful communication with a listed authentication method or the authentication method list is exhausted, in which case authentication fails.

**Note**

Cisco IOS software attempts authentication with the next listed authentication method only when there is no response from the previous method. If authentication fails at any point in this cycle—meaning that the security server or local username database responds by denying the user access—the authentication process stops and no other authentication methods are attempted.

[Figure 1](#) shows a typical AAA network configuration that includes four security servers: R1 and R2 are RADIUS servers, and T1 and T2 are TACACS+ servers.

Figure 1 Typical AAA Network Configuration

Suppose the system administrator has defined a method list where R1 will be contacted first for authentication information, then R2, T1, T2, and finally the local username database on the access server itself. When a remote user attempts to dial in to the network, the network access server first queries R1 for authentication information. If R1 authenticates the user, it issues a PASS response to the network access server and the user is allowed to access the network. If R1 returns a FAIL response, the user is denied access and the session is terminated. If R1 does not respond, then the network access server processes that as an ERROR and queries R2 for authentication information. This pattern continues through the remaining designated methods until the user is either authenticated or rejected, or until the session is terminated. If all of the authentication methods return errors, the network access server will process the session as a failure, and the session will be terminated.

Note

A FAIL response is significantly different from an ERROR. A FAIL means that the user has not met the criteria contained in the applicable authentication database to be successfully authenticated. Authentication ends with a FAIL response. An ERROR means that the security server has not responded to an authentication query. Because of this, no authentication has been attempted. Only when an ERROR is detected will AAA select the next authentication method defined in the authentication method list.

Where to Begin

You must first decide what kind of security solution you want to implement. You need to assess the security risks in your particular network and decide on the appropriate means to prevent unauthorized entry and attack. For more information about assessing your security risks and possible security solutions, refer to the chapter “Security Overview.” Cisco recommends that you use AAA, no matter how minor your security needs might be.

This section includes the following subsections:

- [Overview of the AAA Configuration Process](#)
- [Enabling AAA](#)
- [Disabling AAA](#)

Overview of the AAA Configuration Process

Configuring AAA is relatively simple after you understand the basic process involved. To configure security on a Cisco router or access server using AAA, follow this process:

1. Enable AAA by using the **aaa new-model** global configuration command.
2. If you decide to use a separate security server, configure security protocol parameters, such as RADIUS, TACACS+, or Kerberos.
3. Define the method lists for authentication by using an AAA authentication command.
4. Apply the method lists to a particular interface or line, if required.
5. (Optional) Configure authorization using the **aaa authorization** command.
6. (Optional) Configure accounting using the **aaa accounting** command.

For a complete description of the commands used in this chapter, refer to the chapter “Authentication Commands” of the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

Enabling AAA

Note

Before you can use any of the services AAA network security services provide, you must enable AAA.

When you enable AAA, you can no longer access the commands to configure the older protocols, TACACS or extended TACACS. If you decided to use TACACS or extended TACACS in your security solution, do not enable AAA.

To enable AAA, use the following command in global configuration mode:

Command	Purpose
Router (config)# aaa new-model	Enables AAA.

Disabling AAA

You can disable AAA functionality with a single command if you decide that your security needs cannot be met by AAA but can be met by using TACACS, extended TACACS, or a line security method that can be implemented without AAA. To disable AAA, use the following command in global configuration mode:

Command	Purpose
Router(config)# no aaa new-model	Disables AAA.

What to Do Next

Once you have enabled AAA, you are ready to configure the other elements relating to your selected security solution. [Table 3](#) describes AAA configuration tasks and where to find more information.

Table 3 **AAA Access Control Security Solutions Methods**

Task	Chapter in the <i>Cisco IOS Security Configuration Guide</i>
Configuring local login authentication	"Configuring Authentication"
Controlling login using security server authentication	"Configuring Authentication"
Defining method lists for authentication	"Configuring Authentication"
Applying method lists to a particular interface or line	"Configuring Authentication"
Configuring RADIUS security protocol parameters	"Configuring RADIUS"
Configuring TACACS+ security protocol parameters	"Configuring TACACS+"
Configuring Kerberos security protocol parameters	"Configuring Kerberos"
Enabling TACACS+ authorization	"Configuring Authorization"
Enabling RADIUS authorization	"Configuring Authorization"
Viewing supported IETF RADIUS attributes	"RADIUS Attributes" (Appendix)
Viewing supported vendor-specific RADIUS attributes	"RADIUS Attributes" (Appendix)
Viewing supported TACACS+ AV pairs	"TACACS+ AV Pairs" (Appendix)
Enabling accounting	"Configuring Accounting"

If you have elected not to use the AAA security services, see the "Configuring Authentication" chapter for the non-AAA configuration task "Configuring Login Authentication."

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

Release	Modification
Cisco IOS	For information about feature support in Cisco IOS software, use Cisco Feature Navigator.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

Authentication verifies users before they are allowed access to the network and network services. The Cisco IOS software implementation of authentication is divided into two main categories:

- [AAA Authentication Methods Configuration Task List](#)
- [Non-AAA Authentication Methods](#)

Authentication, for the most part, is implemented through the AAA security services. Cisco recommends that, whenever possible, AAA be used to implement authentication.

This chapter describes both AAA and non-AAA authentication methods. For authentication configuration examples, refer to the “[Authentication Examples](#)” section at the end of this chapter. For a complete description of the AAA commands used in this chapter, refer to the “Authentication, Authorization, and Accounting (AAA)” part of the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature, or refer to the software release notes for a specific release. For more information, see the section “Identifying Supported Platforms” in the chapter “Using Cisco IOS Software.”

In This Chapter

This chapter contains the following sections:

- [Named Method Lists for Authentication](#)
- [AAA Authentication Methods Configuration Task List](#)

- [Non-AAA Authentication Methods](#)
- [Authentication Examples](#)

Named Method Lists for Authentication

To configure AAA authentication, you must first define a named list of authentication methods, and then apply that list to various interfaces. The method list defines the types of authentication to be performed and the sequence in which they will be performed; it must be applied to a specific interface before any of the defined authentication methods will be performed. The only exception is the default method list (which is named “default”). The default method list is automatically applied to all interfaces except those that have a named method list explicitly defined. A defined method list overrides the default method list.

A method list is a sequential list describing the authentication methods to be queried in order to authenticate a user. Method lists enable you to designate one or more security protocols to be used for authentication, thus ensuring a backup system for authentication in case the initial method fails. Cisco IOS software uses the first listed method to authenticate users. If that method fails to respond, the Cisco IOS software selects the next authentication method listed in the method list. This process continues until there is successful communication with a listed authentication method, or all methods defined in the method list are exhausted.

It is important to note that the Cisco IOS software attempts authentication with the next listed authentication method only when there is no response from the previous method. If authentication fails at any point in this cycle—meaning that the security server or local username database responds by denying the user access—the authentication process stops and no other authentication methods are attempted.

**Note**

Effective with Cisco IOS Release 12.3, the number of AAA method lists that can be configured is 250.

This section contains the following subsections:

- [Method Lists and Server Groups](#)
- [Method List Examples](#)
- [AAA Authentication General Configuration Procedure](#)

Method Lists and Server Groups

A server group is a way to group existing RADIUS or TACACS+ server hosts for use in method lists. [Figure 2](#) shows a typical AAA network configuration that includes four security servers: R1 and R2 are RADIUS servers and T1 and T2 are TACACS+ servers. R1 and R2 make up the group of RADIUS servers. T1 and T2 make up the group of TACACS+ servers.

Figure 2 Typical AAA Network Configuration

Using server groups, you can specify a subset of the configured server hosts and use them for a particular service. For example, server groups allow you to define R1 and R2 as a server group, and define T1 and T2 as a separate server group. For example, you can specify R1 and T1 in the method list for authentication login, while specifying R2 and T2 in the method list for PPP authentication.

Server groups also can include multiple host entries for the same server, as long as each entry has a unique identifier. The combination of an IP address and a UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, authentication—the second host entry configured acts as failover backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server will try the second host entry configured on the same device for accounting services. (The RADIUS host entries will be tried in the order in which they are configured.)

For more information about configuring server groups and about configuring server groups based on Dialed Number Identification Service (DNIS) numbers, refer to the “Configuring RADIUS” or “Configuring TACACS+” chapter.

Method List Examples

Suppose the system administrator has decided on a security solution where all interfaces will use the same authentication methods to authenticate PPP connections. In the RADIUS group, R1 is contacted first for authentication information, then if there is no response, R2 is contacted. If R2 does not respond, T1 in the TACACS+ group is contacted; if T1 does not respond, T2 is contacted. If all designated servers fail to respond, authentication falls to the local username database on the access server itself. To implement this solution, the system administrator would create a default method list by entering the following command:

```
aaa authentication ppp default group radius group tacacs+ local
```

In this example, “default” is the name of the method list. The protocols included in this method list are listed after the name, in the order they are to be queried. The default list is automatically applied to all interfaces.

When a remote user attempts to dial in to the network, the network access server first queries R1 for authentication information. If R1 authenticates the user, it issues a PASS response to the network access server and the user is allowed to access the network. If R1 returns a FAIL response, the user is denied access and the session is terminated. If R1 does not respond, then the network access server processes that as an ERROR and queries R2 for authentication information. This pattern would continue through the remaining designated methods until the user is either authenticated or rejected, or until the session is terminated.

It is important to remember that a FAIL response is significantly different from an ERROR. A FAIL means that the user has not met the criteria contained in the applicable authentication database to be successfully authenticated. Authentication ends with a FAIL response. An ERROR means that the security server has not responded to an authentication query. Because of this, no authentication has been attempted. Only when an ERROR is detected will AAA select the next authentication method defined in the authentication method list.

Suppose the system administrator wants to apply a method list only to a particular interface or set of interfaces. In this case, the system administrator creates a named method list and then applies this named list to the applicable interfaces. The following example shows how the system administrator can implement an authentication method that will be applied only to interface 3:

```
aaa authentication ppp default group radius group tacacs+ local
aaa authentication ppp apple group radius group tacacs+ local none
interface async 3
 ppp authentication chap apple
```

In this example, “apple” is the name of the method list, and the protocols included in this method list are listed after the name in the order in which they are to be performed. After the method list has been created, it is applied to the appropriate interface. Note that the method list name (apple) in both the AAA and PPP authentication commands must match.

In the following example, the system administrator uses server groups to specify that only R2 and T2 are valid servers for PPP authentication. To do this, the administrator must define specific server groups whose members are R2 (172.16.2.7) and T2 (172.16.2.77), respectively. In this example, the RADIUS server group “rad2only” is defined as follows using the **aaa group server** command:

```
aaa group server radius rad2only
 server 172.16.2.7
```

The TACACS+ server group “tac2only” is defined as follows using the **aaa group server** command:

```
aaa group server tacacs+ tac2only
 server 172.16.2.77
```

The administrator then applies PPP authentication using the server groups. In this example, the default methods list for PPP authentication follows this order: **group rad2only**, **group tac2only**, and **local**:

```
aaa authentication ppp default group rad2only group tac2only local
```

AAA Authentication General Configuration Procedure

To configure AAA authentication, perform the following tasks:

1. Enable AAA by using the **aaa new-model** global configuration command. For more information about configuring AAA, refer to the chapter “AAA Overview”.
2. Configure security protocol parameters, such as RADIUS, TACACS+, or Kerberos if you are using a security server. For more information about RADIUS, refer to the chapter “Configuring RADIUS”. For more information about TACACS+, refer to the chapter “Configuring TACACS+”. For more information about Kerberos, refer to the chapter “Configuring Kerberos”.

3. Define the method lists for authentication by using an AAA authentication command.
4. Apply the method lists to a particular interface or line, if required.

AAA Authentication Methods Configuration Task List

This section discusses the following AAA authentication methods:

- [Configuring Login Authentication Using AAA](#)
- [Configuring PPP Authentication Using AAA](#)
- [Configuring AAA Scalability for PPP Requests](#)
- [Configuring ARAP Authentication Using AAA](#)
- [Configuring NASI Authentication Using AAA](#)
- [Specifying the Amount of Time for Login Input](#)
- [Enabling Password Protection at the Privileged Level](#)
- [Changing the Text Displayed at the Password Prompt](#)
- [Configuring Message Banners for AAA Authentication](#)
- [Configuring AAA Packet of Disconnect](#)
- [Enabling Double Authentication](#)
- [Enabling Automated Double Authentication](#)

Note

AAA features are not available for use until you enable AAA globally by issuing the **aaa new-model** command. For more information about enabling AAA, refer to the “AAA Overview” chapter.

For authentication configuration examples using the commands in this chapter, refer to the section “[Authentication Examples](#)” at the end of the this chapter.

Configuring Login Authentication Using AAA

The AAA security services facilitate a variety of login authentication methods. Use the **aaa authentication login** command to enable AAA authentication no matter which of the supported login authentication methods you decide to use. With the **aaa authentication login** command, you create one or more lists of authentication methods that are tried at login. These lists are applied using the **login authentication** line configuration command.

To configure login authentication by using AAA, use the following commands beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa new-model	Enables AAA globally.
Step 2	Router(config)# aaa authentication login {default list-name} method1 [method2...]	Creates a local authentication list.

	Command	Purpose
Step 3	Router(config)# line [aux console tty vty] line-number [ending-line-number]	Enters line configuration mode for the lines to which you want to apply the authentication list.
Step 4	Router(config-line)# login authentication { default <i>list-name</i> }	Applies the authentication list to a line or set of lines.

The *list-name* is a character string used to name the list you are creating. The method argument refers to the actual method the authentication algorithm tries. The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify **none** as the final method in the command line.

For example, to specify that authentication should succeed even if (in this example) the TACACS+ server returns an error, enter the following command:

```
aaa authentication login default group tacacs+ none
```

Note

Because the **none** keyword enables *any* user logging in to successfully authenticate, it should be used only as a backup method of authentication.

To create a default list that is used when a named list is *not* specified in the **login authentication** command, use the **default** keyword followed by the methods that are to be used in default situations. The default method list is automatically applied to all interfaces.

For example, to specify RADIUS as the default method for user authentication during login, enter the following command:

```
aaa authentication login default group radius
```

Table 4 lists the supported login authentication methods.

Table 4 **AAA Authentication Login Methods**

Keyword	Description
enable	Uses the enable password for authentication.
krb5	Uses Kerberos 5 for authentication.
krb5-telnet	Uses Kerberos 5 Telnet authentication protocol when using Telnet to connect to the router. If selected, this keyword must be listed as the first method in the method list.
line	Uses the line password for authentication.
local	Uses the local username database for authentication.
local-case	Uses case-sensitive local username authentication.
none	Uses no authentication.
group radius	Uses the list of all RADIUS servers for authentication.
group tacacs+	Uses the list of all TACACS+ servers for authentication.
group <i>group-name</i>	Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the aaa group server radius or aaa group server tacacs+ command.

**Note**

The **login** command only changes username and privilege level but does not execute a shell; therefore autocommands will not be executed. To execute autocommands under this circumstance, you need to establish a Telnet session back into the router (loop-back). Make sure that the router has been configured for secure Telnet sessions if you choose to implement autocommands this way.

This section includes the following sections:

- [Login Authentication Using Enable Password](#)
- [Login Authentication Using Kerberos](#)
- [Login Authentication Using Line Password](#)
- [Login Authentication Using Local Password](#)
- [Login Authentication Using Group RADIUS](#)
- [Login Authentication Using Group TACACS+](#)
- [Login Authentication Using group group-name](#)

Login Authentication Using Enable Password

Use the **aaa authentication login** command with the **enable method** keyword to specify the enable password as the login authentication method. For example, to specify the enable password as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default enable
```

Before you can use the enable password as the login authentication method, you need to define the enable password. For more information about defining enable passwords, refer to the chapter “Configuring Passwords and Privileges.”

Login Authentication Using Kerberos

Authentication via Kerberos is different from most other authentication methods: the user’s password is never sent to the remote access server. Remote users logging in to the network are prompted for a username. If the key distribution center (KDC) has an entry for that user, it creates an encrypted ticket granting ticket (TGT) with the password for that user and sends it back to the router. The user is then prompted for a password, and the router attempts to decrypt the TGT with that password. If it succeeds, the user is authenticated and the TGT is stored in the user’s credential cache on the router.

While **krb5** does use the KINIT program, a user does not need to run the KINIT program to get a TGT to authenticate to the router. This is because KINIT has been integrated into the login procedure in the Cisco IOS implementation of Kerberos.

Use the **aaa authentication login** command with the **krb5 method** keyword to specify Kerberos as the login authentication method. For example, to specify Kerberos as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default krb5
```

Before you can use Kerberos as the login authentication method, you need to enable communication with the Kerberos security server. For more information about establishing communication with a Kerberos server, refer to the chapter “Configuring Kerberos.”

Login Authentication Using Line Password

Use the **aaa authentication login** command with the **line method** keyword to specify the line password as the login authentication method. For example, to specify the line password as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default line
```

Before you can use a line password as the login authentication method, you need to define a line password. For more information about defining line passwords, refer to the section [“Configuring Line Password Protection”](#) in this chapter.

Login Authentication Using Local Password

Use the **aaa authentication login** command with the **local method** keyword to specify that the Cisco router or access server will use the local username database for authentication. For example, to specify the local username database as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default local
```

For information about adding users into the local username database, refer to the section [“Establishing Username Authentication”](#) in this chapter.

Login Authentication Using Group RADIUS

Use the **aaa authentication login** command with the **group radius method** to specify RADIUS as the login authentication method. For example, to specify RADIUS as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default group radius
```

Before you can use RADIUS as the login authentication method, you need to enable communication with the RADIUS security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS.”

Configuring RADIUS Attribute 8 in Access Requests

Once you have used the **aaa authentication login** command to specify RADIUS and your login host has been configured to request its IP address from the NAS, you can send attribute 8 (Framed-IP-Address) in access-request packets by using the **radius-server attribute 8 include-in-access-req** command in global configuration mode. This command makes it possible for a NAS to provide the RADIUS server with a hint of the user IP address in advance of user authentication. For more information about attribute 8, refer to the appendix “RADIUS Attributes” at the end of the book.

Login Authentication Using Group TACACS+

Use the **aaa authentication login** command with the **group tacacs+ method** to specify TACACS+ as the login authentication method. For example, to specify TACACS+ as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default group tacacs+
```

Before you can use TACACS+ as the login authentication method, you need to enable communication with the TACACS+ security server. For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

Login Authentication Using group group-name

Use the **aaa authentication login** command with the **group group-name** method to specify a subset of RADIUS or TACACS+ servers to use as the login authentication method. To specify and define the group name and the members of the group, use the **aaa group server** command. For example, use the **aaa group server** command to first define the members of **group loginrad**:

```
aaa group server radius loginrad
  server 172.16.2.3
  server 172.16.2.17
  server 172.16.2.32
```

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the group *loginrad*.

To specify **group loginrad** as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default group loginrad
```

Before you can use a group name as the login authentication method, you need to enable communication with the RADIUS or TACACS+ security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS.” For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

Configuring PPP Authentication Using AAA

Many users access network access servers through dialup via async or ISDN. Dialup via async or ISDN bypasses the CLI completely; instead, a network protocol (such as PPP or ARA) starts as soon as the connection is established.

The AAA security services facilitate a variety of authentication methods for use on serial interfaces running PPP. Use the **aaa authentication ppp** command to enable AAA authentication no matter which of the supported PPP authentication methods you decide to use.

To configure AAA authentication methods for serial lines using PPP, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa new-model	Enables AAA globally.
Step 2	Router(config)# aaa authentication ppp {default list-name} method1 [method2...]	Creates a local authentication list.

	Command	Purpose
Step 3	Router(config)# interface <i>interface-type</i> <i>interface-number</i>	Enters interface configuration mode for the interface to which you want to apply the authentication list.
Step 4	Router(config-if)# ppp authentication { <i>protocol1</i> [<i>protocol2...</i>]} [if-needed] { default <i>list-name</i> } [callin] [one-time][optional]	Applies the authentication list to a line or set of lines. In this command, <i>protocol1</i> and <i>protocol2</i> represent the following protocols: CHAP, MS-CHAP, and PAP. PPP authentication is attempted first using the first authentication method, specified by <i>protocol1</i> . If <i>protocol1</i> is unable to establish authentication, the next configured protocol is used to negotiate authentication.

With the **aaa authentication ppp** command, you create one or more lists of authentication methods that are tried when a user tries to authenticate via PPP. These lists are applied using the **ppp authentication** line configuration command.

To create a default list that is used when a named list is *not* specified in the **ppp authentication** command, use the **default** keyword followed by the methods you want used in default situations.

For example, to specify the local username database as the default method for user authentication, enter the following command:

```
aaa authentication ppp default local
```

The *list-name* is any character string used to name the list you are creating. The method argument refers to the actual method the authentication algorithm tries. The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify **none** as the final method in the command line.

For example, to specify that authentication should succeed even if (in this example) the TACACS+ server returns an error, enter the following command:

```
aaa authentication ppp default group tacacs+ none
```

Note

Because **none** allows all users logging in to authenticate successfully, it should be used as a backup method of authentication.

Table 5 lists the supported login authentication methods.

Table 5 AAA Authentication PPP Methods

Keyword	Description
if-needed	Does not authenticate if user has already been authenticated on a TTY line.
krb5	Uses Kerberos 5 for authentication (can only be used for PAP authentication).
local	Uses the local username database for authentication.
local-case	Uses case-sensitive local username authentication.
none	Uses no authentication.
group radius	Uses the list of all RADIUS servers for authentication.

Table 5 **AAA Authentication PPP Methods (continued)**

Keyword	Description
group tacacs+	Uses the list of all TACACS+ servers for authentication.
group group-name	Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the aaa group server radius or aaa group server tacacs+ command.

This section includes the following sections:

- [PPP Authentication Using Kerberos](#)
- [PPP Authentication Using Local Password](#)
- [PPP Authentication Using Group RADIUS](#)
- [PPP Authentication Using Group TACACS+](#)
- [PPP Authentication Using group group-name](#)

PPP Authentication Using Kerberos

Use the **aaa authentication ppp** command with the **krb5 method** keyword to specify Kerberos as the authentication method for use on interfaces running PPP. For example, to specify Kerberos as the method of user authentication when no other method list has been defined, enter the following command:

```
aaa authentication ppp default krb5
```

Before you can use Kerberos as the PPP authentication method, you need to enable communication with the Kerberos security server. For more information about establishing communication with a Kerberos server, refer to the chapter “Configuring Kerberos”.

**Note**

Kerberos login authentication works only with PPP PAP authentication.

PPP Authentication Using Local Password

Use the **aaa authentication ppp** command with the **method local** keyword to specify that the Cisco router or access server will use the local username database for authentication. For example, to specify the local username database as the method of authentication for use on lines running PPP when no other method list has been defined, enter the following command:

```
aaa authentication ppp default local
```

For information about adding users into the local username database, refer to the section “[Establishing Username Authentication](#)” in this chapter.

PPP Authentication Using Group RADIUS

Use the **aaa authentication ppp** command with the **group radius method** keyword to specify RADIUS as the login authentication method. For example, to specify RADIUS as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication ppp default group radius
```

Before you can use RADIUS as the PPP authentication method, you need to enable communication with the RADIUS security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS.”

Configuring RADIUS Attribute 44 in Access Requests

Once you have used the **aaa authentication ppp** command with the **group radius method** to specify RADIUS as the login authentication method, you can configure your router to send attribute 44 (Acct-Session-ID) in access-request packets by using the **radius-server attribute 44 include-in-access-req** command in global configuration mode. This command allows the RADIUS daemon to track a call from the beginning of the call to the end of the call. For more information on attribute 44, refer to the appendix “RADIUS Attributes” at the end of the book.

PPP Authentication Using Group TACACS+

Use the **aaa authentication ppp** command with the **group tacacs+ method** to specify TACACS+ as the login authentication method. For example, to specify TACACS+ as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication ppp default group tacacs+
```

Before you can use TACACS+ as the PPP authentication method, you need to enable communication with the TACACS+ security server. For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

PPP Authentication Using group group-name

Use the **aaa authentication ppp** command with the **group group-name method** to specify a subset of RADIUS or TACACS+ servers to use as the login authentication method. To specify and define the group name and the members of the group, use the **aaa group server** command. For example, use the **aaa group server** command to first define the members of **group ppprad**:

```
aaa group server radius ppprad
server 172.16.2.3
server 172.16.2.17
server 172.16.2.32
```

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the group *ppprad*.

To specify **group ppprad** as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication ppp default group ppprad
```

Before you can use a group name as the PPP authentication method, you need to enable communication with the RADIUS or TACACS+ security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS”. For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

Configuring AAA Scalability for PPP Requests

You can configure and monitor the number of background processes allocated by the PPP manager in the network access server (NAS) to deal with AAA authentication and authorization requests. In previous Cisco IOS releases, only one background process was allocated to handle all AAA requests for PPP. This meant that parallelism in AAA servers could not be fully exploited. The AAA Scalability feature enables you to configure the number of processes used to handle AAA requests for PPP, thus increasing the number of users that can be simultaneously authenticated or authorized.

To allocate a specific number of background processes to handle AAA requests for PPP, use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa processes <i>number</i>	Allocates a specific number of background processes to handle AAA authentication and authorization requests for PPP.

The argument *number* defines the number of background processes earmarked to process AAA authentication and authorization requests for PPP and can be configured for any value from 1 to 2147483647. Because of the way the PPP manager handles requests for PPP, this argument also defines the number of new users that can be simultaneously authenticated. This argument can be increased or decreased at any time.

Note

Allocating additional background processes can be expensive. You should configure the minimum number of background processes capable of handling the AAA requests for PPP.

Configuring ARAP Authentication Using AAA

With the **aaa authentication arap** command, you create one or more lists of authentication methods that are tried when AppleTalk Remote Access Protocol (ARAP) users attempt to log in to the router. These lists are used with the **arap authentication** line configuration command.

Use the following commands starting in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa new-model	Enables AAA globally.
Step 2	Router(config)# aaa authentication arap { default <i>list-name</i> } <i>method1</i> [<i>method2...</i>]	Enables authentication for ARAP users.
Step 3	Router(config)# line <i>number</i>	(Optional) Changes to line configuration mode.
Step 4	Router(config-line)# autoselect arap	(Optional) Enables autoselection of ARAP.
Step 5	Router(config-line)# autoselect during-login	(Optional) Starts the ARAP session automatically at user login.
Step 6	Router(config-line)# arap authentication <i>list-name</i>	(Optional—not needed if default is used in the aaa authentication arap command) Enables TACACS+ authentication for ARAP on a line.

The *list-name* is any character string used to name the list you are creating. The method argument refers to the actual list of methods the authentication algorithm tries, in the sequence entered.

To create a default list that is used when a named list is *not* specified in the **arap authentication** command, use the **default** keyword followed by the methods you want to be used in default situations.

The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify **none** as the final method in the command line.

**Note**

Because **none** allows all users logging in to authenticate successfully, it should be used as a backup method of authentication.

Table 6 lists the supported login authentication methods.

Table 6 **AAA Authentication ARAP Methods**

Keyword	Description
auth-guest	Allows guest logins only if the user has already logged in to EXEC.
guest	Allows guest logins.
line	Uses the line password for authentication.
local	Uses the local username database for authentication.
local-case	Uses case-sensitive local username authentication.
group radius	Uses the list of all RADIUS servers for authentication.
group tacacs+	Uses the list of all TACACS+ servers for authentication.
group <i>group-name</i>	Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the aaa group server radius or aaa group server tacacs+ command.

For example, to create a default AAA authentication method list used with ARAP, enter the following command:

```
aaa authentication arap default if-needed none
```

To create the same authentication method list for ARAP but name the list *MIS-access*, enter the following command:

```
aaa authentication arap MIS-access if-needed none
```

This section includes the following sections:

- [ARAP Authentication Allowing Authorized Guest Logins](#)
- [ARAP Authentication Allowing Guest Logins](#)
- [ARAP Authentication Using Line Password](#)
- [ARAP Authentication Using Local Password](#)
- [ARAP Authentication Using Group RADIUS](#)
- [ARAP Authentication Using Group TACACS+](#)
- [ARAP Authentication Using Group group-name](#)

ARAP Authentication Allowing Authorized Guest Logins

Use the **aaa authentication arap** command with the **auth-guest** keyword to allow guest logins only if the user has already successfully logged in to the EXEC. This method must be the first listed in the ARAP authentication method list but it can be followed by other methods if it does not succeed. For example, to allow all authorized guest logins—meaning logins by users who have already successfully logged in to the EXEC—as the default method of authentication, using RADIUS only if that method fails, enter the following command:

```
aaa authentication arap default auth-guest group radius
```

For more information about ARAP authorized guest logins, refer to the chapter “Configuring AppleTalk” in the *Cisco IOS AppleTalk and Novell IPX Configuration Guide*.

Note

By default, guest logins through ARAP are disabled when you initialize AAA. To allow guest logins, you must use the **aaa authentication arap** command with either the **guest** or the **auth-guest** keyword.

ARAP Authentication Allowing Guest Logins

Use the **aaa authentication arap** command with the **guest** keyword to allow guest logins. This method must be the first listed in the ARAP authentication method list but it can be followed by other methods if it does not succeed. For example, to allow all guest logins as the default method of authentication, using RADIUS only if that method fails, enter the following command:

```
aaa authentication arap default guest group radius
```

For more information about ARAP guest logins, refer to the chapter “Configuring AppleTalk” in the *Cisco IOS AppleTalk and Novell IPX Configuration Guide*.

ARAP Authentication Using Line Password

Use the **aaa authentication arap** command with the *method* keyword **line** to specify the line password as the authentication method. For example, to specify the line password as the method of ARAP user authentication when no other method list has been defined, enter the following command:

```
aaa authentication arap default line
```

Before you can use a line password as the ARAP authentication method, you need to define a line password. For more information about defining line passwords, refer to the section “[Configuring Line Password Protection](#)” in this chapter.

ARAP Authentication Using Local Password

Use the **aaa authentication arap** command with the *method* keyword **local** to specify that the Cisco router or access server will use the local username database for authentication. For example, to specify the local username database as the method of ARAP user authentication when no other method list has been defined, enter the following command:

```
aaa authentication arap default local
```

For information about adding users to the local username database, refer to the section “[Establishing Username Authentication](#)” in this chapter.

ARAP Authentication Using Group RADIUS

Use the **aaa authentication arap** command with the **group radius method** to specify RADIUS as the ARAP authentication method. For example, to specify RADIUS as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication arap default group radius
```

Before you can use RADIUS as the ARAP authentication method, you need to enable communication with the RADIUS security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS.”

ARAP Authentication Using Group TACACS+

Use the **aaa authentication arap** command with the **group tacacs+ method** to specify TACACS+ as the ARAP authentication method. For example, to specify TACACS+ as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication arap default group tacacs+
```

Before you can use TACACS+ as the ARAP authentication method, you need to enable communication with the TACACS+ security server. For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

ARAP Authentication Using Group group-name

Use the **aaa authentication arap** command with the **group group-name method** to specify a subset of RADIUS or TACACS+ servers to use as the ARAP authentication method. To specify and define the group name and the members of the group, use the **aaa group server** command. For example, use the **aaa group server** command to first define the members of **group araprad**:

```
aaa group server radius araprad
server 172.16.2.3
server 172.16.2.17
server 172.16.2.32
```

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the group *araprad*.

To specify **group araprad** as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication arap default group araprad
```

Before you can use a group name as the ARAP authentication method, you need to enable communication with the RADIUS or TACACS+ security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS.” For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

Configuring NASI Authentication Using AAA

With the **aaa authentication nasi** command, you create one or more lists of authentication methods that are tried when NetWare Asynchronous Services Interface (NASI) users attempt to log in to the router. These lists are used with the **nasi authentication** line configuration command.

To configure NASI authentication using AAA, use the following commands starting in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa new-model	Enables AAA globally.
Step 2	Router(config)# aaa authentication nasi { default <i>list-name</i> } <i>method1</i> [<i>method2...</i>]	Enables authentication for NASI users.
Step 3	Router(config)# line <i>number</i>	(Optional—not needed if default is used in the aaa authentication nasi command) Enters line configuration mode.
Step 4	Router(config-line)# nasi authentication <i>list-name</i>	(Optional—not needed if default is used in the aaa authentication nasi command) Enables authentication for NASI on a line.

The *list-name* is any character string used to name the list you are creating. The method argument refers to the actual list of methods the authentication algorithm tries, in the sequence entered.

To create a default list that is used when a named list is *not* specified in the **aaa authentication nasi** command, use the **default** keyword followed by the methods you want to be used in default situations.

The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify **none** as the final method in the command line.

Note

Because **none** allows all users logging in to authenticate successfully, it should be used as a backup method of authentication.

Table 7 lists the supported NASI authentication methods.

Table 7 AAA Authentication NASI Methods

Keyword	Description
enable	Uses the enable password for authentication.
line	Uses the line password for authentication.
local	Uses the local username database for authentication.
local-case	Uses case-sensitive local username authentication.
none	Uses no authentication.
group radius	Uses the list of all RADIUS servers for authentication.
group tacacs+	Uses the list of all TACACS+ servers for authentication.
group <i>group-name</i>	Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the aaa group server radius or aaa group server tacacs+ command.

This section includes the following sections:

- [NASI Authentication Using Enable Password](#)
- [NASI Authentication Using Line Password](#)
- [NASI Authentication Using Local Password](#)

- [NASI Authentication Using Group RADIUS](#)
- [NASI Authentication Using Group TACACS+](#)
- [NASI Authentication Using group group-name](#)

NASI Authentication Using Enable Password

Use the **aaa authentication nasi** command with the *method* keyword **enable** to specify the enable password as the authentication method. For example, to specify the enable password as the method of NASI user authentication when no other method list has been defined, enter the following command:

```
aaa authentication nasi default enable
```

Before you can use the enable password as the authentication method, you need to define the enable password. For more information about defining enable passwords, refer to the chapter “Configuring Passwords and Privileges.”

NASI Authentication Using Line Password

Use the **aaa authentication nasi** command with the *method* keyword **line** to specify the line password as the authentication method. For example, to specify the line password as the method of NASI user authentication when no other method list has been defined, enter the following command:

```
aaa authentication nasi default line
```

Before you can use a line password as the NASI authentication method, you need to define a line password. For more information about defining line passwords, refer to the section “[Configuring Line Password Protection](#)” in this chapter.

NASI Authentication Using Local Password

Use the **aaa authentication nasi** command with the *method* keyword **local** to specify that the Cisco router or access server will use the local username database for authentication information. For example, to specify the local username database as the method of NASI user authentication when no other method list has been defined, enter the following command:

```
aaa authentication nasi default local
```

For information about adding users to the local username database, refer to the section “[Establishing Username Authentication](#)” in this chapter.

NASI Authentication Using Group RADIUS

Use the **aaa authentication nasi** command with the **group radius** *method* to specify RADIUS as the NASI authentication method. For example, to specify RADIUS as the method of NASI user authentication when no other method list has been defined, enter the following command:

```
aaa authentication nasi default group radius
```

Before you can use RADIUS as the NASI authentication method, you need to enable communication with the RADIUS security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS.”

NASI Authentication Using Group TACACS+

Use the **aaa authentication nasi** command with the **group tacacs+ method** keyword to specify TACACS+ as the NASI authentication method. For example, to specify TACACS+ as the method of NASI user authentication when no other method list has been defined, enter the following command:

```
aaa authentication nasi default group tacacs+
```

Before you can use TACACS+ as the authentication method, you need to enable communication with the TACACS+ security server. For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

NASI Authentication Using group group-name

Use the **aaa authentication nasi** command with the **group group-name** method to specify a subset of RADIUS or TACACS+ servers to use as the NASI authentication method. To specify and define the group name and the members of the group, use the **aaa group server** command. For example, use the **aaa group server** command to first define the members of **group nasirad**:

```
aaa group server radius nasirad
server 172.16.2.3
server 172.16.2.17
server 172.16.2.32
```

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the group *nasirad*.

To specify **group nasirad** as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication nasi default group nasirad
```

Before you can use a group name as the NASI authentication method, you need to enable communication with the RADIUS or TACACS+ security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS”. For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

Specifying the Amount of Time for Login Input

The **timeout login response** command allows you to specify how long the system will wait for login input (such as username and password) before timing out. The default login value is 30 seconds; with the **timeout login response** command, you can specify a timeout value from 1 to 300 seconds. To change the login timeout value from the default of 30 seconds, use the following command in line configuration mode:

Command	Purpose
Router(config-line)# timeout login response <i>seconds</i>	Specifies how long the system will wait for login information before timing out.

Enabling Password Protection at the Privileged Level

Use the **aaa authentication enable default** command to create a series of authentication methods that are used to determine whether a user can access the privileged EXEC command level. You can specify up to four authentication methods. The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify **none** as the final method in the command line.

Use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa authentication enable default <i>method1 [method2...]</i>	Enables user ID and password checking for users requesting privileged EXEC level. Note All aaa authentication enable default requests sent by the router to a RADIUS server include the username "\$enab15\$." Requests sent to a TACACS+ server will include the username that is entered for login authentication.

The method argument refers to the actual list of methods the authentication algorithm tries, in the sequence entered. [Table 8](#) lists the supported enable authentication methods.

Table 8 AAA Authentication Enable Default Methods

Keyword	Description
enable	Uses the enable password for authentication.
line	Uses the line password for authentication.
none	Uses no authentication.
group radius	Uses the list of all RADIUS hosts for authentication. Note The RADIUS method does not work on a per-username basis.
group tacacs+	Uses the list of all TACACS+ hosts for authentication.
group <i>group-name</i>	Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the aaa group server radius or aaa group server tacacs+ command.

Changing the Text Displayed at the Password Prompt

Use the **aaa authentication password-prompt** command to change the default text that the Cisco IOS software displays when prompting a user to enter a password. This command changes the password prompt for the enable password as well as for login passwords that are not supplied by remote security servers. The **no** form of this command returns the password prompt to the following default value:

Password:

The **aaa authentication password-prompt** command does not change any dialog that is supplied by a remote TACACS+ or RADIUS server.

The **aaa authentication password-prompt** command works when RADIUS is used as the login method. You will be able to see the password prompt defined in the command shown even when the RADIUS server is unreachable. The **aaa authentication password-prompt** command does not work with

TACACS+. TACACS+ supplies the NAS with the password prompt to display to the users. If the TACACS+ server is reachable, the NAS gets the password prompt from the server and uses that prompt instead of the one defined in the **aaa authentication password-prompt** command. If the TACACS+ server is not reachable, the password prompt defined in the **aaa authentication password-prompt** command may be used.

Use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa authentication password-prompt <i>text-string</i>	Changes the default text displayed when a user is prompted to enter a password.

Configuring Message Banners for AAA Authentication

AAA supports the use of configurable, personalized login and failed-login banners. You can configure message banners that will be displayed when a user logs in to the system to be authenticated using AAA and when, for whatever reason, authentication fails.

This section includes the following sections:

- [Configuring a Login Banner](#)
- [Configuring a Failed-Login Banner](#)

Configuring a Login Banner

To create a login banner, you need to configure a delimiting character, which notifies the system that the following text string is to be displayed as the banner, and then the text string itself. The delimiting character is repeated at the end of the text string to signify the end of the banner. The delimiting character can be any single character in the extended ASCII character set, but once defined as the delimiter, that character cannot be used in the text string making up the banner.

To configure a banner that will be displayed whenever a user logs in (replacing the default message for login), use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa new-model	Enables AAA.
Step 2	Router(config)# aaa authentication banner <i>delimiter string delimiter</i>	Creates a personalized login banner.

The maximum number of characters that can be displayed in the login banner is 2996 characters.

Configuring a Failed-Login Banner

To create a failed-login banner, you need to configure a delimiting character, which notifies the system that the following text string is to be displayed as the banner, and then the text string itself. The delimiting character is repeated at the end of the text string to signify the end of the failed-login banner. The delimiting character can be any single character in the extended ASCII character set, but once defined as the delimiter, that character cannot be used in the text string making up the banner.

To configure a message that will be displayed whenever a user fails login (replacing the default message for failed login), use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa new-model	Enables AAA.
Step 2	Router(config)# aaa authentication fail-message <i>delimiter string delimiter</i>	Creates a message to be displayed when a user fails login.

The maximum number of characters that can be displayed in the failed-login banner is 2996 characters.

Configuring AAA Packet of Disconnect

Packet of disconnect (POD) terminates connections on the network access server (NAS) when particular session attributes are identified. By using session information obtained from AAA, the POD client residing on a UNIX workstation sends disconnect packets to the POD server running on the network access server. The NAS terminates any inbound user session with one or more matching key attributes. It rejects requests when required fields are missing or when an exact match is not found.

To configure POD, perform the following tasks in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa accounting network default start-stop radius	Enables AAA accounting records.
Step 2	Router(config)# aaa accounting delay-start	(Optional) Delays generation of the start accounting record until the Framed-IP-Address is assigned, allowing its use in the POD packet.
Step 3	Router(config)# aaa pod server server-key string	Enables POD reception.
Step 4	Router(config)# radius-server host IP address non-standard	Declares a RADIUS host that uses a vendor-proprietary version of RADIUS.

Enabling Double Authentication

Previously, PPP sessions could only be authenticated by using a single authentication method: either PAP or CHAP. Double authentication requires remote users to pass a second stage of authentication—after CHAP or PAP authentication—before gaining network access.

This second (“double”) authentication requires a password that is known to the user but *not* stored on the user’s remote host. Therefore, the second authentication is specific to a user, not to a host. This provides an additional level of security that will be effective even if information from the remote host is stolen. In addition, this also provides greater flexibility by allowing customized network privileges for each user.

The second stage authentication can use one-time passwords such as token card passwords, which are not supported by CHAP. If one-time passwords are used, a stolen user password is of no use to the perpetrator.

This section includes the following subsections:

- [How Double Authentication Works](#)

- [Configuring Double Authentication](#)
- [Accessing the User Profile After Double Authentication](#)

How Double Authentication Works

With double authentication, there are two authentication/authorization stages. These two stages occur after a remote user dials in and a PPP session is initiated.

In the first stage, the user logs in using the remote host name; CHAP (or PAP) authenticates the remote host, and then PPP negotiates with AAA to authorize the remote host. In this process, the network access privileges associated with the remote host are assigned to the user.

Note

We suggest that the network administrator restrict authorization at this first stage to allow only Telnet connections to the local host.

In the second stage, the remote user must Telnet to the network access server to be authenticated. When the remote user logs in, the user must be authenticated with AAA login authentication. The user then must enter the **access-profile** command to be reauthorized using AAA. When this authorization is complete, the user has been double authenticated, and can access the network according to per-user network privileges.

The system administrator determines what network privileges remote users will have after each stage of authentication by configuring appropriate parameters on a security server. To use double authentication, the user must activate it by issuing the **access-profile** command.

Caution

Double authentication can cause certain undesirable events if multiple hosts share a PPP connection to a network access server, as shown in [Figure 3](#).

First, if a user, Bob, initiates a PPP session and activates double authentication at the network access server (per [Figure 3](#)), any other user will automatically have the same network privileges as Bob until Bob's PPP session expires. This happens because Bob's authorization profile is applied to the network access server's interface during the PPP session and any PPP traffic from other users will use the PPP session Bob established.

Second, if Bob initiates a PPP session and activates double authentication, and then—before Bob's PPP session has expired—another user, Jane, executes the **access-profile** command (or, if Jane Telnets to the network access server and **autocommand access-profile** is executed), a reauthorization will occur and Jane's authorization profile will be applied to the interface—replacing Bob's profile. This can disrupt or halt Bob's PPP traffic, or grant Bob additional authorization privileges Bob should not have.

Figure 3 *Possibly Risky Topology: Multiple Hosts Share a PPP Connection to a Network Access Server*

Configuring Double Authentication

To configure double authentication, you must complete the following steps:

1. Enable AAA by using the **aaa-new model** global configuration command. For more information about enabling AAA, refer to the chapter “AAA Overview.”
2. Use the **aaa authentication** command to configure your network access server to use login and PPP authentication method lists, then apply those method lists to the appropriate lines or interfaces.
3. Use the **aaa authorization** command to configure AAA network authorization at login. For more information about configuring network authorization, refer to the “Configuring Authorization” chapter.
4. Configure security protocol parameters (for example, RADIUS or TACACS+). For more information about RADIUS, refer to the chapter “Configuring RADIUS”. For more information about TACACS+, refer to the chapter “Configuring TACACS+.”
5. Use access control list AV pairs on the security server that the user can connect to the local host only by establishing a Telnet connection.
6. (Optional) Configure the **access-profile** command as an autocommand. If you configure the autocommand, remote users will not have to manually enter the **access-profile** command to access authorized rights associated with their personal user profile. To learn about configuring autocommands, refer to the **autocommand** command in the *Cisco IOS Dial Technologies Command Reference: Network Services*.

Note

If the **access-profile** command is configured as an autocommand, users will still have to Telnet to the local host and log in to complete double authentication.

Follow these rules when creating the user-specific authorization statements (These rules relate to the default behavior of the **access-profile** command):

- Use valid AV pairs when configuring access control list AV pairs on the security server. For a list of valid AV pairs, refer to the chapter “Authentication Commands” in the *Cisco IOS Security Command Reference*.
- If you want remote users to use the interface’s existing authorization (that which existed prior to the second stage authentication/authorization), but you want them to have different access control lists (ACLs), you should specify *only* ACL AV pairs in the user-specific authorization definition. This might be desirable if you set up a default authorization profile to apply to the remote host, but want to apply specific ACLs to specific users.

- When these user-specific authorization statements are later applied to the interface, they can either be *added* to the existing interface configuration or they can *replace* the existing interface configuration—depending on which form of the **access-profile** command is used to authorize the user. You should understand how the **access-profile** command works before configuring the authorization statements.
- If you will be using ISDN or Multilink PPP, you must also configure virtual templates at the local host.

To troubleshoot double authentication, use the **debug aaa per-user** debug command. For more information about this command, refer to the *Cisco IOS Debug Command Reference*.

Accessing the User Profile After Double Authentication

In double authentication, when a remote user establishes a PPP link to the local host using the local host name, the remote host is CHAP (or PAP) authenticated. After CHAP (or PAP) authentication, PPP negotiates with AAA to assign network access privileges associated with the remote host to the user. (We suggest that privileges at this stage be restricted to allow the user to connect to the local host only by establishing a Telnet connection.)

When the user needs to initiate the second phase of double authentication, establishing a Telnet connection to the local host, the user enters a personal username and password (different from the CHAP or PAP username and password). This action causes AAA reauthentication to occur according to the personal username/password. The initial rights associated with the local host, though, are still in place. By using the **access-profile** command, the rights associated with the local host are replaced by or merged with those defined for the user in the user's profile.

To access the user profile after double authentication, use the following command in EXEC configuration mode:

Command	Purpose
Router> access-profile [merge replace] [ignore-sanity-checks]	Accesses the rights associated for the user after double authentication.

If you configured the **access-profile** command to be executed as an autocommand, it will be executed automatically after the remote user logs in.

Enabling Automated Double Authentication

You can make the double authentication process easier for users by implementing automated double authentication. Automated double authentication provides all of the security benefits of double authentication, but offers a simpler, more user-friendly interface for remote users. With double authentication, a second level of user authentication is achieved when the user Telnets to the network access server or router and enters a username and password. With automated double authentication, the user does not have to Telnet to the network access server; instead the user responds to a dialog box that requests a username and password or personal identification number (PIN). To use the automated double authentication feature, the remote user hosts must be running a companion client application. As of Cisco IOS Release 12.0, the only client application software available is the Glacier Bay application server software for PCs.

**Note**

Automated double authentication, like the existing double authentication feature, is for Multilink PPP ISDN connections only. Automated double authentication cannot be used with other protocols such as X.25 or SLIP.

Automated double authentication is an enhancement to the existing double authentication feature. To configure automated double authentication, you must first configure double authentication by completing the following steps:

1. Enable AAA by using the **aaa-new model** global configuration command. For more information about enabling AAA, refer to the chapter “AAA Overview.”
2. Use the **aaa authentication** command to configure your network access server to use login and PPP authentication method lists, then apply those method lists to the appropriate lines or interfaces.
3. Use the **aaa authorization** command to configure AAA network authorization at login. For more information about configuring network authorization, refer to the chapter “Configuring Authorization.”
4. Configure security protocol parameters (for example, RADIUS or TACACS+). For more information about RADIUS, refer to the chapter “Configuring RADIUS”. For more information about TACACS+, refer to the chapter “Configuring TACACS+.”
5. Use access control list AV pairs on the security server that the user can connect to the local host only by establishing a Telnet connection.
6. Configure the **access-profile** command as an autocommand. If you configure the autocommand, remote users will not have to manually enter the **access-profile** command to access authorized rights associated with their personal user profile. To learn about configuring autocommands, refer to the **autocommand** command in the *Cisco IOS Dial Technologies Command Reference*, Release 12.2.

**Note**

If the **access-profile** command is configured as an autocommand, users will still have to Telnet to the local host and log in to complete double authentication.

Follow these rules when creating the user-specific authorization statements (These rules relate to the default behavior of the **access-profile** command):

- Use valid AV pairs when configuring access control list AV pairs on the security server. For a list of valid AV pairs, refer to the chapter “Authentication Commands” in the *Cisco IOS Security Command Reference*.
- If you want remote users to use the interface’s existing authorization (that which existed prior to the second stage authentication/authorization), but you want them to have different access control lists (ACLs), you should specify *only* ACL AV pairs in the user-specific authorization definition. This might be desirable if you set up a default authorization profile to apply to the remote host, but want to apply specific ACLs to specific users.
- When these user-specific authorization statements are later applied to the interface, they can either be *added* to the existing interface configuration, or *replace* the existing interface configuration—depending on which form of the **access-profile** command is used to authorize the user. You should understand how the **access-profile** command works before configuring the authorization statements.
- If you will be using ISDN or Multilink PPP, you must also configure virtual templates at the local host.

To troubleshoot double authentication, use the **debug aaa per-user** debug command. For more information about this command, refer to the *Cisco IOS Debug Command Reference*.

After you have configured double authentication, you are ready to configure the automation enhancement.

To configure automated double authentication, use the following commands, starting in global configuration mode.

:

	Command	Purpose
Step 1	Router(config)# ip trigger-authentication [<i>timeout seconds</i>] [<i>port number</i>]	Enables automation of double authentication.
Step 2	Router(config)# interface bri number or Router(config)# interface serial number:23	Selects an ISDN BRI or ISDN PRI interface and enter the interface configuration mode.
Step 3	Router(config-if)# ip trigger-authentication	Applies automated double authentication to the interface.

To troubleshoot automated double authentication, use the following commands in privileged EXEC mode:

	Command	Purpose
Step 1	Router# show ip trigger-authentication	Displays the list of remote hosts for which automated double authentication has been attempted (successfully or unsuccessfully).
Step 2	Router# clear ip trigger-authentication	Clears the list of remote hosts for which automated double authentication has been attempted. (This clears the table displayed by the show ip trigger-authentication command.)
Step 3	Router# debug ip trigger-authentication	Displays debug output related to automated double authentication.

Non-AAA Authentication Methods

This section discusses the following non-AAA authentication tasks:

- [Configuring Line Password Protection](#)
- [Establishing Username Authentication](#)
- [Enabling CHAP or PAP Authentication](#)
- [Using MS-CHAP](#)

Configuring Line Password Protection

You can provide access control on a terminal line by entering the password and establishing password checking. To do so, use the following commands in line configuration mode:

	Command	Purpose
Step 1	<code>Router(config-line)# password <i>password</i></code>	Assigns a password to a terminal or other device on a line.
Step 2	<code>Router(config-line)# login</code>	Enables password checking at login.

The password checker is case sensitive and can include spaces; for example, the password “Secret” is different from the password “secret,” and “two words” is an acceptable password.

You can disable line password verification by disabling password checking. To do so, use the following command in line configuration mode:

Command	Purpose
<code>Router(config-line)# no login</code>	Disables password checking or allow access to a line without password verification.

If you configure line password protection and then configure TACACS or extended TACACS, the TACACS username and password take precedence over line passwords. If you have not yet implemented a security policy, we recommend that you use AAA.

**Note**

The **login** command only changes username and privilege level but it does not execute a shell; therefore autocommands will not be executed. To execute autocommands under this circumstance, you need to establish a Telnet session back into the router (loop-back). Make sure that the router has been configured for secure Telnet sessions if you choose to implement autocommands this way.

Establishing Username Authentication

You can create a username-based authentication system, which is useful in the following situations:

- To provide a TACACS-like username and encrypted password-authentication system for networks that cannot support TACACS
- To provide special-case logins: for example, access list verification, no password verification, autocommand execution at login, and “no escape” situations

To establish username authentication, use the following commands in global configuration mode as needed for your system configuration:

	Command	Purpose
Step 1	<code>Router(config)# username <i>name</i> [nopassword password <i>password</i> password <i>encryption-type</i> <i>encrypted password</i>]</code> or <code>Router(config)# username <i>name</i> [access-class <i>number</i>]</code>	Establishes username authentication with encrypted passwords. or (Optional) Establishes username authentication by access list.
Step 2	<code>Router(config)# username <i>name</i> [privilege <i>level</i>]</code>	(Optional) Sets the privilege level for the user.

	Command	Purpose
Step 3	Router(config)# username name [autocommand command]	(Optional) Specifies a command to be executed automatically.
Step 4	Router(config)# username name [noescape] [nohangup]	(Optional) Sets a “no escape” login environment.

The keyword **noescape** prevents users from using escape characters on the hosts to which they are connected. The **nohangup** feature does not disconnect after using the autocommand.

**Caution**

Passwords will be displayed in clear text in your configuration unless you enable the **service password-encryption** command. For more information about the **service password-encryption** command, refer to the chapter “Passwords and Privileges Commands” in the *Cisco IOS Security Command Reference*.

Enabling CHAP or PAP Authentication

One of the most common transport protocols used in Internet service providers’ (ISPs’) dial solutions is the Point-to-Point Protocol (PPP). Traditionally, remote users dial in to an access server to initiate a PPP session. After PPP has been negotiated, remote users are connected to the ISP network and to the Internet.

Because ISPs want only customers to connect to their access servers, remote users are required to authenticate to the access server before they can start up a PPP session. Normally, a remote user authenticates by typing in a username and password when prompted by the access server. Although this is a workable solution, it is difficult to administer and awkward for the remote user.

A better solution is to use the authentication protocols built into PPP. In this case, the remote user dials in to the access server and starts up a minimal subset of PPP with the access server. This does not give the remote user access to the ISP’s network—it merely allows the access server to talk to the remote device.

PPP currently supports two authentication protocols: Password Authentication Protocol (PAP) and Challenge Handshake Authentication Protocol (CHAP). Both are specified in RFC 1334 and are supported on synchronous and asynchronous interfaces. Authentication via PAP or CHAP is equivalent to typing in a username and password when prompted by the server. CHAP is considered to be more secure because the remote user’s password is never sent across the connection.

PPP (with or without PAP or CHAP authentication) is also supported in dialout solutions. An access server utilizes a dialout feature when it initiates a call to a remote device and attempts to start up a transport protocol such as PPP.

See the chapter “Configuring Interfaces” in the *Cisco IOS Configuration Fundamentals Configuration Guide* for more information about CHAP and PAP.

**Note**

To use CHAP or PAP, you must be running PPP encapsulation.

When CHAP is enabled on an interface and a remote device attempts to connect to it, the access server sends a CHAP packet to the remote device. The CHAP packet requests or “challenges” the remote device to respond. The challenge packet consists of an ID, a random number, and the host name of the local router.

When the remote device receives the challenge packet, it concatenates the ID, the remote device's password, and the random number, and then encrypts all of it using the remote device's password. The remote device sends the results back to the access server, along with the name associated with the password used in the encryption process.

When the access server receives the response, it uses the name it received to retrieve a password stored in its user database. The retrieved password should be the same password the remote device used in its encryption process. The access server then encrypts the concatenated information with the newly retrieved password—if the result matches the result sent in the response packet, authentication succeeds.

The benefit of using CHAP authentication is that the remote device's password is never transmitted in clear text. This prevents other devices from stealing it and gaining illegal access to the ISP's network.

CHAP transactions occur only at the time a link is established. The access server does not request a password during the rest of the call. (The local device can, however, respond to such requests from other devices during a call.)

When PAP is enabled, the remote router attempting to connect to the access server is required to send an authentication request. If the username and password specified in the authentication request are accepted, the Cisco IOS software sends an authentication acknowledgment.

After you have enabled CHAP or PAP, the access server will require authentication from remote devices dialing in to the access server. If the remote device does not support the enabled protocol, the call will be dropped.

To use CHAP or PAP, you must perform the following tasks:

1. Enable PPP encapsulation.
2. Enable CHAP or PAP on the interface.
3. For CHAP, configure host name authentication and the secret or password for each remote system with which authentication is required.

This section includes the following sections:

- [Enabling PPP Encapsulation](#)
- [Enabling PAP or CHAP](#)
- [Inbound and Outbound Authentication](#)
- [Enabling Outbound PAP Authentication](#)
- [Refusing PAP Authentication Requests](#)
- [Creating a Common CHAP Password](#)
- [Refusing CHAP Authentication Requests](#)
- [Delaying CHAP Authentication Until Peer Authenticates](#)

Enabling PPP Encapsulation

To enable PPP encapsulation, use the following command in interface configuration mode:

Command	Purpose
<code>Router(config-if)# encapsulation ppp</code>	Enables PPP on an interface.

Enabling PAP or CHAP

To enable CHAP or PAP authentication on an interface configured for PPP encapsulation, use the following command in interface configuration mode:

Command	Purpose
Router(config-if)# ppp authentication { <i>protocol1</i> [<i>protocol2...</i>] [<i>if-needed</i>] [<i>default</i> <i>list-name</i>] [<i>callin</i>] [<i>one-time</i>]	Defines the authentication protocols supported and the order in which they are used. In this command, <i>protocol1</i> , <i>protocol2</i> represent the following protocols: CHAP, MS-CHAP, and PAP. PPP authentication is attempted first using the first authentication method, which is <i>protocol1</i> . If <i>protocol1</i> is unable to establish authentication, the next configured protocol is used to negotiate authentication.

If you configure **ppp authentication chap** on an interface, all incoming calls on that interface that initiate a PPP connection will have to be authenticated using CHAP; likewise, if you configure **ppp authentication pap**, all incoming calls that start a PPP connection will have to be authenticated via PAP. If you configure **ppp authentication chap pap**, the access server will attempt to authenticate all incoming calls that start a PPP session with CHAP. If the remote device does not support CHAP, the access server will try to authenticate the call using PAP. If the remote device does not support either CHAP or PAP, authentication will fail and the call will be dropped. If you configure **ppp authentication pap chap**, the access server will attempt to authenticate all incoming calls that start a PPP session with PAP. If the remote device does not support PAP, the access server will try to authenticate the call using CHAP. If the remote device does not support either protocol, authentication will fail and the call will be dropped. If you configure the **ppp authentication** command with the **callin** keyword, the access server will only authenticate the remote device if the remote device initiated the call.

Authentication method lists and the **one-time** keyword are only available if you have enabled AAA—they will not be available if you are using TACACS or extended TACACS. If you specify the name of an authentication method list with the **ppp authentication** command, PPP will attempt to authenticate the connection using the methods defined in the specified method list. If AAA is enabled and no method list is defined by name, PPP will attempt to authenticate the connection using the methods defined as the default. The **ppp authentication** command with the **one-time** keyword enables support for one-time passwords during authentication.

The **if-needed** keyword is only available if you are using TACACS or extended TACACS. The **ppp authentication** command with the **if-needed** keyword means that PPP will only authenticate the remote device via PAP or CHAP if they have not yet authenticated during the life of the current call. If the remote device authenticated via a standard login procedure and initiated PPP from the EXEC prompt, PPP will not authenticate via CHAP if **ppp authentication chap if-needed** is configured on the interface.

Caution

If you use a *list-name* that has not been configured with the **aaa authentication ppp** command, you disable PPP on the line.

For information about adding a **username** entry for each remote system from which the local router or access server requires authentication, see the section “[Establishing Username Authentication](#).”

Inbound and Outbound Authentication

PPP supports two-way authentication. Normally, when a remote device dials in to an access server, the access server requests that the remote device prove that it is allowed access. This is known as inbound authentication. At the same time, the remote device can also request that the access server prove that it is who it says it is. This is known as outbound authentication. An access server also does outbound authentication when it initiates a call to a remote device.

Enabling Outbound PAP Authentication

To enable outbound PAP authentication, use the following command in interface configuration mode:

Command	Purpose
<code>Router(config-if)# ppp pap sent-username <i>username</i> password <i>password</i></code>	Enables outbound PAP authentication.

The access server uses the username and password specified by the **ppp pap sent-username** command to authenticate itself whenever it initiates a call to a remote device or when it has to respond to a remote device's request for outbound authentication.

Refusing PAP Authentication Requests

To refuse PAP authentication from peers requesting it, meaning that PAP authentication is disabled for all calls, use the following command in interface configuration mode:

Command	Purpose
<code>Router(config-if)# ppp pap refuse</code>	Refuses PAP authentication from peers requesting PAP authentication.

If the **refuse** keyword is not used, the router will not refuse any PAP authentication challenges received from the peer.

Creating a Common CHAP Password

For remote CHAP authentication only, you can configure your router to create a common CHAP secret password to use in response to challenges from an unknown peer; for example, if your router calls a rotary of routers (either from another vendor, or running an older version of the Cisco IOS software) to which a new (that is, unknown) router has been added. The **ppp chap password** command allows you to replace several username and password configuration commands with a single copy of this command on any dialer interface or asynchronous group interface.

To enable a router calling a collection of routers to configure a common CHAP secret password, use the following command in interface configuration mode:

Command	Purpose
<code>Router(config-if)# ppp chap password <i>secret</i></code>	Enables a router calling a collection of routers to configure a common CHAP secret password.

Refusing CHAP Authentication Requests

To refuse CHAP authentication from peers requesting it, meaning that CHAP authentication is disabled for all calls, use the following command in interface configuration mode:

Command	Purpose
<code>Router(config-if)# ppp chap refuse [callin]</code>	Refuses CHAP authentication from peers requesting CHAP authentication.

If the **callin** keyword is used, the router will refuse to answer CHAP authentication challenges received from the peer, but will still require the peer to answer any CHAP challenges the router sends.

If outbound PAP has been enabled (using the **ppp pap sent-username** command), PAP will be suggested as the authentication method in the refusal packet.

Delaying CHAP Authentication Until Peer Authenticates

To specify that the router will not authenticate to a peer requesting CHAP authentication until after the peer has authenticated itself to the router, use the following command in interface configuration mode:

Command	Purpose
<code>Router(config-if)# ppp chap wait secret</code>	Configures the router to delay CHAP authentication until after the peer has authenticated itself to the router.

This command (which is the default) specifies that the router will not authenticate to a peer requesting CHAP authentication until the peer has authenticated itself to the router. The **no ppp chap wait** command specifies that the router will respond immediately to an authentication challenge.

Using MS-CHAP

Microsoft Challenge Handshake Authentication Protocol (MS-CHAP) is the Microsoft version of CHAP and is an extension of RFC 1994. Like the standard version of CHAP, MS-CHAP is used for PPP authentication; in this case, authentication occurs between a PC using Microsoft Windows NT or Microsoft Windows 95 and a Cisco router or access server acting as a network access server.

MS-CHAP differs from the standard CHAP as follows:

- MS-CHAP is enabled by negotiating CHAP Algorithm 0x80 in LCP option 3, Authentication Protocol.
- The MS-CHAP Response packet is in a format designed to be compatible with Microsoft Windows NT 3.5 and 3.51, Microsoft Windows 95, and Microsoft LAN Manager 2.x. This format does not require the authenticator to store a clear or reversibly encrypted password.
- MS-CHAP provides an authenticator-controlled authentication retry mechanism.
- MS-CHAP provides an authenticator-controlled change password mechanism.
- MS-CHAP defines a set of “reason-for failure” codes returned in the Failure packet message field.

Depending on the security protocols you have implemented, PPP authentication using MS-CHAP can be used with or without AAA security services. If you have enabled AAA, PPP authentication using MS-CHAP can be used in conjunction with both TACACS+ and RADIUS. Table 9 lists the vendor-specific RADIUS attributes (IETF Attribute 26) that enable RADIUS to support MS-CHAP.

Table 9 Vendor-Specific RADIUS Attributes for MS-CHAP

Vendor-ID Number	Vendor-Type Number	Vendor-Proprietary Attribute	Description
311	11	MSCHAP-Challenge	Contains the challenge sent by a network access server to an MS-CHAP user. It can be used in both Access-Request and Access-Challenge packets.
211	11	MSCHAP-Response	Contains the response value provided by a PPP MS-CHAP user in response to the challenge. It is only used in Access-Request packets. This attribute is identical to the PPP CHAP Identifier.

To define PPP authentication using MS-CHAP, use the following commands in interface configuration mode:

	Command	Purpose
Step 1	Router(config-if)# encapsulation ppp	Enables PPP encapsulation.
Step 2	Router(config-if)# ppp authentication ms-chap [if-needed] [list-name default] [callin] [one-time]	Defines PPP authentication using MS-CHAP.

If you configure **ppp authentication ms-chap** on an interface, all incoming calls on that interface that initiate a PPP connection will have to be authenticated using MS-CHAP. If you configure the **ppp authentication** command with the **callin** keyword, the access server will only authenticate the remote device if the remote device initiated the call.

Authentication method lists and the **one-time** keyword are only available if you have enabled AAA—they will not be available if you are using TACACS or extended TACACS. If you specify the name of an authentication method list with the **ppp authentication** command, PPP will attempt to authenticate the connection using the methods defined in the specified method list. If AAA is enabled and no method list is defined by name, PPP will attempt to authenticate the connection using the methods defined as the default. The **ppp authentication** command with the **one-time** keyword enables support for one-time passwords during authentication.

The **if-needed** keyword is only available if you are using TACACS or extended TACACS. The **ppp authentication** command with the **if-needed** keyword means that PPP will only authenticate the remote device via MS-CHAP if that device has not yet authenticated during the life of the current call. If the remote device authenticated through a standard login procedure and initiated PPP from the EXEC prompt, PPP will not authenticate through MS-CHAP if **ppp authentication chap if-needed** is configured.

**Note**

If PPP authentication using MS-CHAP is used with username authentication, you must include the MS-CHAP secret in the local username/password database. For more information about username authentication, refer to the “Establish Username Authentication” section.

Authentication Examples

The following sections provide authentication configuration examples:

- [RADIUS Authentication Examples](#)
- [TACACS+ Authentication Examples](#)
- [Kerberos Authentication Examples](#)
- [AAA Scalability Example](#)
- [Login and Failed Banner Examples](#)
- [AAA Packet of Disconnect Server Key Example](#)
- [Double Authentication Examples](#)
- [Automated Double Authentication Example](#)
- [MS-CHAP Example](#)

RADIUS Authentication Examples

This section provides two sample configurations using RADIUS.

The following example shows how to configure the router to authenticate and authorize using RADIUS:

```
aaa authentication login radius-login group radius local
aaa authentication ppp radius-ppp if-needed group radius
aaa authorization exec default group radius if-authenticated
aaa authorization network default group radius
line 3
login authentication radius-login
interface serial 0
ppp authentication radius-ppp
```

The lines in this sample RADIUS authentication and authorization configuration are defined as follows:

- The **aaa authentication login radius-login group radius local** command configures the router to use RADIUS for authentication at the login prompt. If RADIUS returns an error, the user is authenticated using the local database.
- The **aaa authentication ppp radius-ppp if-needed group radius** command configures the Cisco IOS software to use PPP authentication using CHAP or PAP if the user has not already logged in. If the EXEC facility has authenticated the user, PPP authentication is not performed.
- The **aaa authorization exec default group radius if-authenticated** command queries the RADIUS database for information that is used during EXEC authorization, such as autocommands and privilege levels, but only provides authorization if the user has successfully authenticated.
- The **aaa authorization network default group radius** command queries RADIUS for network authorization, address assignment, and other access lists.
- The **login authentication radius-login** command enables the radius-login method list for line 3.

- The **ppp authentication radius-ppp** command enables the radius-ppp method list for serial interface 0.

The following example shows how to configure the router to prompt for and verify a username and password, authorize the user's EXEC level, and specify it as the method of authorization for privilege level 2. In this example, if a local username is entered at the username prompt, that username is used for authentication.

If the user is authenticated using the local database, EXEC authorization using RADIUS will fail because no data is saved from the RADIUS authentication. The method list also uses the local database to find an autocommand. If there is no autocommand, the user becomes the EXEC user. If the user then attempts to issue commands that are set at privilege level 2, TACACS+ is used to attempt to authorize the command.

```
aaa authentication login default group radius local
aaa authorization exec default group radius local
aaa authorization command 2 default group tacacs+ if-authenticated
radius-server host 172.16.71.146 auth-port 1645 acct-port 1646
radius-server attribute 44 include-in-access-req
radius-server attribute 8 include-in-access-req
```

The lines in this sample RADIUS authentication and authorization configuration are defined as follows:

- The **aaa authentication login default group radius local** command specifies that the username and password are verified by RADIUS or, if RADIUS is not responding, by the router's local user database.
- The **aaa authorization exec default group radius local** command specifies that RADIUS authentication information be used to set the user's EXEC level if the user authenticates with RADIUS. If no RADIUS information is used, this command specifies that the local user database be used for EXEC authorization.
- The **aaa authorization command 2 default group tacacs+ if-authenticated** command specifies TACACS+ authorization for commands set at privilege level 2, if the user has already successfully authenticated.
- The **radius-server host 172.16.71.146 auth-port 1645 acct-port 1646** command specifies the IP address of the RADIUS server host, the UDP destination port for authentication requests, and the UDP destination port for accounting requests.
- The **radius-server attribute 44 include-in-access-req** command sends RADIUS attribute 44 (Acct-Section-ID) in access-request packets.
- The **radius-server attribute 8 include-in-access-req** command sends RADIUS attribute 8 (Framed-IP-Address) in access-request packets.

TACACS+ Authentication Examples

The following example shows how to configure TACACS+ as the security protocol to be used for PPP authentication:

```
aaa new-model
aaa authentication ppp test group tacacs+ local
interface serial 0
ppp authentication chap pap test
tacacs-server host 10.1.2.3
tacacs-server key goaway
```

The lines in this sample TACACS+ authentication configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines a method list, “test,” to be used on serial interfaces running PPP. The keywords **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.
- The **interface** command selects the line.
- The **ppp authentication** command applies the test method list to this line.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3.
- The **tacacs-server key** command defines the shared encryption key to be “goaway.”

The following example shows how to configure AAA authentication for PPP:

```
aaa authentication ppp default if-needed group tacacs+ local
```

In this example, the keyword **default** means that PPP authentication is applied by default to all interfaces. The **if-needed** keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP is not necessary and can be skipped. If authentication is needed, the keywords **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.

The following example shows how to create the same authentication algorithm for PAP, but it calls the method list “MIS-access” instead of “default”:

```
aaa authentication ppp MIS-access if-needed group tacacs+ local
interface serial 0
ppp authentication pap MIS-access
```

In this example, because the list does not apply to any interfaces (unlike the default list, which applies automatically to all interfaces), the administrator must select interfaces to which this authentication scheme should apply by using the **interface** command. The administrator must then apply this method list to those interfaces by using the **ppp authentication** command.

Kerberos Authentication Examples

To specify Kerberos as the login authentication method, use the following command:

```
aaa authentication login default krb5
```

To specify Kerberos authentication for PPP, use the following command:

```
aaa authentication ppp default krb5
```

AAA Scalability Example

The following example shows a general security configuration using AAA with RADIUS as the security protocol. In this example, the network access server is configured to allocate 16 background processes to handle AAA requests for PPP.

```
aaa new-model
radius-server host alcatraz
radius-server key myRaDiUSpassWoRd
radius-server configure-nas
username root password ALongPassword
```

```

aaa authentication ppp dialins group radius local
aaa authentication login admins local
aaa authorization network default group radius local
aaa accounting network default start-stop group radius
aaa processes 16
line 1 16
  autoselect ppp
  autoselect during-login
  login authentication admins
  modem dialin
interface group-async 1
  group-range 1 16
  encapsulation ppp
  ppp authentication pap dialins

```

The lines in this sample RADIUS AAA configuration are defined as follows:

- The **aaa new-model** command enables AAA network security services.
- The **radius-server host** command defines the name of the RADIUS server host.
- The **radius-server key** command defines the shared secret text string between the network access server and the RADIUS server host.
- The **radius-server configure-nas** command defines that the Cisco router or access server will query the RADIUS server for static routes and IP pool definitions when the device first starts up.
- The **username** command defines the username and password to be used for the PPP Password Authentication Protocol (PAP) caller identification.
- The **aaa authentication ppp dialins group radius local** command defines the authentication method list “dialins,” which specifies that RADIUS authentication, then (if the RADIUS server does not respond) local authentication will be used on serial lines using PPP.
- The **aaa authentication login admins local** command defines another method list, “admins,” for login authentication.
- The **aaa authorization network default group radius local** command is used to assign an address and other network parameters to the RADIUS user.
- The **aaa accounting network default start-stop group radius** command tracks PPP usage.
- The **aaa processes** command allocates 16 background processes to handle AAA requests for PPP.
- The **line** command switches the configuration mode from global configuration to line configuration and identifies the specific lines being configured.
- The **autoselect ppp** command configures the Cisco IOS software to allow a PPP session to start up automatically on these selected lines.
- The **autoselect during-login** command is used to display the username and password prompt without pressing the Return key. After the user logs in, the autoselect function (in this case, PPP) begins.
- The **login authentication admins** command applies the “admins” method list for login authentication.
- The **modem dialin** command configures modems attached to the selected lines to only accept incoming calls.
- The **interface group-async** command selects and defines an asynchronous interface group.
- The **group-range** command defines the member asynchronous interfaces in the interface group.
- The **encapsulation ppp** command sets PPP as the encapsulation method used on the specified interfaces.

- The **ppp authentication pap dialins** command applies the “dialins” method list to the specified interfaces.

Login and Failed Banner Examples

The following example shows how to configure a login banner (in this case, the phrase “Unauthorized Access Prohibited”) that will be displayed when a user logs in to the system. The asterisk (*) is used as the delimiting character. (RADIUS is specified as the default login authentication method.)

```
aaa new-model
aaa authentication banner *Unauthorized Access Prohibited*
aaa authentication login default group radius
```

This configuration produces the following login banner:

```
Unauthorized Access Prohibited
Username:
```

The following example shows how to additionally configure a failed login banner (in this case, the phrase “Failed login. Try again.”) that will be displayed when a user tries to log in to the system and fails. The asterisk (*) is used as the delimiting character. (RADIUS is specified as the default login authentication method.)

```
aaa new-model
aaa authentication banner *Unauthorized Access Prohibited*
aaa authentication fail-message *Failed login. Try again.*
aaa authentication login default group radius
```

This configuration produces the following login and failed login banner:

```
Unauthorized Access Prohibited
Username:
Password:
Failed login. Try again.
```

AAA Packet of Disconnect Server Key Example

The following example shows how to configure POD (packet of disconnect), which terminates connections on the network access server (NAS) when particular session attributes are identified.

```
aaa new-model
aaa authentication ppp default radius
aaa accounting network default start-stop radius
aaa accounting delay-start
aaa pod server server-key xyz123
radius-server host 172.16.0.0 non-standard
radius-server key rad123
```

Double Authentication Examples

The examples in this section illustrate possible configurations to be used with double authentication. Your configurations could differ significantly, depending on your network and security requirements.

This section includes the following examples:

- [Configuration of the Local Host for AAA with Double Authentication Examples](#)
- [Configuration of the AAA Server for First-Stage \(PPP\) Authentication and Authorization Example](#)

- [Configuration of the AAA Server for Second-Stage \(Per-User\) Authentication and Authorization Examples](#)
- [Complete Configuration with TACACS+ Example](#)

**Note**

These configuration examples include specific IP addresses and other specific information. This information is for illustration purposes only: your configuration will use different IP addresses, different usernames and passwords, and different authorization statements.

Configuration of the Local Host for AAA with Double Authentication Examples

These two examples show how to configure a local host to use AAA for PPP and login authentication, and for network and EXEC authorization. One example is shown for RADIUS and one example for TACACS+.

In both examples, the first three lines configure AAA, with a specific server as the AAA server. The next two lines configure AAA for PPP and login authentication, and the last two lines configure network and EXEC authorization. The last line is necessary only if the **access-profile** command will be executed as an autocommand.

The following example shows router configuration with a RADIUS AAA server:

```
aaa new-model
radius-server host secureserver
radius-server key myradiuskey
aaa authentication ppp default group radius
aaa authentication login default group radius
aaa authorization network default group radius
aaa authorization exec default group radius
```

The following example shows router configuration with a TACACS+ server:

```
aaa new-model
tacacs-server host security
tacacs-server key mytacacskey
aaa authentication ppp default group tacacs+
aaa authentication login default group tacacs+
aaa authorization network default group tacacs+
aaa authorization exec default group tacacs+
```

Configuration of the AAA Server for First-Stage (PPP) Authentication and Authorization Example

This example shows a configuration on the AAA server. A partial sample AAA configuration is shown for RADIUS.

TACACS+ servers can be configured similarly. (See the section “[Complete Configuration with TACACS+ Example](#)” later in this chapter.)

This example defines authentication/authorization for a remote host named “hostx” that will be authenticated by CHAP in the first stage of double authentication. Note that the ACL AV pair limits the remote host to Telnet connections to the local host. The local host has the IP address 10.0.0.2.

The following example shows a partial AAA server configuration for RADIUS:

```
hostx Password = "welcome"
      User-Service-Type = Framed-User,
      Framed-Protocol = PPP,
      cisco-avpair = "lcp:interface-config=ip unnumbered ethernet 0",
      cisco-avpair = "ip:inac1#3=permit tcp any 172.21.114.0 0.0.0.255 eq telnet",
```

```
cisco-avpair = "ip:inacl#4=deny icmp any any",
cisco-avpair = "ip:route#5=55.0.0.0 255.0.0.0",
cisco-avpair = "ip:route#6=66.0.0.0 255.0.0.0",
cisco-avpair = "ipx:inacl#3=deny any"
```

Configuration of the AAA Server for Second-Stage (Per-User) Authentication and Authorization Examples

This section contains partial sample AAA configurations on a RADIUS server. These configurations define authentication and authorization for a user (Pat) with the username "patuser," who will be user-authenticated in the second stage of double authentication.

TACACS+ servers can be configured similarly. (See the section "[Complete Configuration with TACACS+ Example](#)" later in this chapter.)

Three examples show sample RADIUS AAA configurations that could be used with each of the three forms of the **access-profile** command.

The first example shows a partial sample AAA configuration that works with the default form (no keywords) of the **access-profile** command. Note that only ACL AV pairs are defined. This example also sets up the **access-profile** command as an autocommand.

```
patuser Password = "welcome"
        User-Service-Type = Shell-User,
        cisco-avpair = "shell:autocmd=access-profile"
        User-Service-Type = Framed-User,
        Framed-Protocol = PPP,
        cisco-avpair = "ip:inacl#3=permit tcp any host 10.0.0.2 eq telnet",
        cisco-avpair = "ip:inacl#4=deny icmp any any"
```

The second example shows a partial sample AAA configuration that works with the **access-profile merge** form of the **access-profile** command. This example also sets up the **access-profile merge** command as an autocommand.

```
patuser Password = "welcome"
        User-Service-Type = Shell-User,
        cisco-avpair = "shell:autocmd=access-profile merge"
        User-Service-Type = Framed-User,
        Framed-Protocol = PPP,
        cisco-avpair = "ip:inacl#3=permit tcp any any"
        cisco-avpair = "ip:route=10.0.0.0 255.255.0.0",
        cisco-avpair = "ip:route=10.1.0.0 255.255.0.0",
        cisco-avpair = "ip:route=10.2.0.0 255.255.0.0"
```

The third example shows a partial sample AAA configuration that works with the **access-profile replace** form of the **access-profile** command. This example also sets up the **access-profile replace** command as an autocommand.

```
patuser Password = "welcome"
        User-Service-Type = Shell-User,
        cisco-avpair = "shell:autocmd=access-profile replace"
        User-Service-Type = Framed-User,
        Framed-Protocol = PPP,
        cisco-avpair = "ip:inacl#3=permit tcp any any",
        cisco-avpair = "ip:inacl#4=permit icmp any any",
        cisco-avpair = "ip:route=10.10.0.0 255.255.0.0",
        cisco-avpair = "ip:route=10.11.0.0 255.255.0.0",
        cisco-avpair = "ip:route=10.12.0.0 255.255.0.0"
```

Complete Configuration with TACACS+ Example

This example shows TACACS+ authorization profile configurations both for the remote host (used in the first stage of double authentication) and for specific users (used in the second stage of double authentication). This TACACS+ example contains approximately the same configuration information as shown in the previous RADIUS examples.

This sample configuration shows authentication/authorization profiles on the TACACS+ server for the remote host “hostx” and for three users, with the usernames “pat_default,” “pat_merge,” and “pat_replace.” The configurations for these three usernames illustrate different configurations that correspond to the three different forms of the **access-profile** command. The three user configurations also illustrate setting up the autocommand for each form of the **access-profile** command.

Figure 4 shows the topology. The example that follows the figure shows a TACACS+ configuration file.

Figure 4 Example Topology for Double Authentication

This sample configuration shows authentication/authorization profiles on the TACACS+ server for the remote host “hostx” and for three users, with the usernames “pat_default,” “pat_merge,” and “pat_replace.”

```
key = "mytacacskey"
```

```
default authorization = permit
```

```
#-----Remote Host (BRI)-----
#
# This allows the remote host to be authenticated by the local host
# during fist-stage authentication, and provides the remote host
# authorization profile.
#
#-----

user = hostx
{
    login = cleartext "welcome"
    chap = cleartext "welcome"

    service = ppp protocol = lcp {
        interface-config="ip unnumbered ethernet 0"
    }

    service = ppp protocol = ip {
        # It is important to have the hash sign and some string after
        # it. This indicates to the NAS that you have a per-user
        # config.

        inacl#3="permit tcp any 172.21.114.0 0.0.0.255 eq telnet"
        inacl#4="deny icmp any any"
```

```

        route#5="55.0.0.0 255.0.0.0"
        route#6="66.0.0.0 255.0.0.0"
    }

        # here.
        # If you leave this blank, the user will have NO IPX
        # access-lists (not even the ones installed prior to
        # this)!
    }

}

#----- "access-profile merge" user -----
#
# With the 'merge' option, first all old access-lists are removed (as before),
# but then (almost) all AV pairs are uploaded and installed. This will allow
# for uploading any custom static routes, sap-filters, and so on, that the user
# may need in his or her profile. This needs to be used with care, as it leaves
# open the possibility of conflicting configurations.

```

```

#
#-----

user = pat_merge
{
    login = cleartext "welcome"
    chap = cleartext "welcome"

    service = exec
    {
        # This is the autocommand that executes when pat_merge logs in.
        autocmd = "access-profile merge"
    }

    service = ppp protocol = ip
    {
        # Put whatever access-lists, static routes, whatever
        # here.
        # If you leave this blank, the user will have NO IP
        # access-lists (not even the ones installed prior to
        # this)!

        inacl#3="permit tcp any any"
        route#2="10.0.0.0 255.255.0.0"
        route#3="10.1.0.0 255.255.0.0"
        route#4="10.2.0.0 255.255.0.0"

    }

    service = ppp protocol = ipx
    {
        # Put whatever access-lists, static routes, whatever
        # here.
        # If you leave this blank, the user will have NO IPX
        # access-lists (not even the ones installed prior to
        # this)!

    }

}

#----- "access-profile replace" user -----
#
# With the 'replace' option, ALL old configuration is removed and ALL new
# configuration is installed.
#
# One caveat: access-profile checks the new configuration for address-pool and
# address AV pairs. As addresses cannot be renegotiated at this point, the
# command will fail (and complain) when it encounters such an AV pair.
# Such AV pairs are considered to be "invalid" for this context.
#-----

user = pat_replace
{
    login = cleartext "welcome"

        # this)!
    }
}

```

Automated Double Authentication Example

This example shows a complete configuration file for a Cisco 2509 router with automated double authentication configured. The configuration commands that apply to automated double authentication are preceded by descriptions with a double asterisk (**).

Current configuration:

```

!
version 11.3
no service password-encryption
!
hostname myrouter
!
!
! **The following AAA commands are used to configure double authentication:
!
! **The following command enables AAA:
aaa new-model
! **The following command enables user authentication via the TACACS+ AAA server:
aaa authentication login default group tacacs+
aaa authentication login console none
! **The following command enables device authentication via the TACACS+ AAA server:
aaa authentication ppp default group tacacs+
! **The following command causes the remote user's authorization profile to be
! downloaded from the AAA server to the Cisco 2509 router when required:
aaa authorization exec default group tacacs+
! **The following command causes the remote device's authorization profile to be
! downloaded from the AAA server to the Cisco 2509 router when required:
aaa authorization network default group tacacs+
enable password mypassword

```

```

!
ip host blue 172.21.127.226
ip host green 172.21.127.218
ip host red 172.21.127.114
ip domain-name example.com
ip name-server 171.69.2.75
! **The following command globally enables automated double authentication:
ip trigger-authentication timeout 60 port 7500
isdn switch-type basic-5ess
!
!
interface Ethernet0
 ip address 172.21.127.186 255.255.255.248
 no ip route-cache
 no ip mroute-cache
 no keepalive
 ntp disable
 no cdp enable
!
interface Virtual-Template1
 ip unnumbered Ethernet0
 no ip route-cache
 no ip mroute-cache
!
interface Serial0
 ip address 172.21.127.105 255.255.255.248
 encapsulation ppp
 no ip mroute-cache
 no keepalive
 shutdown
 clockrate 2000000
 no cdp enable
!
interface Serial1
 no ip address
 no ip route-cache
 no ip mroute-cache
 shutdown
 no cdp enable
!
! **Automated double authentication occurs via the ISDN BRI interface BRI0:
interface BRI0
 ip unnumbered Ethernet0
! **The following command turns on automated double authentication at this interface:
 ip trigger-authentication
! **PPP encapsulation is required:
 encapsulation ppp
 no ip route-cache
 no ip mroute-cache
 dialer idle-timeout 500
 dialer map ip 172.21.127.113 name myrouter 60074
 dialer-group 1
 no cdp enable

```

```

! **The following command specifies that device authentication occurs via PPP CHAP:
ppp authentication chap
!
router eigrp 109
 network 172.21.0.0
 no auto-summary
!
ip default-gateway 172.21.127.185
no ip classless
ip route 172.21.127.114 255.255.255.255 172.21.127.113
! **Virtual profiles are required for double authentication to work:
virtual-profile virtual-template 1
dialer-list 1 protocol ip permit
no cdp run
! **The following command defines where the TACACS+ AAA server is:
tacacs-server host 171.69.57.35 port 1049
tacacs-server timeout 90
! **The following command defines the key to use with TACACS+ traffic (required):
tacacs-server key mytacacskey
snmp-server community public R0
!
line con 0
 exec-timeout 0 0
 login authentication console
line aux 0
 transport input all
line vty 0 4
 exec-timeout 0 0
 password lab
!
end

```

MS-CHAP Example

The following example shows how to configure a Cisco AS5200 Universal Access Server (enabled for AAA and communication with a RADIUS security server) for PPP authentication using MS-CHAP:

```

aaa new-model
aaa authentication login admins local
aaa authentication ppp dialins group radius local
aaa authorization network default group radius local
aaa accounting network default start-stop group radius

username root password ALongPassword

radius-server host alcatraz
radius-server key myRaDiUSpassWoRd

interface group-async 1
 group-range 1 16
 encapsulation ppp
 ppp authentication ms-chap dialins

line 1 16
 autoselect ppp
 autoselect during-login
 login authentication admins
 modem dialin

```

The lines in this sample RADIUS AAA configuration are defined as follows:

- The **aaa new-model** command enables AAA network security services.
- The **aaa authentication login admins local** command defines another method list, “admins”, for login authentication.
- The **aaa authentication ppp dialins group radius local** command defines the authentication method list “dialins,” which specifies that RADIUS authentication then (if the RADIUS server does not respond) local authentication will be used on serial lines using PPP.
- The **aaa authorization network default group radius local** command is used to assign an address and other network parameters to the RADIUS user.
- The **aaa accounting network default start-stop group radius** command tracks PPP usage.
- The **username** command defines the username and password to be used for the PPP Password Authentication Protocol (PAP) caller identification.
- The **radius-server host** command defines the name of the RADIUS server host.
- The **radius-server key** command defines the shared secret text string between the network access server and the RADIUS server host.
- The **interface group-async** command selects and defines an asynchronous interface group.
- The **group-range** command defines the member asynchronous interfaces in the interface group.
- The **encapsulation ppp** command sets PPP as the encapsulation method used on the specified interfaces.
- The **ppp authentication ms-chap dialins** command selects MS-CHAP as the method of PPP authentication and applies the “dialins” method list to the specified interfaces.
- The **line** command switches the configuration mode from global configuration to line configuration and identifies the specific lines being configured.
- The **autoselect ppp** command configures the Cisco IOS software to allow a PPP session to start up automatically on these selected lines.
- The **autoselect during-login** command is used to display the username and password prompt without pressing the Return key. After the user logs in, the autoselect function (in this case, PPP) begins.
- The **login authentication admins** command applies the “admins” method list for login authentication.
- The **modem dialin** command configures modems attached to the selected lines to only accept incoming calls.

Configuring Authorization

Feature History

Release	Modification
Cisco IOS	For information about feature support in Cisco IOS software, use Cisco Feature Navigator.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

AAA authorization enables you to limit the services available to a user. When AAA authorization is enabled, the network access server uses information retrieved from the user’s profile, which is located either in the local user database or on the security server, to configure the user’s session. Once this is done, the user will be granted access to a requested service only if the information in the user profile allows it.

For a complete description of the authorization commands used in this chapter, refer to the chapter “Authorization Commands” in the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the chapter “Identifying Supported Platforms” section in the “Using Cisco IOS Software.”

In This Chapter

This chapter contains the following sections:

- [Named Method Lists for Authorization](#)
- [AAA Authorization Methods](#)
- [Method Lists and Server Groups](#)
- [AAA Authorization Types](#)
- [AAA Authorization Prerequisites](#)
- [AAA Authorization Configuration Task List](#)

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

- [Authorization Attribute-Value Pairs](#)
- [Authorization Configuration Examples](#)

Named Method Lists for Authorization

Method lists for authorization define the ways that authorization will be performed and the sequence in which these methods will be performed. A method list is simply a named list describing the authorization methods to be queried (such as RADIUS or TACACS+), in sequence. Method lists enable you to designate one or more security protocols to be used for authorization, thus ensuring a backup system in case the initial method fails. Cisco IOS software uses the first method listed to authorize users for specific network services; if that method fails to respond, the Cisco IOS software selects the next method listed in the method list. This process continues until there is successful communication with a listed authorization method, or all methods defined are exhausted.

Note

The Cisco IOS software attempts authorization with the next listed method only when there is no response from the previous method. If authorization fails at any point in this cycle—meaning that the security server or local username database responds by denying the user services—the authorization process stops and no other authorization methods are attempted.

Method lists are specific to the authorization type requested:

- **Auth-proxy**—Applies specific security policies on a per-user basis. For detailed information on the authentication proxy feature, refer to the chapter “Configuring Authentication Proxy” in the “Traffic Filtering and Firewalls” part of this book.
- **Commands**—Applies to the EXEC mode commands a user issues. Command authorization attempts authorization for all EXEC mode commands, including global configuration commands, associated with a specific privilege level.
- **EXEC**—Applies to the attributes associated with a user EXEC terminal session.
- **Network**—Applies to network connections. This can include a PPP, SLIP, or ARAP connection.
- **Reverse Access**—Applies to reverse Telnet sessions.

When you create a named method list, you are defining a particular list of authorization methods for the indicated authorization type.

Once defined, method lists must be applied to specific lines or interfaces before any of the defined methods will be performed. The only exception is the default method list (which is named “default”). If the **aaa authorization** command for a particular authorization type is issued without a named method list specified, the default method list is automatically applied to all interfaces or lines except those that have a named method list explicitly defined. (A defined method list overrides the default method list.) If no default method list is defined, local authorization takes place by default.

AAA Authorization Methods

AAA supports five different methods of authorization:

- **TACACS+**—The network access server exchanges authorization information with the TACACS+ security daemon. TACACS+ authorization defines specific rights for users by associating attribute-value pairs, which are stored in a database on the TACACS+ security server, with the appropriate user.

- **If-Authenticated**—The user is allowed to access the requested function provided the user has been authenticated successfully.
- **None**—The network access server does not request authorization information; authorization is not performed over this line/interface.
- **Local**—The router or access server consults its local database, as defined by the **username** command, for example, to authorize specific rights for users. Only a limited set of functions can be controlled via the local database.
- **RADIUS**—The network access server requests authorization information from the RADIUS security server. RADIUS authorization defines specific rights for users by associating attributes, which are stored in a database on the RADIUS server, with the appropriate user.

Method Lists and Server Groups

A server group is a way to group existing RADIUS or TACACS+ server hosts for use in method lists. [Figure 5](#) shows a typical AAA network configuration that includes four security servers: R1 and R2 are RADIUS servers, and T1 and T2 are TACACS+ servers. R1 and R2 make up the group of RADIUS servers. T1 and T2 make up the group of TACACS+ servers.

Figure 5 Typical AAA Network Configuration

Using server groups, you can specify a subset of the configured server hosts and use them for a particular service. For example, server groups allow you to define R1 and R2 as separate server groups, and T1 and T2 as separate server groups. This means you can specify either R1 and T1 in the method list or R2 and T2 in the method list, which provides more flexibility in the way that you assign RADIUS and TACACS+ resources.

Server groups also can include multiple host entries for the same server, as long as each entry has a unique identifier. The combination of an IP address and a UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, authorization—the second host entry configured acts as fail-over

backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server will try the second host entry configured on the same device for accounting services. (The RADIUS host entries will be tried in the order they are configured.)

For more information about configuring server groups and about configuring server groups based on DNIS numbers, refer to the chapter “Configuring RADIUS” or the chapter “Configuring TACACS+”

AAA Authorization Types

Cisco IOS software supports five different types of authorization:

- **Auth-proxy**—Applies specific security policies on a per-user basis. For detailed information on the authentication proxy feature, refer to the “Configuring Authentication Proxy” chapter in the “Traffic Filtering and Firewalls” section of this book.
- **Commands**—Applies to the EXEC mode commands a user issues. Command authorization attempts authorization for all EXEC mode commands, including global configuration commands, associated with a specific privilege level.
- **EXEC**—Applies to the attributes associated with a user EXEC terminal session.
- **Network**—Applies to network connections. This can include a PPP, SLIP, or ARAP connection.
- **Reverse Access**—Applies to reverse Telnet sessions.
- **Configuration**—Applies to downloading configurations from the AAA server.
- **IP Mobile**—Applies to authorization for IP mobile services.

AAA Authorization Prerequisites

Before configuring authorization using named method lists, you must first perform the following tasks:

- Enable AAA on your network access server. For more information about enabling AAA on your Cisco router or access server, refer to the “AAA Overview” chapter.
- Configure AAA authentication. Authorization generally takes place after authentication and relies on authentication to work properly. For more information about AAA authentication, refer to the “Configuring Authentication” chapter.
- Define the characteristics of your RADIUS or TACACS+ security server if you are issuing RADIUS or TACACS+ authorization. For more information about configuring your Cisco network access server to communicate with your RADIUS security server, refer to the chapter “Configuring RADIUS”. For more information about configuring your Cisco network access server to communicate with your TACACS+ security server, refer to the chapter “Configuring TACACS+”.
- Define the rights associated with specific users by using the **username** command if you are issuing local authorization. For more information about the **username** command, refer to the *Cisco IOS Security Command Reference*.

AAA Authorization Configuration Task List

This section describes the following configuration tasks:

- [Configuring AAA Authorization Using Named Method Lists](#)

- [Disabling Authorization for Global Configuration Commands](#)
- [Configuring Authorization for Reverse Telnet](#)

For authorization configuration examples using the commands in this chapter, refer to the section “[Authorization Configuration Examples](#)” at the end of the this chapter.

Configuring AAA Authorization Using Named Method Lists

To configure AAA authorization using named method lists, use the following commands beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa authorization { auth-proxy network exec commands <i>level</i> reverse-access configuration ipmobile } { default <i>list-name</i> } [<i>method1</i> [<i>method2</i> ...]]	Creates an authorization method list for a particular authorization type and enable authorization.
Step 2	Router(config)# line [aux console tty vty] <i>line-number</i> [<i>ending-line-number</i>] or Router(config)# interface <i>interface-type</i> <i>interface-number</i>	Enters the line configuration mode for the lines to which you want to apply the authorization method list. Alternately, enters the interface configuration mode for the interfaces to which you want to apply the authorization method list.
Step 3	Router(config-line)# authorization { arap commands <i>level</i> exec reverse-access } { default <i>list-name</i> } or Router(config-line)# ppp authorization { default <i>list-name</i> }	Applies the authorization list to a line or set of lines. Alternately, applies the authorization list to an interface or set of interfaces.

This section includes the following sections:

- [Authorization Types](#)
- [Authorization Methods](#)

Authorization Types

Named authorization method lists are specific to the indicated type of authorization.

To create a method list to enable authorization that applies specific security policies on a per-user basis, use the **auth-proxy** keyword. For detailed information on the authentication proxy feature, refer to the chapter “Configuring Authentication Proxy” in the “Traffic Filtering and Firewalls” part of this book.

To create a method list to enable authorization for all network-related service requests (including SLIP, PPP, PPP NCPs, and ARAP), use the **network** keyword.

To create a method list to enable authorization to determine if a user is allowed to run an EXEC shell, use the **exec** keyword.

To create a method list to enable authorization for specific, individual EXEC commands associated with a specific privilege level, use the **commands** keyword. (This allows you to authorize all commands associated with a specified command level from 0 to 15.)

To create a method list to enable authorization for reverse Telnet functions, use the **reverse-access** keyword.

For information about the types of authorization supported by the Cisco IOS software, refer to the “[AAA Authorization Types](#)” section of this chapter.

Authorization Methods

To have the network access server request authorization information via a TACACS+ security server, use the **aaa authorization** command with the **group tacacs+ method** keyword. For more specific information about configuring authorization using a TACACS+ security server, refer to the chapter “Configuring TACACS+.” For an example of how to enable a TACACS+ server to authorize the use of network services, including PPP and ARA, see the section “[TACACS+ Authorization Examples](#)” at the end of this chapter.

To allow users to have access to the functions they request as long as they have been authenticated, use the **aaa authorization** command with the **if-authenticated method** keyword. If you select this method, all requested functions are automatically granted to authenticated users.

There may be times when you do not want to run authorization from a particular interface or line. To stop authorization activities on designated lines or interfaces, use the **none method** keyword. If you select this method, authorization is disabled for all actions.

To select local authorization, which means that the router or access server consults its local user database to determine the functions a user is permitted to use, use the **aaa authorization** command with the **local method** keyword. The functions associated with local authorization are defined by using the **username** global configuration command. For a list of permitted functions, refer to the chapter “Configuring Authentication.”

To have the network access server request authorization via a RADIUS security server, use the **radius method** keyword. For more specific information about configuring authorization using a RADIUS security server, refer to the chapter “Configuring RADIUS.”

To have the network access server request authorization via a RADIUS security server, use the **aaa authorization** command with the **group radius method** keyword. For more specific information about configuring authorization using a RADIUS security server, refer to the chapter “Configuring RADIUS”. For an example of how to enable a RADIUS server to authorize services, see the “[RADIUS Authorization Example](#)” section at the end of this chapter.

Note

Authorization method lists for SLIP follow whatever is configured for PPP on the relevant interface. If no lists are defined and applied to a particular interface (or no PPP settings are configured), the default setting for authorization applies.

Disabling Authorization for Global Configuration Commands

The **aaa authorization** command with the keyword **commands** attempts authorization for all EXEC mode commands, including global configuration commands, associated with a specific privilege level. Because there are configuration commands that are identical to some EXEC-level commands, there can be some confusion in the authorization process. Using **no aaa authorization config-commands** stops the network access server from attempting configuration command authorization.

To disable AAA authorization for all global configuration commands, use the following command in global configuration mode:

Command	Purpose
Router(config)# no aaa authorization config-commands	Disables authorization for all global configuration commands.

Configuring Authorization for Reverse Telnet

Telnet is a standard terminal emulation protocol used for remote terminal connection. Normally, you log in to a network access server (typically through a dialup connection) and then use Telnet to access other network devices from that network access server. There are times, however, when it is necessary to establish a reverse Telnet session. In reverse Telnet sessions, the Telnet connection is established in the opposite direction—from inside a network to a network access server on the network periphery to gain access to modems or other devices connected to that network access server. Reverse Telnet is used to provide users with dialout capability by allowing them to Telnet to modem ports attached to a network access server.

It is important to control access to ports accessible through reverse Telnet. Failure to do so could, for example, allow unauthorized users free access to modems where they can trap and divert incoming calls or make outgoing calls to unauthorized destinations.

Authentication during reverse Telnet is performed through the standard AAA login procedure for Telnet. Typically the user has to provide a username and password to establish either a Telnet or reverse Telnet session. Reverse Telnet authorization provides an additional (optional) level of security by requiring authorization in addition to authentication. When enabled, reverse Telnet authorization can use RADIUS or TACACS+ to authorize whether or not this user is allowed reverse Telnet access to specific asynchronous ports, after the user successfully authenticates through the standard Telnet login procedure.

Reverse Telnet authorization offers the following benefits:

- An additional level of protection by ensuring that users engaged in reverse Telnet activities are indeed authorized to access a specific asynchronous port using reverse Telnet.
- An alternative method (other than access lists) to manage reverse Telnet authorization.

To configure a network access server to request authorization information from a TACACS+ or RADIUS server before allowing a user to establish a reverse Telnet session, use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa authorization reverse-access <i>method1 [method2 ...]</i>	Configures the network access server to request authorization information before allowing a user to establish a reverse Telnet session.

This feature enables the network access server to request reverse Telnet authorization information from the security server, whether RADIUS or TACACS+. You must configure the specific reverse Telnet privileges for the user on the security server itself.

Authorization Attribute-Value Pairs

RADIUS and TACACS+ authorization both define specific rights for users by processing attributes, which are stored in a database on the security server. For both RADIUS and TACACS+, attributes are defined on the security server, associated with the user, and sent to the network access server where they are applied to the user's connection.

For a list of supported RADIUS attributes, refer to the appendix "RADIUS Attributes". For a list of supported TACACS+ AV pairs, refer to the appendix "TACACS+ Attribute-Value Pairs."

Authorization Configuration Examples

The following sections provide authorization configuration examples:

- [Named Method List Configuration Example](#)
- [TACACS+ Authorization Examples](#)
- [RADIUS Authorization Example](#)
- [Reverse Telnet Authorization Examples](#)

Named Method List Configuration Example

The following example shows how to configure a Cisco AS5300 (enabled for AAA and communication with a RADIUS security server) for AAA services to be provided by the RADIUS server. If the RADIUS server fails to respond, then the local database will be queried for authentication and authorization information, and accounting services will be handled by a TACACS+ server.

```
aaa new-model
aaa authentication login admins local
aaa authentication ppp dialins group radius local
aaa authorization network scoobee group radius local
aaa accounting network charley start-stop group radius

username root password ALongPassword

radius-server host alcatraz
radius-server key myRaDiUSpassWoRd

interface group-async 1
 group-range 1 16
 encapsulation ppp
 ppp authentication chap dialins
 ppp authorization scoobee
 ppp accounting charley

line 1 16
 autoselect ppp
 autoselect during-login
 login authentication admins
 modem dialin
```

The lines in this sample RADIUS AAA configuration are defined as follows:

- The **aaa new-model** command enables AAA network security services.
- The **aaa authentication login admins local** command defines a method list, admins, for login authentication.
- The **aaa authentication ppp dialins group radius local** command defines the authentication method list “dialins,” which specifies that RADIUS authentication then (if the RADIUS server does not respond) local authentication will be used on serial lines using PPP.
- The **aaa authorization network scoobee group radius local** command defines the network authorization method list named scoobee, which specifies that RADIUS authorization will be used on serial lines using PPP. If the RADIUS server fails to respond, then local network authorization will be performed.

- The **aaa accounting network charley start-stop group radius** command defines the network accounting method list named charley, which specifies that RADIUS accounting services (in this case, start and stop records for specific events) will be used on serial lines using PPP.
- The **username** command defines the username and password to be used for the PPP Password Authentication Protocol (PAP) caller identification.
- The **radius-server host** command defines the name of the RADIUS server host.
- The **radius-server key** command defines the shared secret text string between the network access server and the RADIUS server host.
- The **interface group-async** command selects and defines an asynchronous interface group.
- The **group-range** command defines the member asynchronous interfaces in the interface group.
- The **encapsulation ppp** command sets PPP as the encapsulation method used on the specified interfaces.
- The **ppp authentication chap dialins** command selects Challenge Handshake Authentication Protocol (CHAP) as the method of PPP authentication and applies the “dialins” method list to the specified interfaces.
- The **ppp authorization scoobee** command applies the scoobee network authorization method list to the specified interfaces.
- The **ppp accounting charley** command applies the charley network accounting method list to the specified interfaces.
- The **line** command switches the configuration mode from global configuration to line configuration and identifies the specific lines being configured.
- The **autoselect ppp** command configures the Cisco IOS software to allow a PPP session to start up automatically on these selected lines.
- The **autoselect during-login** command is used to display the username and password prompt without pressing the Return key. After the user logs in, the autoselect function (in this case, PPP) begins.
- The **login authentication admins** command applies the admins method list for login authentication.
- The **modem dialin** command configures modems attached to the selected lines to only accept incoming calls.

TACACS+ Authorization Examples

The following examples show how to use a TACACS+ server to authorize the use of network services, including PPP and ARA. If the TACACS+ server is not available or an error occurs during the authorization process, the fallback method (none) is to grant all authorization requests:

```
aaa authorization network default group tacacs+ none
```

The following example shows how to allow network authorization using TACACS+:

```
aaa authorization network default group tacacs+
```

The following example shows how to provide the same authorization, but it also creates address pools called “mci” and “att”:

```
aaa authorization network default group tacacs+
ip address-pool local
ip local-pool mci 172.16.0.1 172.16.0.255
ip local-pool att 172.17.0.1 172.17.0.255
```

These address pools can then be selected by the TACACS daemon. A sample configuration of the daemon follows:

```
user = mci_customer1 {
    login = cleartext "some password"
    service = ppp protocol = ip {
        addr-pool=mci
    }
}

user = att_customer1 {
    login = cleartext "some other password"
    service = ppp protocol = ip {
        addr-pool=att
    }
}
```

RADIUS Authorization Example

The following example shows how to configure the router to authorize using RADIUS:

```
aaa new-model
aaa authorization exec default group radius if-authenticated
aaa authorization network default group radius
radius-server host ip
radius-server key
```

The lines in this sample RADIUS authorization configuration are defined as follows:

- The **aaa authorization exec default group radius if-authenticated** command configures the network access server to contact the RADIUS server to determine if users are permitted to start an EXEC shell when they log in. If an error occurs when the network access server contacts the RADIUS server, the fallback method is to permit the CLI to start, provided the user has been properly authenticated.

The RADIUS information returned may be used to specify an autocommand or a connection access list be applied to this connection.

- The **aaa authorization network default group radius** command configures network authorization via RADIUS. This can be used to govern address assignment, the application of access lists, and various other per-user quantities.

Note

Because no fallback method is specified in this example, authorization will fail if, for any reason, there is no response from the RADIUS server.

Reverse Telnet Authorization Examples

The following examples show how to cause the network access server to request authorization information from a TACACS+ security server before allowing a user to establish a reverse Telnet session:

```
aaa new-model
aaa authentication login default group tacacs+
aaa authorization reverse-access default group tacacs+
!
tacacs-server host 172.31.255.0
tacacs-server timeout 90
tacacs-server key goaway
```

The lines in this sample TACACS+ reverse Telnet authorization configuration are defined as follows:

- The **aaa new-model** command enables AAA.
- The **aaa authentication login default group tacacs+** command specifies TACACS+ as the default method for user authentication during login.
- The **aaa authorization reverse-access default group tacacs+** command specifies TACACS+ as the method for user authorization when trying to establish a reverse Telnet session.
- The **tacacs-server host** command identifies the TACACS+ server.
- The **tacacs-server timeout** command sets the interval of time that the network access server waits for the TACACS+ server to reply.
- The **tacacs-server key** command defines the encryption key used for all TACACS+ communications between the network access server and the TACACS+ daemon.

The following example shows how to configure a generic TACACS+ server to grant a user, pat, reverse Telnet access to port tty2 on the network access server named “maple” and to port tty5 on the network access server named “oak”:

```
user = pat
  login = cleartext lab
  service = raccess {
    port#1 = maple/tty2
    port#2 = oak/tty5
```

Note

In this example, “maple” and “oak” are the configured host names of network access servers, not DNS names or alias.

The following example shows how to configure the TACACS+ server (CiscoSecure) to grant a user named pat reverse Telnet access:

```
user = pat
profile_id = 90
profile_cycle = 1
member = Tacacs_Users
service=shell {
  default cmd=permit
}
service=raccess {
  allow "c2511e0" "tty1" ".*"
  refuse ".*" ".*" ".*"
  password = clear "goaway"
```

Note

CiscoSecure only supports reverse Telnet using the command line interface in versions 2.1(x) through version 2.2(1).

An empty “service=raccess {}” clause permits a user to have unconditional access to network access server ports for reverse Telnet. If no “service=raccess” clause exists, the user is denied access to any port for reverse Telnet.

For more information about configuring TACACS+, refer to the chapter “Configuring TACACS+.” For more information about configuring CiscoSecure, refer to the *CiscoSecure Access Control Server User Guide*, version 2.1(2) or greater.

The following example shows how to cause the network access server to request authorization from a RADIUS security server before allowing a user to establish a reverse Telnet session:

```
aaa new-model
```

```
aaa authentication login default group radius
aaa authorization reverse-access default group radius
!
radius-server host 172.31.255.0
radius-server key go away
auth-port 1645 acct-port 1646
```

The lines in this sample RADIUS reverse Telnet authorization configuration are defined as follows:

- The **aaa new-model** command enables AAA.
- The **aaa authentication login default group radius** command specifies RADIUS as the default method for user authentication during login.
- The **aaa authorization reverse-access default group radius** command specifies RADIUS as the method for user authorization when trying to establish a reverse Telnet session.
- The **radius-server host** command identifies the RADIUS server.
- The **radius-server key** command defines the encryption key used for all RADIUS communications between the network access server and the RADIUS daemon.

The following example shows how to send a request to the RADIUS server to grant a user named “pat” reverse Telnet access at port tty2 on the network access server named “maple”:

```
Username = "pat"
Password = "goaway"
User-Service-Type = Shell-User
cisco-avpair = "raccess:port#1=maple/tty2"
```

The syntax "raccess:port=any/any" permits a user to have unconditional access to network access server ports for reverse Telnet. If no "raccess:port={nasname}/{tty number}" clause exists in the user profile, the user is denied access to reverse Telnet on all ports.

For more information about configuring RADIUS, refer to the chapter “Configuring RADIUS.”

Configuring Accounting

The AAA accounting feature allows the services that users are accessing and the amount of network resources that users are consuming to be tracked. When AAA accounting is enabled, the network access server reports user activity to the TACACS+ or RADIUS security server (depending on which security method is implemented) in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server. This data can then be analyzed for network management, client billing, and auditing.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the [“Feature Information for Configuring Accounting” section on page 28](#).

Use Cisco Feature Navigator to find information about platform support and Cisco IOS, Catalyst OS, and Cisco IOS XE software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Configuring Accounting

The following tasks must be performed before configuring accounting using named method lists:

- Enable AAA on the network access server. For more information about enabling AAA on a Cisco router or access server, see the chapter “[AAA Overview](#)” in the *Cisco IOS Security Configuration Guide*.
- Define the characteristics of the RADIUS or TACACS+ security server if RADIUS or TACACS+ authorization is issued. For more information about configuring the Cisco network access server to communicate with the RADIUS security server, see the chapter “[Configuring RADIUS](#).” For more information about configuring the Cisco network access server to communicate with the TACACS+ security server, see the chapter “[Configuring TACACS+](#).”

Restrictions for Configuring Accounting

The AAA Accounting feature has the following restrictions:

- Accounting information can be sent simultaneously to a maximum of four AAA servers.
- SSG Restriction—For SSG systems, the **aaa accounting network broadcast** command broadcasts only **start-stop** accounting records. If interim accounting records are configured using the **sbg accounting interval** command, the interim accounting records are sent only to the configured default RADIUS server.

Information About Configuring Accounting

The following sections discuss how Accounting feature:

- [Named Method Lists for Accounting, page 2](#)
- [AAA Accounting Types, page 5](#)
- [AAA Accounting Enhancements, page 14](#)

Named Method Lists for Accounting

Like authentication and authorization method lists, method lists for accounting define the way accounting is performed and the sequence in which these methods are performed.

Named accounting method lists allow particular security protocol to be designated and used on specific lines or interfaces for accounting services. The only exception is the default method list (which, by coincidence, is named “default”). The default method list is automatically applied to all interfaces except those that have a named method list explicitly defined. A defined method list overrides the default method list.

A method list is simply a named list describing the accounting methods to be queried (such as RADIUS or TACACS+), in sequence. Method lists allow one or more security protocols to be designated and used for accounting, thus ensuring a backup system for accounting in case the initial method fails. Cisco IOS software uses the first method listed to support accounting; if that method fails to respond, the Cisco IOS software selects the next accounting method listed in the method list. This process continues until there is successful communication with a listed accounting method, or all methods defined are exhausted.

**Note**

The Cisco IOS software attempts accounting with the next listed accounting method only when there is no response from the previous method. If accounting fails at any point in this cycle—meaning that the security server responds by denying the user access—the accounting process stops and no other accounting methods are attempted.

Accounting method lists are specific to the type of accounting being requested. AAA supports six different types of accounting:

- **Network**—Provides information for all PPP, SLIP, or ARAP sessions, including packet and byte counts.
- **EXEC**—Provides information about user EXEC terminal sessions of the network access server.
- **Commands**—Provides information about the EXEC mode commands that a user issues. Command accounting generates accounting records for all EXEC mode commands, including global configuration commands, associated with a specific privilege level.
- **Connection**—Provides information about all outbound connections made from the network access server, such as Telnet, local-area transport (LAT), TN3270, packet assembler/disassembler (PAD), and rlogin.
- **System**—Provides information about system-level events.
- **Resource**—Provides “start” and “stop” records for calls that have passed user authentication, and provides “stop” records for calls that fail to authenticate.

**Note**

System accounting does not use named accounting lists; only the default list for system accounting can be defined.

Once again, when a named method list is created, a particular list of accounting methods for the indicated accounting type are defined.

Accounting method lists must be applied to specific lines or interfaces before any of the defined methods are performed. The only exception is the default method list (which is named “default”). If the **aaa accounting** command for a particular accounting type is issued without a named method list specified, the default method list is automatically applied to all interfaces or lines except those that have a named method list explicitly defined. (A defined method list overrides the default method list.) If no default method list is defined, then no accounting takes place.

This section includes the following subsections:

- [Method Lists and Server Groups, page 4](#)
- [AAA Accounting Methods, page 5](#)

Method Lists and Server Groups

A server group is a way to group existing RADIUS or TACACS+ server hosts for use in method lists. [Figure 1](#) shows a typical AAA network configuration that includes four security servers: R1 and R2 are RADIUS servers, and T1 and T2 are TACACS+ servers. R1 and R2 comprise the group of RADIUS servers. T1 and T2 comprise the group of TACACS+ servers.

Figure 1 Typical AAA Network Configuration

In Cisco IOS software, RADIUS and TACACS+ server configurations are global. A subset of the configured server hosts can be specified using server groups. These server groups can be used for a particular service. For example, server groups allow R1 and R2 to be defined as separate server groups (SG1 and SG2), and T1 and T2 as separate server groups (SG3 and SG4). This means either R1 and T1 (SG1 and SG3) can be specified in the method list or R2 and T2 (SG2 and SG4) in the method list, which provides more flexibility in the way that RADIUS and TACACS+ resources are assigned.

Server groups also can include multiple host entries for the same server, as long as each entry has a unique identifier. The combination of an IP address and a UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, accounting—the second host entry configured acts as failover backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server tries the second host entry configured on the same device for accounting services. (The RADIUS host entries are tried in the order in which they are configured.)

For more information about configuring server groups and about configuring server groups based on DNIS numbers, see “Configuring RADIUS” or “Configuring TACACS+” in the *Cisco IOS Security Configuration Guide*.

AAA Accounting Methods

Cisco IOS supports the following two methods for accounting:

- **TACACS+—**The network access server reports user activity to the TACACS+ security server in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server.
- **RADIUS—**The network access server reports user activity to the RADIUS security server in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server.

AAA Accounting Types

AAA supports six different accounting types:

- [Network Accounting](#)
- [Connection Accounting](#)
- [EXEC Accounting](#)
- [System Accounting](#)
- [Command Accounting](#)
- [Resource Accounting](#)

Network Accounting

Network accounting provides information for all PPP, SLIP, or ARAP sessions, including packet and byte counts.

The following example shows the information contained in a RADIUS network accounting record for a PPP user who comes in through an EXEC session:

```
Wed Jun 27 04:44:45 2001
  NAS-IP-Address = "172.16.25.15"
  NAS-Port = 5
  User-Name = "username1"
  Client-Port-DNIS = "4327528"
  Caller-ID = "562"
  Acct-Status-Type = Start
  Acct-Authentic = RADIUS
  Service-Type = Exec-User
  Acct-Session-Id = "0000000D"
  Acct-Delay-Time = 0
  User-Id = "username1"
  NAS-Identifier = "172.16.25.15"
```

```
Wed Jun 27 04:45:00 2001
  NAS-IP-Address = "172.16.25.15"
  NAS-Port = 5
  User-Name = "username1"
  Client-Port-DNIS = "4327528"
  Caller-ID = "562"
  Acct-Status-Type = Start
  Acct-Authentic = RADIUS
  Service-Type = Framed
  Acct-Session-Id = "0000000E"
  Framed-IP-Address = "10.1.1.2"
```

```

Framed-Protocol = PPP
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

Wed Jun 27 04:47:46 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 5
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "562"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Framed
Acct-Session-Id = "0000000E"
Framed-IP-Address = "10.1.1.2"
Framed-Protocol = PPP
Acct-Input-Octets = 3075
Acct-Output-Octets = 167
Acct-Input-Packets = 39
Acct-Output-Packets = 9
Acct-Session-Time = 171
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

Wed Jun 27 04:48:45 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 5
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "408"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Exec-User
Acct-Session-Id = "0000000D"
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

```

The following example shows the information contained in a TACACS+ network accounting record for a PPP user who first started an EXEC session:

```

Wed Jun 27 04:00:35 2001 172.16.25.15 username1 tty4 562/4327528
starttask_id=28 service=shell
Wed Jun 27 04:00:46 2001 172.16.25.15 username1 tty4 562/4327528 starttask_id=30
addr=10.1.1.1 service=ppp
Wed Jun 27 04:00:49 2001 172.16.25.15 username1 tty4 408/4327528 update
task_id=30 addr=10.1.1.1 service=ppp protocol=ip addr=10.1.1.1
Wed Jun 27 04:01:31 2001 172.16.25.15 username1 tty4 562/4327528
stoptask_id=30 addr=10.1.1.1 service=ppp protocol=ip addr=10.1.1.1
bytes_in=2844 bytes_out=1682 paks_in=36 paks_out=24 elapsed_time=51
Wed Jun 27 04:01:32 2001 172.16.25.15 username1 tty4 562/4327528
stoptask_id=28 service=shell elapsed_time=57

```

**Note**

The precise format of accounting packets records may vary depending on the security server daemon.

The following example shows the information contained in a RADIUS network accounting record for a PPP user who comes in through autoselect:

```

Wed Jun 27 04:30:52 2001

```

```

NAS-IP-Address = "172.16.25.15"
NAS-Port = 3
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "562"
Acct-Status-Type = Start
Acct-Authentic = RADIUS
Service-Type = Framed
Acct-Session-Id = "0000000B"
Framed-Protocol = PPP
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

Wed Jun 27 04:36:49 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 3
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "562"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Framed
Acct-Session-Id = "0000000B"
Framed-Protocol = PPP
Framed-IP-Address = "10.1.1.1"
Acct-Input-Octets = 8630
Acct-Output-Octets = 5722
Acct-Input-Packets = 94
Acct-Output-Packets = 64
Acct-Session-Time = 357
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

```

The following example shows the information contained in a TACACS+ network accounting record for a PPP user who comes in through autoselect:

```

Wed Jun 27 04:02:19 2001 172.16.25.15 username1 Async5 562/4327528
starttask_id=35 service=ppp
Wed Jun 27 04:02:25 2001 172.16.25.15 username1 Async5 562/4327528 update
task_id=35 service=ppp protocol=ip addr=10.1.1.2
Wed Jun 27 04:05:03 2001 172.16.25.15 username1 Async5 562/4327528
stoptask_id=35 service=ppp protocol=ip addr=10.1.1.2 bytes_in=3366
bytes_out=2149 paks_in=42 paks_out=28 elapsed_time=164

```

Connection Accounting

Connection accounting provides information about all outbound connections made from the network access server, such as Telnet, local-area transport (LAT), TN3270, packet assembler/disassembler (PAD), and rlogin.

The following example shows the information contained in a RADIUS connection accounting record for an outbound Telnet connection:

```

Wed Jun 27 04:28:00 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 2
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "5622329477"
Acct-Status-Type = Start

```

```

Acct-Authentic = RADIUS
Service-Type = Login
Acct-Session-Id = "00000008"
Login-Service = Telnet
Login-IP-Host = "10.68.202.158"
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

```

```

Wed Jun 27 04:28:39 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 2
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "5622329477"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Login
Acct-Session-Id = "00000008"
Login-Service = Telnet
Login-IP-Host = "10.68.202.158"
Acct-Input-Octets = 10774
Acct-Output-Octets = 112
Acct-Input-Packets = 91
Acct-Output-Packets = 99
Acct-Session-Time = 39
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

```

The following example shows the information contained in a TACACS+ connection accounting record for an outbound Telnet connection:

```

Wed Jun 27 03:47:43 2001      172.16.25.15      username1  tty3      5622329430/4327528
start   task_id=10      service=connection      protocol=telnet  addr=10.68.202.158
cmd=telnet username1-sun
Wed Jun 27 03:48:38 2001      172.16.25.15      username1  tty3      5622329430/4327528
stop    task_id=10      service=connection      protocol=telnet  addr=10.68.202.158
cmd=telnet username1-sun      bytes_in=4467  bytes_out=96      paks_in=61      paks_out=72
elapsed_time=55

```

The following example shows the information contained in a RADIUS connection accounting record for an outbound rlogin connection:

```

Wed Jun 27 04:29:48 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 2
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "5622329477"
Acct-Status-Type = Start
Acct-Authentic = RADIUS
Service-Type = Login
Acct-Session-Id = "0000000A"

VAX
Wed Jun 27 03:54:15 2001      172.16.25.15      username1  tty3      5622329430/4327528
stop    task_id=18      service=connection      protocol=lat      addr=VAX      cmd=lat
VAX bytes_in=0      bytes_out=0      paks_in=0      paks_out=0      elapsed_time=6

```

EXEC Accounting

EXEC accounting provides information about user EXEC terminal sessions (user shells) on the network access server, including username, date, start and stop times, the access server IP address, and (for dial-in users) the telephone number the call originated from.

The following example shows the information contained in a RADIUS EXEC accounting record for a dial-in user:

```

Wed Jun 27 04:26:23 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 1
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "5622329483"
Acct-Status-Type = Start
Acct-Authentic = RADIUS
Service-Type = Exec-User
Acct-Session-Id = "00000006"
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

```

```

Wed Jun 27 04:27:25 2001
  NAS-IP-Address = "172.16.25.15"
  NAS-Port = 1
  User-Name = "username1"
  Client-Port-DNIS = "4327528"
  Caller-ID = "5622329483"
  Acct-Status-Type = Stop
  Acct-Authentic = RADIUS
  Service-Type = Exec-User
  Acct-Session-Id = "00000006"
  Acct-Session-Time = 62
  Acct-Delay-Time = 0
  User-Id = "username1"
  NAS-Identifier = "172.16.25.15"

```

The following example shows the information contained in a TACACS+ EXEC accounting record for a dial-in user:

```

Wed Jun 27 03:46:21 2001      172.16.25.15      username1      tty3      5622329430/4327528
start      task_id=2      service=shell
Wed Jun 27 04:08:55 2001      172.16.25.15      username1      tty3      5622329430/4327528
stop      task_id=2      service=shell      elapsed_time=1354

```

The following example shows the information contained in a RADIUS EXEC accounting record for a Telnet user:

```

Wed Jun 27 04:48:32 2001
  NAS-IP-Address = "172.16.25.15"
  NAS-Port = 26
  User-Name = "username1"
  Caller-ID = "10.68.202.158"
  Acct-Status-Type = Start
  Acct-Authentic = RADIUS
  Service-Type = Exec-User
  Acct-Session-Id = "00000010"
  Acct-Delay-Time = 0
  User-Id = "username1"
  NAS-Identifier = "172.16.25.15"

Wed Jun 27 04:48:46 2001
  NAS-IP-Address = "172.16.25.15"
  NAS-Port = 26
  User-Name = "username1"
  Caller-ID = "10.68.202.158"
  Acct-Status-Type = Stop
  Acct-Authentic = RADIUS
  Service-Type = Exec-User
  Acct-Session-Id = "00000010"
  Acct-Session-Time = 14
  Acct-Delay-Time = 0
  User-Id = "username1"
  NAS-Identifier = "172.16.25.15"

```

The following example shows the information contained in a TACACS+ EXEC accounting record for a Telnet user:

```

Wed Jun 27 04:06:53 2001      172.16.25.15      username1      tty26      10.68.202.158
starttask_id=41      service=shell
Wed Jun 27 04:07:02 2001      172.16.25.15      username1      tty26      10.68.202.158
stoptask_id=41      service=shell      elapsed_time=9

```

System Accounting

System accounting provides information about all system-level events (for example, when the system reboots or when accounting is turned on or off).

The following accounting record shows a typical TACACS+ system accounting record server indicating that AAA accounting has been turned off:

```
Wed Jun 27 03:55:32 2001      172.16.25.15   unknown unknown unknown start   task_id=25
service=system event=sys_acct reason=reconfigure
```

Note

The precise format of accounting packets records may vary depending on the TACACS+ daemon.

The following accounting record shows a TACACS+ system accounting record indicating that AAA accounting has been turned on:

```
Wed Jun 27 03:55:22 2001      172.16.25.15   unknown unknown unknown stop    task_id=23
service=system event=sys_acct reason=reconfigure
```

Additional tasks for measuring system resources are covered in the Cisco IOS software configuration guides. For example, IP accounting tasks are described in the chapter “[Configuring IP Services](#)” in the *Cisco IOS Application Services Configuration Guide*.

Command Accounting

Command accounting provides information about the EXEC shell commands for a specified privilege level that are being executed on a network access server. Each command accounting record includes a list of the commands executed for that privilege level, as well as the date and time each command was executed, and the user who executed it.

The following example shows the information contained in a TACACS+ command accounting record for privilege level 1:

```
Wed Jun 27 03:46:47 2001      172.16.25.15   username1 tty3 5622329430/4327528
stop task_id=3 service=shell priv-lvl=1 cmd=show version <cr>
Wed Jun 27 03:46:58 2001      172.16.25.15   username1 tty3 5622329430/4327528
stop task_id=4 service=shell priv-lvl=1 cmd=show interfaces Ethernet 0
<cr>
Wed Jun 27 03:47:03 2001      172.16.25.15   username1 tty3 5622329430/4327528
stop task_id=5 service=shell priv-lvl=1 cmd=show ip route <cr>
```

The following example shows the information contained in a TACACS+ command accounting record for privilege level 15:

```
Wed Jun 27 03:47:17 2001      172.16.25.15   username1 tty3 5622329430/4327528
stop task_id=6 service=shell priv-lvl=15 cmd=configure terminal <cr>
Wed Jun 27 03:47:21 2001      172.16.25.15   username1 tty3 5622329430/4327528
stop task_id=7 service=shell priv-lvl=15 cmd=interface Serial 0 <cr>
Wed Jun 27 03:47:29 2001      172.16.25.15   username1 tty3 5622329430/4327528
stop task_id=8 service=shell priv-lvl=15 cmd=ip address 10.1.1.1
255.255.255.0 <cr>
```

Note

The Cisco Systems implementation of RADIUS does not support command accounting.

Resource Accounting

The Cisco implementation of AAA accounting provides “start” and “stop” record support for calls that have passed user authentication. The additional feature of generating “stop” records for calls that fail to authenticate as part of user authentication is also supported. Such records are necessary for users employing accounting records to manage and monitor their networks.

This section includes the following subsections:

- [AAA Resource Failure Stop Accounting, page 12](#)
- [AAA Resource Accounting for Start-Stop Records, page 14](#)

AAA Resource Failure Stop Accounting

Before AAA resource failure stop accounting, there was no method of providing accounting records for calls that failed to reach the user authentication stage of a call setup sequence. Such records are necessary for users employing accounting records to manage and monitor their networks and their wholesale customers.

This functionality generates a “stop” accounting record for any calls that do not reach user authentication; “stop” records are generated from the moment of call setup. All calls that pass user authentication behave as they did before; that is, no additional accounting records are seen.

[Figure 2](#) illustrates a call setup sequence with normal call flow (no disconnect) and without AAA resource failure stop accounting enabled.

Figure 2 *Modem Dial-In Call Setup Sequence With Normal Flow and Without Resource Failure Stop Accounting Enabled*

[Figure 3](#) illustrates a call setup sequence with normal call flow (no disconnect) and with AAA resource failure stop accounting enabled.

35771

Figure 3 *Modem Dial-In Call Setup Sequence With Normal Flow and With Resource Failure Stop Accounting Enabled*

Figure 4 illustrates a call setup sequence with call disconnect occurring before user authentication and with AAA resource failure stop accounting enabled.

Figure 4 *Modem Dial-In Call Setup Sequence With Call Disconnect Occurring Before User Authentication and With Resource Failure Stop Accounting Enabled*

Figure 11 illustrates a call setup sequence with call disconnect occurring before user authentication and without AAA resource failure stop accounting enabled.

Figure 5 *Modem Dial-In Call Setup Sequence With Call Disconnect Occurring Before User Authentication and Without Resource Failure Stop Accounting Enabled*

AAA Resource Accounting for Start-Stop Records

AAA resource accounting for start-stop records supports the ability to send a “start” record at each call setup, followed by a corresponding “stop” record at the call disconnect. This functionality can be used to manage and monitor wholesale customers from one source of data reporting, such as accounting records.

With this feature, a call setup and call disconnect “start-stop” accounting record tracks the progress of the resource connection to the device. A separate user authentication “start-stop” accounting record tracks the user management progress. These two sets of accounting records are interlinked by using a unique session ID for the call.

Figure 6 illustrates a call setup sequence with AAA resource start-stop accounting enabled.

Figure 6 *Modem Dial-In Call Setup Sequence With Resource Start-Stop Accounting Enabled*

AAA Accounting Enhancements

The section includes the following enhancements:

- [AAA Broadcast Accounting, page 14](#)
- [AAA Session MIB, page 14](#)

AAA Broadcast Accounting

AAA broadcast accounting allows accounting information to be sent to multiple AAA servers at the same time; that is, accounting information can be broadcast to one or more AAA servers simultaneously. This functionality allows service providers to send accounting information to their own private AAA servers and to the AAA servers of their end customers. It also provides redundant billing information for voice applications.

Broadcasting is allowed among groups of RADIUS or TACACS+ servers, and each server group can define its backup servers for failover independently of other groups.

Thus, service providers and their end customers can use different protocols (RADIUS or TACACS+) for the accounting server. Service providers and their end customers can also specify their backup servers independently. As for voice applications, redundant accounting information can be managed independently through a separate group with its own failover sequence.

AAA Session MIB

The AAA session MIB feature allows customers to monitor and terminate their authenticated client connections using Simple Network Management Protocol (SNMP). The data of the client is presented so that it correlates directly to the AAA accounting information reported by either the RADIUS or the TACACS+ server. AAA session MIB provides the following information:

- Statistics for each AAA function (when used in conjunction with the **show radius statistics** command)
- Status of servers providing AAA functions
- Identities of external AAA servers
- Real-time information (such as idle times), providing additional criteria for use by SNMP networks for assessing whether or not to terminate an active call

**Note**

This command is supported only on Cisco AS5300 and Cisco AS5800 universal access server platforms.

Table 1 shows the SNMP user-end data objects that can be used to monitor and terminate authenticated client connections with the AAA session MIB feature.

Table 1 *SNMP End-User Data Objects*

SessionId	The session identification used by the AAA accounting protocol (same value as reported by RADIUS attribute 44 (Acct-Session-ID)).
UserId	The user login ID or zero-length string if a login is unavailable.
IpAddr	The IP address of the session or 0.0.0.0 if an IP address is not applicable or unavailable.
IdleTime	The elapsed time in seconds that the session has been idle.
Disconnect	The session termination object used to disconnect the given client.
CallId	The entry index corresponding to this accounting session that the Call Tracker record stored.

Table 2 describes the AAA summary information provided by the AAA session MIB feature using SNMP on a per-system basis.

Table 2 *SNMP AAA Session Summary*

ActiveTableEntries	Number of sessions currently active.
ActiveTableHighWaterMark	Maximum number of sessions present at once since last system reinstallation.
TotalSessions	Total number of sessions since last system reinstallation.
DisconnectedSessions	Total number of sessions that have been disconnected using since last system reinstallation.

How to Configure AAA Accounting

This section describes the following configuration tasks involved in configuring AAA Accounting:

- [Configuring AAA Accounting Using Named Method Lists](#)
- [Suppressing Generation of Accounting Records for Null Username Sessions](#)
- [Generating Interim Accounting Records](#)
- [Generating Accounting Records for Failed Login or Session](#)
- [Specifying Accounting NETWORK-Stop Records Before EXEC-Stop Records](#)
- [Configuring AAA Resource Failure Stop Accounting](#)
- [Configuring AAA Resource Accounting for Start-Stop Records](#)
- [Configuring AAA Broadcast Accounting](#)
- [Configuring AAA Resource Failure Stop Accounting](#)
- [Configuring AAA Session MIB](#)
- [Establishing a Session with a Router if the AAA Server is Unreachable](#)
- [Monitoring Accounting](#)
- [Troubleshooting Accounting](#)

Configuring AAA Accounting Using Named Method Lists

To configure AAA accounting using named method lists, use the following commands beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa accounting {system network exec connection commands <i>level</i> } {default <i>list-name</i> } {start-stop stop-only none} [<i>method1</i> [<i>method2...</i>]]	Creates an accounting method list and enables accounting. The argument <i>list-name</i> is a character string used to name the created list.
Step 2	Router(config)# line [aux console tty vty] <i>line-number</i> [<i>ending-line-number</i>] or Router(config)# interface <i>interface-type</i> <i>interface-number</i>	Enters the line configuration mode for the lines to which the accounting method list is applied. or Enters the interface configuration mode for the interfaces to which the accounting method list is applied.
Step 3	Router(config-line)# accounting {arap commands <i>level</i> connection exec} {default <i>list-name</i> } or Router(config-if)# ppp accounting {default <i>list-name</i> }	Applies the accounting method list to a line or set of lines. or Applies the accounting method list to an interface or set of interfaces.

Note

System accounting does not use named method lists. For system accounting, define only the default method list.

This section includes the following sections:

- [Accounting Types, page 17](#)
- [Accounting Record Types, page 17](#)
- [Accounting Methods, page 17](#)

Accounting Types

Named accounting method lists are specific to the indicated type of accounting.

- **network**—To create a method list to enable authorization for all network-related service requests (including SLIP, PPP, PPP NCPs, and ARA protocols), use the **network** keyword. For example, to create a method list that provides accounting information for ARAP (network) sessions, use the **arap** keyword.
- **exec**—To create a method list that provides accounting records about user EXEC terminal sessions on the network access server, including username, date, start and stop times, use the **exec** keyword.
- **commands**—To create a method list that provides accounting information about specific, individual EXEC commands associated with a specific privilege level, use the **commands** keyword.
- **connection**—To create a method list that provides accounting information about all outbound connections made from the network access server, use the **connection** keyword.
- **resource**—Creates a method list to provide accounting records for calls that have passed user authentication or calls that failed to be authenticated.

Note

System accounting does not support named method lists.

Accounting Record Types

For minimal accounting, use the **stop-only** keyword, which instructs the specified method (RADIUS or TACACS+) to send a stop record accounting notice at the end of the requested user process. For more accounting information, use the **start-stop** keyword to send a start accounting notice at the beginning of the requested event and a stop accounting notice at the end of the event. To stop all accounting activities on this line or interface, use the **none** keyword.

Accounting Methods

[Table 3](#) lists the supported accounting methods.

Table 3 *AAA Accounting Methods*

Keyword	Description
group radius	Uses the list of all RADIUS servers for accounting.
group tacacs+	Uses the list of all TACACS+ servers for accounting.
group group-name	Uses a subset of RADIUS or TACACS+ servers for accounting as defined by the server group <i>group-name</i> .

The method argument refers to the actual method the authentication algorithm tries. Additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all other methods return an error, specify additional methods in the command. For example, to create a method list named `acct_tac1` that specifies RADIUS as the backup method of authentication in the event that TACACS+ authentication returns an error, enter the following command:

```
aaa accounting network acct_tac1 stop-only group tacacs+ group radius
```

To create a default list that is used when a named list is *not* specified in the **aaa accounting** command, use the **default** keyword followed by the methods that are wanted to be used in default situations. The default method list is automatically applied to all interfaces.

For example, to specify RADIUS as the default method for user authentication during login, enter the following command:

```
aaa accounting network default stop-only group radius
```

AAA accounting supports the following methods:

- **group tacacs**—To have the network access server send accounting information to a TACACS+ security server, use the **group tacacs+ method** keyword.
- **group radius**—To have the network access server send accounting information to a RADIUS security server, use the **group radius method** keyword.

Note

Accounting method lists for SLIP follow whatever is configured for PPP on the relevant interface. If no lists are defined and applied to a particular interface (or no PPP settings are configured), the default setting for accounting applies.

- **group group-name**—To specify a subset of RADIUS or TACACS+ servers to use as the accounting method, use the **aaa accounting** command with the **group group-name** method. To specify and define the group name and the members of the group, use the **aaa group server** command. For example, use the **aaa group server** command to first define the members of **group loginrad**:

```
aaa group server radius loginrad
server 172.16.2.3
server 172.16.2.17
server 172.16.2.32
```

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the group *loginrad*.

To specify **group loginrad** as the method of network accounting when no other method list has been defined, enter the following command:

```
aaa accounting network default start-stop group loginrad
```

Before a group name can be used as the accounting method, communication with the RADIUS or TACACS+ security server must be enabled.

Suppressing Generation of Accounting Records for Null Username Sessions

When AAA accounting is activated, the Cisco IOS software issues accounting records for all users on the system, including users whose username string, because of protocol translation, is NULL. An example of this is users who come in on lines where the **aaa authentication login method-list none** command is applied. To prevent accounting records from being generated for sessions that do not have usernames associated with them, use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa accounting suppress null-username	Prevents accounting records from being generated for users whose username string is NULL.

Generating Interim Accounting Records

To enable periodic interim accounting records to be sent to the accounting server, use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa accounting update {[newinfo] [periodic] number}	Enables periodic interim accounting records to be sent to the accounting server.

When the **aaa accounting update** command is activated, the Cisco IOS software issues interim accounting records for all users on the system. If the keyword **newinfo** is used, interim accounting records are sent to the accounting server every time there is new accounting information to report. An example of this would be when IPCP completes IP address negotiation with the remote peer. The interim accounting record includes the negotiated IP address used by the remote peer.

When used with the keyword **periodic**, interim accounting records are sent periodically as defined by the argument number. The interim accounting record contains all of the accounting information recorded for that user up to the time the interim accounting record is sent.

Caution

Using the **aaa accounting update periodic** command can cause heavy congestion when many users are logged in to the network.

Generating Accounting Records for Failed Login or Session

When AAA accounting is activated, the Cisco IOS software does not generate accounting records for system users who fail login authentication, or who succeed in login authentication but fail PPP negotiation for some reason.

To specify that accounting stop records be generated for users who fail to authenticate at login or during session negotiation, use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa accounting send stop-record authentication failure	Generates “stop” records for users who fail to authenticate at login or during session negotiation using PPP.

Specifying Accounting NETWORK-Stop Records Before EXEC-Stop Records

For PPP users who start EXEC terminal sessions, it can be specified that NETWORK records be generated before EXEC-stop records. In some cases, such as billing customers for specific services, it can be desirable to keep network start and stop records together, essentially “nesting” them within the framework of the EXEC start and stop messages. For example, a user dialing in using PPP can create the following records: EXEC-start, NETWORK-start, EXEC-stop, NETWORK-stop. By nesting the accounting records, NETWORK-stop records follow NETWORK-start messages: EXEC-start, NETWORK-start, NETWORK-stop, EXEC-stop.

To nest accounting records for user sessions, use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa accounting nested	Nests network accounting records.

Configuring AAA Resource Failure Stop Accounting

To enable resource failure stop accounting, use the following command in global configuration:

Command	Purpose
Router(config)# aaa accounting resource <i>method-list stop-failure group server-group</i>	Generates a “stop” record for any calls that do not reach user authentication. Note Before configuring this feature, the tasks described in the section “Prerequisites for Configuring Accounting” must be performed, and SNMP must be enabled on the network access server. For more information about enabling SNMP on a Cisco router or access server, see the chapter “Configuring SNMP Support” in the <i>Cisco IOS Network Management Configuration Guide</i>.

Configuring AAA Resource Accounting for Start-Stop Records

To enable full resource accounting for start-stop records, use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa accounting resource <i>method-list start-stop group server-group</i>	Supports the ability to send a “start” record at each call setup, followed with a corresponding “stop” record at the call disconnect. Note Before configuring this feature, the tasks described in the section “Prerequisites for Configuring Accounting” must be performed, and SNMP must be enabled on the network access server. For more information about enabling SNMP on a Cisco router or access server, see the chapter “Configuring SNMP Support” in the <i>Cisco IOS Network Management Configuration Guide</i> .

Configuring AAA Broadcast Accounting

To configure AAA broadcast accounting, use the **aaa accounting** command in global configuration mode. This command has been modified to allow the **broadcast** keyword.

Command	Purpose
Router(config)# aaa accounting {system network exec connection commands level} {default list-name} {start-stop stop-only none} [broadcast] method1 [method2...]	Enables sending accounting records to multiple AAA servers. Simultaneously sends accounting records to the first server in each group. If the first server is unavailable, failover occurs using the backup servers defined within that group.

Configuring Per-DNIS AAA Broadcast Accounting

To configure AAA broadcast accounting per Dialed Number Identification Service (DNIS), use the **aaa dnis map accounting network** command in global configuration mode. This command has been modified to allow the **broadcast** keyword and multiple server groups.

Command	Purpose
Router(config)# aaa dnis map dnis-number accounting network [start-stop stop-only none] [broadcast] method1 [method2...]	Allows per-DNIS accounting configuration. This command has precedence over the global aaa accounting command. Enables sending accounting records to multiple AAA servers. Simultaneously sends accounting records to the first server in each group. If the first server is unavailable, failover occurs using the backup servers defined within that group.

Configuring AAA Session MIB

The following tasks must be performed before configuring the AAA session MIB feature:

- Configure SNMP. For information on SNMP, see the chapter “[Configuring SNMP Support](#)” in the *Cisco IOS Network Management Configuration Guide*.
- Configure AAA.
- Define the RADIUS or TACACS+ server characteristics.

Note

Overusing SNMP can affect the overall system performance; therefore, normal network management performance must be considered when this feature is used.

To configure AAA session MIB, use the following command in global configuration mode

	Command	Purpose
Step 1	Router(config)# aaa session-mib disconnect	Monitors and terminates authenticated client connections using SNMP. To terminate the call, the disconnect keyword must be used.

Establishing a Session with a Router if the AAA Server is Unreachable

To establish a console or telnet session with a router if the AAA server is unreachable, use the following command in Global Configuration mode:

Command	Purpose
Router(config)# no aaa accounting system guarantee-first	The aaa accounting system guarantee-first command guarantees system accounting as the first record, which is the default condition. In some situations, users may be prevented from starting a session on the console or terminal connection until after the system reloads, which can take more than three minutes. To resolve this problem, the no aaa accounting system guarantee-first command can be used.

Note

Entering the **no aaa accounting system guarantee-first** command is not the only condition by which the console or telnet session can be started. For example, if the Privileged EXEC session is being authenticated by TACACS and the TACACS server is not reachable, then the session cannot start.

Monitoring Accounting

No specific **show** command exists for either RADIUS or TACACS+ accounting. To obtain accounting records displaying information about users currently logged in, use the following command in privileged EXEC mode:

Command	Purpose
Router# show accounting	Allows display of the active accountable events on the network and helps collect information in the event of a data loss on the accounting server.

Troubleshooting Accounting

To troubleshoot accounting information, use the following command in privileged EXEC mode:

Command	Purpose
Router# debug aaa accounting	Displays information on accountable events as they occur.

Accounting Attribute-Value Pairs

The network access server monitors the accounting functions defined in either TACACS+ attribute-value (AV) pairs or RADIUS attributes, depending on which security method is implemented.

Configuration Examples for AAA Accounting

This section contains the following examples:

- [Configuring Named Method List: Example](#)
- [Configuring AAA Resource Accounting: Example](#)
- [Configuring AAA Broadcast Accounting: Example](#)
- [Configuring Per-DNIS AAA Broadcast Accounting: Example](#)
- [AAA Session MIB: Example](#)

Configuring Named Method List: Example

The following example shows how to configure a Cisco AS5200 (enabled for AAA and communication with a RADIUS security server) in order for AAA services to be provided by the RADIUS server. If the RADIUS server fails to respond, then the local database is queried for authentication and authorization information, and accounting services are handled by a TACACS+ server.

```
aaa new-model
aaa authentication login admins local
aaa authentication ppp dialins group radius local
aaa authorization network blue1 group radius local
aaa accounting network red1 start-stop group radius group tacacs+

username root password ALongPassword

tacacs-server host 172.31.255.0
tacacs-server key goaway

radius-server host 172.16.2.7
radius-server key myRaDiUSpassWoRd

interface group-async 1
 group-range 1 16
 encapsulation ppp
 ppp authentication chap dialins
 ppp authorization blue1
 ppp accounting red1

line 1 16
 autoselect ppp
 autoselect during-login
 login authentication admins
 modem dialin
```

The lines in this sample RADIUS AAA configuration are defined as follows:

- The **aaa new-model** command enables AAA network security services.
- The **aaa authentication login admins local** command defines a method list, “admins”, for login authentication.
- The **aaa authentication ppp dialins group radius local** command defines the authentication method list “dialins”, which specifies that first RADIUS authentication and then (if the RADIUS server does not respond) local authentication is used on serial lines using PPP.
- The **aaa authorization network blue1 group radius local** command defines the network authorization method list named “blue1”, which specifies that RADIUS authorization is used on serial lines using PPP. If the RADIUS server fails to respond, then local network authorization is performed.
- The **aaa accounting network red1 start-stop group radius group tacacs+** command defines the network accounting method list named red1, which specifies that RADIUS accounting services (in this case, start and stop records for specific events) are used on serial lines using PPP. If the RADIUS server fails to respond, accounting services are handled by a TACACS+ server.
- The **username** command defines the username and password to be used for the PPP Password Authentication Protocol (PAP) caller identification.
- The **tacacs-server host** command defines the name of the TACACS+ server host.
- The **tacacs-server key** command defines the shared secret text string between the network access server and the TACACS+ server host.

- The **radius-server host** command defines the name of the RADIUS server host.
- The **radius-server key** command defines the shared secret text string between the network access server and the RADIUS server host.
- The **interface group-async** command selects and defines an asynchronous interface group.
- The **group-range** command defines the member asynchronous interfaces in the interface group.
- The **encapsulation ppp** command sets PPP as the encapsulation method used on the specified interfaces.
- The **ppp authentication chap dialins** command selects Challenge Handshake Authentication Protocol (CHAP) as the method of PPP authentication and applies the “dialins” method list to the specified interfaces.
- The **ppp authorization blue1** command applies the blue1 network authorization method list to the specified interfaces.
- The **ppp accounting red1** command applies the red1 network accounting method list to the specified interfaces.
- The **line** command switches the configuration mode from global configuration to line configuration and identifies the specific lines being configured.
- The **autoselect ppp** command configures the Cisco IOS software to allow a PPP session to start up automatically on these selected lines.
- The **autoselect during-login** command is used to display the username and password prompt without pressing the Return key. After the user logs in, the autoselect function (in this case, PPP) begins.
- The **login authentication admins** command applies the admins method list for login authentication.
- The **modem dialin** command configures modems attached to the selected lines to only accept incoming calls.

The **show accounting** command yields the following output for the preceding configuration:

```
Active Accounted actions on tty1, User username2 Priv 1
Task ID 5, Network Accounting record, 00:00:52 Elapsed
task_id=5 service=ppp protocol=ip address=10.0.0.98
```

Table 4 describes the fields contained in the preceding output.

Table 4 *show accounting Field Descriptions*

Field	Description
Active Accounted actions on	Terminal line or interface name user with which the user logged in.
User	User's ID.
Priv	User's privilege level.
Task ID	Unique identifier for each accounting session.
Accounting Record	Type of accounting session.
Elapsed	Length of time (hh:mm:ss) for this session type.
attribute=value	AV pairs associated with this accounting session.

Configuring AAA Resource Accounting: Example

The following example shows how to configure the resource failure stop accounting and resource accounting for start-stop records functions:

```
!Enable AAA on your network access server.
aaa new-model
!Enable authentication at login and list the AOL string name to use for login
authentication.
aaa authentication login AOL group radius local
!Enable authentication for ppp and list the default method to use for PPP authentication.
aaa authentication ppp default group radius local
!Enable authorization for all exec sessions and list the AOL string name to use for
authorization.
aaa authorization exec AOL group radius if-authenticated
!Enable authorization for all network-related service requests and list the default method
to use for all network-related authorizations.
aaa authorization network default group radius if-authenticated
!Enable accounting for all exec sessions and list the default method to use for all
start-stop accounting services.
aaa accounting exec default start-stop group radius
!Enable accounting for all network-related service requests and list the default method to
use for all start-stop accounting services.
aaa accounting network default start-stop group radius
!Enable failure stop accounting.
aaa accounting resource default stop-failure group radius
!Enable resource accounting for start-stop records.
aaa accounting resource default start-stop group radius
```

Configuring AAA Broadcast Accounting: Example

The following example shows how to turn on broadcast accounting using the global **aaa accounting** command:

```
aaa group server radius isp
server 10.0.0.1
server 10.0.0.2

aaa group server tacacs+ isp_customer
server 172.0.0.1

aaa accounting network default start-stop broadcast group isp group isp_customer

radius-server host 10.0.0.1
radius-server host 10.0.0.2
radius-server key key1
tacacs-server host 172.0.0.1 key key2
```

The **broadcast** keyword causes “start” and “stop” accounting records for network connections to be sent simultaneously to server 10.0.0.1 in the group isp and to server 172.0.0.1 in the group isp_customer. If server 10.0.0.1 is unavailable, failover to server 10.0.0.2 occurs. If server 172.0.0.1 is unavailable, no failover occurs because backup servers are not configured for the group isp_customer.

Configuring Per-DNIS AAA Broadcast Accounting: Example

The following example shows how to turn on per DNIS broadcast accounting using the global **aaa dnis map accounting network** command:

```
aaa group server radius isp
  server 10.0.0.1
  server 10.0.0.2

aaa group server tacacs+ isp_customer
  server 172.0.0.1

aaa dnis map enable
aaa dnis map 7777 accounting network start-stop broadcast group isp group isp_customer

radius-server host 10.0.0.1
radius-server host 10.0.0.2
radius-server key key_1
tacacs-server host 172.0.0.1 key key_2
```

The **broadcast** keyword causes “start” and “stop” accounting records for network connection calls having DNIS number 7777 to be sent simultaneously to server 10.0.0.1 in the group **isp** and to server 172.0.0.1 in the group **isp_customer**. If server 10.0.0.1 is unavailable, failover to server 10.0.0.2 occurs. If server 172.0.0.1 is unavailable, no failover occurs because backup servers are not configured for the group **isp_customer**.

AAA Session MIB: Example

The following example shows how to set up the AAA session MIB feature to disconnect authenticated client connections for PPP users:

```
aaa new-model
aaa authentication ppp default group radius
aaa authorization network default group radius
aaa accounting network default start-stop group radius
aaa session-mib disconnect
```

Feature Information for Configuring Accounting

Table 5 lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Releases 12.2(1) or 12.0(3)S or a later release appear in the table.

Not all commands may be available in the Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

Table 5 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 5 Feature Information for Configuring Accounting

Feature Name	Releases	Feature Information
—	Cisco IOS	For information about feature support in Cisco IOS software, use Cisco Feature Navigator.
Connection Accounting	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.
AAA Session MIB	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.
AAA Broadcast Accounting	Cisco IOS XE Release 2.2	This feature was introduced on Cisco ASR 1000 Series Routers.

About RADIUS

RADIUS is a distributed client/server system that secures networks against unauthorized access. In the Cisco implementation, RADIUS clients run on Cisco routers and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.

RADIUS is a fully open protocol, distributed in source code format, that can be modified to work with any security system currently available on the market.

Cisco supports RADIUS under its AAA security paradigm. RADIUS can be used with other AAA security protocols, such as TACACS+, Kerberos, and local username lookup. RADIUS is supported on all Cisco platforms, but some RADIUS-supported features run only on specified platforms.

RADIUS has been implemented in a variety of network environments that require high levels of security while maintaining network access for remote users.

Use RADIUS in the following network environments that require access security:

- Networks with multiple-vendor access servers, each supporting RADIUS. For example, access servers from several vendors use a single RADIUS server-based security database. In an IP-based network with multiple vendors' access servers, dial-in users are authenticated through a RADIUS server that has been customized to work with the Kerberos security system.
- Turnkey network security environments in which applications support the RADIUS protocol, such as in an access environment that uses a "smart card" access control system. In one case, RADIUS has been used with Enigma's security cards to validate users and grant access to network resources.
- Networks already using RADIUS. You can add a Cisco router with RADIUS to the network. This might be the first step when you make a transition to a Terminal Access Controller Access Control System Plus (TACACS+) server.
- Networks in which a user must only access a single service. Using RADIUS, you can control user access to a single host, to a single utility such as Telnet, or to a single protocol such as Point-to-Point Protocol (PPP). For example, when a user logs in, RADIUS identifies this user as having authorization to run PPP using IP address 10.2.3.4 and the defined access list is started.
- Networks that require resource accounting. You can use RADIUS accounting independent of RADIUS authentication or authorization. The RADIUS accounting functions allow data to be sent at the start and end of services, indicating the amount of resources (such as time, packets, bytes, and so on) used during the session. An Internet service provider (ISP) might use a freeware-based version of RADIUS access control and accounting software to meet special security and billing needs.
- Networks that wish to support preauthentication. Using the RADIUS server in your network, you can configure AAA preauthentication and set up the preauthentication profiles. Preauthentication enables service providers to better manage ports using their existing RADIUS solutions, and to efficiently manage the use of shared resources to offer differing service-level agreements.

RADIUS is not suitable in the following network security situations:

- Multiprotocol access environments. RADIUS does not support the following protocols:
 - AppleTalk Remote Access (ARA)
 - NetBIOS Frame Control Protocol (NBFCP)
 - NetWare Asynchronous Services Interface (NASI)
 - X.25 PAD connections

- Router-to-router situations. RADIUS does not provide two-way authentication. RADIUS can be used to authenticate from one router to a non-Cisco router if the non-Cisco router requires RADIUS authentication.
- Networks using a variety of services. RADIUS generally binds a user to one service model.

RADIUS Operation

When a user attempts to log in and authenticate to an access server using RADIUS, the following steps occur:

1. The user is prompted for and enters a username and password.
2. The username and encrypted password are sent over the network to the RADIUS server.

3. The user receives one of the following responses from the RADIUS server:
 - a. **ACCEPT**—The user is authenticated.
 - b. **REJECT**—The user is not authenticated and is prompted to reenter the username and password, or access is denied.
 - c. **CHALLENGE**—A challenge is issued by the RADIUS server. The challenge collects additional data from the user.
 - d. **CHANGE PASSWORD**—A request is issued by the RADIUS server, asking the user to select a new password.

The **ACCEPT** or **REJECT** response is bundled with additional data that is used for **EXEC** or network authorization. You must first complete RADIUS authentication before using RADIUS authorization. The additional data included with the **ACCEPT** or **REJECT** packets consists of the following:

- Services that the user can access, including Telnet, rlogin, or local-area transport (LAT) connections, and PPP, Serial Line Internet Protocol (SLIP), or **EXEC** services.
- Connection parameters, including the host or client IP address, access list, and user timeouts.

RADIUS Configuration Task List

To configure RADIUS on your Cisco router or access server, you must perform the following tasks:

- Use the **aaa new-model** global configuration command to enable AAA. AAA must be configured if you plan to use RADIUS. For more information about using the **aaa new-model** command, refer to the “AAA Overview” chapter.
- Use the **aaa authentication** global configuration command to define method lists for RADIUS authentication. For more information about using the **aaa authentication** command, refer to the “Configuring Authentication” chapter.
- Use **line** and **interface** commands to enable the defined method lists to be used. For more information, refer to the “Configuring Authentication” chapter.

The following configuration tasks are optional:

- You may use the **aaa group server** command to group selected RADIUS hosts for specific services. For more information about using the **aaa group server** command, refer to the [“Configuring AAA Server Groups”](#) section in this chapter.
- You may use the **aaa dnis map** command to select RADIUS server groups based on DNIS number. To use this command, you must define RADIUS server groups using the **aaa group server** command. For more information about using the **aaa dnis map** command, refer to the section [“Configuring AAA Server Group Selection Based on DNIS”](#) in this chapter.
- You may use the **aaa authorization** global command to authorize specific user functions. For more information about using the **aaa authorization** command, refer to the chapter “Configuring Authorization.”
- You may use the **aaa accounting** command to enable accounting for RADIUS connections. For more information about using the **aaa accounting** command, refer to the chapter “Configuring Accounting.”
- You may use the **dialer aaa** interface configuration command to create remote site profiles that contain outgoing call attributes on the AAA server. For more information about using the **dialer aaa** command, refer to the section [“Configuring Suffix and Password in RADIUS Access Requests”](#) in this chapter.

This section describes how to set up RADIUS for authentication, authorization, and accounting on your network, and includes the following sections:

- [Configuring Router to RADIUS Server Communication](#) (Required)
- [Configuring Router to Use Vendor-Specific RADIUS Attributes](#) (Optional)
- [Configuring Router for Vendor-Proprietary RADIUS Server Communication](#) (Optional)
- [Configuring Router to Query RADIUS Server for Static Routes and IP Addresses](#) (Optional)
- [Configuring Router to Expand Network Access Server Port Information](#) (Optional)
- [Configuring AAA Server Groups](#) (Optional)
- [Configuring AAA Server Groups with Deadtme](#) (Optional)
- [Configuring AAA DNIS Authentication](#)
- [Configuring AAA Server Group Selection Based on DNIS](#) (Optional)
- [Configuring AAA Preauthentication](#)
- [Configuring a Guard Timer](#)
- [Specifying RADIUS Authentication](#)
- [Specifying RADIUS Authorization](#) (Optional)
- [Specifying RADIUS Accounting](#) (Optional)
- [Configuring RADIUS Login-IP-Host](#) (Optional)
- [Configuring RADIUS Prompt](#) (Optional)
- [Configuring Suffix and Password in RADIUS Access Requests](#) (Optional)

For RADIUS configuration examples using the commands in this chapter, refer to the section “[RADIUS Configuration Examples](#)” at the end of this chapter.

Configuring Router to RADIUS Server Communication

The RADIUS host is normally a multiuser system running RADIUS server software from Cisco (CiscoSecure ACS), Livingston, Merit, Microsoft, or another software provider. Configuring router to RADIUS server communication can have several components:

- Host name or IP address
- Authentication destination port
- Accounting destination port
- Timeout period
- Retransmission value
- Key string

RADIUS security servers are identified on the basis of their host name or IP address, host name and specific UDP port numbers, or IP address and specific UDP port numbers. The combination of the IP address and UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, accounting—the second host entry configured acts as fail-over backup to the first one. Using this

example, if the first host entry fails to provide accounting services, the network access server will try the second host entry configured on the same device for accounting services. (The RADIUS host entries will be tried in the order they are configured.)

A RADIUS server and a Cisco router use a shared secret text string to encrypt passwords and exchange responses. To configure RADIUS to use the AAA security commands, you must specify the host running the RADIUS server daemon and a secret text (key) string that it shares with the router.

The timeout, retransmission, and encryption key values are configurable globally for all RADIUS servers, on a per-server basis, or in some combination of global and per-server settings. To apply these settings globally to all RADIUS servers communicating with the router, use the three unique global commands: **radius-server timeout**, **radius-server retransmit**, and **radius-server key**. To apply these values on a specific RADIUS server, use the **radius-server host** command.

Note

You can configure both global and per-server timeout, retransmission, and key value commands simultaneously on the same Cisco network access server. If both global and per-server functions are configured on a router, the per-server timer, retransmission, and key value commands override global timer, retransmission, and key value commands.

To configure per-server RADIUS server communication, use the following command in global configuration mode:

Command	Purpose
<pre>Router(config)# radius-server host {hostname ip-address} [auth-port port-number] [acct-port port-number] [timeout seconds] [retransmit retries] [key string] [alias {hostname ip address}]</pre>	Specifies the IP address or host name of the remote RADIUS server host and assign authentication and accounting destination port numbers. Use the auth-port port-number option to configure a specific UDP port on this RADIUS server to be used solely for authentication. Use the acct-port port-number option to configure a specific UDP port on this RADIUS server to be used solely for accounting. Use the alias keyword to configure up to eight multiple IP addresses for use when referring to RADIUS servers. To configure the network access server to recognize more than one host entry associated with a single IP address, simply repeat this command as many times as necessary, making sure that each UDP port number is different. Set the timeout, retransmit, and encryption key values to use with the specific RADIUS host. If no timeout is set, the global value is used; otherwise, enter a value in the range 1 to 1000. If no retransmit value is set, the global value is used; otherwise enter a value in the range 1 to 1000. If no key string is specified, the global value is used. Note The key is a text string that must match the encryption key used on the RADIUS server. Always configure the key as the last item in the radius-server host command syntax because the leading spaces are ignored, but spaces within and at the end of the key are used. If you use spaces in your key, do not enclose the key in quotation marks unless the quotation marks themselves are part of the key.

To configure global communication settings between the router and a RADIUS server, use the following **radius-server** commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# radius-server key { <i>0 string</i> <i>7 string</i> <i>string</i> }	Specifies the shared secret text string used between the router and a RADIUS server. Use the 0 line option to configure an unencrypted shared secret. Use the 7 line option to configure an encrypted shared secret.
Step 2	Router(config)# radius-server retransmit <i>retries</i>	Specifies how many times the router transmits each RADIUS request to the server before giving up (the default is 3).
Step 3	Router(config)# radius-server timeout <i>seconds</i>	Specifies for how many seconds a router waits for a reply to a RADIUS request before retransmitting the request.
Step 4	Router(config)# radius-server deadtime <i>minutes</i>	Specifies for how many minutes a RADIUS server that is not responding to authentication requests is passed over by requests for RADIUS authentication.

Configuring Router to Use Vendor-Specific RADIUS Attributes

The Internet Engineering Task Force (IETF) draft standard specifies a method for communicating vendor-specific information between the network access server and the RADIUS server by using the vendor-specific attribute (attribute 26). Vendor-specific attributes (VSAs) allow vendors to support their own extended attributes not suitable for general use. The Cisco RADIUS implementation supports one vendor-specific option using the format recommended in the specification. Cisco's vendor-ID is 9, and the supported option has vendor-type 1, which is named "cisco-avpair." The value is a string of the following format:

```
protocol : attribute sep value *
```

"Protocol" is a value of the Cisco "protocol" attribute for a particular type of authorization; protocols that can be used include IP, IPX, VPDN, VOIP, SHELL, RSVP, SIP, AIRNET, OUTBOUND. "Attribute" and "value" are an appropriate attribute-value (AV) pair defined in the Cisco TACACS+ specification, and "sep" is "=" for mandatory attributes and "*" for optional attributes. This allows the full set of features available for TACACS+ authorization to also be used for RADIUS.

For example, the following AV pair causes Cisco's "multiple named ip address pools" feature to be activated during IP authorization (during PPP's IPCP address assignment):

```
cisco-avpair= "ip:addr-pool=first"
```

If you insert an "*", the AV pair "ip:addr-pool=first" becomes optional. Note that any AV pair can be made optional.

```
cisco-avpair= "ip:addr-pool*first"
```

The following example shows how to cause a user logging in from a network access server to have immediate access to EXEC commands:

```
cisco-avpair= "shell:priv-lvl=15"
```

Other vendors have their own unique vendor-IDs, options, and associated VSAs. For more information about vendor-IDs and VSAs, refer to RFC 2138, Remote Authentication Dial-In User Service (RADIUS).

To configure the network access server to recognize and use VSAs, use the following command in global configuration mode:

Command	Purpose
Router(config)# radius-server vsa send [accounting authentication]	Enables the network access server to recognize and use VSAs as defined by RADIUS IETF attribute 26.

For a complete list of RADIUS attributes or more information about vendor-specific attribute 26, refer to the appendix “RADIUS Attributes.”

Configuring Router for Vendor-Proprietary RADIUS Server Communication

Although an Internet Engineering Task Force (IETF) draft standard for RADIUS specifies a method for communicating vendor-specific information between the network access server and the RADIUS server, some vendors have extended the RADIUS attribute set in a unique way. Cisco IOS software supports a subset of vendor-specific RADIUS attributes.

As mentioned earlier, to configure RADIUS (whether vendor-specific or IETF draft-compliant), you must specify the host running the RADIUS server daemon and the secret text string it shares with the Cisco device. You specify the RADIUS host and secret text string by using the **radius-server** commands. To identify that the RADIUS server is using a vendor-specific implementation of RADIUS, use the **radius-server host non-standard** command. Vendor-specific attributes will not be supported unless you use the **radius-server host non-standard** command.

To specify a vendor-specific RADIUS server host and a shared secret text string, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# radius-server host { <i>hostname</i> <i>ip-address</i> } non-standard	Specifies the IP address or host name of the remote RADIUS server host and identifies that it is using a vendor-specific implementation of RADIUS.
Step 2	Router(config)# radius-server key { <i>0 string</i> <i>7 string</i> <i>string</i> }	Specifies the shared secret text string used between the router and the vendor-specific RADIUS server. The router and the RADIUS server use this text string to encrypt passwords and exchange responses.

Configuring Router to Query RADIUS Server for Static Routes and IP Addresses

Some vendor-specific implementations of RADIUS let the user define static routes and IP pool definitions on the RADIUS server instead of on each individual network access server in the network. Each network access server then queries the RADIUS server for static route and IP pool information.

To have the Cisco router or access server query the RADIUS server for static routes and IP pool definitions when the device first starts up, use the following command in global configuration mode:

Command	Purpose
Router(config)# radius-server configure-nas	Tells the Cisco router or access server to query the RADIUS server for the static routes and IP pool definitions used throughout its domain.

**Note**

Because the **radius-server configure-nas** command is performed when the Cisco router starts up, it will not take effect until you issue a **copy system:running config nvram:startup-config** command.

Configuring Router to Expand Network Access Server Port Information

There are some situations when PPP or login authentication occurs on an interface different from the interface on which the call itself comes in. For example, in a V.120 ISDN call, login or PPP authentication occurs on a virtual asynchronous interface “**ttt**” but the call itself occurs on one of the channels of the ISDN interface.

The **radius-server attribute nas-port extended** command configures RADIUS to expand the size of the NAS-Port attribute (RADIUS IETF attribute 5) field to 32 bits. The upper 16 bits of the NAS-Port attribute display the type and number of the controlling interface; the lower 16 bits indicate the interface undergoing authentication.

To display expanded interface information in the NAS-Port attribute field, use the following command in global configuration mode:

Command	Purpose
Router(config)# radius-server attribute nas-port format	Expands the size of the NAS-Port attribute from 16 to 32 bits to display extended interface information.

**Note**

This command replaces the **radius-server extended-portnames** command and the **radius-server attribute nas-port extended** command.

On platforms with multiple interfaces (ports) per slot, the Cisco RADIUS implementation will not provide a unique NAS-Port attribute that permits distinguishing between the interfaces. For example, if a dual PRI interface is in slot 1, calls on both Serial1/0:1 and Serial1/1:1 will appear as NAS-Port = 20101.

Once again, this is because of the 16-bit field size limitation associated with RADIUS IETF NAS-Port attribute. In this case, the solution is to replace the NAS-Port attribute with a vendor-specific attribute (RADIUS IETF attribute 26). Cisco's vendor-ID is 9, and the Cisco-NAS-Port attribute is subtype 2. Vendor-specific attributes (VSAs) can be turned on by entering the **radius-server vsa send** command. The port information in this attribute is provided and configured using the **aaa nas port extended** command.

To replace the NAS-Port attribute with RADIUS IETF attribute 26 and to display extended field information, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# radius-server vsa send [accounting authentication]	Enables the network access server to recognize and use vendor-specific attributes as defined by RADIUS IETF attribute 26.
Step 2	Router(config)# aaa nas port extended	Expands the size of the VSA NAS-Port field from 16 to 32 bits to display extended interface information.

The standard NAS-Port attribute (RADIUS IETF attribute 5) will continue to be sent. If you do not want this information to be sent, you can suppress it by using the **no radius-server attribute nas-port** command. When this command is configured, the standard NAS-Port attribute will no longer be sent.

For a complete list of RADIUS attributes, refer to the appendix “RADIUS Attributes.”

For information about configuring RADIUS port identification for PPP, see the *Cisco IOS Wide-Area Networking Configuration Guide*.

Configuring AAA Server Groups

Configuring the router to use AAA server groups provides a way to group existing server hosts. This allows you to select a subset of the configured server hosts and use them for a particular service. A server group is used in conjunction with a global server-host list. The server group lists the IP addresses of the selected server hosts.

Server groups also can include multiple host entries for the same server, as long as each entry has a unique identifier. The combination of an IP address and a UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, accounting—the second host entry configured acts as failover backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server will try the second host entry configured on the same device for accounting services. (The RADIUS host entries will be tried in the order in which they are configured.)

To define a server host with a server group name, enter the following commands in global configuration mode. The listed server must exist in global configuration mode:

	Command	Purpose
Step 1	Router(config)# radius-server host { <i>hostname</i> <i>ip-address</i> } [auth-port <i>port-number</i>] [acct-port <i>port-number</i>] [timeout <i>seconds</i>] [retransmit <i>retries</i>] [key <i>string</i>] [alias { <i>hostname</i> <i>ip address</i> }]	Specifies and defines the IP address of the server host before configuring the AAA server-group. Refer to the section “ Configuring Router to RADIUS Server Communication ” of this chapter for more information on the radius-server host command.

	Command	Purpose
Step 2	Router(config-if)# aaa group server {radius tacacs+} <i>group-name</i>	Defines the AAA server group with a group name. All members of a group must be the same type; that is, RADIUS or TACACS+. This command puts the router in server group subconfiguration mode.
Step 3	Router(config-sg)# server <i>ip-address</i> [auth-port <i>port-number</i>] [acct-port <i>port-number</i>]	Associates a particular RADIUS server with the defined server group. Each security server is identified by its IP address and UDP port number. Repeat this step for each RADIUS server in the AAA server group. Note Each server in the group must be defined previously using the radius-server host command.

Configuring AAA Server Groups with Deadtime

After you have configured a server host with a server name, you can use the **deadtime** command to configure each server per server group. Configuring deadtime within a server group allows you to direct AAA traffic to separate groups of servers that have different operational characteristics.

Configuring deadtime is no longer limited to a global configuration. A separate timer has been attached to each server host in every server group. Therefore, when a server is found to be unresponsive after numerous retransmissions and timeouts, the server is assumed to be dead. The timers attached to each server host in all server groups are triggered. In essence, the timers are checked and subsequent requests to a server (once it is assumed to be dead) are directed to alternate timers, if configured. When the network access server receives a reply from the server, it checks and stops all configured timers (if running) for that server in all server groups.

If the timer has expired, only the server to which the timer is attached is assumed to be alive. This becomes the only server that can be tried for later AAA requests using the server groups to which the timer belongs.

Note

Since one server has different timers and may have different deadtime values configured in the server groups, the same server may in the future have different states (dead and alive) at the same time.

Note

To change the state of a server, you must start and stop all configured timers in all server groups.

The size of the server group will be slightly increased because of the addition of new timers and the deadtime attribute. The overall impact of the structure depends on the number and size of the server groups and how the servers are shared among server groups in a specific configuration.

To configure deadtime within a server group, use the following commands beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa group server radius group1	Defines a RADIUS type server group.
Step 2	Router(config-sg)# deadtime 1	Configures and defines deadtime value in minutes. Note Local server group deadtime will override the global configuration. If omitted from the local server group configuration, the value will be inherited from the master list.
Step 3	Router(config-sg)# exit	Exits server group configuration mode.

Configuring AAA DNIS Authentication

DNIS preauthentication enables preauthentication at call setup based on the number dialed. The DNIS number is sent directly to the security server when a call is received. If authenticated by AAA, the call is accepted.

To configure DNIS authentication, perform the following tasks in global configuration mode:

	Command	Purpose
Step 1	Router# config term	Enters global configuration mode.
Step 2	Router(config)# aaa preauth	Enters AAA preauthentication mode.
Step 3	Router(config-preauth)# group {radius tacacs+ server-group}	(Optional) Selects the security server to use for AAA preauthentication requests. The default is RADIUS.
Step 4	Router(config-preauth)# dnis [password string]	Enables preauthentication using DNIS and optionally specifies a password to use in Access-Request packets.

Configuring AAA Server Group Selection Based on DNIS

Cisco IOS software allows you to assign a Dialed Number Identification Service (DNIS) number to a particular AAA server group so that the server group can process authentication, authorization, and accounting requests for users dialing in to the network using that particular DNIS. Any phone line (a regular home phone or a commercial T1/PRI line) can be associated with several phone numbers. The DNIS number identifies the number that was called to reach you.

For example, suppose you want to share the same phone number with several customers, but you want to know which customer is calling before you pick up the phone. You can customize how you answer the phone because DNIS allows you to know which customer is calling when you answer.

Cisco routers with either ISDN or internal modems can receive the DNIS number. This functionality allows users to assign different RADIUS server groups for different customers (that is, different RADIUS servers for different DNIS numbers). Additionally, using server groups you can specify the same server group for AAA services or a separate server group for each AAA service.

Cisco IOS software provides the flexibility to implement authentication and accounting services in several ways:

- Globally—AAA services are defined using global configuration access list commands and applied in general to all interfaces on a specific network access server.
- Per Interface—AAA services are defined using interface configuration commands and applied specifically to the interface being configured on a specific network access server.
- DNIS mapping—You can use DNIS to specify an AAA server to supply AAA services.

Because each of these AAA configuration methods can be configured simultaneously, Cisco has established an order of precedence to determine which server or groups of servers provide AAA services. The order of precedence is as follows:

- Per DNIS—If you configure the network access server to use DNIS to identify/determine which server group provides AAA services, then this method takes precedence over any additional AAA selection method.
- Per interface—If you configure the network access server per interface to use access lists to determine how a server provides AAA services, this method takes precedence over any global configuration AAA access lists.
- Globally—If you configure the network access server by using global AAA access lists to determine how the security server provides AAA services, this method has the least precedence.

Note

Prior to configuring AAA Server Group Selection Based on DNIS, you must configure the list of RADIUS server hosts and configure the AAA server groups. See the sections [“Configuring Router to RADIUS Server Communication”](#) and [“Configuring AAA Server Groups”](#) of this chapter.

To configure the router to select a particular AAA server group based on the DNIS of the server group, configure DNIS mapping. To map a server group with a group name with DNIS number, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa dnis map enable	Enables DNIS mapping.
Step 2	Router(config)# aaa dnis map <i>dnis-number</i> authentication ppp group <i>server-group-name</i>	Maps a DNIS number to a defined AAA server group; the servers in this server group are being used for authentication.
Step 3	Router(config)# aaa dnis map <i>dnis-number</i> authorization network group <i>server-group-name</i>	Maps a DNIS number to a defined AAA server group; the servers in this server group are being used for authorization.
Step 4	Router(config)# aaa dnis map <i>dnis-number</i> accounting network [none start-stop stop-only] group <i>server-group-name</i>	Maps a DNIS number to a defined AAA server group; the servers in this server group are being used for accounting.

Configuring AAA Preauthentication

Configuring AAA preauthentication with ISDN PRI or channel-associated signalling (CAS) allows service providers to better manage ports using their existing RADIUS solutions and efficiently manage the use of shared resources to offer differing service-level agreements. With ISDN PRI or CAS, information about an incoming call is available to the network access server (NAS) before the call is connected. The available call information includes the following:

- The Dialed Number Identification Service (DNIS) number, also referred to as the called number
- The Calling Line Identification (CLID) number, also referred to as the calling number
- The call type, also referred to as the bearer capability

This feature allows a Cisco NAS to decide—on the basis of the DNIS number, the CLID number, or the call type—whether to connect an incoming call. (With ISDN PRI, it enables user authentication and authorization before a call is answered. With CAS, the call must be answered; however, the call can be dropped if preauthentication fails.)

When an incoming call arrives from the public network switch, but before it is connected, AAA preauthentication enables the NAS to send the DNIS number, CLID number, and call type to a RADIUS server for authorization. If the server authorizes the call, then the NAS accepts the call. If the server does not authorize the call, then the NAS sends a disconnect message to the public network switch to reject the call.

In the event that the RADIUS server application becomes unavailable or is slow to respond, a guard timer can be set in the NAS. When the timer expires, the NAS uses a configurable parameter to accept or reject the incoming call that has no authorization.

This feature supports the use of attribute 44 by the RADIUS server application and the use of RADIUS attributes that are configured in the RADIUS preauthentication profiles to specify preauthentication behavior. They may also be used, for instance, to specify whether subsequent authentication should occur and, if so, what authentication method should be used.

The following restrictions apply to AAA preauthentication with ISDN PRI and CAS:

- Attribute 44 is available for CAS calls only when preauthentication or resource pooling is enabled.
- MMP is not available with ISDN PRI.
- AAA preauthentication is available only on the Cisco AS5300, Cisco AS5400, and Cisco AS5800 platforms.

Note

Prior to configuring AAA preauthentication, you must enable the **aaa new-model** command and make sure the supporting preauthentication application is running on a RADIUS server in your network.

To configure AAA preauthentication, use the following commands beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa preauth	Enters AAA preauthentication configuration mode.
Step 2	Router(config-preauth)# group <i>server-group</i>	Specifies the AAA RADIUS server group to use for preauthentication.
Step 3	Router(config-preauth)# clid [if-avail required] [accept-stop] [password <i>string</i>]	Preauthenticates calls on the basis of the CLID number.

	Command	Purpose
Step 4	Router(config-preauth)# ctype [if-avail required] [accept-stop] [password <i>string</i>]	Preauthenticates calls on the basis of the call type.
Step 5	Router(config-preauth)# dnis [if-avail required] [accept-stop] [password <i>string</i>]	Preauthenticates calls on the basis of the DNIS number.
Step 6	Router(config-preauth)# dnis bypass { <i>dnis-group-name</i> }	Specifies a group of DNIS numbers that will be bypassed for preauthentication.

To configure DNIS preauthentication, use the following commands beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa preauth	Enters AAA preauthentication mode.
Step 2	Router(config-preauth)# group { radius tacacs+ <i>server-group</i> }	(Optional) Selects the security server to use for AAA preauthentication requests. The default is RADIUS.
Step 3	Router(config-preauth)# dnis [password <i>string</i>]	Enables preauthentication using DNIS and optionally specifies a password to use in Access-Request packets.

In addition to configuring preauthentication on your Cisco router, you must set up the preauthentication profiles on the RADIUS server. For information on setting up the preauthentication profiles, see the following sections:

- [Setting Up the RADIUS Profile for DNIS or CLID Preauthentication](#)
- [Setting Up the RADIUS Profile for Call Type Preauthentication](#)
- [Setting Up the RADIUS Profile for Preauthentication Enhancements for Callback](#)
- [Setting Up the RADIUS Profile for a Remote Host Name Used for Large-Scale Dial-Out](#)
- [Setting Up the RADIUS Profile for Modem Management](#)
- [Setting Up the RADIUS Profile for Subsequent Authentication](#)
- [Setting Up the RADIUS Profile for Subsequent Authentication Type](#)
- [Setting Up the RADIUS Profile to Include the Username](#)
- [Setting Up the RADIUS Profile for Two-Way Authentication](#)
- [Setting Up the RADIUS Profile to Support Authorization](#)

Setting Up the RADIUS Profile for DNIS or CLID Preauthentication

To set up the RADIUS preauthentication profile, use the DNIS or CLID number as the username, and use the password defined in the **dnis** or **clid** command as the password.

**Note**

The preauthentication profile must have “outbound” as the service type because the password is predefined on the NAS. Setting up the preauthentication profile in this manner prevents users from trying to log in to the NAS with the username of the DNIS number, CLID number, or call type and an obvious password. The “outbound” service type is also included in the access-request packet sent to the RADIUS server.

Setting Up the RADIUS Profile for Call Type Preauthentication

To set up the RADIUS preauthentication profile, use the call type string as the username, and use the password defined in the **ctype** command as the password. The following table shows the call type strings that may be used in the preauthentication profile:

Call Type String	ISDN Bearer Capabilities
digital	Unrestricted digital, restricted digital.
speech	Speech, 3.1 kHz audio, 7 kHz audio. Note This is the only call type available for CAS.
v.110	Anything with V.110 user information layer.
v.120	Anything with V.120 user information layer.

**Note**

The preauthentication profile must have “outbound” as the service type because the password is predefined on the NAS. Setting up the preauthentication profile in this manner prevents users from trying to log in to the NAS with the username of the DNIS number, CLID number, or call type and an obvious password. The “outbound” service type is also included in the access-request packet sent to the RADIUS server and should be a check-in item if the RADIUS server supports check-in items.

Setting Up the RADIUS Profile for Preauthentication Enhancements for Callback

Callback allows remote network users such as telecommuters to dial in to the NAS without being charged. When callback is required, the NAS hangs up the current call and dials the caller back. When the NAS performs the callback, only information for the outgoing connection is applied. The rest of the attributes from the preauthentication access-accept message are discarded.

**Note**

The destination IP address is not required to be returned from the RADIUS server.

The following example shows a RADIUS profile configuration with a callback number of 555-1111 and the service type set to outbound. The cisco-avpair = “preauth:send-name=<string>” uses the string “andy” and the cisco-avpair = “preauth:send-secret=<string>” uses the password “cisco.”

```
5551111 password = "cisco", Service-Type = Outbound
  Service-Type = Callback-Framed
  Framed-Protocol = PPP,
  Dialback-No = "5551212"
  Class = "ISP12"
  cisco-avpair = "preauth:send-name=andy"
```

```
cisco-avpair = "preauth:send-secret=cisco"
```

Setting Up the RADIUS Profile for a Remote Host Name Used for Large-Scale Dial-Out

The following example adds to the previous example by protecting against accidentally calling a valid telephone number but accessing the wrong router by providing the name of the remote, for use in large-scale dial-out:

```
5551111 password = "cisco", Service-Type = Outbound
    Service-Type = Callback-Framed
    Framed-Protocol = PPP,
    Dialback-No = "5551212"
    Class = "ISP12"
    cisco-avpair = "preauth:send-name=andy"
    cisco-avpair = "preauth:send-secret=cisco"
    cisco-avpair = "preauth:remote-name=Router2"
```

Setting Up the RADIUS Profile for Modem Management

When DNIS, CLID, or call type preauthentication is used, the affirmative response from the RADIUS server may include a modem string for modem management in the NAS through vendor-specific attribute (VSA) 26. The modem management VSA has the following syntax:

```
cisco-avpair = "preauth:modem-service=modem min-speed <x> max-speed <y>
modulation <z> error-correction <a> compression <b>"
```

The modem management string within the VSA may contain the following:

Command	Argument
min-speed	<300 to 56000>, any
max-speed	<300 to 56000>, any
modulation	K56Flex, v22bis, v32bis, v34, v90, any
error-correction	lapm, mnp4
compression	mnp5, v42bis

When the modem management string is received from the RADIUS server in the form of a VSA, the information is passed to the Cisco IOS software and applied on a per-call basis. Modem ISDN channel aggregation (MICA) modems provide a control channel through which messages can be sent during the call setup time. Hence, this modem management feature is supported only with MICA modems and newer technologies. This feature is not supported with Microcom modems.

For more information on modem management, refer to the “Modem Configuration and Management” chapter of the *Cisco IOS Dial Technologies Configuration Guide*, Release 12.2.

Setting Up the RADIUS Profile for Subsequent Authentication

If preauthentication passes, you may use vendor-proprietary RADIUS attribute 201 (Require-Auth) in the preauthentication profile to determine whether subsequent authentication is to be performed. If attribute 201, returned in the access-accept message, has a value of 0, then subsequent authentication will not be performed. If attribute 201 has a value of 1, then subsequent authentication will be performed as usual.

Attribute 201 has the following syntax:

```
cisco-avpair = "preauth:auth-required=<n>"
```

where <n> has the same value range as attribute 201 (that is, 0 or 1).

If attribute 201 is missing in the preauthentication profile, then a value of 1 is assumed, and subsequent authentication is performed.

**Note**

To perform subsequent authentication, you must set up a regular user profile in addition to a preauthentication profile.

Setting Up the RADIUS Profile for Subsequent Authentication Type

If you have specified subsequent authentication in the preauthentication profile, you must also specify the authentication types to be used for subsequent authentication. To specify the authentication types allowed in subsequent authentication, use the following VSA:

```
cisco-avpair = "preauth:auth-type=<string>"
```

where <string> can be one of the following:

String	Description
chap	Requires username and password of CHAP for PPP authentication.
ms-chap	Requires username and password of MS-CHAP for PPP authentication.
pap	Requires username and password of PAP for PPP authentication.

To specify that multiple authentication types are allowed, you can configure more than one instance of this VSA in the preauthentication profile. The sequence of the authentication type VSAs in the preauthentication profile is significant because it specifies the order of authentication types to be used in the PPP negotiation.

This VSA is a per-user attribute and replaces the authentication type list in the **ppp authentication** interface command.

**Note**

You should use this VSA only if subsequent authentication is required because it specifies the authentication type for subsequent authentication.

Setting Up the RADIUS Profile to Include the Username

If only preauthentication is used to authenticate a call, the NAS could be missing a username when it brings up the call. RADIUS may provide a username for the NAS to use through RADIUS attribute 1 (User-Name) or through a VSA returned in the access-accept packet. The VSA for specifying the username has the following syntax:

```
cisco-avpair = "preauth:username=<string>"
```

If no username is specified, the DNIS number, CLID number, or call type is used, depending on the last preauthentication command that has been configured (for example, if **clid** was the last preauthentication command configured, the CLID number will be used as the username).

If subsequent authentication is used to authenticate a call, there might be two usernames: one provided by RADIUS and one provided by the user. In this case, the username provided by the user overrides the one contained in the RADIUS preauthentication profile; the username provided by the user is used for both authentication and accounting.

Setting Up the RADIUS Profile for Two-Way Authentication

In the case of two-way authentication, the calling networking device will need to authenticate the NAS. The Password Authentication Protocol (PAP) username and password or Challenge Handshake Authentication Protocol (CHAP) username and password need not be configured locally on the NAS. Instead, username and password can be included in the access-accept messages for preauthentication.

Note

The **ppp authentication** command must be configured with the **radius** method.

To apply for PAP, do not configure the **ppp pap sent-name password** command on the interface. The vendor-specific attributes (VSAs) “preauth:send-name” and “preauth:send-secret” will be used as the PAP username and PAP password for outbound authentication.

For CHAP, “preauth:send-name” will be used not only for outbound authentication, but also for inbound authentication. For a CHAP inbound case, the NAS will use the name defined in “preauth:send-name” in the challenge packet to the caller networking device. For a CHAP outbound case, both “preauth:send-name” and “preauth:send-secret” will be used in the response packet.

The following example shows a configuration that specifies two-way authentication:

```
5551111 password = "cisco", Service-Type = Outbound
  Service-Type = Framed-User
  cisco-avpair = "preauth:auth-required=1"
  cisco-avpair = "preauth:auth-type=pap"
  cisco-avpair = "preauth:send-name=andy"
  cisco-avpair = "preauth:send-secret=cisco"
  class = "<some class>"
```

Note

Two-way authentication does not work when resource pooling is enabled.

Setting Up the RADIUS Profile to Support Authorization

If only preauthentication is configured, then subsequent authentication will be bypassed. Note that because the username and password are not available, authorization will also be bypassed. However, you may include authorization attributes in the preauthentication profile to apply per-user attributes and avoid having to return subsequently to RADIUS for authorization. To initiate the authorization process, you must also configure the **aaa authorization network** command on the NAS.

You may configure authorization attributes in the preauthentication profile with one exception: the service-type attribute (attribute 6). The service-type attribute must be converted to a VSA in the preauthentication profile. This VSA has the following syntax:

```
cisco-avpair = "preauth:service-type=<n>"
```

where <n> is one of the standard RFC 2138 values for attribute 6. For a list of possible Service-Type values, refer to the appendix RADIUS Attributes.

**Note**

If subsequent authentication is required, the authorization attributes in the preauthentication profile will not be applied.

Configuring a Guard Timer

Because response times for preauthentication and authentication requests can vary, the guard timer allows you to control the handling of calls. The guard timer starts when the DNIS is sent to the RADIUS server. If the NAS does not receive a response from AAA before the guard timer expires, it accepts or rejects the calls on the basis of the configuration of the timer.

To set a guard timer to accept or reject a call in the event that the RADIUS server fails to respond to an authentication or preauthentication request, use one of the following commands in interface configuration mode:

Command	Purpose
Router(config-if)# isdn guard-timer <i>milliseconds</i> [on-expiry { accept reject }]	Sets an ISDN guard timer to accept or reject a call in the event that the RADIUS server fails to respond to a preauthentication request.
Router(control-config)# call guard-timer <i>milliseconds</i> [on-expiry { accept reject }]	Sets a CAS guard timer to accept or reject a call in the event that the RADIUS server fails to respond to a preauthentication request.

Specifying RADIUS Authentication

After you have identified the RADIUS server and defined the RADIUS authentication key, you must define method lists for RADIUS authentication. Because RADIUS authentication is facilitated through AAA, you must enter the **aaa authentication** command, specifying RADIUS as the authentication method. For more information, refer to the chapter “Configuring Authentication.”

Specifying RADIUS Authorization

AAA authorization lets you set parameters that restrict a user’s access to the network. Authorization using RADIUS provides one method for remote access control, including one-time authorization or authorization for each service, per-user account list and profile, user group support, and support of IP, IPX, ARA, and Telnet. Because RADIUS authorization is facilitated through AAA, you must issue the **aaa authorization** command, specifying RADIUS as the authorization method. For more information, refer to the chapter “Configuring Authorization.”

Specifying RADIUS Accounting

The AAA accounting feature enables you to track the services users are accessing as well as the amount of network resources they are consuming. Because RADIUS accounting is facilitated through AAA, you must issue the **aaa accounting** command, specifying RADIUS as the accounting method. For more information, refer to the chapter “Configuring Accounting.”

Configuring RADIUS Login-IP-Host

To enable the network access server to attempt more than one login host when trying to connect a dial in user, you can enter as many as three Login-IP-Host entries in the user's profile on the RADIUS server. The following example shows that three Login-IP-Host instances have been configured for the user *joeuser*, and that TCP-Clear will be used for the connection:

```
joeuser      Password = xyz
             Service-Type = Login,
             Login-Service = TCP-Clear,
             Login-IP-Host = 10.0.0.0,
             Login-IP-Host = 10.2.2.2,
             Login-IP-Host = 10.255.255.255,
             Login-TCP-Port = 23
```

The order in which the hosts are entered is the order in which they are attempted. Use the **ip tcp synwait-time** command to set the number of seconds that the network access server waits before trying to connect to the next host on the list; the default is 30 seconds.

Your RADIUS server might permit more than three Login-IP-Host entries; however, the network access server supports only three hosts in access-accept packets.

Configuring RADIUS Prompt

To control whether user responses to access-challenge packets are echoed to the screen, you can configure the Prompt attribute in the user profile on the RADIUS server. This attribute is included only in access-challenge packets. The following example shows the Prompt attribute set to No-Echo, which prevents the user's responses from echoing:

```
joeuser Password = xyz
             Service-Type = Login,
             Login-Service = Telnet,
             Prompt = No-Echo,
             Login-IP-Host = 172.31.255.255
```

To allow user responses to echo, set the attribute to Echo. If the Prompt attribute is not included in the user profile, responses are echoed by default.

This attribute overrides the behavior of the **radius-server challenge-noecho** command configured on the access server. For example, if the access server is configured to suppress echoing, but the individual user profile allows echoing, then the user responses are echoed.

**Note**

To use the Prompt attribute, your RADIUS server must be configured to support access-challenge packets.

Configuring Suffix and Password in RADIUS Access Requests

Large-scale dial-out eliminates the need to configure dialer maps on every NAS for every destination. Instead, you can create remote site profiles that contain outgoing call attributes on the AAA server. The profile is downloaded by the NAS when packet traffic requires a call to be placed to a remote site.

You can configure the username in the access-request message to RADIUS. The default suffix of the username, "-out," is appended to the username. The format for composing the username attribute is IP address plus configured suffix.

To provide username configuration capability for large-scale dial-out, the **dialer aaa** command is implemented with the new **suffix** and **password** keywords.

	Command	Purpose
Step 1	Router(config)# aaa new-model	Enables the AAA access control model.
Step 2	Router(config)# aaa route download min	Enables the download static route feature and sets the amount of time between downloads.
Step 3	Router(config)# aaa authorization configuration default	Downloads static route configuration information from the AAA server using TACACS+ or RADIUS.
Step 4	Router(config)# interface dialer 1	Defines a dialer rotary group.
Step 5	Router(config-if)# dialer aaa	Allows a dialer to access the AAA server for dialing information.
Step 6	Router(config-if)# dialer aaa suffix suffix password password	Allows a dialer to access the AAA server for dialing information and specifies a suffix and nondefault password for authentication.

Monitoring and Maintaining RADIUS

To monitor and maintain RADIUS, use the following commands in privileged EXEC mode:

Command	Purpose
Router# debug radius	Displays information associated with RADIUS.
Router# show radius statistics	Displays the RADIUS statistics for accounting and authentication packets.

RADIUS Attributes

The network access server monitors the RADIUS authorization and accounting functions defined by RADIUS attributes in each user-profile. For a list of supported RADIUS attributes, refer to the appendix “RADIUS Attributes.”

This section includes the following sections:

- [Vendor-Proprietary RADIUS Attributes](#)
- [RADIUS Tunnel Attributes](#)

Vendor-Proprietary RADIUS Attributes

An Internet Engineering Task Force (IETF) draft standard for RADIUS specifies a method for communicating vendor-proprietary information between the network access server and the RADIUS server. Some vendors, nevertheless, have extended the RADIUS attribute set in a unique way. Cisco IOS software supports a subset of vendor-proprietary RADIUS attributes. For a list of supported vendor-proprietary RADIUS attributes, refer to the appendix “RADIUS Attributes.”

RADIUS Tunnel Attributes

RADIUS is a security server authentication, authorization, and accounting (AAA) protocol originally developed by Livingston, Inc. RADIUS uses attribute value (AV) pairs to communicate information between the security server and the network access server. RFC 2138 and RFC 2139 describe the basic functionality of RADIUS and the original set of Internet Engineering Task Force (IETF)-standard AV pairs used to send AAA information. Two draft IETF standards, “RADIUS Attributes for Tunnel Protocol Support” and “RADIUS Accounting Modifications for Tunnel Protocol Support,” extend the IETF-defined set of AV pairs to include attributes specific to virtual private networks (VPNs); these attributes are used to carry the tunneling information between the RADIUS server and the tunnel initiator. RFC 2865 and RFC 2868 extend the IETF-defined set of AV pairs to include attributes specific to compulsory tunneling in VPNs by allowing the user to specify authentication names for the network access server and the RADIUS server.

Cisco routers and access servers now support new RADIUS IETF-standard VPDN tunnel attributes. These new RADIUS IETF-standard attributes are listed in the “RADIUS Attributes” appendix. Refer to the following three configuration examples later in this chapter:

- [RADIUS User Profile with RADIUS Tunneling Attributes Example](#)
- [L2TP Access Concentrator Examples](#)
- [L2TP Network Server Examples](#)

For more information about L2F, L2TP, VPN, or VPDN, refer to the *Cisco IOS Dial Technologies Configuration Guide*, Release 12.2.

RADIUS Configuration Examples

The following sections provide RADIUS configuration examples:

- [RADIUS Authentication and Authorization Example](#)
- [RADIUS Authentication, Authorization, and Accounting Example](#)
- [Vendor-Proprietary RADIUS Configuration Example](#)
- [RADIUS Server with Server-Specific Values Example](#)
- [Multiple RADIUS Servers with Global and Server-Specific Values Example](#)
- [Multiple RADIUS Server Entries for the Same Server IP Address Example](#)
- [RADIUS Server Group Examples](#)
- [Multiple RADIUS Server Entries Using AAA Server Groups Example](#)
- [AAA Server Group Selection Based on DNIS Example](#)
- [AAA Preauthentication Examples](#)
- [RADIUS User Profile with RADIUS Tunneling Attributes Example](#)
- [Guard Timer Examples](#)
- [L2TP Access Concentrator Examples](#)
- [L2TP Network Server Examples](#)

RADIUS Authentication and Authorization Example

The following example shows how to configure the router to authenticate and authorize using RADIUS:

```
aaa authentication login use-radius group radius local
aaa authentication ppp user-radius if-needed group radius
aaa authorization exec default group radius
aaa authorization network default group radius
```

The lines in this sample RADIUS authentication and authorization configuration are defined as follows:

- The **aaa authentication login use-radius group radius local** command configures the router to use RADIUS for authentication at the login prompt. If RADIUS returns an error, the user is authenticated using the local database. In this example, **use-radius** is the name of the method list, which specifies RADIUS and then local authentication.
- The **aaa authentication ppp user-radius if-needed group radius** command configures the Cisco IOS software to use RADIUS authentication for lines using PPP with CHAP or PAP if the user has not already been authorized. If the EXEC facility has authenticated the user, RADIUS authentication is not performed. In this example, **user-radius** is the name of the method list defining RADIUS as the if-needed authentication method.
- The **aaa authorization exec default group radius** command sets the RADIUS information that is used for EXEC authorization, autocommands, and access lists.
- The **aaa authorization network default group radius** command sets RADIUS for network authorization, address assignment, and access lists.

RADIUS Authentication, Authorization, and Accounting Example

The following example shows a general configuration using RADIUS with the AAA command set:

```
radius-server host 123.45.1.2
radius-server key myRaDiUSpassWoRd
username root password ALongPassword
aaa authentication ppp dialins group radius local
aaa authorization network default group radius local
aaa accounting network default start-stop group radius
aaa authentication login admins local
aaa authorization exec default local
line 1 16
  autoselect ppp
  autoselect during-login
  login authentication admins
  modem ri-is-cd
interface group-async 1
  encaps ppp
  ppp authentication pap dialins
```

The lines in this example RADIUS authentication, authorization, and accounting configuration are defined as follows:

- The **radius-server host** command defines the IP address of the RADIUS server host.
- The **radius-server key** command defines the shared secret text string between the network access server and the RADIUS server host.
- The **aaa authentication ppp dialins group radius local** command defines the authentication method list “dialins,” which specifies that RADIUS authentication and then (if the RADIUS server does not respond) local authentication will be used on serial lines using PPP.

- The **ppp authentication pap dialins** command applies the “dialins” method list to the lines specified.
- The **aaa authorization network default group radius local** command is used to assign an address and other network parameters to the RADIUS user.
- The **aaa accounting network default start-stop group radius** command tracks PPP usage.
- The **aaa authentication login admins local** command defines another method list, “admins,” for login authentication.
- The **login authentication admins** command applies the “admins” method list for login authentication.

Vendor-Proprietary RADIUS Configuration Example

The following example shows a general configuration using vendor-proprietary RADIUS with the AAA command set:

```
radius-server host alcatraz non-standard
radius-server key myRaDiUSpassWoRd
radius-server configure-nas
username root password ALongPassword
aaa authentication ppp dialins group radius local
aaa authorization network default group radius local
aaa accounting network default start-stop group radius
aaa authentication login admins local
aaa authorization exec default local
line 1 16
autoselect ppp
autoselect during-login
login authentication admins
modem ri-is-cd
interface group-async 1
encaps ppp
ppp authentication pap dialins
```

The lines in this example RADIUS authentication, authorization, and accounting configuration are defined as follows:

- The **radius-server host non-standard** command defines the name of the RADIUS server host and identifies that this RADIUS host uses a vendor-proprietary version of RADIUS.
- The **radius-server key** command defines the shared secret text string between the network access server and the RADIUS server host.
- The **radius-server configure-nas** command defines that the Cisco router or access server will query the RADIUS server for static routes and IP pool definitions when the device first starts up.
- The **aaa authentication ppp dialins group radius local** command defines the authentication method list “dialins,” which specifies that RADIUS authentication, and then (if the RADIUS server does not respond) local authentication will be used on serial lines using PPP.
- The **ppp authentication pap dialins** command applies the “dialins” method list to the lines specified.
- The **aaa authorization network default group radius local** command is used to assign an address and other network parameters to the RADIUS user.
- The **aaa accounting network default start-stop group radius** command tracks PPP usage.

- The **aaa authentication login admins local** command defines another method list, “admins,” for login authentication.
- The **login authentication admins** command applies the “admins” method list for login authentication.

RADIUS Server with Server-Specific Values Example

The following example shows how to configure server-specific timeout, retransmit, and key values for the RADIUS server with IP address 172.31.39.46:

```
radius-server host 172.31.39.46 timeout 6 retransmit 5 key rad123
```

Multiple RADIUS Servers with Global and Server-Specific Values Example

The following example shows how to configure two RADIUS servers with specific timeout, retransmit, and key values. In this example, the **aaa new-model** command enables AAA services on the router, while specific AAA commands define the AAA services. The **radius-server retransmit** command changes the global retransmission value to 4 for all RADIUS servers. The **radius-server host** command configures specific timeout, retransmission, and key values for the RADIUS server hosts with IP addresses 172.16.1.1 and 172.29.39.46.

```
! Enable AAA services on the router and define those services.
aaa new-model
aaa authentication login default group radius
aaa authentication login console-login none
aaa authentication ppp default group radius
aaa authorization network default group radius
aaa accounting exec default start-stop group radius
aaa accounting network default start-stop group radius
enable password tryit1
!
! Change the global retransmission value for all RADIUS servers.
radius-server retransmit 4
!
! Configure per-server specific timeout, retransmission, and key values.
! Change the default auth-port and acct-port values.
radius-server host 172.16.1.1 auth-port 1612 acct-port 1616 timeout 3 retransmit 3 key
radkey
!
! Configure per-server specific timeout and key values. This server uses the global
! retransmission value.
radius-server host 172.29.39.46 timeout 6 key rad123
```

Multiple RADIUS Server Entries for the Same Server IP Address Example

The following example shows how to configure the network access server to recognize several RADIUS host entries with the same IP address. Two different host entries on the same RADIUS server are configured for the same services—authentication and accounting. The second host entry configured acts as fail-over backup to the first one. (The RADIUS host entries will be tried in the order they are configured.)

```
! This command enables AAA.
aaa new-model
! The next command configures default RADIUS parameters.
aaa authentication ppp default group radius
```

```
! The next set of commands configures multiple host entries for the same IP address.
radius-server host 172.20.0.1 auth-port 1000 acct-port 1001
radius-server host 172.20.0.1 auth-port 2000 acct-port 2000
```

RADIUS Server Group Examples

The following example shows how to create server group *radgroup1* with three different RADIUS server members, each using the default authentication port (1645) and accounting port (1646):

```
aaa group server radius radgroup1
server 172.16.1.11
server 172.17.1.21
server 172.18.1.31
```

The following example shows how to create server group *radgroup2* with three RADIUS server members, each with the same IP address but with unique authentication and accounting ports:

```
aaa group server radius radgroup2
server 172.16.1.1 auth-port 1000 acct-port 1001
server 172.16.1.1 auth-port 2000 acct-port 2001
server 172.16.1.1 auth-port 3000 acct-port 3001
```

Multiple RADIUS Server Entries Using AAA Server Groups Example

The following example shows how to configure the network access server to recognize two different RADIUS server groups. One of these groups, group1, has two different host entries on the same RADIUS server configured for the same services. The second host entry configured acts as failover backup to the first one. Each group is individually configured for deadline; deadline for group 1 is one minute, and deadline for group 2 is two minutes.

Note

In cases where both global commands and server commands are used, the server command will take precedence over the global command.

```
! This command enables AAA.
aaa new-model
! The next command configures default RADIUS parameters.
aaa authentication ppp default group group1
! The following commands define the group1 RADIUS server group and associate servers
! with it and configures a deadline of one minute.
aaa group server radius group1
server 1.1.1.1 auth-port 1645 acct-port 1646
server 2.2.2.2 auth-port 2000 acct-port 2001
deadline 1
! The following commands define the group2 RADIUS server group and associate servers
! with it and configures a deadline of two minutes.
aaa group server radius group2
server 2.2.2.2 auth-port 2000 acct-port 2001
server 3.3.3.3 auth-port 1645 acct-port 1646
deadline 2
! The following set of commands configures the RADIUS attributes for each host entry
! associated with one of the defined server groups.
radius-server host 1.1.1.1 auth-port 1645 acct-port 1646
radius-server host 2.2.2.2 auth-port 2000 acct-port 2001
radius-server host 3.3.3.3 auth-port 1645 acct-port 1646
```

AAA Server Group Selection Based on DNIS Example

The following example shows how to select RADIUS server groups based on DNIS to provide specific AAA services:

```
! This command enables AAA.
aaa new-model
!
! The following set of commands configures the RADIUS attributes for each server
! that will be associated with one of the defined server groups.
radius-server host 172.16.0.1 auth-port 1645 acct-port 1646 key cisco1
radius-server host 172.17.0.1 auth-port 1645 acct-port 1646 key cisco2
radius-server host 172.18.0.1 auth-port 1645 acct-port 1646 key cisco3
radius-server host 172.19.0.1 auth-port 1645 acct-port 1646 key cisco4
radius-server host 172.20.0.1 auth-port 1645 acct-port 1646 key cisco5

! The following commands define the sg1 RADIUS server group and associate servers
! with it.
aaa group server radius sg1
  server 172.16.0.1
  server 172.17.0.1
! The following commands define the sg2 RADIUS server group and associate a server
! with it.
aaa group server radius sg2
  server 172.18.0.1
! The following commands define the sg3 RADIUS server group and associate a server
! with it.
aaa group server radius sg3
  server 172.19.0.1
! The following commands define the default-group RADIUS server group and associate
! a server with it.
aaa group server radius default-group
  server 172.20.0.1
!
! The next set of commands configures default-group RADIUS server group parameters.
aaa authentication ppp default group default-group
aaa accounting network default start-stop group default-group
!
```

```
! The next set of commands enables DNIS mapping and maps DNIS numbers to the defined
! RADIUS server groups. In this configuration, all PPP connection requests using
! DNIS 7777 are sent to the sg1 server group. The accounting records for these
! connections (specifically, start-stop records) are handled by the sg2 server group.
! Calls with a DNIS of 8888 use server group sg3 for authentication and server group
! default-group for accounting. Calls with a DNIS of 9999 use server group
! default-group for authentication and server group sg3 for accounting records
! (stop records only). All other calls with DNIS other than the ones defined use the
! server group default-group for both authentication and stop-start accounting records.
aaa dnis map enable
aaa dnis map 7777 authentication ppp group sg1
aaa dnis map 7777 accounting network start-stop group sg2
aaa dnis map 8888 authentication ppp group sg3
aaa dnis map 9999 accounting network stop-only group sg3
```

AAA Preauthentication Examples

The following example shows a simple configuration that specifies that the DNIS number be used for preauthentication:

```
aaa preauth
group radius
dnis required
```

The following example shows a configuration that specifies that both the DNIS number and the CLID number be used for preauthentication. DNIS preauthentication will be performed first, followed by CLID preauthentication.

```
aaa preauth
  group radius
  dnis required
  clid required
```

The following example specifies that preauthentication be performed on all DNIS numbers except the two DNIS numbers specified in the DNIS group called “hawaii”:

```
aaa preauth
  group radius
  dnis required
  dnis bypass hawaii
```

```
dialer dnis group hawaii
number 12345
number 12346
```

The following example shows a sample AAA configuration with DNIS preauthentication:

```
aaa new-model
aaa authentication login CONSOLE none
aaa authentication login RADIUS_LIST group radius
aaa authentication login TAC_PLUS group tacacs+ enable
aaa authentication login V.120 none
aaa authentication enable default enable group tacacs+
aaa authentication ppp RADIUS_LIST if-needed group radius
aaa authorization exec RADIUS_LIST group radius if-authenticated
aaa authorization exec V.120 none
aaa authorization network default group radius if-authenticated
aaa authorization network RADIUS_LIST if-authenticated group radius
aaa authorization network V.120 group radius if-authenticated
aaa accounting suppress null-username
aaa accounting exec default start-stop group radius
aaa accounting commands 0 default start-stop group radius
```

```

aaa accounting network default start-stop group radius
aaa accounting connection default start-stop group radius
aaa accounting system default start-stop group radius
aaa preauth
  dnis password Cisco-DNIS
aaa nas port extended
!
radius-server configure-nas
radius-server host 10.0.0.0 auth-port 1645 acct-port 1646 non-standard
radius-server host 10.255.255.255 auth-port 1645 acct-port 1646 non-standard
radius-server retransmit 2
radius-server deadtime 1
radius-server attribute nas-port format c
radius-server unique-ident 18
radius-server key MyKey

```

**Note**

To configure preauthentication, you must also set up preauthentication profiles on the RADIUS server.

RADIUS User Profile with RADIUS Tunneling Attributes Example

The following example shows a RADIUS user profile (Merit Daemon format) that includes RADIUS tunneling attributes. This entry supports two tunnels, one for L2F and the other for L2TP. The tag entries with :1 support L2F tunnels, and the tag entries with :2 support L2TP tunnels.

```

cisco.com Password = "cisco", Service-Type = Outbound
  Service-Type = Outbound,
  Tunnel-Type = :1:L2F,
  Tunnel-Medium-Type = :1:IP,
  Tunnel-Client-Endpoint = :1:"10.0.0.2",
  Tunnel-Server-Endpoint = :1:"10.0.0.3",
  Tunnel-Client-Auth-Id = :1:"l2f-cli-auth-id",
  Tunnel-Server-Auth-Id = :1:"l2f-svr-auth-id",
  Tunnel-Assignment-Id = :1:"l2f-assignment-id",
  Cisco-Avpair = "vpdn:nas-password=l2f-cli-pass",
  Cisco-Avpair = "vpdn:gw-password=l2f-svr-pass",
  Tunnel-Preference = :1:1,
  Tunnel-Type = :2:L2TP,
  Tunnel-Medium-Type = :2:IP,
  Tunnel-Client-Endpoint = :2:"10.0.0.2",
  Tunnel-Server-Endpoint = :2:"10.0.0.3",
  Tunnel-Client-Auth-Id = :2:"l2tp-cli-auth-id",
  Tunnel-Server-Auth-Id = :2:"l2tp-svr-auth-id",
  Tunnel-Assignment-Id = :2:"l2tp-assignment-id",
  Cisco-Avpair = "vpdn:l2tp-tunnel-password=l2tp-tnl-pass",
  Tunnel-Preference = :2:2

```

Guard Timer Examples

The following example shows an ISDN guard timer that is set at 8000 milliseconds. A call will be rejected if the RADIUS server has not responded to a preauthentication request when the timer expires.

```

interface serial1/0/0:23
  isdn guard-timer 8000 on-expiry reject

aaa preauth
  group radius
  dnis required

```

The following example shows a CAS guard timer that is set at 20,000 milliseconds. A call will be accepted if the RADIUS server has not responded to a preauthentication request when the timer expires.

```

controller T1 0
  framing esf
  clock source line primary
  linecode b8zs
  ds0-group 0 timeslots 1-24 type e&m-fgb dtmf dnis
  cas-custom 0
  call guard-timer 20000 on-expiry accept

aaa preauth
group radius
dnis required

```

L2TP Access Concentrator Examples

The following example shows a basic L2TP configuration for the L2TP access concentrator (LAC) for the topology shown in Figure 12. The local name is not defined, so the host name used is the local name. Because the L2TP tunnel password is not defined, the username password is used. In this example, VPDN is configured locally on the LAC and does not take advantage of the new RADIUS tunnel attributes.

Figure 12 Topology for Configuration Examples

```

! Enable AAA globally.
aaa new-model
! Enable AAA authentication for PPP and list the default method to use for PPP
! authentication.
aaa authentication ppp default local
! Define the username as "DJ."
username DJ password 7 030C5E070A00781B
! Enable VPDN.
vpdn enable
! Define VPDN group number 1.
vpdn-group 1
! Allow the LAC to respond to dialin requests using L2TP from IP address 172.21.9.13
! domain "cisco.com."
request dialin
protocol l2tp
domain cisco.com
initiate-ip to 172.21.9.13
local name nas-1

```

The following example shows how to configure the LAC if RADIUS tunnel attributes are supported. In this example, there is no local VPDN configuration on the LAC; the LAC, instead, is configured to query the remote RADIUS security server.

```

! Enable global AAA securities services.
aaa new-model

```

```

! Enable AAA authentication for PPP and list RADIUS as the default method to use
! for PPP authentication.
aaa authentication ppp default group radius local
! Enable AAA (network) authorization and list RADIUS as the default method to use for
! authorization.
aaa authorization network default group radius
! Define the username as "DJ."
username DJ password 7 030C5E070A00781B
! Enable VPDN.
vpdn enable
! Configure the LAC to interface with the remote RADIUS security server.
radius host 171.69.1.1 auth-port 1645 acct-port 1646
radius-server key cisco

```

L2TP Network Server Examples

The following example shows a basic L2TP configuration with corresponding comments on the L2TP network server (LNS) for the topology shown in [Figure 12](#):

```

! Enable AAA globally.
aaa new-model
! Enable AAA authentication for PPP and list the default method to use for PPP
! authentication.
aaa authentication ppp default local
! Define the username as "partner."
username partner password 7 030C5E070A00781B
! Create virtual-template 1 and assign all values for virtual access interfaces.
interface Virtual-Template1
! Borrow the IP address from interface ethernet 1.
ip unnumbered Ethernet0
! Disable multicast fast switching.
no ip mroute-cache
! Use CHAP to authenticate PPP.
ppp authentication chap
! Enable VPDN.
vpdn enable
! Create vpdn-group number 1.
vpdn-group 1
! Accept all dialin l2tp tunnels from virtual-template 1 from remote peer DJ.
accept dialin l2tp virtual-template 1 remote DJ
protocol any
virtual-template 1
terminate-from hostname nas1
local name hgw1

```

The following example shows how to configure the LNS with a basic L2F and L2TP configuration using RADIUS tunneling attributes:

```

aaa new-model
aaa authentication login default none
aaa authentication login console none
aaa authentication ppp default local group radius
aaa authorization network default group radius if-authenticated
!
username l2f-cli-auth-id password 0 l2f-cli-pass
username l2f-svr-auth-id password 0 l2f-svr-pass
username l2tp-svr-auth-id password 0 l2tp-tnl-pass
!
vpdn enable
vpdn search-order domain
!
vpdn-group 1

```

```
accept-dialin
protocol l2f
virtual-template 1
terminate-from hostname l2f-cli-auth-id
local name l2f-svr-auth-id
!
vpdn-group 2
accept-dialin
protocol l2tp
virtual-template 2
terminate-from hostname l2tp-cli-auth-id
local name l2tp-svr-auth-id
!
interface Ethernet1/0
ip address 10.0.0.3 255.255.255.0
no ip route-cache
no ip mroute-cache
!
interface Virtual-Template1
ip unnumbered Ethernet1/0
ppp authentication pap
!
interface Virtual-Template2
ip unnumbered Ethernet1/0
ppp authentication pap
!
radius-server host 1.1.1.1 auth-port 1645 acct-port 1646
radius-server key <deleted>
!
```

Offload Server Accounting Enhancement

First Published: 12.2(4)T

Last Updated: December 31, 2007

The Offload Server Accounting Enhancement feature allows users to maintain authentication and accounting information between their network access servers (NASs) and the offload server.

History for the Offload Server Accounting Enhancement Feature

Release	Modification
12.2(4)T	This feature was introduced.
12.2(28)SB	This feature was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRC	This feature was integrated into Cisco IOS Release 12.2(33)SRC.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

For the latest feature information and caveats, see the release notes for your Cisco IOS software release.

Feature Overview

The Offload Server Accounting Enhancement feature allows users to configure their network access servers (NAS) to synchronize authentication and accounting information—NAS-IP-Address (attribute 4) and Class (attribute 25)—with the offload server.

An offload server interacts with a NAS via Virtual Private Network (VPN) to perform required Point-to-Point Protocol (PPP) negotiation for calls. The NAS performs call preauthentication, whereas the offload server performs user authentication. This feature allows the authentication and accounting data of the NAS to synchronize with the offload server as follows:

- During preauthentication, the NAS generates a unique session-id, adding the Acct-Session-Id (attribute 44) before the existing session-id (NAS-IP-Address), and retrieves a Class attribute. The new session-id is sent in preauthentication requests and resource accounting requests; the Class attribute is sent in resource accounting requests.

**Note**

Unique session-ids are needed when multiple NASs are being processed by one offload server.

- The NAS-IP-Address, the Acct-Session-Id, and the Class attribute are transmitted to the offload server via Layer 2 Forwarding (L2F) options.
- The offload server will include the new, unique session-id in user access requests and user session accounting requests. The Class attribute that was passed from the NAS will be included in the user access request, but a new Class attribute will be received in the user access reply; this new Class attribute should be included in user session accounting requests.

Benefits

The Offload Server Accounting Enhancement feature allows users to maintain authentication and accounting information between their NAS and offload server.

Although NASs can already synchronize information with an offload server, this feature extends the functionality to include a unique session-id, adding the Acct-Session-Id (attribute 44) before the existing session-id (NAS-IP-Address), and Class (attribute 25) information collected by the NASs.

Prerequisites

Before configuring the Offload Server Accounting Enhancement feature, you must perform the following tasks:

- Enable AAA. (For more information, refer to chapter “Configuring Authentication” of the *Cisco IOS Security Configuration Guide*)
- Enable VPN. (For more information, refer to the chapter “Configuring Virtual Private Networks” of the *Cisco IOS Dial Technologies Configuration Guide*)

Configuration Tasks

See the following sections for configuration tasks for the Offload Server Accounting Enhancement feature. Each task in the list is identified as either required or optional.

- [Configuring Unique Session IDs, page 3](#)(required)
- [Configuring Offload Server to Synchronize with NAS Clients, page 3](#)(required)
- [Verifying Offload Server Accounting, page 4](#)(optional)

Configuring Unique Session IDs

To maintain unique session IDs among NASs, use the following global configuration command. When multiple NASs are being processed by one offload server, this feature must be enabled by all NASs and by the offload server to ensure a common and unique session-id.

Command	Purpose
Router(config)# radius-server attribute 44 extend-with-addr	Adds the accounting IP address in front of the existing AAA session ID. Note The unique session-id is different from other NAS session-ids because it adds the Acct-Session-Id (attribute 44) before the existing session-id (NAS-IP-Address).

Configuring Offload Server to Synchronize with NAS Clients

To configure the offload server to synchronize accounting session information with the NAS clients, use the following global configuration command:

Command	Purpose
Router(config)# radius-server attribute 44 sync-with-client	Configures the offload server to synchronize accounting session information with the NAS clients.

Verifying Offload Server Accounting

To verify whether the NAS has synchronized authentication and accounting data with the offload server, use the following commands in privileged EXEC mode:

Command	Purpose
Router# more system:running-config	Displays the contents of the current running configuration file. (Note that the more system:running-config command has replaced the show running-config command.)
Router(config)# debug radius	Displays information associated with RADIUS. The output of this command shows whether attribute 44 is being sent in access requests. The output, however, does not show the entire value for attribute 44. To view the entire value for attribute 44, refer to your RADIUS server log.

Configuration Examples

This section provides the following configuration examples:

- [Unique Session ID Configuration Example, page 4](#)
- [Offload Server Synchronization with NAS Clients Example, page 4](#)

Unique Session ID Configuration Example

The following example shows how to configure unique session IDs among NASs:

```
aaa new-model
aaa authentication ppp default group radius
radius-server host 10.100.1.34
radius-server attribute 44 include-in-access-req

Glossary

AAA—authentication, authorization, and accounting. Suite of network security services that provide the primary framework through which access control can be set up on your Cisco router or access server.

Acct-Session-ID (attribute 44)—A unique accounting identifier that makes it easy to match start and stop records in a log file. Acct-Session ID numbers restart at 1 each time the router is power-cycled or the software is reloaded.

Class (attribute 25)—An accounting attribute. Arbitrary value that the network access server includes in all accounting packets for this user if the attribute is supplied by the RADIUS server.

L2F—Layer 2 Forwarding. A Layer 2 tunneling protocol that enables an ISP or other access service to create a virtual tunnel to link customer remote sites or remote users with corporate home networks. In particular, a network access server (NAS) at the ISP point of presence (POP) exchanges PPP messages with the remote users and communicates by L2F or L2TP requests and responses with the customer tunnel server to set up tunnels.

NAS—network access server. A Cisco platform (or collection of platforms, such as an AccessPath system) that interfaces between the packet world (for example, the Internet) and the circuit world (for example, the public switched telephone network).

NAS-IP Address (attribute 4)—Specifies the IP address of the network access server that is requesting authentication. The default value is 0.0.0.0/0.

PPP—Point-to-Point Protocol. Successor to SLIP that provides router-to-router and host-to-network connections over synchronous and asynchronous circuits. Whereas SLIP was designed to work with IP, PPP was designed to work with several network layer protocols, such as IP, IPX, and ARA. PPP also has built-in security mechanisms, such as CHAP and PAP. PPP relies on two protocols: LCP and NCP.

RADIUS—Remote Authentication Dial-In User Service. RADIUS is a distributed client/server system that secures networks against unauthorized access. In the Cisco implementation, RADIUS clients run on Cisco routers and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.

VPN—A system that permits dial-in networks to exist remotely to home networks, while giving the appearance of being directly connected. VPNs use L2TP and L2F to terminate the Layer 2 and higher parts of the network connection at the LNS instead of the LAC.

Per IP Subscriber DHCP Triggered RADIUS Accounting

First Published: February 19, 2007

Last Updated: February 19, 2007

The Per IP Subscriber DHCP Triggered RADIUS Accounting feature enables system administrators to track IP session activity on a per-subscriber basis and periodically extract subscriber accounting records. Transactions between the client and the RADIUS accounting server are authenticated via an Access Client module that maintains per-subscriber accounting statistics.

Per IP Subscriber RADIUS Accounting works with DHCP IP address assignment on Cisco 7600 series routers only, and it improves the authentication, authorization, and accounting (AAA) of broadband service delivery. Subscribers are attributed a unique AAA ID in addition to the unique ID created by DHCP in order to process secure START and STOP accounting messages and allow them to abstract accounting information in a client-server environment.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for Per IP Subscriber DHCP Triggered RADIUS Accounting” section on page 10.](#)

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/com>. An account on Cisco.com is not required.

- [Additional References, page 7](#)
- [Command Reference, page 9](#)
- [Feature Information for Per IP Subscriber DHCP Triggered RADIUS Accounting, page 10](#)

Prerequisites for Per IP Subscriber DHCP Triggered RADIUS Accounting

- You must configure accounting on a subset of RADIUS servers to which subscriber accounting statistics will be exported, as defined by the **aaa accounting** command.
- You must configure the number of IP address assignment leases offered to DHCP clients to only one per subscriber, as defined by the **ip dhcp limit lease per interface 1** command.

Restrictions for Per IP Subscriber DHCP Triggered RADIUS Accounting

- The Per IP Subscriber DHCP Triggered RADIUS Accounting feature is enabled only for subscribers operating with Access Type interfaces on a Cisco 7600 series Broadband Remote Access Server (B-RAS).
- This feature does not support the collection of IP statistics from each source IP address. The feature collects IP statistics for each subinterface rather than each subscriber, and it is triggered only if the command to allow one IP address assignment via DHCP is configured.

Information About Per IP Subscriber DHCP Triggered RADIUS Accounting

To configure this feature, you should understand the following concepts:

- [Per IP Subscriber DHCP Triggered RADIUS Accounting Network Topology, page 2](#)
- [Per IP Subscriber Triggered RADIUS Accounting Behavior, page 3](#)

Per IP Subscriber DHCP Triggered RADIUS Accounting Network Topology

Per IP Subscriber DHCP Triggered RADIUS Accounting is implemented in a distributed networking environment, based on the following client-server components:

- Access Interface—Used by subscribers to operate on a Cisco 7600 router.
- DHCP Server—Grants permission to the DHCP client to use a particular IP address for a specified lease time.
- AAA Server—Transmits secure START and STOP accounting messages.

After the periodic timer is configured on the unit under test (UUT), the AAA module on the UUT sends an interim periodic update to the RADIUS server.

- RADIUS Server—Receives and responds to accounting requests.

Figure 1 shows how the Access Client, referred to as the “aaa-access-client” module, is initialized to serve as a client of the RADIUS accounting server. The module is independent of existing DHCP RADIUS Accounting modules.

Figure 1 AAA Access Client Module Interaction

The Access Client comprises two sub-modules that enable improved IP session awareness, tracking, and reporting functionality:

- Access-Subscriber Management module (Access-Acct-Mgmt): Invoked by a successful DHCP IP assignment, this sub-module generates a unique AAA ID for each subscriber that combines with the DHCP unique ID to track an accounting session.
- Access-Subscriber Accounting Management (Access-Acct-Update): Invoked by the AAA server, this sub-module collects subscriber statistics and periodically reports on the accounting session.

Benefits of Per IP Subscriber DHCP Triggered RADIUS Accounting

IP Session Awareness and Security

RADIUS accounting provides information about subscribers’ network connections and usage in the form of accounting records.

The Access Client passes per-subscriber accounting statistics to the designated server, with a secure unique AAA ID. The periodic reporting of IP session activity gives system administrators the accounting information they need to make informed security, billing, and resource allocation decisions.

Per IP Subscriber Triggered RADIUS Accounting Behavior

When a client with an Access Type of interface is configured for Per IP Subscriber RADIUS Accounting, the statistics collection and reporting mechanism can be invoked by the DHCP module. A successful DHCP IP assignment or release triggers three types of accounting events via the Access Client module:

1. RADIUS accounting start: An Accounting Start packet, ACCT_START, is sent to the accounting server to flag the start of service delivery, the type of service being delivered, and the user it is being delivered to.

2. RADIUS accounting interim-update: An Accounting Interim Update packet, ACCT_UPDATE, is sent to the accounting server to flag an ongoing client association and IP session activity.
3. RADIUS accounting stop: An Accounting Stop packet, ACCT_STOP, is sent to the accounting server to flag the end of service delivery, the type of service that was delivered and optional statistics such as elapsed time, and input and output packets.

Accounting requests, for any packet type, are submitted to the RADIUS accounting server via the network, and are acknowledged in these forms:

- RADIUS Accounting Response (START)
- RADIUS Interim Accounting Response
- RADIUS Accounting Response (STOP)

Figure 2 shows the AAA Access Client process flow and how the client interacts with the required modules.

Figure 2 AAA Access Client Process Flow

230303

How to Configure Per IP Subscriber DHCP Triggered RADIUS Accounting

This section contains the following procedure:

- [Configuring Method Lists for Per IP Subscriber DHCP Triggered RADIUS Accounting, page 5.](#)

Configuring Method Lists for Per IP Subscriber DHCP Triggered RADIUS Accounting

Each subscriber is configured on a per-interface basis. To invoke the Access Client and trigger the statistics collection mechanism on a subinterface, you must specify RADIUS as the accounting method and define a backup system for accounting in case the initial method fails. A method list is a named list describing the accounting methods to be queried in sequence.

Perform this task to configure a named method list for Per IP Subscriber DHCP Triggered RADIUS Accounting.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number* [*name-tag*] *access*
4. **encapsulation dot1q** *vlan-id* [**native**]
5. **ip address** *ip-address mask* [**secondary**]
6. **accounting dhcp source-ip aaa list** *method-list-name*
7. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface type number [name-tag] access Example: Router(config)# interface gigabitethernet 1/0/1.2 access	Configures an interface type and enters access interface configuration mode.
Step 4	encapsulation dot1q vlan-id [native] Example: Router(config-subif)# encapsulation dot1q 102	Enables IEEE 802.1q encapsulation of traffic on a specified subinterface in a virtual LAN (VLAN).
Step 5	ip address ip-address mask [secondary] Example: Router(config-subif)# ip address 10.0.2.1 255.255.255.0	Sets a primary or secondary IP address for an interface.
Step 6	accounting dhcp source-ip aaa list method-list-name Example: Router(config-subif)# accounting dhcp source-ip aaa list default	Enables the Per IP Subscriber DHCP RADIUS Accounting feature for DHCP clients, and configures accounting method lists that define the way accounting will be performed and the sequence in which methods are performed. Use the <i>method-list-name</i> argument to apply the accounting method list to a subinterface.
Step 7	end Example: Router(config-subif)# end	Ends the current configuration session and returns to privileged EXEC mode.

Configuration Examples for Per IP Subscriber DHCP Triggered RADIUS Accounting

This section provides the following configuration example:

- [Subinterface RADIUS Accounting Configuration: Example, page 7](#)

Subinterface RADIUS Accounting Configuration: Example

In the following example, the **aaa accounting** command for periodic RADIUS accounting is issued in the context of an IP address assignment via DHCP. A named method list is not explicitly defined, and the default method list automatically applies to the subinterface. If no method list is defined, no accounting takes place.

```
configure terminal
aaa new-model
radius-server host 75.0.1.1 auth-port 1645 acct-port 1646 key lab
radius-server key lab
!
aaa accounting network default start-stop group radius
aaa accounting update periodic 1
end
!
configure terminal
ip dhcp pool pool1
    network 10.0.1.0 255.255.255.0
    lease 0 0 3
!
configure terminal
interface GigabitEthernet 1/0/1.2 access
encapsulation dot1q 102
ip address 10.0.2.1 255.255.255.0
accounting dhcp source-ip aaa list default
end
```

Throttling of AAA (RADIUS) Records

First Published: December 3, 2007

Last Updated: July 11, 2008

The Throttling of AAA (RADIUS) Records feature supports throttling of access (authentication and authorization) and accounting records that are sent to the RADIUS server. This feature allows a user to configure the appropriate throttling rate to avoid network congestion and instability; such as when there is insufficient bandwidth to accommodate a sudden burst of records generated from the Cisco IOS router to the RADIUS server.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for Throttling of AAA \(RADIUS\) Records” section on page 8](#).

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Americas Headquarters:

Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

Information About Throttling of AAA (RADIUS) Records

To configure the Throttling of AAA (RADIUS) Records feature, you should understand the following concepts:

- [Benefits of the Throttling of AAA \(RADIUS\) Records Feature, page 2](#)
- [Throttling Access Requests and Accounting Records, page 2](#)

Benefits of the Throttling of AAA (RADIUS) Records Feature

A Network Access Server (NAS), acting as RADIUS client, can generate a burst of accounting or access requests, causing severe network congestion or causing the RADIUS server to become overloaded with a burst of RADIUS traffic. This problem could be compounded when multiple NASs interact with the RADIUS servers.

The following conditions can trigger a sudden burst of RADIUS traffic:

- An interface flap, which in turn brings down all the subscriber sessions and generates accounting requests for each subscriber.
- The Cisco IOS High Availability (HA) program generating a START record for every session that survived a switchover, such as the scenario described the preceding bullet.

A large number of generated requests can make the network unstable if there is insufficient bandwidth or if the RADIUS server is slow to respond. Neither the User Datagram Protocol (UDP) transport layer nor the RADIUS protocol has a flow control mechanism. The throttling mechanism provided by this feature provides a solution for these issues.

Throttling Access Requests and Accounting Records

The Throttling of AAA (RADIUS) Records feature introduces a mechanism to control packets (flow control) at the NAS level, which improves the RADIUS server performance.

Because of their specific uses, access requests and accounting records must be treated separately. Access request packets are time sensitive, while accounting record packets are not.

- If a response to an access request is not returned to the client in a timely manner, the protocol or the user will time out, impacting the device transmission rates.
- Accounting records packets are not real-time critical.

When configuring threshold values on the same server, it is important to prioritize threshold values for the handling of the time-sensitive access request packets and to place a lesser threshold value on the accounting records packets.

In some cases, when an Internet Service Provider (ISP) is using separate RADIUS servers for access requests and accounting records, only accounting records throttling may be required.

Summary

- The Throttling of AAA (RADIUS) Records is disabled, by default.
- Throttling functionality can be configured globally or at server group level.

How to Configure Throttling of AAA (RADIUS) Records

This section describes how to configure throttling of access (authentication and authorization) and accounting records that are sent to the RADIUS server for both, global and server groups.

Server-group configurations are used to enable or disable throttling for a particular server group and to specify the threshold value for that server group.

**Note**

Server-group configurations override any configured global configurations.

This section includes the following tasks.

- [Throttling Accounting and Access Request Packets Globally, page 3](#)
- [Throttling Accounting and Access Request Packets Per Server Group, page 4](#)

Throttling Accounting and Access Request Packets Globally

To globally configure the throttling of accounting and access request packets, perform the following task.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **radius-server throttle** {[**accounting threshold**] [**access threshold**] [**access-timeout number-of-timeouts**]}
4. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	radius-server throttle {[accounting threshold] [access threshold [access-timeout number-of-timeouts]]} Example: Router(config)# radius-server throttle accounting 100 access 200 access-timeout 2	Configures global throttling for accounting and access request packets. For this example: - The accounting threshold value (the range is 0-65536) is set to 100, and the access threshold value is set to 200. Note The default threshold value is 0 (throttling disabled). - The number of timeouts per transaction value (the range is 1-10) is set to 2.
Step 4	exit Example: Router(config)# exit	Exits global configuration mode.

Throttling Accounting and Access Request Packets Per Server Group

The following server-group configuration can be used to enable or disable throttling for a specified server group and to specify the threshold value for that server group.

To configure throttling of server-group accounting and access request packets, perform the following task.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa group server radius server-group-name**
4. **throttle** {[**accounting threshold**] [**access threshold** [**access-timeout number-of-timeouts**]]}
5. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	aaa group server radius <i>server-group-name</i> Example: Router(config)# aaa group server radius myservergroup	Enters server-group configuration mode.
Step 4	throttle {[accounting threshold] [access threshold] [access-timeout number-of-timeouts] } Example: Router(config-sg-radius)# throttle accounting 100 access 200 access-timeout 2	Configures the specified server-group throttling values for accounting and access request packets. For this example: - The accounting threshold value (the range is 0-65536) is set to 100, and the access threshold value is set to 200. Note The default threshold value is 0 (throttling disabled). - The number of time-outs per transaction value (the range is 1-10) is set to 2.
Step 5	exit Example: Router(config-sg-radius)# exit	Exits server-group configuration mode.

Configuration Examples for Throttling of AAA (RADIUS) Records

This section provides the following configuration examples:

- [Throttling Accounting and Access Request Packets Globally: Example, page 5](#)
- [Throttling Accounting and Access Request Packets Per Server Group: Example, page 6](#)

Throttling Accounting and Access Request Packets Globally: Example

The following example shows how to limit the number of accounting requests sent to a server to 100:

```
enable
configure terminal
radius-server throttle accounting 100
```

The following example shows how to limit the number of access requests packets sent to a server to 200 and sets the number of time-outs allowed per transactions to 2:

```
enable
configure terminal
radius-server throttle access 200
radius-server throttle access 200 access-timeout 2
```

The following example shows how to throttle both accounting and access request packets:

```
enable
configure terminal
radius-server throttle accounting 100 access 200
```

Throttling Accounting and Access Request Packets Per Server Group: Example

The following example shows how to limit the number of accounting requests sent to server-group-A to 100:

```
enable
configure terminal
aaa group server radius server-group-A
throttle accounting 100
```

The following example shows how to limit the number of access requests packets sent to server-group-A to 200 and sets the number of time-outs allowed per transactions to 2:

```
enable
configure terminal
aaa group server radius server-group-A
throttle access 200 access-timeout 2
```

The following example shows how to throttle both accounting and access request packets for server-group-A:

```
enable
configure terminal
aaa group server radius server-group-A
throttle accounting 100 access 200
```

Additional References

The following sections provide references related to the Throttling of AAA (RADIUS) Records feature.

Define Interface Policy-Map AV Pairs AAA

First Published: November 11, 2004

Last Published: July 11, 2008

The Define Interface Policy-Map AV Pairs AAA feature introduces two Cisco RADIUS vendor-specific attributes (VSAs) that allow a new policy map to be applied or an existing policy map to be modified, without affecting its session, during a Point-to-Point Protocol over ATM (PPPoA) or Point-to-Point Protocol over Ethernet over ATM (PPPoEoA) session establishment. The process occurs on the ATM virtual circuit (VC) level.

The Define Interface Policy-Map AV Pairs AAA has the following benefits:

- The ability to apply QoS policies transparently as required without the disruption of session reauthentication provides a high degree of flexibility, smaller configuration files, and more efficient usage of queuing resources. This ability eliminated the need to pre-provision subscribers.
- The ability to modify the applied policy map as needed without session disruption (session dropped and reauthenticated) is an advantage to service providers.
- Nondisruptive support for special event triggers is essential to support new dynamic bandwidth services such as pre-paid and turbo button services.

The QoS policy map is used to define the subscriber user experience for broadband service and can facilitate delivery of higher value services such as VoIP and video.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for Define Interface Policy-Map AV Pairs AAA” section on page 18](#).

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Define Interface Policy-Map AV Pairs AAA

- Authentication, Authorization, and Accounting (AAA) must be enabled and already set up to use RADIUS.
- Configuring a service policy on the ATM subinterface requires enabling Dynamic Bandwidth Selection (DBS) on the VC.

Restrictions for Define Interface Policy-Map AV Pairs AAA

For the Cisco 7000 series routers:

- Only the PA-A3-OC3/T3/E3 and PA-A6-OC3/T3/E3 port adapters are supported for this feature.

For the Cisco 10000 series routers:

- You cannot configure a service policy on a VC and on a session at the same time.
- All ATM line cards, including the 4-Port OC-3/STM-1 ATM, 8-Port E3/DS3 ATM, and 1-Port OC-12 ATM line cards, are supported for this feature.

Information About Define Interface Policy-Map AV Pairs AAA

This section lists the concepts that the user should understand in order to perform the tasks in the [How to Configure Define Interface Policy-Map AV Pairs AAA](#). The following concept is described in this section:

- [Dynamically Applying and Modifying a Policy Map](#)

Dynamically Applying and Modifying a Policy Map

The Define Interface Policy-Map AV Pairs AAA feature introduces two Cisco VSAs that allow you to dynamically apply a policy map and modify a policy map applied to a session, without session reauthentication, at the ATM VC level using RADIUS. The purpose of the Cisco VSA (attribute 26) is to

communicate vendor-specific information between the network access server (NAS) and the RADIUS server. The Cisco VSA encapsulates vendor-specific attributes that allow vendors such as Cisco to support their own extended attributes.

The Define Interface Policy-Map AV Pairs AAA feature allows the two new Cisco VSAs to be installed on an ATM VC after a PPPoA or PPPoEoA session establishment. Using RADIUS, this feature allows a policy map to be applied (“pulled”) and then modified by specific events (“pushed” by the policy server) while that session remains active.

Previously, a policy map could only be configured on a VC or ATM point-to-point subinterface by using the modular QoS CLI (MQC) or manually with the virtual template. Also previously, a service policy on a VC could be modified in the session but that session was dropped and reauthenticated. Currently for a PPPoA or PPPoEoA session, the pull part of the feature uses RADIUS to dynamically apply policy maps on an ATM VC and eliminates the need to statically configure a policy map on each VC. After a policy map is applied directly on the interface, certain events can signal the policy server to push a policy map onto a specific VC without the need for session reauthentication.

Note

Configuring a service policy on the ATM subinterface still requires MQC configuration.

Two new Cisco AV pairs for service policy are set up in the user file on the RADIUS server. When the router requests the policy map name, the policy map name in the user file is pulled to the VC on the router when the PPPoA or PPPoEoA session is established. The Cisco AV pairs identify a “service policy-output” and “service policy-input” to identify QoS policies configured on the router from a RADIUS server. The Cisco AV pairs apply the appropriate policy map directly on the interface. Service policies are only applied at this time when the subscriber first authenticates the VC.

The “push” functionality of the feature allows you to modify an existing QoS profile (a policy map) applied to a session while that session remains active, thus allowing QoS policies to be applied as required without session reauthentication disruption. Specific events, including time-of-day, byte count, and user request, can signal the policy server to push a policy map onto a specific VC.

The policy server has the ability to send a Change of Authorization (CoA), which is the ability to change authorization of active sessions on the fly. The push functionality requires that CoA is enabled on the AAA server. One of the session attributes CoA pushes is the policy map, in an input and output direction.

[Figure 1](#) shows that a CoA request is sent from the policy server to a broadband rate access server (BRAS), which causes a policy map change on PPPoA sessions set up between the BRAS and the routing gateway (RG).

Figure 1 *Change of Authorization—Policy Map Change on PPPoA Sessions*

For more information on Configuring CoA support on the server, see the “Enabling ISA to Interact with External Policy Servers” chapter in the *Cisco ISA RADIUS COA Interface Guide* at the following URL: http://www.cisco.com/univercd/cc/td/doc/product/software/ios122s/122snwft/release/122sba27/isa/isa_cg/is_aaa.htm

For clarification, a policy map defines QoS actions and rules and associates these to a class map. In a policy map, you can define QoS actions for such things as policing and class-based weighted fair queuing (CBWFQ). After a policy map is configured on the router with the **policy-map** command, using the **service-policy** command attaches the configured policy map to a VC interface and specifies the direction (inbound or outbound) that the policy should be applied.

When a service policy is configured on the VC (or ATM point-to-point subinterface), the service policy is applied to all sessions that use that VC.

**Note**

For the Cisco 7200 series routers, you can configure a service policy on a VC and on a session at the same time. On the Cisco 10000 series routers, you must either configure a service policy on a VC or on a session, but not both at the same time.

**Note**

The Cisco 7200 series routers and Cisco 7301 router only support the PA-A3-OC3/T3/E3 and PA-A6-OC3/T3/E3 port adapters for this feature. The Cisco 10000 series routers support all ATM line cards, including the 4-Port OC-3/STM-1 ATM, 8-Port E3/DS3 ATM, and 1-Port OC-12 ATM line cards, for this feature.

New Cisco VSAs

To support the Define Interface Policy-Map AV Pairs AAA feature, the following two new Cisco AV pairs for policy map are defined at the ATM VC level:

- Cisco VSA attribute is `vc-qos-policy-in`
- Cisco VSA attribute is `vc-qos-policy-out`

They are formatted as:

- `cisco-avpair = "atm:vc-qos-policy-in=<in policy name>"`
- `cisco-avpair = "atm:vc-qos-policy-out=<out policy name>"`

To further support the Define Interface Policy-Map AV Pairs AAA feature, two existing Cisco Generic RADIUS VSAs will replace and deprecate two others that do not correctly follow the Cisco VSA naming guidelines.

The two replacement VSAs are:

- `cisco-avpair = "ip:sub-qos-policy-in=<in policy name>"`
- `cisco-avpair = "ip:sub-qos-policy-out=<out policy name>"`

The replacement VSAs replace the following existing VSAs:

- `cisco-avpair = "ip:sub-policy-In=<in policy name>"`
- `cisco-avpair = "ip:sub-policy-Out=<out policy name>"`

We recommend using the new VSAs. However, the replaced attributes are currently still supported.

Policy Map Troubleshooting Scenarios

- If a policy map is already configured on the ATM VC, the policy map pulled from the RADIUS server has higher precedence. This means that a **show policy-map** command shows the policy map pulled from the RADIUS server.
- After a policy map is successfully pulled on the VC, any configuration or unconfiguration after that using the **[no] service-policy input/output name** command does not affect the policy map used by the VC. Issuing a **show policy-map** command displays the pulled policy map. Issuing a **show run** command displays the current user configuration on the router.
- To remove the dynamic policy that is pulled from the RADIUS server, use the **no dbs enable** command or clear the PPPoA or PPPoEoA session associated with the VC.
- You should push both the input and output policy map together on the VC. If you push only one policy in one direction (for example, the input direction), then the output direction by default is a null policy push. The result is that on the VC, the input policy map is the policy pushed by the CoA. The output policy map is whatever policy was configured locally on the VC. If no output policy map was configured on the VC, there is no output policy map.

How to Configure Define Interface Policy-Map AV Pairs AAA

This section contains the following tasks:

- [Configuring AV Pairs, Dynamic Authorization, and the Policy Map, page 5](#)
- [Verifying Define Interface Policy-Map AV Pairs AAA, page 8](#)

Configuring AV Pairs, Dynamic Authorization, and the Policy Map

To configure the Define Interface Policy-Map AV Pairs AAA feature, follow the steps below on both the router and RADIUS server.

Prerequisites

- AAA must be enabled and already set up to use RADIUS.
- A PPPoEoA or PPPoA session is established.
- The CoA functionality is enabled—required for the push functionality.
- The **dbs enable** CLI is configured on the VC.
- The policy map is configured on the router.

SUMMARY STEPS

On the RADIUS server, configure the new Cisco AV pair attributes in the user file:

1. **atm:vc-qos-policy-in**=<in policy name>
atm:vc-qos-policy-out=<out policy name>

On the local AAA server, configure dynamic authorization that supports CoA.

1. **aaa server radius dynamic-author**
client {ip_addr | name} [**vrf** {vrfname}] [**server-key** {string}]

- On the router:
- 1. **enable**
 - 2. **configure terminal**
 - 3. **interface atm** *[module/slot/port.subinterface]* **point-to-point**
 - 4. **pvc** *vpi/vci*
 - 5. **dbas enable**
 - 6. **exit**
 - 7. **policy-map** *policy-map-name*
 - 8. **end**

DETAILED STEPS—RADIUS Server

	Command or Action	Purpose
Step 1	<pre>atm:vc-qos-policy-in=<in policy name> atm:vc-qos-policy-out=<out policy name></pre> Example: On the RADIUS server, configure in the user file: <pre>userid Password ="cisco" Service-Type = Framed, Framed-Protocol = PPP, cisco-avpair = "atm:vc-qos-policy-out=dyn_out", cisco-avpair = "atm:vc-qos-policy-in=test_vc"</pre>	Enters the two new Cisco AV pairs for service policy on the RADIUS server in the user file. When the router requests the policy name, this information in the user file is “pulled.” A RADIUS user file contains an entry for each user that the RADIUS server will authenticate. Each entry, which is also referred to as a <i>user profile</i>, establishes an attribute the user can access. When looking at a user file, the data to the left of the equal sign (=) is an attribute defined in the dictionary file, and the data to the right of the equal sign is the configuration data. In this example, you have configured a service policy that attaches a policy map to the ATM VC interface and specifies the direction (inbound for data packets traveling into the interface or outbound for data packets leaving the interface). The policy map applied in the outbound direction is <i>dyn_out</i> and the inbound policy map is <i>test_vc</i>.

DETAILED STEPS—AAA Server

	Command or Action	Purpose
Step 1	<pre>aaa server radius dynamic-author client {ip_addr name} [vrf {vrfname}] [server-key {string}] server-key [0 7] {string} port {port-num} auth-type {any all session-key} ignore session-key ignore server-key</pre> Example: On the AAA server, the following is an example configuration: <pre>aaa server radius dynamic-author client 192.168.0.5 vrf coa server-key cisco1 client 192.168.1.5 vrf coa server-key cisco2</pre>	Sets up the local AAA server for dynamic authorization service, which must be enabled to support the CoA functionality that can push the policy map in an input and output direction. To enable CoA to work, you must configure the aaa server radius dynamic-author command, and client and server-key keywords. You can configure the server-key by using the client [server-key {string}] keywords to configure at the “client” level, or use the server-key {string} keyword to configure at the “global” level. Using the server-key {string} keyword in submode is global because it allows all the clients already configured using client [server-key {string}] to use the server-key as specified in the server-key {string} keyword. However, note that configuring at the client level overrides the global level. For security purposes, we recommend configuring each client and using different server-keys for each client. The example configuration enables change of authorization with the dynamic-author command that also configures two client routers with different server-keys (cisco1 and cisco2). The port, auth-type, ignore session-key, and ignore server-key keywords are optional.

DETAILED STEPS—Router

	Command or Action	Purpose
Step 1	<pre>enable</pre> Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	<pre>configure terminal</pre> Example: Router# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	interface atm [<i>module/slot/port.subinterface</i>] point-to-point Example: Router(config)# interface ATM 4/0/1 point-to-point	Specifies the interface, for example ATM4/0, and the encapsulation type on an ATM PVC. Enters subinterface mode.
Step 4	pvc vpi/vci Example: Router(config-if)# pvc 1/101	Creates or assigns a name to an ATM permanent virtual circuit (PVC) in subinterface configuration mode. The pvc command creates a PVC and attaches it to the virtual path identifier (VPI) and virtual channel identifier (VCI) specified. Enters ATM virtual circuit configuration mode. The example specifies VPI 1 and VCI 101 for this PVC.
Step 5	dbns enable Example: Router(config-if-atm-vc)# dbns enable	Enables Dynamic Bandwidth Selection (DBS) in ATM VC configuration mode. Enabling this command allows the ATM shaping parameters to be retrieved from the RADIUS user profile.  Note The no dbns enable command re-creates the VC and removes the dynamic policy that is pulled from the RADIUS server. Consequently, any configured modular QoS CLI (MQC) policy map on the PVC will be installed on the VC. Do not issue the no dbns enable command when the VC is active.
Step 6	exit Example: Router(config-if-atm-vc)# exit	Exits ATM VC configuration mode and returns to subinterface configuration mode. Repeat this step one more time to exit subinterface configuration mode and return to global configuration mode.
Step 7	policy-map policy-map-name Example: Router(config)# policy-map voice	Creates a policy map on the router. In the example, a policy map named voice is created.
Step 8	end Example: Router(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

Verifying Define Interface Policy-Map AV Pairs AAA

Perform this optional task to verify the configuration of the Define Interface Policy-Map AV Pairs AAA feature.

SUMMARY STEPS

1. **show policy-map interface**
2. **show running-config (on router)**
3. **show running-config (on client)**

DETAILED STEPS

Step 1 **show policy-map interface**

The **show policy-map interface** command shows the policy map voice attached to the ATM VC:

```
Router# show policy-map interface atm 4/0
```

```
ATM4/0: VC 1/101 -
```

```
Service-policy input: voice
```

```
Class-map: class-default (match-any)
```

```
  0 packets, 0 bytes
```

```
  5 minute offered rate 0 bps, drop rate 0 bps
```

```
Match: any
```

Step 2 **show running-config**

The following example displays the running configuration on the router showing the AAA setup; policy map configuration; ATM VC, PPPoA, and DBS-enabled CLI configuration; Virtual-Template configuration; and RADIUS server configuration:

```
Router# show running-config
```

```
.  
. .  
.
```

```
aaa new-model
```

```
!
```

```
aaa user profile TEST
```

```
!
```

```
aaa authentication ppp default group radius
```

```
aaa authorization network default group radius
```

```
!
```

```
aaa session-id common
```

```
ip subnet-zero
```

```
.  
. .  
.
```

```
policy-map voice
```

```
class Class-Default
```

```
fair-queue
```

```
.  
. .  
.
```

```
!
```

```
interface ATM4/0.1 point-to-point
```

```
  pvc 1/101
```

```
    dbs enable
```

```

    encapsulation aal5mux ppp Virtual-Template1
    !
    .
    .
    .
interface Virtual-Template1
    ip address negotiated
    peer default ip address pool P00L1
    ppp authentication chap
    !
    .
    .
    .
    !
radius-server host 172.19.197.225 auth-port 1890 acct-port 1891
radius-server timeout 15
radius-server key 7 060506324F41
radius-server vsa send accounting
radius-server vsa send authentication
    !
    .
    .
    .
    !
    !
end

```

Step 3 show running-config

The following example displays the PPPoA client configuration:

```

    .
    .
    .
    !
interface ATM4/0.1 point-to-point
    pvc 1/101
        encapsulation aal5mux ppp Virtual-Template1
    !
    !
interface Virtual-Template1
    ip address negotiated
    peer default ip address pool P00L1
    ppp chap hostname userid
    ppp chap password 7 030752180500
    !
    .
    .
    .

```

Configuration Examples for Define Interface Policy-Map AV Pairs AAA

This section contains the following examples:

- [Service-Policy Map Already Configured: Example, page 11](#)
- [Service-Policy Map Pulled: Example, page 12](#)
- [Service-Policy Map Pushed: Example, page 13](#)

Service-Policy Map Already Configured: Example

The following example shows the existing MQC used to attach policy maps voice and outname under PVC 4/103. Using the **show policy-map interface** command shows that MQC-configured policy maps voice and outname are installed on the VC:

```
!
interface ATM4/0.3 multipoint
 no atm enable-ilmi-trap
 pvc 4/103
  service-policy input voice
  service-policy output outname
!
Router# show policy-map interface atm 4/0.3
ATM4/0.3: VC 4/103 -

Service-policy input: voice

Class-map: class-default (match-any)
 0 packets, 0 bytes
 5 minute offered rate 0 bps, drop rate 0 bps
Match: any
 0 packets, 0 bytes
 5 minute rate 0 bps

Service-policy output: outname

Class-map: class-default (match-any)
 0 packets, 0 bytes
 5 minute offered rate 0 bps, drop rate 0 bps
Match: any
 0 packets, 0 bytes
 5 minute rate 0 bps
Router#
```

The following example shows MQC used to establish a PPPoEoA session, which causes the policy maps (test_vc and dyn_out) set up on the RADIUS server to be downloaded or “pulled” to the VC. The policy maps downloaded from the RADIUS server have higher precedence than the MQC service-policy maps (voice and outname) configured on the PVC. Using the **show policy-map interface** command shows that the pulled policy maps are installed on the VC:

```
!
interface ATM4/0.3 multipoint
 no atm enable-ilmi-trap
 pvc 4/103
  dba enable
  encapsulation aal5autoppp Virtual-Template1
  service-policy input voice
```

```

service-policy output outname
!
end

Router# show policy-map interface atm 4/0.3
ATM4/0.3: VC 4/103 -

Service-policy input: test_vc

Class-map: class-default (match-any)
  0 packets, 0 bytes
  5 minute offered rate 0 bps, drop rate 0 bps
Match: any
  0 packets, 0 bytes
  5 minute rate 0 bps

Service-policy output: dyn_out

Class-map: class-default (match-any)
  5 packets, 370 bytes
  5 minute offered rate 0 bps, drop rate 0 bps
Match: any
  5 packets, 370 bytes
  5 minute rate 0 bps
Router#

PPPoE Session Information
Uniq ID  PPPoE  RemMAC      Port          VT  VA      State
      SID  LocMAC
      2      2  0010.1436.bc70  ATM4/0.3      1  Vi3.1   PTA
                        0010.1436.b070  VC:  4/103      UP
Router#

```

Service-Policy Map Pulled: Example

The following example shows a policy named voice configured for input service policy on the RADIUS server. The router is already configured for PPPoA and AAA. The PPPoA session pulls the service policy name from the RADIUS server.

The **show policy-map interface** command displays the input service policy named voice attached to the ATM interface:

```

Router# show policy-map interface atm 4/0.1
ATM4/0: VC 1/101 -

Service-policy input: voice

Class-map: class-default (match-any)
  0 packets, 0 bytes
  5 minute offered rate 0 bps, drop rate 0 bps
Match: any

```

Using the **show run interface** command displays the currently running configuration, but not the pulled service policy:

```
Router# show run interface atm 4/0.1
```

```
Building configuration...
```

```
Current configuration : 107 bytes
!
interface ATM 4/0.1
  pvc 1/101
    dba enable
    encapsulation aal5mux ppp Virtual-Template 1
  !
!
end
```

Service-Policy Map Pushed: Example

This configuration example has five parts that show that PPPoA sessions are established between a broadband remote access server (BRAS) and a routing gateway (RG), the change of authorization (CoA push request) that passes between a policy server and the BRAS, and how the pulled policy maps are replaced by pushed policy maps after the CoA request.

The five parts are: BRAS PPPoA configuration, RG PPPoA configuration, session information on BRAS prior to a push, debug on BRAS after receiving the CoA request, and session information on BRAS after a CoA push request has taken place.

The following example shows the current PPPoA configuration on BRAS:

```
aaa new-model
!
aaa authentication ppp default group radius
aaa authorization network default group radius
!
aaa server radius dynamic-author
  client <address> server-key <key>
!
aaa session-id common
!
ip routing
!
policy-map DefaultIn
  class class-default
    set ip precedence 0
policy-map DefaultOut
  class class-default
    set ip precedence 0
!
policy-map PullMapIn
  class class-default
    set ip precedence 0
policy-map PullMapOut
  class class-default
    set ip precedence 0
!
policy-map 7up
  class class-default
    fair-queue
policy-map Sprite
  class class-default
    bandwidth 1000
```

```

!
policy-map PushMapIn
  class class-default
    set ip precedence 0
policy-map PushMapOut
  class class-default
    set ip precedence 0
!
!
vc-class atm xyz
  protocol ppp Virtual-Template1
  encapsulation aal5snap
!
interface Loopback0
  ip address 10.1.1.2 255.255.255.0
!
interface ATM4/0
  no ip address
  no atm ilmi-keepalive
  no atm enable-ilmi-trap
  no clns route-cache
  no shutdown
!
interface ATM4/0.1 point-to-point
  no atm enable-ilmi-trap
  pvc 0/101
    class-vc xyz
    vbr-nrt 400 300 50
    dba enable
    service-policy in DefaultIn
    service-policy out DefaultOut
!
!
interface Virtual-Template1
  ip unnumbered Loopback0
  ppp authentication chap
!
radius-server host <address> auth-port <port> acct-port <port>
radius-server key <key>
radius-server vsa send authentication

```

The following example shows the PPPoA configuration set up on the RG:

```

aaa new-model
!
aaa session-id common
!
ip routing
!
interface Loopback0
  ip address 10.1.1.1 255.255.255.0
!
interface ATM2/0/0
  no ip address
  no atm ilmi-keepalive
  no atm enable-ilmi-trap
  no clns route-cache
  no shutdown
!
interface ATM2/0/0.1 point-to-point
  pvc 0/101
    protocol ppp Virtual-Template1
!

```

```

!
interface Virtual-Template1
 ip unnumbered Loopback0
 no peer default ip address
 ppp chap hostname InOut
 ppp chap password 0 <password>

```

The following example uses the **show subscriber session all** command to display session information on BRAS prior to policy maps being pushed. PullMapIn and PullMapOut are the profiles pulled from the AAA server. The CoA request pushes the BRAS to change its input policy map (PullMapIn) and output policy map (PullMapOut) to PushMapIn and PushMapOut respectively.

```
Router# show subscriber session all
```

```

Current Subscriber Information:Total sessions 1
-----

2d20h:6523AF6C 0 00000009 vc-qos-policy-in(342) 7 PushMapIn
2d20h:6523AF7C 0 00000009 vc-qos-policy-out(343) 4 PushMapOut
2d20h:
2d20h: PPPATM:Received VALID vc policy PushMapIn
2d20h: PPPATM:Received VALID vc policy PushMapOut
2d20h:PPPATM:ATM4/0.1 0/101 [54], Event = SSS Msg Received = 5
2d20h:Service policy input PushMapIn policy output PushMapOut applied on 0/101
2d20h: PPPATM:Applied VALID vc policy PushMapIn and PushMapOut
2d20h:RADIUS(00000000):sending
2d20h:RADIUS(00000000):Send CoA Ack Response to 10.0.56.145:1700 id 41, len 20
2d20h:RADIUS: authenticator 04 D5 05 E2 FE A3 A6 E5 - B2 07 C0 A1 53 89 E0 FF

```

The following example uses the **show subscriber session all** command to display session information on the BRAS after the BRAS received the CoA push request from the policy server. The policy information shows that PushMapIn and PushMapOut are the current policy maps on the BRAS that were pushed by the CoA request:

```
Router# show subscriber session all
Current Subscriber Information:Total sessions 1
-----
Unique Session ID:54
Identifier:InOut
SIP subscriber access type(s):PPPoA/PPP
Current SIP options:Req Fwding/Req Fwded
Session Up-time:00:00:44, Last Changed:00:00:22
AAA unique ID:55
Interface:Virtual-Access1.1

Policy information:
  Context 6531F6AC:Handle C700008A

Feature Information for Define Interface Policy-Map AV Pairs AAA

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 1 Feature Information for Define Interface Policy-Map AV Pairs AAA

Feature Name	Releases	Feature Information
Define Interface Policy-Map AV Pairs AAA	12.3(7)XI2 12.2(28)SB 12.2(33)SRC 12.4(20)T Cisco IOS XE Release 2.1	The Define Interface Policy-Map AV Pairs AAA feature introduces two Cisco Remote Authentication Dial-In User Service (RADIUS) vendor-specific attributes (VSAs) that allow a new policy map to be applied or an existing policy map to be modified, without affecting its session, during a Point-to-Point Protocol over ATM (PPPoA) or Point-to-Point Protocol over Ethernet over ATM (PPPoEoA) session establishment. The process occurs on the ATM virtual circuit (VC) level. This feature was integrated into Cisco IOS Release 12.3(7)XI2 and introduced for the Cisco 10000 series routers, Cisco 7200 series routers, and Cisco 7301 router. The “pull” functionality was implemented. This feature was integrated into Cisco IOS Release 12.2(28)SB. Support for the “push” functionality was added on the Cisco 10000 series routers, Cisco 7200 series routers, and Cisco 7301 router. The name for this functionality is RADIUS Push for MOD CLI Policies, which was integrated into the Define Interface Policy-Map AV Pairs AAA feature module. This feature was integrated into Cisco IOS Release 12.2(33)SRC. This feature was integrated into Cisco IOS Release 12.4(20)T. In Cisco IOS XE Release 2.1, this feature was introduced on Cisco ASR 1000 Series Routers.

RADIUS: Separate Retransmit Counter for Accounting

First Published: February 3, 2003

Last Updated: January 10, 2008

The RADIUS: Separate Retransmit Counter for Accounting feature allows users to configure an exponential backoff retransmit. That is, after the normally configured retransmission retries have been used, the router will keep on trying with an interval that doubles on each retransmission failure until a configured maximum interval is reached. This functionality allows users to retransmit accounting requests for many hours without overloading the RADIUS server when it does come back up.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for RADIUS: Separate Retransmit Counter for Accounting”](#) section on page 9.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restrictions for RADIUS: Separate Retransmit Counter for Accounting

The following tasks will result in excessive memory consumption on the router:

- Configuring this feature on a router with a high call rate.
- Configuring the **aaa accounting send stop-record authentication failure** command: an accounting record and a RADIUS packet will be generated for each user that fails to authenticate while the RADIUS server is down.
- Configuring interim accounting: new accounting records are generated and stored on the router.

Information About RADIUS: Separate Retransmit Counter for Accounting

In many environments, a single RADIUS server is used for authentication and accounting. Whenever this server is down for approximately 24 hours, the accounting records of users already on the router are lost after authentication, authorization, and accounting (AAA) does all the retransmissions. Before the introduction of this feature, the retransmissions could be configured for a maximum of 100 retries and the timeout could be configured for 1,000 seconds. Although these configurations keep the accounting records on the router for 24 hours, a timeout of 1,000 seconds is unreasonable, causing problems when the RADIUS server cannot be reached due to network congestion.

The RADIUS: Separate Retransmit Counter for Accounting feature allows users to configure an exponential backoff retransmit. That is, after the normally configured retransmission retries have been used, the router will keep on trying with an interval that doubles on each retransmission failure until a configured maximum interval is reached. This functionality allows users to retransmit accounting requests for many hours without overloading the RADIUS server when it does come back up.

This feature can be configured globally (via the **radius-server backoff exponential** command), per server (via the **radius-server host** command), or per group (via the **backoff exponential** command).

Benefits

With this feature, users can extend the time in which the RADIUS client (the router) sends accounting requests to the RADIUS server in the event that the RADIUS server or the connection to the server is down and there is no accounting response confirmation. This functionality enables accounting records to remain on the router for up to 24 hours.

How to Configure RADIUS: Separate Retransmit Counter for Accounting

This section contains the following tasks:

- [Configuring a Retransmit Counter for Accounting Globally or per RADIUS Host](#) (required)
- [Configuring a Retransmit Counter for Accounting per RADIUS Server Group](#) (required)
- [Verifying Retransmit Configurations](#) (optional)

Configuring a Retransmit Counter for Accounting Globally or per RADIUS Host

To configure exponential backoffs of RADIUS retransmits over an extended period of time on a global basis and per RADIUS host, perform the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **radius-server backoff exponential** [**max-delay** *minutes*] [**backoff-retry** *retransmits*]
4. **radius-server host** {*hostname* | *ip-address*} [**test username** *user-name*] [**auth-port** *port-number*] [**ignore-auth-port**] [**acct-port** *port-number*] [**ignore-acct-port**] [**timeout** *seconds*] [**retransmit** *retries*] [**key** *string*] [**alias** {*hostname* | *ip-address*}] [**idle-time** *seconds*] [**backoff exponential** {**backoff-retry** *number-of-retransmits* | **key** *encryption-key* | **max-delay** *minutes*}]

DETAILED STEPS

	Command	Purpose
Step 1	enable Example: Router> enable	Enters privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	Router(config)# radius-server backoff exponential [max-delay <i>minutes</i>] [backoff-retry <i>retransmits</i>] Example: Router (config)# radius-server backoff exponential max-delay 60 backoff-retry 32	Configures the router for exponential backoff retransmit of accounting requests.
Step 4	Router(config)# radius-server host { <i>hostname</i> <i>ip-address</i> } [test username <i>user-name</i>] [auth-port <i>port-number</i>] [ignore-auth-port] [acct-port <i>port-number</i>] [ignore-acct-port] [timeout <i>seconds</i>] [retransmit <i>retries</i>] [key <i>string</i>] [alias { <i>hostname</i> <i>ip-address</i> }] [idle-time <i>seconds</i>] [backoff exponential { backoff-retry <i>number-of-retransmits</i> key <i>encryption-key</i> max-delay <i>minutes</i> }] Example: Router (config)# radius-server host 192.0.2.1 test username test1 auth-port 1645 acct-port 1646	Specifies a RADIUS server host and configures that RADIUS server host for exponential backoff retransmit of accounting requests.

Configuring a Retransmit Counter for Accounting per RADIUS Server Group

To configure exponential backoffs of RADIUS retransmits over an extended period of time per RADIUS server group, perform the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa group server radius** *group-name*
4. **backoff exponential** [**max-delay** *minutes*] [**backoff-retry** *retransmits*]

DETAILED STEPS

	Command	Purpose
Step 1	enable Example: Router> enable	Enters privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router (config)# configure terminal	Enters global configuration mode.
Step 3	Router(config)# aaa group server radius <i>group-name</i>	Groups different RADIUS server hosts into distinct lists and distinct methods and enters server-group RADIUS configuration mode.
Step 4	Router(config-sg-radius)# backoff exponential [max-delay <i>minutes</i>] [backoff-retry <i>retransmits</i>]	Configures the router for exponential backoff retransmit of accounting requests per RADIUS server group.

Verifying Retransmit Configurations

To verify feature functionality, use any of the following EXEC commands:

SUMMARY STEPS

1. **enable**
1. **debug radius**
2. **show accounting**
3. **show radius statistics**

DETAILED STEPS

	Command	Purpose
Step 1	enable Example: Router> enable	Enters privileged EXEC mode. Enter your password if prompted.
Step 2	debug radius Example: Router# debug radius	Displays information associated with RADIUS.
Step 3	show accounting Example: Router# show accounting	Displays all active sessions and prints all the accounting records for actively accounted functions.
Step 4	show radius statistics Example: Router# show radius statistics	Displays the RADIUS statistics for accounting packets.

Configuration Examples for RADIUS: Separate Retransmit Counter for Accounting

This section provides the following configuration examples:

- [Retransmit Counter for Accounting Comprehensive Configuration: Example](#)
- [Per-Server Configuration: Example](#)

Retransmit Counter for Accounting Comprehensive Configuration: Example

The following example shows how to configure your router for exponential backoff retransmit of accounting requests. In this example, an exponential backoff is configured globally (via the **radius-server backoff exponential** command) and for the RADIUS server host “172.107.164.206” (via the **radius-server host** command).

```
aaa new-model
aaa authentication login default group radius
aaa authentication ppp default group radius
aaa authorization exec default group radius
aaa authorization network default group radius
aaa accounting send stop-record authentication failure
aaa accounting update periodic 1
aaa accounting network default start-stop group radius
!
interface BRI1/0
 ip address 10.0.0.2 255.0.0.0
 encapsulation ppp
 no ip mroute-cache
```

```

dialer idle-timeout 0
dialer-group 1
isdn switch-type basic-5ess
!
radius-server host 172.107.164.206 auth-port 1645 acct-port 1646 backoff exponential
max-delay 60 backoff-retry 32
radius-server backoff exponential max-delay 60 backoff-retry 32
radius-server retransmit 3
radius-server key rad123
end

```

Per-Server Configuration: Example

The following example shows how to enable exponential backoff retransmits on a per-server basis. In this example, assume that the retransmit is configured for 3 retries and the timeout is configured for 5 seconds; that is, the RADIUS request will be transmitted 3 times with a delay of 5 seconds. Thereafter, the router will continue to retransmit RADIUS requests with a delayed interval that doubles each time until 32 retries have been achieved. The router will stop doubling the retransmit intervals after the interval surpasses the configured 60 minutes; it will transmit every 60 minutes.

```
radius-server host foo.xyz.com backoff exponential max-delay 60 backoff-retry 32
```

After enabling this command, the retransmits will be sent as follows (“t” equals seconds):

```

t = 0 req sent
t = 5 retrans 1
t = 10 retrans 2
t = 15 retrans 3
t = 25 retrans 4
t = 45 retrans 5
t = 85 retrans 6
t = 165 retrans 7
t = 325 retrans 8
t = 645 retrans 9
t = 1285 retrans 10
t = 2565 retrans 11
t = 5125 retrans 12
t = 8725 retrans 13 (The interval has stabilized to 60 minutes here).
t = 12325 retrans 14 till retransmit 35

```

After all the retransmits are sent, the RADIUS request follows the same path that it would when all the normal retransmits are done.

TACACS+

Configuring TACACS+

Feature History

Release	Modification
Cisco IOS	For information about feature support in Cisco IOS software, use Cisco Feature Navigator.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

This chapter discusses how to enable and configure TACACS+, which provides detailed accounting information and flexible administrative control over authentication and authorization processes. TACACS+ is facilitated through AAA and can be enabled only through AAA commands.

For a complete description of the TACACS+ commands used in this chapter, refer to the chapter “TACACS+ Commands” in the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature, or refer to the software release notes for a specific release. For more information, see the section “Identifying Supported Platforms” in the chapter “Using Cisco IOS Software.”

In This Chapter

This chapter includes the following sections:

- [About TACACS+](#)
- [TACACS+ Operation](#)
- [TACACS+ Configuration Task List](#)
- [TACACS+ AV Pairs](#)
- [TACACS+ Configuration Examples](#)

About TACACS+

TACACS+ is a security application that provides centralized validation of users attempting to gain access to a router or network access server. TACACS+ services are maintained in a database on a TACACS+ daemon running, typically, on a UNIX or Windows NT workstation. You must have access to and must configure a TACACS+ server before the configured TACACS+ features on your network access server are available.

TACACS+ provides for separate and modular authentication, authorization, and accounting facilities. TACACS+ allows for a single access control server (the TACACS+ daemon) to provide each service—authentication, authorization, and accounting—independently. Each service can be tied into its own database to take advantage of other services available on that server or on the network, depending on the capabilities of the daemon.

The goal of TACACS+ is to provide a methodology for managing multiple network access points from a single management service. The Cisco family of access servers and routers and the Cisco IOS user interface (for both routers and access servers) can be network access servers.

Network access points enable traditional “dumb” terminals, terminal emulators, workstations, personal computers (PCs), and routers in conjunction with suitable adapters (for example, modems or ISDN adapters) to communicate using protocols such as Point-to-Point Protocol (PPP), Serial Line Internet Protocol (SLIP), Compressed SLIP (CSLIP), or AppleTalk Remote Access (ARA) protocol. In other words, a network access server provides connections to a single user, to a network or subnetwork, and to interconnected networks. The entities connected to the network through a network access server are called *network access clients*; for example, a PC running PPP over a voice-grade circuit is a network access client. TACACS+, administered through the AAA security services, can provide the following services:

- **Authentication**—Provides complete control of authentication through login and password dialog, challenge and response, messaging support.

The authentication facility provides the ability to conduct an arbitrary dialog with the user (for example, after a login and password are provided, to challenge a user with a number of questions, like home address, mother’s maiden name, service type, and social security number). In addition, the TACACS+ authentication service supports sending messages to user screens. For example, a message could notify users that their passwords must be changed because of the company’s password aging policy.

- **Authorization**—Provides fine-grained control over user capabilities for the duration of the user’s session, including but not limited to setting autocommands, access control, session duration, or protocol support. You can also enforce restrictions on what commands a user may execute with the TACACS+ authorization feature.
- **Accounting**—Collects and sends information used for billing, auditing, and reporting to the TACACS+ daemon. Network managers can use the accounting facility to track user activity for a security audit or to provide information for user billing. Accounting records include user identities, start and stop times, executed commands (such as PPP), number of packets, and number of bytes.

The TACACS+ protocol provides authentication between the network access server and the TACACS+ daemon, and it ensures confidentiality because all protocol exchanges between a network access server and a TACACS+ daemon are encrypted.

You need a system running TACACS+ daemon software to use the TACACS+ functionality on your network access server.

Cisco makes the TACACS+ protocol specification available as a draft RFC for those customers interested in developing their own TACACS+ software.

TACACS+ Operation

When a user attempts a simple ASCII login by authenticating to a network access server using TACACS+, the following process typically occurs:

1. When the connection is established, the network access server will contact the TACACS+ daemon to obtain a username prompt, which is then displayed to the user. The user enters a username and the network access server then contacts the TACACS+ daemon to obtain a password prompt. The network access server displays the password prompt to the user, the user enters a password, and the password is then sent to the TACACS+ daemon.

**Note**

TACACS+ allows an arbitrary conversation to be held between the daemon and the user until the daemon receives enough information to authenticate the user. This is usually done by prompting for a username and password combination, but may include other items, such as mother's maiden name, all under the control of the TACACS+ daemon.

2. The network access server will eventually receive one of the following responses from the TACACS+ daemon:
 - a. **ACCEPT**—The user is authenticated and service may begin. If the network access server is configured to require authorization, authorization will begin at this time.
 - b. **REJECT**—The user has failed to authenticate. The user may be denied further access, or will be prompted to retry the login sequence depending on the TACACS+ daemon.
 - c. **ERROR**—An error occurred at some time during authentication. This can be either at the daemon or in the network connection between the daemon and the network access server. If an **ERROR** response is received, the network access server will typically try to use an alternative method for authenticating the user.
 - d. **CONTINUE**—The user is prompted for additional authentication information.
3. A PAP login is similar to an ASCII login, except that the username and password arrive at the network access server in a PAP protocol packet instead of being typed in by the user, so the user is not prompted. PPP CHAP logins are also similar in principle.

Following authentication, the user will also be required to undergo an additional authorization phase, if authorization has been enabled on the network access server. Users must first successfully complete TACACS+ authentication before proceeding to TACACS+ authorization.

4. If TACACS+ authorization is required, the TACACS+ daemon is again contacted and it returns an **ACCEPT** or **REJECT** authorization response. If an **ACCEPT** response is returned, the response will contain data in the form of attributes that are used to direct the **EXEC** or **NETWORK** session for that user, determining services that the user can access.

Services include the following:

- a. Telnet, rlogin, Point-to-Point Protocol (PPP), Serial Line Internet Protocol (SLIP), or EXEC services
- b. Connection parameters, including the host or client IP address, access list, and user timeouts

TACACS+ Configuration Task List

To configure your router to support TACACS+, you must perform the following tasks:

- Use the **aaa new-model** global configuration command to enable AAA. AAA must be configured if you plan to use TACACS+. For more information about using the **aaa new-model** command, refer to the chapter “AAA Overview”.
- Use the **tacacs-server host** command to specify the IP address of one or more TACACS+ daemons. Use the **tacacs-server key** command to specify an encryption key that will be used to encrypt all exchanges between the network access server and the TACACS+ daemon. This same key must also be configured on the TACACS+ daemon.
- Use the **aaa authentication** global configuration command to define method lists that use TACACS+ for authentication. For more information about using the **aaa authentication** command, refer to the chapter “Configuring Authentication”.
- Use **line** and **interface** commands to apply the defined method lists to various interfaces. For more information, refer to the chapter “Configuring Authentication”.
- If needed, use the **aaa authorization** global command to configure authorization for the network access server. Unlike authentication, which can be configured per line or per interface, authorization is configured globally for the entire network access server. For more information about using the **aaa authorization** command, refer to the “Configuring Authorization” chapter.
- If needed, use the **aaa accounting** command to enable accounting for TACACS+ connections. For more information about using the **aaa accounting** command, refer to the “Configuring Accounting” chapter.

To configure TACACS+, perform the tasks in the following sections:

- [Identifying the TACACS+ Server Host](#) (Required)
- [Setting the TACACS+ Authentication Key](#) (Optional)
- [Configuring AAA Server Groups](#) (Optional)
- [Configuring AAA Server Group Selection Based on DNIS](#) (Optional)
- [Specifying TACACS+ Authentication](#) (Required)
- [Specifying TACACS+ Authorization](#) (Optional)
- [Specifying TACACS+ Accounting](#) (Optional)

For TACACS+ configuration examples using the commands in this chapter, refer to the “[TACACS+ Configuration Examples](#)” section at the end of this chapter.

Identifying the TACACS+ Server Host

The **tacacs-server host** command enables you to specify the names of the IP host or hosts maintaining a TACACS+ server. Because the TACACS+ software searches for the hosts in the order specified, this feature can be useful for setting up a list of preferred daemons.

To specify a TACACS+ host, use the following command in global configuration mode:

Command	Purpose
Router(config)# tacacs-server host <i>hostname</i> [single-connection] [port <i>integer</i>] [timeout <i>integer</i>] [key <i>string</i>]	Specifies a TACACS+ host.

Using the **tacacs-server host** command, you can also configure the following options:

- Use the **single-connection** keyword to specify single-connection (only valid with CiscoSecure Release 1.0.1 or later). Rather than have the router open and close a TCP connection to the daemon each time it must communicate, the single-connection option maintains a single open connection between the router and the daemon. This is more efficient because it allows the daemon to handle a higher number of TACACS operations.

Note The daemon must support single-connection mode for this to be effective, otherwise the connection between the network access server and the daemon will lock up or you will receive spurious errors.

- Use the **port** *integer* argument to specify the TCP port number to be used when making connections to the TACACS+ daemon. The default port number is 49.
- Use the **timeout** *integer* argument to specify the period of time (in seconds) the router will wait for a response from the daemon before it times out and declares an error.

Note Specifying the timeout value with the **tacacs-server host** command overrides the default timeout value set with the **tacacs-server timeout** command for this server only.

- Use the **key** *string* argument to specify an encryption key for encrypting and decrypting all traffic between the network access server and the TACACS+ daemon.

Note Specifying the encryption key with the **tacacs-server host** command overrides the default key set by the global configuration **tacacs-server key** command for this server only.

Because some of the parameters of the **tacacs-server host** command override global settings made by the **tacacs-server timeout** and **tacacs-server key** commands, you can use this command to enhance security on your network by uniquely configuring individual TACACS+ connections.

Setting the TACACS+ Authentication Key

To set the global TACACS+ authentication key and encryption key, use the following command in global configuration mode:

Command	Purpose
Router(config)# tacacs-server key <i>key</i>	Sets the encryption key to match that used on the TACACS+ daemon.

Note You must configure the same key on the TACACS+ daemon for encryption to be successful.

Configuring AAA Server Groups

Configuring the router to use AAA server groups provides a way to group existing server hosts. This allows you to select a subset of the configured server hosts and use them for a particular service. A server group is used in conjunction with a global server-host list. The server group lists the IP addresses of the selected server hosts.

Server groups can include multiple host entries as long as each entry has a unique IP address. If two different host entries in the server group are configured for the same service—for example, accounting—the second host entry configured acts as fail-over backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server will try the second host entry for accounting services. (The TACACS+ host entries will be tried in the order in which they are configured.)

To define a server host with a server group name, enter the following commands starting in global configuration mode. The listed server must exist in global configuration mode:

	Command	Purpose
Step 1	Router(config)# tacacs-server host <i>name</i> [single-connection] [port <i>integer</i>] [timeout <i>integer</i>] [key <i>string</i>]	Specifies and defines the IP address of the server host before configuring the AAA server-group. Refer to the “Identifying the TACACS+ Server Host” section of this chapter for more information on the tacacs-server host command.
Step 2	Router(config-if)# aaa group server { radius tacacs+ } <i>group-name</i>	Defines the AAA server-group with a group name. All members of a group must be the same type; that is, RADIUS or TACACS+. This command puts the router in server group subconfiguration mode.
Step 3	Router(config-sg)# server <i>ip-address</i> [auth-port <i>port-number</i>] [acct-port <i>port-number</i>]	Associates a particular TACACS+ server with the defined server group. Use the auth-port <i>port-number</i> option to configure a specific UDP port solely for authentication. Use the acct-port <i>port-number</i> option to configure a specific UDP port solely for accounting. Repeat this step for each TACACS+ server in the AAA server group. Note Each server in the group must be defined previously using the tacacs-server host command.

Configuring AAA Server Group Selection Based on DNIS

Cisco IOS software allows you to authenticate users to a particular AAA server group based on the Dialed Number Identification Service (DNIS) number of the session. Any phone line (a regular home phone or a commercial T1/PRI line) can be associated with several phone numbers. The DNIS number identifies the number that was called to reach you.

For example, suppose you want to share the same phone number with several customers, but you want to know which customer is calling before you pick up the phone. You can customize how you answer the phone because DNIS allows you to know which customer is calling when you answer.

Cisco routers with either ISDN or internal modems can receive the DNIS number. This functionality allows users to assign different TACACS+ server groups for different customers (that is, different TACACS+ servers for different DNIS numbers). Additionally, using server groups you can specify the same server group for AAA services or a separate server group for each AAA service.

Cisco IOS software provides the flexibility to implement authentication and accounting services in several ways:

- Globally—AAA services are defined using global configuration access list commands and applied in general to all interfaces on a specific network access server.
- Per interface—AAA services are defined using interface configuration commands and applied specifically to the interface being configured on a specific network access server.
- DNIS mapping—You can use DNIS to specify an AAA server to supply AAA services.

Because AAA configuration methods can be configured simultaneously, Cisco has established an order of precedence to determine which server or groups of servers provide AAA services. The order of precedence is as follows:

- Per DNIS—If you configure the network access server to use DNIS to identify which server group provides AAA services, then this method takes precedence over any additional AAA selection method.
- Per interface—If you configure the network access server per interface to use access lists to determine how a server provides AAA services, this method takes precedence over any global configuration AAA access lists.
- Globally—If you configure the network access server by using global AAA access lists to determine how the security server provides AAA services, this method has the lowest precedence.

Note

Prior to configuring AAA Server Group Selection Based on DNIS, you must configure the remote security servers associated with each AAA server group. See the sections [“Identifying the TACACS+ Server Host”](#) and [“Configuring AAA Server Groups”](#) in this chapter.

To configure the router to select a particular AAA server group based on the DNIS of the server group, configure DNIS mapping. To map a server group with a group name with DNIS number, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa dnis map enable	Enables DNIS mapping.
Step 2	Router(config)# aaa dnis map dnis-number authentication ppp group server-group-name	Maps a DNIS number to a defined AAA server group; the servers in this server group are being used for authentication.
Step 3	Router(config)# aaa dnis map dnis-number accounting network [none start-stop stop-only] group server-group-name	Maps a DNIS number to a defined AAA server group; the servers in this server group are being used for accounting.

Specifying TACACS+ Authentication

After you have identified the TACACS+ daemon and defined an associated TACACS+ encryption key, you must define method lists for TACACS+ authentication. Because TACACS+ authentication is operated via AAA, you need to issue the **aaa authentication** command, specifying TACACS+ as the authentication method. For more information, refer to the chapter “Configuring Authentication.”

Specifying TACACS+ Authorization

AAA authorization enables you to set parameters that restrict a user’s access to the network. Authorization via TACACS+ may be applied to commands, network connections, and EXEC sessions. Because TACACS+ authorization is facilitated through AAA, you must issue the **aaa authorization** command, specifying TACACS+ as the authorization method. For more information, refer to the chapter “Configuring Authorization.”

Specifying TACACS+ Accounting

AAA accounting enables you to track the services users are accessing as well as the amount of network resources they are consuming. Because TACACS+ accounting is facilitated through AAA, you must issue the **aaa accounting** command, specifying TACACS+ as the accounting method. For more information, refer to the chapter “Configuring Accounting.”

TACACS+ AV Pairs

The network access server implements TACACS+ authorization and accounting functions by transmitting and receiving TACACS+ attribute-value (AV) pairs for each user session. For a list of supported TACACS+ AV pairs, refer to the appendix “TACACS+ Attribute-Value Pairs.”

TACACS+ Configuration Examples

The following sections provide TACACS+ configuration examples:

- [TACACS+ Authentication Examples](#)
- [TACACS+ Authorization Example](#)
- [TACACS+ Accounting Example](#)
- [TACACS+ Server Group Example](#)
- [AAA Server Group Selection Based on DNIS Example](#)
- [TACACS+ Daemon Configuration Example](#)

TACACS+ Authentication Examples

The following example shows how to configure TACACS+ as the security protocol for PPP authentication:

```
aaa new-model
```

```
aaa authentication ppp test group tacacs+ local
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
 ppp authentication chap pap test
```

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines a method list, “test,” to be used on serial interfaces running PPP. The keyword **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The **tacacs-server key** command defines the shared encryption key to be “goaway.”
- The **interface** command selects the line, and the **ppp authentication** command applies the test method list to this line.

The following example shows how to configure TACACS+ as the security protocol for PPP authentication, but instead of the “test” method list, the “default” method list is used.

```
aaa new-model
aaa authentication ppp default if-needed group tacacs+ local
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
 ppp authentication chap default
```

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines a method list, “default,” to be used on serial interfaces running PPP. The keyword **default** means that PPP authentication is applied by default to all interfaces. The **if-needed** keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP authentication is not necessary and can be skipped. If authentication is needed, the keyword **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The **tacacs-server key** command defines the shared encryption key to be “goaway.”
- The **interface** command selects the line, and the **ppp authentication** command applies the default method list to this line.

The following example shows how to create the same authentication algorithm for PAP, but it calls the method list “MIS-access” instead of “default”:

```
aaa new-model
aaa authentication pap MIS-access if-needed group tacacs+ local
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
 ppp authentication pap MIS-access
```

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.

- The **aaa authentication** command defines a method list, “MIS-access,” to be used on serial interfaces running PPP. The method list, “MIS-access,” means that PPP authentication is applied to all interfaces. The **if-needed** keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP authentication is not necessary and can be skipped. If authentication is needed, the keyword **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The **tacacs-server key** command defines the shared encryption key to be “goaway.”
- The **interface** command selects the line, and the **ppp authentication** command applies the default method list to this line.

The following example shows the configuration for a TACACS+ daemon with an IP address of 10.2.3.4 and an encryption key of “apple”:

```
aaa new-model
aaa authentication login default group tacacs+ local
tacacs-server host 10.2.3.4
tacacs-server key apple
```

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines the default method list. Incoming ASCII logins on all interfaces (by default) will use TACACS+ for authentication. If no TACACS+ server responds, then the network access server will use the information contained in the local username database for authentication.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.2.3.4. The **tacacs-server key** command defines the shared encryption key to be “apple.”

TACACS+ Authorization Example

The following example shows how to configure TACACS+ as the security protocol for PPP authentication using the default method list; it also shows how to configure network authorization via TACACS+:

```
aaa new-model
aaa authentication ppp default if-needed group tacacs+ local
aaa authorization network default group tacacs+
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
ppp authentication chap default
```

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines a method list, “default,” to be used on serial interfaces running PPP. The keyword **default** means that PPP authentication is applied by default to all interfaces. The **if-needed** keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP authentication is not necessary and can be skipped. If authentication is needed, the keyword **group tacacs+** means that authentication will be done

through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.

- The **aaa authorization** command configures network authorization via TACACS+. Unlike authentication lists, this authorization list always applies to all incoming network connections made to the network access server.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The **tacacs-server key** command defines the shared encryption key to be “goaway.”
- The **interface** command selects the line, and the **ppp authentication** command applies the default method list to this line.

TACACS+ Accounting Example

The following example shows how to configure TACACS+ as the security protocol for PPP authentication using the default method list; it also shows how to configure accounting via TACACS+:

```
aaa new-model
aaa authentication ppp default if-needed group tacacs+ local
aaa accounting network default stop-only group tacacs+
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
  ppp authentication chap default
```

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines a method list, “default,” to be used on serial interfaces running PPP. The keyword **default** means that PPP authentication is applied by default to all interfaces. The **if-needed** keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP authentication is not necessary and can be skipped. If authentication is needed, the keyword **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.
- The **aaa accounting** command configures network accounting via TACACS+. In this example, accounting records describing the session that just terminated will be sent to the TACACS+ daemon whenever a network connection terminates.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The **tacacs-server key** command defines the shared encryption key to be “goaway.”
- The **interface** command selects the line, and the **ppp authentication** command applies the default method list to this line.

TACACS+ Server Group Example

The following example shows how to create a server group with three different TACACS+ servers members:

```
aaa group server tacacs tacgroup1
  server 172.16.1.1
  server 172.16.1.21
```

```
server 172.16.1.31
```

AAA Server Group Selection Based on DNIS Example

The following example shows how to select TACACS+ server groups based on DNIS to provide specific AAA services:

```
! This command enables AAA.
aaa new-model
!
! The following set of commands configures the TACACS+ servers that will be associated
! with one of the defined server groups.
tacacs-server host 172.16.0.1
tacacs-server host 172.17.0.1
tacacs-server host 172.18.0.1
tacacs-server host 172.19.0.1
tacacs-server host 172.20.0.1
tacacs-server key abcdefg

! The following commands define the sg1 TACACS+ server group and associate servers
! with it.
aaa group server tacacs sg1
    server 172.16.0.1
    server 172.17.0.1
! The following commands define the sg2 TACACS+ server group and associate a server
! with it.
aaa group server tacacs sg2
    server 172.18.0.1
! The following commands define the sg3 TACACS+ server group and associate a server
! with it.
aaa group server tacacs sg3
    server 172.19.0.1
! The following commands define the default-group TACACS+ server group and associate
! a server with it.
aaa group server tacacs default-group
    server 172.20.0.1
!
! The next set of commands configures default-group tacacs server group parameters.
aaa authentication ppp default group default-group
aaa accounting network default start-stop group default-group
!
! The next set of commands enables DNIS mapping and maps DNIS numbers to the defined
! RADIUS server groups. In this configuration, all PPP connection requests using DNIS
! 7777 are sent to the sg1 server group. The accounting records for these connections
! (specifically, start-stop records) are handled by the sg2 server group. Calls with a
! DNIS of 8888 use server group sg3 for authentication and server group default-group
! for accounting. Calls with a DNIS of 9999 use server group default-group for
! authentication and server group sg3 for accounting records (stop records only). All
! other calls with DNIS other than the ones defined use the server group default-group
! for both authentication and stop-start accounting records.
aaa dnis map enable
aaa dnis map 7777 authentication ppp group sg1
aaa dnis map 7777 accounting network start-stop group sg2
aaa dnis map 8888 authentication ppp group sg3
aaa dnis map 9999 accounting network stop-only group sg3
```

TACACS+ Daemon Configuration Example

The following example shows a sample configuration of the TACACS+ daemon. The precise syntax used by your TACACS+ daemon may be different from what is included in this example.

```
user = mci_customer1 {  
  chap = cleartext "some chap password"  
  service = ppp protocol = ip {  
    inacl#1="permit ip any any precedence immediate"  
    inacl#2="deny igrp 0.0.1.2 255.255.0.0 any"  
  }  
}
```

Configuring Kerberos

Feature History

Release	Modification
Cisco IOS	For information about feature support in Cisco IOS software, use Cisco Feature Navigator.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

This chapter describes the Kerberos security system. For a complete description of the Kerberos commands used in this chapter, refer to the “Kerberos Commands” chapter in the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature, or refer to the software release notes for a specific release. For more information, see the section “Identifying Supported Platforms” in the chapter “Using Cisco IOS Software.”

In This Chapter

This chapter includes the following topics and tasks:

- [About Kerberos](#)
- [Kerberos Client Support Operation](#)
- [Kerberos Configuration Task List](#)
- [Kerberos Configuration Examples](#)

About Kerberos

Kerberos is a secret-key network authentication protocol, developed at the Massachusetts Institute of Technology (MIT), that uses the Data Encryption Standard (DES) cryptographic algorithm for encryption and authentication. Kerberos was designed to authenticate requests for network resources.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

Kerberos, like other secret-key systems, is based on the concept of a trusted third party that performs secure verification of users and services. In the Kerberos protocol, this trusted third party is called the key distribution center (KDC).

The primary use of Kerberos is to verify that users and the network services they use are really who and what they claim to be. To accomplish this, a trusted Kerberos server issues tickets to users. These tickets, which have a limited lifespan, are stored in a user's credential cache and can be used in place of the standard username-and-password authentication mechanism.

The Kerberos credential scheme embodies a concept called "single logon." This process requires authenticating a user once, and then allows secure authentication (without encrypting another password) wherever that user's credential is accepted.

Starting with Cisco IOS Release 11.2, Cisco IOS software includes Kerberos 5 support, which allows organizations already deploying Kerberos 5 to use the same Kerberos authentication database on their routers that they are already using on their other network hosts (such as UNIX servers and PCs).

The following network services are supported by the Kerberos authentication capabilities in Cisco IOS software:

- Telnet
- rlogin
- rsh
- rcp

Note

Cisco Systems' implementation of Kerberos client support is based on code developed by CyberSafe, which was derived from the MIT code. As a result, the Cisco Kerberos implementation has successfully undergone full compatibility testing with the CyberSafe Challenger commercial Kerberos server and MIT's server code, which is freely distributed.

[Table 20](#) lists common Kerberos-related terms and their definitions.

Table 20 ***Kerberos Terminology***

Term	Definition
authentication	A process by which a user or service identifies itself to another service. For example, a client can authenticate to a router or a router can authenticate to another router.
authorization	A means by which the router determines what privileges you have in a network or on the router and what actions you can perform.
credential	A general term that refers to authentication tickets, such as ticket granting tickets (TGTs) and service credentials. Kerberos credentials verify the identity of a user or service. If a network service decides to trust the Kerberos server that issued a ticket, it can be used in place of retyping in a username and password. Credentials have a default lifespan of eight hours.

Table 20 **Kerberos Terminology (continued)**

Term	Definition
instance	An authorization level label for Kerberos principals. Most Kerberos principals are of the form user@REALM (for example, smith@EXAMPLE.COM). A Kerberos principal with a Kerberos instance has the form user/instance@REALM (for example, smith/admin@EXAMPLE.COM). The Kerberos instance can be used to specify the authorization level for the user if authentication is successful. It is up to the server of each network service to implement and enforce the authorization mappings of Kerberos instances. Note that the Kerberos realm name must be in uppercase characters.
Kerberized	Applications and services that have been modified to support the Kerberos credential infrastructure.
Kerberos realm	A domain consisting of users, hosts, and network services that are registered to a Kerberos server. The Kerberos server is trusted to verify the identity of a user or network service to another user or network service. Kerberos realms must always be in uppercase characters.
Kerberos server	A daemon running on a network host. Users and network services register their identity with the Kerberos server. Network services query the Kerberos server to authenticate to other network services.
key distribution center (KDC)	A Kerberos server and database program running on a network host.
principal	Also known as a Kerberos identity, this is who you are or what a service is according to the Kerberos server.
service credential	A credential for a network service. When issued from the KDC, this credential is encrypted with the password shared by the network service and the KDC, and with the user's TGT.
SRVTAB	A password that a network service shares with the KDC. The network service authenticates an encrypted service credential by using the SRVTAB (also known as a KEYTAB) to decrypt it.
ticket granting ticket (TGT)	A credential that the key distribution center (KDC) issues to authenticated users. When users receive a TGT, they can authenticate to network services within the Kerberos realm represented by the KDC.

Kerberos Client Support Operation

This section describes how the Kerberos security system works with a Cisco router functioning as the security server. Although (for convenience or technical reasons) you can customize Kerberos in a number of ways, remote users attempting to access network services must pass through three layers of security before they can access network services.

This section includes the following sections:

- [Authenticating to the Boundary Router](#)
- [Obtaining a TGT from a KDC](#)
- [Authenticating to Network Services](#)

Authenticating to the Boundary Router

This section describes the first layer of security that remote users must pass through when they attempt to access a network. The first step in the Kerberos authentication process is for users to authenticate themselves to the boundary router. The following process describes how users authenticate to a boundary router:

1. The remote user opens a PPP connection to the corporate site router.
2. The router prompts the user for a username and password.
3. The router requests a TGT from the KDC for this particular user.
4. The KDC sends an encrypted TGT to the router that includes (among other things) the user's identity.
5. The router attempts to decrypt the TGT using the password the user entered. If the decryption is successful, the remote user is authenticated to the router.

A remote user who successfully initiates a PPP session and authenticates to the boundary router is inside the firewall but still must authenticate to the KDC directly before being allowed to access network services. This is because the TGT issued by the KDC is stored on the router and is not useful for additional authentication unless the user physically logs on to the router.

Obtaining a TGT from a KDC

This section describes how remote users who are authenticated to the boundary router authenticate themselves to a KDC.

When a remote user authenticates to a boundary router, that user technically becomes part of the network; that is, the network is extended to include the remote user and the user's machine or network. To gain access to network services, however, the remote user must obtain a TGT from the KDC. The following process describes how remote users authenticate to the KDC:

1. The remote user, at a workstation on a remote site, launches the KINIT program (part of the client software provided with the Kerberos protocol).
2. The KINIT program finds the user's identity and requests a TGT from the KDC.
3. The KDC creates a TGT, which contains the identity of the user, the identity of the KDC, and the expiration time of the TGT.
4. Using the user's password as a key, the KDC encrypts the TGT and sends the TGT to the workstation.
5. When the KINIT program receives the encrypted TGT, it prompts the user for a password (this is the password that is defined for the user in the KDC).
6. If the KINIT program can decrypt the TGT with the password the user enters, the user is authenticated to the KDC, and the KINIT program stores the TGT in the user's credential cache.

At this point, the user has a TGT and can communicate securely with the KDC. In turn, the TGT allows the user to authenticate to other network services.

Authenticating to Network Services

The following process describes how a remote user with a TGT authenticates to network services within a given Kerberos realm. Assume the user is on a remote workstation (Host A) and wants to log in to Host B.

1. The user on Host A initiates a Kerberized application (such as Telnet) to Host B.
2. The Kerberized application builds a service credential request and sends it to the KDC. The service credential request includes (among other things) the user's identity and the identity of the desired network service. The TGT is used to encrypt the service credential request.
3. The KDC tries to decrypt the service credential request with the TGT it issued to the user on Host A. If the KDC can decrypt the packet, it is assured that the authenticated user on Host A sent the request.
4. The KDC notes the network service identity in the service credential request.
5. The KDC builds a service credential for the appropriate network service on Host B on behalf of the user on Host A. The service credential contains the client's identity and the desired network service's identity.
6. The KDC then encrypts the service credential twice. It first encrypts the credential with the SRVTAB that it shares with the network service identified in the credential. It then encrypts the resulting packet with the TGT of the user (who, in this case, is on Host A).
7. The KDC sends the twice-encrypted credential to Host A.
8. Host A attempts to decrypt the service credential with the user's TGT. If Host A can decrypt the service credential, it is assured the credential came from the real KDC.
9. Host A sends the service credential to the desired network service. Note that the credential is still encrypted with the SRVTAB shared by the KDC and the network service.
10. The network service attempts to decrypt the service credential using its SRVTAB.
11. If the network service can decrypt the credential, it is assured the credential was in fact issued from the KDC. Note that the network service trusts anything it can decrypt from the KDC, even if it receives it indirectly from a user. This is because the user first authenticated with the KDC.

At this point, the user is authenticated to the network service on Host B. This process is repeated each time a user wants to access a network service in the Kerberos realm.

Kerberos Configuration Task List

For hosts and the KDC in your Kerberos realm to communicate and mutually authenticate, you must identify them to each other. To do this, you add entries for the hosts to the Kerberos database on the KDC and add SRVTAB files generated by the KDC to all hosts in the Kerberos realm. You also make entries for users in the KDC database.

This section describes how to set up a Kerberos-authenticated server-client system and contains the following topics:

- [Configuring the KDC Using Kerberos Commands](#)
- [Configuring the Router to Use the Kerberos Protocol](#)

This section assumes that you have installed the Kerberos administrative programs on a UNIX host, known as the KDC, initialized the database, and selected a Kerberos realm name and password. For instructions about completing these tasks, refer to documentation that came with your Kerberos software.

**Note**

Write down the host name or IP address of the KDC, the port number you want the KDC to monitor for queries, and the name of the Kerberos realm it will serve. You need this information to configure the router.

Configuring the KDC Using Kerberos Commands

After you set up a host to function as the KDC in your Kerberos realm, you must make entries to the KDC database for all principals in the realm. Principals can be network services on Cisco routers and hosts or they can be users.

To use Kerberos commands to add services to the KDC database (and to modify existing database information), complete the tasks in the following sections:

- [Adding Users to the KDC Database](#)
- [Creating SRVTABs on the KDC](#)
- [Extracting SRVTABs](#)

**Note**

All Kerberos command examples are based on Kerberos 5 Beta 5 of the original MIT implementation. Later versions use a slightly different interface.

Adding Users to the KDC Database

To add users to the KDC and create privileged instances of those users, use the **su** command to become root on the host running the KDC and use the `kdb5_edit` program to use the following commands in privileged EXEC mode:

	Command	Purpose
Step 1	Router# ank <i>username@REALM</i>	Use the ank (add new key) command to add a user to the KDC. This command prompts for a password, which the user must enter to authenticate to the router.
Step 2	Router# ank <i>username/instance@REALM</i>	Use the ank command to add a privileged instance of a user.

For example, to add user *loki* of Kerberos realm CISCO.COM, enter the following Kerberos command:
`ank loki@CISCO.COM`

**Note**

The Kerberos realm name must be in uppercase characters.

You might want to create privileged instances to allow network administrators to connect to the router at the enable level, for example, so that they need not enter a clear text password (and compromise security) to enter enable mode.

To add an instance of *loki* with additional privileges (in this case, *enable*, although it could be anything) enter the following Kerberos command:

```
ank loki/enable@CISCO.COM
```

In each of these examples, you are prompted to enter a password, which you must give to user *loki* to use at login.

The “[Enabling Kerberos Instance Mapping](#)” section describes how to map Kerberos instances to various Cisco IOS privilege levels.

Creating SRVTABs on the KDC

All routers that you want to authenticate to use the Kerberos protocol must have an SRVTAB. This section and the “[Extracting SRVTABs](#)” section describe how to create and extract SRVTABs for a router called *router1*. The section “[Copying SRVTAB Files](#)” describes how to copy SRVTAB files to the router.

To make SRVTAB entries on the KDC, use the following command in privileged EXEC mode:

Command	Purpose
Router# ark SERVICE/HOSTNAME@REALM	Use the ark (add random key) command to add a network service supported by a host or router to the KDC.

For example, to add a Kerberized authentication service for a Cisco router called *router1* to the Kerberos realm CISCO.COM, enter the following Kerberos command:

```
ark host/router1.cisco.com@CISCO.COM
```

Make entries for all network services on all Kerberized hosts that use this KDC for authentication.

Extracting SRVTABs

SRVTABs contain (among other things) the passwords or randomly generated keys for the service principals you entered into the KDC database. Service principal keys must be shared with the host running that service. To do this, you must save the SRVTAB entries to a file, then copy the file to the router and all hosts in the Kerberos realm. Saving SRVTAB entries to a file is called *extracting* SRVTABs. To extract SRVTABs, use the following command in privileged EXEC mode:

Command	Purpose
Router# xst router-name host	Use the kdb5_edit command xst to write an SRVTAB entry to a file.

For example, to write the host/router1.cisco.com@CISCO.COM SRVTAB to a file, enter the following Kerberos command:

```
xst router1.cisco.com@CISCO.COM host
```

Use the **quit** command to exit the kdb5_edit program.

Configuring the Router to Use the Kerberos Protocol

To configure a Cisco router to function as a network security server and authenticate users using the Kerberos protocol, complete the tasks in the following sections:

- [Defining a Kerberos Realm](#)
- [Copying SRVTAB Files](#)
- [Specifying Kerberos Authentication](#)
- [Enabling Credentials Forwarding](#)
- [Opening a Telnet Session to the Router](#)
- [Establishing an Encrypted Kerberized Telnet Session](#)
- [Enabling Mandatory Kerberos Authentication](#)
- [Enabling Kerberos Instance Mapping](#)
- [Monitoring and Maintaining Kerberos](#)

Defining a Kerberos Realm

For a router to authenticate a user defined in the Kerberos database, it must know the host name or IP address of the host running the KDC, the name of the Kerberos realm and, optionally, be able to map the host name or Domain Name System (DNS) domain to the Kerberos realm.

To configure the router to authenticate to a specified KDC in a specified Kerberos realm, use the following commands in global configuration mode. Note that DNS domain names must begin with a leading dot (.):

	Command	Purpose
Step 1	Router(config)# kerberos local-realm <i>kerberos-realm</i>	Defines the default realm for the router.
Step 2	Router(config)# kerberos server <i>kerberos-realm</i> <i>{hostname ip-address}</i> [<i>port-number</i>]	Specifies to the router which KDC to use in a given Kerberos realm and, optionally, the port number that the KDC is monitoring. (The default is 88.)
Step 3	Router(config)# kerberos realm <i>{dns-domain host}</i> <i>kerberos-realm</i>	(Optional) Maps a host name or DNS domain to a Kerberos realm.

Note

Because the machine running the KDC and all Kerberized hosts must interact within a 5-minute window or authentication fails, all Kerberized machines, and especially the KDC, should be running the Network Time Protocol (NTP).

The **kerberos local-realm**, **kerberos realm**, and **kerberos server** commands are equivalent to the UNIX *krb.conf* file. [Table 21](#) identifies mappings from the Cisco IOS configuration commands to a Kerberos 5 configuration file (*krb5.conf*).

Table 21 **Kerberos 5 Configuration File and Commands**

krb5.conf File	Cisco IOS Configuration Command
[libdefaults] default_realm = DOMAIN.COM	(in configuration mode) kerberos local-realm DOMAIN.COM
[domain_realm] .domain.com = DOMAIN.COM domain.com = DOMAIN.COM	(in configuration mode) kerberos realm.domain.com DOMAIN.COM kerberos realm domain.com DOMAIN.COM
[realms] kdc = DOMAIN.PIL.COM:750 admin_server = DOMAIN.PIL.COM default_domain = DOMAIN.COM	(in configuration mode) kerberos server DOMAIN.COM 172.65.44.2 (172.65.44.2 is the example IP address for DOMAIN.PIL.COM)

For an example of defining a Kerberos realm, see the section “[Defining a Kerberos Realm](#)” later in this chapter.

Copying SRVTAB Files

To make it possible for remote users to authenticate to the router using Kerberos credentials, the router must share a secret key with the KDC. To do this, you must give the router a copy of the SRVTAB you extracted on the KDC.

The most secure method to copy SRVTAB files to the hosts in your Kerberos realm is to copy them onto physical media and go to each host in turn and manually copy the files onto the system. To copy SRVTAB files to the router, which does not have a physical media drive, you must transfer them via the network using TFTP.

To remotely copy SRVTAB files to the router from the KDC, use the following command in global configuration mode:

Command	Purpose
Router(config)# kerberos srvtab remote {hostname ip-address} {filename}	Retrieves an SRVTAB file from the KDC.

When you copy the SRVTAB file from the router to the KDC, the **kerberos srvtab remote** command parses the information in this file and stores it in the router’s running configuration in the **kerberos srvtab entry** format. To ensure that the SRVTAB is available (does not need to be acquired from the KDC) when you reboot the router, use the **write memory** configuration command to write your running configuration (which contains the parsed SRVTAB file) to NVRAM.

For an example of copying SRVTAB files, see the section “[SRVTAB File Copying Example](#)” later in this chapter.

Specifying Kerberos Authentication

You have now configured Kerberos on your router. This makes it possible for the router to authenticate using Kerberos. The next step is to tell it to do so. Because Kerberos authentication is facilitated through AAA, you need to enter the **aaa authentication** command, specifying Kerberos as the authentication method. For more information, refer to the chapter “Configuring Authentication”.

Enabling Credentials Forwarding

With Kerberos configured thus far, a user authenticated to a Kerberized router has a TGT and can use it to authenticate to a host on the network. However, if the user tries to list credentials after authenticating to a host, the output will show no Kerberos credentials present.

You can optionally configure the router to forward users' TGTs with them as they authenticate from the router to Kerberized remote hosts on the network when using Kerberized Telnet, rcp, rsh, and rlogin (with the appropriate flags).

To force all clients to forward users' credentials as they connect to other hosts in the Kerberos realm, use the following command in global configuration mode:

Command	Purpose
Router(config)# kerberos credentials forward	Forces all clients to forward user credentials upon successful Kerberos authentication.

With credentials forwarding enabled, users' TGTs are automatically forwarded to the next host they authenticate to. In this way, users can connect to multiple hosts in the Kerberos realm without running the KINIT program each time to get a new TGT.

Opening a Telnet Session to the Router

To use Kerberos to authenticate users opening a Telnet session to the router from within the network, use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa authentication login {default list-name} krb5_telnet	Sets login authentication to use the Kerberos 5 Telnet authentication protocol when using Telnet to connect to the router.

Although Telnet sessions to the router are authenticated, users must still enter a clear text password if they want to enter enable mode. The **kerberos instance map** command, discussed in a later section, allows them to authenticate to the router at a predefined privilege level.

Establishing an Encrypted Kerberized Telnet Session

Another way for users to open a secure Telnet session is to use Encrypted Kerberized Telnet. With Encrypted Kerberized Telnet, users are authenticated by their Kerberos credentials before a Telnet session is established. The Telnet session is encrypted using 56-bit Data Encryption Standard (DES) encryption with 64-bit Cipher Feedback (CFB). Because data sent or received is encrypted, not clear text, the integrity of the dialed router or access server can be more easily controlled.

Note

This feature is available only if you have the 56-bit encryption image. 56-bit DES encryption is subject to U.S. Government export control regulations.

To establish an encrypted Kerberized Telnet session from a router to a remote host, use either of the following commands in EXEC command mode:

Command	Purpose
Router(config)# connect host [port] /encrypt kerberos	Establishes an encrypted Telnet session.
OR Router(config)# telnet host [port] /encrypt kerberos	

When a user opens a Telnet session from a Cisco router to a remote host, the router and remote host negotiate to authenticate the user using Kerberos credentials. If this authentication is successful, the router and remote host then negotiate whether or not to use encryption. If this negotiation is successful, both inbound and outbound traffic is encrypted using 56-bit DES encryption with 64-bit CFB.

When a user dials in from a remote host to a Cisco router configured for Kerberos authentication, the host and router will attempt to negotiate whether or not to use encryption for the Telnet session. If this negotiation is successful, the router will encrypt all outbound data during the Telnet session.

If encryption is not successfully negotiated, the session will be terminated and the user will receive a message stating that the encrypted Telnet session was not successfully established.

For information about enabling bidirectional encryption from a remote host, refer to the documentation specific to the remote host device.

For an example of using encrypted Kerberized Telnet to open a secure Telnet session, see the section “[Encrypted Telnet Session Example](#)” later in this chapter.

Enabling Mandatory Kerberos Authentication

As an added layer of security, you can optionally configure the router so that, after remote users authenticate to it, these users can authenticate to other services on the network only with Kerberized Telnet, rlogin, rsh, and rcp. If you do not make Kerberos authentication mandatory and Kerberos authentication fails, the application attempts to authenticate users using the default method of authentication for that network service; for example, Telnet and rlogin prompt for a password, and rsh attempts to authenticate using the local rhost file.

To make Kerberos authentication mandatory, use the following command in global configuration mode:

Command	Purpose
Router(config)# kerberos clients mandatory	Sets Telnet, rlogin, rsh, and rcp to fail if they cannot negotiate the Kerberos protocol with the remote server.

Enabling Kerberos Instance Mapping

As mentioned in the section “[Creating SRVTABs on the KDC](#),” you can create administrative instances of users in the KDC database. The **kerberos instance map** command allows you to map those instances to Cisco IOS privilege levels so that users can open secure Telnet sessions to the router at a predefined privilege level, obviating the need to enter a clear text password to enter enable mode.

To map a Kerberos instance to a Cisco IOS privilege level, use the following command in global configuration mode:

Command	Purpose
Router(config)# kerberos instance map <i>instance privilege-level</i>	Maps a Kerberos instance to a Cisco IOS privilege level.

If there is a Kerberos instance for user *loki* in the KDC database (for example, *loki/admin*), user *loki* can now open a Telnet session to the router as *loki/admin* and authenticate automatically at privilege level 15, assuming instance “admin” is mapped to privilege level 15. (See the section “[Adding Users to the KDC Database](#)” earlier in this chapter.)

Cisco IOS commands can be set to various privilege levels using the **privilege level** command.

After you map a Kerberos instance to a Cisco IOS privilege level, you must configure the router to check for Kerberos instances each time a user logs in. To run authorization to determine if a user is allowed to run an EXEC shell based on a mapped Kerberos instance, use the **aaa authorization** command with the **krb5-instance** keyword. For more information, refer to the chapter “Configuring Authorization.”

Monitoring and Maintaining Kerberos

To display or remove a current user’s credentials, use the following commands in EXEC mode:

	Command	Purpose
Step 1	Router# show kerberos creds	Lists the credentials in a current user’s credentials cache.
Step 2	Router# clear kerberos creds	Destroys all credentials in a current user’s credentials cache, including those forwarded.

For an example of Kerberos configuration, see the section “[Kerberos Configuration Examples](#)”.

Kerberos Configuration Examples

The following sections provide Kerberos configuration examples:

- [Kerberos Realm Definition Examples](#)
- [SRVTAB File Copying Example](#)
- [Kerberos Configuration Examples](#)
- [Encrypted Telnet Session Example](#)

Kerberos Realm Definition Examples

To define CISCO.COM as the default Kerberos realm, use the following command:

```
kerberos local-realm CISCO.COM
```

To tell the router that the CISCO.COM KDC is running on host 10.2.3.4 at port number 170, use the following Kerberos command:

```
kerberos server CISCO.COM 10.2.3.4 170
```

To map the DNS domain cisco.com to the Kerberos realm CISCO.COM, use the following command:

```
kerberos realm.cisco.com CISCO.COM
```

SRVTAB File Copying Example

To copy over the SRVTAB file on a host named `host123.cisco.com` for a router named `router1.cisco.com`, the command would look like this:

```
kerberos srvtab remote host123.cisco.com router1.cisco.com-new-srvtab
```

Kerberos Configuration Examples

This section provides a typical non-Kerberos router configuration and shows output for this configuration from the **write term** command, then builds on this configuration by adding optional Kerberos functionality. Output for each configuration is presented for comparison against the previous configuration.

This example shows how to use the `kdb5_edit` program to perform the following configuration tasks:

- Adding user `chet` to the Kerberos database
- Adding a privileged Kerberos instance of user `chet` (`chet/admin`) to the Kerberos database
- Adding a restricted instance of `chet` (`chet/restricted`) to the Kerberos database
- Adding workstation `chet-ss20.cisco.com`
- Adding router `chet-2500.cisco.com` to the Kerberos database
- Adding workstation `chet-ss20.cisco.com` to the Kerberos database
- Extracting SRVTABs for the router and workstations
- Listing the contents of the KDC database (with the **ldb** command)

Note that, in this sample configuration, host `chet-ss20` is also the KDC:

```
chet-ss20# sbin/kdb5_edit
kdb5_edit: ank chet
Enter password:
Re-enter password for verification:
kdb5_edit: ank chet/admin
Enter password:
Re-enter password for verification:
kdb5_edit: ank chet/restricted
Enter password:
Re-enter password for verification:
kdb5_edit: ark host/chet-ss20.cisco.com
kdb5_edit: ark host/chet-2500.cisco.com
kdb5_edit: xst chet-ss20.cisco.com host
'host/chet-ss20.cisco.com@CISCO.COM' added to keytab
'WRFIL:chet-ss20.cisco.com-new-srvtab'
kdb5_edit: xst chet-2500.cisco.com host
'host/chet-2500.cisco.com@CISCO.COM' added to keytab
'WRFIL:chet-2500.cisco.com-new-srvtab'
kdb5_edit: ldb
entry: host/chet-2500.cisco.com@CISCO.COM
entry: chet/restricted@CISCO.COM
entry: chet@CISCO.COM
entry: K/M@CISCO.COM
entry: host/chet-ss20.cisco.com@CISCO.COM
entry: krbtgt/CISCO.COM@CISCO.COM
entry: chet/admin@CISCO.COM
```

```
kdb5_edit: q
chet-ss20#
```

The following example shows output from a **write term** command, which displays the configuration of router chet-2500. This is a typical configuration with no Kerberos authentication.

```
chet-2500# write term

The following example shows how to authenticate to the router using Kerberos credentials. To authenticate using Kerberos credentials, you would perform the following tasks:

- Entering configuration mode
- Remotely copying over the SRVTAB file from the KDC
- Setting authentication at login to use the Kerberos 5 Telnet authentication protocol when using Telnet to connect to the router
- Writing the configuration to the terminal

Note that the new configuration contains a **kerberos srvtab entry** line. This line is created by the **kerberos srvtab remote** command.

```

chet-2500# configure term
Enter configuration commands, one per line.  End with CNTL/Z.

```

```

chet-2500(config)# kerberos srvtab remote earth chet/chet-2500.cisco.com-new-srvtab

chet-2500>q
Connection closed by foreign host.
chet-ss20%

```

The following example shows how to map Kerberos instances to Cisco's privilege levels. To map Kerberos instances to privilege levels, you would perform the following tasks:

- Entering configuration mode

- Mapping the Kerberos instance admin to privilege level 15
- Mapping the Kerberos instance restricted to privilege level 3
- Specifying that the instance defined by the **kerberos instance map** command be used for AAA Authorization
- Writing the configuration to the terminal

```

chet-2500# configure term
Enter configuration commands, one per line. End with CNTL/Z.
chet-2500(config)# kerberos instance map admin 15
chet-2500(config)# kerberos instance map restricted 3
chet-2500(config)# aaa authorization exec default krb5-instance

Traffic Filtering, Firewalls, and Virus Detection

Cisco IOS Firewall Overview

This chapter describes how you can configure your Cisco networking device to function as a firewall, using Cisco IOS Firewall security features.

This chapter has the following sections:

- [About Firewalls](#)
- [The Cisco IOS Firewall Solution](#)
- [Creating a Customized Firewall](#)
- [Other Guidelines for Configuring Your Firewall](#)

About Firewalls

Firewalls are networking devices that control access to your organization's network assets. Firewalls are positioned at the entrance points into your network. If your network has multiple entrance points, you must position a firewall at each point to provide effective network access control.

Firewalls are often placed in between the internal network and an external network such as the Internet. With a firewall between your network and the Internet, all traffic coming from the Internet must pass through the firewall before entering your network.

Firewalls can also be used to control access to a specific part of your network. For example, you can position firewalls at all the entry points into a research and development network to prevent unauthorized access to proprietary information.

The most basic function of a firewall is to monitor and filter traffic. Firewalls can be simple or elaborate, depending on your network requirements. Simple firewalls are usually easier to configure and manage. However, you might require the flexibility of a more elaborate firewall.

The Cisco IOS Firewall Solution

Cisco IOS software provides an extensive set of security features, allowing you to configure a simple or elaborate firewall, according to your particular requirements. You can configure a Cisco device as a firewall if the device is positioned appropriately at a network entry point. Security features that provide firewall functionality are listed in the [“Creating a Customized Firewall”](#) section.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

In addition to the security features available in standard Cisco IOS feature sets, Cisco IOS Firewall gives your router additional firewall capabilities.

The Cisco IOS Firewall Feature Set

The Cisco IOS Firewall feature set combines existing Cisco IOS firewall technology and Context-based Access Control (CBAC). When you configure the Cisco IOS Firewall on your Cisco router, you turn your router into an effective, robust firewall.

The Cisco IOS Firewall features are designed to prevent unauthorized external individuals from gaining access to your internal network and to block attacks on your network, while at the same time allowing authorized users to access network resources.

You can use the Cisco IOS Firewall features to configure your Cisco IOS router as one of the following:

- An Internet firewall or part of an Internet firewall
- A firewall between groups in your internal network
- A firewall providing secure connections to or from branch offices
- A firewall between your company's network and your company's partners' networks

The Cisco IOS Firewall features provide the following benefits:

- Protection of internal networks from intrusion
- Monitoring of traffic through network perimeters
- Enabling of network commerce via the World Wide Web

Creating a Customized Firewall

To create a firewall customized to fit your organization's security policy, you should determine which Cisco IOS Firewall features are appropriate, and configure those features. At a minimum, you must configure basic traffic filtering to provide a basic firewall. You can configure your Cisco networking device to function as a firewall by using the following Cisco IOS Firewall features:

- Standard Access Lists and Static Extended Access Lists
- Reflexive Access Lists
- Lock-and-Key (Dynamic Access Lists)
- TCP Intercept
- Context-based Access Control
- Intrusion Prevention System (IPS) (formerly known as Cisco IOS Firewall Intrusion Detection System)
- Authentication Proxy
- Port to Application Mapping
- Security Server Support
- Network Address Translation
- IPSec Network Security
- Neighbor Router Authentication

- Event Logging
- User Authentication and Authorization

In addition to configuring these features, you should follow the guidelines listed in the “[Other Guidelines for Configuring Your Firewall](#)” section. This section outlines important security practices to protect your firewall and network. [Table 23](#) describes Cisco IOS security features.

Table 23 *Cisco IOS Features for a Robust Firewall*

Feature	Chapter	Comments
Standard Access Lists and Static Extended Access Lists	“Access Control Lists: Overview and Guidelines”	Standard and static extended access lists provide basic traffic filtering capabilities. You configure criteria that describe which packets should be forwarded, and which packets should be dropped at an interface, based on each packet’s network layer information. For example, you can block all UDP packets from a specific source IP address or address range. Some extended access lists can also examine transport layer information to determine whether to block or forward packets. To configure a basic firewall, you should at a minimum configure basic traffic filtering. You should configure basic access lists for all network protocols that will be routed through your firewall, such as IP, IPX, AppleTalk, and so forth.
Lock-and-Key (Dynamic Access Lists)	“Configuring Lock-and-Key Security (Dynamic Access Lists)”	Lock-and-Key provides traffic filtering with the ability to allow temporary access through the firewall for certain individuals. These individuals must first be authenticated (by a username/password mechanism) before the firewall allows their traffic through the firewall. Afterwards, the firewall closes the temporary opening. This provides tighter control over traffic at the firewall than with standard or static extended access lists.
Reflexive Access Lists	“Configuring IP Session Filtering (Reflexive Access Lists)”	Reflexive access lists filter IP traffic so that TCP or UDP “session” traffic is only permitted through the firewall if the session originated from within the internal network. You would only configure Reflexive Access Lists when not using Context-based Access Control.
TCP Intercept	“Configuring TCP Intercept (Preventing Denial-of-Service Attacks)”	TCP Intercept protects TCP servers within your network from TCP SYN-flooding attacks, a type of denial-of-service attack. You would only configure TCP Intercept when not using Context-based Access Control.

Table 23 *Cisco IOS Features for a Robust Firewall (continued)*

Feature	Chapter	Comments
Context-based Access Control	“Configuring Context-Based Access Control”	CBAC examines not only network layer and transport layer information, but also examines the application-layer protocol information (such as FTP information) to learn about the state of TCP and UDP connections. CBAC maintains connection state information for individual connections. This state information is used to make intelligent decisions about whether packets should be permitted or denied, and dynamically creates and deletes temporary openings in the firewall. CBAC also generates real-time alerts and audit trails. Enhanced audit trail features use SYSLOG to track all network transactions. Real-time alerts send SYSLOG error messages to central management consoles upon detecting suspicious activity. Using CBAC inspection rules, you can configure alerts and audit trail information on a per-application protocol basis. CBAC is only available in the Cisco IOS Firewall feature set.
Cisco IOS Intrusion Prevention System (IPS)	“Configuring Cisco IOS Intrusion Prevention System (IPS)”	The Cisco IOS IPS acts as an in-line intrusion detection sensor, “watching” packets and sessions as they flow through the router and scanning each packet to match any of the Cisco IOS IPS signatures. When Cisco IOS IPS detects suspicious activity, it responds before network security can be compromised and logs the event through Cisco IOS syslog messages or Security Device Event Exchange (SDEE). The network administrator can configure Cisco IOS IPS to choose the appropriate response to various threats. When packets in a session match a signature, Cisco IOS IPS can take any of the following actions, as appropriate: • Send an alarm to a syslog server or a centralized management interface • Drop the packet • Reset the connection • Deny traffic from the source IP address of the attacker for a specified amount of time • Deny traffic on the connection for which the signature was seen for a specified amount of time
Authentication Proxy	“Configuring Authentication Proxy”	The Cisco IOS Firewall authentication proxy feature allows network administrators to apply specific security policies on a per-user basis. Previously, user identity and related authorized access was associated with a user’s IP address, or a single security policy had to be applied to an entire user group or sub network. Now, users can be identified and authorized on the basis of their per-user policy, and access privileges tailored on an individual basis are possible, as opposed to general policy applied across multiple users.

Table 23 *Cisco IOS Features for a Robust Firewall (continued)*

Feature	Chapter	Comments
Port to Application Mapping	“Configuring Port to Application Mapping”	Port to Application Mapping (PAM) is a feature of Cisco IOS Firewall. PAM allows you to customize TCP or UDP port numbers for network services or applications. PAM uses this information to support network environments that run services using ports that are different from the registered or well-known ports associated with an application. The information in the PAM table enables CBAC supported services to run on nonstandard ports.
Security Server Support	“Configuring TACACS+,” “Configuring RADIUS,” and “Configuring Kerberos”	The Cisco IOS Firewall feature set can be configured as a client of the following supported security servers: • TACACS+ (including CiscoSecure) • RADIUS • Kerberos You can use any of these security servers to store a database of user profiles. To gain access into your firewall or to gain access through the firewall into another network, users must enter authentication information (such as a username and password), which is matched against the information on the security server. When users pass authentication, they are granted access according to their specified privileges.
Network Address Translation	“Configuring NAT for IP Address Conservation”	You can use Network Address Translation (NAT) to hide internal IP network addresses from the world outside the firewall. NAT was designed to provide IP address conservation and for internal IP networks that have unregistered (not globally unique) IP addresses: NAT translates these unregistered IP addresses into legal addresses at the firewall. NAT can also be configured to advertise only one address for the entire internal network to the outside world. This provides security by effectively hiding the entire internal network from the world. NAT gives you limited spoof protection because internal addresses are hidden. Additionally, NAT removes all your internal services from the external name space. NAT does not work with the application-layer protocols RPC, VDOLive, or SQL*Net “Redirected.” (NAT does work with SQL*Net “Bequeathed.”) Do not configure NAT with networks that will carry traffic for these incompatible protocols.

Table 23 *Cisco IOS Features for a Robust Firewall (continued)*

Feature	Chapter	Comments
IPSec Network Security	“Configuring Security for VPNs with IPSec ”	IPSec is a framework of open standards developed by the Internet Engineering Task Force (IETF) that provides security for transmission of sensitive information over unprotected networks such as the Internet. IPSec acts at the network layer, protecting and authenticating IP packets between participating IPSec devices (“peers”) such as Cisco routers.
Neighbor Router Authentication	“Neighbor Router Authentication: Overview and Guidelines”	Neighbor router authentication requires the firewall to authenticate all neighbor routers before accepting any route updates from that neighbor. This ensures that the firewall receives legitimate route updates from a trusted source.
Event Logging	“System Monitoring and Logging” chapter in the <i>Cisco IOS Network Management Configuration Guide</i>	Event logging automatically logs output from system error messages and other events to the console terminal. You can also redirect these messages to other destinations such as virtual terminals, internal buffers, or syslog servers. You can also specify the severity of the event to be logged, and you can configure the logged output to be timestamped. The logged output can be used to assist real-time debugging and management, and to track potential security breaches or other nonstandard activities throughout a network.
User Authentication and Authorization	“Configuring Authentication” and “Configuring Authorization”	Authentication and authorization help protect your network from access by unauthorized users.

Other Guidelines for Configuring Your Firewall

As with all networking devices, you should always protect access into the firewall by configuring passwords as described in the module “Configuring Security with Passwords, Privilege Levels, and Login Usernames for CLI Sessions on Networking Devices.” You should also consider configuring user authentication, authorization, and accounting as described in the chapters in the “Authentication, Authorization, and Accounting (AAA)” part of this guide.

You should also consider the following recommendations:

- When setting passwords for privileged access to the firewall, use the **enable secret** command rather than the **enable password** command, which does not have as strong an encryption algorithm.
- Put a password on the console port. In authentication, authorization, and accounting (AAA) environments, use the same authentication for the console as for elsewhere. In a non-AAA environment, at a minimum configure the **login** and **password password** commands.
- Think about access control *before* you connect a console port to the network in any way, including attaching a modem to the port. Be aware that a *break* on the console port might give total control of the firewall, even with access control configured.
- Apply access lists and password protection to all virtual terminal ports. Use access lists to limit who can Telnet into your router.

- Do not enable any local service (such as SNMP or NTP) that you do not use. Cisco Discovery Protocol (CDP) and Network Time Protocol (NTP) are on by default, and you should turn these off if you do not need them.

To turn off CDP, enter the **no cdp run** global configuration command. To turn off NTP, enter the **ntp disable** interface configuration command on each interface not using NTP.

If you must run NTP, configure NTP only on required interfaces, and configure NTP to listen only to certain peers.

Any enabled service could present a potential security risk. A determined, hostile party might be able to find creative ways to misuse the enabled services to access the firewall or the network.

For local services that are enabled, protect against misuse. Protect by configuring the services to communicate only with specific peers, and protect by configuring access lists to deny packets for the services at specific interfaces.

- Protect against spoofing: protect the networks on both sides of the firewall from being spoofed from the other side. You could protect against spoofing by configuring input access lists at all interfaces to pass only traffic from expected source addresses, and to deny all other traffic.

You should also disable source routing. For IP, enter the **no ip source-route** global configuration command. Disabling source routing at *all* routers can also help prevent spoofing.

You should also disable minor services. For IP, enter the **no service tcp-small-servers** and **no service udp-small-servers** global configuration commands.

- Prevent the firewall from being used as a relay by configuring access lists on any asynchronous Telnet ports.
- Normally, you should disable directed broadcasts for all applicable protocols on your firewall and on all your other routers. For IP, use the **no ip directed-broadcast** command. Rarely, some IP networks do require directed broadcasts; if this is the case, do not disable directed broadcasts.

Directed broadcasts can be misused to multiply the power of denial-of-service attacks, because every denial-of-service packet sent is broadcast to every host on a subnet. Furthermore, some hosts have other intrinsic security risks present when handling broadcasts.
- Configure the **no ip proxy-arp** command to prevent internal addresses from being revealed. (This is important to do if you do not already have NAT configured to prevent internal addresses from being revealed.)
- Keep the firewall in a secured (locked) room.

Access Control Lists (ACLs)

IP Access List Features Roadmap

First Published: August 18, 2006

Last Updated: August 18, 2006

This roadmap lists the access list features documented in the *Cisco IOS Security Configuration Guide* and maps them to the modules in which they appear.

Feature and Release Support

[Table 1](#) lists access list feature support for the Cisco IOS software releases 12.2S, 12.3T, and 12.4T.

Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table. *Not all features may be supported in your Cisco IOS software release*

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

Table 1 **Supported Access List Features**

Release	Feature Name	Feature Description	Where Documented
Cisco IOS Releases 12.2S, 12.3T, and 12.4T			
12.2(25)S	ACL Support for Filtering IP Options	This feature allows you to filter packets having IP Options, in order to prevent routers from becoming saturated with spurious packets.	Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values

Americas Headquarters:

Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

Supported Access List Features (continued)

12.3(4)T 12.2(25)S	ACL TCP Flags Filtering	This feature provides a flexible mechanism for filtering on TCP flags. Before Cisco IOS Release 12.3(4)T, an incoming packet was matched as long as any TCP flag in the packet matched a flag specified in the access control entry (ACE). This behavior allows for a security loophole, because packets with all flags set could get past the access control list (ACL). The ACL TCP Flags Filtering feature allows you to select any combination of flags on which to filter. The ability to match on a flag set and on a flag not set gives you a greater degree of control for filtering on TCP flags, thus enhancing security.	Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values
12.3(7)T 12.2(25)S	ACL—Named ACL Support for Noncontiguous Ports on an Access Control Entry	This feature allows you to specify noncontiguous ports in a single access control entry, which greatly reduces the number of entries required in an access control list when several entries have the same source address, destination address, and protocol, but differ only in the ports.	Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values
12.4(2)T	ACL Support for Filtering on TTL Value	You may use extended IP access lists (named or numbered) to filter packets based on their time-to-live (TTL) value, from 0 to 255. This filtering enhances your control over which packets reach a router.	Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values
12.4(6)T	ACL Manageability	The ACL Manageability feature enables users to display and clear Access Control Entry (ACE) statistics per interface and per incoming or outgoing traffic direction for access control lists (ACLs).	Displaying and Clearing IP Access List Data Using ACL Manageability http://lbgj/push_targets1/ucdit/cc/td/doc/product/software/ios124/124tcg/sec_c/tsaclsho.htm

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and

IP Access List Overview

Feature History

Release	Modification
Cisco IOS	For information about feature support in Cisco IOS software, use Cisco Feature Navigator.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

First Published: August 18, 2006

Last Updated: August 18, 2006

Access control lists (ACLs) perform packet filtering to control which packets move through the network and where. Such control provides security by helping to limit network traffic, restrict the access of users and devices to the network, and prevent traffic from leaving a network. IP access lists can reduce the chance of spoofing and denial-of-service attacks and allow dynamic, temporary user access through a firewall.

IP access lists can also be used for purposes other than security, such as bandwidth control, restricting the content of routing updates, redistributing routes, triggering dial-on-demand (DDR) calls, limiting debug output, and identifying or classifying traffic for quality of service (QoS) features. This module provides an overview of IP access lists.

- [Where to Apply an Access List, page 11](#)

Benefits of IP Access Lists

Access control lists (ACLs) perform packet filtering to control which packets move through the network and where. Such control can restrict the access of users and devices to the network, providing a measure of security. Access lists can save network resources by reducing traffic. Access lists provide diverse benefits, depending on how they are used. Many of the benefits fall into the following categories:

Block Unwanted Traffic or Users

Access lists can filter incoming or outgoing packets on an interface, thereby controlling access based on source addresses, destination addresses, or user authentication. You can also use access lists to determine which types of traffic are forwarded or blocked at the router interfaces. For example, you can permit e-mail traffic to be routed, but at the same time block all Telnet traffic.

Reduce the Chance of DOS Attacks

There are a number of ways to reduce the chance of denial-of-service attacks. For example, by specifying IP source addresses, you can control whether traffic from hosts, networks, or users access your network. You can filter on specific time-to-live (TTL) values in packets to control how many hops a packet can take before reaching a router in your network. By configuring the TCP Intercept feature, you can prevent servers from being flooded with requests for a connection.

Control Access to Virtual Terminal Lines

You can place an access list on inbound vty (Telnet) line access from certain nodes or networks. You can also place an access list on outbound vty access, blocking or permitting Telnet access to other devices.

Restrict the Content of Routing Updates

Access lists can control routing updates being sent, received, or redistributed.

Provide Bandwidth Control

An access list on a slow link can prevent excess traffic.

Identify or Classify Traffic for QoS Features

Access lists can provide congestion avoidance by setting IP precedence for WRED or CAR. It can provide congestion management for class-based weighted fair queuing (WFQ), priority queuing, and custom queuing.

Trigger Dial-on-Demand (DDR) Calls

An access list can enforce dialing and disconnect criteria.

Limit Debug Command Output

An access list can limit debug output based on an address or protocol.

Provide NAT Control

Access lists can control which addresses are translated by Network Address Translation (NAT).

Authenticate Incoming RSH and RCP Requests

To enable the Cisco IOS software to receive incoming remote shell (rsh) protocol and remote copy (rcp) protocol requests, customers must configure an authentication database to control access to the router. Access lists can simplify the identification of local users, remote hosts, and remote users in the database authentication configuration.

Border Routers and Firewall Routers Should Use Access Lists

There are many reasons to configure access lists; for example, you can use access lists to restrict contents of routing updates or to provide traffic flow control. One of the most important reasons to configure access lists is to provide a basic level of security for your network by controlling access to it. If you do not configure access lists on your router, all packets passing through the router could be allowed onto all parts of your network.

An access list can allow one host to access a part of your network and prevent another host from accessing the same area. In [Figure 1](#), by applying an appropriate access list to the interfaces of the router, Host A is allowed to access the Human Resources network and Host B is prevented from accessing the Human Resources network.

Figure 1 Traffic Filters to Prevent Traffic from Being Routed to a Network

Access lists should be used in firewall routers, which are often positioned between your internal network and an external network such as the Internet. You can also use access lists on a router positioned between two parts of your network, to control traffic entering or exiting a specific part of your internal network.

To provide some security benefits of access lists, you should at least configure access lists on border routers—routers located at the edges of your networks. Such an access list provides a basic buffer from the outside network or from a less controlled area of your own network into a more sensitive area of your network. On these border routers, you should configure access lists for each network protocol configured on the router interfaces. You can configure access lists so that inbound traffic or outbound traffic or both are filtered on an interface.

Access lists are defined on a per-protocol basis. In other words, you should define access lists for every protocol enabled on an interface if you want to control traffic flow for that protocol.

Definition of an Access List

An access list is a sequential list consisting of at least one **permit** statement and possibly one or more **deny** statements. In the case of IP access lists, the statements can apply to IP addresses, upper-layer IP protocols, or other fields in IP packets. The access list is identified and referenced by a name or a number. The access list acts as a packet filter, filtering packets based on the criteria defined in the access list.

An access list may be configured, but it does not take effect until the access list is either applied to an interface (with the **ip access-group** command), a virtual terminal line (vty) (with the **access-class** command), or referenced by some other command that accepts an access list. Access lists have many uses, and therefore many Cisco IOS software commands accept a reference to an access list in their command syntax. Multiple commands can reference the same access list.

In the following configuration excerpt, the first three lines are an example of an IP access list named `branchoffices`, which is applied to serial interface 0 on incoming packets. No sources other than those on the networks specified by each source address and mask pair can access this interface. The destinations for packets coming from sources on network 172.20.7.0 are unrestricted. The destination for packets coming from sources on network 172.29.2.0 must be 172.25.5.4.

```
ip access-list extended branchoffices
10 permit 172.20.7.0 0.0.0.3 any
20 permit 172.29.2.0 0.0.0.255 host 172.25.5.4
```

```
!  
interface serial 0  
 ip access-group branchoffices in
```

Software Processing of an Access List

The following general steps describe how the Cisco IOS software processes an access list when it is applied to an interface, a vty, or referenced by some other Cisco IOS command. These steps apply to an access list that has 13 or fewer access list entries.

- The software receives an IP packet and tests parts of each packet being filtered against the conditions in the access list, one condition (**permit** or **deny** statement) at a time. For example, the software tests the source and destination addresses of the packet against the source and destination addresses in a **permit** or **deny** statement.
- If a packet does not match an access list statement, the packet is then tested against the next statement in the list.
- If a packet and an access list statement match, the rest of the statements in the list are skipped and the packet is permitted or denied as specified in the matched statement. The first entry that the packet matches determines whether the software permits or denies the packet. That is, after the first match, no subsequent entries are considered.
- If the access list denies a packet, the software discards the packet and returns an ICMP Host Unreachable message.
- If no conditions match, the software drops the packet. This is because each access list ends with an unwritten, implicit **deny** statement. That is, if the packet has not been permitted by the time it was tested against each statement, it is denied.

In later Cisco IOS releases such as Release 12.4, 12.2S, and 12.0S, by default, an access list that has more than 13 access list entries is processed differently from one that has 13 or fewer entries. In order to be more efficient, an access list with more than 13 entries is processed using a trie-based lookup algorithm. This process will happen automatically; it does not need to be configured.

Access List Rules

Keep the following rules and characteristics of access lists in mind when creating one:

- Only one access list per interface, per protocol, per direction is allowed.
- The access list must contain at least one **permit** statement or else all packets are denied.
- Because the software stops testing conditions after the first match, the order of the conditions is critical. The same **permit** or **deny** statements specified in a different order could result in a packet being passed under one circumstance and denied in another circumstance.
- If an access list is referenced by name in a command, but the access list does not exist, all packets pass. That is, an interface or command with an empty access list applied to it permits all traffic.
- Standard access lists and extended access lists cannot have the same name.
- Inbound access lists process packets arriving at the router. Incoming packets are processed before being routed to an outbound interface. An inbound access list is efficient because it saves the overhead of routing lookups if the packet is to be discarded because it is denied by the filtering tests. If the packet is permitted by the tests, it is then processed for routing. For inbound lists, **permit** means continue to process the packet after receiving it on an inbound interface; **deny** means discard the packet.

- Outbound access lists process packets before they leave the router. Incoming packets are routed to the outbound interface and then processed through the outbound access list. For outbound lists, **permit** means send it to the output buffer; **deny** means discard the packet.
- An access list can control traffic arriving at the router or leaving the router, but not traffic originating at the router.

Helpful Hints for Creating IP Access Lists

The following tips will help you avoid unintended consequences and help you create more efficient, useful access lists.

- Create the access list before applying it to an interface (or elsewhere), because if you apply a nonexistent access list to an interface and then proceed to configure the access list, the first statement is put into effect, and the implicit **deny** statement that follows could cause you immediate access problems.
- Another reason to configure an access list before applying it is because an interface with an empty access list applied to it permits all traffic.
- All access lists need at least one **permit** statement; otherwise, all packets are denied and no traffic passes.
- Because the software stops testing conditions after it encounters the first match (to either a **permit** or **deny** statement), you will reduce processing time and resources if you put the statements that packets are most likely to match at the beginning of the access list. Place more frequently occurring conditions before less frequent conditions.
- Organize your access list so that more specific references in a network or subnet appear before more general ones.
- Use the statement **permit any any** if you want to allow all other packets not already denied. Using the statement **permit any any** in effect avoids denying all other packets with the implicit deny statement at the end of an access list. Do not make your first access list entry **permit any any** because all traffic will get through; no packets will reach the subsequent testing. In fact, once you specify **permit any any**, all traffic not already denied will get through.
- Although all access lists end with an implicit **deny** statement, we recommend use of an explicit **deny** statement (for example, **deny ip any any**). On most platforms, you can display the count of packets denied by issuing the **show access-list** command, thus finding out more information about who your access list is disallowing. Only packets denied by explicit **deny** statements are counted, which is why the explicit **deny** statement will yield more complete data for you.
- While you are creating an access list or after it is created, you might want to delete an entry.
 - You cannot delete an entry from a *numbered* access list; trying to do so will delete the entire access list. If you need to delete an entry, you need to delete the entire access list and start over.
 - You can delete an entry from a *named* access list. Use the **no permit** or **no deny** command to delete the appropriate entry.
- In order to make the purpose of individual statements more scannable and easily understood at a glance, you can write a helpful remark before or after any statement by using the **remark** command.
- If you want to deny access to a particular host or network and find out if someone from that network or host is attempting to gain access, include the **log** keyword with the corresponding **deny** statement so that the packets denied from that source are logged for you.

- This hint applies to the placement of your access list. When trying to save resources, remember that an inbound access list applies the filter conditions *before* the routing table lookup. An outbound access list applies the filter conditions *after* the routing table lookup.

Named or Numbered Access Lists

All access lists must be identified by a name or a number. Named and numbered access lists have different command syntax. Named access lists are compatible with Cisco IOS Release 11.2 and later. Named access lists are more convenient than numbered access lists because you can specify a meaningful name that is easier to remember and associate with a purpose. You may reorder statements in or add statements to a named access list.

Named access lists are newer than numbered access lists and support the following features that are not supported in numbered access lists:

- TCP flag filtering
- IP option filtering
- noncontiguous ports
- reflexive access lists
- ability to delete entries with the **no permit** or **no deny** command

Not all commands that accept a numbered access list will accept a named access list. For example, virtual terminal lines use only numbered access lists.

Standard or Extended Access Lists

All access lists are either standard or extended access lists. If you only intend to filter on a source address, the simpler standard access list is sufficient. For filtering on anything other than a source address, an extended access list is necessary.

- Named access lists are specified as standard or extended based on the keyword **standard** or **extended** in the **ip access-list** command syntax.
- Numbered access lists are specified as standard or extended based on their number in the **access-list** command syntax. Standard IP access lists are numbered 1 to 99 or 1300 to 1999; extended IP access lists are numbered 100 to 199 or 2000 to 2699. The range of standard IP access lists was initially only 1 to 99, and was subsequently expanded with the range 1300 to 1999 (the intervening numbers were assigned to other protocols). The extended access list range was similarly expanded.

Standard Access Lists

Standard IP access lists test only source addresses of packets (except for two exceptions). Because standard access lists test source addresses, they are very efficient at blocking traffic close to a destination. There are two exceptions when the address in a standard access list is not a source address:

- On outbound VTY access lists, when someone is trying to telnet, the address in the access list entry is used as a destination address rather than a source address.
- When filtering routes, you are filtering the network being advertised to you rather than a source address.

Extended Access Lists

Extended access lists are good for blocking traffic anywhere. Extended access lists test source and destination addresses and other IP packet data, such as protocols, TCP or UDP port numbers, type of service (ToS), precedence, TCP flags, IP options, and TTL value. Extended access lists can also provide capabilities that standard access lists cannot, such as the following:

- Filtering IP Options
- Filtering TCP flags
- Filtering noninitial fragments of packets (see the module “Refining an IP Access List”)
- Time-based entries (see the “[Time-Based and Distributed Time-Based Access Lists](#)” section on [page 11](#) and the module “Refining an IP Access List”)
- Dynamic access lists (see the section “[Types of IP Access Lists](#)” section on [page 11](#))
- Reflexive access lists (see the section “[Types of IP Access Lists](#)” section on [page 11](#) and the module “Configuring IP Session Filtering [Reflexive Access Lists]”)

**Note**

Packets that are subject to an extended access list will not be autonomous switched.

IP Packet Fields You Can Filter to Control Access

You can use an extended access list to filter on any of the following fields in an IP packet. Source address and destination address are the two most frequently specified fields on which to base an access list:

- Source address—Specifies a source address to control packets coming from certain networking devices or hosts.
- Destination address—Specifies a destination address to control packets being sent to certain networking devices or hosts.
- Protocol—Specifies an IP protocol indicated by the keyword **eigrp**, **gre**, **icmp**, **igmp**, **ip**, **ipinip**, **nos**, **ospf**, **tcp**, or **udp**, or indicated by an integer in the range from 0 to 255 (representing an Internet protocol). If you specify a transport layer protocol (**icmp**, **igmp**, **tcp**, or **udp**), the command has a specific syntax.
 - Ports and non-contiguous ports—Specifies TCP or UDP ports by a port name or port number. The port numbers can be noncontiguous port numbers. Port numbers can be useful to filter Telnet traffic or HTTP traffic, for example.
 - TCP flags—Specifies that packets match any flag or all flags set in TCP packets. Filtering on specific TCP flags can help prevent false synchronization packets.
- IP options—Specifies IP options; one reason to filter on IP options is to prevent routers from being saturated with spurious packets containing them.
- TTL value—Specifies TTL values indicated by an operator and possibly a range of values. Filtering on TTL value can control who can reach an interface based on how many hops away the source is. Such filtering can also prevent packets from reaching the process level.

Wildcard Mask for Addresses in an Access List

Address filtering uses wildcard masking to indicate to the software whether to check or ignore corresponding IP address bits when comparing the address bits in an access list entry to a packet being submitted to the access list. By carefully setting wildcard masks, you can specify one or more IP addresses for permit or deny tests.

Wildcard masking for IP address bits uses the number 1 and the number 0 to specify how the software treats the corresponding IP address bits. A wildcard mask is sometimes referred to as an inverted mask because a 1 and 0 mean the opposite of what they mean in a subnet (network) mask.

- A wildcard mask bit 0 means *check* the corresponding bit value; they must match.
- A wildcard mask bit 1 means *ignore* that corresponding bit value; they need not match.

If you do not supply a wildcard mask with a source or destination address in an access list statement, the software assumes an implicit wildcard mask of 0.0.0.0, meaning all values must match.

Unlike subnet masks, which require contiguous bits indicating network and subnet to be ones, wildcard masks allow noncontiguous bits in the mask.

Table 1 shows examples of IP addresses and masks from an access list, along with the corresponding addresses that are considered a match.

Table 1 Sample IP Addresses, Wildcard Masks, and Match Results

Address	Wildcard Mask	Match Results
0.0.0.0	255.255.255.255	All addresses will match the access list conditions.
172.18.0.0/16	0.0.255.255	Network 172.18.0.0
172.18.5.2/16	0.0.0.0	Only host 172.18.5.2 matches
172.18.8.0	0.0.0.7	Only subnet 172.18.8.0/29 matches
172.18.8.8	0.0.0.7	Only subnet 172.18.8.8/29 matches
172.18.8.15	0.0.0.3	Only subnet 172.18.8.15/30 matches
10.1.2.0	0.0.252.255 (noncontiguous bits in mask)	Matches any even-numbered network in the range of 10.1.2.0 to 10.1.254.0

Access List Sequence Numbers

The ability to apply sequence numbers to IP access list entries simplifies access list changes. Prior to the IP Access List Entry Sequence Numbering feature, there was no way to specify the position of an entry within an access list. If you wanted to insert an entry in the middle of an existing list, all of the entries after the desired position had to be removed, then the new entry was added, and then all the removed entries had to be reentered. This method was cumbersome and error prone.

This feature allows users to add sequence numbers to access list entries and resequence them. When you add a new entry, you specify the sequence number so that it is in a desired position in the access list. If necessary, entries currently in the access list can be resequenced to create room to insert the new entry.

Access List Logging

The Cisco IOS software can provide logging messages about packets permitted or denied by a single standard or extended IP access list entry. That is, any packet that matches the entry will cause an informational logging message about the packet to be sent to the console. The level of messages logged to the console is controlled by the **logging console** global configuration command.

The first packet that triggers the access list entry causes an immediate logging message, and subsequent packets are collected over 5-minute intervals before they are displayed or logged. The logging message includes the access list number, whether the packet was permitted or denied, the source IP address of the packet, and the number of packets from that source permitted or denied in the prior 5-minute interval.

However, you can use the **ip access-list log-update** command to set the number of packets that, when match an access list (and are permitted or denied), cause the system to generate a log message. You might want to do this to receive log messages more frequently than at 5-minute intervals.

Caution

If you set the *number-of-matches* argument to 1, a log message is sent right away, rather than caching it; every packet that matches an access list causes a log message. A setting of 1 is not recommended because the volume of log messages could overwhelm the system.

Even if you use the **ip access-list log-update** command, the 5-minute timer remains in effect, so each cache is emptied at the end of 5 minutes, regardless of the count of messages in each cache. Regardless of when the log message is sent, the cache is flushed and the count reset to 0 for that message the same way it is when a threshold is not specified.

Note

The logging facility might drop some logging message packets if there are too many to be handled or if there is more than one logging message to be handled in 1 second. This behavior prevents the router from crashing due to too many logging packets. Therefore, the logging facility should not be used as a billing tool or an accurate source of the number of matches to an access list.

Alternative to Access List Logging

Packets matching an entry in an ACL with a log option are process switched. It is not recommended to use the log option on ACLs, but rather use NetFlow export and match on a destination interface of Null0. This is done in the CEF path. The destination interface of Null0 is set for any packet that is dropped by the ACL.

Additional IP Access List Features

Beyond the basic steps to create a standard or extended access list, you can enhance your access lists as mentioned below. Each of these methods is described completely in the module entitled “[Refining an Access List](#).”

- You can impose dates and times when **permit** or **deny** statements in an extended access list are in effect, making your access list more granular and specific to an absolute or periodic time period.
- After you create a named access list, you might want to add entries or change the order of the entries, known as resequencing an access list.
- You can achieve finer granularity when filtering packets by filtering on noninitial fragments of packets.

Time-Based and Distributed Time-Based Access Lists

Time-based access lists implement access list entries based on particular times of the day or week. This is an advantage when you don't want access list entries always in effect or in effect as soon as they are applied. Use time-based access lists to make the enforcement of permit or deny conditions granular, based on time and date.

Distributed time-based access lists are those that are supported on line cards for the Cisco 7500 series routers. Packets destined for an interface configured with time-based access lists are distributed switched through the line card.

Types of IP Access Lists

There are several types of access lists that are distinct because of how they are triggered, their temporary nature, or how their behavior differs from an ordinary access list.

Authentication Proxy

Authentication proxy provides dynamic, per-user authentication and authorization, authenticating users against industry standard TACACS+ and RADIUS authentication protocols. Authenticating and authorizing connections by users provides more robust protection against network attacks.

Context-Based Access Control

Context-based access control (CBAC) examines not only network layer and transport layer information, but also the application-layer protocol information (such as FTP information) to learn about the state of TCP and UDP connections. CBAC maintains connection state information for individual connections. This state information is used to make intelligent decisions about whether packets should be permitted or denied, and dynamically creates and deletes temporary openings in the firewall.

Dynamic Access Lists with the Lock-and-Key Feature

Dynamic access lists provide temporary access to designated users who are using Telnet to reach designated hosts through a firewall. Dynamic access lists involve user authentication and authorization.

Reflexive Access Lists

Reflexive access lists provide filtering on upper-layer IP protocol sessions. They contain temporary entries that are automatically created when a new IP session begins. They are nested within extended, named IP access lists that are applied to an interface. Reflexive access lists are typically configured on border routers, which pass traffic between an internal and external network. These are often firewall routers. Reflexive access lists do not end with an implicit deny statement because they are nested within an access list and the subsequent statements need to be examined.

Where to Apply an Access List

If you are applying an access list to an interface, carefully consider whether to specify it as **in** (inbound) or **out** (outbound). Applying an access list to an incoming or outgoing interface controls the traffic that will enter or leave the router's interface or process level (in the case of filtering on TTL values).

- When an inbound access list is applied to an interface, after the software receives a packet, the software checks the packet against the access list statements. If the access list permits the packet, the software continues to process the packet. Therefore, filtering on incoming packets can save router resources because filtered packets will not go through the router.

- Access lists that apply to outbound packets are filtering packets that have already gone through the router. Packets that pass the access list are transmitted (sent) out the interface.
- The TCP ACL splitting feature of Rate-Based Satellite Control Protocol (RBSCP) is an example of a feature that can be used on an outgoing interface. The access list controls which packets are subject to TCP ACK splitting.

Access lists can be used in ways other than applying them to interfaces. The following are additional places to apply an access list.

- To restrict incoming and outgoing connections between a particular vty (into a Cisco device) and the network devices at addresses in an access list, apply an access list to a line. See the “[Controlling Access to a Virtual Terminal Line](#)” module.
- Referencing an access list from a **debug** command limits the amount of information displayed to only the information permitted by the access list, such as sources, destinations, or protocols, for example.
- Access lists can be used to control routing updates, to control dial-on-demand routing (DDR), and to control quality of service (QoS) features, for example. See the appropriate configuration chapters for using access lists with these features.

Where to Go Next

You must first decide what you want to restrict, and then select the type of access list that achieves your goal. Next, you will create an access list that permits or denies packets based on values in the fields you specify, and finally, you will apply the access list (which determines its placement).

Assuming you have decided what you want to restrict and what type of access list you need, your next step is to create an access list. Creating an access list based on source address, destination address, or protocol is described in the “[Creating an IP Access List and Applying It to an Interface](#)” module. You could create an access list that filters on other fields, as described in “[Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values](#).” If you want to control access to a virtual line, see “Controlling Access to a Virtual Terminal Line.” If the purpose of your access list is to control routing updates or QoS features, for example, see the appropriate technology chapter.

Creating an IP Access List and Applying It to an Interface

First Published: August 18, 2006

Last Updated: August 18, 2006

IP access lists provide many benefits for securing a network and achieving nonsecurity goals, such as determining quality of service (QoS) factors or limiting **debug** command output. This module describes how to create standard, extended, named, and numbered IP access lists. An access list can be referenced by a name or a number. Standard access lists filter on only the source address in IP packets. Extended access lists can filter on source address, destination address, and other fields in an IP packet.

After you create an access list, you must apply it to something in order for it to have any effect. This module describes how to apply an access list to an interface. However, there are many other uses for an access list, which are referenced in this module and described in other modules and in other configuration guides for various technologies.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for Creating IP Access Lists](#)” section on page 24.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Creating an IP Access List and Applying It to an Interface

Before you create or apply an IP access list, you should understand the concepts in the “IP Access List Overview” module. You should also have IP running in your network.

Information About Creating an IP Access List and Applying It to an Interface

You should understand the following concepts before creating an IP access list.

- [Helpful Hints for Creating IP Access Lists, page 2](#)
- [Access List Remarks, page 3](#)
- [Additional IP Access List Features, page 3](#)

Helpful Hints for Creating IP Access Lists

The following tips will help you avoid unintended consequences and help you create more efficient access lists.

- Create the access list before applying it to an interface (or elsewhere), because if you apply a nonexistent access list to an interface and then proceed to configure the access list, the first statement is put into effect, and the implicit **deny** statement that follows could cause you immediate access problems.
- Another reason to configure an access list before applying it is because an interface with an empty access list applied to it permits all traffic.
- All access lists need at least one **permit** statement; otherwise, all packets are denied and no traffic passes.
- Because the software stops testing conditions after it encounters the first match (to either a **permit** or **deny** statement), you will reduce processing time and resources if you put the statements that packets are most likely to match at the beginning of the access list. Place more frequently occurring conditions before less frequent conditions.
- Organize your access list so that more specific references in a network or subnet appear before more general ones.
- Use the statement **permit any any** if you want to allow all other packets not already denied. Using the statement **permit any any** in effect avoids denying all other packets with the implicit deny statement at the end of an access list. Do not make your first access list entry **permit any any** because all traffic will get through; no packets will reach the subsequent testing. In fact, once you specify **permit any any**, all traffic not already denied will get through.

- Although all access lists end with an implicit **deny** statement, we recommend use of an explicit **deny** statement (for example, **deny ip any any**). On most platforms, you can display the count of packets denied by issuing the **show access-list** command, thus finding out more information about who your access list is disallowing. Only packets denied by explicit **deny** statements are counted, which is why the explicit **deny** statement will yield more complete data for you.
- While you are creating an access list or after it is created, you might want to delete an entry.
 - You cannot delete an entry from a *numbered* access list; trying to do so will delete the entire access list. If you need to delete an entry, you need to delete the entire access list and start over.
 - You can delete an entry from a *named* access list. Use the **no permit** or **no deny** command to delete the appropriate entry.
- In order to make the purpose of individual statements more scannable and easily understood at a glance, you can write a helpful remark before or after any statement by using the **remark** command.
- If you want to deny access to a particular host or network and find out if someone from that network or host is attempting to gain access, include the **log** keyword with the corresponding **deny** statement so that the packets denied from that source are logged for you.
- This hint applies to the placement of your access list. When trying to save resources, remember that an inbound access list applies the filter conditions *before* the routing table lookup. An outbound access list applies the filter conditions *after* the routing table lookup.

Access List Remarks

You can include comments (remarks) about entries in a named IP access list. An access list remark is an optional comment before or after an access list entry that describes the entry for you at a glance, so you do not have to interpret the purpose of the entry by its command syntax. Each remark is limited to 100 characters.

The remark can go before or after a **permit** or **deny** statement. You should be consistent about where you put your remarks so that it is clear which remark describes which statement. It could be confusing to have some remarks before the associated **permit** or **deny** statements and some remarks after the associated statements.

The following example of a remark is a user-friendly description of what the subsequent **deny** statement does.

```
ip access-list extended telnetting
remark Do not allow host1 subnet to telnet out
deny tcp host 172.69.2.88 any eq telnet
```

Additional IP Access List Features

Beyond the basic steps to create a standard or extended access list, you can enhance your access lists as mentioned below. Each of these methods is described completely in the module entitled “[Refining an Access List](#).”

- You can impose dates and times when **permit** or **deny** statements in an extended access list are in effect, making your access list more granular and specific to an absolute or periodic time period.
- After you create a named or numbered access list, you might want to add entries or change the order of the entries, known as resequencing an access list.
- You can achieve finer granularity when filtering packets by filtering on noninitial fragments of packets.

How to Create an IP Access List and Apply It to an Interface

This section describes the general ways to create a standard or extended access list using either a name or a number. Access lists are very flexible; the tasks simply illustrate one **permit** command and one **deny** command to provide you the command syntax of each. Only you can determine how many **permit** and **deny** commands you need and their order.

Note

The first two tasks in this module create an access list; you must apply the access list in order for it to function. If you want to apply the access list to an interface, perform the task [“Applying the Access List to an Interface” section on page 16](#).

If you don’t intend to apply the access list to an interface, see the [“Where to Go Next” section on page 21](#) for pointers to modules that describe other ways to apply access lists.

- [Creating a Standard Access List to Filter on Source Address, page 4](#)
- [Creating an Extended Access List, page 10](#)
- [Applying the Access List to an Interface, page 16](#)

Creating a Standard Access List to Filter on Source Address

If you want to filter on source address only, a standard access list is simple and sufficient. There are two alternative types of standard access list: named and numbered. Named access lists allow you to identify your access lists with a more intuitive name rather than a number, and they also support more features than numbered access lists.

- [Creating a Named Access List to Filter on Source Address, page 4](#)
- [Creating a Numbered Access List to Filter on Source Address, page 7](#)

Creating a Named Access List to Filter on Source Address

Use a standard, named access list if you need to filter on source address only. This task illustrates one **permit** statement and one **deny** statement, but the actual statements you use and their order depend on what you want to filter or allow. Define your **permit** and **deny** statements in the order that achieves your filtering goals.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list standard** *name*
4. **remark** *remark*
5. **deny** {*source* [*source-wildcard*] | **any**} [**log**]
6. **remark** *remark*
7. **permit** {*source* [*source-wildcard*] | **any**} [**log**]
8. Repeat some combination of Steps 4 through 7 until you have specified the source networks and hosts on which you want to base your access list.

9. `end`
10. `show ip access-list`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list standard <i>name</i> Example: Router(config)# ip access-list standard R&D	Defines a standard IP access list using a name and enters standard named access list configuration mode.
Step 4	remark <i>remark</i> Example: Router(config-std-nacl)# remark deny Sales network	(Optional) Adds a user-friendly comment about an access list entry. - A remark can precede or follow an access list entry. - In this example, the remark reminds the network administrator that the subsequent entry denies the Sales network access to the interface (assuming this access list is later applied to an interface).
Step 5	deny {<i>source</i> [<i>source-wildcard</i>] any} [log] Example: Router(config-std-nacl)# deny 172.16.0.0 0.0.255.255 log	(Optional) Denies the specified source based on a source address and wildcard mask. - If the <i>source-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source address. - Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> to specify the source and source wildcard of 0.0.0.0 255.255.255.255. - In this example, all hosts on network 172.16.0.0 are denied passing the access list. - Because this example explicitly denies a source address and the log keyword is specified, any packets from that source are logged when they are denied. This is a way to be notified that someone on a network or host is trying to gain access.
Step 6	remark <i>remark</i> Example: Router(config-std-nacl)# remark Give access to Tester's host	(Optional) Adds a user-friendly comment about an access list entry. - A remark can precede or follow an access list entry. - This remark reminds the network administrator that the subsequent entry allows the Tester's host access to the interface.

	Command or Action	Purpose
Step 7	permit { <i>source</i> [<i>source-wildcard</i>] any } [log] Example: Router(config-std-nacl)# permit 172.18.5.22 0.0.0.0	Permits the specified source based on a source address and wildcard mask. - Every access list needs at least one permit statement; it need not be the first entry. - If the <i>source-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source address. - Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> to specify the source and source wildcard of 0.0.0.0 255.255.255.255. - In this example, host 172.18.5.22 is allowed to pass the access list.
Step 8	Repeat some combination of Steps 4 through 7 until you have specified the sources on which you want to base your access list.	Remember that all sources not specifically permitted are denied by an implicit deny statement at the end of the access list.
Step 9	end Example: Router(config-std-nacl)# end	Ends configuration mode and brings the system to privileged EXEC mode.
Step 10	show ip access-list Example: Router# show ip access-list	(Optional) Displays the contents of all current IP access lists.

What to Do Next

The access list you created is not in effect until you apply it to an interface, a vty line, or reference it from a command that uses an access list. See the [“Applying the Access List to an Interface”](#) section on page 16 or the [“Where to Go Next”](#) section on page 21 for pointers to modules that describe other ways to use access lists.

Creating a Numbered Access List to Filter on Source Address

Configure a standard, numbered access list if you need to filter on source address only and you prefer not to use a named access list.

IP standard access lists are numbered 1 to 99 or 1300 to 1999. This task illustrates one **permit** statement and one **deny** statement, but the actual statements you use and their order depend on what you want to filter or allow. Define your **permit** and **deny** statements in the order that achieves your filtering goals.

SUMMARY STEPS

- enable**
- configure terminal**
- access-list** *access-list-number* **remark** *remark*
- access-list** *access-list-number* **permit** {*source* [*source-wildcard*] | **any**} [**log**]

5. **access-list** *access-list-number* **remark** *remark*
6. **access-list** *access-list-number* **deny** {*source* [*source-wildcard*] | **any**} [**log**]
7. Repeat some combination of Steps 3 through 6 until you have specified the sources on which you want to base your access list.
8. **end**
9. **show ip access-list**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	access-list access-list-number remark remark Example: Router(config)# access-list 1 remark Give access to Jones	(Optional) Adds a user-friendly comment about an access list entry. A remark of up to 100 characters can precede or follow an access list entry.
Step 4	access-list access-list-number permit {source [source-wildcard] any} [log] Example: Router(config)# access-list 1 permit 172.16.5.22 0.0.0.0	Permits the specified source based on a source address and wildcard mask. - Every access list needs at least one permit statement; it need not be the first entry. - Standard IP access lists are numbered 1 to 99 or 1300 to 1999. - If the <i>source-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source address. - Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> to specify the source and source wildcard of 0.0.0.0 255.255.255.255. - In this example, host 172.16.5.22 is allowed to pass the access list.
Step 5	access-list access-list-number remark remark Example: Router(config)# access-list 1 remark Don't give access to Johnson and log any attempts	(Optional) Adds a user-friendly comment about an access list entry. A remark of up to 100 characters can precede or follow an access list entry.
Step 6	access-list access-list-number deny {source [source-wildcard] any} [log] Example: Router(config)# access-list 1 deny 172.16.7.34 0.0.0.0	Denies the specified source based on a source address and wildcard mask. - If the <i>source-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source address. - Optionally use the abbreviation any as a substitute for the <i>source source-wildcard</i> to specify the source and source wildcard of 0.0.0.0 255.255.255.255. - In this example, host 172.16.7.34 is denied passing the access list.

	Command or Action	Purpose
Step 7	Repeat some combination of Steps 3 through 6 until you have specified the sources on which you want to base your access list.	Remember that all sources not specifically permitted are denied by an implicit deny statement at the end of the access list.
Step 8	end Example: Router(config-std-nacl)# end	Ends configuration mode and brings the system to privileged EXEC mode.
Step 9	show ip access-list Example: Router# show ip access-list	(Optional) Displays the contents of all current IP access lists.

What to Do Next

The access list you created is not in effect until you apply it to an interface, a vty line, or reference it from a command that uses an access list. See the [“Applying the Access List to an Interface” section on page 16](#) or the [“Where to Go Next” section on page 21](#) for pointers to modules that describe other ways to use access lists.

Creating an Extended Access List

If you want to filter on anything other than source address, you need to create an extended access list. There are two alternative types of extended access list: named and numbered. Named access lists allow you to identify your access lists with a more intuitive name rather than a number, and they also support more features.

For details on how to filter something other than source or destination address, see the syntax descriptions in the command reference documentation.

- [Creating a Named Extended Access List, page 10](#)
- [Creating a Numbered Extended Access List, page 13](#)

Creating a Named Extended Access List

Create a named extended access list if you want to filter on source and destination address, or a combination of addresses and other IP fields.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list extended** *name*
4. **remark** *remark*
5. **deny** *protocol source* [*source-wildcard*] *destination* [*destination-wildcard*] [**option** *option-name*] [**precedence** *precedence*] [**tos** *tos*] [**established**] [**log** | **log-input**] [**time-range** *time-range-name*] [**fragments**]

6. **remark** *remark*
7. **permit** *protocol source [source-wildcard] destination [destination-wildcard]* [**option** *option-name*]
[**precedence** *precedence*] [**tos** *tos*] [**established**] [**log** | **log-input**] [**time-range** *time-range-name*]
[**fragments**]
8. Repeat some combination of Steps 4 through 7 until you have specified the fields and values on which you want to base your access list.
9. **end**
10. **show ip access-list**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list extended name Example: Router(config)# ip access-list extended nomarketing	Defines an extended IP access list using a name and enters extended named access list configuration mode.
Step 4	remark remark Example: Router(config-ext-nacl)# remark protect server by denying access from the Marketing network	(Optional) Adds a user-friendly comment about an access list entry. - A remark can precede or follow an access list entry. - In this example, the remark reminds the network administrator that the subsequent entry denies the Sales network access to the interface.
Step 5	deny protocol source [source-wildcard] destination [destination-wildcard] [option option-name] [precedence precedence] [tos tos] [established] [log log-input] [time-range time-range-name] [fragments] Example: Router(config-ext-nacl)# deny ip 172.18.0.0 0.0.255.255 host 172.16.40.10 log	(Optional) Denies any packet that matches all of the conditions specified in the statement. - If the <i>source-wildcard</i> or <i>destination-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source or destination address, respectively. - Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> or <i>destination destination-wildcard</i> to specify the address and wildcard of 0.0.0.0 255.255.255.255. - Optionally use the keyword host source to indicate a source and source wildcard of <i>source</i> 0.0.0.0 or the abbreviation host destination to indicate a destination and destination wildcard of <i>destination</i> 0.0.0.0. - In this example, packets from all sources are denied access to the destination network 172.18.0.0. Logging messages about packets permitted or denied by the access list are sent to the facility configured by the logging facility command (for example, console, terminal, or syslog). That is, any packet that matches the access list will cause an informational logging message about the packet to be sent to the configured facility. The level of messages logged to the console is controlled by the logging console command.

	Command or Action	Purpose
Step 6	<code>remark remark</code> Example: Router(config-ext-nacl)# remark allow TCP from any source to any destination	(Optional) Adds a user-friendly comment about an access list entry. A remark can precede or follow an access list entry.
Step 7	<code>permit protocol source [source-wildcard] destination [destination-wildcard] [option option-name] [precedence precedence] [tos tos] [established] [log log-input] [time-range time-range-name] [fragments]</code> Example: Router(config-ext-nacl)# permit tcp any any	Permits any packet that matches all of the conditions specified in the statement. - Every access list needs at least one permit statement. - If the <i>source-wildcard</i> or <i>destination-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source or destination address, respectively. - Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> or <i>destination destination-wildcard</i> to specify the address and wildcard of 0.0.0.0 255.255.255.255. - In this example, TCP packets are allowed from any source to any destination. - Use the log-input keyword to include input interface, source MAC address, or virtual circuit in the logging output.
Step 8	Repeat some combination of Steps 4 through 7 until you have specified the fields and values on which you want to base your access list.	Remember that all sources not specifically permitted are denied by an implicit deny statement at the end of the access list.
Step 9	<code>end</code> Example: Router(config-ext-nacl)# end	Ends configuration mode and brings the system to privileged EXEC mode.
Step 10	<code>show ip access-list</code> Example: Router# show ip access-list	(Optional) Displays the contents of all current IP access lists.

What to Do Next

The access list you created is not in effect until you apply it to an interface, a vty line, or reference it from a command that uses an access list. See the [“Applying the Access List to an Interface” section on page 16](#) or the [“Where to Go Next” section on page 21](#) for pointers to modules that describe other ways to use access lists.

Creating a Numbered Extended Access List

Create a numbered extended access list if you want to filter on source and destination address, or a combination of addresses and other IP fields, and you prefer not to use a name. Extended IP access lists are numbered 100 to 199 or 2000 to 2699.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **access-list** *access-list-number* **remark** *remark*
4. **access-list** *access-list-number* **permit** *protocol* {*source* [*source-wildcard*] | **any**} {*destination* [*destination-wildcard*] | **any**} [**precedence** *precedence*] [**tos** *tos*] [**established**] [**log** | **log-input**] [**time-range** *time-range-name*] [**fragments**]
5. **access-list** *access-list-number* **remark** *remark*
6. **access-list** *access-list-number* **deny** *protocol* {*source* [*source-wildcard*] | **any**} {*destination* [*destination-wildcard*] | **any**} [**precedence** *precedence*] [**tos** *tos*] [**established**] [**log** | **log-input**] [**time-range** *time-range-name*] [**fragments**]
7. Repeat some combination of Steps 3 through 6 until you have specified the fields and values on which you want to base your access list.
8. **end**
9. **show ip access-list**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	access-list access-list-number remark remark Example: Router(config)# access-list 107 remark allow Telnet packets from any source to network 173.69.0.0 (headquarters)	(Optional) Adds a user-friendly comment about an access list entry. A remark of up to 100 characters can precede or follow an access list entry.
Step 4	access-list access-list-number permit protocol {source [source-wildcard] any} {destination [destination-wildcard] any} [precedence precedence] [tos tos] [established] [log log-input] [time-range time-range-name] [fragments] Example: Router(config)# access-list 107 permit tcp any 173.69.0.0 0.0.255.255 eq telnet	Permits any packet that matches all of the conditions specified in the statement. - Every access list needs at least one permit statement; it need not be the first entry. - Extended IP access lists are numbered 100 to 199 or 2000 to 2699. - If the <i>source-wildcard</i> or <i>destination-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source or destination address, respectively. - Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> or <i>destination destination-wildcard</i> to specify the address and wildcard of 0.0.0.0 255.255.255.255. - TCP and other protocols have additional syntax available. See the access-list command in the command reference for complete syntax.
Step 5	access-list access-list-number remark remark Example: Router(config)# access-list 107 remark deny all other TCP packets	(Optional) Adds a user-friendly comment about an access list entry. A remark of up to 100 characters can precede or follow an access list entry.

	Command or Action	Purpose
Step 6	access-list <i>access-list-number</i> deny <i>protocol</i> {<i>source</i> [<i>source-wildcard</i>] any} {<i>destination</i> [<i>destination-wildcard</i>] any} [precedence <i>precedence</i>] [tos <i>tos</i>] [established] [log log-input] [time-range <i>time-range-name</i>] [fragments] Example: Router(config)# access-list 107 deny tcp any any	Denies any packet that matches all of the conditions specified in the statement. - If the <i>source-wildcard</i> or <i>destination-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source or destination address, respectively. - Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> or <i>destination destination-wildcard</i> to specify the address and wildcard of 0.0.0.0 255.255.255.255.
Step 7	Repeat some combination of Steps 3 through 6 until you have specified the fields and values on which you want to base your access list.	Remember that all sources not specifically permitted are denied by an implicit deny statement at the end of the access list.
Step 8	end Example: Router(config)# end	Ends configuration mode and brings the system to privileged EXEC mode.
Step 9	show ip access-list Example: Router# show ip access-list	(Optional) Displays the contents of all current IP access lists.

Applying the Access List to an Interface

Perform this task to apply an access list to an interface.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **ip access-group** {*access-list-number* | *access-list-name*} {**in** | **out**}

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface type number Example: Router(config)# interface ethernet 0	Specifies an interface and enters interface configuration mode.
Step 4	ip access-group {access-list-number access-list-name} {in out} Example: Router(config-if)# ip access-group noncorp in	Applies the specified access list to the incoming or outgoing interface. - When you are filtering on source addresses, you typically apply the access list to an incoming interface. - Filtering on source addresses is most efficient when applied near the destination.

What to Do Next

The access list you created is not in effect until you apply it to an interface, a vty line, or reference it from a command that uses an access list. See the [“Applying the Access List to an Interface”](#) section on page 16 or the [“Where to Go Next”](#) section on page 21 for pointers to modules that describe other ways to use access lists.

Configuration Examples for IP Access Lists

This section contains the following examples of named and numbered, standard and extended IP access lists that are applied to an interface or referenced by a command:

- [Filtering on Source Address \(Hosts\): Example, page 18](#)
- [Filtering on Source Address \(Subnet\): Example, page 18](#)
- [Filtering on Source Address, Destination Address, and IP Protocols: Example, page 18](#)
- [Filtering on Source Address \(Host and Subnets\) Using a Numbered Access List: Example, page 19](#)
- [Preventing Telnet Access to a Subnet: Example, page 19](#)
- [Filtering on TCP and ICMP Using Port Numbers: Example, page 19](#)
- [Allowing SMTP \(E-mail\) and Established TCP Connections: Example, page 19](#)
- [Preventing Access to the Web By Filtering on Port Name: Example, page 20](#)
- [Filtering on Source Address and Logging the Packets Permitted and Denied: Example, page 20](#)
- [Limiting Debug Output: Example, page 21](#)

Filtering on Source Address (Hosts): Example

In the following example, the workstation belonging to Jones is allowed access to Ethernet interface 0 and the workstation belonging to Smith is not allowed access:

```
interface ethernet 0
 ip access-group workstations in
!
ip access-list standard workstations
 remark Permit only Jones workstation through
 permit 172.16.2.88
 remark Do not allow Smith workstation through
 deny 172.16.3.13
```

Filtering on Source Address (Subnet): Example

In the following example, the Jones subnet is not allowed access to Ethernet interface 0, but the Main subnet is allowed access:

```
interface ethernet 0
 ip access-group prevention in
!
ip access-list standard prevention
 remark Do not allow Jones subnet through
 deny 172.22.0.0 0.0.255.255
 remark Allow Main subnet
 permit 172.25.0.0 0.0.255.255
```

Filtering on Source Address, Destination Address, and IP Protocols: Example

The following configuration example shows an interface with two access lists, one applied to outgoing packets and one applied to incoming packets. The standard access list named Internet_filter filters outgoing packets on source address. The only packets allowed out the interface must be from source 172.16.3.4.

The extended access list named marketing_group filters incoming packets. The access list permits Telnet packets from any source to network 172.26.0.0 and denies all other TCP packets. It permits any ICMP packets. It denies UDP packets from any source to network 172.26.0.0 on port numbers less than 1024. Finally, the access list denies all other IP packets and performs logging of packets passed or denied by that entry.

```
interface Ethernet0/5
 ip address 172.20.5.1 255.255.255.0
 ip access-group Internet_filter out
 ip access-group marketing_group in
!
ip access-list standard Internet_filter
 permit 172.16.3.4
ip access-list extended marketing_group
 permit tcp any 172.26.0.0 0.0.255.255 eq telnet
 deny tcp any any
 permit icmp any any
 deny udp any 172.26.0.0 0.0.255.255 lt 1024
 deny ip any any
```

Filtering on Source Address (Host and Subnets) Using a Numbered Access List: Example

In the following example, network 10.0.0.0 is a Class A network whose second octet specifies a subnet; that is, its subnet mask is 255.255.0.0. The third and fourth octets of a network 10.0.0.0 address specify a particular host. Using access list 2, the Cisco IOS software would accept one address on subnet 48 and reject all others on that subnet. The last line of the list shows that the software would accept addresses on all other network 10.0.0.0 subnets.

```
interface ethernet 0
 ip access-group 2 in
!
access-list 2 permit 10.48.0.3
access-list 2 deny 10.48.0.0 0.0.255.255
access-list 2 permit 10.0.0.0 0.255.255.255
```

Preventing Telnet Access to a Subnet: Example

In the following example, the Jones subnet is not allowed to Telnet out Ethernet interface 0:

```
interface ethernet 0
 ip access-group telnetting out
!
ip access-list extended telnetting
 remark Do not allow Jones subnet to telnet out
 deny tcp 172.20.0.0 0.0.255.255 any eq telnet
 remark Allow Top subnet to telnet out
 permit tcp 172.33.0.0 0.0.255.255 any eq telnet
```

Filtering on TCP and ICMP Using Port Numbers: Example

In the following example, the first line of the extended access list named goodports permits any incoming TCP connections with destination ports greater than 1023. The second line permits incoming TCP connections to the Simple Mail Transfer Protocol (SMTP) port of host 172.28.1.2. The last line permits incoming ICMP messages for error feedback.

```
interface ethernet 0
 ip access-group goodports in
!
ip access-list extended goodports
 permit tcp any 172.28.0.0 0.0.255.255 gt 1023
 permit tcp any host 172.28.1.2 eq 25
 permit icmp any 172.28.0.0 255.255.255.255
```

Allowing SMTP (E-mail) and Established TCP Connections: Example

Suppose you have a network connected to the Internet, and you want any host on an Ethernet to be able to form TCP connections to any host on the Internet. However, you do not want IP hosts to be able to form TCP connections to hosts on the Ethernet except to the mail (SMTP) port of a dedicated mail host.

SMTP uses TCP port 25 on one end of the connection and a random port number on the other end. The same two port numbers are used throughout the life of the connection. Mail packets coming in from the Internet will have a destination port of 25. Outbound packets will have the port numbers reversed. The

fact that the secure system behind the router always will accept mail connections on port 25 is what makes possible separate control of incoming and outgoing services. The access list can be configured on either the outbound or inbound interface.

In the following example, the Ethernet network is a Class B network with the address 172.18.0.0, and the address of the mail host is 172.18.1.2. The **established** keyword is used only for the TCP protocol to indicate an established connection. A match occurs if the TCP datagram has the ACK or RST bits set, which indicate that the packet belongs to an existing connection.

```
interface ethernet 0
 ip access-group 102 in
!
access-list 102 permit tcp any 172.18.0.0 0.0.255.255 established
access-list 102 permit tcp any host 172.18.1.2 eq 25
```

Preventing Access to the Web By Filtering on Port Name: Example

In the following example, the Winter and Smith workstations are not allowed web access; other hosts on network 172.20.0.0 are allowed web access:

```
interface ethernet 0
 ip access-group no_web out
!
ip access-list extended no_web
 remark Do not allow Winter to browse the web
 deny host 172.20.3.85 any eq http
 remark Do not allow Smith to browse the web
 deny host 172.20.3.13 any eq http
 remark Allow others on our network to browse the web
 permit 172.20.0.0 0.0.255.255 any eq http
```

Filtering on Source Address and Logging the Packets Permitted and Denied: Example

The following example defines access lists 1 and 2, both of which have logging enabled:

```
interface ethernet 0
 ip address 172.16.1.1 255.0.0.0
 ip access-group 1 in
 ip access-group 2 out
!
access-list 1 permit 172.25.0.0 0.0.255.255 log
access-list 1 deny 172.30.0.0 0.0.255.255 log
!
access-list 2 permit 172.27.3.4 log
access-list 2 deny 172.17.0.0 0.0.255.255 log
```

If the interface receives 10 packets from 172.25.7.7 and 14 packets from 172.17.23.21, the first log will look like the following:

```
list 1 permit 172.25.7.7 1 packet
list 2 deny 172.17.23.21 1 packet
```

Five minutes later, the console will receive the following log:

```
list 1 permit 172.25.7.7 9 packets
list 2 deny 172.17.23.21 13 packets
```

Limiting Debug Output: Example

The following example configuration example uses an access list to limit the **debug** command output displayed. Limiting debug output narrows the volume of data to what you are interested in, saving you time and resources.

```
ip access-list idaho
  remark Displays only advertisements for LDP peer in idaho
  permit host 10.0.0.44

Router# debug mpls ldp advertisements peer-acl idaho

tagcon: peer 10.0.0.44:0 (pp 0x60E105BC): advertise 172.17.0.33
tagcon: peer 10.0.0.44:0 (pp 0x60E105BC): advertise 172.16.0.31
tagcon: peer 10.0.0.44:0 (pp 0x60E105BC): advertise 172.22.0.33
tagcon: peer 10.0.0.44:0 (pp 0x60E105BC): advertise 192.168.0.1
tagcon: peer 10.0.0.44:0 (pp 0x60E105BC): advertise 192.168.0.3
tagcon: peer 10.0.0.44:0 (pp 0x60E105BC): advertise 192.168.1.33
```

Where to Go Next

This module describes how to create an access list that permits or denies packets based on source or destination address or protocol. However, there are other fields you could filter on, and other ways to use access lists. If you want to create an access list that filters on other fields or if you want to apply an access list to something other than an interface, you should decide what you want to restrict in your network and determine the type of access list that achieves your goal.

See the following table for references to other fields to filter and other ways to use an IP access list.

Feature Information for Creating IP Access Lists

[Table 1](#) lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table.

For information on a feature in this technology that is not documented here, see the IP Access List Roadmap.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

[Table 1](#) lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 1 *Feature Information for Creating IP Access Lists*

Feature Name	Releases	Feature Configuration Information
—	Cisco IOS	For information about feature support in Cisco IOS software, use Cisco Feature Navigator.
Commented IP Access List Entries	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.
Standard IP Access List Logging	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values

First Published: August 18, 2006

Last Updated: August 18, 2006

This module describes how to use an IP access list to filter IP packets that contain certain IP Options, TCP flags, noncontiguous ports, or time-to-live (TTL) values.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for Using an IP Access List to Filter Packets](#)” section on page 21.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values

Before you perform any of the tasks in this module, you should be familiar with the information in the following modules:

- “IP Access List Overview”
- “Creating an IP Access List and Applying It to an Interface”

How to Create an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values

This section includes the following optional tasks:

- [Filtering Packets That Contain IP Options, page 2](#)
- [Filtering Packets That Contain TCP Flags, page 5](#)
- [Configuring an Access Control Entry with Noncontiguous Ports, page 8](#)
- [Consolidating Access List Entries with Noncontiguous Ports into One Access List Entry, page 10](#)
- [Filtering Packets Based on TTL Value, page 12](#)
- [Enabling Control Plane Policing to Filter on TTL Values 0 and 1, page 15](#)

Filtering Packets That Contain IP Options

The task in this section configures an access list to filter packets that contain IP Options and verifies that the access list has been configured correctly.

IP Options

IP uses four key mechanisms in providing its service: Type of Service, Time to Live, Options, and Header Checksum.

The Options, commonly referred to as IP Options, provide for control functions that are required in some situations but unnecessary for the most common communications. IP Options include provisions for time stamps, security, and special routing.

IP Options may or may not appear in datagrams. They must be implemented by all IP modules (host and gateways). What is optional is their transmission in any particular datagram, not their implementation. In some environments the security option may be required in all datagrams.

The option field is variable in length. There may be zero or more options. IP Options can have one of two formats:

- Format 1: A single octet of option-type.
- Format 2: An option-type octet, an option-length octet, and the actual option-data octets.

The option-length octet counts the option-type octet, the option-length octet, and the option-data octets.

The option-type octet is viewed as having three fields: a 1-bit copied flag, a 2-bit option class, and a 5-bit option number. These fields form an 8-bit value for the option type field. IP Options are commonly referred to by their 8-bit value.

For a complete list and description of IP Options, refer to RFC 791, *Internet Protocol* at the following URL:

<http://www.faqs.org/rfcs/rfc791.html>

Benefits of Filtering IP Options

- Filtering of packets that contain IP Options from the network relieves downstream routers and hosts of the load from options packets.
- This feature also minimizes load to the Route Processor (RP) for packets with IP Options that require RP processing on distributed systems. Previously, the packets were always routed to or processed by the RP CPU. Filtering the packets prevents them from impacting the RP.

Restrictions

- The ACL Support for Filtering IP Options feature can be used only with named, extended ACLs.
- Resource Reservation Protocol (RSVP) Multiprotocol Label Switching Traffic Engineering (MPLS TE), Internet Group Management Protocol Version 2 (IGMPV2), and other protocols that use IP Options packets may not function in drop or ignore mode if this feature is configured.
- On most Cisco routers, a packet with IP Options is not switched in hardware, but requires control plane software processing (primarily because there is a need to process the options and rewrite the IP header), so all IP packets with IP Options will be filtered and switched in software.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list extended** *access-list-name*
4. [*sequence-number*] **deny** *protocol source source-wildcard destination destination-wildcard* [**option** *option-value*] [**precedence** *precedence*] [**tos** *tos*] [**log**] [**time-range** *time-range-name*] [**fragments**]
5. [*sequence-number*] **permit** *protocol source source-wildcard destination destination-wildcard* [**option** *option-value*] [**precedence** *precedence*] [**tos** *tos*] [**log**] [**time-range** *time-range-name*] [**fragments**]
6. Repeat Step 4 or Step 5 as necessary.
7. **end**
8. **show ip access-lists** *access-list-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list extended <i>access-list-name</i> Example: Router(config)# ip access-list extended mylist1	Specifies the IP access list by name and enters named access list configuration mode. Note The ACL Support for Filtering IP Options feature works only with named, extended ACLs.
Step 4	[<i>sequence-number</i>] deny <i>protocol source source-wildcard destination destination-wildcard</i> [option <i>option-value</i>] [precedence <i>precedence</i>] [tos <i>tos</i>] [log] [time-range <i>time-range-name</i>] [fragments] Example: Router(config-ext-nacl)# deny ip any any option traceroute	(Optional) Specifies a deny statement in named IP access list mode. - This access list happens to use a deny statement first, but a permit statement could appear first, depending on the order of statements you need. - Use the option keyword and <i>option-value</i> argument to filter packets that contain a particular IP Option. - In this example, any packet that contains the traceroute IP Option will be filtered out. - Use the no sequence-number form of this command to delete an entry.
Step 5	[<i>sequence-number</i>] permit <i>protocol source source-wildcard destination destination-wildcard</i> [option <i>option-value</i>] [precedence <i>precedence</i>] [tos <i>tos</i>] [log] [time-range <i>time-range-name</i>] [fragments] Example: Router(config-ext-nacl)# permit ip any any option security	Specifies a permit statement in named IP access list mode. - In this example, any packet (not already filtered) that contains the security IP Option will be permitted. - Use the no sequence-number form of this command to delete an entry.
Step 6	Repeat Step 4 or Step 5 as necessary.	Allows you to revise the access list.
Step 7	end Example: Router(config-ext-nacl)# end	(Optional) Exits the configuration mode and returns to privileged EXEC mode.
Step 8	show ip access-lists <i>access-list-name</i> Example: Router# show ip access-lists mylist1	(Optional) Displays the contents of the IP access list. Review the output to verify that the access list includes the new entry.

What to Do Next

Apply the access list to an interface or reference it from a command that accepts an access list.

Note

To effectively eliminate all packets that contain IP Options, we recommend that you configure the global **ip options drop** command.

Filtering Packets That Contain TCP Flags

The task in this section configures an access list to filter packets that contain TCP flags and verifies that the access list has been configured correctly.

Benefits of Filtering on TCP Flags

The ACL TCP Flags Filtering feature provides a flexible mechanism for filtering on TCP flags. Before Cisco IOS Release 12.3(4)T, an incoming packet was matched as long as any TCP flag in the packet matched a flag specified in the access control entry (ACE). This behavior allows for a security loophole, because packets with all flags set could get past the access control list (ACL). The ACL TCP Flags Filtering feature allows you to select any combination of flags on which to filter. The ability to match on a flag set and on a flag not set gives you a greater degree of control for filtering on TCP flags, thus enhancing security.

Because TCP packets can be sent as false synchronization packets that can be accepted by a listening port, it is recommended that administrators of firewall devices set up some filtering rules to drop false TCP packets.

The ACEs that make up an access list can be configured to detect and drop unauthorized TCP packets by allowing only the packets that have a very specific group of TCP flags set or not set. The ACL TCP Flags Filtering feature gives users a greater degree of packet-filtering control in the following ways:

- Users can select any desired combination of TCP flags on which to filter TCP packets.
- Users can configure ACEs in order to allow matching on a flag that is set, as well as on a flag that is not set.

TCP Flags

[Table 1](#) lists the TCP flags, which are further described in RFC 793, *Transmission Control Protocol*.

Table 1 TCP Flags

TCP Flag	Purpose
ACK	Acknowledge flag—Indicates that the acknowledgment field of a segment specifies the next sequence number the sender of this segment is expecting to receive.
FIN	Finish flag—Used to clear connections.
PSH	Push flag— Indicates the data in the call should be immediately pushed through to the receiving user.
RST	Reset flag—Indicates that the receiver should delete the connection without further interaction.

Table 1 *TCP Flags (continued)*

TCP Flag	Purpose
SYN	Synchronize flag—Used to establish connections.
URG	Urgent flag—Indicates that the urgent field is meaningful and must be added to the segment sequence number.

Restrictions

- TCP flag filtering can be used only with named, extended ACLs.
- The ACL TCP Flags Filtering feature is supported only for Cisco IOS ACLs.
- Before Cisco IOS Release 12.3(4)T, the following command-line interface (CLI) format could be used to configure a TCP flag-checking mechanism:

permit tcp any any rst

The following format that represents the same ACE can be used with Cisco IOS Release 12.3(4)T and later releases:

permit tcp any any match-any +rst

Both the CLI formats are accepted; however, if the new keywords **match-all** or **match-any** are chosen, they must be followed by the new flags that are prefixed with “+” or “-”. It is advisable to use only the old format or the new format in a single ACL. You cannot mix and match the old and new CLI formats.

Caution

If a router having ACEs with the new syntax format is reloaded with an older version of Cisco IOS software that does not support the ACL TCP Flags Filtering feature, the ACEs will not be applied, leading to possible security loopholes.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list extended** *access-list-name*
4. *[sequence-number]* **permit tcp** *source source-wildcard [operator [port]] destination destination-wildcard [operator [port]] [established | {match-any | match-all} {+ | -} flag-name [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]*
5. *[sequence-number]* **deny tcp** *source source-wildcard [operator [port]] destination destination-wildcard [operator [port]] [established | {match-any | match-all} {+ | -} flag-name [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]*
6. Repeat Step 4 or Step 5 as necessary, adding statements by sequence number where you planned. Use the **no sequence-number** command to delete an entry.
7. **end**
8. **show ip access-lists** *access-list-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list extended access-list-name Example: Router(config)# ip access-list extended kmd1	Specifies the IP access list by name and enters named access list configuration mode. Note The ACL TCP Flags Filtering feature works only with named, extended ACLs.
Step 4	[sequence-number] permit tcp source source-wildcard [operator [port]] destination destination-wildcard [operator [port]] [established {match-any match-all} {+ -} flag-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments] Example: Router(config-ext-nacl)# permit tcp any any match-any +rst	Specifies a permit statement in named IP access list mode. - This access list happens to use a permit statement first, but a deny statement could appear first, depending on the order of statements you need. - Use the TCP command syntax of the permit command. - Any packet with the RST TCP header flag set will be matched and allowed to pass the named access list kmd1 in Step 3.
Step 5	[sequence-number] deny tcp source source-wildcard [operator [port]] destination destination-wildcard [operator [port]] [established {match-any match-all} {+ -} flag-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments] Example: Router(config-ext-nacl)# deny tcp any any match-all -ack -fin	(Optional) Specifies a deny statement in named IP access list mode. - This access list happens to use a permit statement first, but a deny statement could appear first, depending on the order of statements you need. - Use the TCP command syntax of the deny command. - Any packet that does not have the ACK flag set, and also does not have the FIN flag set, will not be allowed to pass the named access list kmd1 in Step 3. - See the deny (IP) command for additional command syntax to permit upper-layer protocols (ICMP, IGMP, TCP, and UDP).
Step 6	Repeat Step 4 or Step 5 as necessary, adding statements by sequence number where you planned. Use the no sequence-number command to delete an entry.	Allows you to revise the access list.

	Command or Action	Purpose
Step 7	end Example: Router(config-ext-nacl)# end	(Optional) Exits the configuration mode and returns to privileged EXEC mode.
Step 8	show ip access-lists <i>access-list-name</i> Example: Router# show ip access-lists kmd1	(Optional) Displays the contents of the IP access list. Review the output to confirm that the access list includes the new entry.

What to Do Next

Apply the access list to an interface or reference it from a command that accepts an access list.

Configuring an Access Control Entry with Noncontiguous Ports

Perform this task to create access list entries that use noncontiguous TCP or UDP port numbers. Although this task uses TCP ports, you could use the UDP syntax of the **permit** and **deny** commands to filter noncontiguous UDP ports.

Although this task uses a **permit** command first, use the **permit** and **deny** commands in the order that achieves your filtering goals.

Benefits of Using the ACL—Named ACL Support for Noncontiguous Ports on an Access Control Entry Feature

This feature greatly reduces the number of ACEs required in an access control list to handle multiple entries for the same source address, destination address, and protocol. If you maintain large numbers of ACEs, we recommend that you use this feature to consolidate existing groups of access list entries wherever it is possible and also when you create new access list entries. When you configure access list entries with noncontiguous ports, you will have fewer access list entries to maintain.

Restrictions

The ACL—Named ACL Support for Noncontiguous Ports on an Access Control Entry feature can be used only with named, extended ACLs.

SUMMARY STEPS

- enable**
- configure terminal**
- ip access-list extended** *access-list-name*
- [*sequence-number*] **permit tcp** *source source-wildcard* [*operator port* [*port*]] *destination destination-wildcard* [*operator* [*port*]] [**established** | {**match-any** | **match-all**} {+ | -} *flag-name*] [**precedence** *precedence*] [**tos** *tos*] [**log**] [**time-range** *time-range-name*] [**fragments**]

5. `[sequence-number] deny tcp source source-wildcard [operator port [port]] destination destination-wildcard [operator [port]] [established | {match-any | match-all} {+ | -} flag-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]`
6. Repeat Step 4 or Step 5 as necessary, adding statements by sequence number where you planned. Use the **no** `sequence-number` command to delete an entry.
7. **end**
8. **show ip access-lists** *access-list-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list extended <i>access-list-name</i> Example: Router(config)# ip access-list extended kmd1	Specifies the IP access list by name and enters named access list configuration mode.
Step 4	<code>[sequence-number] permit tcp source source-wildcard [operator port [port]] destination destination-wildcard [operator [port]] [established {match-any match-all} {+ -} flag-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]</code> Example: Router(config-ext-nacl)# permit tcp any eq telnet ftp any eq 450 679	Specifies a permit statement in named IP access list configuration mode. - Operators include lt (less than), gt (greater than), eq (equal), neq (not equal), and range (inclusive range). - If the operator is positioned after the source and source-wildcard arguments, it must match the source port. If the operator is positioned after the destination and destination-wildcard arguments, it must match the destination port. - The range operator requires two port numbers. You can configure up to 10 ports after the eq and neq operators. All other operators require one port number. - To filter UDP ports, use the UDP syntax of this command.

	Command or Action	Purpose
Step 5	<pre>[sequence-number] deny tcp source source-wildcard [operator port [port]] destination destination-wildcard [operator [port]] [established {match-any match-all} {+ -} flag-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]</pre> Example: Router(config-ext-nacl)# deny tcp any neq 45 565 632	(Optional) Specifies a deny statement in named access list configuration mode. - Operators include lt (less than), gt (greater than), eq (equal), neq (not equal), and range (inclusive range). - If the <i>operator</i> is positioned after the <i>source</i> and <i>source-wildcard</i> arguments, it must match the source port. If the <i>operator</i> is positioned after the <i>destination</i> and <i>destination-wildcard</i> arguments, it must match the destination port. - The range operator requires two port numbers. You can configure up to 10 ports after the eq and neq operators. All other operators require one port number. - To filter UDP ports, use the UDP syntax of this command.
Step 6	Repeat Step 4 or Step 5 as necessary, adding statements by sequence number where you planned. Use the no sequence-number command to delete an entry.	Allows you to revise the access list.
Step 7	end Example: Router(config-ext-nacl)# end	(Optional) Exits named access list configuration mode and returns to privileged EXEC mode.
Step 8	<pre>show ip access-lists access-list-name</pre> Example: Router# show ip access-lists kmd1	(Optional) Displays the contents of the access list. Review the output to verify that the access list displays the new entries that you created.

Consolidating Access List Entries with Noncontiguous Ports into One Access List Entry

Perform this task to consolidate a group of access list entries with noncontiguous ports into one access list entry.

Although this task uses TCP ports, you could use the UDP syntax of the **permit** and **deny** commands to filter noncontiguous UDP ports.

Although this task uses a **permit** command first, use the **permit** and **deny** commands in the order that achieves your filtering goals.

SUMMARY STEPS

1. **enable**
2. **show ip access-lists** *access-list-name*
3. **configure terminal**
4. **ip access-list extended** *access-list-name*

5. **no** *[sequence-number]* **permit** *protocol source source-wildcard destination destination-wildcard* [**option** *option-name*] [**precedence** *precedence*] [**tos** *tos*] [**log**] [**time-range** *time-range-name*] [**fragments**]
6. *[sequence-number]* **permit** *protocol source source-wildcard* [*operator port [port]*] *destination destination-wildcard* [*operator port [port]*] [**option** *option-name*] [**precedence** *precedence*] [**tos** *tos*] [**log**] [**time-range** *time-range-name*] [**fragments**]
7. Repeat Steps 5 and 6 as necessary, adding **permit** or **deny** statements to consolidate access list entries where possible. Use the **no sequence-number** command to delete an entry.
8. **end**
9. **show ip access-lists** *access-list-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	show ip access-lists <i>access-list-name</i> Example: Router# show ip access-lists mylist1	(Optional) Displays the contents of the IP access list. Review the output to see if you can consolidate any access list entries.
Step 3	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 4	ip access-list extended <i>access-list-name</i> Example: Router(config)# ip access-list extended mylist1	Specifies the IP access list by name and enters named access list configuration mode.
Step 5	no <i>[sequence-number]</i> permit <i>protocol source source-wildcard destination destination-wildcard</i> [option <i>option-name</i>] [precedence <i>precedence</i>] [tos <i>tos</i>] [log] [time-range <i>time-range-name</i>] [fragments] Example: Router(config-ext-nacl)# no 10	Removes the redundant access list entry that can be consolidated. - Repeat this step to remove entries to be consolidated because only the port numbers differ. - After this step is repeated to remove the access list entries 20, 30, and 40, for example, those entries are removed because they will be consolidated into one permit statement. - If a <i>sequence-number</i> is specified, the rest of the command syntax is optional.

	Command or Action	Purpose
Step 6	<code>[sequence-number] permit protocol source source-wildcard [operator port [port]] destination destination-wildcard [operator port [port]] [option option-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]</code> Example: Router(config-ext-nacl)# permit tcp any neq 45 565 632 any eq 23 45 34 43	Specifies a permit statement in named access list configuration mode. - In this instance, a group of access list entries with noncontiguous ports was consolidated into one permit statement. - You can configure up to 10 ports after the eq and neq operators.
Step 7	Repeat Steps 5 and 6 as necessary, adding permit or deny statements to consolidate access list entries where possible. Use the no sequence-number command to delete an entry.	Allows you to revise the access list.
Step 8	end Example: Router(config-std-nacl)# end	(Optional) Exits named access list configuration mode and returns to privileged EXEC mode.
Step 9	show ip access-lists access-list-name Example: Router# show ip access-lists mylist1	(Optional) Displays the contents of the access list. Review the output to verify that the redundant access list entries have been replaced with your new consolidated entries.

What To Do Next

Apply the access list to an interface or reference it from a command that accepts an access list.

Filtering Packets Based on TTL Value

Because access lists are very flexible, it is not possible to define only one combination of **permit** and **deny** commands to filter packets based on the TTL value. This task illustrates just one example that achieves TTL filtering. Configure the appropriate **permit** and **deny** statements that will accomplish your filtering plan.

How Filtering on TTL Works

IP extended named and numbered access lists may filter on the TTL value of packets arriving at or leaving an interface. Packets with any possible TTL values 0 through 255 may be permitted or denied (filtered). Like filtering on other fields, such as source or destination address, the **ip access-group** command specifies **in** or **out**, which makes the access list ingress or egress and applies it to incoming or outgoing packets, respectively. The TTL value is checked in conjunction with the specified protocol, application, and any other settings in the access list entry, and all conditions must be met.

Special Handling for Packets with TTL of 0 or 1 Arriving on Ingress Interface

The software switching paths—distributed Cisco Express Forwarding (dCEF), CEF, fast switching, and process switching—will usually permit or discard the packets based on the access list statements. However, when the TTL value of packets arriving on an *ingress* interface have a TTL of 0 or 1, special

handling is required. The packets with a TTL of 0 or 1 get sent to the process level before the ingress access list is checked in CEF, dCEF, or fast switching paths. The ingress access list is applied to packets with TTL values 2 through 255 and a permit or deny decision is made.

Packets with a TTL value of 0 or 1 are sent to the process level because they will never be forwarded out of the device; the process level must check whether each packet is destined for the router or not and whether an Internet Control Message Protocol (ICMP) TTL Expire message needs to be sent back or not. This means that even if an ACL with TTL value 0 or 1 filtering is configured on the ingress interface with the intention to drop packets with a TTL of 0 or 1, the dropping of the packets will not happen in the faster paths. It will instead happen in the process level when the process applies the ACL. This is also true for hardware switching platforms. Packets with TTL 0 or 1 are sent to the process level of the route processor (RP) or Multilayer Switch Feature Card (MSFC).

On egress interfaces, access list filtering on TTL work just like other access list features. The check will happen in the fastest switching path enabled in the device. This is because the faster switching paths handle all the TTL values (0-255) equally on the egress interface.

Control Plane Policing for Filtering TTL Values 0 and 1

The special behavior for packets with a TTL of 0 or 1 results in higher CPU usage for the device. If you are filtering on TTL value 0 or 1, you should use control plane policing (CPP) to protect the CPU from being overwhelmed. In order to leverage CPP, you must configure an access list especially for filtering TTL values 0 and 1 and apply the access list through CPP. This access list will be a separate access list from any interface access lists. Because CPP works for the entire system, not just on individual interfaces, you would need to configure only one such special access list for the entire device. This task is described in the section [“Enabling Control Plane Policing to Filter on TTL Values 0 and 1”](#) section on page 15.

Benefits of Filtering on TTL

- Filtering on TTL provides a way to control which packets are allowed to reach the router or prevented from reaching the router. By looking at your network layout, you can choose whether to accept or deny packets from a certain router based on how many hops away it is. For example, in a small network, you can deny packets from a location more than three hops away. Filtering on TTL allows you to validate if the traffic originated from a neighboring device, as follows. You can accept only packets that reach you in one hop, for example, by accepting only packets with a TTL of one less than the initial TTL value of a particular protocol.
- Many control plane protocols communicate only with their neighbors, but receive packets from everyone. By applying to receiving routers an access list that filters on TTL, you can block unwanted packets.
- The Cisco IOS software sends all packets with a TTL of 0 or 1 to the process level to be processed. The device must then send an ICMP TTL expire message to the source. By filtering packets that have a TTL of 0 through 2, you can reduce the load on the process level.

Restrictions

- When the access list specifies the operation EQ or NEQ, routers running Cisco IOS Release 12.2S can have that access list specify up to ten TTL values. However, for Release 12.0S, only one TTL value can be specified.

SUMMARY STEPS

1. **enable**

2. **configure terminal**
3. **ip access-list extended** *access-list-name*
4. [*sequence-number*] **permit** *protocol source source-wildcard destination destination-wildcard* [**option** *option-name*] [**precedence** *precedence*] [**tos** *tos*] [**ttl** *operator value*] [**log**] [**time-range** *time-range-name*] [**fragments**]
5. Continue to add **permit** or **deny** statements to achieve the filtering you want.
6. **exit**
7. **interface** *type number*
8. **ip access-group** *access-list-name* {**in** | **out**}

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list extended <i>access-list-name</i> Example: Router(config)# ip access-list extended ttlfilter	Defines an IP access list by name. An access list that filters on TTL value must be an extended access list.
Step 4	[<i>sequence-number</i>] permit <i>protocol source source-wildcard destination destination-wildcard</i> [option <i>option-name</i>] [precedence <i>precedence</i>] [tos <i>tos</i>] [ttl <i>operator value</i>] [log] [time-range <i>time-range-name</i>] [fragments] Example: Router(config-ext-nacl)# permit ip host 172.16.1.1 any ttl lt 2	Sets conditions to allow a packet to pass a named IP access list. - Every access list must have at least one permit statement. - This example permits packets from source 172.16.1.1 to any destination with a TTL value less than 2.
Step 5	Continue to add permit or deny statements to achieve the filtering you want.	—
Step 6	exit Example: Router(config-ext-nacl)# exit	Exits any configuration mode to the next highest mode in the CLI mode hierarchy.

	Command or Action	Purpose
Step 7	<code>interface type number</code> Example: Router(config)# interface ethernet 0	Configures an interface type and enters interface configuration mode.
Step 8	<code>ip access-group access-list-name {in out}</code> Example: Router(config-if)# ip access-group ttlfilter in	Applies the access list to an interface.

Enabling Control Plane Policing to Filter on TTL Values 0 and 1

Perform this task if you want to filter IP packets based on a TTL value of 0 or 1 and you want to protect the CPU from being overwhelmed. This task configures an access list for classification on TTL 0 and 1, configures Modular QoS CLI (MQC), and applies the policy map to the control plane. Any packets that pass the access list are dropped. This special access list is separate from any interface access lists.

Because access lists are very flexible, it is not possible to define only one combination of **permit** and **deny** commands to filter packets based on the TTL value. This task illustrates just one example that achieves TTL filtering. Configure the appropriate **permit** and **deny** statements that will accomplish your filtering plan.

SUMMARY STEPS

- enable**
- configure terminal**
- ip access-list extended** *access-list-name*
- [sequence-number]* **permit** *protocol source source-wildcard destination destination-wildcard ttl operator value*
- Continue to add **permit** or **deny** statements to achieve the filtering you want.
- exit**
- class-map** *class-map-name* [match-all | match-any]
- match** access-group {*access-group* | name *access-group-name*}
- exit**
- policy-map** *policy-map-name*
- class** {*class-name* | class-default}
- drop**
- exit**
- exit**
- control-plane**
- service-policy** {input | output} *policy-map-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list extended <i>access-list-name</i> Example: Router(config)# ip access-list extended ttlfilter	Defines an IP access list by name. An access list that filters on a TTL value must be an extended access list.
Step 4	[<i>sequence-number</i>] permit <i>protocol source source-wildcard destination destination-wildcard</i> tcl <i>operator value</i> Example: Router(config-ext-nacl)# permit ip host 172.16.1.1 any tcl lt 2	Sets conditions to allow a packet to pass a named IP access list. - Every access list must have at least one permit statement. - This example permits packets from source 172.16.1.1 to any destination with a TTL value less than 2.
Step 5	Continue to add permit or deny statements to achieve the filtering you want.	The packets that pass the access list will be dropped.
Step 6	exit Example: Router(config-ext-nacl)# exit	Exits any configuration mode to the next highest mode in the CLI mode hierarchy.
Step 7	class-map <i>class-map-name</i> [match-all match-any] Example: Router(config)# class-map acl-filtering	Creates a class map to be used for matching packets to a specified class.
Step 8	match access-group { <i>access-group</i> name <i>access-group-name</i> } Example: Router(config-cmap)# match access-group name ttlfilter	Configures the match criteria for a class map on the basis of the specified access control list.
Step 9	exit Example: Router(config-cmap)# exit	Exits any configuration mode to the next highest mode in the CLI mode hierarchy.

	Command or Action	Purpose
Step 10	policy-map <i>policy-map-name</i> Example: Router(config)# policy-map acl-filter	Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.
Step 11	class { <i>class-name</i> class-default } Example: Router(config-pmap)# class acl-filter-class	Specifies the name of the class whose policy you want to create or change or to specify the default class (commonly known as the class-default class) before you configure its policy.
Step 12	drop Example: Router(config-pmap-c)# drop	Configures a traffic class to discard packets belonging to a specific class.
Step 13	exit Example: Router(config-pmap-c)# exit	Exits any configuration mode to the next highest mode in the CLI mode hierarchy.
Step 14	exit Example: Router(config-pmap)# exit	Exits any configuration mode to the next highest mode in the CLI mode hierarchy.
Step 15	control-plane Example: Router(config)# control-plane	Associates or modifies attributes or parameters that are associated with the control plane of the device.
Step 16	service-policy { input output } <i>policy-map-name</i> Example: Router(config-cp)# service-policy input acl-filter	Attaches a policy map to a control plane for aggregate control plane services.

Configuration Examples for Filtering IP Options, TCP Flags, Noncontiguous Ports, and TTL Values

- This section provides the following configuration examples:
- [Filtering Packets That Contain IP Options: Example, page 18](#)
 - [Filtering Packets That Contain TCP Flags: Example, page 18](#)
 - [Creating an Access List Entry with Noncontiguous Ports: Example, page 18](#)
 - [Consolidating Some Existing Access List Entries into One Access List Entry with Noncontiguous Ports: Example, page 19](#)
 - [Filtering on TTL Value: Example, page 19](#)
 - [Control Plane Policing to Filter on TTL Values 0 and 1: Example, page 20](#)

Filtering Packets That Contain IP Options: Example

The following example shows an extended access list named `mylist2` that contains access list entries (ACEs) that are configured to permit TCP packets only if they contain the IP Options that are specified in the ACEs:

```
ip access-list extended mylist2
 10 permit ip any any option eool
 20 permit ip any any option record-route
 30 permit ip any any option zsu
 40 permit ip any any option mtup
```

The **show access-list** command has been entered to show how many packets were matched and therefore permitted:

```
Router# show ip access-list mylist2

Extended IP access list test
10 permit ip any any option eool (1 match)
20 permit ip any any option record-route (1 match)
30 permit ip any any option zsu (1 match)
40 permit ip any any option mtup (1 match)
```

Filtering Packets That Contain TCP Flags: Example

The following access list allows TCP packets only if the TCP flags ACK and SYN are set and the FIN flag is not set:

```
ip access-list extended aaa
 permit tcp any any match-all +ack +syn -fin
end
```

The **show access-list** command has been entered to display the ACL:

```
Router# show access-list aaa

Extended IP access list aaa
 10 permit tcp any any match-all +ack +syn -fin
```

Creating an Access List Entry with Noncontiguous Ports: Example

The following access list entry can be created because up to ten ports can be entered after the **eq** and **neq** operators:

```
ip access-list extended aaa
 permit tcp any eq telnet ftp any eq 23 45 34
end
```

Enter the **show access-lists** command to display the newly created access list entry.

```
Router# show access-lists aaa

Extended IP access list aaa
 10 permit tcp any eq telnet ftp any eq 23 45 34
```

Consolidating Some Existing Access List Entries into One Access List Entry with Noncontiguous Ports: Example

The **show access-lists** command is used to display a group of access list entries for the access list named abc:

```
Router# show access-lists abc
```

```
Extended IP access list abc
 10 permit tcp any eq telnet any eq 450
 20 permit tcp any eq telnet any eq 679
 30 permit tcp any eq ftp any eq 450
 40 permit tcp any eq ftp any eq 679
```

Because the entries are all for the same **permit** statement and simply show different ports, they can be consolidated into one new access list entry. The following example shows the removal of the redundant access list entries and the creation of a new access list entry that consolidates the previously displayed group of access list entries:

```
ip access-list extended abc
 no 10
 no 20
 no 30
 no 40
 permit tcp any eq telnet ftp any eq 450 679
end
```

When the **show access-lists** command is reentered, the consolidated access list entry is displayed:

```
Router# show access-lists abc
```

```
Extended IP access list abc
 10 permit tcp any eq telnet ftp any eq 450 679
```

Filtering on TTL Value: Example

The following access list filters IP packets containing type of service (ToS) level 3 with TTL values 10 and 20. It also filters IP packets with a TTL greater than 154 and applies that rule to noninitial fragments. It permits IP packets with a precedence level of flash and a TTL not equal to 1, and it sends log messages about such packets to the console. All other packets are denied.

```
ip access-list extended incomingfilter
 deny ip any any tos 3 ttl eq 10 20
 deny ip any any ttl gt 154 fragments
 permit ip any any precedence flash ttl neq 1 log
!
interface ethernet 0
ip access-group incomingfilter in
```

Control Plane Policing to Filter on TTL Values 0 and 1: Example

The following example configures a traffic class called `acl-filter-class` for use in a policy map called `acl-filter`. An access list permits IP packets from any source having a TTL of 0 or 1. Any packets matching the access list are dropped. The policy map is attached to the control plane.

```
ip access-list extended ttlfilter
  permit ip any any ttl eq 0 1
class-map acl-filter-class
  match access-group name ttlfilter
policy-map acl-filter
  class acl-filter-class
    drop
control-plane
  service-policy input acl-filter
```

Feature Information for Using an IP Access List to Filter Packets

Table 2 lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table.

Not all commands may be available in your Cisco IOS software release. For details on when support for a specific command was introduced, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

**Note**

Table 2 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 2 *Feature Information for Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values*

Feature Name	Releases	Feature Configuration Information
ACL Support for Filtering IP Options	12.3(4)T 12.2(25)S	This feature allows you to filter packets having IP Options, in order to prevent routers from becoming saturated with spurious packets. See the following sections: • Filtering Packets That Contain IP Options, page 2 • Filtering Packets That Contain IP Options: Example, page 18
ACL TCP Flags Filtering	12.3(4)T 12.2(25)S	This feature provides a flexible mechanism for filtering on TCP flags. Before Cisco IOS Release 12.3(4)T, an incoming packet was matched as long as any TCP flag in the packet matched a flag specified in the access control entry (ACE). This behavior allows for a security loophole, because packets with all flags set could get past the access control list (ACL). The ACL TCP Flags Filtering feature allows you to select any combination of flags on which to filter. The ability to match on a flag set and on a flag not set gives you a greater degree of control for filtering on TCP flags, thus enhancing security. See the following sections: • Filtering Packets That Contain TCP Flags, page 5 • Filtering Packets That Contain TCP Flags: Example, page 18
ACL—Named ACL Support for Noncontiguous Ports on an Access Control Entry	12.3(7)T 12.2(25)S	This feature allows you to specify noncontiguous ports in a single access control entry, which greatly reduces the number of entries required in an access control list when several entries have the same source address, destination address, and protocol, but differ only in the ports. See the following sections: • Configuring an Access Control Entry with Noncontiguous Ports, page 8 • Consolidating Access List Entries with Noncontiguous Ports into One Access List Entry, page 10 • Creating an Access List Entry with Noncontiguous Ports: Example, page 18 • Consolidating Some Existing Access List Entries into One Access List Entry with Noncontiguous Ports: Example, page 19

Table 2 *Feature Information for Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values (continued)*

Feature Name	Releases	Feature Configuration Information
ACL Support for Filtering on TTL Value	12.4(2)T	Customers may use extended IP access lists (named or numbered) to filter packets based on their time-to-live (TTL) value, from 0 to 255. This filtering enhances a customer's control over which packets reach a router. See the following sections: • Filtering Packets Based on TTL Value, page 12 • Enabling Control Plane Policing to Filter on TTL Values 0 and 1, page 15 • Filtering on TTL Value: Example, page 19 • Control Plane Policing to Filter on TTL Values 0 and 1: Example, page 20
ACL - Named ACL Support for Noncontiguous Ports on an Access Control Entry	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.
ACL - TCP Flags Filtering	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.
ACL Support for Filtering IP Options	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.
Selective Drop/ Ignore of IP Options	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

Refining an IP Access List

First Published: August 18, 2006

Last Updated: August 18, 2006

There are several ways to refine an access list while or after you create it. You can change the order of the entries in an access list or add entries to an access list. You can restrict access list entries to a certain time of day or week, or achieve finer granularity when filtering packets by filtering noninitial fragments of packets.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for Refining an IP Access List”](#) section on page 19.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Refining an IP Access List

Before you perform any of the tasks in this module, you should be familiar with the concepts in the “IP Access List Overview” module.

Americas Headquarters:

Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

Information About Refining an IP Access List

You should understand the following concept before configuring an IP access list with sequence numbers:

- [Access List Sequence Numbers, page 2](#)

Access List Sequence Numbers

The ability to apply sequence numbers to IP access list entries simplifies access list changes. Prior to the IP Access List Entry Sequence Numbering feature, there was no way to specify the position of an entry within an access list. If you wanted to insert an entry in the middle of an existing list, all of the entries after the desired position had to be removed, then the new entry was added, and then all the removed entries had to be reentered. This method was cumbersome and error prone.

Sequence numbers allow users to add access list entries and resequence them. When you add a new entry, you specify the sequence number so that it is in a desired position in the access list. If necessary, entries currently in the access list can be resequenced to create room to insert the new entry.

How to Refine an IP Access List

The tasks in this module provide you with various ways to refine an access list if you did not already do so while you were creating it. You can change the order of the entries in an access list, add entries to an access list, restrict access list entries to a certain time of day or week, or achieve finer granularity when filtering packets by filtering on noninitial fragments of packets.

This section includes the following tasks:

- [Revising an Access List Using Sequence Numbers, page 2](#) (optional)
- [Restricting an Access List Entry to a Time of Day or Week, page 6](#) (optional)
- [Filtering Noninitial Fragments of Packets, page 11](#) (optional)

Revising an Access List Using Sequence Numbers

Perform this task if you want to add entries to an existing access list, change the order of entries, or simply number the entries in an access list to accommodate future changes.

Note

Remember that if you want to delete an entry from an access list, you can simply use the **no deny** or **no permit** form of the command, or the **no sequence-number** command if the statement already has a sequence number.

Benefits of Access List Sequence Numbers

An access list sequence number is a number at the beginning of a **permit** or **deny** command in an access list. The sequence number determines the order that the entry appears in the access list. The ability to apply sequence numbers to IP access list entries simplifies access list changes.

Prior to having sequence numbers, users could only add access list entries to the end of an access list; therefore, needing to add statements anywhere except the end of the list required reconfiguring the entire access list. There was no way to specify the position of an entry within an access list. If a user wanted to insert an entry (statement) in the middle of an existing list, all of the entries after the desired position had to be removed, then the new entry was added, and then all the removed entries had to be reentered. This method was cumbersome and error prone.

This feature allows users to add sequence numbers to access list entries and resequence them. When a user adds a new entry, the user chooses the sequence number so that it is in a desired position in the access list. If necessary, entries currently in the access list can be resequenced to create room to insert the new entry. Sequence numbers make revising an access list much easier.

Sequence Numbering Behavior

- For backward compatibility with previous releases, if entries with no sequence numbers are applied, the first entry is assigned a sequence number of 10, and successive entries are incremented by 10. The maximum sequence number is 2147483647. If the generated sequence number exceeds this maximum number, the following message is displayed:
Exceeded maximum sequence number.
- If the user enters an entry without a sequence number, it is assigned a sequence number that is 10 greater than the last sequence number in that access list and is placed at the end of the list.
- If the user enters an entry that matches an already existing entry (except for the sequence number), then no changes are made.
- If the user enters a sequence number that is already present, the following error message is generated:
Duplicate sequence number.
- If a new access list is entered from global configuration mode, then sequence numbers for that access list are generated automatically.
- Distributed support is provided so that the sequence numbers of entries in the Route Processor (RP) and line card are in synchronization at all times.
- Sequence numbers are not nvgened. That is, the sequence numbers themselves are not saved. In the event that the system is reloaded, the configured sequence numbers revert to the default sequence starting number and increment. The function is provided for backward compatibility with software releases that do not support sequence numbering.
- This feature works with named and numbered, standard and extended IP access lists.

Restrictions

- Access list sequence numbers do not support dynamic, reflexive, or firewall access lists.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list resequence** *access-list-name starting-sequence-number increment*
4. **ip access-list {standard | extended}** *access-list-name*
5. *sequence-number permit source source-wildcard*

or

sequence-number **permit** *protocol source source-wildcard destination destination-wildcard*
[**precedence** *precedence*] [**tos** *tos*] [**log**] [**time-range** *time-range-name*] [**fragments**]

6. *sequence-number* **deny** *source source-wildcard*

or

sequence-number **deny** *protocol source source-wildcard destination destination-wildcard*
[**precedence** *precedence*] [**tos** *tos*] [**log**] [**time-range** *time-range-name*] [**fragments**]

7. Repeat Step 5 and Step 6 as necessary, adding statements by sequence number where you planned. Use the **no** *sequence-number* command to delete an entry.
8. **end**
9. **show ip access-lists** *access-list-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list resequence <i>access-list-name</i> <i>starting-sequence-number</i> <i>increment</i> Example: Router(config)# ip access-list resequence kmd1 100 15	Resequences the specified IP access list using the starting sequence number and the increment of sequence numbers. This example resequences an access list named kmd1. The starting sequence number is 100 and the increment is 15.
Step 4	ip access-list {standard extended} <i>access-list-name</i> Example: Router(config)# ip access-list standard xyz123	Specifies the IP access list by name and enters named access list configuration mode. - If you specify standard, make sure you specify subsequent permit and deny statements using the standard access list syntax. - If you specify extended, make sure you specify subsequent permit and deny statements using the extended access list syntax.
Step 5	<i>sequence-number</i> permit <i>source</i> <i>source-wildcard</i> or <i>sequence-number</i> permit <i>protocol</i> <i>source</i> <i>source-wildcard</i> <i>destination</i> <i>destination-wildcard</i> [precedence <i>precedence</i>] [tos <i>tos</i>] [log] [time-range <i>time-range-name</i>] [fragments] Example: Router(config-std-nacl)# 105 permit 10.5.5.5 0.0.0.255	Specifies a permit statement in named IP access list mode. - This access list happens to use a permit statement first, but a deny statement could appear first, depending on the order of statements you need. - See the permit (IP) command for additional command syntax to permit upper layer protocols (ICMP, IGMP, TCP, and UDP). - Use the no <i>sequence-number</i> command to delete an entry. - As the prompt indicates, this access list was a standard access list. If you had specified extended in Step 4, the prompt for this step would be Router(config-ext-nacl)# and you would use the extended permit command syntax.

	Command or Action	Purpose
Step 6	<code>sequence-number deny source source-wildcard</code> or <code>sequence-number deny protocol source source-wildcard destination destination-wildcard [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]</code> Example: Router(config-std-nacl)# 110 deny 10.6.6.7 0.0.0.255	(Optional) Specifies a deny statement in named IP access list mode. - This access list happens to use a permit statement first, but a deny statement could appear first, depending on the order of statements you need. - See the deny (IP) command for additional command syntax to permit upper layer protocols (ICMP, IGMP, TCP, and UDP). - Use the no sequence-number command to delete an entry. - As the prompt indicates, this access list was a standard access list. If you had specified extended in Step 4, the prompt for this step would be Router(config-ext-nacl)# and you would use the extended deny command syntax.
Step 7	Repeat Step 5 and Step 6 as necessary, adding statements by sequence number where you planned. Use the no sequence-number command to delete an entry.	Allows you to revise the access list.
Step 8	end Example: Router(config-std-nacl)# end	(Optional) Exits the configuration mode and returns to privileged EXEC mode.
Step 9	show ip access-lists access-list-name Example: Router# show ip access-lists xyz123	(Optional) Displays the contents of the IP access list. Review the output to see that the access list includes the new entry.

Examples

The following is sample output from the **show ip access-lists** command when the **xyz123** access list is specified.

```
Router# show ip access-lists xyz123
```

```
Standard IP access list xyz123
100 permit 10.4.4.0, wildcard bits 0.0.0.255
105 permit 10.5.5.5, wildcard bits 0.0.0.255
115 permit 10.0.0.0, wildcard bits 0.0.0.255
130 permit 10.5.5.0, wildcard bits 0.0.0.255
145 permit 10.0.0.0, wildcard bits 0.0.0.255
```

Restricting an Access List Entry to a Time of Day or Week

By default, access list statements are always in effect once they are applied. However, you can define the times of the day or week that **permit** or **deny** statements are in effect by defining a time range, and then referencing the time range by name in an individual access list statement. IP and Internetwork Packet Exchange (IPX) named or numbered extended access lists can use time ranges.

Benefits of Time Ranges

Benefits and possible uses of time ranges include the following:

- The network administrator has more control over permitting or denying a user access to resources. These resources could be an application (identified by an IP address/mask pair and a port number), policy routing, or an on-demand link (identified as interesting traffic to the dialer).
- Network administrators can set time-based security policy, including the following:
 - Perimeter security using the Cisco IOS Firewall feature set or access lists
 - Data confidentiality with Cisco Encryption Technology or IP Security Protocol (IPSec)
- Policy-based routing (PBR) and queueing functions are enhanced.
- When provider access rates vary by time of day, it is possible to automatically reroute traffic cost effectively.
- Service providers can dynamically change a committed access rate (CAR) configuration to support the quality of service (QoS) service level agreements (SLAs) that are negotiated for certain times of day.
- Network administrators can control logging messages. Access list entries can log traffic at certain times of the day, but not constantly. Therefore, administrators can simply deny access without needing to analyze many logs generated during peak hours.

Distributed Time-Based Access Lists

Before the introduction of the Distributed Time-Based Access Lists feature, time-based access lists were not supported on line cards for the Cisco 7500 series routers. If time-based access lists were configured, they behaved as normal access lists. If an interface on a line card were configured with a time-based access list, the packets switched into the interface were not distributed switched through the line card, but were forwarded to the Route Processor for processing.

The Distributed Time-Based Access Lists feature allows packets destined for an interface configured with a time-based access list to be distributed switched through the line card.

For this functionality to work, the software clock must remain synchronized between the Route Processor and the line card. This synchronization occurs through an exchange of interprocess communications (IPC) messages from the Route Processor to the line card. When a time range or a time-range entry is changed, added, or deleted, an IPC message is sent by the Route Processor to the line card.

There is no difference between how the user configures a time-based access list and a distributed time-based access list.

Prerequisites

The time range relies on the software clock of the routing device. For the time range feature to work the way you intend, you need a reliable clock source. We recommend that you use Network Time Protocol (NTP) to synchronize the software clock of the routing device.

Restrictions

The Distributed Time-Based Access Lists feature is supported on Cisco 7500 series routers with a Versatile Interface Processor (VIP) enabled.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **time-range** *time-range-name*
4. **periodic** *days-of-the-week hh:mm to [days-of-the-week] hh:mm*
5. Repeat Step 4 if you want more than one period of time applied to an access list statement.
6. **absolute** [*start time date*] [*end time date*]
7. **exit**
8. Repeat Steps 3 through 7 if you want different time ranges to apply to **permit** or **deny** statements.
9. **ip access-list extended** *name*
10. **deny** *protocol source [source-wildcard] destination [destination-wildcard] [option option-name] [precedence precedence] [tos tos] [established] [log | log-input] time-range time-range-name*
11. **permit** *protocol source [source-wildcard] destination [destination-wildcard] [option option-name] [precedence precedence] [tos tos] [established] [log | log-input] time-range time-range-name*
12. Optionally repeat some combination of Steps 10 and 11 until you have specified the values on which you want to base your access list.
13. **end**
14. **show ip access-list**
15. **show time-range**
16. **show time-range ipc**
17. **clear time-range ipc**
18. **debug time-range ipc**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	time-range <i>time-range-name</i> Example: Router(config)# time-range limit_http	Defines a time range and enters time-range configuration mode. - The name cannot contain a space or quotation mark, and must begin with a letter. - Multiple time ranges can occur in a single access list.
Step 4	periodic <i>days-of-the-week hh:mm to [days-of-the-week] hh:mm</i> Example: Router(config-time-range)# periodic Monday 6:00 to Wednesday 19:00	(Optional) Specifies a recurring (weekly) time range. - The first occurrence of <i>days-of-the-week</i> is the starting day or day of the week that the associated time range is in effect. The second occurrence is the ending day or day of the week the associated statement is in effect. - The <i>days-of-the-week</i> argument can be any single day or combinations of days: Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, and Sunday. Other possible values are: daily—Monday through Sunday weekdays—Monday through Friday weekend—Saturday and Sunday - If the ending days of the week are the same as the starting days of the week, they can be omitted. - The first occurrence of <i>hh:mm</i> is the starting hours:minutes that the associated time range is in effect. The second occurrence is the ending hours:minutes the associated statement is in effect. - The hours:minutes are expressed in a 24-hour clock. For example, 8:00 is 8:00 a.m. and 20:00 is 8:00 p.m.
Step 5	Repeat Step 4 if you want more than one period of time applied to an access list statement.	(Optional) Multiple periodic commands are allowed in a time range.

	Command or Action	Purpose
Step 6	absolute <i>[start time date]</i> <i>[end time date]</i> Example: Router(config-time-range)# absolute start 6:00 1 August 2005 end 18:00 31 October 2005	(Optional) Specifies an absolute time when a time range is in effect. - Only one absolute command is allowed in a time range. - The time is expressed in 24-hour notation, in the form of hours:minutes. For example, 8:00 is 8:00 a.m. and 20:00 is 8:00 p.m. The date is expressed in the format <i>day month year</i>. The minimum start is 00:00 1 January 1993. If no start time and date are specified, the permit or deny statement is in effect immediately. - Absolute time and date that the permit or deny statement of the associated access list is no longer in effect. Same time and date format as described for the start keyword. The end time and date must be after the start time and date. The maximum end time is 23:59 31 December 2035. If no end time and date are specified, the associated permit or deny statement is in effect indefinitely.
Step 7	exit Example: Router(config-time-range)# exit	Exits to the next highest mode.
Step 8	Repeat Steps 3 through 7 if you want different time ranges to apply to permit or deny statements.	—
Step 9	ip access-list extended <i>name</i> Example: Router(config)# ip access-list extended autumn	Defines an extended IP access list using a name and enters extended named access list configuration mode.
Step 10	deny <i>protocol source [source-wildcard] destination [destination-wildcard] [option option-name] [precedence precedence] [tos tos] [established] [log log-input] time-range time-range-name</i> Example: Router(config-ext-nacl)# deny tcp 172.16.22.23 any eq http time-range limit_http	(Optional) Denies any packet that matches all of the conditions specified in the statement. - Specify the time range you created in Step 3. - In this example, one host is denied HTTP access during the time defined by the time range called “limit_http.”
Step 11	permit <i>protocol source [source-wildcard] destination [destination-wildcard] [option option-name] [precedence precedence] [tos tos] [established] [log log-input] time-range time-range-name</i> Example: Router(config-ext-nacl)# permit tcp any any eq http time-range limit_http	Permits any packet that matches all of the conditions specified in the statement. - You can specify the time range you created in Step 3 or in a different instance of Step 3, depending on whether you want the time ranges for your statements to be the same or different. - In this example, all other sources are given access to HTTP during the time defined by the time range called “limit_http.”

	Command or Action	Purpose
Step 12	Optionally repeat some combination of Steps 10 and 11 until you have specified the values on which you want to base your access list.	—
Step 13	end Example: Router(config-ext-nacl)# end	Ends configuration mode and returns the system to privileged EXEC mode.
Step 14	show ip access-list Example: Router# show ip access-list	(Optional) Displays the contents of all current IP access lists.
Step 15	show time-range Example: Router# show time-range	(Optional) Displays the time ranges that are set.
Step 16	show time-range ipc Example: Router# show time-range ipc	(Optional) Displays the statistics about the time-range IPC messages between the Route Processor and line card on the Cisco 7500 series router.
Step 17	clear time-range ipc Example: Router# clear time-range ipc	(Optional) Clears the time-range IPC message statistics and counters between the Route Processor and line card on the Cisco 7500 series router.
Step 18	debug time-range ipc Example: Router# debug time-range ipc	(Optional) Enables debugging output for monitoring the time-range IPC messages between the Route Processor and line card on the Cisco 7500 series router.

What to Do Next

Apply the access list to an interface or reference it from a command that accepts an access list.

Filtering Noninitial Fragments of Packets

Filter noninitial fragments of packets with an extended access list if you want to block more of the traffic you intended to block, not just the initial fragment of such packets. You should first understand the following concepts.

Benefits of Filtering Noninitial Fragments of Packets

If the **fragments** keyword is used in additional IP access list entries that deny fragments, the fragment control feature provides the following benefits:

Additional Security

You are able to block more of the traffic you intended to block, not just the initial fragment of such packets. The unwanted fragments no longer linger at the receiver until the reassembly timeout is reached because they are blocked before being sent to the receiver. Blocking a greater portion of unwanted traffic improves security and reduces the risk from potential hackers.

Reduced Cost

By blocking unwanted noninitial fragments of packets, you are not paying for traffic you intended to block.

Reduced Storage

By blocking unwanted noninitial fragments of packets from ever reaching the receiver, that destination does not have to store the fragments until the reassembly timeout period is reached.

Expected Behavior Is Achieved

The noninitial fragments will be handled in the same way as the initial fragment, which is what you would expect. There are fewer unexpected policy routing results and fewer fragments of packets being routed when they should not be.

Access List Processing of Fragments

The behavior of access list entries regarding the use or lack of use of the **fragments** keyword can be summarized as follows:

If the Access-List Entry Has...	Then...
...no fragments keyword (the default), and assuming all of the access-list entry information matches,	For an access list entry that contains only Layer 3 information: - The entry is applied to nonfragmented packets, initial fragments, and noninitial fragments. For an access list entry that contains Layer 3 and Layer 4 information: - The entry is applied to nonfragmented packets and initial fragments. - If the entry is a permit statement, then the packet or fragment is permitted. - If the entry is a deny statement, then the packet or fragment is denied. - The entry is also applied to noninitial fragments in the following manner. Because noninitial fragments contain only Layer 3 information, only the Layer 3 portion of an access list entry can be applied. If the Layer 3 portion of the access list entry matches, and - If the entry is a permit statement, then the noninitial fragment is permitted. - If the entry is a deny statement, then the next access list entry is processed. Note The deny statements are handled differently for noninitial fragments versus nonfragmented or initial fragments.
...the fragments keyword, and assuming all of the access-list entry information matches,	The access list entry is applied only to noninitial fragments. The fragments keyword cannot be configured for an access list entry that contains any Layer 4 information.

Be aware that you should not add the **fragments** keyword to every access list entry because the first fragment of the IP packet is considered a nonfragment and is treated independently of the subsequent fragments. An initial fragment will not match an access list **permit** or **deny** entry that contains the **fragments** keyword. The packet is compared to the next access list entry, and so on, until it is either permitted or denied by an access list entry that does not contain the **fragments** keyword. Therefore, you may need two access list entries for every **deny** entry. The first **deny** entry of the pair will not include the **fragments** keyword and applies to the initial fragment. The second **deny** entry of the pair will include the **fragments** keyword and applies to the subsequent fragments. In the cases in which there are multiple **deny** entries for the same host but with different Layer 4 ports, a single **deny** access list entry with the **fragments** keyword for that host is all that needs to be added. Thus all the fragments of a packet are handled in the same manner by the access list.

Packet fragments of IP datagrams are considered individual packets, and each counts individually as a packet in access list accounting and access list violation counts.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list extended** *name*
4. *[sequence-number]* **deny** *protocol source [source-wildcard] [operator port [port]] destination [destination-wildcard] [operator port [port]]*
5. *[sequence-number]* **deny** *protocol source [source-wildcard] [operator port [port]] destination [destination-wildcard] [operator port [port]] [fragments]*
6. *[sequence-number]* **permit** *protocol source [source-wildcard] [operator port [port]] destination [destination-wildcard] [operator port [port]]*
7. Repeat some combination of Steps 4 through 6 until you have specified the values on which you want to base your access list.
8. **end**
9. **show ip access-list**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list extended name Example: Router(config)# ip access-list extended rstrct4	Defines an extended IP access list using a name and enters extended named access list configuration mode.
Step 4	<i>[sequence-number] deny protocol source [source-wildcard] [operator port [port]] destination [destination-wildcard] [operator port [port]]</i> Example: Router(config-ext-nacl)# deny ip any 172.20.1.1	(Optional) Denies any packet that matches all of the conditions specified in the statement. This statement will apply to nonfragmented packets and initial fragments.
Step 5	<i>[sequence-number] deny protocol source [source-wildcard] [operator port [port]] destination [destination-wildcard] [operator port [port]] fragments</i> Example: Router(config-ext-nacl)# deny ip any 172.20.1.1 fragments	(Optional) Denies any packet that matches all of the conditions specified in the statement This statement will apply to noninitial fragments.
Step 6	<i>[sequence-number] permit protocol source [source-wildcard] [operator port [port]] destination [destination-wildcard] [operator port [port]]</i> Example: Router(config-ext-nacl)# permit tcp any any	Permits any packet that matches all of the conditions specified in the statement. - Every access list needs at least one permit statement. - If the <i>source-wildcard</i> or <i>destination-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source or destination address, respectively. - Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> or <i>destination destination-wildcard</i> to specify the address and wildcard of 0.0.0.0 255.255.255.255.
Step 7	Repeat some combination of Steps 4 through 6 until you have specified the values on which you want to base your access list.	Remember that all sources not specifically permitted are denied by an implicit deny statement at the end of the access list.

	Command or Action	Purpose
Step 8	end Example: Router(config-ext-nacl)# end	Ends configuration mode and returns the system to privileged EXEC mode.
Step 9	show ip access-list Example: Router# show ip access-list	(Optional) Displays the contents of all current IP access lists.

What to Do Next

Apply the access list to an interface or reference it from a command that accepts an access list.

Configuration Examples for Refining an IP Access List

This section provides the following configuration examples:

- [Resequencing Entries in an Access List: Example, page 16](#)
- [Adding an Entry with a Sequence Number: Example, page 17](#)
- [Adding an Entry with No Sequence Number: Example, page 17](#)
- [Time Ranges Applied to IP Access List Entries: Example, page 18](#)
- [Filtering IP Packet Fragments: Example, page 18](#)

Resequencing Entries in an Access List: Example

The following example shows an access list before and after resequencing. The starting value is 1, and increment value is 2. The subsequent entries are ordered based on the increment values that users provide, and the range is from 1 to 2147483647.

When an entry with no sequence number is entered, by default it has a sequence number of 10 more than the last entry in the access list.

```
Router# show access-list carls
```

```
Extended IP access list carls
 10 permit ip host 10.3.3.3 host 172.16.5.34
 20 permit icmp any any
 30 permit tcp any host 10.3.3.3
 40 permit ip host 10.4.4.4 any
 50 dynamic test permit ip any any
 60 permit ip host 172.16.2.2 host 10.3.3.12
 70 permit ip host 10.3.3.3 any log
 80 permit tcp host 10.3.3.3 host 10.1.2.2
 90 permit ip host 10.3.3.3 any
100 permit ip any any
```

```
Router(config)# ip access-list extended carls
Router(config)# ip access-list resequence carls 1 2
Router(config)# end
```

```
Router# show access-list carls

Extended IP access list carls
 1 permit ip host 10.3.3.3 host 172.16.5.34
 3 permit icmp any any
 5 permit tcp any host 10.3.3.3
 7 permit ip host 10.4.4.4 any
 9 Dynamic test permit ip any any
11 permit ip host 172.16.2.2 host 10.3.3.12
13 permit ip host 10.3.3.3 any log
15 permit tcp host 10.3.3.3 host 10.1.2.2
17 permit ip host 10.3.3.3 any
19 permit ip any any
```

Adding an Entry with a Sequence Number: Example

In the following example, a new entry (sequence number 15) is added to an access list:

```
Router# show ip access-list

Standard IP access list tryon
 2 permit 10.4.4.2, wildcard bits 0.0.255.255
 5 permit 10.0.0.44, wildcard bits 0.0.0.255
10 permit 10.0.0.1, wildcard bits 0.0.0.255
20 permit 10.0.0.2, wildcard bits 0.0.0.255

Router(config)# ip access-list standard tryon

Router(config-std-nacl)# 15 permit 10.5.5.5 0.0.0.255

Router# show ip access-list

Standard IP access list tryon
 2 permit 10.4.0.0, wildcard bits 0.0.255.255
 5 permit 10.0.0.0, wildcard bits 0.0.0.255
10 permit 10.0.0.0, wildcard bits 0.0.0.255
15 permit 10.5.5.0, wildcard bits 0.0.0.255
20 permit 10.0.0.0, wildcard bits 0.0.0.255
```

Adding an Entry with No Sequence Number: Example

The following example shows how an entry with no specified sequence number is added to the end of an access list. When an entry is added without a sequence number, it is automatically given a sequence number that puts it at the end of the access list. Because the default increment is 10, the entry will have a sequence number 10 higher than the last entry in the existing access list.

```
Router(config)# ip access-list standard resources

Router(config-std-nacl)# permit 10.1.1.1 0.0.0.255
Router(config-std-nacl)# permit 10.2.2.2 0.0.0.255
Router(config-std-nacl)# permit 10.3.3.3 0.0.0.255

Router# show access-list

Standard IP access list resources
10 permit 10.1.1.1, wildcard bits 0.0.0.255
20 permit 10.2.2.2, wildcard bits 0.0.0.255
30 permit 10.3.3.3, wildcard bits 0.0.0.255

Router(config)# ip access-list standard resources
```

```
Router(config-std-nacl)# permit 10.4.4.4 0.0.0.255
Router(config-std-nacl)# end
```

```
Router# show access-list
```

```
Standard IP access list resources
10 permit 10.1.1.1, wildcard bits 0.0.0.255
20 permit 10.2.2.2, wildcard bits 0.0.0.255
30 permit 10.3.3.3, wildcard bits 0.0.0.255
40 permit 10.4.4.4, wildcard bits 0.0.0.255
```

Time Ranges Applied to IP Access List Entries: Example

The following example creates a time range called no-http, which extends from Monday to Friday from 8:00 a.m. to 6:00 p.m. That time range is applied to the **deny** statement, thereby denying HTTP traffic on Monday through Friday from 8:00 a.m. to 6:00 p.m.

The time range called udp-yes defines weekends from noon to 8:00 p.m. That time range is applied to the **permit** statement, thereby allowing UDP traffic on Saturday and Sunday from noon to 8:00 p.m. only. The access list containing both statements is applied to inbound packets on Ethernet interface 0.

```
time-range no-http
  periodic weekdays 8:00 to 18:00
!
time-range udp-yes
  periodic weekend 12:00 to 20:00
!
ip access-list extended strict
  deny tcp any any eq http time-range no-http
  permit udp any any time-range udp-yes
!
interface ethernet 0
  ip access-group strict in
```

Filtering IP Packet Fragments: Example

In the following access list, the first statement will deny only noninitial fragments destined for host 172.16.1.1. The second statement will permit only the remaining nonfragmented and initial fragments that are destined for host 172.16.1.1 TCP port 80. The third statement will deny all other traffic. In order to block noninitial fragments for any TCP port, we must block noninitial fragments for all TCP ports, including port 80 for host 172.16.1.1. That is, non-initial fragments will not contain Layer 4 port information, so, in order to block such traffic for a given port, we have to block fragments for all ports.

```
access-list 101 deny ip any host 172.16.1.1 fragments
access-list 101 permit tcp any host 172.16.1.1 eq 80
access-list 101 deny ip any any
```

Additional References

The following sections provide references related to access list entry resequencing, time-based access lists, or IP fragment filtering.

Feature Information for Refining an IP Access List

Table 1 lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table.

Not all commands may be available in your Cisco IOS software release. For details on when support for a specific command was introduced, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

**Note**

[Table 1](#) lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 1 *Feature Information for Refining an IP Access List*

Feature Name	Releases	Feature Configuration Information
Distributed Time-Based Access Lists	12.2(2)T	Before the introduction of this feature, time-based access lists were not supported on line cards for the Cisco 7500 series routers. If time-based access lists were configured, they behaved as normal access lists. If an interface on a line card were configured with a time-based access list, the packets switched into the interface were not distributed switched through the line card, but were forwarded to the Route Processor for processing. The Distributed Time-Based Access Lists feature allows packets destined for an interface configured with a time-based access list to be distributed switched through the line card. See the following section: • Distributed Time-Based Access Lists, page 7

About Lock-and-Key

Lock-and-key is a traffic filtering security feature that dynamically filters IP protocol traffic. Lock-and-key is configured using IP dynamic extended access lists. Lock-and-key can be used in conjunction with other standard access lists and static extended access lists.

When lock-and-key is configured, designated users whose IP traffic is normally blocked at a router can gain temporary access through the router. When triggered, lock-and-key reconfigures the interface's existing IP access list to permit designated users to reach their designated host(s). Afterwards, lock-and-key reconfigures the interface back to its original state.

For a user to gain access to a host through a router with lock-and-key configured, the user must first open a Telnet session to the router. When a user initiates a standard Telnet session to the router, lock-and-key automatically attempts to authenticate the user. If the user is authenticated, they will then gain temporary access through the router and be able to reach their destination host.

This section has the following sections:

- [Benefits of Lock-and-Key](#)
- [When to Use Lock-and-Key](#)
- [How Lock-and-Key Works](#)

Benefits of Lock-and-Key

Lock-and-key provides the same benefits as standard and static extended access lists (these benefits are discussed in the chapter "Access Control Lists: Overview and Guidelines"). However, lock-and-key also has the following security benefits over standard and static extended access lists:

- Lock-and-key uses a challenge mechanism to authenticate individual users.
- Lock-and-key provides simpler management in large internetworks.
- In many cases, lock-and-key reduces the amount of router processing required for access lists.
- Lock-and-key reduces the opportunity for network break-ins by network hackers.

With lock-and-key, you can specify which users are permitted access to which source and destination hosts. These users must pass a user authentication process before they are permitted access to their designated hosts. Lock-and-key creates dynamic user access through a firewall, without compromising other configured security restrictions.

When to Use Lock-and-Key

Two examples of when you might use lock-and-key follow:

- When you want a specific remote user (or group of remote users) to be able to access a host within your network, connecting from their remote hosts via the Internet. Lock-and-key authenticates the user, then permits limited access through your firewall router for the individual's host or subnet, for a finite period of time.

- When you want a subset of hosts on a local network to access a host on a remote network protected by a firewall. With lock-and-key, you can enable access to the remote host only for the desired set of local user's hosts. Lock-and-key require the users to authenticate through a TACACS+ server, or other security server, before allowing their hosts to access the remote hosts.

How Lock-and-Key Works

The following process describes the lock-and-key access operation:

1. A user opens a Telnet session to a border (firewall) router configured for lock-and-key. The user connects via the virtual terminal port on the router.
2. The Cisco IOS software receives the Telnet packet, opens a Telnet session, prompts for a password, and performs a user authentication process. The user must pass authentication before access through the router is allowed. The authentication process can be done by the router or by a central access security server such as a TACACS+ or RADIUS server.
3. When the user passes authentication, they are logged out of the Telnet session, and the software creates a temporary entry in the dynamic access list. (Per your configuration, this temporary entry can limit the range of networks to which the user is given temporary access.)
4. The user exchanges data through the firewall.
5. The software deletes the temporary access list entry when a configured timeout is reached, or when the system administrator manually clears it. The configured timeout can either be an idle timeout or an absolute timeout.

Note

The temporary access list entry is not automatically deleted when the user terminates a session. The temporary access list entry remains until a configured timeout is reached or until it is cleared by the system administrator.

Compatibility with Releases Before Cisco IOS Release 11.1

Enhancements to the **access-list** command are used for lock-and-key. These enhancements are backward compatible—if you migrate from a release before Cisco IOS Release 11.1 to a newer release, your access lists will be automatically converted to reflect the enhancements. However, if you try to use lock-and-key with a release before Cisco IOS Release 11.1, you might encounter problems as described in the following caution paragraph:

Caution

Cisco IOS releases before Release 11.1 are not upwardly compatible with the lock-and-key access list enhancements. Therefore, if you save an access list with software older than Release 11.1, and then use this software, the resulting access list will not be interpreted correctly. *This could cause you severe security problems.* You must save your old configuration files with Cisco IOS Release 11.1 or later software before booting an image with these files.

Risk of Spoofing with Lock-and-Key

Caution

Lock-and-key access allows an external event (a Telnet session) to place an opening in the firewall. While this opening exists, the router is susceptible to source address spoofing.

When lock-and-key is triggered, it creates a dynamic opening in the firewall by temporarily reconfiguring an interface to allow user access. While this opening exists, another host might spoof the authenticated user's address to gain access behind the firewall. Lock-and-key does not cause the address spoofing problem; the problem is only identified here as a concern to the user. Spoofing is a problem inherent to all access lists, and lock-and-key does not specifically address this problem.

To prevent spoofing, configure encryption so that traffic from the remote host is encrypted at a secured remote router, and decrypted locally at the router interface providing lock-and-key. You want to ensure that all traffic using lock-and-key will be encrypted when entering the router; this way no hackers can spoof the source address, because they will be unable to duplicate the encryption or to be authenticated as is a required part of the encryption setup process.

Router Performance Impacts with Lock-and-Key

When lock-and-key is configured, router performance can be affected in the following ways:

- When lock-and-key is triggered, the dynamic access list forces an access list rebuild on the silicon switching engine (SSE). This causes the SSE switching path to slow down momentarily.
- Dynamic access lists require the idle timeout facility (even if the timeout is left to default) and therefore cannot be SSE switched. These entries must be handled in the protocol fast-switching path.
- When remote users trigger lock-and-key at a border router, additional access list entries are created on the border router interface. The interface's access list will grow and shrink dynamically. Entries are dynamically removed from the list after either the idle-timeout or max-timeout period expires. Large access lists can degrade packet switching performance, so if you notice performance problems, you should look at the border router configuration to see if you should remove temporary access list entries generated by lock-and-key.

Prerequisites to Configuring Lock-and-Key

Lock-and-key uses IP extended access lists. You must have a solid understanding of how access lists are used to filter traffic, before you attempt to configure lock-and-key. Access lists are described in the chapter "Access Control Lists: Overview and Guidelines."

Lock-and-key employs user authentication and authorization as implemented in Cisco's authentication, authorization, and accounting (AAA) paradigm. You must understand how to configure AAA user authentication and authorization before you configure lock-and-key. User authentication and authorization is explained in the "Authentication, Authorization, and Accounting (AAA)" part of this document.

Lock-and-key uses the **autocommand** command, which you should understand. This command is described in the "Modem Support and Asynchronous Device Commands" chapter of the *Cisco IOS Dial Technologies Command Reference*.

Configuring Lock-and-Key

To configure lock-and-key, use the following commands beginning in global configuration mode. While completing these steps, be sure to follow the guidelines listed in the “[Lock-and-Key Configuration Guidelines](#)” section of this chapter.

	Command	Purpose
Step 1	Router(config)# access-list <i>access-list-number</i> [dynamic <i>dynamic-name</i> [<i>timeout minutes</i>]] { deny permit } telnet <i>source source-wildcard destination destination-wildcard</i> [precedence <i>precedence</i>] [tos <i>tos</i>] [established] [log]	Configures a dynamic access list, which serves as a template and placeholder for temporary access list entries.
Step 2	Router(config)# access-list dynamic-extend	(Optional) Extends the absolute timer of the dynamic ACL by six minutes when you open another Telnet session into the router to re-authenticate yourself using lock-and-key. Use this command if your job will run past the ACL’s absolute timer.
Step 3	Router(config)# interface <i>type number</i>	Configures an interface and enters interface configuration mode.
Step 4	Router(config-if)# ip access-group <i>access-list-number</i>	Applies the access list to the interface.
Step 5	Router(config-if)# exit	Exits interface configuration mode and enters global configuration mode.
Step 6	Router(config)# line vty <i>line-number</i> [<i>ending-line-number</i>]	Defines one or more virtual terminal (VTY) ports and enters line configuration mode. If you specify multiple VTY ports, they must all be configured identically because the software hunts for available VTY ports on a round-robin basis. If you do not want to configure all your VTY ports for lock-and-key access, you can specify a group of VTY ports for lock-and-key support only.
Step 7	Router(config-line)# login tacacs or Router(config-line)# password <i>password</i> or Router(config-line)# login local or Router(config-line)# exit then Router(config)# username <i>name</i> password <i>secret</i>	Configures user authentication in line or global configuration mode.
Step 8	Router(config-line)# autocommand access-enable [<i>host</i>] [<i>timeout minutes</i>] or Router(config)# autocommand access-enable [<i>host</i>] [<i>timeout minutes</i>]	Enables the creation of temporary access list entries in line or global configuration mode. If the optional host keyword is <i>not</i> specified, all hosts on the entire network are allowed to set up a temporary access list entry. The dynamic access list contains the network mask to enable the new network connection.

For an example of a lock-and-key configuration, see the section “[Lock-and-Key Configuration Examples](#)” later in this chapter.

Lock-and-Key Configuration Guidelines

Before you configure lock-and-key, you should understand the guidelines discussed in the following sections:

- [Dynamic Access Lists](#)
- [Lock-and-Key Authentication](#)
- [The autocommand Command](#)

Dynamic Access Lists

Use the following guidelines for configuring dynamic access lists:

- Do *not* create more than one dynamic access list for any one access list. The software only refers to the first dynamic access list defined.
- Do *not* assign the same *dynamic-name* to another access list. Doing so instructs the software to reuse the existing list. All named entries must be globally unique within the configuration.
- Assign attributes to the dynamic access list in the same way you assign attributes for a static access list. The temporary access list entries inherit the attributes assigned to this list.
- Configure Telnet as the protocol so that users must open a Telnet session into the router to be authenticated before they can gain access through the router.
- Either define an idle timeout now with the **timeout** keyword in the **access-enable** command in the **autocommand** command, or define an absolute timeout value later with the **access-list** command. You must define either an idle timeout or an absolute timeout—otherwise, the temporary access list entry will remain configured indefinitely on the interface (even after the user has terminated their session) until the entry is removed manually by an administrator. (You could configure both idle and absolute timeouts if you wish.)
- If you configure an idle timeout, the idle timeout value should be equal to the WAN idle timeout value.
- If you configure both idle and absolute timeouts, the idle timeout value must be less than the absolute timeout value.
- If you realize that a job will run past the ACL's absolute timer, use the **access-list dynamic-extend** command to extend the absolute timer of the dynamic ACL by six minutes. This command allows you to open a new Telnet session into the router to re-authentication yourself using lock-and-key.
- The only values replaced in the temporary entry are the source or destination address, depending whether the access list was in the input access list or output access list. All other attributes, such as port, are inherited from the main dynamic access list.
- Each addition to the dynamic list is always put at the beginning of the dynamic list. You cannot specify the order of temporary access list entries.
- Temporary access list entries are never written to NVRAM.
- To manually clear or to display dynamic access lists, refer to the section "[Maintaining Lock-and-Key](#)" later in this chapter.

Lock-and-Key Authentication

There are three possible methods to configure an authentication query process. These three methods are described in this section.

**Note**

Cisco recommends that you use the TACACS+ server for your authentication query process. TACACS+ provides authentication, authorization, and accounting services. It also provides protocol support, protocol specification, and a centralized security database. Using a TACACS+ server is described in the next section, “[Method 1—Configuring a Security Server](#).”

Method 1—Configuring a Security Server

Use a network access security server such as TACACS+ server. This method requires additional configuration steps on the TACACS+ server but allows for stricter authentication queries and more sophisticated tracking capabilities.

```
Router(config-line)# login tacacs
```

Method 2—Configuring the username Command

Use the **username** command. This method is more effective because authentication is determined on a user basis.

```
Router(config)# username name {nopassword | password {mutual-password | encryption-type encryption-password}}
```

Method 3—Configuring the password and login Commands

Use the **password** and **login** commands. This method is less effective because the password is configured for the port, not for the user. Therefore, any user who knows the password can authenticate successfully.

```
Router(config-line)# password password
Router(config-line)# login local
```

The autocommand Command

Use the following guidelines for configuring the **autocommand** command:

- If you use a TACACS+ server to authenticate the user, you should configure the **autocommand** command on the TACACS+ server as a per-user autocommand. If you use local authentication, use the **autocommand** command on the line.
- Configure all virtual terminal (VTY) ports with the same **autocommand** command. Omitting an **autocommand** command on a VTY port allows a random host to gain EXEC mode access to the router and does not create a temporary access list entry in the dynamic access list.
- If you did not previously define an idle timeout with the **autocommand access-enable** command, you must define an absolute timeout now with the **access-list** command. You must define either an idle timeout or an absolute timeout—otherwise, the temporary access list entry will remain configured indefinitely on the interface (even after the user has terminated their session) until the entry is removed manually by an administrator. (You could configure both idle and absolute timeouts if you wish.)
- If you configure both idle and absolute timeouts, the absolute timeout value must be greater than the idle timeout value.

Verifying Lock-and-Key Configuration

You can verify that lock-and-key is successfully configured on the router by asking a user to test the connection. The user should be at a host that is permitted in the dynamic access list, and the user should have AAA authentication and authorization configured.

To test the connection, the user should Telnet to the router, allow the Telnet session to close, and then attempt to access a host on the other side of the router. This host must be one that is permitted by the dynamic access list. The user should access the host with an application that uses the IP protocol.

The following sample display illustrates what end-users might see if they are successfully authenticated. Notice that the Telnet connection is closed immediately after the password is entered and authenticated. The temporary access list entry is then created, and the host that initiated the Telnet session now has access inside the firewall.

```
Router% telnet corporate
Trying 172.21.52.1 ...
Connected to corporate.example.com.
Escape character is '^]'.
User Access Verification
Password:Connection closed by foreign host.
```

You can then use the **show access-lists** command at the router to view the dynamic access lists, which should include an additional entry permitting the user access through the router.

Maintaining Lock-and-Key

When lock-and-key is in use, dynamic access lists will dynamically grow and shrink as entries are added and deleted. You need to make sure that entries are being deleted in a timely way, because while entries exist, the risk of a spoofing attack is present. Also, the more entries there are, the bigger the router performance impact will be.

If you do not have an idle or absolute timeout configured, entries will remain in the dynamic access list until you manually remove them. If this is the case, make sure that you are extremely vigilant about removing entries.

Displaying Dynamic Access List Entries

You can display temporary access list entries when they are in use. After a temporary access list entry is cleared by you or by the absolute or idle timeout parameter, it can no longer be displayed. The number of matches displayed indicates the number of times the access list entry was hit.

To view dynamic access lists and any temporary access list entries that are currently established, use the following command in privileged EXEC mode:

Command	Purpose
Router# show access-lists [<i>access-list-number</i>]	Displays dynamic access lists and temporary access list entries.

Manually Deleting Dynamic Access List Entries

To manually delete a temporary access list entry, use the following command in privileged EXEC mode:

Command	Purpose
Router# clear access-template [<i>access-list-number</i> <i>name</i>] [<i>dynamic-name</i>] [<i>source</i>] [<i>destination</i>]	Deletes a dynamic access list.

Lock-and-Key Configuration Examples

The following sections provide lock-and-key configuration examples:

- [Lock-and-Key with Local Authentication Example](#)
- [Lock-and-Key with TACACS+ Authentication Example](#)

Cisco recommends that you use a TACACS+ server for authentication, as shown in the second example.

Lock-and-Key with Local Authentication Example

This example shows how to configure lock-and-key access, with authentication occurring locally at the router. Lock-and-key is configured on the Ethernet 0 interface.

```
interface ethernet0
 ip address 172.18.23.9 255.255.255.0
 ip access-group 101 in

access-list 101 permit tcp any host 172.18.21.2 eq telnet
access-list 101 dynamic mytestlist timeout 120 permit ip any any

line vty 0
 login local
 autocommand access-enable timeout 5
```

The first access-list entry allows only Telnet into the router. The second access-list entry is always ignored until lock-and-key is triggered.

In the **access-list** command, the timeout is the absolute timeout. In this example, the lifetime of the mytestlist ACL is 120 minutes; that is, when a user logs in and enable the **access-enable** command, a dynamic ACL is created for 120 minutes (the maximum absolute time). The session is closed after 120 minutes, whether or not anyone is using it.

In the **autocommand** command, the timeout is the idle timeout. In this example, each time the user logs in or authenticates there is a 5-minute session. If there is no activity, the session closes in 5 minutes and the user has to reauthenticate. If the user uses the connection, the absolute time takes affect and the session closes in 120 minutes.

After a user opens a Telnet session into the router, the router will attempt to authenticate the user. If authentication is successful, the **autocommand** executes and the Telnet session terminates. The **autocommand** creates a temporary inbound access list entry at the Ethernet 0 interface, based on the second access-list entry (mytestlist). This temporary entry will expire after 5 minutes, as specified by the timeout.

Lock-and-Key with TACACS+ Authentication Example

The following example shows how to configure lock-and-key access, with authentication on a TACACS+ server. Lock-and-key access is configured on the BRI0 interface. Four VTY ports are defined with the password “cisco”.

```

aaa authentication login default group tacacs+ enable
aaa accounting exec stop-only group tacacs+
aaa accounting network stop-only group tacacs+
enable password ciscotac

Configuring IP Session Filtering (Reflexive Access Lists)

This chapter describes how to configure reflexive access lists on your router. Reflexive access lists provide the ability to filter network traffic at a router, based on IP upper-layer protocol “session” information.

For a complete description of reflexive access list commands, refer to the “Reflexive Access List Commands” chapter of the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the chapter “Identifying Supported Platforms” section in the “Using Cisco IOS Software.”

In This Chapter

This chapter has the following sections:

- [About Reflexive Access Lists](#)
- [Prework: Before You Configure Reflexive Access Lists](#)
- [Reflexive Access Lists Configuration Task List](#)
- [Reflexive Access List Configuration Examples](#)

About Reflexive Access Lists

Reflexive access lists allow IP packets to be filtered based on upper-layer session information. You can use reflexive access lists to permit IP traffic for sessions originating from within your network but to deny IP traffic for sessions originating from outside your network. This is accomplished by reflexive filtering, a kind of session filtering.

Reflexive access lists can be defined with extended named IP access lists only. You cannot define reflexive access lists with numbered or standard named IP access lists or with other protocol access lists.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

You can use reflexive access lists in conjunction with other standard access lists and static extended access lists.

This section has the following sections:

- [Benefits of Reflexive Access Lists](#)
- [What Is a Reflexive Access List?](#)
- [How Reflexive Access Lists Implement Session Filtering](#)
- [Where to Configure Reflexive Access Lists](#)
- [How Reflexive Access Lists Work](#)
- [Restrictions on Using Reflexive Access Lists](#)

Benefits of Reflexive Access Lists

Reflexive access lists are an important part of securing your network against network hackers, and can be included in a firewall defense. Reflexive access lists provide a level of security against spoofing and certain denial-of-service attacks. Reflexive access lists are simple to use, and, compared to basic access lists, provide greater control over which packets enter your network.

What Is a Reflexive Access List?

Reflexive access lists are similar in many ways to other access lists. Reflexive access lists contain condition statements (entries) that define criteria for permitting IP packets. These entries are evaluated in order, and when a match occurs, no more entries are evaluated.

However, reflexive access lists have significant differences from other types of access lists. Reflexive access lists contain only temporary entries; these entries are automatically created when a new IP session begins (for example, with an outbound packet), and the entries are removed when the session ends. Reflexive access lists are not themselves applied directly to an interface, but are “nested” within an extended named IP access list that is applied to the interface. (For more information about this, see the section “[Reflexive Access Lists Configuration Task List](#)” later in this chapter.) Also, reflexive access lists do not have the usual implicit “deny all traffic” statement at the end of the list, because of the nesting.

How Reflexive Access Lists Implement Session Filtering

This section compares session filtering with basic access lists to session filtering with reflexive access lists. This section contains the following sections:

- [With Basic Access Lists](#)
- [With Reflexive Access Lists](#)

With Basic Access Lists

With basic standard and static extended access lists, you can approximate session filtering by using the **established** keyword with the **permit** command. The **established** keyword filters TCP packets based on whether the ACK or RST bits are set. (Set ACK or RST bits indicate that the packet is not the first in the session, and therefore, that the packet belongs to an established session.) This filter criterion would be part of an access list applied permanently to an interface.

With Reflexive Access Lists

Reflexive access lists, however, provide a truer form of session filtering, which is much harder to spoof because more filter criteria must be matched before a packet is permitted through. (For example, source and destination addresses and port numbers are checked, not just ACK and RST bits.) Also, session filtering uses temporary filters which are removed when a session is over. This limits the hacker's attack opportunity to a smaller time window.

Moreover, the previous method of using the **established** keyword was available only for the TCP upper-layer protocol. So, for the other upper-layer protocols (such as UDP, ICMP, and so forth), you would have to either permit all incoming traffic or define all possible permissible source/destination host/port address pairs for each protocol. (Besides being an unmanageable task, this could exhaust NVRAM space.)

Where to Configure Reflexive Access Lists

Configure reflexive access lists on border routers—routers that pass traffic between an internal and external network. Often, these are firewall routers.

Note

In this chapter, the words “within your network” and “internal network” refer to a network that is controlled (secured), such as your organization's intranet, or to a part of your organization's internal network that has higher security requirements than another part. “Outside your network” and “external network” refer to a network that is uncontrolled (unsecured) such as the Internet or to a part of your organization's network that is not as highly secured.

How Reflexive Access Lists Work

A reflexive access list is triggered when a new IP upper-layer session (such as TCP or UDP) is initiated from inside your network, with a packet traveling to the external network. When triggered, the reflexive access list generates a new, temporary entry. This entry will permit traffic to enter your network if the traffic is part of the session, but will not permit traffic to enter your network if the traffic is not part of the session.

For example, if an outbound TCP packet is forwarded to outside of your network, and this packet is the first packet of a TCP session, then a new, temporary reflexive access list entry will be created. This entry is added to the reflexive access list, which applies to inbound traffic. The temporary entry has characteristics as described next.

This section contains the following sections:

- [Temporary Access List Entry Characteristics](#)
- [When the Session Ends](#)

Temporary Access List Entry Characteristics

- The entry is always a **permit** entry.
- The entry specifies the same protocol (TCP) as the original outbound TCP packet.
- The entry specifies the same source and destination addresses as the original outbound TCP packet, except the addresses are swapped.
- The entry specifies the same source and destination port numbers as the original outbound TCP packet, except the port numbers are swapped.
(This entry characteristic applies only for TCP and UDP packets. Other protocols, such as ICMP and IGMP, do not have port numbers, and other criteria are specified. For example, for ICMP, type numbers are used instead.)
- Inbound TCP traffic will be evaluated against the entry, until the entry expires. If an inbound TCP packet matches the entry, the inbound packet will be forwarded into your network.
- The entry will expire (be removed) after the last packet of the session passes through the interface.
- If no packets belonging to the session are detected for a configurable length of time (the timeout period), the entry will expire.

When the Session Ends

Temporary reflexive access list entries are removed at the end of the session. For TCP sessions, the entry is removed 5 seconds after two set FIN bits are detected, or immediately after matching a TCP packet with the RST bit set. (Two set FIN bits in a session indicate that the session is about to end; the 5-second window allows the session to close gracefully. A set RST bit indicates an abrupt session close.) Or, the temporary entry is removed after no packets of the session have been detected for a configurable length of time (the timeout period).

For UDP and other protocols, the end of the session is determined differently than for TCP. Because other protocols are considered to be connectionless (sessionless) services, there is no session tracking information embedded in packets. Therefore, the end of a session is considered to be when no packets of the session have been detected for a configurable length of time (the timeout period).

Restrictions on Using Reflexive Access Lists

Reflexive access lists do not work with some applications that use port numbers that change during a session. For example, if the port numbers for a return packet are different from the originating packet, the return packet will be denied, even if the packet is actually part of the same session.

The TCP application of FTP is an example of an application with changing port numbers. With reflexive access lists, if you start an FTP request from within your network, the request will not complete. Instead, you must use Passive FTP when originating requests from within your network.

Prework: Before You Configure Reflexive Access Lists

Before you configure reflexive access lists, you must decide whether to configure reflexive access lists on an internal or external interface, as described in the next section, “[Choosing an Interface: Internal or External](#).”

You should also be sure that you have a basic understanding of the IP protocol and of access lists; specifically, you should know how to configure extended named IP access lists. To learn about configuring IP extended access lists, refer to the “Configuring IP Services” chapter of the *Cisco IOS IP Configuration Guide*.

Choosing an Interface: Internal or External

Reflexive access lists are most commonly used with one of two basic network topologies. Determining which of these topologies is most like your own can help you decide whether to use reflexive access lists with an internal interface or with an external interface (the interface connecting to an internal network, or the interface connecting to an external network).

The first topology is shown in [Figure 18](#). In this simple topology, reflexive access lists are configured for the *external* interface Serial 1. This prevents IP traffic from entering the router and the internal network, unless the traffic is part of a session already established from within the internal network.

Figure 18 Simple Topology—Reflexive Access Lists Configured at the External Interface

The second topology is shown in [Figure 19](#). In this topology, reflexive access lists are configured for the *internal* interface Ethernet 0. This allows external traffic to access the services in the Demilitarized Zone (DMZ), such as DNS services, but prevents IP traffic from entering your internal network—unless the traffic is part of a session already established from within the internal network.

Figure 19 DMZ Topology—Reflexive Access Lists Configured at the Internal Interface

Use these two example topologies to help you decide whether to configure reflexive access lists for an internal or external interface.

Reflexive Access Lists Configuration Task List

In the previous section, “[Prework: Before You Configure Reflexive Access Lists](#),” you decided whether to configure reflexive access lists for an internal or external interface.

Now, complete the tasks in one of the following configuration task lists:

- [External Interface Configuration Task List](#)
- [Internal Interface Configuration Task List](#)

For configuration examples, refer to the “[Reflexive Access List Configuration Examples](#)” section at the end of this chapter.

External Interface Configuration Task List

To configure reflexive access lists for an external interface, perform the following tasks:

1. Defining the reflexive access list(s) in an *outbound* IP extended named access list
2. Nesting the reflexive access list(s) in an *inbound* IP extended named access list
3. Setting a global timeout value

These tasks are described in the sections following the “[Internal Interface Configuration Task List](#)” section.

**Note**

The defined (outbound) reflexive access list evaluates traffic traveling out of your network: if the defined reflexive access list is matched, temporary entries are created in the nested (inbound) reflexive access list. These temporary entries will then be applied to traffic traveling into your network.

Internal Interface Configuration Task List

To configure reflexive access lists for an internal interface, perform the following tasks:

1. Defining the reflexive access list(s) in an *inbound* IP extended named access list
2. Nesting the reflexive access list(s) in an *outbound* IP extended named access list
3. Setting a global timeout value

These tasks are described in the next sections.

**Note**

The defined (inbound) reflexive access list is used to evaluate traffic traveling out of your network: if the defined reflexive access list is matched, temporary entries are created in the nested (outbound) reflexive access list. These temporary entries will then be applied to traffic traveling into your network.

Defining the Reflexive Access List(s)

To define a reflexive access list, you use an entry in an extended named IP access list. This entry must use the **reflect** keyword.

- If you are configuring reflexive access lists for an external interface, the extended named IP access list should be one that is applied to outbound traffic.

- If you are configuring reflexive access lists for an internal interface, the extended named IP access list should be one that is applied to inbound traffic.

To define reflexive access lists, use the following commands, beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# ip access-list extended <i>name</i>	External interface: Specifies the outbound access list. or Internal interface: Specifies the inbound access list. (This command enters access-list configuration mode.)
Step 2	Router(config-ext-nacl)# permit <i>protocol any any</i> reflect <i>name</i> [<i>timeout seconds</i>]	Defines the reflexive access list using the reflexive permit entry. Repeat this step for each IP upper-layer protocol; for example, you can define reflexive filtering for TCP sessions and also for UDP sessions. You can use the same <i>name</i> for multiple protocols. For additional guidelines for this task, see the following section, “ Mixing Reflexive Access List Statements with Other Permit and Deny Entries .”

If the extended named IP access list you just specified has never been applied to the interface, you must also apply the extended named IP access list to the interface.

To apply the extended named IP access list to the interface, use the following command in interface configuration mode:

Command	Purpose
Router(config-if)# ip access-group <i>name</i> out	External interface: Applies the extended access list to the interface’s outbound traffic.
or	
Router(config-if)# ip access-group <i>name</i> in	Internal interface: Applies the extended access list to the interface’s inbound traffic.

Mixing Reflexive Access List Statements with Other Permit and Deny Entries

The extended IP access list that contains the reflexive access list **permit** statement can also contain other normal **permit** and **deny** statements (entries). However, as with all access lists, the order of entries is important, as explained in the next few paragraphs.

If you configure reflexive access lists for an external interface, when an outbound IP packet reaches the interface, the packet will be evaluated sequentially by each entry in the outbound access list until a match occurs.

If the packet matches an entry prior to the reflexive **permit** entry, the packet will not be evaluated by the reflexive **permit** entry, and no temporary entry will be created for the reflexive access list (reflexive filtering will not be triggered).

The outbound packet will be evaluated by the reflexive **permit** entry only if no other match occurs first. Then, if the packet matches the protocol specified in the reflexive **permit** entry, the packet is forwarded out of the interface and a corresponding temporary entry is created in the inbound reflexive access list (unless the corresponding entry already exists, indicating the outbound packet belongs to a session in progress). The temporary entry specifies criteria that permits inbound traffic only for the same session.

Nesting the Reflexive Access List(s)

After you define a reflexive access list in one IP extended access list, you must “nest” the reflexive access list within a different extended named IP access list.

- If you are configuring reflexive access lists for an external interface, nest the reflexive access list within an extended named IP access list applied to inbound traffic.
- If you are configuring reflexive access lists for an internal interface, nest the reflexive access list within an extended named IP access list applied to outbound traffic.

After you nest a reflexive access list, packets heading into your internal network can be evaluated against any reflexive access list temporary entries, along with the other entries in the extended named IP access list.

To nest reflexive access lists, use the following commands, beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# ip access-list extended <i>name</i>	External interface: Specifies the inbound access list. or Internal interface: Specifies the outbound access list. (This command enters access-list configuration mode.)
Step 2	Router(config-ext-nacl)# evaluate <i>name</i>	Adds an entry that “points” to the reflexive access list. Adds an entry for each reflexive access list <i>name</i> previously defined.

Again, the order of entries is important. Normally, when a packet is evaluated against entries in an access list, the entries are evaluated in sequential order, and when a match occurs, no more entries are evaluated. With a reflexive access list nested in an extended access list, the extended access list entries are evaluated sequentially up to the nested entry, then the reflexive access list entries are evaluated sequentially, and then the remaining entries in the extended access list are evaluated sequentially. As usual, after a packet matches *any* of these entries, no more entries will be evaluated.

If the extended named IP access list you just specified has never been applied to the interface, you must also apply the extended named IP access list to the interface.

To apply the extended named IP access list to the interface, use one of the following commands in interface configuration mode:

Command	Purpose
Router(config-if)# ip access-group <i>name</i> in	External interface: Applies the extended access list to the interface's inbound traffic.
or	
Router(config-if)# ip access-group <i>name</i> out	Internal interface: Applies the extended access list to the interface's outbound traffic.

Setting a Global Timeout Value

Reflexive access list entries expire after no packets in the session have been detected for a certain length of time (the “timeout” period). You can specify the timeout for a particular reflexive access list when you define the reflexive access list. But if you do not specify the timeout for a given reflexive access list, the list will use the global timeout value instead.

The global timeout value is 300 seconds by default. But, you can change the global timeout to a different value at any time.

To change the global timeout value, use the following command in global configuration mode:

Command	Purpose
Router(config)# ip reflexive-list timeout <i>seconds</i>	Changes the global timeout value for temporary reflexive access list entries. Use a positive integer from 0 to 2,147,483.

Reflexive Access List Configuration Examples

The following sections provide reflexive access list configuration examples:

- [External Interface Configuration Example](#)
- [Internal Interface Configuration Example](#)

External Interface Configuration Example

This example shows reflexive access lists configured for an external interface, for a topology similar to the one in [Figure 18](#) (shown earlier in this chapter).

This configuration example permits both inbound and outbound TCP traffic at interface Serial 1, but only if the first packet (in a given session) originated from inside your network. The interface Serial 1 connects to the Internet.

Define the interface where the session-filtering configuration is to be applied:

```
interface serial 1
  description Access to the Internet via this interface
```

Apply access lists to the interface, for inbound traffic and for outbound traffic:

```
ip access-group inboundfilters in
ip access-group outboundfilters out
```

Define the outbound access list. This is the access list that evaluates all outbound traffic on interface Serial 1.

```
ip access-list extended outboundfilters
```

Define the reflexive access list *tcptraffic*. This entry permits *all* outbound TCP traffic and creates a new access list named *tcptraffic*. Also, when an outbound TCP packet is the first in a new session, a corresponding temporary entry will be automatically created in the reflexive access list *tcptraffic*.

```
permit tcp any any reflect tcptraffic
```

Define the inbound access list. This is the access list that evaluates all inbound traffic on interface Serial 1.

```
ip access-list extended inboundfilters
```

Define the inbound access list entries. This example shows Enhanced IGRP permitted on the interface. Also, no ICMP traffic is permitted. The last entry points to the reflexive access list. If a packet does not match the first two entries, the packet will be evaluated against all the entries in the reflexive access list *tcptraffic*.

```
permit eigrp any any
deny icmp any any
evaluate tcptraffic
```

Define the global idle timeout value for all reflexive access lists. In this example, when the reflexive access list *tcptraffic* was defined, no timeout was specified, so *tcptraffic* uses the global timeout. Therefore, if for 120 seconds there is no TCP traffic that is part of an established session, the corresponding reflexive access list entry will be removed.

```
ip reflexive-list timeout 120
```

The example configuration looks as follows:

```
interface Serial 1
  description Access to the Internet via this interface
  ip access-group inboundfilters in
  ip access-group outboundfilters out
!
ip reflexive-list timeout 120
!
ip access-list extended outboundfilters
  permit tcp any any reflect tcptraffic
!
ip access-list extended inboundfilters
  permit eigrp any any
  deny icmp any any
  evaluate tcptraffic
```

With this configuration, before any TCP sessions have been initiated the **show access-list EXEC** command displays the following:

```
Extended IP access list inboundfilters
  permit eigrp any any
  deny icmp any any
  evaluate tcptraffic
Extended IP access list outboundfilters
  permit tcp any any reflect tcptraffic
```

Notice that the reflexive access list does not appear in this output. This is because before any TCP sessions have been initiated, no traffic has triggered the reflexive access list, and the list is empty (has no entries). When empty, reflexive access lists do not show up in **show access-list** output.

After a Telnet connection is initiated from within your network to a destination outside of your network, the **show access-list EXEC** command displays the following:

```
Extended IP access list inboundfilters
  permit eigrp any any
  deny icmp any any
  evaluate tcptraffic
Extended IP access list outboundfilters
  permit tcp any any reflect tcptraffic
Reflexive IP access list tcptraffic
  permit tcp host 172.19.99.67 eq telnet host 192.168.60.185 eq 11005 (5 matches) (time
left 115 seconds)
```

Notice that the reflexive access list *tcptraffic* now appears and displays the temporary entry generated when the Telnet session initiated with an outbound packet.

Internal Interface Configuration Example

This is an example configuration for reflexive access lists configured for an internal interface. This example has a topology similar to the one in [Figure 19](#) (shown earlier in this chapter).

This example is similar to the previous example; the only difference between this example and the previous example is that the entries for the outbound and inbound access lists are swapped. Please refer to the previous example for more details and descriptions.

```
interface Ethernet 0
  description Access from the I-net to our Internal Network via this interface
  ip access-group inboundfilters in
  ip access-group outboundfilters out
  !
ip reflexive-list timeout 120
!
ip access-list extended outboundfilters
  permit eigrp any any
  deny icmp any any
  evaluate tcptraffic
!
ip access-list extended inboundfilters
  permit tcp any any reflect tcptraffic
```

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

Configuring TCP Intercept (Preventing Denial-of-Service Attacks)

Feature History

Release	Modification
Cisco IOS	For information about feature support in Cisco IOS software, use Cisco Feature Navigator.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

This chapter describes how to configure your router to protect TCP servers from TCP SYN-flooding attacks, a type of denial-of-service attack. This is accomplished by configuring the Cisco IOS feature known as TCP Intercept.

For a complete description of TCP Intercept commands, refer to the “TCP Intercept Commands” chapter of the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the chapter “Identifying Supported Platforms” section in the “Using Cisco IOS Software.”

In This Chapter

This chapter has the following sections:

- [About TCP Intercept](#)
- [TCP Intercept Configuration Task List](#)
- [TCP Intercept Configuration Example](#)

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

About TCP Intercept

The TCP intercept feature implements software to protect TCP servers from TCP SYN-flooding attacks, which are a type of denial-of-service attack.

A SYN-flooding attack occurs when a hacker floods a server with a barrage of requests for connection. Because these messages have unreachable return addresses, the connections cannot be established. The resulting volume of unresolved open connections eventually overwhelms the server and can cause it to deny service to valid requests, thereby preventing legitimate users from connecting to a web site, accessing e-mail, using FTP service, and so on.

The TCP intercept feature helps prevent SYN-flooding attacks by intercepting and validating TCP connection requests. In intercept mode, the TCP intercept software intercepts TCP synchronization (SYN) packets from clients to servers that match an extended access list. The software establishes a connection with the client on behalf of the destination server, and if successful, establishes the connection with the server on behalf of the client and knits the two half-connections together transparently. Thus, connection attempts from unreachable hosts will never reach the server. The software continues to intercept and forward packets throughout the duration of the connection. The number of SYNs per second and the number of concurrent connections proxied depends on the platform, memory, processor, and other factors.

In the case of illegitimate requests, the software's aggressive timeouts on half-open connections and its thresholds on TCP connection requests protect destination servers while still allowing valid requests.

When establishing your security policy using TCP intercept, you can choose to intercept all requests or only those coming from specific networks or destined for specific servers. You can also configure the connection rate and threshold of outstanding connections.

You can choose to operate TCP intercept in watch mode, as opposed to intercept mode. In watch mode, the software passively watches the connection requests flowing through the router. If a connection fails to get established in a configurable interval, the software intervenes and terminates the connection attempt.

TCP options that are negotiated on handshake (such as RFC 1323 on window scaling) will not be negotiated because the TCP intercept software does not know what the server can do or will negotiate.

TCP Intercept Configuration Task List

To configure TCP intercept, perform the tasks in the following sections. The first task is required; the rest are optional.

- [Enabling TCP Intercept](#) (Required)
- [Setting the TCP Intercept Mode](#) (Optional)
- [Setting the TCP Intercept Drop Mode](#) (Optional)
- [Changing the TCP Intercept Timers](#) (Optional)
- [Changing the TCP Intercept Aggressive Thresholds](#) (Optional)
- [Monitoring and Maintaining TCP Intercept](#) (Optional)

For TCP intercept configuration examples using the commands in this chapter, refer to the [“TCP Intercept Configuration Example”](#) section at the end of this chapter.

Enabling TCP Intercept

To enable TCP intercept, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# access-list <i>access-list-number</i> {deny permit} tcp any <i>destination destination-wildcard</i>	Defines an IP extended access list.
Step 2	Router(config)# ip tcp intercept list <i>access-list-number</i>	Enables TCP intercept.

You can define an access list to intercept all requests or only those coming from specific networks or destined for specific servers. Typically the access list will define the source as **any** and define specific destination networks or servers. That is, you do not attempt to filter on the source addresses because you do not necessarily know who to intercept packets from. You identify the destination in order to protect destination servers.

If no access list match is found, the router allows the request to pass with no further action.

Setting the TCP Intercept Mode

The TCP intercept can operate in either active intercept mode or passive watch mode. The default is intercept mode.

In intercept mode, the software actively intercepts each incoming connection request (SYN) and responds on behalf of the server with a SYN-ACK, then waits for an ACK from the client. When that ACK is received, the original SYN is sent to the server and the software performs a three-way handshake with the server. When this is complete, the two half-connections are joined.

In watch mode, connection requests are allowed to pass through the router to the server but are watched until they become established. If they fail to become established within 30 seconds (configurable with the **ip tcp intercept watch-timeout** command), the software sends a Reset to the server to clear up its state.

To set the TCP intercept mode, use the following command in global configuration mode:

Command	Purpose
Router(config)# ip tcp intercept mode {intercept watch}	Sets the TCP intercept mode.

Setting the TCP Intercept Drop Mode

When under attack, the TCP intercept feature becomes more aggressive in its protective behavior. If the number of incomplete connections exceeds 1100 or the number of connections arriving in the last one minute exceeds 1100, each new arriving connection causes the oldest partial connection to be deleted. Also, the initial retransmission timeout is reduced by half to 0.5 seconds (so the total time trying to establish a connection is cut in half).

By default, the software drops the oldest partial connection. Alternatively, you can configure the software to drop a random connection. To set the drop mode, use the following command in global configuration mode:

Command	Purpose
Router(config)# ip tcp intercept drop-mode {oldest random}	Sets the drop mode.

Changing the TCP Intercept Timers

By default, the software waits for 30 seconds for a watched connection to reach established state before sending a Reset to the server. To change this value, use the following command in global configuration mode:

Command	Purpose
Router(config)# ip tcp intercept watch-timeout <i>seconds</i>	Changes the time allowed to reach established state.

By default, the software waits for 5 seconds from receipt of a reset or FIN-exchange before it ceases to manage the connection. To change this value, use the following command in global configuration mode:

Command	Purpose
Router(config)# ip tcp intercept finrst-timeout <i>seconds</i>	Changes the time between receipt of a reset or FIN-exchange and dropping the connection.

By default, the software still manages a connection for 24 hours after no activity. To change this value, use the following command in global configuration mode:

Command	Purpose
Router(config)# ip tcp intercept connection-timeout <i>seconds</i>	Changes the time the software will manage a connection after no activity.

Changing the TCP Intercept Aggressive Thresholds

Two factors determine when aggressive behavior begins and ends: total incomplete connections and connection requests during the last one-minute sample period. Both thresholds have default values that can be redefined.

When a threshold is exceeded, the TCP intercept assumes the server is under attack and goes into aggressive mode. When in aggressive mode, the following occurs:

- Each new arriving connection causes the oldest partial connection to be deleted. (You can change to a random drop mode.)
- The initial retransmission timeout is reduced by half to 0.5 seconds, and so the total time trying to establish the connection is cut in half. (When not in aggressive mode, the code does exponential back-off on its retransmissions of SYN segments. The initial retransmission timeout is 1 second. The subsequent timeouts are 2 seconds, 4 seconds, 8 seconds, and 16 seconds. The code retransmits 4 times before giving up, so it gives up after 31 seconds of no acknowledgment.)
- If in watch mode, the watch timeout is reduced by half. (If the default is in place, the watch timeout becomes 15 seconds.)

The drop strategy can be changed from the oldest connection to a random connection with the **ip tcp intercept drop-mode** command.

**Note**

The two factors that determine aggressive behavior are related and work together. When *either* of the **high** values is exceeded, aggressive behavior begins. When *both* quantities fall below the **low** value, aggressive behavior ends.

You can change the threshold for triggering aggressive mode based on the total number of incomplete connections. The default values for **low** and **high** are 900 and 1100 incomplete connections, respectively. To change these values, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# ip tcp intercept max-incomplete low number	Sets the threshold for stopping aggressive mode.
Step 2	Router(config)# ip tcp intercept max-incomplete high number	Sets the threshold for triggering aggressive mode.

You can also change the threshold for triggering aggressive mode based on the number of connection requests received in the last 1-minute sample period. The default values for **low** and **high** are 900 and 1100 connection requests, respectively. To change these values, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# ip tcp intercept one-minute low number	Sets the threshold for stopping aggressive mode.
Step 2	Router(config)# ip tcp intercept one-minute high number	Sets the threshold for triggering aggressive mode.

Monitoring and Maintaining TCP Intercept

To display TCP intercept information, use either of the following commands in EXEC mode:

Command	Purpose
Router# show tcp intercept connections	Displays incomplete connections and established connections.
Router# show tcp intercept statistics	Displays TCP intercept statistics.

TCP Intercept Configuration Example

The following configuration defines extended IP access list 101, causing the software to intercept packets for all TCP servers on the 192.168.1.0/24 subnet:

```
ip tcp intercept list 101
!
access-list 101 permit tcp any 192.168.1.0 0.0.0.255
```

IP Access List Entry Sequence Numbering

Users can apply sequence numbers to **permit** or **deny** statements and also reorder, add, or remove such statements from a named IP access list. This feature makes revising IP access lists much easier. Prior to this feature, users could add access list entries to the end of an access list only; therefore needing to add statements anywhere except the end required reconfiguring the access list entirely.

Feature History for the IP Access List Entry Additions Feature

Release	Modification
12.2(14)S	This feature was introduced.
12.2(15)T	This feature was integrated into Cisco IOS Release 12.2(15)T.
12.3(2T	This feature was integrated into Cisco IOS Release 12.3(2)T.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Restrictions for IP Access List Entry Sequence Numbering

- This feature does not support dynamic, reflexive, or firewall access lists.
- This feature does not support old-style numbered access lists, which existed before named access lists. Keep in mind that you can name an access list with a number, so numbers are allowed when they are entered in the standard or extended named access list (NACL) configuration mode.

Information About IP Access Lists

Before you resequence or add entries to an IP access list, you should understand the following concepts:

- [Purpose of IP Access Lists, page 2](#)
- [How an IP Access List Works, page 2](#)
- [IP Access List Entry Sequence Numbering, page 4](#)

Purpose of IP Access Lists

Access lists perform packet filtering to control which packets move through the network and where. Such control can help limit network traffic and restrict the access of users and devices to the network. Access lists have many uses, and therefore many commands accept a reference to an access list in their command syntax. Access lists can be used to do the following:

- Filter incoming packets on an interface.
- Filter outgoing packets on an interface.
- Restrict the contents of routing updates.
- Limit debug output based on an address or protocol.
- Control virtual terminal line access.
- Identify or classify traffic for advanced features, such as congestion avoidance, congestion management, and priority and custom queuing.
- Trigger dial-on-demand routing (DDR) calls.

How an IP Access List Works

An access list is a sequential list consisting of at least one **permit** statement and possibly one or more **deny** statements that apply to IP addresses and possibly upper-layer IP protocols. The access list has a name by which it is referenced. Many software commands accept an access list as part of their syntax.

An access list can be configured and named, but it is not in effect until the access list is referenced by a command that accepts an access list. Multiple commands can reference the same access list. An access list can control traffic arriving at the router or leaving the router, but not traffic originating at the router.

IP Access List Process and Rules

- The software tests the source or destination address or the protocol of each packet being filtered against the conditions in the access list, one condition (**permit** or **deny** statement) at a time.

- If a packet does not match an access list statement, the packet is then tested against the next statement in the list.
- If a packet and an access list statement match, the rest of the statements in the list are skipped and the packet is permitted or denied as specified in the matched statement. The first entry that the packet matches determines whether the software permits or denies the packet. That is, after the first match, no subsequent entries are considered.
- If the access list denies the address or protocol, the software discards the packet and returns an ICMP Host Unreachable message.
- If no conditions match, the software drops the packet. This is because each access list ends with an unwritten or implicit **deny** statement. That is, if the packet has not been permitted by the time it was tested against each statement, it is denied.
- The access list must contain at least one **permit** statement or else all packets are denied.
- Because the software stops testing conditions after the first match, the order of the conditions is critical. The same **permit** or **deny** statements specified in a different order could result in a packet being passed under one circumstance and denied in another circumstance.
- If an access list is referenced by name in a command, but the access list does not exist, all packets pass.
- Only one access list per interface, per protocol, per direction is allowed.
- Inbound access lists process packets arriving at the router. Incoming packets are processed before being routed to an outbound interface. An inbound access list is efficient because it saves the overhead of routing lookups if the packet is to be discarded because it is denied by the filtering tests. If the packet is permitted by the tests, it is then processed for routing. For inbound lists, **permit** means continue to process the packet after receiving it on an inbound interface; **deny** means discard the packet.
- Outbound access lists process packets before they leave the router. Incoming packets are routed to the outbound interface and then processed through the outbound access list. For outbound lists, **permit** means send it to the output buffer; **deny** means discard the packet.

Helpful Hints for Creating IP Access Lists

- Create the access list before applying it to an interface. An interface with an empty access list applied to it permits all traffic.
- Another reason to configure an access list before applying it is because if you applied a nonexistent access list to an interface and then proceed to configure the access list, the first statement is put into effect, and the implicit **deny** statement that follows could cause you immediate access problems.
- Because the software stops testing conditions after it encounters the first match (to either a **permit** or **deny** statement), you will reduce processing time and resources if you put the statements that packets are most likely to match at the beginning of the access list. Place more frequently occurring conditions before less frequent conditions.
- Organize your access list so that more specific references in a network or subnet appear before more general ones.
- In order to make the purpose of individual statements more easily understood at a glance, you can write a helpful remark before or after any statement.

Source and Destination Addresses

Source address and destination addresses are two of the most typical fields in an IP packet on which to base an access list. Specify source addresses to control packets from certain networking devices or hosts. Specify destination addresses to control packets being sent to certain networking devices or hosts.

Wildcard Mask and Implicit Wildcard Mask

Address filtering uses wildcard masking to indicate to the software whether to check or ignore corresponding IP address bits when comparing the address bits in an access list entry to a packet being submitted to the access list. By carefully setting wildcard masks, an administrator can select single or several IP addresses for permit or deny tests.

Wildcard masking for IP address bits uses the number 1 and the number 0 to specify how the software treats the corresponding IP address bits. A wildcard mask is sometimes referred to as an inverted mask because a 1 and 0 mean the opposite of what they mean in a subnet (network) mask.

- A wildcard mask bit 0 means *check* the corresponding bit value.
- A wildcard mask bit 1 means *ignore* that corresponding bit value.

If you do not supply a wildcard mask with a source or destination address in an access list statement, the software assumes a default wildcard mask of 0.0.0.0.

Unlike subnet masks, which require contiguous bits indicating network and subnet to be ones, wildcard masks allow noncontiguous bits in the mask.

Transport Layer Information

You can filter packets based on transport layer information, such as whether the packet is a TCP, UDP, ICMP or IGMP packet.

IP Access List Entry Sequence Numbering

Benefits

The ability to apply sequence numbers to IP access list entries simplifies access list changes. Prior to the IP Access List Entry Sequence Numbering feature, there was no way to specify the position of an entry within an access list. If a user wanted to insert an entry (statement) in the middle of an existing list, all of the entries after the desired position had to be removed, then the new entry was added, and then all the removed entries had to be reentered. This method was cumbersome and error prone.

This feature allows users to add sequence numbers to access list entries and resequence them. When a user adds a new entry, the user chooses the sequence number so that it is in a desired position in the access list. If necessary, entries currently in the access list can be resequenced to create room to insert the new entry.

Sequence Numbering Behavior

- For backward compatibility with previous releases, if entries with no sequence numbers are applied, the first entry is assigned a sequence number of 10, and successive entries are incremented by 10. The maximum sequence number is 2147483647. If the generated sequence number exceeds this maximum number, the following message is displayed:

Exceeded maximum sequence number.

- If the user enters an entry without a sequence number, it is assigned a sequence number that is 10 greater than the last sequence number in that access list and is placed at the end of the list.
- If the user enters an entry that matches an already existing entry (except for the sequence number), then no changes are made.
- If the user enters a sequence number that is already present, the following error message is generated:
Duplicate sequence number.
- If a new access list is entered from global configuration mode, then sequence numbers for that access list are generated automatically.
- Distributed support is provided so that the sequence numbers of entries in the Route Processor (RP) and line card (LC) are in synchronization at all times.
- Sequence numbers are not nvgened. That is, the sequence numbers themselves are not saved. In the event that the system is reloaded, the configured sequence numbers revert to the default sequence starting number and increment. The function is provided for backward compatibility with software releases that do not support sequence numbering.
- This feature works with named standard and extended IP access lists. Because the name of an access list can be designated as a number, numbers are acceptable.

How to Use Sequence Numbers in an IP Access List

This section describes how to use sequence numbers in an IP access list.

- [Sequencing Access-List Entries and Revising the Access List, page 5](#)

Sequencing Access-List Entries and Revising the Access List

This task shows how to assign sequence numbers to entries in a named IP access list and how to add or delete an entry to or from an access list. It is assumed a user wants to revise an access list. The context of this task is the following:

- A user need not resequence access lists for no reason; resequencing in general is optional. The resequencing step in this task is shown as required because that is one purpose of this feature and this task demonstrates the feature.
- Step 5 happens to be a **permit** statement and Step 6 happens to be a **deny** statement, but they need not be in that order.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list resequence** *access-list-name* *starting-sequence-number* *increment*
4. **ip access-list {standard | extended}** *access-list-name*
5. *sequence-number* **permit** *source* *source-wildcard*

or

sequence-number **permit** *protocol source source-wildcard destination destination-wildcard*
[**precedence** *precedence*] [**tos** *tos*] [**log**] [**time-range** *time-range-name*] [**fragments**]

6. *sequence-number* **deny** *source source-wildcard*

or

sequence-number **deny** *protocol source source-wildcard destination destination-wildcard*
[**precedence** *precedence*] [**tos** *tos*] [**log**] [**time-range** *time-range-name*] [**fragments**]

7. Repeat Step 5 and/or Step 6 as necessary, adding statements by sequence number where you planned. Use the **no** *sequence-number* command to delete an entry.
8. **end**
9. **show ip access-lists** *access-list-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list resequence <i>access-list-name</i> <i>starting-sequence-number increment</i> Example: Router(config)# ip access-list resequence kmd1 100 15	Resequences the specified IP access list using the starting sequence number and the increment of sequence numbers. This example resequences an access list named kmd1. The starting sequence number is 100 and the increment is 15.
Step 4	ip access-list { standard extended } <i>access-list-name</i> Example: Router(config)# ip access-list standard kmd1	Specifies the IP access list by name and enters named access list configuration mode. - If you specify standard, make sure you subsequently specify permit and/or deny statements using the standard access list syntax. - If you specify extended, make sure you subsequently specify permit and/or deny statements using the extended access list syntax.

	Command or Action	Purpose
Step 5	<i>sequence-number permit source source-wildcard</i> or <i>sequence-number permit protocol source source-wildcard destination destination-wildcard [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]</i> Example: Router(config-std-nacl)# 105 permit 10.5.5.5 0.0.0 255	Specifies a permit statement in named IP access list mode. - This access list happens to use a permit statement first, but a deny statement could appear first, depending on the order of statements you need. - See the permit (IP) command for additional command syntax to permit upper layer protocols (ICMP, IGMP, TCP, and UDP). - Use the no sequence-number command to delete an entry. - As the prompt indicates, this access list was a standard access list. If you had specified extended in Step 4, the prompt for this step would be Router(config-ext-nacl) and you would use the extended permit command syntax.
Step 6	<i>sequence-number deny source source-wildcard</i> or <i>sequence-number deny protocol source source-wildcard destination destination-wildcard [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]</i> Example: Router(config-std-nacl)# 105 deny 10.6.6.7 0.0.0 255	(Optional) Specifies a deny statement in named IP access list mode. - This access list happens to use a permit statement first, but a deny statement could appear first, depending on the order of statements you need. - See the deny (IP) command for additional command syntax to permit upper layer protocols (ICMP, IGMP, TCP, and UDP). - Use the no sequence-number command to delete an entry. - As the prompt indicates, this access list was a standard access list. If you had specified extended in Step 4, the prompt for this step would be Router(config-ext-nacl) and you would use the extended deny command syntax.
Step 7	Repeat Step 5 and/or Step 6 as necessary, adding statements by sequence number where you planned. Use the no sequence-number command to delete an entry.	Allows you to revise the access list.

	Command or Action	Purpose
Step 8	end Example: Router(config-std-nacl)# end	(Optional) Exits the configuration mode and returns to privileged EXEC mode.
Step 9	show ip access-lists access-list-name Example: Router# show ip access-lists kmd1	(Optional) Displays the contents of the IP access list. Review the output to see that the access list includes the new entry. Router# show ip access-lists kmd1 Standard IP access list kmd1 100 permit 10.4.4.0, wildcard bits 0.0.0.255 105 permit 10.5.5.0, wildcard bits 0.0.0.255 115 permit 10.0.0.0, wildcard bits 0.0.0.255 130 permit 10.5.5.0, wildcard bits 0.0.0.255 145 permit 10.0.0.0, wildcard bits 0.0.0.255

What to Do Next

If your access list is not already applied to an interface or line or otherwise referenced, apply the access list. Refer to the “Configuring IP Services” chapter of the *Cisco IOS IP Configuration Guide* for information about how to apply an IP access list.

Configuration Examples for IP Access List Entry Sequence Numbering

This section provides the following examples related to sequence numbering of entries in an IP access list:

- [Resequencing Entries in an Access List: Example, page 8](#)
- [Adding Entries with Sequence Numbers: Example, page 9](#)
- [Entry without Sequence Number: Example, page 9](#)

Resequencing Entries in an Access List: Example

The following example shows access list resequencing. The starting value is 1, and increment value is 2. The subsequent entries are ordered based on the increment values that users provide, and the range is from 1 to 2147483647.

When an entry with no sequence number is entered, by default it has a sequence number of 10 more than the last entry in the access list.

```
Router# show access-list 150
```

```
Extended IP access list 150
 10 permit ip host 10.3.3.3 host 172.16.5.34
 20 permit icmp any any
 30 permit tcp any host 10.3.3.3
 40 permit ip host 10.4.4.4 any
 50 Dynamic test permit ip any any
```

```
60 permit ip host 172.16.2.2 host 10.3.3.12
70 permit ip host 10.3.3.3 any log
80 permit tcp host 10.3.3.3 host 10.1.2.2
90 permit ip host 10.3.3.3 any
100 permit ip any any
```

```
Router(config)# ip access-list extended 150
Router(config)# ip access-list resequence 150 1 2
Router(config)# end
```

```
Router# show access-list 150
```

```
Extended IP access list 150
 1 permit ip host 10.3.3.3 host 172.16.5.34
 3 permit icmp any any
 5 permit tcp any host 10.3.3.3
 7 permit ip host 10.4.4.4 any
 9 Dynamic test permit ip any any
11 permit ip host 172.16.2.2 host 10.3.3.12
13 permit ip host 10.3.3.3 any log
15 permit tcp host 10.3.3.3 host 10.1.2.2
17 permit ip host 10.3.3.3 any
19 permit ip any any
```

Adding Entries with Sequence Numbers: Example

In the following example, an new entry is added to a specified access list:

```
Router# show ip access-list
```

```
Standard IP access list tryon
 2 permit 10.4.4.2, wildcard bits 0.0.255.255
 5 permit 10.0.0.44, wildcard bits 0.0.0.255
10 permit 10.0.0.1, wildcard bits 0.0.0.255
20 permit 10.0.0.2, wildcard bits 0.0.0.255
```

```
Router(config)# ip access-list standard tryon
```

```
Router(config-std-nacl)# 15 permit 10.5.5.5 0.0.0.255
```

```
Router# show ip access-list
```

```
Standard IP access list tryon
 2 permit 10.4.0.0, wildcard bits 0.0.255.255
 5 permit 10.0.0.0, wildcard bits 0.0.0.255
10 permit 10.0.0.0, wildcard bits 0.0.0.255
15 permit 10.5.5.0, wildcard bits 0.0.0.255
20 permit 10.0.0.0, wildcard bits 0.0.0.255
```

Entry without Sequence Number: Example

The following example shows how an entry with no specified sequence number is added to the end of an access list. When an entry is added without a sequence number, it is automatically given a sequence number that puts it at the end of the access list. Because the default increment is 10, the entry will have a sequence number 10 higher than the last entry in the existing access list.

```
Router(config)# ip access-list standard 1
```

```
Router(config-std-nacl)# permit 1.1.1.1 0.0.0.255
```

```
Router(config-std-nacl)# permit 2.2.2.2 0.0.0.255  
Router(config-std-nacl)# permit 3.3.3.3 0.0.0.255
```

```
Router# show access-list  
Standard IP access list 1  
10 permit 0.0.0.0, wildcard bits 0.0.0.255  
20 permit 0.0.0.0, wildcard bits 0.0.0.255  
30 permit 0.0.0.0, wildcard bits 0.0.0.255
```

```
Router(config)# ip access-list standard 1  
Router(config-std-nacl)# permit 4.4.4.4 0.0.0.255  
Router(config-std-nacl)# end
```

```
Router# show access-list  
  
Standard IP access list 1  
10 permit 0.0.0.0, wildcard bits 0.0.0.255  
20 permit 0.0.0.0, wildcard bits 0.0.0.255  
30 permit 0.0.0.0, wildcard bits 0.0.0.255  
40 permit 0.4.0.0, wildcard bits 0.0.0.255
```

Turbo Access Control List Scalability Enhancements

First Published: December 5, 2006
Last Updated: December 5, 2006

The Turbo Access Control List (ACL) Scalability Enhancements feature introduced in Cisco IOS Release 12.2(31)SB2 improves overall performance on the Cisco 7304 router using a Network Services Engine (NSE) by allowing Turbo ACLs to be processed in PXF using less memory, thereby allowing more traffic traversing the Cisco 7304 router using an NSE to be PXF-accelerated. This feature also introduces user-configuration options that allow users to define the amount of memory used for Turbo ACL purposes in the Route Processor (RP) processing path.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for Turbo ACL Scalability Enhancements on the NSEs”](#) section on [page 20](#).

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

- [Glossary, page 21](#)

Prerequisites for Turbo Access Control List Scalability Enhancements on the NSEs

Because the portion of this feature that more expediently removes older entries works in the PXF processing path, PXF must be enabled for this particular functionality to have any benefit. PXF processing is enabled by default.

Restrictions for Turbo Access Control List Scalability Enhancements on the NSEs

This feature is not available for Cisco 7304 routers using an NPE-G100.

Information About Turbo Access Control List Scalability Enhancements on the NSEs

To benefit from the Turbo Access Control List Scalability Enhancements for the NSEs, you should understand the following concepts:

- [How Turbo ACL on the Cisco 7304 Router Using an NSE Works, page 2](#)
- [How Turbo ACL Scalability Enhancements on the NSEs Improves Overall PXF Performance, page 3](#)
- [How Turbo ACL Scalability Enhancements on the NSEs Improves Overall Route Processing Performance, page 3](#)
- [Understanding Memory Limits for Turbo ACL Processes on the Route Processor, page 3](#)
- [Benefits, page 4](#)

How Turbo ACL on the Cisco 7304 Router Using an NSE Works

With the exception that most Turbo ACL classification is PXF-accelerated on a Cisco 7304 router using an NSE-100 or an NSE-150, Turbo ACL classification on the Cisco 7304 router using an NSE-100 or NSE-150 is similar in behavior to Turbo ACL on other platforms. For information on Turbo ACL, see [Turbo Access Control Lists](#).

For information on PXF on Cisco 7304 routers using an NSE-100 or an NSE-150, including the Turbo ACL features that are PXF-accelerated, see [PXF Information for the Cisco 7304 Router](#).

How Turbo ACL Scalability Enhancements on the NSEs Improves Overall PXF Performance

The memory allocated in PXF for Turbo Access Control Lists (ACLs) on the NSE-100 especially is limited to the point where even modestly-sized ACL configurations cause a large amount of PXF memory to be used for Turbo ACL processing. As a result, a large amount of network traffic that should be processed through the PXF processing path is instead processed through the RP path.

This enhancement is part of a series of enhancements to improve Turbo ACL functionality on the Cisco 7304 router using the NSE-100. Specifically, this feature keeps the entries for PXF-based Turbo ACL classification current by more actively removing older entries. The older entries, which are no longer used for current traffic flows, still consume memory and, therefore, cause traffic that would normally be PXF-accelerated to instead be punted to the RP. This portion of the feature, which does not require user configuration, improves overall traffic flow on the Cisco 7304 router using an NSE by allowing more network traffic to be PXF-accelerated.

How Turbo ACL Scalability Enhancements on the NSEs Improves Overall Route Processing Performance

These Turbo ACL scalability enhancements also introduce an enhancement that allows users, via configuration commands, to configure the amount of memory reserved for ACL processing on the RP. The ability to configure the amount of memory reserved for ACL processing in the RP path gives users the option either to improve ACL processing performance in the RP path by reserving more memory for ACL processing, or to improve all other RP path functionality by reserving less memory for ACL processing.

In Cisco IOS releases not containing this feature, the amount of memory reserved for RP ACL handling is fixed.

Understanding Memory Limits for Turbo ACL Processes on the Route Processor

An NSE-150 has 2 GB of DRAM. NSE-100 RAM is user-configurable using an SDRAM SODIMM. While most NSE-100s have 512 MB of RAM, 256-MB and 128-MB SDRAM SODIMMs for the NSE-100 exist.

On a Cisco 7304 router using an NSE-150, the default memory limit for Turbo ACL processes (such as classification, compilation, and table storage) of Layer 3 and Layer 4 data in the RP path is always 256 MB. The default memory limit for Turbo ACL processes for Layer 2 data in the RP path for a Cisco 7304 router using an NSE-150 is always 128 MB.

On a Cisco 7304 router using an NSE-100, the default amount of memory reserved for Turbo ACL processes in the RP path is dependant upon the amount of SDRAM configured on the NSE-100. If the NSE has 512 MB of SDRAM or more, the default memory limit for Turbo ACL processes for Layer 3 and Layer 4 traffic processing is 256 MB. If the processor has less than 512 MB of SDRAM, the default memory limit for Turbo ACL processes for Layer 3 and Layer 4 traffic is 128 MB.

The default amount of memory reserved for Layer 2 Turbo ACL processes for a Cisco 7304 router using an NSE-100 is always 128 MB, regardless of the amount of memory configured on the processor.

To see the default amount of memory reserved for Layer 2 or for Layer 3 and Layer 4 Turbo ACL processing on your Cisco 7304 router, enter the **show access-list compiled** command. The “Mb default limit” output, which appears in both the “Compiled ACL statistics for IPv4” and “Compiled ACL

statistics for Data-Link” sections of the output, shows you the default memory reservations for either Layer 2 or Layer 3 and Layer 4 Turbo ACL processing. See the [“Monitoring Turbo ACL Memory Usage in the Route Processing Path” section on page 5](#) for a more detailed explanation of this procedure.

To change the default amount of memory reserved for Layer 2 or Layer 3 and Layer 4 Turbo ACL processing on your Cisco 7304 router, enter the **access-list compiled [ipv4 | data-link] limit memory number** command.

To restore the default amount of memory reserved for Layer 2 or Layer 3 and Layer 4 Turbo ACL processing on your Cisco 7304 router, enter the **default access-list compiled [ipv4 | data-link] limit memory** command.

To learn more about the SDRAM SODIMMs that determine the amount of SDRAM available for Cisco 7304 routers using an NSE-100, see [NSE-100 Memory Information](#).

Benefits

Improved Traffic Flow

This feature improves the Turbo ACL processing process in PXF by more expediently removing older entries. As a result, more Turbo ACL processing can be done in the PXF processing path, thereby allowing more router traffic to be accelerated using the PXF processing path.

Configuration of Route Processor Memory Limits for ACL Processing

This feature allows users to set the amount of memory reserved for ACL processes (such as compilation, storage, and classification) in the RP path. Users who need more memory for ACL processes now have the ability to set aside additional memory resources in the RP path for ACL processes. Users who need more more memory for other processes in the RP path now can set aside less memory for ACL processes.

How to Configure Turbo Access Control List Scalability Enhancements on the NSEs

It is important to note that the portion of this feature that more expediently removes older ACL entries for ACLs being processed in the PXF processing path occurs automatically without user configuration.

The following sections contain procedures for configuring memory reservations for Turbo ACL processing on the RP:

- [Monitoring Turbo ACL Memory Usage in the Route Processing Path, page 5](#)
- [Configuring a User-Defined Memory Limitations for Turbo ACL Processing of Layer 3 and Layer 4 Data in the Route Processing Path, page 7 \(optional\)](#)
- [Removing Memory Limits for Turbo ACL Processing of Layer 3 and Layer 4 Data in the Route Processing Path, page 7 \(optional\)](#)
- [Restoring the Default Memory Limits for Turbo ACL Processing of Layer 3 and 4 Data in the Route Processing Path, page 8 \(optional\)](#)
- [Configuring a User-Defined Memory Limitation for Turbo ACL Processing of Layer 2 Data in the Route Processing Path, page 9 \(optional\)](#)
- [Removing Memory Limits for Turbo ACL Processing of Layer 2 Data in the Route Processing Path, page 10 \(optional\)](#)
- [Restoring the Default Memory Limits for Turbo ACL Processing of Layer 2 Data in the Route Processing Path, page 11 \(optional\)](#)
- [Verifying Memory Limitation Settings for Turbo ACL Processing, page 12 \(optional\)](#)

Monitoring Turbo ACL Memory Usage in the Route Processing Path

Before setting the actual memory limits for RP-based Turbo ACL usage, it may be helpful to gather information regarding the amount of memory being used for Turbo ACL usage.

To monitor your Turbo ACL memory usage in the RP path, you must complete the following steps.

SUMMARY STEPS

1. **enable**
2. **show access-list compiled**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	show access-list compiled Example: Router# show access-list compiled	Displays the status and condition of the Turbo ACL tables associated with each access list. When using this command to verify memory limitation settings for Turbo ACL processing, look for the following: - The output for show access-list compiled is separated for Layer 2 and for Layer 3 and Layer 4 data. Layer 3 and Layer 4 ACL compilation tables and information can be seen in the “Compiled ACL statistics for IPv4” section of the output, while Layer 2 ACL compilation tables and information can be seen in the “Compiled ACL statistics for Data-Link” section. - The “mem limits” output that shows the number of times a compile has occurred and the ACL has reached its configured limit. - The “Mb limit” output that shows the current memory limit setting. - The “Mb max memory” output that shows the maximum amount of memory the current ACL configuration could actually consume under maximum usage conditions. For additional information and an example, see the “Monitoring Memory Limitations for Layer 2 or Layer 3 and Layer 4 ACL Processing: Example” section on page 14.

Configuring a User-Defined Memory Limitations for Turbo ACL Processing of Layer 3 and Layer 4 Data in the Route Processing Path

To enable memory limitations for Turbo ACL processing of Layer 3 and Layer 4 data in the RP path, you must complete the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **access-list compiled ipv4 limit memory *number***

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	access-list compiled ipv4 limit memory <i>number</i> Example: Router(config)# access-list compiled ipv4 limit memory 300	Specifies the limit, in megabytes, reserved for Turbo ACL instance 0, which is used for processing Layer 3 and Layer 4 data.

Removing Memory Limits for Turbo ACL Processing of Layer 3 and Layer 4 Data in the Route Processing Path

Removing all memory limits for Turbo ACL processes in the Route Processor allows all route processing memory to be used for Turbo ACL processing of Layer 3 and Layer 4 data, if necessary. It is important to note that this functionality is not used to remove a previously configured limit, even though it is a **no** form of a command.

To remove all memory limits for Turbo ACL processing for Layer 3 and Layer 4 data and to allow as much memory as needed for Layer 3 and Layer 4 Turbo ACL processing in the RP path, you must complete the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no access-list compiled ipv4 limit memory**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	no access-list compiled ipv4 limit memory Example: Router(config)# no access-list compiled ipv4 limit memory	Removes any memory limits for Layer 3 and Layer 4 Turbo ACL processing, thereby allowing all available memory to be used for Layer 3 and Layer 4 Turbo ACL processing, if necessary.

Restoring the Default Memory Limits for Turbo ACL Processing of Layer 3 and 4 Data in the Route Processing Path

The default memory limit for Turbo ACL processing of Layer 3 and Layer 4 data in the RP path is always 256 MB on the NSE-150.

On the NSE-100, the default memory limit for Turbo ACL processing of Layer 3 and Layer 4 data in the RP path is dependant on the amount of memory on your NSE-100. If you have more than 512 MB of memory configured on your processor, your default memory limit for RP-based Turbo ACL processing is 256 MB. If you have less than 512 MB of memory, your default memory limit for RP-based Turbo ACL processing is 128 MB.

To restore the default RP memory limit settings for Turbo ACL processing of Layer 3 and Layer 4 traffic, you must complete the following steps.

SUMMARY STEPS

- enable**
- configure terminal**
- default access-list compiled ipv4 limit memory**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	default access-list compiled ipv4 limit memory Example: Router(config)# default access-list compiled ipv4 limit memory	Restores the default memory limit setting for Layer 3 and Layer 4 Turbo ACL traffic processing. The default memory limit for Turbo ACL processing of Layer 3 and Layer 4 data in the RP path is always 256 MB on the NSE-150. On the NSE-100, the default memory limit for Turbo ACL processing of Layer 3 and Layer 4 data in the RP path is dependant on the amount of memory on your NSE-100. If you have more than 512 MB of memory configured on your processor, your default memory limit for RP-based Turbo ACL processing is 256 MB. If you have less than 512 MB of memory, your default memory limit for RP-based Turbo ACL processing is 128 MB.

Configuring a User-Defined Memory Limitation for Turbo ACL Processing of Layer 2 Data in the Route Processing Path

To enable a memory limitation setting for Turbo ACL processing of Layer 2 data in the RP path, you must complete the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **access-list compiled data-link limit memory *number***

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	access-list compiled data-link limit memory number Example: Router(config)# access-list compiled data-link limit memory 150	Specifies the limit, in megabytes, reserved for Turbo ACL instance 1, which is used by the Turbo ACL algorithm to classify Layer 2 frames.

Removing Memory Limits for Turbo ACL Processing of Layer 2 Data in the Route Processing Path

Removing all memory limits for Turbo ACL processing of Layer 2 data in the Route Processor allows all route processing memory to be used for Turbo ACL processing of Layer 2 data, if necessary. It is important to note that this functionality is not used to remove a previously configured limit, even though it is a **no** form of a command.

To remove all RP-based memory limits for Turbo ACL processing for Layer 2 data and to allow as much memory as needed for Layer 2 Turbo ACL processing, you must complete the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no access-list compiled data-link limit memory**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	no access-list compiled data-link limit memory Example: Router(config)# no access-list compiled data-link limit memory	Removes any memory limits for Layer 2 Turbo ACL processing, thereby allowing all available memory to be used for Layer 2 Turbo ACL processing, if necessary.

Restoring the Default Memory Limits for Turbo ACL Processing of Layer 2 Data in the Route Processing Path

The default memory limit for Turbo ACL processing of Layer 2 data in the RP processing path is 128 MB for the NSE-100 and NSE-150.

To restore the default RP-based memory limit setting for Turbo ACL processing of Layer 2 data, you must complete the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **default access-list compiled data-link limit memory**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	default access-list compiled data-link limit memory Example: Router(config)# default access-list compiled data-link limit memory	Restores the default memory limit setting for Layer 2 Turbo ACL processing. The default memory limit setting for Layer 2 Turbo ACL processing is always 128 MB.

Verifying Memory Limitation Settings for Turbo ACL Processing

To verify RP-based memory limitation settings for Turbo ACL processing, you must complete the following steps.

SUMMARY STEPS

1. **enable**
2. **show access-list compiled**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example: Router> enable	Enter your password if prompted.
Step 2	show access-list compiled	Displays the status and condition of the Turbo ACL tables associated with each access list.
	Example: Router# show access-list compiled	When using this command to verify memory limitation settings for Turbo ACL processing, look at the “Mb limit” output for both IPv4 and Data-Link. The new MB limit setting should be listed in the “Mb limit” output for IPv4 or Data-Link, depending on which memory limit was changed. For an example of the show access-list compiled command with these outputs highlighted, see the “Verifying ACL Memory Limit Configurations: Example” section on page 16.

Configuration Examples for Turbo Access Control List Scalability Enhancements on the NSEs

This section provides the following configuration examples:

- [Monitoring Memory Limitations for Layer 2 or Layer 3 and Layer 4 ACL Processing: Example, page 14](#)
- [Reserving a Set Amount of Memory for Layer 2 ACL Processing: Example, page 15](#)
- [Allowing All Available Memory to Be Used for Layer 2 ACL Processing: Example, page 15](#)
- [Restoring the Default Amount of Memory Reserved for Layer 2 ACL Processing: Example, page 15](#)
- [Reserving a Set Amount of Memory for Layer 3 and Layer 4 ACL Processing: Example, page 16](#)
- [Allowing All Available Memory to Be Used for Layer 3 and Layer 4 ACL Processing: Example, page 16](#)
- [Restoring the Default Amount of Memory Reserved for Layer 3 and Layer 4 ACL Processing: Example, page 16](#)
- [Verifying ACL Memory Limit Configurations: Example, page 16](#)

Monitoring Memory Limitations for Layer 2 or Layer 3 and Layer 4 ACL Processing: Example

In the following example, the **show access-list compiled** command is entered.

Note the following, which are italicized in the example output:

- The output for **show access-list compiled** is separated for Layer 2 and for Layer 3 and Layer 4 data. Layer 3 and Layer 4 ACL compilation tables and information can be seen in the “Compiled ACL statistics for IPv4” section of the output, while Layer 2 ACL compilation tables and information can be seen in the “Compiled ACL statistics for Data-Link” section.
- The “mem limits” output shows the number of times a compile has occurred and the ACL has reached its configured limit. If you have reached the configured limit numerous times, you may want to consider modifying the memory limit to allow more memory.
In this example, ACL memory for Layer 3 and Layer 4 data has never reached its configured limit. The same is true for Layer 2 data in this example.
- The “Mb limit” output shows the current memory limit setting.
In this example, the Layer 3 and Layer 4 memory limit was previously set to 65 MB (via the **access-list compiled ipv4 limit memory 65** command), while the Layer 2 memory limit has not been changed from its default limit of 128 MB.
- The “Mb default limit” output shows the current default memory limit setting. If the **default** form of the **access-list compiled ipv4 limit memory** command or **access-list compiled data-link limit memory** command is entered, the “Mb default limit” will become the “Mb limit.”
In this example, the default limits are 256 MB for Layer 3 and Layer 4 data and 128 MB for Layer 2 data.
- The “Mb max memory” output shows the maximum amount of memory the current ACL configuration could actually consume under maximum usage conditions. This number is helpful for configuring memory limits for ACL processing. If you want to free up RP memory, for instance, and you have a small number of ACLs with a low “max memory,” you could configure a reservation of a small amount of memory for ACL processing using the **access-list compiled [ipv4 | data-link] limit memory number** command, thereby freeing up memory for other RP processes. Conversely, if you have a high memory limit, you may want to use the **access-list compiled [ipv4 | data-link] limit memory number** command to commit more memory to ACL processing, or even the **no access-list compiled [ipv4 | data-link] limit memory** command to allow as much memory as is available for ACL processing.
In this example, the max memory for the current Layer 3 and Layer 4 Turbo ACL configuration data on the router is 1 MB, and the max memory for Layer 2 Turbo ACL configuration data is 0 Mb.

```
Router# show access-lists compiled
Compiled ACL statistics for IPv4:
ACL State      Entries Config Fragment Redundant
102 Operational 1      1      0      0

Reserving a Set Amount of Memory for Layer 2 ACL Processing: Example

The following example reserves 100 MB of memory for Layer 2 ACL processing in the RP path:

```
access-list compiled data-link limit memory 100
```

Allowing All Available Memory to Be Used for Layer 2 ACL Processing: Example

The following example allows Layer 2 ACL processing to use as much memory as is needed for Layer 2 ACL processing:

```
no access-list compiled data-link limit memory
```

Restoring the Default Amount of Memory Reserved for Layer 2 ACL Processing: Example

The following example restores the default amount of memory reserved for Layer 2 ACL processing in the RP path:

```
default access-list compiled data-link limit memory
```

Reserving a Set Amount of Memory for Layer 3 and Layer 4 ACL Processing: Example

The following example reserves 100 MB of memory for Layer 3 and Layer 4 ACL processing in the RP path:

```
access-list compiled ipv4 limit memory 100
```

Allowing All Available Memory to Be Used for Layer 3 and Layer 4 ACL Processing: Example

The following example allows Layer 3 and Layer 4 ACL processing to use as much memory as is needed for Layer 3 and Layer 4 ACL data:

```
no access-list compiled ipv4 limit memory
```

Restoring the Default Amount of Memory Reserved for Layer 3 and Layer 4 ACL Processing: Example

The following example restores the default amount of memory reserved for Layer 3 and Layer 4 ACL processing in the RP path:

```
default access-list compiled ipv4 limit memory
```

Verifying ACL Memory Limit Configurations: Example

In the following example, a 65-MB limit has been configured for Layer 3 and Layer 4 ACL processing, while the Layer 2 ACL memory reservations have not been changed.

See the italicized output in the following example to view the changes:

```
Router# show access-lists compiled
Compiled ACL statistics for IPv4:
ACL State      Entries Config Fragment Redundant

Command Reference

The following commands are introduced or modified in the feature or features

- **access-list compiled data-link limit memory**
- **access-list compiled ipv4 limit memory**

For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html.

For information about all Cisco IOS commands, see the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the Master Command List.

Feature Information for Turbo ACL Scalability Enhancements on the NSEs

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 1 Feature Information for Turbo ACL Scalability Enhancements on the NSEs

Feature Name	Releases	Feature Information
Turbo ACL Scalability Enhancements on the NSEs	12.2(31)SB2	This feature was introduced.
Performance Enhancements for IOS ACL	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

Glossary

Access Control List—A list kept by routers to control access to or from the router for a number of services.

NSE—network services engine. The Cisco 7304 router has two types of processor, the NSE and the network processing engine (NPE). Two versions of the NSE exist, the NSE-100 and the NSE-150.

RP—Route Processor. One of two processing paths on a Cisco 7304 router using an NSE, with the Parallel eXpress Forwarding path being the other path. All traffic not supported in the PXF path on a Cisco 7304 router using an NSE is forwarded using the RP path.

Turbo Access Control Lists—A Turbo Access Control list is an access list that more expediently processes traffic by compiling the ACLs into a set of lookup tables while still maintaining the match requirements.

PXF—Parallel eXpress Forwarding. One of two processing paths on a Cisco 7304 router using an NSE, with the Route Processor (RP) path being the other path. The PXF processing path is used to accelerate the performance for certain supported features.

Context-Based Access Control

Configuring Context-Based Access Control

This chapter describes how to configure Context-based Access Control (CBAC). CBAC provides advanced traffic filtering functionality and can be used as an integral part of your network's firewall. For more information regarding firewalls, refer to the chapter "Cisco IOS Firewall Overview."

For a complete description of the CBAC commands used in this chapter, refer to the "Context-Based Access Control Commands" chapter in the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the chapter "Identifying Supported Platforms" section in the "Using Cisco IOS Software."

In This Chapter

This chapter has the following sections:

- [About Context-Based Access Control](#)
- [CBAC Configuration Task List](#)
- [Monitoring and Maintaining CBAC](#)
- [CBAC Configuration Examples](#)

About Context-Based Access Control

This section describes CBAC features and functions:

- [What CBAC Does](#)
- [What CBAC Does Not Do](#)
- [How CBAC Works](#)
- [When and Where to Configure CBAC](#)
- [The CBAC Process](#)

- [Restrictions](#)
- [Memory and Performance Impact](#)

What CBAC Does

CBAC works to provide network protection on multiple levels using the following functions:

- [Traffic Filtering](#)
- [Traffic Inspection](#)
- [Alerts and Audit Trails](#)
- [Intrusion Prevention](#)

Traffic Filtering

CBAC intelligently filters TCP and UDP packets based on application-layer protocol session information. You can configure CBAC to permit specified TCP and UDP traffic through a firewall only when the connection is initiated from within the network you want to protect. CBAC can inspect traffic for sessions that originate from either side of the firewall, and CBAC can be used for intranet, extranet, and Internet perimeters of your network.

Without CBAC, traffic filtering is limited to access list implementations that examine packets at the network layer, or at most, the transport layer. However, CBAC examines not only network layer and transport layer information but also examines the application-layer protocol information (such as FTP connection information) to learn about the state of the session. This allows support of protocols that involve multiple channels created as a result of negotiations in the control channel. Most of the multimedia protocols as well as some other protocols (such as FTP, RPC, and SQL*Net) involve multiple channels.

Using CBAC, Java blocking can be configured to filter HTTP traffic based on the server address or to completely deny access to Java applets that are not embedded in an archived or compressed file. With Java, you must protect against the risk of users inadvertently downloading destructive applets into your network. To protect against this risk, you could require all users to disable Java in their browser. If this is not an acceptable solution, you can create a CBAC inspection rule to filter Java applets at the firewall, which allows users to download only applets residing within the firewall and trusted applets from outside the firewall. For extensive content filtering of Java, Active-X, or virus scanning, you might want to consider purchasing a dedicated content filtering product.

Traffic Inspection

CBAC inspects traffic that travels through the firewall to discover and manage state information for TCP and UDP sessions. This state information is used to create temporary openings in the firewall's access lists to allow return traffic and additional data connections for permissible sessions.

Inspecting packets at the application layer, and maintaining TCP and UDP session information, provides CBAC with the ability to detect and prevent certain types of network attacks such as SYN-flooding. A SYN-flood attack occurs when a network attacker floods a server with a barrage of requests for connection and does not complete the connection. The resulting volume of half-open connections can overwhelm the server, causing it to deny service to valid requests. Network attacks that deny access to a network device are called denial-of-service (DoS) attacks.

CBAC helps to protect against DoS attacks in other ways. CBAC inspects packet sequence numbers in TCP connections to see if they are within expected ranges—CBAC drops any suspicious packets. You can also configure CBAC to drop half-open connections, which require firewall processing and memory resources to maintain. Additionally, CBAC can detect unusually high rates of new connections and issue alert messages.

CBAC can help by protecting against certain DoS attacks involving fragmented IP packets. Even though the firewall prevents an attacker from making actual connections to a given host, the attacker can disrupt services provided by that host. This is done by sending many non-initial IP fragments or by sending complete fragmented packets through a router with an ACL that filters the first fragment of a fragmented packet. These fragments can tie up resources on the target host as it tries to reassemble the incomplete packets.

Alerts and Audit Trails

CBAC also generates real-time alerts and audit trails. Enhanced audit trail features use SYSLOG to track all network transactions; recording time stamps, source host, destination host, ports used, and the total number of transmitted bytes, for advanced, session-based reporting. Real-time alerts send SYSLOG error messages to central management consoles upon detecting suspicious activity. Using CBAC inspection rules, you can configure alerts and audit trail information on a per-application protocol basis. For example, if you want to generate audit trail information for HTTP traffic, you can specify that in the CBAC rule covering HTTP inspection.

Intrusion Prevention

CBAC provides a limited amount of intrusion detection to protect against specific SMTP attacks. With intrusion detection, SYSLOG messages are reviewed and monitored for specific “attack signatures.” Certain types of network attacks have specific characteristics, or signatures. When CBAC detects an attacks, it resets the offending connections and sends SYSLOG information to the SYSLOG server. Refer to the section [“Interpreting Syslog and Console Messages Generated by CBAC”](#) later in this chapter for a list of supported signatures.

In addition to the limited intrusion detection offered by CBAC, the Cisco IOS Firewall feature set offers intrusion detection technology for mid-range and high-end router platforms using the Cisco IOS Intrusion Prevention System (IPS). Cisco IOS IPS restructures and replaces the existing Cisco IOS Intrusion Detection System (IDS). It is ideal for any network perimeter, and especially for locations in which a router is being deployed and additional security between network segments is required. It also can protect intranet and extranet connections where additional security is mandated, and branch-office sites connecting to the corporate office or Internet.

The Cisco IOS IPS acts as an in-line intrusion detection sensor, watching packets and sessions as they flow through the router and scanning each packet to match any of the Cisco IOS IPS signatures. When Cisco IOS IPS detects suspicious activity, it responds before network security can be compromised and logs the event through Cisco IOS syslog messages or Security Device Event Exchange (SDEE).

For more information about Cisco IOS IPS, refer to the module “Configuring Cisco IOS Intrusion Prevention System (IPS).”

What CBAC Does Not Do

CBAC does not provide intelligent filtering for all protocols; it only works for the protocols that you specify. If you do not specify a certain protocol for CBAC, the existing access lists will determine how that protocol is filtered. No temporary openings will be created for protocols not specified for CBAC inspection.

CBAC does not protect against attacks originating from within the protected network unless that traffic travels through a router that has the Cisco IOS Firewall feature set deployed on it. CBAC only detects and protects against attacks that travel through the firewall. This is a scenario in which you might want to deploy CBAC on an intranet-based router.

CBAC protects against certain types of attacks, but not every type of attack. CBAC should not be considered a perfect, impenetrable defense. Determined, skilled attackers might be able to launch effective attacks. While there is no such thing as a perfect defense, CBAC detects and prevents most of the popular attacks on your network.

How CBAC Works

You should understand the material in this section before you configure CBAC. If you do not understand how CBAC works, you might inadvertently introduce security risks by configuring CBAC inappropriately. This section contains the following sections:

- [How CBAC Works—Overview](#)
- [How CBAC Works—Details](#)

How CBAC Works—Overview

CBAC creates temporary openings in access lists at firewall interfaces. These openings are created when specified traffic exits your internal network through the firewall. The openings allow returning traffic (that would normally be blocked) and additional data channels to enter your internal network back through the firewall. The traffic is allowed back through the firewall only if it is part of the same session as the original traffic that triggered CBAC when exiting through the firewall.

Throughout this chapter, the terms “inbound” and “outbound” are used to describe the direction of traffic relative to the router interface on which CBAC is applied. For example, if a CBAC rule is applied inbound on interface E0, then packets entering interface E0 from the network will be inspected. If a CBAC rule is applied outbound on interface E0, then packets leaving interface E0 to the network will be inspected. This is similar to the way ACLs work.

For example, consider a CBAC inspection rule named *hqusers*, and suppose that rule is applied inbound at interface E0:

```
router (config-if)# ip inspect hqusers in
```

This command causes CBAC to inspect the packets coming into this interface from the network. If a packet is attempting to initiate a session, CBAC will then determine if this protocol is allowed, create a CBAC session, add the appropriate ACLs to allow return traffic and do any needed content inspection on any future packets for this session.

The terms “input” and “output” are used to describe the interfaces at which network traffic enters or exits the firewall router. A packet enters the firewall router via the input interface, is inspected by the firewall software and then exits the router via the output interface.

In [Figure 20](#), the inbound access lists at S0 and S1 are configured to block Telnet traffic, and there is no outbound access list configured at E0. When the connection request for User1's Telnet session passes through the firewall, CBAC creates a temporary opening in the inbound access list at S0 to permit returning Telnet traffic for User1's Telnet session. (If the same access list is applied to both S0 and S1, the same opening would appear at both interfaces.) If necessary, CBAC would also have created a similar opening in an outbound access list at E0 to permit return traffic.

Figure 20 *CBAC Opens Temporary Holes in Firewall Access Lists*

How CBAC Works—Details

This section describes how CBAC inspects packets and maintains state information about sessions to provide intelligent filtering.

Packets Are Inspected

With CBAC, you specify which protocols you want to be inspected, and you specify an interface and interface direction (in or out) where inspection originates. Only specified protocols will be inspected by CBAC.

Packets entering the firewall are inspected by CBAC only if they first pass the inbound access list at the input interface and outbound access list at the output interface. If a packet is denied by the access list, the packet is simply dropped and not inspected by CBAC.

CBAC inspection tracks sequence numbers in all TCP packets, and drops those packets with sequence numbers that are not within expected ranges.

CBAC inspection recognizes application-specific commands (such as illegal SMTP commands) in the control channel, and detects and prevents certain application-level attacks.

When CBAC suspects an attack, the DoS feature can take several actions:

- Generate alert messages
- Protect system resources that could impede performance
- Block packets from suspected attackers

CBAC uses timeout and threshold values to manage session state information, helping to determine when to drop sessions that do not become fully established. Setting timeout values for network sessions helps prevent DoS attacks by freeing up system resources, dropping sessions after a specified amount of time. Setting threshold values for network sessions helps prevent DoS attacks by controlling the number of half-open sessions, which limits the amount of system resources applied to half-open sessions. When a

session is dropped, CBAC sends a reset message to the devices at both end points (source and destination) of the session. When the system under DoS attack receives a reset command, it releases, or frees up, processes and resources related to that incomplete session.

CBAC provides three thresholds against DoS attacks:

- The total number of half-open TCP or UDP sessions
- The number of half-open sessions based upon time
- The number of half-open TCP-only sessions per host

If a threshold is exceeded, CBAC has two options:

- Send a reset message to the end points of the oldest half-open session, making resources available to service newly arriving SYN packets.
- In the case of half open TCP only sessions, CBAC blocks all SYN packets temporarily for the duration configured by the threshold value. When the router blocks a SYN packet, the TCP three-way handshake is never initiated, which prevents the router from using memory and processing resources needed for valid connections.

DoS detection and prevention requires that you create a CBAC inspection rule and apply that rule on an interface. The inspection rule must include the protocols that you want to monitor against DoS attacks. For example, if you have TCP inspection enabled on the inspection rule, then CBAC can track all TCP connections to watch for DoS attacks. If the inspection rule includes FTP protocol inspection but not TCP inspection, CBAC tracks only FTP connections for DoS attacks.

For detailed information about setting timeout and threshold values in CBAC to detect and prevent DoS attacks, refer in the [“Configuring Global Timeouts and Thresholds”](#) section.

A State Table Maintains Session State Information

Whenever a packet is inspected, a state table is updated to include information about the state of the session.

Return traffic will only be permitted back through the firewall if the state table contains information indicating that the packet belongs to a permissible session. CBAC controls the traffic that belongs to a valid session. When return traffic is inspected, the state table information is updated as necessary.

UDP “Sessions” Are Approximated

With UDP—a connectionless service—there are no actual sessions, so the software approximates sessions by examining the information in the packet and determining if the packet is similar to other UDP packets (for example, same source/destination addresses and port numbers) and if the packet was detected soon after another similar UDP packet. “Soon” means within the configurable UDP idle timeout period.

Access List Entries Are Dynamically Created and Deleted to Permit Return Traffic and Additional Data Connections

CBAC dynamically creates and deletes access list entries at the firewall interfaces, according to the information maintained in the state tables. These access list entries are applied to the interfaces to examine traffic flowing back into the internal network. These entries create temporary openings in the firewall to permit only traffic that is part of a permissible session.

The temporary access list entries are never saved to NVRAM.

When and Where to Configure CBAC

Configure CBAC at firewalls protecting internal networks. Such firewalls should be Cisco routers with the Cisco IOS Firewall feature set configured as described previously in the section “Cisco IOS Firewall.”

Use CBAC when the firewall will be passing traffic such as the following:

- Standard TCP and UDP Internet applications
- Multimedia applications
- Oracle support

Use CBAC for these applications if you want the application’s traffic to be permitted through the firewall only when the traffic session is initiated from a particular side of the firewall (usually from the protected internal network).

In many cases, you will configure CBAC in one direction only at a single interface, which causes traffic to be permitted back into the internal network only if the traffic is part of a permissible (valid, existing) session. This is a typical configuration for protecting your internal networks from traffic that originates on the Internet.

You can also configure CBAC in two directions at one or more interfaces. CBAC is configured in two directions when the networks on both sides of the firewall should be protected, such as with extranet or intranet configurations, and to protect against DoS attacks. For example, if the firewall is situated between two partner companies’ networks, you might wish to restrict traffic in one direction for certain applications, and restrict traffic in the opposite direction for other applications.

The CBAC Process

This section describes a sample sequence of events that occurs when CBAC is configured at an external interface that connects to an external network such as the Internet.

In this example, a TCP packet exits the internal network through the firewall’s external interface. The TCP packet is the first packet of a Telnet session, and TCP is configured for CBAC inspection.

1. The packet reaches the firewall’s external interface.
2. The packet is evaluated against the interface’s existing outbound access list, and the packet is permitted. (A denied packet would simply be dropped at this point.)
3. The packet is inspected by CBAC to determine and record information about the state of the packet’s connection. This information is recorded in a new state table entry created for the new connection.

(If the packet’s application—Telnet—was not configured for CBAC inspection, the packet would simply be forwarded out the interface at this point without being inspected by CBAC. See the section “[Defining an Inspection Rule](#)” later in this chapter for information about configuring CBAC inspection.)

4. Based on the obtained state information, CBAC creates a temporary access list entry which is inserted at the beginning of the external interface’s inbound extended access list. This temporary access list entry is designed to permit inbound packets that are part of the same connection as the outbound packet just inspected.
5. The outbound packet is forwarded out the interface.
6. Later, an inbound packet reaches the interface. This packet is part of the same Telnet connection previously established with the outbound packet. The inbound packet is evaluated against the inbound access list, and it is permitted because of the temporary access list entry previously created.

7. The permitted inbound packet is inspected by CBAC, and the connection's state table entry is updated as necessary. Based on the updated state information, the inbound extended access list temporary entries might be modified in order to permit only packets that are valid for the current state of the connection.
8. Any additional inbound or outbound packets that belong to the connection are inspected to update the state table entry and to modify the temporary inbound access list entries as required, and they are forwarded through the interface.
9. When the connection terminates or times out, the connection's state table entry is deleted, and the connection's temporary inbound access list entries are deleted.

In the sample process just described, the firewall access lists are configured as follows:

- An outbound IP access list (standard or extended) is applied to the external interface. This access list permits all packets that you want to allow to exit the network, including packets you want to be inspected by CBAC. In this case, Telnet packets are permitted.
- An inbound extended IP access list is applied to the external interface. This access list denies any traffic to be inspected by CBAC—including Telnet packets. When CBAC is triggered with an outbound packet, CBAC creates a temporary opening in the inbound access list to permit only traffic that is part of a valid, existing session.

If the inbound access list had been configured to permit *all* traffic, CBAC would be creating pointless openings in the firewall for packets that would be permitted anyway.

Supported Protocols

This section provides a list of CBAC supported protocols and includes a more detailed look at support for multimedia applications, specifically RTSP and H.323.

CBAC Supported Protocols

You can configure CBAC to inspect the following types of sessions:

- All TCP sessions, regardless of the application-layer protocol (sometimes called “single-channel” or “generic” TCP inspection)
- All UDP sessions, regardless of the application-layer protocol (sometimes called “single-channel” or “generic” UDP inspection)

You can also configure CBAC to specifically inspect certain application-layer protocols. The following application-layer protocols can all be configured for CBAC:

- CU-SeeMe (only the White Pine version)
- FTP
- H.323 (such as NetMeeting, ProShare)
- HTTP (Java blocking)
- Microsoft NetShow
- UNIX R-commands (such as rlogin, rexec, and rsh)
- RealAudio
- RTSP (Real Time Streaming Protocol)
- RPC (Sun RPC, not DCE RPC)

- SMTP (Simple Mail Transport Protocol)

**Note**

CBAC can be configured to inspect SMTP but not ESMTP (Extended Simple Mail Transport Protocol). SMTP is described in RFC 821. CBAC SMTP inspect does not inspect the ESMTP session or command sequence. Configuring SMTP inspection is not useful for ESMTP, and it can cause problems.

To determine whether a mail-server is doing SMTP or ESMTP, contact your mail-server software vendor, or telnet to the mail-server port 25 and observe the banner to see if it reports SMTP or ESMTP.

- SQL*Net
- StreamWorks
- TFTP
- VDOLive

When a protocol is configured for CBAC, that protocol traffic is inspected, state information is maintained, and in general, packets are allowed back through the firewall only if they belong to a permissible session.

RTSP and H.323 Protocol Support for Multimedia Applications

CBAC supports a number of protocols for multimedia applications that require delivery of data with real-time properties such as audio and video conferencing. This support includes the following multimedia application protocols:

- Real Time Streaming Protocol (RTSP)
- H.323 Version 2 (H.323 V2)

RTSP and H.323 V2 inspection allows clients on a protected network to receive data associated with a multimedia session from a server on an unprotected network.

RTSP Support

RTSP is the IETF standards-based protocol (RFC 2326) for control over the delivery of data with real-time properties such as audio and video streams. It is useful for large-scale broadcasts and audio or video on demand streaming, and is supported by a variety of vendor products of streaming audio and video multimedia, including Cisco IP/TV, RealNetworks RealAudio G2 Player, and Apple QuickTime 4 software.

RFC 2326 allows RTSP to run over either UDP or TCP, though CBAC currently supports only TCP-based RTSP. RTSP establishes a TCP-based control connection, or channel, between the multimedia client and server. RTSP uses this channel to control commands such as “play” and “pause” between the client and server. These control commands and responses are text-based and are similar to HTTP.

RTSP typically relies on a UDP-based data transport protocol such as standard Real-Time Transport Protocol (RTP) to open separate channels for data and for RTP Control Protocol (RTCP) messages. RTP and RTCP channels occur in pairs, with RTP being an even numbered port and RTCP being the next consecutive port. Understanding the relationship of RTP and RTCP is important for verifying session information using CBAC **show** commands.

The RTSP client uses TCP port 554 or 8554 to open a multimedia connection with a server. The data channel or data control channel (using RTCP) between the client and the server is dynamically negotiated between the client and the server using any of the high UDP ports (1024 to 65536).

CBAC uses this port information along with connection information from the client to create dynamic access control list (ACL) entries in the firewall. As TCP or UDP connections are terminated, CBAC removes these dynamic entries from the appropriate ACLs.

CBAC support for RTSP includes the following data transport modes:

- **Standard Real-Time Transport Protocol (RTP)**
RTP is an IETF standard (RFC 1889) supporting delivery of real-time data such as audio and video. RTP uses the RTP Control Protocol (RTCP) for managing the delivery of the multimedia data stream. This is the normal mode of operation for Cisco IP/TV and Apple QuickTime 4 software.
- **RealNetworks Real Data Transport (RDT)**
RDT is a proprietary protocol developed by RealNetworks for data transport. This mode uses RTSP for communication control and uses RDT for the data connection and retransmission of lost packets. This is the normal mode of operation for the RealServer G2 from RealNetworks.
- **Interleaved (Tunnel Mode)**
In this mode, RTSP uses the control channel to tunnel RTP or RDT traffic.
- **Synchronized Multimedia Integration Language (SMIL)**
SMIL is a layout language that enables the creation of multimedia presentations consisting of multiple elements of music, voice, images, text, video and graphics. This involves multiple RTSP control and data streams between the player and the servers. This mode is available only using RTSP and RDT. SMIL is a proposed specification of the World Wide Web Consortium (W3C). The RealNetworks RealServer and RealServer G2 provide support for SMIL—Cisco IP/TV and Apple QuickTime 4 do not.

H.323 Support

CBAC support for H.323 inspection includes H.323 Version 2 and H.323 Version 1. H.323 V2 provides additional options over H.323 V1, including a “fast start” option. The fast start option minimizes the delay between the time that a user initiates a connection and the time that the user gets the data (voice, video). H.323 V2 inspection is backward compatible with H.323 V1.

With H.323 V1, after a TCP connection is established between the client and server (H.225 Channel), a separate channel for media control (H.245 Channel) is opened through which multimedia channels for audio and video are further negotiated.

The H.323 V2 client opens a connection to server which is listening on port 1720. The data channel between the client and the server is dynamically negotiated using any of the high UDP ports (1024 to 65536).

CBAC uses this port information along with connection information from the client to create dynamic access control list (ACL) entries in the firewall. As TCP or UDP connections are terminated, CBAC removes these dynamic entries from the appropriate ACLs.

Restrictions

CBAC has the following restrictions:

- CBAC is available only for IP protocol traffic. Only TCP and UDP packets are inspected. (Other IP traffic, such as ICMP, cannot be inspected with CBAC and should be filtered with basic access lists instead.)
- If you reconfigure your access lists when you configure CBAC, be aware that if your access lists block TFTP traffic into an interface, you will not be able to netboot over that interface. (This is not a CBAC-specific limitation, but is part of existing access list functionality.)
- Packets with the firewall as the source or destination address are not inspected by CBAC.
- CBAC ignores ICMP Unreachable messages.
- H.323 V2 and RTSP protocol inspection supports only the following multimedia client-server applications: Cisco IP/TV, RealNetworks RealAudio G2 Player, Apple QuickTime 4.

You can use CBAC together with all the other firewall features mentioned previously in the “Cisco IOS Firewall Overview” chapter.

CBAC works with fast switching and process switching.

This section also discusses restrictions concerning:

- [FTP Traffic and CBAC](#)
- [IPSec and CBAC Compatibility](#)

FTP Traffic and CBAC

- With FTP, CBAC does not allow third-party connections (three-way FTP transfer).
- When CBAC inspects FTP traffic, it only allows data channels with the destination port in the range of 1024 to 65535.
- CBAC will not open a data channel if the FTP client-server authentication fails.

IPSec and CBAC Compatibility

When CBAC and IPSec are enabled on the same router, and the firewall router is an endpoint for IPSec for the particular flow, then IPSec is compatible with CBAC (that is, CBAC can do its normal inspection processing on the flow).

If the router is not an IPSec endpoint, but the packet is an IPSec packet, then CBAC will not inspect the packets because the protocol number in the IP header of the IPSec packet is not TCP or UDP. CBAC only inspects UDP and TCP packets.

Memory and Performance Impact

CBAC uses less than approximately 600 bytes of memory per connection. Because of the memory usage, you should use CBAC only when you need to. There is also a slight amount of additional processing that occurs whenever packets are inspected.

Sometimes CBAC must evaluate long access lists, which might have presented a negative impact to performance. However, this impact is avoided, because CBAC evaluates access lists using an accelerated method (CBAC hashes access lists and evaluates the hash).

CBAC Configuration Task List

To configure CBAC, perform the tasks described in the following sections. The tasks in the first seven sections are required; the task of verifying the CBAC configuration is optional.

- [Picking an Interface: Internal or External](#) (Required)
- [Configuring IP Access Lists at the Interface](#) (Required)
- [Configuring Global Timeouts and Thresholds](#) (Required)
- [Defining an Inspection Rule](#) (Required)
- [Applying the Inspection Rule to an Interface](#) (Required)
- [Configuring Logging and Audit Trail](#) (Required)
- [Other Guidelines for Configuring a Firewall](#) (Required)
- [Verifying CBAC](#) (Optional)

Following CBAC configuration, you can monitor and maintain CBAC using the information in this section.

**Note**

If you try to configure Context-based Access Control (CBAC) but do not have a good understanding of how CBAC works, you might inadvertently introduce security risks to the firewall and to the protected network. You should be sure you understand what CBAC does before you configure CBAC.

**Note**

As with all networking devices, protect access into the firewall by configuring passwords as described in the “Configuring Passwords and Privileges” chapter. You should also consider configuring user authentication, authorization, and accounting as described in the “Authentication, Authorization, and Accounting (AAA)” part of this guide. Additional guidelines to help you establish a good security policy can be found in the “Cisco IOS Firewall Overview” chapter.

For CBAC configuration examples, refer to the “[CBAC Configuration Examples](#)” section at the end of this chapter.

Picking an Interface: Internal or External

You must decide whether to configure CBAC on an internal or external interface of your firewall.

“Internal” refers to the side where sessions must originate for their traffic to be permitted through the firewall. “External” refers to the side where sessions cannot originate (sessions originating from the external side will be blocked).

If you will be configuring CBAC in two directions, you should configure CBAC in one direction first, using the appropriate “internal” and “external” interface designations. When you configure CBAC in the other direction, the interface designations will be swapped. (CBAC can be configured in two directions at one or more interfaces. Configure CBAC in two directions when the networks on both sides of the firewall require protection, such as with extranet or intranet configurations, and for protection against DoS attacks.)

The firewall is most commonly used with one of two basic network topologies. Determining which of these topologies is most like your own can help you decide whether to configure CBAC on an internal interface or on an external interface.

The first topology is shown in [Figure 21](#). In this simple topology, CBAC is configured for the *external* interface Serial 1. This prevents specified protocol traffic from entering the firewall and the internal network, unless the traffic is part of a session initiated from within the internal network.

Figure 21 Simple Topology—CBAC Configured at the External Interface

The second topology is shown in [Figure 22](#). In this topology, CBAC is configured for the *internal* interface Ethernet 0. This allows external traffic to access the services in the Demilitarized Zone (DMZ), such as DNS services, but prevents specified protocol traffic from entering your internal network—unless the traffic is part of a session initiated from within the internal network.

Figure 22 DMZ Topology—CBAC Configured at the Internal Interface

Using these two sample topologies, decide whether to configure CBAC on an internal or external interface.

To view various firewall configuration scenarios, see the [“CBAC Configuration Examples”](#) section at the end of this chapter.

Configuring IP Access Lists at the Interface

For CBAC to work properly, you need to make sure that you have IP access lists configured appropriately at the interface.

Follow these three general rules when evaluating your IP access lists at the firewall:

- Start with a basic configuration.

If you try to configure access lists without a good understanding of how access lists work, you might inadvertently introduce security risks to the firewall and to the protected network. You should be sure you understand what access lists do before you configure your firewall. For more information about access control lists, refer to the “Access Control Lists: Overview and Guidelines” chapter.

A basic initial configuration allows all network traffic to flow from the protected networks to the unprotected networks, while blocking network traffic from any unprotected networks.

- Permit CBAC traffic to leave the network through the firewall.

All access lists that evaluate traffic leaving the protected network should permit traffic that will be inspected by CBAC. For example, if Telnet will be inspected by CBAC, then Telnet traffic should be permitted on all access lists that apply to traffic leaving the network.

- Use extended access lists to deny CBAC return traffic entering the network through the firewall.

For temporary openings to be created in an access list, the access list must be an extended access list. So wherever you have access lists that will be applied to returning traffic, you must use extended access lists. The access lists should deny CBAC return traffic because CBAC will open up temporary holes in the access lists. (You want traffic to be normally blocked when it enters your network.)

Note

If your firewall only has two connections, one to the internal network and one to the external network, using all inbound access lists works well because packets are stopped before they get a chance to affect the router itself.

This section contains the following sections:

- [Basic Configuration](#)
- [External Interface](#)
- [Internal Interface](#)

Basic Configuration

The first time you configure the Cisco IOS Firewall, it is helpful to start with a basic access list configuration that makes the operation of the firewall easy to understand without compromising security. The basic configuration allows all network traffic from the protected networks access to the unprotected networks, while blocking all network traffic (with some exceptions) from the unprotected networks to the protected networks.

Any firewall configuration depends on your site security policy. If the basic configuration does not meet your initial site security requirements, configure the firewall to meet your policy. If you are unfamiliar with that policy or need help with the configuration, contact your network administration group for assistance. For additional guidelines on configuring a firewall, refer to the “[Other Guidelines for Configuring a Firewall](#)” section in this chapter.

Use the following guidelines for configuring the initial firewall access lists:

- Do not configure an access list for traffic from the protected networks to the unprotected networks, meaning that all traffic from the protected networks can flow through the interface.

This helps to simplify firewall management by reducing the number of access lists applied at the interfaces. Of course this assumes a high level of trust for the users on the protected networks, and it assumes there are no malicious users on the protected networks who might launch attacks from the “inside.” You can fine tune network access for users on the protected networks as you gain experience with access list configuration and the operation of the firewall.

- Configure an access list that includes entries permitting certain ICMP traffic from unprotected networks.

While an access list that denies all IP traffic not part of a connection inspected by CBAC seems most secure, it is not practical for normal operation of the router. The router expects to see ICMP traffic from other routers in the network. Additionally, ICMP traffic is not inspected by CBAC, meaning specific entries are needed in the access list to permit return traffic for ICMP commands. For example, a user on a protected network uses the **ping** command to get the status of a host on an unprotected network; without entries in the access list that permit **echo reply** messages, the user on the protected network gets no response to the **ping** command.

Include access list entries to permit the following ICMP messages:

Message	Description
echo reply	Outgoing ping commands require echo-reply messages to come back.
time-exceeded	Outgoing traceroute commands require time-exceeded messages to come back.
packet-too-big	Path MTU discovery requires “too-big” messages to come back.
traceroute	Allow an incoming traceroute.
unreachable	Permit all “unreachable” messages to come back. If a router cannot forward or deliver a datagram, it sends an ICMP unreachable message back to the source and drops the datagram.

- Add an access list entry denying any network traffic from a source address matching an address on the protected network.

This is known as anti-spoofing protection because it prevents traffic from an unprotected network from assuming the identity of a device on the protected network.

- Add an entry denying broadcast messages with a source address of 255.255.255.255.

This entry helps to prevent broadcast attacks.

- By default, the last entry in an extended access list is an implicit denial of all IP traffic not specifically allowed by other entries in the access list.

Although this is the default setting, this final deny statement is not shown by default in an access list. Optionally, you can add an entry to the access list denying IP traffic with any source or destination address with no undesired effects.

For complete information about how to configure IP access lists, refer to the “Configuring IP Services” chapter of the *Cisco IOS IP Addressing Services Configuration Guide*.

For tips on applying access lists at an external or internal interface, review the sections “[External Interface](#)” and “[Internal Interface](#)” in this chapter.

External Interface

Here are some guidelines for your access lists when you will be configuring CBAC on an external interface:

- If you have an outbound IP access list at the external interface, the access list can be a standard or extended access list. This outbound access list should permit traffic that you want to be inspected by CBAC. If traffic is not permitted, it will not be inspected by CBAC, but will be simply dropped.

- The inbound IP access list at the external interface must be an extended access list. This inbound access list should deny traffic that you want to be inspected by CBAC. (CBAC will create temporary openings in this inbound access list as appropriate to permit only return traffic that is part of a valid, existing session.)
- For complete information about how to configure IP access lists, refer to the “Configuring IP Services” chapter of the *Cisco IOS IP Addressing Services Configuration Guide*.

Internal Interface

Here are some tips for your access lists when you will be configuring CBAC on an internal interface:

- If you have an inbound IP access list at the internal interface or an outbound IP access list at external interface(s), these access lists can be either a standard or extended access list. These access lists should permit traffic that you want to be inspected by CBAC. If traffic is not permitted, it will not be inspected by CBAC, but will be simply dropped.
- The outbound IP access list at the internal interface and the inbound IP access list at the external interface must be extended access lists. These outbound access lists should deny traffic that you want to be inspected by CBAC. (CBAC will create temporary openings in these outbound access lists as appropriate to permit only return traffic that is part of a valid, existing session.) You do not necessarily need to configure an extended access list at both the outbound internal interface and the inbound external interface, but at least one is necessary to restrict traffic flowing through the firewall into the internal protected network.
- For complete information about how to configure IP access lists, refer to the “Configuring IP Services” chapter of the *Cisco IOS IP Addressing Services Configuration Guide*.

Configuring Global Timeouts and Thresholds

CBAC uses timeouts and thresholds to determine how long to manage state information for a session, and to determine when to drop sessions that do not become fully established. These timeouts and thresholds apply globally to all sessions.

You can use the default timeout and threshold values, or you can change to values more suitable to your security requirements. You should make any changes to the timeout and threshold values before you continue configuring CBAC.

Note

If you want to enable the more aggressive TCP host-specific denial-of-service prevention that includes the blocking of connection initiation to a host, you must set the **block-time** specified in the **ip inspect tcp max-incomplete host** command (see the last row in [Table 24](#)).

All the available CBAC timeouts and thresholds are listed in [Table 24](#), along with the corresponding command and default value. To change a global timeout or threshold listed in the “Timeout or Threshold Value to Change” column, use the global configuration command in the “Command” column:

Table 24 **Timeout and Threshold Values**

Timeout or Threshold Value to Change	Command	Default
The length of time the software waits for a TCP session to reach the established state before dropping the session.	ip inspect tcp synwait-time <i>seconds</i>	30 seconds
The length of time a TCP session will still be managed after the firewall detects a FIN-exchange.	ip inspect tcp finwait-time <i>seconds</i>	5 seconds
The length of time a TCP session will still be managed after no activity (the TCP idle timeout). ¹	ip inspect tcp idle-time <i>seconds</i>	3600 seconds (1 hour)
The length of time a UDP session will still be managed after no activity (the UDP idle timeout). ¹	ip inspect udp idle-time <i>seconds</i>	30 seconds
The length of time a DNS name lookup session will still be managed after no activity.	ip inspect dns-timeout <i>seconds</i>	5 seconds
The number of existing half-open sessions that will cause the software to start deleting half-open sessions. ²	ip inspect max-incomplete high <i>number</i>	500 existing half-open sessions
The number of existing half-open sessions that will cause the software to stop deleting half-open sessions. ²	ip inspect max-incomplete low <i>number</i>	400 existing half-open sessions
The rate of new sessions that will cause the software to start deleting half-open sessions. ²	ip inspect one-minute high <i>number</i>	500 half-open sessions per minute
The rate of new sessions that will cause the software to stop deleting half-open sessions. ²	ip inspect one-minute low <i>number</i>	400 half-open sessions per minute
The number of existing half-open TCP sessions with the same destination host address that will cause the software to start dropping half-open sessions to the same destination host address. ³	ip inspect tcp max-incomplete host <i>number</i> block-time <i>minutes</i>	50 existing half-open TCP sessions; 0 minutes

1. The global TCP and UDP idle timeouts can be overridden for specified application-layer protocols' sessions as described in the **ip inspect name** (global configuration) command description, found in the "Context-Based Access Control Commands" chapter of the *Cisco IOS Security Command Reference*.
2. See the following section, "Half-Open Sessions," for more information.
3. Whenever the **max-incomplete host** threshold is exceeded, the software will drop half-open sessions differently depending on whether the **block-time** timeout is zero or a positive non-zero number. If the **block-time** timeout is zero, the software will delete the oldest existing half-open session for the host for every new connection request to the host and will let the SYN packet through. If the **block-time** timeout is greater than zero, the software will delete all existing half-open sessions for the host, and then block all new connection requests to the host. The software will continue to block all new connection requests until the **block-time** expires.

To reset any threshold or timeout to the default value, use the **no** form of the command in [Table 24](#).

Half-Open Sessions

An unusually high number of half-open sessions (either absolute or measured as the arrival rate) could indicate that a denial-of-service attack is occurring. For TCP, "half-open" means that the session has not reached the established state—the TCP three-way handshake has not yet been completed. For UDP, "half-open" means that the firewall has detected no return traffic.

CBAC measures both the total number of existing half-open sessions and the rate of session establishment attempts. Both TCP and UDP half-open sessions are counted in the total number and rate measurements. Rate measurements are made several times per minute.

When the number of existing half-open sessions rises above a threshold (the **max-incomplete high** number), the software will delete half-open sessions as required to accommodate new connection requests. The software will continue to delete half-open requests as necessary, until the number of existing half-open sessions drops below another threshold (the **max-incomplete low** number).

When the rate of new connection attempts rises above a threshold (the **one-minute high** number), the software will delete half-open sessions as required to accommodate new connection attempts. The software will continue to delete half-open sessions as necessary, until the rate of new connection attempts drops below another threshold (the **one-minute low** number). The rate thresholds are measured as the number of new session connection attempts detected in the last one-minute sample period.

Defining an Inspection Rule

After you configure global timeouts and thresholds, you must define an inspection rule. This rule specifies what IP traffic (which application-layer protocols) will be inspected by CBAC at an interface.

Normally, you define only one inspection rule. The only exception might occur if you want to enable CBAC in two directions as described earlier in the section “When and Where to Configure CBAC.” For CBAC configured in both directions at a single firewall interface, you should configure two rules, one for each direction.

An inspection rule should specify each desired application-layer protocol as well as generic TCP or generic UDP if desired. The inspection rule consists of a series of statements each listing a protocol and specifying the same inspection rule name.

Inspection rules include options for controlling alert and audit trail messages and for checking IP packet fragmentation.

To define an inspection rule, follow the instructions in the following sections:

- [Configuring Application-Layer Protocol Inspection](#)
- [Configuring Generic TCP and UDP Inspection](#)

Configuring Application-Layer Protocol Inspection

This section provides instructions for configuring CBAC with the following inspection information:

- [Configuring Application-Layer Protocols](#)
- [Configuring Java Blocking](#)
- [Configuring IP Packet Fragmentation Inspection](#)

Note

For CBAC inspection to work with NetMeeting 2.0 traffic (an H.323 application-layer protocol), you must also configure inspection for TCP, as described later in the “[Configuring Generic TCP and UDP Inspection](#)” section. This requirement exists because NetMeeting 2.0 uses an additional TCP channel not defined in the H.323 specification.

Configuring Application-Layer Protocols

To configure CBAC inspection for an application-layer protocol, use one or both of the following commands in global configuration mode:

Command	Purpose
Router(config)# ip inspect name <i>inspection-name</i> <i>protocol</i> [alert {on off}] [audit-trail {on off}] [timeout <i>seconds</i>]	Configures CBAC inspection for an application-layer protocol (except for RPC and Java). Use one of the protocol keywords defined in Table 25 . Repeat this command for each desired protocol. Use the same <i>inspection-name</i> value to create a single inspection rule.
Router(config)# ip inspect name <i>inspection-name</i> rpc program-number <i>number</i> [wait-time <i>minutes</i>] [alert {on off}] [audit-trail {on off}] [timeout <i>seconds</i>]	Enables CBAC inspection for the RPC application-layer protocol. You can specify multiple RPC program numbers by repeating this command for each program number. Use the same <i>inspection-name</i> value to create a single inspection rule.

Refer to the description of the **ip inspect name** global configuration command in the “Context-Based Access Control Commands” chapter of the *Cisco IOS Security Command Reference* for more information about how the command works with each application-layer protocol.

To enable CBAC inspection for Java blocking, see the following section, “[Configuring Java Blocking](#).” [Table 25](#) identifies application protocol keywords for the **ip inspect name** command.

Table 25 Application Protocol Keywords for the **ip inspect name** Command

Application Protocol	Protocol Keyword
CU-SeeMe	cuseeme
FTP	ftp
H.323	h323
Microsoft NetShow	netshow
UNIX R commands (rlogin, rexec, rsh)	rcmd
RealAudio	realaudio
SMTP	smtp
SQL*Net	sqlnet
StreamWorks	streamworks
TFTP	tftp
VDOLive	vdolive

Configuring Java Blocking

Java applet filtering distinguishes between trusted and untrusted applets by relying on a list of external sites that you designate as “friendly.” If an applet is from a friendly site, the firewall allows the applet through. If the applet is not from a friendly site, the applet will be blocked. (Alternately, you could permit applets from all external sites except for those you specifically designate as hostile.)

To block all Java applets except for applets from friendly locations, use the following commands in global configuration mode:

Command	Purpose
<pre>Router(config)# ip access-list standard name permit ... deny ... (Use permit and deny statements as appropriate.)</pre> or <pre>Router(config)# access-list access-list-number {deny permit} protocol source [source-wildcard]eq www destination [destination-wildcard]</pre>	Creates a standard access list that permits traffic only from friendly sites, and denies traffic from hostile sites. Use the any keyword for the destination as appropriate—but be careful to not misuse the any keyword to inadvertently allow all applets through.
<pre>Router(config)# ip inspect name inspection-name http [java-list access-list] [alert {on off}] [audit-trail {on off}] [timeout seconds]</pre>	Blocks all Java applets except for applets from the friendly sites defined previously in the access list. Java blocking only works with numbered standard access lists. To create a single inspection rule, use the same <i>inspection-name</i> value as when you specified other protocols.

CBAC does not detect or block encapsulated Java applets. Therefore, Java applets that are wrapped or encapsulated, such as applets in .zip or .jar format, are *not* blocked at the firewall. CBAC also does not detect or block applets loaded from FTP, gopher, HTTP on a nonstandard port, and so forth.

Configuring IP Packet Fragmentation Inspection

Using fragmentation inspection, the firewall maintains an *interfragment state* (structure) for IP traffic. Non-initial fragments are discarded unless the corresponding initial fragment was permitted to pass through the firewall. Non-initial fragments received before the corresponding initial fragments are discarded.

Fragmentation inspection can have undesirable effects in certain cases, because it can result in the firewall discarding any packet whose fragments arrive out of order. There are many circumstances that can cause out-of-order delivery of legitimate fragments. Applying fragmentation inspection in situations where legitimate fragments, which are likely to arrive out of order, might have a severe performance impact.

Because routers running Cisco IOS software are used in a large variety of networks, and because the CBAC feature is often used to isolate parts of internal networks from one another, the fragmentation inspection feature is disabled by default. Fragmentation detection must be explicitly enabled for an inspection rule using the **ip inspect name** command. Unfragmented traffic is never discarded because it lacks a fragment state. Even when the system is under heavy attack with fragmented packets, legitimate fragmented traffic, if any, gets some fraction of the firewall's fragment state resources, and legitimate, unfragmented traffic can flow through the firewall unimpeded.

Configuring Generic TCP and UDP Inspection

You can configure TCP and UDP inspection to permit TCP and UDP packets to enter the internal network through the firewall, even if the application-layer protocol is not configured to be inspected. However, TCP and UDP inspection do not recognize application-specific commands, and therefore might not permit all return packets for an application, particularly if the return packets have a different port number than the previous exiting packet.

Any application-layer protocol that is inspected will take precedence over the TCP or UDP packet inspection. For example, if inspection is configured for FTP, all control channel information will be recorded in the state table, and all FTP traffic will be permitted back through the firewall if the control channel information is valid for the state of the FTP session. The fact that TCP inspection is configured is irrelevant to the FTP state information.

With TCP and UDP inspection, packets entering the network must exactly match the corresponding packet that previously exited the network. The entering packets must have the same source/destination addresses and source/destination port numbers as the exiting packet (but reversed); otherwise, the entering packets will be blocked at the interface. Also, all TCP packets with a sequence number outside of the window are dropped.

With UDP inspection configured, replies will only be permitted back in through the firewall if they are received within a configurable time after the last request was sent out. (This time is configured with the **ip inspect udp idle-time** command.)

To configure CBAC inspection for TCP or UDP packets, use one or both of the following commands in global configuration mode:

Command	Purpose
Router(config)# ip inspect name <i>inspection-name</i> tcp [alert {on off}] [audit-trail {on off}] [timeout seconds]	Enables CBAC inspection for TCP packets. To create a single inspection rule, use the same <i>inspection-name</i> value as when you specified other protocols.
Router(config)# ip inspect name <i>inspection-name</i> udp [alert {on off}] [audit-trail {on off}] [timeout seconds]	Enables CBAC inspection for UDP packets. To create a single inspection rule, use the same <i>inspection-name</i> value as when you specified other protocols.

Applying the Inspection Rule to an Interface

After you define an inspection rule, you apply this rule to an interface.

Normally, you apply only one inspection rule to one interface. The only exception might occur if you want to enable CBAC in two directions as described earlier in the section “When and Where to Configure CBAC.” For CBAC configured in both directions at a single firewall interface, you should apply two rules, one for each direction.

If you are configuring CBAC on an external interface, apply the rule to outbound traffic.

If you are configuring CBAC on an internal interface, apply the rule to inbound traffic.

To apply an inspection rule to an interface, use the following command in interface configuration mode:

Command	Purpose
Router(config-if)# ip inspect <i>inspection-name</i> {in out}	Applies an inspection rule to an interface.

Configuring Logging and Audit Trail

Turn on logging and audit trail to provide a record of network access through the firewall, including illegitimate access attempts, and inbound and outbound services. To configure logging and audit trail functions, enter the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# service timestamps log datetime	Adds the date and time to syslog and audit trail messages.
Step 2	Router(config)# logging host	Specifies the host name or IP address of the host where you want to send syslog messages.
Step 3	Router(config)# logging facility facility-type	Configures the syslog facility in which error messages are sent.
Step 4	Router(config)# logging trap level	(Optional) Uses this command to limit messages logged to the syslog servers based on severity. The default is level 7 (informational).
Step 5	Router(config)# ip inspect audit-trail	Turns on CBAC audit trail messages.

For information on how to interpret the syslog and audit trail messages, refer to the “[Interpreting Syslog and Console Messages Generated by CBAC](#)” section.

To configure audit trail functions on a per-application basis, refer to the “[Defining an Inspection Rule](#)” section for more information.

For complete information about how to configure logging, refer to the “Troubleshooting the Router” chapter of the *Cisco IOS Network Management Configuration Guide*.

Other Guidelines for Configuring a Firewall

As with all networking devices, you should always protect access into the firewall by configuring passwords as described in the module “Configuring Security with Passwords, Privilege Levels, and Login Usernames for CLI Sessions on Networking Devices.” You should also consider configuring user authentication, authorization, and accounting as described in the “Authentication, Authorization, and Accounting (AAA)” part of this guide.

You should also consider the following recommendations:

- When setting passwords for privileged access to the firewall, use the **enable secret** command rather than the **enable password** command, which does not have as strong an encryption algorithm.

- Put a password on the console port. In authentication, authorization, and accounting (AAA) environments, use the same authentication for the console as for elsewhere. In a non-AAA environment, at a minimum configure the **login** and **password password** commands.
- Think about access control *before* you connect a console port to the network in any way, including attaching a modem to the port. Be aware that a *break* on the console port might give total control of the firewall, even with access control configured.
- Apply access lists and password protection to all virtual terminal ports. Use access lists to limit who can Telnet into your router.
- Do not enable any local service (such as SNMP or NTP) that you do not use. Cisco Discovery Protocol (CDP) and Network Time Protocol (NTP) are on by default, and you should turn these off if you do not need them.

To turn off CDP, enter the **no cdp run** global configuration command. To turn off NTP, enter the **ntp disable** interface configuration command on each interface not using NTP.

If you must run NTP, configure NTP only on required interfaces, and configure NTP to listen only to certain peers.

Any enabled service could present a potential security risk. A determined, hostile party might be able to find creative ways to misuse the enabled services to access the firewall or the network.

For local services that are enabled, protect against misuse. Protect by configuring the services to communicate only with specific peers, and protect by configuring access lists to deny packets for the services at specific interfaces.

- Protect against spoofing: protect the networks on both sides of the firewall from being spoofed from the other side. You could protect against spoofing by configuring input access lists at all interfaces to pass only traffic from expected source addresses, and to deny all other traffic.

You should also disable source routing. For IP, enter the **no ip source-route** global configuration command. Disabling source routing at *all* routers can also help prevent spoofing.

You should also disable minor services. For IP, enter the **no service tcp-small-servers** and **no service udp-small-servers** global configuration commands. In Cisco IOS Release 12.0 and later, these services are disabled by default.

- Prevent the firewall from being used as a relay by configuring access lists on any asynchronous Telnet ports.
- Normally, you should disable directed broadcasts for all applicable protocols on your firewall and on all your other routers. For IP, use the **no ip directed-broadcast** command. Rarely, some IP networks do require directed broadcasts; if this is the case, do not disable directed broadcasts.

Directed broadcasts can be misused to multiply the power of denial-of-service attacks, because every denial-of-service packet sent is broadcast to every host on a subnet. Furthermore, some hosts have other intrinsic security risks present when handling broadcasts.
- Configure the **no proxy-arp** command to prevent internal addresses from being revealed. (This is important to do if you do not already have NAT configured to prevent internal addresses from being revealed.)
- Keep the firewall in a secured (locked) room.

Verifying CBAC

You can view and verify CBAC configuration, status, statistics, and session information by using one or more of the following commands in EXEC mode:

Command	Purpose
Router# show ip access-lists	Displays the contents of all current IP access lists.
Router# show ip inspect name <i>inspection-name</i>	Shows a particular configured inspection rule.
Router# show ip inspect config	Shows the complete CBAC inspection configuration.
Router# show ip inspect interfaces	Shows interface configuration with regards to applied inspection rules and access lists.
Router# show ip inspect session [detail]	Shows existing sessions that are currently being tracked and inspected by CBAC.
Router# show ip inspect all	Shows all CBAC configuration and all existing sessions that are currently being tracked and inspected by CBAC.

In most cases, you can tell whether CBAC is inspecting network traffic properly because network applications are working as expected. In some cases, however, you might want to verify CBAC operation. For example, to verify RTSP or H.323 inspection, initiate an RTSP- or H.323-based application through the firewall. Use the **show ip inspect session** and **show ip access lists** commands to verify CBAC operation. These commands display the dynamic ACL entries and the established connections for a multimedia session.

In the case of RTSP inspection, session output can vary based on the multimedia protocol and the transport mode. This section uses examples of RTSP and H.323 V2 sessions to illustrate verification procedures and to illustrate how session information, and the interpretation of that session information, varies based on the protocol being inspected. This section provides the following sample session output:

- [RTSP with RDT](#)
- [RTSP with TCP Only \(Interleaved Mode\)](#)
- [RTSP with SMIL](#)
- [RTSP with RTP \(IP/TV\)](#)
- [H.323 V2](#)

RTSP with RDT

The following example illustrates the result of the **show ip inspect session** command. It shows that a control channel (rtsp) and data channel (rtsp-data) are open between hosts 192.168.155.2 and 192.168.35.1.

```
router# show ip inspect session
Established Sessions
  Session 616B4F1C (192.168.155.2:7548)=>(192.168.35.1:6970) rtsp-data SIS_OPEN
  Session 611E2904 (192.168.35.1:1221)=>(192.168.155.2:554) rtsp SIS_OPEN
```

The following example illustrates the result of the **show ip access-list** command. It shows that two dynamic entries (permit statements) were added to ACL 100 for the multimedia session. The TCP entry creates a dynamic opening through the firewall between port 554 (RTSP protocol port) on the client and port 1221 on the server. The UDP entry creates a dynamic opening between data port 7548 on the client and data port 6970 on the server.

```
router# show ip access-list
Extended IP access list 100
  permit udp host 192.168.155.2 eq 7548 host 192.168.35.1 eq 6970 (31 matches)
  permit tcp host 192.168.155.2 eq 554 host 192.168.35.1 eq 1221 (27 matches)
```

After closing the multimedia session, review the session output using the **show** commands to verify the firewall software has removed the dynamic entries from the configuration.

RTSP with TCP Only (Interleaved Mode)

The following example illustrates the result of the **show ip inspect session** command. It shows that only a single control channel (rtsp) is open between hosts 192.168.155.2 and 192.168.35.1. In this mode, data is tunneled through the firewall using the TCP connection to interleave RDT or RTP data.

```
router# show ip inspect session
Established Sessions
  Session 611E2904 (192.168.35.1:1228)=>(192.168.155.2:554) rtsp SIS_OPEN
```

The following example illustrates the result of the **show ip access-list** command. It shows that a single dynamic entry (permit statement) was added to ACL 100 for the multimedia session. The TCP entry creates a dynamic opening through the firewall between port 554 (RTSP protocol port) on the client and port 1228 on the server.

```
router# show ip access-lists
Extended IP access list 100
  permit tcp host 192.168.155.2 eq 554 host 192.168.35.1 eq 1228 (391 matches)
```

After closing the multimedia session, review the session output using the **show** commands to verify the firewall software has removed the dynamic entries from the configuration.

RTSP with SMIL

The following example illustrates the result of the **show ip inspect session** command for RTSP using Synchronized Multimedia Integration Language (SMIL). It shows that a single control channel (rtsp) and multiple data channels (rtsp-data) are open between hosts 192.168.155.2 and 192.168.35.1. The data channels appear as half open sessions because the UDP data flows in one direction only, which is from the server to the client.

```
router# show ip inspect session
Established Sessions
  Session 616CA914 (192.168.155.2:30616)=>(192.168.35.1:6974) rtsp-data SIS_OPEN
  Session 616B4E78 (192.168.35.1:1230)=>(192.168.155.2:554) rtsp SIS_OPEN
  Session 614AB61C (192.168.155.2:29704)=>(192.168.35.1:6976) rtsp-data SIS_OPEN
  Session 616CAA88 (192.168.155.2:26764)=>(192.168.35.1:6972) rtsp-data SIS_OPEN
Half-open Sessions
  Session 614AAEF0 (192.168.155.2:15520)=>(192.168.35.1:6970) rtsp-data SIS_OPENING
```

The following example illustrates the result of the **show ip access-lists** command. It shows that multiple dynamic entries (permit statements) were added to ACL 100 for the multimedia session. The TCP entry creates a dynamic opening through the firewall between port 554 (RTSP protocol port) on the client and port 1230 on the server. The UDP entries create dynamic openings between negotiated data ports on the client (192.168.155.2) and the server (192.168.35.1).

```
router# show ip access-list
Extended IP access list 100
  permit udp host 192.168.155.2 eq 29704 host 192.168.35.1 eq 6976 (182 matches)
  permit udp host 192.168.155.2 eq 30616 host 192.168.35.1 eq 6974 (268 matches)
  permit udp host 192.168.155.2 eq 26764 host 192.168.35.1 eq 6972 (4 matches)
  permit udp host 192.168.155.2 eq 15520 host 192.168.35.1 eq 6970 (12 matches)
  permit tcp host 192.168.155.2 eq 554 host 192.168.35.1 eq 1230 (41 matches)
```

After closing the multimedia session, review the session output using the **show** commands to verify the firewall software has removed the dynamic entries from the configuration.

RTSP with RTP (IP/TV)

The following example illustrates the result of the **show ip inspect session** command for RTSP with the Cisco IP/TV application. The output shows that a single control channel (rtsp) and multiple data channels (rtsp-data) are open between hosts 192.168.2.15 and 192.168.102.23. The data channels appear as half-open sessions because the UDP data flows in one direction only, which is from the server to the client.

```
router# show ip inspect session
Established Sessions
  Session 611493C0 (192.168.2.15:2571)=>(192.168.102.23:8554) rtsp SIS_OPEN
Half-open Sessions
  Session 6114A22C (192.168.102.23:2428)=>(192.168.2.15:20112) rtsp-data SIS_OPENING
  Session 61149F44 (192.168.102.23:2428)=>(192.168.2.15:20113) rtsp-data SIS_OPENING
  Session 6114A0B8 (192.168.102.23:2429)=>(192.168.2.15:20115) rtsp-data SIS_OPENING
  Session 6114A3A0 (192.168.102.23:2429)=>(192.168.2.15:20114) rtsp-data SIS_OPENING
```

The following example illustrates the result of the **show ip access-lists** command. It shows that multiple dynamic entries (permit statements) were added to ACL 100 for the multimedia session. The TCP entry creates a dynamic opening through the firewall between port 554 (RTSP protocol port) on the client and port 1230 on the server. The UDP entries create dynamic openings between negotiated data ports on the client (192.168.2.15) and the server (192.168.102.23).

```
router# show ip access-lists
Extended IP access list 100
  permit udp host 192.168.102.23 eq 2428 host 192.168.2.15 eq 20113 (11 matches)
  permit udp host 192.168.102.23 eq 2428 host 192.168.2.15 eq 20112 (256 matches)
  permit udp host 192.168.102.23 eq 2429 host 192.168.2.15 eq 20115 (11 matches)
  permit udp host 192.168.102.23 eq 2429 host 192.168.2.15 eq 20114 (4598 matches)
  permit tcp host 192.168.102.23 eq 8554 host 192.168.2.15 eq 2571 (22 matches)
```

After closing the multimedia session, review the session output using the **show** commands to verify that the firewall software has removed the dynamic entries from the configuration.

H.323 V2

The following example illustrates the result of the **show ip inspect session** command for H.323 V2. It shows a single H.323 control channel, an RTP Control Protocol channel for both audio and video data, and an RTP data channel between hosts 192.168.155.2 and 192.168.35.1.

```
Session 615E2688 (192.168.35.1:49609)=>(192.168.155.1:49609) H323-RTCP-audio SIS_OPEN
Session 615E2688 (192.168.35.1:49508)=>(192.168.155.1:49508) H323-RTP-audio SIS_OPEN
Session 615E2688 (192.168.35.1:49410)=>(192.168.155.1:49410) H323-RTP-video SIS_OPEN
Session 615E2688 (192.168.35.1:49611)=>(192.168.155.1:49611) H323-RTCP-video SIS_OPEN
Session 615E1640 (192.168.35.1:4414)=>(192.168.155.1:1720) H323 SIS_OPEN
```

The following example illustrates the result of the **show ip access-lists** command. It shows that multiple dynamic entries (permit statements) were added to ACL 100 for the multimedia session. The TCP entry creates a dynamic opening through the firewall between port 1720 (H.323 V2 protocol port) on the client and port 4414 on the server. The UDP entries create dynamic openings between negotiated data ports on the client (192.168.155.1) and the server (192.168.35.1).

```
router# show ip access-lists
Extended IP access list 100
  permit udp host 192.168.155.1 eq 49609 host 192.168.35.1 eq 49609 (11 matches)
  permit udp host 192.168.155.1 eq 49508 host 192.168.35.1 eq 49508 (256 matches)
  permit udp host 192.168.155.1 eq 49411 host 192.168.35.1 eq 49411 (11 matches)
  permit udp host 192.168.155.1 eq 49610 host 192.168.35.1 eq 49610 (4598 matches)
  permit tcp host 192.168.155.1 eq 1720 host 192.168.35.1 eq 4414 (22 matches)
```

Monitoring and Maintaining CBAC

You can watch for network attacks and investigate network problems using debug commands and system messages. This section has the following sections:

- [Debugging Context-Based Access Control](#)
- [Interpreting Syslog and Console Messages Generated by CBAC](#)
- [Turning Off CBAC](#)

Debugging Context-Based Access Control

To assist CBAC debugging, you can turn on audit trail messages that will be displayed on the console after each CBAC session closes. Audit trail information is also configurable on a per-application basis using the CBAC inspection rules.

To turn on audit trail messages, use the following command in global configuration mode:

Command	Purpose
Router(config)# ip inspect audit-trail	Turns on CBAC audit trail messages.

If required, you can also use the CBAC **debug** commands listed in this section. (Debugging can be turned off for each of the commands in this section by using the **no** form of the command. To disable all debugging, use the privileged EXEC commands **no debug all** or **undebg all**.)

The following **debug** commands are available:

- [Generic Debug Commands](#)
- [Transport Level Debug Commands](#)
- [Application Protocol Debug Commands](#)

For a complete description of the debug commands, refer to the *Cisco IOS Debug Command Reference*.

**Note**

Effective with Cisco IOS Release 12.4(20)T, the **debug ip inspect** command is replaced by the **debug policy-firewall** command. See the *Cisco IOS Debug Command Reference* for more information.

Generic Debug Commands

You can use the following generic **debug** commands, entered in privileged EXEC mode:

Command	Purpose
Router# debug ip inspect function-trace	Displays messages about software functions called by CBAC.
Router# debug ip inspect object-creation	Displays messages about software objects being created by CBAC. Object creation corresponds to the beginning of CBAC-inspected sessions.
Router# debug ip inspect object-deletion	Displays messages about software objects being deleted by CBAC. Object deletion corresponds to the closing of CBAC-inspected sessions.

Command	Purpose
Router# debug ip inspect events	Displays messages about CBAC software events, including information about CBAC packet processing.
Router# debug ip inspect timers	Displays messages about CBAC timer events such as when a CBAC idle timeout is reached.
Router# debug ip inspect detail	Enables the detailed option, which can be used in combination with other options to get additional information.

Transport Level Debug Commands

You can use the following transport-level **debug** commands, entered in privileged EXEC mode:

Command	Purpose
Router# debug ip inspect tcp	Displays messages about CBAC-inspected TCP events, including details about TCP packets.
Router# debug ip inspect udp	Displays messages about CBAC-inspected UDP events, including details about UDP packets.

Application Protocol Debug Commands

You can use the following application protocol **debug** command, entered in privileged EXEC mode:

Command	Purpose
Router# debug ip inspect protocol	Displays messages about CBAC-inspected protocol events, including details about the protocol's packets. Refer to Table 26 to determine the protocol keyword.

[Table 26](#) identifies application protocol keywords for the **debug ip inspect** command.

Table 26 Application Protocol Keywords for the **debug ip inspect** Command

Application Protocol	Protocol Keyword
CU-SeeMe	cuseeme
FTP commands and responses	ftp-cmd
FTP token (enables tracing of the FTP tokens parsed)	ftp-token
H.323	h323
HTTP (Java applets)	http
Microsoft NetShow	netshow
UNIX R commands (rlogin, rexec, rsh)	rcmd
RealAudio	realaudio
RPC	rpc
SMTP	smtp

Table 26 *Application Protocol Keywords for the debug ip inspect Command (continued)*

Application Protocol	Protocol Keyword
SQL*Net	sqlnet
StreamWorks	streamworks
TFTP	tftp
VDOLive	vdolive

Interpreting Syslog and Console Messages Generated by CBAC

CBAC provides syslog messages, console alert messages, and audit trail messages. These messages are useful because they can alert you to network attacks and because they provide an audit trail that provides details about sessions inspected by CBAC. While they are generally referred to as error messages, not all error messages indicate problems with your system.

Audit trail and alert information is configurable on a per-application basis using the CBAC inspection rules.

The following types of messages can be generated by CBAC:

- [Denial-of-Service Attack Detection Error Messages](#)
- [SMTP Attack Detection Error Messages](#)
- [Java Blocking Error Messages](#)
- [FTP Error Messages](#)
- [Audit Trail Messages](#)

For explanations and recommended actions related to the error messages mentioned in this section, refer to the *Cisco IOS System Error Messages*.

Denial-of-Service Attack Detection Error Messages

CBAC detects and blocks denial-of-service attacks and notifies you when denial-of-service attacks occur. Error messages such as the following may indicate that denial-of-service attacks have occurred:

```
%FW-4-ALERT_ON: getting aggressive, count (550/500) current 1-min rate: 250
%FW-4-ALERT_OFF: calming down, count (0/400) current 1-min rate: 0
```

When %FW-4-ALERT_ON and %FW-4-ALERT_OFF error messages appear together, each “aggressive/calming” pair of messages indicates a separate attack. The preceding example shows one separate attack.

Error messages such as the following may indicate that a denial-of-service attack has occurred on a specific TCP host:

```
%FW-4-HOST_TCP_ALERT_ON: Max tcp half-open connections (50) exceeded for host
172.21.127.242.
%FW-4-BLOCK_HOST: Blocking new TCP connections to host 172.21.127.242 for 2 minutes
(half-open count 50 exceeded)
%FW-4-UNBLOCK_HOST: New TCP connections to host 172.21.127.242 no longer blocked
```

SMTP Attack Detection Error Messages

CBAC detects and blocks SMTP attacks (illegal SMTP commands) and notifies you when SMTP attacks occur. Error messages such as the following may indicate that an SMTP attack has occurred:

```
%FW-4-SMTP_INVALID_COMMAND: Invalid SMTP command from initiator (192.168.12.3:52419)
```

CBAC also detects a limited number of SMTP attack signatures. A signature in a SYSLOG message indicates a possible attack against the protected network, such as the detection of illegal SMTP commands in a packet. Whenever a signature is detected, the connection will be reset.

The Cisco IOS Firewall supports the following SMTP attack signatures:

Signature	Description
Mail: bad rcpt	Triggers on any mail message with a “pipe” () symbol in the recipient field.
Mail: bad from	Triggers on any mail message with a “pipe” () symbol in the “From:” field.
Mail: old attack	Triggers when “wiz” or “debug” commands are sent to the SMTP port.
Mail: decode	Triggers on any mail message with a “:decode@” in the header.
Majordomo	A bug in the Majordomo program will allow remote users to execute arbitrary commands at the privilege level of the server.

The following is a sample SMTP attack signature message:

```
02:04:55: %FW-4-TCP_MAJORDOMO_EXEC_BUG: Sig:3107:Majordomo Execute Attack - from
192.168.25.1 to 192.168.205.1:
```

Java Blocking Error Messages

CBAC detects and selectively blocks Java applets and notifies you when a Java applet has been blocked. Error messages such as the following may indicate that a Java applet has been blocked:

```
%FW-4-HTTP_JAVA_BLOCK: JAVA applet is blocked from (172.21.127.218:80) to
(172.16.57.30:44673).
```

FTP Error Messages

CBAC detects and prevents certain FTP attacks and notifies you when this occurs. Error messages such as the following may appear when CBAC detects these FTP attacks:

```
%FW-3-FTP_PRIV_PORT: Privileged port 1000 used in PORT command -- FTP client 10.0.0.1 FTP
server 10.1.0.1
%FW-3-FTP_SESSION_NOT_AUTHENTICATED: Command issued before the session is authenticated
-- FTP client 10.0.0.1
%FW-3-FTP_NON_MATCHING_IP_ADDR: Non-matching address 172.19.148.154 used in PORT command
-- FTP client 172.19.54.143 FTP server 172.16.127.242
```

Audit Trail Messages

CBAC provides audit trail messages to record details about inspected sessions. Audit trail information is configurable on a per-application basis using the CBAC inspection rules. To determine which protocol was inspected, use the responder's port number. The port number follows the responder's address. The following are sample audit trail messages:

```
%FW-6-SESS_AUDIT_TRAIL: tcp session initiator (192.168.1.13:33192) sent 22 bytes --  
responder (192.168.129.11:25) sent 208 bytes  
%FW-6-SESS_AUDIT_TRAIL: http session initiator (172.16.57.30:44673) sent 1599 bytes --  
responder (172.21.127.218:80) sent 93124 bytes
```

Turning Off CBAC

You can turn off CBAC using the **no ip inspect** global configuration command.

**Note**

The **no ip inspect** command removes all CBAC configuration entries and resets all CBAC global timeouts and thresholds to the defaults. All existing sessions are deleted and their associated access lists removed.

In most situations, turning off CBAC has no negative security impact because CBAC creates “permit” access lists. Without CBAC configured, no “permit” access lists are maintained. Therefore, no derived traffic (returning traffic or traffic from the data channels) can go through the firewall. The exception is SMTP and Java blocking. With CBAC turned off, unacceptable SMTP commands or Java applets may go through the firewall.

CBAC Configuration Examples

The following sections provide CBAC configuration examples:

- [Ethernet Interface Configuration Example](#)
- [ATM Interface Configuration Example](#)
- [Remote Office to ISP Configuration Example](#)
- [Remote Office to Branch Office Configuration Example](#)
- [Two-Interface Branch Office Configuration Example](#)
- [Multiple-Interface Branch Office Configuration Example](#)

The first example develops a CBAC inspection rule for specific protocols and a supporting access control list (ACL). This example focuses how to configure CBAC; it does not provide a complete router configuration and does not describe other elements of the configuration.

The next example develops a CBAC inspection rule for sites that might have remote traffic through an ATM interface. This example further illustrates on how to configure CBAC and emphasizes the application of the configuration rule at the interface, whatever that interface might be. This example does not provide a complete router configuration and does not describe other elements of the configuration.

The remote-office examples also focus on the firewall configuration but do not provide detailed descriptions of other configuration elements, such as the Basic Rate Interface (BRI) and dialer interface configurations.

Other examples provide more complete firewall configurations, further illustrating ways in which to apply CBAC.

In each example, configuring protocol inspection using CBAC has four components:

- Defining an access list with the appropriate permissions.
- Applying the ACL at an interface where you want to control access.
- Defining an inspection rule that includes the protocol that you want to inspect.
- Applying the inspection rule at an interface where you want to inspect traffic.

Ethernet Interface Configuration Example

This example looks at each of these four components. For this example, CBAC is being configured to inspect RTSP and H.323 protocol traffic inbound from the protected network on a router with two Ethernet interfaces. Interface Ethernet1/0 is the protected network and interface Ethernet1/1 is the unprotected network. The security policy for the protected site uses access control lists (ACLs) to restrict inbound traffic on the unprotected interface to specific ICMP protocol traffic, denying inbound access for TCP and UDP protocol traffic. Inbound access for specific protocol traffic is provided through dynamic access lists, which are generated according to CBAC inspection rules.

ACL 100 denies TCP and UDP traffic from any source or destination while permitting specific ICMP protocol traffic. The final deny statement is not required, but is included for explicitness—the final entry in any ACL is an implicit denial of all IP protocol traffic.

```
Router(config)# access-list 100 deny tcp any any
Router(config)# access-list 100 deny udp any any
Router(config)# access-list 100 permit icmp any any echo-reply
Router(config)# access-list 100 permit icmp any any time-exceeded
Router(config)# access-list 100 permit icmp any any packet-too-big
Router(config)# access-list 100 permit icmp any any traceroute
Router(config)# access-list 100 permit icmp any any unreachable
Router(config)# access-list 100 deny ip any any
```

ACL 100 is applied inbound at interface Ethernet1/1 to block all access from the unprotected network to the protected network.

```
Router(config)# interface Ethernet1/1
Router(config-if)# ip access-group 100 in
```

An inspection rule is created for “hquers” that covers two protocols: RTSP and H.323.

```
Router(config)# ip inspect name hquers rtsp
Router(config)# ip inspect name hquers h323
```

The inspection rule is applied inbound at interface Ethernet1/0 to inspect traffic from users on the protected network. When CBAC detects multimedia traffic from the protected network, CBAC creates dynamic entries in access list 100 to allow return traffic for multimedia sessions.

```
Router(config)# interface Ethernet1/0
Router(config-if)# ip inspect hquers in
```

ATM Interface Configuration Example

In this example, CBAC inspection (firewall protection) is required against inbound traffic on an ATM interface. This example might apply to sites where local hosts require access to hosts or services on a remote network. The security policy for this site uses access control lists (ACLs) to restrict inbound

traffic on the ATM interface to specific ICMP protocol traffic, denying inbound access for TCP and UDP protocol traffic. Inbound access for specific TCP and UDP protocol traffic is provided through dynamic access lists, which are generated according to CBAC inspection rules.

For information on how to select the interface on which to apply CBAC, refer to the [“Picking an Interface: Internal or External”](#) section.

Note

For Frame Relay or ATM interfaces, you can apply CBAC inspection rules separately on each sub-interface, even though the subinterfaces are physically connected through one interface.

```

! -----
! Create the Inspection Rule
! -----
!
! Create the CBAC inspection rule "test", allowing inspection of the protocol traffic
! specified by the rule. This inspection rule sets the timeout value to 30 seconds for
! each protocol (except for RPC). The timeout value defines the maximum time that a
! connection for a given protocol can remain active without any traffic passing through
! the router. When these timeouts are reached, the dynamic ACLs that are inserted to
! permit the returning traffic are removed, and subsequent packets (possibly even valid
! ones) are not permitted.
ip inspect name test cuseeme timeout 30
ip inspect name test ftp timeout 30
ip inspect name test h323 timeout 30
ip inspect name test realaudio timeout 30
ip inspect name test rpc program-number 100000
ip inspect name test streamworks timeout 30
ip inspect name test vdolive timeout 30
!
! -----
! Create the Access Control List
! -----
!
! In this example, ACL 105 denies all TCP and UDP protocol traffic. ICMP traffic from
! subnet 192.168.1.0 is permitted to allow access for routing and control traffic.
! ACL 105 specifies that only the return traffic for protocols defined in the
! inspection rule is allow access through the interface where this rule is applied. The
! final deny statement is added for explicitness.
access-list 105 deny TCP any any
access-list 105 deny UDP any any
access-list 105 permit icmp any any echo-reply
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 time-exceeded
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 packet-too-big
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 traceroute
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 unreachable
access-list 105 deny ip any any
!
! -----
! Apply the Inspection Rule and ACL
! -----
!
! In this example, the inspection rule "test" is applied to traffic at interface ATM3/0
! for connections initiated in the outbound direction; that is, from hosts that are
! located on a local network. CBAC creates dynamic access list entries for traffic
! initiated by local hosts. These dynamic entries allow inbound (returning) traffic for
! that connection. ACL 105 is applied at interface ATM3/0 in the inbound direction to
! block traffic initiated from hosts on a remote network that is not part of an
! existing connection.
interface ATM3/0
    ip address 10.1.10.1 255.0.0.0
    ip access-group 105 in

```

```

no ip directed-broadcast
ip inspect test out
no shutdown
atm clock INTERNAL
atm pvc 7 7 7 aal5snap
map-group atm

```

Remote Office to ISP Configuration Example

This example describes one possible Cisco IOS Firewall configuration for a remote office router connected to an Internet service provider (ISP). In this configuration, the site security policy allows hosts on the local network to initiate traffic to the ISP while traffic inbound to the router from the ISP is blocked at the ISDN interface. Specific ICMP control message traffic is permitted through the firewall. No mail or Web services are available from the local network. [Figure 23](#) illustrates this example.

Figure 23 Remote Office to ISP Sample Configuration

The firewall has two interfaces:

- An Ethernet interface connects to the internal protected network.
Interface Ethernet0 has no ACL applied to it, meaning that all traffic initiated on the LAN is allowed access to the ISP. In this configuration example, Network Address Translation (NAT) is not turned on, and the addresses on interface Ethernet0 are reserved IP addresses. In a production environment, addresses on Ethernet0 either must be registered network addresses, or you must turn on NAT to hide these inside addresses from being visible on the Internet.
- An ISDN Basic Rate Interface (BRI) connects the router to the ISP. In this example, a dialer profile is used to control the BRI interface. This means that the ACL and CBAC inspection rules are applied at the dialer interface, not directly at the physical ISDN (BRI) interface using a dialer map.

```

! -----
! General Cisco IOS Firewall Guidelines
! -----
! The following global configuration entries illustrate good security practices.
enable secret 5 <elided>
no ip source-route
no cdp run
!
! -----
! Create the CBAC inspection rule
! -----
! Create the CBAC inspection rule STOP to allow inspection of the protocol traffic
! specified by the rule.
ip inspect name STOP tcp
ip inspect name STOP ftp
ip inspect name STOP smtp

```

```

ip inspect name STOP h323
ip inspect name STOP rcmd
!
! -----
! Create Access Control List 105
! -----
! ACL 105 denies all IP protocol traffic except for specific ICMP control traffic.
! This means that only the return traffic for protocols defined in the
! inspection rule and the specified ICMP traffic is allowed access through the
! interface where this rule is applied.
!
! Deny broadcast messages with a source address of 255.255.255.255; this helps to
! prevent broadcast attacks.
access-list 105 deny ip host 255.255.255.255 any
!
! Add anti-spoofing protection by denying traffic with a source address matching a host
! on the Ethernet interface.
acl 105 deny ip 192.168.1.0 0.0.0.255 any
!
! ICMP traffic is not inspected by CBAC. To control the type of ICMP traffic at the
! interface, add static access list entries. This example has the following ICMP
! requirements: outgoing ping commands require echo-reply messages to come back,
! outgoing traceroute commands require time-exceeded messages to come back, path MTU
! discovery requires "too-big" messages to come back, and incoming traceroute
! messages must be allowed. Additionally, permit all "unreachable" messages to come
! back; that is, if a router cannot forward or deliver a datagram, it sends an ICMP
! unreachable message back to the source and drops the datagram.
access-list 105 permit icmp any any echo-reply
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 time-exceeded
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 packet-too-big
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 traceroute
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 unreachable
!
! Final deny for explicitness. This entry is not required but helps complete the access
! list picture. By default, the final entry in any access list is an implicit deny of
! IP protocol traffic. This ensures that the firewall blocks any traffic not explicitly
! permitted by the access list.
access-list 105 deny ip any any
!
! -----
! Configure the interface
! -----
! In this example, no ACLs or inspection rules are applied at interface Ethernet0,
! meaning that all traffic on the local network is allowed to go out. This assumes a
! high-level of trust for the users on the local network.
interface Ethernet0
    ip address 192.168.1.104 255.255.255.0
!
no ip directed-broadcast
!
! This example uses a dialer profile, so the ACL and CBAC inspection rules are applied
! at the dialer interface, not the physical BRI interface. The dialer pool-member
! command is used to associate the physical interface with a dialer profile.
interface BRI0

```

Remote Office to Branch Office Configuration Example

This example describes one possible Cisco IOS Firewall configuration for a remote office router connected to a branch office. In this configuration, the site security policy allows hosts on the local network to initiate traffic to the branch office. Mail or Web services are available from a server on the local network, and access to these services is available from the branch office. Traffic from the branch office, except for mail and Web traffic, is blocked at the outside interface. Specific ICMP control message traffic is permitted through the firewall. [Figure 24](#) illustrates this example.

Figure 24 Remote Office to Branch Office Sample Configuration

The firewall has two interfaces:

- An Ethernet interface connects to the internal protected network.

23076

Interface Ethernet0 has no ACL applied to it, meaning that all traffic initiated from the LAN is allowed access through the firewall.

- An ISDN Basic Rate Interface (BRI) connects the router to the branch office. In this example, a dialer profile is used to control the BRI interface. This means that the ACL and CBAC inspection rules are applied at dialer interface, not directly at the physical ISDN (BRI) interface.

```
! -----
! General firewall configuration guidelines
! -----
! The following global configuration entries illustrate good security practices.
enable secret 5 <elided>
no ip source-route
no cdp run
!
! -----
! Create the Inspection Rule
! -----
! Create the CBAC inspection rule STOP to allow inspection of the specified protocol
! traffic. Create the inspection rule GO to allow inspection of SMTP traffic.
ip inspect name STOP tcp
ip inspect name STOP ftp
ip inspect name STOP smtp
ip inspect name STOP h323
ip inspect name GO smtp
!
! -----
! Create Access Control Lists 106 and 51
! -----
! ACL 106 permits mail and Web traffic from any host to the specified server. ACL 106
! denies all other ip protocol traffic except for specific ICMP control traffic.
! This means that only the return traffic for protocols defined in the
! inspection rule and the specified ICMP traffic is allowed access through the
! interface where this rule is applied.
!
! Deny broadcast messages with a source address of 255.255.255.255; this helps to
! prevent broadcast attacks.
access-list 106 deny ip host 255.255.255.255 any
!
! Add anti-spoofing protection by denying traffic with a source address matching a host
! on the Ethernet interface.
access-list 106 deny ip 192.168.1.0 0.0.0.255 any
!
! ICMP traffic is not inspected by CBAC. To control the type of ICMP traffic at the
! interface, add static access list entries. This example has the following ICMP
! requirements: outgoing ping commands require echo-reply messages to come back,
! outgoing traceroute commands require time-exceeded messages to come back, path MTU
! discovery requires "too-big" messages to come back, and incoming traceroute must be
! allowed. Additionally, permit all "unreachable" messages to come back; that is, if a
! router cannot forward or deliver a datagram, it sends an ICMP unreachable message
! back to the source and drops the datagram.
access-list 106 permit icmp any any echo-reply
access-list 106 permit icmp any 192.168.1.0 0.0.0.255 time-exceeded
access-list 106 permit icmp any 192.168.1.0 0.0.0.255 packet-too-big
access-list 106 permit icmp any 192.168.1.0 0.0.0.255 traceroute
access-list 106 permit icmp any 192.168.1.0 0.0.0.255 unreachable
!
! Permit mail and Web access to a specific server.
access-list 106 permit tcp any host 192.168.1.20 eq smtp
access-list 106 permit tcp any host 192.168.1.20 eq www
!
! Final deny for explicitness. This entry is not required but helps complete the access
! list picture. By default, the final entry in any access list is an implicit deny of
! IP protocol traffic. This ensures that the firewall blocks any traffic not explicitly
```

```

! permitted by the access list.
access-list 106 deny ip any any
!
! -----
! Configure the interface.
! -----
! In this example, no ACLs or inspection rules are applied at interface Ethernet0,
! meaning that all traffic on the local network is allowed to go out. This assumes a
! high-level of trust for the users on the local network.
interface Ethernet0
    ip address 192.168.1.104 255.255.255.0
    no ip directed-broadcast
!
! This example uses a dialer profile, so the ACL and CBAC inspection rules are applied
! at the dialer interface, not the physical BRI interface. The dialer pool-member
! command is used to associate the physical interface with a dialer profile.
interface BRI0
    no ip address
    no ip directed-broadcast
    encapsulation ppp
    dialer pool-member 1
    isdn switch-type basic-5ess
!
! -----
! Apply the ACL and CBAC inspection rules at the dialer interface.
! -----
! Through the dialer profile, the ACL and CBAC inspection rules are
! applied to every pool member. In this example, the ACL is applied in, meaning that it
! applies to traffic inbound from the branch office. The CBAC inspection rule STOP is
! applied out, meaning that CBAC monitors the traffic and controls return traffic to
! the router for an existing connection. The CBAC inspection rule GO is applied in,
! protecting against certain types of DoS attacks as described in this document. Note
! that the GO inspection rule does not control return traffic because there is no ACL
! blocking traffic in that direction; however, it does monitor the connections.
interface Dialer0

Two-Interface Branch Office Configuration Example

This sample configuration file describes a firewall configured with CBAC. The firewall is positioned between a protected field office's internal network and a WAN connection to the corporate headquarters. CBAC is configured on the firewall in order to protect the internal network from potential network threats coming from the WAN side.

The firewall has two interfaces configured:

- Interface Ethernet0 connects to the internal protected network
- Interface Serial0 connects to the WAN with Frame Relay

```
! -----
! This first section contains some configuration that is not required for CBAC,
! but illustrates good security practices. Note that there are no
! services on the Ethernet side. Email is picked up via POP from a server on the
! corporate side.
! -----
!
hostname user1-examplecorp-fr
!
boot system flash c1600-fw1600-l
enable secret 5 <elided>
!
username user1 password <elided>
ip subnet-zero
no ip source-route
ip domain-name example.com
ip name-server 172.19.2.132
ip name-server 198.92.30.32
!
!
! -----
! The next section includes configuration required specifically for CBAC.
! -----
!
! The following commands define the inspection rule "myfw", allowing
! the specified protocols to be inspected. Note that Java applets will be permitted
! according to access list 51, defined later in this configuration.
ip inspect name myfw cuseeme timeout 3600
ip inspect name myfw ftp timeout 3600
ip inspect name myfw http java-list 51 timeout 30
ip inspect name myfw rcmd timeout 3600
ip inspect name myfw realaudio timeout 3600
ip inspect name myfw smtp timeout 3600
ip inspect name myfw tftp timeout 30
ip inspect name myfw udp timeout 15
ip inspect name myfw tcp timeout 3600
!
! The following interface configuration applies the "myfw" inspection rule to
! inbound traffic at Ethernet 0. Since this interface is on the internal network
! side of the firewall, traffic entering Ethernet 0 is actually
! exiting the internal network. Applying the inspection rule to this interface causes
! inbound traffic (which is exiting the network) to be inspected; return traffic will
! only be permitted back through the firewall if part of a session which began from
! within the network.
! Also note that access list 101 is applied to inbound traffic at Ethernet 0.
! (Traffic blocked by the access list will not be inspected.)
interface Ethernet0
description ExampleCorp Ethernet chez user1
ip address 172.19.139.1 255.255.255.248
ip broadcast-address 172.19.131.7
```

```

no ip directed-broadcast
no ip proxy-arp
ip inspect myfw in
ip access-group 101 in
no cdp enable
!
interface Serial0
description Frame Relay (Telco ID 22RTQQ062438-001) to ExampleCorp HQ

no arp frame-relay
bandwidth 56
service-module 56k clock source line
service-module 56k network-type dds
frame-relay lmi-type ansi
!
! Note that the following interface configuration applies access list 111 to
! inbound traffic at the external serial interface. (Inbound traffic is
! entering the network.) When CBAC inspection occurs on traffic exiting the
! network, temporary openings will be added to access list 111 to allow returning
! traffic that is part of existing sessions.
!
interface Serial0.1 point-to-point
ip unnumbered Ethernet0
ip access-group 111 in
bandwidth 56
no cdp enable
frame-relay interface-dlci 16
!
ip classless
ip route 0.0.0.0 0.0.0.0 Serial0.1
!
! The following access list defines "friendly" and "hostile" sites for Java
! applet blocking. Because Java applet blocking is defined in the inspection
! rule "myfw" and references access list 51, applets will be actively denied
! if they are from any of the "deny" addresses and allowed only if they are from
! either of the two "permit" networks.
!
access-list 51 deny 172.19.1.203
access-list 51 deny 172.19.2.147
access-list 51 permit 172.18.0.0 0.1.255.255
access-list 51 permit 192.168.1.0 0.0.0.255
access-list 51 deny any
!
! The following access list 101 is applied to interface Ethernet 0 above.
! This access list permits all traffic that should be CBAC inspected, and also
! provides anti-spoofing. The access list is deliberately set up to deny unknown
! IP protocols, because no such unknown protocols will be in legitimate use.
!
access-list 101 permit tcp 172.19.139.0 0.0.0.7 any
access-list 101 permit udp 172.19.139.0 0.0.0.7 any
access-list 101 permit icmp 172.19.139.0 0.0.0.7 any
access-list 101 deny ip any any
!
! The following access list 111 is applied to interface Serial 0.1 above.
! This access list filters traffic coming in from the external side. When
! CBAC inspection occurs, temporary openings will be added to the beginning of
! this access list to allow return traffic back into the internal network.
! This access list should restrict traffic that will be inspected by
! CBAC. (Remember that CBAC will open holes as necessary to permit returning traffic.)
! Comments precede each access list entry. These entries are not all specifically
! related to CBAC, but are created to provide general good security.
!

```

```
! Anti-spoofing.
access-list 111 deny ip 172.19.139.0 0.0.0.7 any
! Sometimes EIGRP is run on the Frame Relay link. When you use an
! input access list, you have to explicitly allow even control traffic.
! This could be more restrictive, but there would have to be entries
! for the EIGRP multicast as well as for the office's own unicast address.
access-list 111 permit igmp any any
!
! These are the ICMP types actually used...
! administratively-prohibited is useful when you are trying to figure out why
! you cannot reach something you think you should be able to reach.
access-list 111 permit icmp any 172.19.139.0 0.0.0.7 administratively-prohibited
!
! This allows network admins at headquarters to ping hosts at the field office:
access-list 111 permit icmp any 172.19.139.0 0.0.0.7 echo
!
! This allows the field office to do outgoing pings
access-list 111 permit icmp any 172.19.139.0 0.0.0.7 echo-reply
!
! Path MTU discovery requires too-big messages
access-list 111 permit icmp any 172.19.139.0 0.0.0.7 packet-too-big
!
! Outgoing traceroute requires time-exceeded messages to come back
access-list 111 permit icmp any 172.19.139.0 0.0.0.7 time-exceeded
!
! Incoming traceroute
access-list 111 permit icmp any 172.19.139.0 0.0.0.7 traceroute
!
! Permits all unreachable because if you are trying to debug
! things from the remote office, you want to see them. If nobody ever did
! any debugging from the network, it would be more appropriate to permit only
! port unreachables or no unreachables at all.
access-list 111 permit icmp any 172.19.139.0 0.0.0.7 unreachable
!
!
! These next two entries permit users on most ExampleCorp networks to Telnet to
! a host in the field office. This is for remote administration by the network admins.
access-list 111 permit tcp 172.18.0.0 0.1.255.255 host 172.19.139.1 eq telnet
access-list 111 permit tcp 192.168.1.0 0.0.0.255 host 172.19.139.1 eq telnet

Multiple-Interface Branch Office Configuration Example

In this configuration example, a single Cisco 3600 series firewall router is positioned at a branch office. It has four internal networks and two WAN connections to the corporate headquarters. CBAC is configured on the firewall to protect two of the internal networks from potential network threats coming from the WAN side and from less secure internal networks. Anti-spoofing protection is added at each interface with client systems. [Figure 25](#) illustrates this configuration.

**Note**

This example shows a moderately high level of trust by the administrators toward the expected users. Additional protection could be added to this configuration for a situation in a lower level of trust. That configuration would include ICMP filtering statements, significantly more protocol and address control through the use of more restrictive access control lists, and anti-spoofing applied everywhere. This configuration does not contain those additional restrictions because that would detract from the CBAC example.

Figure 25 Sample Cisco IOS Firewall Application Environment

The branch office has this sample network configuration:

- Ethernet interface 0/0 supports the Human Resources department servers. This network includes an email (SMTP and POP3) host and a Windows NT server. The Windows NT server is the Primary Domain Controller (PDC) for the Human Resources domain and has a trust relationship with the rest of the company; however, it contains applications and databases that must not be accessed by the rest of the company or the other groups in the branch office. The devices on this LAN are accessible only by users in the Human Resources department on Ethernet interface 0/1. The Mail server must be able to send and receive email (through SMTP sessions) with all other devices. The Windows 95 machines can use this machine as their email server (for sending email through SMTP sessions) and as a repository for accumulating email that they can then download through POP3 sessions. No one else in the company is allowed to form POP3 sessions to any machine on this LAN.
- Ethernet interface 0/1 supports the Windows 95 computers in the Human Resources department. These users must have access to the Human Resources mail servers located on Ethernet interface 0/0 as well as access to the rest of the company. Access to the Windows NT server resources are controlled through the Windows NT permissions assigned to each user in the Windows NT domain.
- Ethernet interface 1/0 supports the branch office web servers, which can be accessed by everyone in the company. These servers use TCP ports 80 (HTTP) and 443 (SHTTP) for inbound Web access. This network also includes a backup domain controller (BDC) for the overall domain that is also used as file, print, and service server.

Ethernet interface 1/1 supports all users who are not in the Human Resources department. These users have no access to the Human Resources department servers, but they can access the other network interfaces and the serial interfaces for WAN connectivity. Serial interface 0/0 and 0/1 connect to the WAN with T1 links (links to corporate headquarters). In this sample configuration, the Domain Name System (DNS) servers are located somewhere within the rest of the company.

Additionally, network management (SNMP) and Telnet sessions are limited to the management network (192.168.55.0), which is located somewhere within the rest of the company across the serial interface.

```
! -----
! This first section contains some configuration that is not required
! for CBAC, but illustrates good security practices.
! -----
! Add this line to get timestamps on the syslog messages.

ip subnet-zero
!
! Disable source routing to help prevent spoofing.
no ip source-route
!
! Set up the domain name and server IP addresses.
ip domain-name example.com
ip name-server 192.168.55.132
ip name-server 192.168.27.32
!
! The audit-trail command enables the delivery of specific CBAC messages
! through the syslog notification process.
ip inspect audit-trail
!
! Establish the time-out values for DNS queries. When this idle-timer expires,
! the dynamic ACL entries that were created to permit the reply to a DNS request
! will be removed and any subsequent packets will be denied.
ip inspect dns-timeout 10
!
! -----
! The next section includes configuration statements required specifically for CBAC.
! -----
! Define the CBAC inspection rule "inspect1", allowing the specified protocols to be
! inspected. The first rule enables SMTP specific inspection. SMTP inspection causes
! the exchange of the SMTP session to be inspected for illegal commands. Any packets
! with illegal commands are dropped, and the SMTP session will hang and eventually
! time out.
ip inspect name inspect1 smtp timeout 30
!
! In the next two lines of inspect1, define the maximum time that each of the UDP and
! TCP sessions are allowed to continue without any traffic passing
! through the router. When these timeouts are reached, the dynamic ACLs that
! are inserted to permit the returning traffic are removed and subsequent packets
! (possibly even valid ones) will not be permitted.
ip inspect name inspect1 udp timeout 30
ip inspect name inspect1 tcp timeout 30
!
```

```

! Define the CBAC inspection rule "inspect2", allowing the specified protocols to be
! inspected. These rules are similar to those used in the inspection rule "inspect1,"
! except that on the interfaces where this rule is applied, SMTP sessions are not
! expected to go through; therefore, the SMTP rule element is not applied here.
ip inspect name inspect2 udp timeout 30
ip inspect name inspect2 tcp timeout 30
!
! -----
! The next section shows the Ethernet interface configuration statements for each
! interface, including access lists and inspections rules.
! -----
! Apply the "inspect1" inspection rule to sessions that are initiated in the outbound
! direction (toward the LAN) at Ethernet interface 0/0. All packets in these sessions
! will be inspected by CBAC. Provided that network traffic passes the Access Control
! List (ACL) restrictions, traffic is then inspected by CBAC for access through the
! Cisco Secure Integrated Software. Traffic blocked by the access list is not inspected
! by CBAC. Access list 110 is applied to outbound traffic on this interface.
interface Ethernet0/0

Cisco IOS Firewall

Configuring Cisco IOS Firewall Intrusion Detection System

This chapter describes the Cisco IOS Firewall Intrusion Detection System (IDS) feature. Intrusion detection systems provide a level of protection beyond the firewall by protecting the network from internal and external attacks and threats. Cisco IOS Firewall IDS technology enhances perimeter firewall protection by taking appropriate action on packets and flows that violate the security policy or represent malicious network activity.

For a complete description of the Cisco IOS Firewall IDS commands in this chapter, refer to the “Cisco IOS Firewall IDS Commands” chapter of the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the chapter “Identifying Supported Platforms” section in the “Using Cisco IOS Software.”

In This Chapter

This chapter has the following sections:

- [About the Firewall Intrusion Detection System](#)
- [Cisco IOS Firewall IDS Configuration Task List](#)
- [Monitoring and Maintaining Cisco IOS Firewall IDS](#)

About the Firewall Intrusion Detection System

The Cisco IOS Firewall IDS feature supports intrusion detection technology for midrange and high-end router platforms with firewall support. It is ideal for any network perimeter, and especially for locations in which a router is being deployed and additional security between network segments is required. It also can protect intranet and extranet connections where additional security is mandated, and branch-office sites connecting to the corporate office or Internet.

The Cisco IOS Firewall IDS feature identifies 59 of the most common attacks using “signatures” to detect patterns of misuse in network traffic. The intrusion-detection signatures included in the Cisco IOS Firewall were chosen from a broad cross-section of intrusion-detection signatures. The signatures represent severe breaches of security and the most common network attacks and information-gathering scans. For a description of Cisco IOS Firewall IDS signatures, refer to the [“Cisco IOS Firewall IDS Signature List”](#) section.

The Cisco IOS Firewall IDS acts as an in-line intrusion detection sensor, watching packets and sessions as they flow through the router, scanning each to match any of the IDS signatures. When it detects suspicious activity, it responds before network security can be compromised and logs the event through Cisco IOS syslog or the Cisco Secure Intrusion Detection System (Cisco Secure IDS, formerly known as NetRanger) Post Office Protocol. The network administrator can configure the IDS system to choose the appropriate response to various threats. When packets in a session match a signature, the IDS system can be configured to take these actions:

- Send an alarm to a syslog server or a Cisco Secure IDS Director (centralized management interface)
- Drop the packet
- Reset the TCP connection

Cisco developed its Cisco IOS software-based intrusion-detection capabilities in Cisco IOS Firewall with flexibility in mind, so that individual signatures could be disabled in case of false positives. Also, while it is preferable to enable both the firewall and intrusion detection features of the CBAC security engine to support a network security policy, each of these features may be enabled independently and on different router interfaces. Cisco IOS software-based intrusion detection is part of the Cisco IOS Firewall.

This section has the following sections:

- [Interaction with Cisco IOS Firewall Default Parameters](#)
- [Compatibility with Cisco Secure Intrusion Detection](#)
- [Functional Description](#)
- [When to Use Cisco IOS Firewall IDS](#)
- [Memory and Performance Impact](#)
- [Cisco IOS Firewall IDS Signature List](#)

Interaction with Cisco IOS Firewall Default Parameters

When Cisco IOS IDS is enabled, Cisco IOS Firewall is automatically enabled. Thus, IDS uses Cisco IOS Firewall default parameter values to inspect incoming sessions. Default parameter values include the following:

- The rate at which IDS starts deleting half-open sessions (modified via the **ip inspect one-minute high** command)

- The rate at which IDS stops deleting half-open sessions (modified via the **ip inspect one-minute low** command)
- The maximum incomplete sessions (modified via the **ip inspect max-incomplete high** and the **ip inspect max-incomplete low** commands)

After the incoming TCP session setup rate crosses the one-minute high water mark, the router will reset the oldest half-open session, which is the default behavior of the Cisco IOS Firewall. Cisco IOS IDS cannot modify this default behavior. Thus, after a new TCP session rate crosses the one-minute high water mark and a router attempts to open new connections by sending SYN packets at the same time, the latest SYN packet will cause the router to reset the half-open session that was opened by the earlier SYN packet. Only the last SYN request will survive.

Compatibility with Cisco Secure Intrusion Detection

Cisco IOS Firewall is compatible with the Cisco Secure Intrusion Detection System (formally known as NetRanger). The Cisco Secure IDS is an enterprise-scale, real-time, intrusion detection system designed to detect, report, and terminate unauthorized activity throughout a network.

The Cisco Secure IDS consists of three components:

- Sensor
- Director
- Post Office

Cisco Secure IDS Sensors, which are high-speed network appliances, analyze the content and context of individual packets to determine if traffic is authorized. If a network's data stream exhibits unauthorized or suspicious activity, such as a SATAN attack, a ping sweep, or the transmission of a secret research project code word, Cisco Secure IDS Sensors can detect the policy violation in real time, forward alarms to a Cisco Secure IDS Director management console, and remove the offender from the network.

The Cisco Secure IDS Director is a high-performance, software-based management system that centrally monitors the activity of multiple Cisco Secure IDS Sensors located on local or remote network segments.

The Cisco Secure IDS Post Office is the communication backbone that allows Cisco Secure IDS services and hosts to communicate with each other. All communication is supported by a proprietary, connection-based protocol that can switch between alternate routes to maintain point-to-point connections.

Cisco Secure IDS customers can deploy the Cisco IOS Firewall IDS signatures to complement their existing IDS systems. This allows an IDS to be deployed to areas that may not be capable of supporting a Cisco Secure IDS Sensor. Cisco IOS Firewall IDS signatures can be deployed alongside or independently of other Cisco IOS Firewall features.

The Cisco IOS Firewall IDS can be added to the Cisco Secure IDS Director screen as an icon to provide a consistent view of all intrusion detection sensors throughout a network. The Cisco IOS Firewall intrusion detection capabilities have an enhanced reporting mechanism that permits logging to the Cisco Secure IDS Director console in addition to Cisco IOS syslog.

For additional information about Cisco Secure IDS (NetRanger), refer to the *NetRanger User Guide*.

Functional Description

The Cisco IOS Firewall IDS acts as an in-line intrusion detection sensor, watching packets as they traverse the router's interfaces and acting upon them in a definable fashion. When a packet, or a number of packets in a session, match a signature, the Cisco IOS Firewall IDS may perform the following configurable actions:

- Alarm—Sends an alarm to a syslog server or Cisco Secure IDS Director
- Drop—Drops the packet
- Reset—Resets the TCP connection

The following describes the packet auditing process with Cisco IOS Firewall IDS:

- You create an audit rule, which specifies the signatures that should be applied to packet traffic and the actions to take when a match is found. An audit rule can apply informational and attack signatures to network packets. The signature list can have just one signature, all signatures, or any number of signatures in between. Signatures can be disabled in case of false positives or the needs of the network environment.
- You apply the audit rule to an interface on the router, specifying a traffic direction (*in* or *out*).
- If the audit rule is applied to the *in* direction of the interface, packets passing through the interface are audited before the inbound ACL has a chance to discard them. This allows an administrator to be alerted if an attack or information-gathering activity is underway even if the router would normally reject the activity.
- If the audit rule is applied to the *out* direction on the interface, packets are audited after they enter the router through another interface. In this case, the inbound ACL of the other interface may discard packets before they are audited. This may result in the loss of Cisco IOS Firewall IDS alarms even though the attack or information-gathering activity was thwarted.
- Packets going through the interface that match the audit rule are audited by a series of modules, starting with IP; then either ICMP, TCP, or UDP (as appropriate); and finally, the Application level.
- If a signature match is found in a module, then the following user-configured action(s) occur:
 - If the action is **alarm**, then the module completes its audit, sends an alarm, and passes the packet to the next module.
 - If the action is **drop**, then the packet is dropped from the module, discarded, and not sent to the next module.
 - If the action is **reset**, then the packets are forwarded to the next module, and packets with the reset flag set are sent to both participants of the session, if the session is TCP.

Note It is recommended that you use the **drop** and **reset** actions together.

If there are multiple signature matches in a module, only the first match fires an action. Additional matches in other modules fire additional alarms, but only one per module.

Note This process is different than on the Cisco Secure IDS Sensor appliance, which identifies all signature matches for each packet.

When to Use Cisco IOS Firewall IDS

Cisco IOS Firewall IDS capabilities are ideal for providing additional visibility at intranet, extranet, and branch-office Internet perimeters. Network administrators enjoy more robust protection against attacks on the network and can automatically respond to threats from internal or external hosts.

The Cisco IOS Firewall with intrusion detection is intended to satisfy the security goals of all of our customers, and is particularly appropriate for the following scenarios:

- Enterprise customers that are interested in a cost-effective method of extending their perimeter security across all network boundaries, specifically branch-office, intranet, and extranet perimeters.
- Small and medium-sized businesses that are looking for a cost-effective router that has an integrated firewall with intrusion-detection capabilities.
- Service provider customers that want to set up managed services, providing firewalling and intrusion detection to their customers, all housed within the necessary function of a router.

Memory and Performance Impact

The performance impact of intrusion detection will depend on the configuration of the signatures, the level of traffic on the router, the router platform, and other individual features enabled on the router such as encryption, source route bridging, and so on. Enabling or disabling individual signatures will not alter performance significantly, however, signatures that are configured to use Access Control Lists will have a significant performance impact.

Because this router is being used as a security device, no packet will be allowed to bypass the security mechanisms. The IDS process in the Cisco IOS Firewall router sits directly in the packet path and thus will search each packet for signature matches. In some cases, the entire packet will need to be searched, and state information and even application state and awareness must be maintained by the router.

For auditing atomic signatures, there is no traffic-dependent memory requirement. For auditing compound signatures, CBAC allocates memory to maintain the state of each session for each connection. Memory is also allocated for the configuration database and for internal caching.

Cisco IOS Firewall IDS Signature List

The following is a complete list of Cisco IOS Firewall IDS signatures. A signature detects patterns of misuse in network traffic. In Cisco IOS Firewall IDS, signatures are categorized into four types:

- Info Atomic
- Info Compound
- Attack Atomic
- Attack Compound

An info signature detects information-gathering activity, such as a port sweep.

An attack signature detects attacks attempted into the protected network, such as denial-of-service attempts or the execution of illegal commands during an FTP session.

Info and attack signatures can be either atomic or compound signatures. Atomic signatures can detect patterns as simple as an attempt to access a specific port on a specific host. Compound signatures can detect complex patterns, such as a sequence of operations distributed across multiple hosts over an arbitrary period of time.

The intrusion-detection signatures included in the Cisco IOS Firewall were chosen from a broad cross-section of intrusion-detection signatures as representative of the most common network attacks and information-gathering scans that are not commonly found in an operational network.

The following signatures are listed in numerical order by their signature number in the Cisco Secure IDS Network Security Database. After each signature's name is an indication of the type of signature (info or attack, atomic or compound).

**Note**

Atomic signatures marked with an asterisk (Atomic*) are allocated memory for session states by CBAC.

1000 IP options-Bad Option List (Info, Atomic)

Triggers on receipt of an IP datagram where the list of IP options in the IP datagram header is incomplete or malformed. The IP options list contains one or more options that perform various network management or debugging tasks.

1001 IP options-Record Packet Route (Info, Atomic)

Triggers on receipt of an IP datagram where the IP option list for the datagram includes option 7 (Record Packet Route).

1002 IP options-Timestamp (Info, Atomic)

Triggers on receipt of an IP datagram where the IP option list for the datagram includes option 4 (Timestamp).

1003 IP options-Provide s,c,h,tcc (Info, Atomic)

Triggers on receipt of an IP datagram where the IP option list for the datagram includes option 2 (Security options).

1004 IP options-Loose Source Route (Info, Atomic)

Triggers on receipt of an IP datagram where the IP option list for the datagram includes option 3 (Loose Source Route).

1005 IP options-SATNET ID (Info, Atomic)

Triggers on receipt of an IP datagram where the IP option list for the datagram includes option 8 (SATNET stream identifier).

1006 IP options-Strict Source Route (Info, Atomic)

Triggers on receipt of an IP datagram in which the IP option list for the datagram includes option 2 (Strict Source Routing).

1100 IP Fragment Attack (Attack, Atomic)

Triggers when any IP datagram is received with the "more fragments" flag set to 1 or if there is an offset indicated in the offset field.

1101 Unknown IP Protocol (Attack, Atomic)

Triggers when an IP datagram is received with the protocol field set to 101 or greater. These protocol types are undefined or reserved and should not be used.

1102 Impossible IP Packet (Attack, Atomic)

This triggers when an IP packet arrives with source equal to destination address. This signature will catch the so-called Land Attack.

2000 ICMP Echo Reply (Info, Atomic)

Triggers when a IP datagram is received with the “protocol” field in the IP header set to 1 (ICMP) and the “type” field in the ICMP header set to 0 (Echo Reply).

2001 ICMP Host Unreachable (Info, Atomic)

Triggers when an IP datagram is received with the “protocol” field in the IP header set to 1 (ICMP) and the “type” field in the ICMP header set to 3 (Host Unreachable).

2002 ICMP Source Quench (Info, Atomic)

Triggers when an IP datagram is received with the “protocol” field in the IP header set to 1 (ICMP) and the “type” field in the ICMP header set to 4 (Source Quench).

2003 ICMP Redirect (Info, Atomic)

Triggers when an IP datagram is received with the “protocol” field in the IP header set to 1 (ICMP) and the “type” field in the ICMP header set to 5 (Redirect).

2004 ICMP Echo Request (Info, Atomic)

Triggers when an IP datagram is received with the “protocol” field in the IP header set to 1 (ICMP) and the “type” field in the ICMP header set to 8 (Echo Request).

2005 ICMP Time Exceeded for a Datagram (Info, Atomic)

Triggers when an IP datagram is received with the “protocol” field in the IP header set to 1 (ICMP) and the “type” field in the ICMP header set to 11 (Time Exceeded for a Datagram).

2006 ICMP Parameter Problem on Datagram (Info, Atomic)

Triggers when an IP datagram is received with the “protocol” field in the IP header set to 1 (ICMP) and the “type” field in the ICMP header set to 12 (Parameter Problem on Datagram).

2007 ICMP Timestamp Request (Info, Atomic)

Triggers when an IP datagram is received with the “protocol” field in the IP header set to 1 (ICMP) and the “type” field in the ICMP header set to 13 (Timestamp Request).

2008 ICMP Timestamp Reply (Info, Atomic)

Triggers when an IP datagram is received with the “protocol” field in the IP header set to 1 (ICMP) and the “type” field in the ICMP header set to 14 (Timestamp Reply).

2009 ICMP Information Request (Info, Atomic)

Triggers when an IP datagram is received with the “protocol” field in the IP header set to 1 (ICMP) and the “type” field in the ICMP header set to 15 (Information Request).

2010 ICMP Information Reply (Info, Atomic)

Triggers when an IP datagram is received with the “protocol” field in the IP header set to 1 (ICMP) and the “type” field in the ICMP header set to 16 (ICMP Information Reply).

2011 ICMP Address Mask Request (Info, Atomic)

Triggers when an IP datagram is received with the “protocol” field in the IP header set to 1 (ICMP) and the “type” field in the ICMP header set to 17 (Address Mask Request).

2012 ICMP Address Mask Reply (Info, Atomic)

Triggers when an IP datagram is received with the “protocol” field in the IP header set to 1 (ICMP) and the “type” field in the ICMP header set to 18 (Address Mask Reply).

2150 Fragmented ICMP Traffic (Attack, Atomic)

Triggers when an IP datagram is received with the protocol field in the IP header set to 1 (ICMP) and either the more fragments flag is set to 1 (ICMP) or there is an offset indicated in the offset field.

2151 Large ICMP Traffic (Attack, Atomic)

Triggers when an IP datagram is received with the protocol field in the IP header set to 1 (ICMP) and the IP length is greater than 1024.

2154 Ping of Death Attack (Attack, Atomic)

Triggers when an IP datagram is received with the protocol field in the IP header set to 1 (ICMP), the Last Fragment bit is set, and

$$(\text{IP offset} * 8) + (\text{IP data length}) > 65535$$

In other words, the IP offset (which represents the starting position of this fragment in the original packet, and which is in 8-byte units) plus the rest of the packet is greater than the maximum size for an IP packet.

3040 TCP - no bits set in flags (Attack, Atomic)

Triggers when a TCP packet is received with no bits set in the flags field.

3041 TCP - SYN and FIN bits set (Attack, Atomic)

Triggers when a TCP packet is received with both the SYN and FIN bits set in the flag field.

3042 TCP - FIN bit with no ACK bit in flags (Attack, Atomic)

Triggers when a TCP packet is received with the FIN bit set but with no ACK bit set in the flags field.

3050 Half-open SYN Attack/SYN Flood (Attack, Compound)

Triggers when multiple TCP sessions have been improperly initiated on any of several well-known service ports. Detection of this signature is currently limited to FTP, Telnet, HTTP, and e-mail servers (TCP ports 21, 23, 80, and 25 respectively).

3100 Smail Attack (Attack, Compound)

Triggers on the very common “smail” attack against SMTP-compliant e-mail servers (frequently sendmail).

3101 Sendmail Invalid Recipient (Attack, Compound)

Triggers on any mail message with a “pipe” (|) symbol in the recipient field.

3102 Sendmail Invalid Sender (Attack, Compound)

Triggers on any mail message with a “pipe” (|) symbol in the “From:” field.

3103 Sendmail Reconnaissance (Attack, Compound)

Triggers when “expn” or “vrfy” commands are issued to the SMTP port.

3104 Archaic Sendmail Attacks (Attack, Compound)

Triggers when “wiz” or “debug” commands are issued to the SMTP port.

3105 Sendmail Decode Alias (Attack, Compound)

Triggers on any mail message with “: decode@” in the header.

3106 Mail Spam (Attack, Compound)

Counts number of Rcpt to: lines in a single mail message and alarms after a user-definable maximum has been exceeded (default is 250).

3107 Majordomo Execute Attack (Attack, Compound)

A bug in the Majordomo program will allow remote users to execute arbitrary commands at the privilege level of the server.

3150 FTP Remote Command Execution (Attack, Compound)

Triggers when someone tries to execute the FTP SITE command.

3151 FTP SYST Command Attempt (Info, Compound)

Triggers when someone tries to execute the FTP SYST command.

3152 FTP CWD ~root (Attack, Compound)

Triggers when someone tries to execute the CWD ~root command.

3153 FTP Improper Address Specified (Attack, Atomic*)

Triggers if a port command is issued with an address that is not the same as the requesting host.

3154 FTP Improper Port Specified (Attack, Atomic*)

Triggers if a port command is issued with a data port specified that is less than 1024 or greater than 65535.

4050 UDP Bomb (Attack, Atomic)

Triggers when the UDP length specified is less than the IP length specified.

4100 Tftp Passwd File (Attack, Compound)

Triggers on an attempt to access the passwd file (typically /etc/passwd) via TFTP.

6100 RPC Port Registration (Info, Atomic*)

Triggers when attempts are made to register new RPC services on a target host.

6101 RPC Port Unregistration (Info, Atomic*)

Triggers when attempts are made to unregister existing RPC services on a target host.

6102 RPC Dump (Info, Atomic*)

Triggers when an RPC dump request is issued to a target host.

6103 Proxied RPC Request (Attack, Atomic*)

Triggers when a proxied RPC request is sent to the portmapper of a target host.

6150 ypserv Portmap Request (Info, Atomic*)

Triggers when a request is made to the portmapper for the YP server daemon (ypserv) port.

6151 ypbind Portmap Request (Info, Atomic*)

Triggers when a request is made to the portmapper for the YP bind daemon (ypbind) port.

6152 yppasswdd Portmap Request (Info, Atomic*)

Triggers when a request is made to the portmapper for the YP password daemon (yppasswdd) port.

6153 ypubd Portmap Request (Info, Atomic*)

Triggers when a request is made to the portmapper for the YP update daemon (ypubd) port.

6154 ypxfrd Portmap Request (Info, Atomic*)

Triggers when a request is made to the portmapper for the YP transfer daemon (ypxfrd) port.

6155 mntd Portmap Request (Info, Atomic*)

Triggers when a request is made to the portmapper for the mount daemon (mntd) port.

6175 rexd Portmap Request (Info, Atomic*)

Triggers when a request is made to the portmapper for the remote execution daemon (rex) port.

6180 rexd Attempt (Info, Atomic*)

Triggers when a call to the rexd program is made. The remote execution daemon is the server responsible for remote program execution. This may be indicative of an attempt to gain unauthorized access to system resources.

6190 statd Buffer Overflow (Attack, Atomic*)

Triggers when a large statd request is sent. This could be an attempt to overflow a buffer and gain access to system resources.

8000 FTP Retrieve Password File (Attack, Atomic*)

SubSig ID: 2101

Triggers on string “passwd” issued during an FTP session. May indicate someone attempting to retrieve the password file from a machine in order to crack it and gain unauthorized access to system resources.

Cisco IOS Firewall IDS Configuration Task List

See the following sections for configuration tasks for the Cisco IOS Firewall Intrusion Detection System feature. Each task in the list is identified as optional or required:

- [Initializing Cisco IOS Firewall IDS](#) (Required)
- [Initializing the Post Office](#) (Required)
- [Configuring and Applying Audit Rules](#) (Required)

- [Verifying the Configuration](#) (Optional)

For examples using the commands in this chapter, see the “[Cisco IOS Firewall IDS Configuration Examples](#)” section at the end of this chapter.

Initializing Cisco IOS Firewall IDS

To initialize Cisco IOS Firewall IDS on a router, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# ip audit smtp spam recipients	Sets the threshold beyond which spamming in e-mail messages is suspected. Here, <i>recipients</i> is the maximum number of recipients in an e-mail message. The default is 250.
Step 2	Router(config)# ip audit po max-events number_events	Sets the threshold beyond which queued events are dropped from the queue for sending to the Cisco Secure IDS Director. Here, <i>number_events</i> is the number of events in the event queue. The default is 100. Increasing this number may have an impact on memory and performance, as each event in the event queue requires 32 KB of memory.
Step 3	Router(config)# exit	Exits global configuration mode.

Initializing the Post Office

Note

You must reload the router every time you make a Post Office configuration change.

To initialize the Post Office system, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# ip audit notify nr-director	Sends event notifications (alarms) to either a Cisco Secure IDS Director, a syslog server, or both.
	or Router(config)# ip audit notify log	For example, if you are sending alarms to a Cisco Secure IDS Director, use the nr-director keyword in the command syntax. If you are sending alarms to a syslog server, use the log keyword in the command syntax.
Step 2	router(config)# ip audit po local <i>hostid</i> <i>host-id orgid org-id</i>	Sets the Post Office parameters for both the router (using the ip audit po local command) and the Cisco Secure IDS Director (using the ip audit po remote command). Here, <i>host-id</i> is a unique number between 1 and 65535 that identifies the router, and <i>org-id</i> is a unique number between 1 and 65535 that identifies the organization to which the router and Director both belong.
Step 3	Router(config)# ip audit po remote <i>hostid</i> <i>host-id orgid org-id rmtaddress ip-address</i> localaddress <i>ip-address</i> port <i>port-number</i> preference <i>preference-number</i> timeout <i>seconds</i> application <i>application-type</i>	Sets the Post Office parameters for both the Cisco Secure IDS Director (using the ip audit po remote command). <i>host-id</i> is a unique number between 1 and 65535 that identifies the Director. <i>org-id</i> is a unique number between 1 and 65535 that identifies the organization to which the router and Director both belong. rmtaddress <i>ip-address</i> is the Director's IP address. localaddress <i>ip-address</i> is the router's interface IP address. <i>port-number</i> identifies the UDP port on which the Director is listening for alarms (45000 is the default). <i>preference-number</i> is the relative priority of the route to the Director (1 is the default)—if more than one route is used to reach the same Director, then one must be a primary route (preference 1) and the other a secondary route (preference 2). <i>seconds</i> is the number of seconds the Post Office waits before it determines that a connection has timed out (5 is the default). <i>application-type</i> is either director or logger. Note If you are sending Post Office notifications to a Sensor, use logger instead of director as your application. Sending to a logging application means that no alarms are sent to a GUI; instead, the Cisco Secure IDS alarm data is written to a flat file, which can then be processed with filters, such as perl and awk, or staged to a database. Use logger only in advanced applications where you want the alarms only to be logged and not displayed.

	Command	Purpose
Step 4	Router(config)# logging console info	Displays the syslog messages on the router console if you are sending alarms to the syslog console.
Step 5	Router(config)# exit	Exits global configuration mode.
Step 6	Router# write memory	Saves the configuration.
Step 7	Router# reload	Reloads the router.

After you have configured the router, add the Cisco IOS Firewall IDS router's Post Office information to the `/usr/nr/etc/hosts` and `/usr/nr/etc/routes` files on the Cisco Secure IDS Sensors and Directors communicating with the router. You can do this with the nrConfigure tool in Cisco Secure IDS. For more information, refer to the *NetRanger User Guide*.

Configuring and Applying Audit Rules

To configure and apply audit rules, use the following commands starting in global configuration mode:

	Command	Purpose
Step 1	<pre>Router(config)# ip audit info {action [alarm] [drop] [reset]}</pre> and <pre>Router(config)# ip audit attack {action [alarm] [drop] [reset]}</pre>	Sets the default actions for info and attack signatures. Both types of signatures can take any or all of the following actions: alarm, drop, and reset. The default action is alarm .
Step 2	<pre>Router(config)# ip audit name audit-name {info attack} [list standard-acl] [action [alarm] [drop] [reset]]</pre>	Creates audit rules, where <i>audit-name</i> is a user-defined name for an audit rule. For example: <pre>ip audit name audit-name info ip audit name audit-name attack</pre> The default action is alarm. Note Use the same name when you assign attack and info type signatures. You can also use the ip audit name command to attach access control lists to an audit rule for filtering out sources of false alarms. In this case <i>standard-acl</i> is an integer representing an ACL. If you attach an ACL to an audit rule, the ACL must be defined as well: <pre>ip audit name audit-name {info attack} list acl-list</pre> In the following example, ACL 99 is attached to the audit rule INFO, and ACL 99 is defined: <pre>ip audit name INFO info list 99 access-list 99 deny 10.1.1.0 0.0.0.255 access-list 99 permit any</pre> Note The ACL in the preceding example is <i>not</i> denying traffic from the 10.1.1.0 network (as expected if it were applied to an interface). Instead, the hosts on that network are not filtered through the audit process because they are trusted hosts. On the other hand, all other hosts, as defined by permit any, are processed by the audit rule.

	Command	Purpose
Step 3	Router(config)# ip audit signature signature-id { disable list acl-list}	Disables individual signatures. Disabled signatures are not included in audit rules, as this is a global configuration change: <pre>ip audit signature signature-number disable</pre> To re-enable a disabled signature, use the no ip audit signature command, where <i>signature-number</i> is the number of the disabled signature. You can also use the ip audit signature command to apply ACLs to individual signatures for filtering out sources of false alarms. In this case <i>signature-number</i> is the number of a signature, and <i>acl-list</i> is an integer representing an ACL: <pre>ip audit signature signature-number list acl-list</pre> For example, ACL 35 is attached to the 1234 signature, and then defined: <pre>ip audit signature 1234 list 35 access-list 35 deny 10.1.1.0 0.0.0.255 access-list 35 permit any</pre> Note The ACL in the preceding example is <i>not</i> denying traffic from the 10.1.1.0 network (as expected if it were applied to an interface). Instead, the hosts on that network are not filtered through the signature because they are trusted hosts or are otherwise causing false positives to occur. On the other hand, all other hosts, as defined by permit any, are processed by the signature.
Step 4	Router(config-if)# interface interface-number	Enters interface configuration mode.
Step 5	Router(config-if)# ip audit audit-name { in out }	Applies an audit rule at an interface. With this command, <i>audit-name</i> is the name of an existing audit rule, and <i>direction</i> is either in or out .
Step 6	Router(config-if)# exit	Exits interface configuration mode.
Step 7	Router(config)# ip audit po protected ip-addr [to ip-addr]	Configures which network should be protected by the router. Here, <i>ip_addr</i> is the IP address to protect.
Step 8	Router(config)# exit	Exits global configuration mode.

Verifying the Configuration

You can verify that Cisco IOS Firewall IDS is properly configured with the **show ip audit configuration** command (see [Example 1](#)).

Example 1 Output from show ip audit configuration Command

```
ids2611# show ip audit configuration
```

```

Event notification through syslog is enabled
Event notification through Net Director is enabled
Default action(s) for info signatures is alarm
Default action(s) for attack signatures is alarm drop reset
Default threshold of recipients for spam signature is 25
PostOffice:HostID:55 OrgID:123 Msg dropped:0
          :Curr Event Buf Size:100 Configured:100
HID:14 OID:123 S:1 A:2 H:82 HA:49 DA:0 R:0 Q:0
ID:1 Dest:10.1.1.99:45000 Loc:172.16.58.99:45000 T:5 S:ESTAB *

Audit Rule Configuration
Audit name AUDIT.1
  info actions alarm
  attack actions alarm drop reset

```

You can verify which interfaces have audit rules applied to them with the **show ip audit interface** command (see [Example 2](#)).

Example 2 *Output from show ip audit interface Command*

```

ids2611# show ip audit interface

Interface Configuration
Interface Ethernet0
Inbound IDS audit rule is AUDIT.1
  info actions alarm
  attack actions alarm drop reset
Outgoing IDS audit rule is not set
Interface Ethernet1
Inbound IDS audit rule is AUDIT.1
  info actions alarm
  attack actions alarm drop reset
Outgoing IDS audit rule is not set

```

Monitoring and Maintaining Cisco IOS Firewall IDS

This section describes the EXEC commands used to monitor and maintain Cisco IOS Firewall IDS.

Command	Purpose
Router# clear ip audit configuration	Disables Cisco IOS Firewall IDS, removes all intrusion detection configuration entries, and releases dynamic resources.
Router# clear ip audit statistics	Resets statistics on packets analyzed and alarms sent.
Router# show ip audit statistics	Displays the number of packets audited and the number of alarms sent, among other information.

The following display provides sample output from the **show ip audit statistics** command:

```

Signature audit statistics [process switch:fast switch]
signature 2000 packets audited: [0:2]
signature 2001 packets audited: [9:9]
signature 2004 packets audited: [0:2]
signature 3151 packets audited: [0:12]
Interfaces configured for audit 2
Session creations since subsystem startup or last reset 11
Current session counts (estab/half-open/terminating) [0:0:0]

```

```
Maxever session counts (estab/half-open/terminating) [2:1:0]
Last session created 19:18:27
Last statistic reset never

HID:1000 OID:100 S:218 A:3 H:14085 HA:7114 DA:0 R:0
```

Cisco IOS Firewall IDS Configuration Examples

The following sections provide Cisco IOS Firewall IDS configuration examples:

- [Cisco IOS Firewall IDS Reporting to Two Directors Example](#)
- [Adding an ACL to the Audit Rule Example](#)
- [Disabling a Signature Example](#)
- [Adding an ACL to Signatures Example](#)
- [Dual-Tier Signature Response Example](#)

Cisco IOS Firewall IDS Reporting to Two Directors Example

In the following example, Cisco IOS Firewall IDS is initialized. Notice that the router is reporting to two Directors. Also notice that the AUDIT.1 audit rule will apply both info and attack signatures.

```
ip audit smtp spam 25
ip audit notify nr-director
ip audit notify log
ip audit po local hostid 55 orgid 123
ip audit po remote hostid 14 orgid 123 rmtaddress 10.1.1.99 localaddress 10.1.1.1
ip audit po remote hostid 15 orgid 123 rmtaddress 10.1.2.99 localaddress 10.1.1.1

ip audit name AUDIT.1 info action alarm
ip audit name AUDIT.1 attack action alarm drop reset

interface e0
 ip address 10.1.1.1 255.0.0.0
 ip audit AUDIT.1 in

interface e1
 ip address 172.16.57.1 255.255.255.0
 ip audit AUDIT.1 in
```

Adding an ACL to the Audit Rule Example

In the following example, an ACL is added to account for a Cisco Secure IDS Scanner (172.16.59.16) that scans for all types of attacks. As a result, no packets originating from the device will be audited.

```
ip audit smtp spam 25
ip audit notify nr-director
ip audit notify log
ip audit po local hostid 55 orgid 123
ip audit po remote hostid 14 orgid 123 rmtaddress 10.1.1.99 localaddress 10.1.1.1
ip audit po remote hostid 15 orgid 123 rmtaddress 10.1.2.99 localaddress 10.1.1.1

ip audit name AUDIT.1 info list 90 action alarm
ip audit name AUDIT.1 attack list 90 action alarm drop reset
```

```

interface e0
 ip address 10.1.1.1 255.0.0.0
 ip audit AUDIT.1 in

interface e1
 ip address 172.16.57.1 255.255.255.0
 ip audit AUDIT.1 in

access-list 90 deny 172.16.59.16
access-list 90 permit any

```

Disabling a Signature Example

The security administrator notices that the router is generating a lot of false positives for signatures 1234, 2345, and 3456. The system administrator knows that there is an application on the network that is causing signature 1234 to fire, and it is not an application that should cause security concerns. This signature can be disabled, as illustrated in the following example:

```

ip audit smtp spam 25
ip audit notify nr-director
ip audit notify log
ip audit po local hostid 55 orgid 123
ip audit po remote hostid 14 orgid 123 rmtaddress 10.1.1.99 localaddress 10.1.1.1
ip audit po remote hostid 15 orgid 123 rmtaddress 10.1.2.99 localaddress 10.1.1.1

ip audit signature 1234 disable

ip audit name AUDIT.1 info list 90 action alarm
ip audit name AUDIT.1 attack list 90 action alarm drop reset

interface e0
 ip address 10.1.1.1 255.0.0.0
 ip audit AUDIT.1 in

interface e1
 ip address 172.16.57.1 255.255.255.0
 ip audit AUDIT.1 in

access-list 90 deny 172.16.59.16
access-list 90 permit any

```

Adding an ACL to Signatures Example

After further investigation, the security administrator discovers that the false positives for signatures 2345 and 3456 are caused by specific applications on hosts 10.4.1.1 and 10.4.1.2, as well as by some workstations using DHCP on the 172.16.58.0 subnetwork. Attaching an ACL that denies processing of these hosts stops the creation of false positive alarms, as illustrated in the following example:

```

ip audit smtp spam 25
ip audit notify nr-director
ip audit notify log
ip audit po local hostid 55 orgid 123
ip audit po remote hostid 14 orgid 123 rmtaddress 10.1.1.99 localaddress 10.1.1.1
ip audit po remote hostid 15 orgid 123 rmtaddress 10.1.2.99 localaddress 10.1.1.1

ip audit signature 1234 disable
ip audit signature 2345 list 91

```

```
ip audit signature 3456 list 91

ip audit name AUDIT.1 info list 90 action alarm
ip audit name AUDIT.1 attack list 90 action alarm drop reset

interface e0
ip address 10.1.1.1 255.0.0.0
ip audit AUDIT.1 in

interface e1
ip address 172.16.57.1 255.255.255.0
ip audit AUDIT.1 in

access-list 90 deny 172.16.59.16
access-list 90 permit any
access-list 91 deny host 10.4.1.1
access-list 91 deny host 10.4.1.2
access-list 91 deny 172.16.58.0 0.0.0.255
access-list 91 permit any
```

Dual-Tier Signature Response Example

The company has now reorganized and has placed only trusted people on the 172.16.57.0 network. The work done by the employees on these networks must not be disrupted by Cisco IOS Firewall IDS, so attack signatures in the AUDIT.1 audit rule now will only alarm on a match.

For sessions that originate from the outside network, any attack signature matches (other than the false positive ones that are being filtered out) are to be dealt with in the following manner: send an alarm, drop the packet, and reset the TCP session.

This dual-tier method of signature response is accomplished by configuring two different audit specifications and applying each to a different ethernet interface, as illustrated in the following example:

```
ip audit smtp spam 25
ip audit notify nr-director
ip audit notify log
ip audit po local hostid 55 orgid 123
ip audit po remote hostid 14 orgid 123 rmtaddress 10.1.1.99 localaddress 10.1.1.1
ip audit po remote hostid 15 orgid 123 rmtaddress 10.1.2.99 localaddress 10.1.1.1

ip audit signature 1234 disable
ip audit signature 2345 list 91
ip audit signature 3456 list 91

ip audit name AUDIT.1 info list 90 action alarm
ip audit name AUDIT.1 attack list 90 action alarm
ip audit name AUDIT.2 info action alarm
ip audit name AUDIT.2 attack alarm drop reset

interface e0
ip address 10.1.1.1 255.0.0.0
ip audit AUDIT.2 in

interface e1
ip address 172.16.57.1 255.255.255.0
ip audit AUDIT.1 in

access-list 90 deny host 172.16.59.16
access-list 90 permit any
access-list 91 deny host 10.4.1.1
access-list 91 deny host 10.4.1.2
```

```
access-list 91 deny 172.16.58.0 0.0.0.255  
access-list 91 permit any
```

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Authentication Proxy

Configuring Authentication Proxy

This chapter describes the Cisco IOS Firewall Authentication Proxy feature. Authentication proxy provides dynamic, per-user authentication and authorization, authenticating users against industry standard TACACS+ and RADIUS authentication protocols. Authenticating and authorizing connections by users provides more robust protection against network attacks.

For a complete description of the authentication proxy commands in this chapter, refer to the “Authentication Proxy Commands” chapter of the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the “Identifying Supported Platforms” section in the chapter “Using Cisco IOS Software.”

In This Chapter

This chapter contains the following sections:

- [About Authentication Proxy](#)
- [Authentication Proxy Configuration Task List](#)
- [Monitoring and Maintaining the Authentication Proxy](#)
- [Authentication Proxy Configuration Examples](#)

About Authentication Proxy

The Cisco IOS Firewall authentication proxy feature allows network administrators to apply specific security policies on a per-user basis. Previously, user identity and related authorized access were associated with a user IP address, or a single security policy had to be applied to an entire user group or subnetwork. Now, users can be identified and authorized on the basis of their per-user policy. Tailoring of access privileges on an individual basis is possible, as opposed to applying a general policy across multiple users.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

With the authentication proxy feature, users can log in to the network or access the Internet via HTTP, and their specific access profiles are automatically retrieved and applied from a CiscoSecure ACS, or other RADIUS, or TACACS+ authentication server. The user profiles are active only when there is active traffic from the authenticated users.

The authentication proxy is compatible with other Cisco IOS security features such as Network Address Translation (NAT), Context-based Access Control (CBAC), IP Security (IPSec) encryption, and Cisco Secure VPN Client (VPN client) software.

This section contains the following sections:

- [Restrictions](#)
- [Prerequisites to Configuring Authentication Proxy](#)

How the Authentication Proxy Works

When a user initiates an HTTP session through the firewall, the authentication proxy is triggered. The authentication proxy first checks to see if the user has been authenticated. If a valid authentication entry exists for the user, the connection is completed with no further intervention by the authentication proxy. If no entry exists, the authentication proxy responds to the HTTP connection request by prompting the user for a username and password.

[Figure 42](#) illustrates the authentication proxy HTML login page.

Figure 42 Authentication Proxy Login Page

Users must successfully authenticate themselves with the authentication server by entering a valid username and password.

If the authentication succeeds, the user's authorization profile is retrieved from the AAA server. The authentication proxy uses the information in this profile to create dynamic access control entries (ACEs) and add them to the inbound (input) access control list (ACL) of an input interface and to the outbound (output) ACL of an output interface, if an output ACL exists at the interface. This process enables the firewall to allow authenticated users access to the network as permitted by the authorization profile. For example, a user can initiate a Telnet connection through the firewall if Telnet is permitted in the user's profile.

If the authentication fails, the authentication proxy reports the failure to the user and prompts the user with multiple retries. If the user fails to authenticate after five attempts, the user must wait two minutes and initiate another HTTP session to trigger authentication proxy.

The login page is refreshed each time the user makes requests to access information from a web server.

The authentication proxy customizes each of the access list entries in the user profile by replacing the source IP addresses in the downloaded access list with the source IP address of the authenticated host.

At the same time that dynamic ACEs are added to the interface configuration, the authentication proxy sends a message to the user confirming that the login was successful. [Figure 43](#) illustrates the login status in the HTML page.

Figure 43 **Authentication Proxy Login Status Message**

The authentication proxy sets up an inactivity (idle) timer for each user profile. As long as there is activity through the firewall, new traffic initiated from the user's host does not trigger the authentication proxy, and authorized user traffic is permitted access through the firewall.

If the idle timer expires, the authentication proxy removes the user's profile information and dynamic access lists entries. When this happens, traffic from the client host is blocked. The user must initiate another HTTP connection to trigger the authentication proxy.

Secure Authentication

The authentication proxy uses JavaScript to help achieve secure authentication using the client browser. Secure authentication prevents a client from mistakenly submitting a username and password to a network web server other than the authentication proxy router.

This section contains the following sections:

- [Operation with JavaScript](#)
- [Operation Without JavaScript](#)

Operation with JavaScript

Users should enable JavaScript on the browser prior to initiating an HTTP connection. With JavaScript enabled on the browser, secure authentication is done automatically, and the user sees the authentication message shown in [Figure 43](#). The HTTP connection is completed automatically for the user.

Operation Without JavaScript

If the client browser does not support JavaScript, or if site security policy prevents users from enabling JavaScript, any login attempt generates a popup window with instructions for manually completing the connection. [Figure 44](#) illustrates the authentication proxy login status message with JavaScript disabled on the browser.

Figure 44 Authentication Proxy Login Status Message with JavaScript Disabled

To close this window, click Close on the browser File menu.

After closing the popup window, the user should click Reload (Refresh for Internet Explorer) in the browser window in which the authentication login page is displayed. If the user's last authentication attempt succeeds, clicking Reload brings up the web page the user is trying to retrieve. If the user's last attempt fails, clicking Reload causes the authentication proxy to intercept the client HTTP traffic again, prompting the user with another login page that solicits the username and password.

If JavaScript is not enabled, it is strongly recommended that site administrators advise users of the correct procedure for closing the popup window as described in the section "[Establishing User Connections Without JavaScript](#)."

Using the Authentication Proxy

Unlike some Cisco IOS Firewall features that operate transparently to the user, the authentication proxy feature requires some user interaction on the client host. [Table 40](#) describes the interaction of the authentication proxy with the client host.

Table 40 **Authentication Proxy Interaction with the Client Host**

Authentication Proxy Action with Client	Description
Triggering on HTTP connections	If a user is not currently authenticated at the firewall router, any HTTP connection initiated by the user triggers the authentication proxy. If the user is already authenticated, the authentication proxy is transparent to the user.
Logging in using the login page	Triggering the authentication proxy generates an HTML-based login page. The user must enter a username and password to be authenticated with the AAA server. Figure 42 illustrates the authentication proxy login page.
Authenticating the user at the client	Following the login attempt, the authentication proxy action can vary depending on whether JavaScript is enabled in the browser. If JavaScript is enabled, and authentication is successful, the authentication proxy displays a message indicating the status of the authentication as shown in Figure 43. After the authentication status is displayed, the proxy automatically completes the HTTP connection. If JavaScript is disabled, and authentication is successful, the authentication proxy generates a popup window with additional instructions for completing the connection. See Figure 44. If authentication is unsuccessful in any case, the user must log in again from the login page.

When to Use the Authentication Proxy

Here are examples of situations in which you might use the authentication proxy:

- You want to manage access privileges on an individual (per-user) basis using the services provided by the authentication servers instead of configuring access control based on host IP address or global access policies. Authenticating and authorizing users from any host IP address also allows network administrators to configure host IP addresses using DHCP.
- You want to authenticate and authorize local users before permitting access to intranet or Internet services or hosts through the firewall.
- You want to authenticate and authorize remote users before permitting access to local services or hosts through the firewall.
- You want to control access for specific extranet users. For example, you might want to authenticate and authorize the financial officer of a corporate partner with one set of access privileges while authorizing the technology officer for that same partner to use another set of access privileges.
- You want to use the authentication proxy in conjunction with VPN client software to validate users and to assign specific access privileges.
- You want to use the authentication proxy in conjunction with AAA accounting to generate “start” and “stop” accounting records that can be used for billing, security, or resource allocation purposes, thereby allowing users to track traffic from the authenticated hosts.

Applying the Authentication Proxy

Apply the authentication proxy in the inbound direction at any interface on the router where you want per-user authentication and authorization. Applying the authentication proxy inbound at an interface causes it to intercept a user's initial connection request before that request is subjected to any other processing by the firewall. If the user fails to gain authentication with the AAA server, the connection request is dropped.

How you apply the authentication proxy depends on your security policy. For example, you can block all traffic through an interface and enable the authentication proxy feature to require authentication and authorization for all user initiated HTTP connections. Users are authorized for services only after successful authentication with the AAA server.

The authentication proxy feature also allows you to use standard access lists to specify a host or group of hosts whose initial HTTP traffic triggers the proxy.

Figure 45 shows the authentication proxy applied at the LAN interface with all network users required to be authenticated upon the initial connection (all traffic is blocked at each interface).

Figure 45 **Applying the Authentication Proxy at the Local Interface**

Figure 46 shows the authentication proxy applied at the dial-in interface with all network traffic blocked at each interface.

Figure 46 *Applying the Authentication Proxy at an Outside Interface*

Operation with One-Time Passwords

Given a one-time password, the user enters the username and one-time password in the HTML login page as usual.

The user must enter the correct token password within the first three attempts. After three incorrect entries, the user must enter two valid token passwords in succession before authentication is granted by the AAA server.

Compatibility with Other Security Features

The authentication proxy is compatible with Cisco IOS software and with Cisco IOS security features:

- Cisco IOS Firewall Intrusion Detection System (IDS)
- NAT
- CBAC
- IPSec encryption
- VPN client software

The authentication proxy works transparently with the Cisco IOS Firewall IDS and IPSec encryption features. The following sections describe the relationship of the NAT, CBAC, and VPN client software features with the authentication proxy:

- [NAT Compatibility](#)
- [CBAC Compatibility](#)
- [VPN Client Compatibility](#)

NAT Compatibility

The authentication proxy feature is compatible with NAT only if the ACL and authentication are completed prior to the NAT translation. Although NAT is compatible with the authentication proxy feature, NAT is not a requirement of the feature.

CBAC Compatibility

Although authentication proxy is compatible with CBAC security functions, CBAC is not required to use the authentication proxy feature.

Authentication proxy's authorization returns Access Control Entries (ACEs) that are dynamically prepended into a manually created ACL. Thereafter, apply the ACL to the "protected side" inbound interface, allowing or disallowing an authorized user's source IP address access to the remote networks.

VPN Client Compatibility

Using the authentication proxy, network administrators can apply an extra layer of security and access control for VPN client traffic. If a VPN client initiates an HTTP connection, the authentication proxy first checks for prior client authentication. If the client is authenticated, authorized traffic is permitted. If the client is not authenticated, the HTTP request triggers the authentication proxy, and the user is prompted for a username and password.

If the user authentication is successful, the authentication proxy retrieves the user profile from the AAA server. The source address in the user profile entries is replaced with the IP address of the authenticated VPN client from the decrypted packet.

Compatibility with AAA Accounting

Using the authentication proxy, you can generate "start" and "stop" accounting records with enough information to be used for billing and security auditing purposes. Thus, you can monitor the actions of authenticated hosts that use the authentication proxy service.

When an authentication proxy cache and associated dynamic access control lists are created, the authentication proxy will start to track the traffic from the authenticated host. Accounting saves data about this event in a data structure stored with the data of other users. If the accounting start option is enabled, you can generate an accounting record (a "start" record) at this time. Subsequent traffic from the authenticated host will be recorded when the dynamic ACL created by the authentication proxy receives the packets.

When an authentication proxy cache expires and is deleted, additional data, such as elapsed time, is added to the accounting information and a "stop" record is sent to the server. At this point, the information is deleted from the data structure.

The accounting records for the authentication proxy user session are related to the cache and the dynamic ACL usage.

**Note**

The accounting records must include RADIUS attributes 42, 46, and 47 for both RADIUS and TACACS+.

For more information on RADIUS attributes, refer to the appendix "RADIUS Attributes."

Protection Against Denial-of-Service Attacks

The authentication proxy monitors the level of incoming HTTP requests. For each request, the authentication proxy prompts the user's for login credentials. A high number of open requests could indicate that the router is the subject of a denial-of-service (DoS) attack. The authentication proxy limits the level of open requests and drops additional requests until the number of open requests has fallen below 40.

If the firewall is experiencing a high level of connection requests requiring authentication, legitimate network users may experience delays when making connections, or the connection may be rejected and the user must try the connection again.

Risk of Spoofing with Authentication Proxy

When the authentication proxy is triggered, it creates a dynamic opening in the firewall by temporarily reconfiguring an interface with user access privileges. While this opening exists, another host might spoof the authenticated users address to gain access behind the firewall. The authentication proxy does not cause the address spoofing problem; the problem is only identified here as a matter of concern to the user. Spoofing is a problem inherent to all access lists, and the authentication proxy does not specifically address this problem.

Comparison with the Lock-and-Key Feature

Lock-and-key is another Cisco IOS Firewall feature that uses authentication and dynamic access list to provide user access through the firewall. [Table 41](#) compares the authentication proxy and lock-and-key features.

Table 41 *Comparison of the Authentication Proxy and Lock-and-Key Features*

Lock-and-Key	Authentication Proxy
Triggers on Telnet connection requests.	Triggers on HTTP connection requests.
TACACS+, RADIUS, or local authentication.	TACACS+ or RADIUS authentication and authorization.
Access lists are configured on the router only.	Access lists are retrieved from the AAA server only.
Access privileges are granted on the basis of the user's host IP address.	Access privileges are granted on a per-user and host IP address basis.
Access lists are limited to one entry for each host IP address.	Access lists can have multiple entries as defined by the user profiles on the AAA server.
Associates a fixed IP addresses with a specific user. Users must log in from the host with that IP address.	Allows DHCP-based host IP addresses, meaning that users can log in from any host location and obtain authentication and authorization.

Use the authentication proxy in any network environment that provides a per-user security policy. Use lock-and-key in network environments that might benefit from local authentication and a limited number of router-based access control policies based on host addresses. Use lock-and-key in environments not using the Cisco Secure Integrated Software.

Restrictions

- The authentication proxy triggers only on HTTP connections.
- HTTP services must be running on the standard (well-known) port, which is port 80 for HTTP.
- Client browsers must enable JavaScript for secure authentication.
- The authentication proxy access lists apply to traffic passing through the router. Traffic destined to the router is authenticated by the existing authentication methods provided by Cisco IOS software.
- The authentication proxy does not support concurrent usage; that is, if two users try to log in from the same host at the same time, authentication and authorization applies only to the user who first submits a valid username and password.
- Load balancing using multiple or different AAA servers is not supported.

Prerequisites to Configuring Authentication Proxy

Prior to configuring authentication proxy, review the following:

- For the authentication proxy to work properly, the client host must be running the following browser software:
 - Microsoft Internet Explorer 3.0 or later
 - Netscape Navigator 3.0 or later
- The authentication proxy has an option to use standard access lists. You must have a solid understanding of how access lists are used to filter traffic before you attempt to configure the authentication proxy. For an overview of how to use access lists with the Cisco IOS Firewall, refer to the chapter “Access Control Lists: Overview and Guidelines.”
- The authentication proxy employs user authentication and authorization as implemented in the Cisco authentication, authorization, and accounting (AAA) paradigm. You must understand how to configure AAA user authentication, authorization, and accounting before you configure the authentication proxy. User authentication, authorization, and accounting are explained in the chapter “Authentication, Authorization, and Accounting (AAA).”
- To run the authentication proxy successfully with Cisco IOS Firewall, configure CBAC on the firewall. For complete information on the CBAC feature, refer to the chapter “Configuring Context-Based Access Control.”

Authentication Proxy Configuration Task List

To configure the authentication proxy feature, perform the following tasks:

- [Configuring AAA](#) (Required)
- [Configuring the HTTP Server](#) (Required)
- [Configuring the Authentication Proxy](#) (Required)
- [Verifying the Authentication Proxy](#) (Optional)

For authentication proxy configuration examples using the commands in this chapter, refer to the section “[Authentication Proxy Configuration Examples](#)” at the end of this chapter.

Configuring AAA

You must configure the authentication proxy for AAA services. Use the following commands in global configuration mode to enable authorization and to define the authorization methods:

	Command	Purpose
Step 1	<code>router(config)# aaa new-model</code>	Enables the AAA functionality on the router.
Step 2	<code>router(config)# aaa authentication login default TACACS+ RADIUS</code>	Defines the list of authentication methods at login.
Step 3	<code>router(config)# aaa authorization auth-proxy default [method1 [method2...]]</code>	Uses the auth-proxy keyword to enable authentication proxy for AAA methods.
Step 4	<code>router(config)# aaa accounting auth-proxy default start-stop group tacacs+</code>	Uses the auth-proxy keyword to set up the authorization policy as dynamic ACLs that can be downloaded. This command activates authentication proxy accounting.
Step 5	<code>router(config)# tacacs-server host hostname</code>	Specifies an AAA server. For RADIUS servers, use the radius server host command.
Step 6	<code>router(config)# tacacs-server key key</code>	Sets the authentication and encryption key for communications between the router and the AAA server. For RADIUS servers use the radius server key command.
Step 7	<code>router(config)# access-list access-list-number permit tcp host source eq tacacs host destination</code>	Creates an ACL entry to allow the AAA server to return traffic to the firewall. The source address is the IP address of the AAA server, and the destination is the IP address of the router interface where the AAA server resides.

In addition to configuring AAA on the firewall router, the authentication proxy requires a per-user access profile configuration on the AAA server. To support the authentication proxy, configure the AAA authorization service **auth-proxy** on the AAA server as outlined here:

- Define a separate section of authorization for the **auth-proxy** keyword to specify the downloadable user profiles. This keyword does not interfere with other type of services, such as EXEC. The following example shows a user profile on a TACACS server:

```
default authorization = permit
key = cisco
user = newuser1 {
  login = cleartext cisco
  service = auth-proxy
  {
    priv-lvl=15
    proxyacl#1="permit tcp any any eq 26"
    proxyacl#2="permit icmp any host 60.0.0.2"
    proxyacl#3="permit tcp any any eq ftp"
    proxyacl#4="permit tcp any any eq ftp-data"
    proxyacl#5="permit tcp any any eq smtp"
    proxyacl#6="permit tcp any any eq telnet"
  }
}
```

- The only supported attribute in the AAA server user configuration is proxyacl#n. Use the proxyacl#n attribute when configuring the access lists in the profile. The attribute proxyacl#n is for both RADIUS and TACACS+ attribute-value (AV) pairs.
- The privilege level must be set to 15 for all users.

- The access lists in the user profile on the AAA server must have access commands that contain only the **permit** keyword.
- Set the source address to the **any** keyword in each of the user profile access list entries. The source address in the access lists is replaced with the source address of the host making the authentication proxy request when the user profile is downloaded to the firewall.
- The supported AAA servers are:
 - CiscoSecure ACS 2.1.x for Windows NT
 - CiscoSecure ACS 2.3 for Windows NT
 - CiscoSecure ACS 2.2.4 for UNIX
 - CiscoSecure ACS 2.3 for UNIX
 - TACACS+ server (vF4.02.alpha)
 - Ascend RADIUS server radius-980618 (required attribute-value pair patch)
 - Livingston RADIUS server (v1.16)

Refer to the section [“AAA Server User Profile Example”](#) for sample AAA server configurations.

Configuring the HTTP Server

To use authentication proxy, you must also enable the HTTP server on the firewall and set the HTTP server authentication method to use AAA. Enter the following commands in global configuration mode:

	Command	Purpose
Step 1	router(config)# ip http server	Enables the HTTP server on the router. The authentication proxy uses the HTTP server to communicate with the client for user authentication.
Step 2	router(config)# ip http access-class <i>access-list-number</i>	Specifies the access list for the HTTP server. Use the standard access list number configured in the section “Interface Configuration Example.”

Configuring the Authentication Proxy

Note

Set the **auth-cache-time** option for any authentication proxy rule to a higher value than the idle timeout value for any CBAC inspection rule. When the authentication proxy removes an authentication cache along with its associated dynamic user ACL, there may be some idle connections monitored by CBAC, and removal of user-specific ACLs could cause those idle connections to hang. If CBAC has a shorter idle timeout, CBAC resets these connections when the idle timeout expires; that is, before the authentication proxy removes the user profile.

To configure the authentication proxy, use the following commands, beginning in global configuration mode:

	Command	Purpose
Step 1	router(config)# ip auth-proxy auth-cache-time <i>min</i>	Sets the global authentication proxy idle timeout value in minutes. If the timeout expires, user authentication entries are removed, along with any associated dynamic access lists. The default value is 60 minutes.
Step 2	router(config)# ip auth-proxy auth-proxy-banner	(Optional) Displays the name of the firewall router in the authentication proxy login page. The banner is disabled by default.
Step 3	router(config)# ip auth-proxy name <i>auth-proxy-name</i> http [<i>auth-cache-time min</i>] [list { <i>acl</i> <i>acl-name</i> }]	Creates authentication proxy rules. The rules define how you apply authentication proxy. This command associates connections initiating HTTP protocol traffic with an authentication proxy name. You can associate the named rule with an access control list (ACL), providing control over which hosts use the authentication proxy feature. If no standard access list is defined, the named authentication proxy rule intercepts HTTP traffic from all hosts whose connection initiating packets are received at the configured interface. (Optional) The auth-cache-time option overrides the global authentication proxy cache timer. This option provides more control over timeout values for a specific authentication proxy rule. If no value is specified, the proxy rule assumes the value set with the ip auth-proxy auth-cache-time command. (Optional) The list option allows you to apply a standard, extended (1-199), or named access list to a named authentication proxy rule. HTTP connections initiated by hosts in the access list are intercepted by the authentication proxy.
Step 4	router(config)# interface <i>type</i>	Enters interface configuration mode by specifying the interface type on which to apply the authentication proxy.
Step 5	router(config-if)# ip auth-proxy <i>auth-proxy-name</i>	In interface configuration mode, applies the named authentication proxy rule at the interface. This command enables the authentication proxy rule with that name.

Verifying the Authentication Proxy

Verifying the authentication proxy configuration can have several components:

- [Checking the Authentication Proxy Configuration](#) (Optional)
- [Establishing User Connections with JavaScript](#) (Optional)
- [Establishing User Connections Without JavaScript](#) (Optional)

Checking the Authentication Proxy Configuration

To check the current authentication proxy configuration, use the **show ip auth-proxy configuration** command in privileged EXEC mode:

Command	Purpose
router# show ip auth-proxy configuration	Displays the authentication proxy configuration.

In the following example, the global authentication proxy idle timeout value is set to 60 minutes, the named authentication proxy rule is “pxy”, and the idle timeout value for this named rule is one minute. The display shows that no host list is specified, meaning that all connections initiating HTTP traffic at the interface are subject to the authentication proxy rule.

```
router# show ip auth-proxy configuration
Authentication cache time is 60 minutes
Authentication Proxy Rule Configuration
Auth-proxy name pxy
http list not specified auth-cache-time 1 minutes
```

To verify that the authentication proxy is successfully configured on the router, ask a user to initiate an HTTP connection through the router. The user must have authentication and authorization configured at the AAA server. If the user authentication is successful, the firewall completes the HTTP connection for the user. If the authentication is unsuccessful, check the access list and the AAA server configurations.

Display the user authentication entries using the **show ip auth-proxy cache** command in privileged EXEC mode:

Command	Purpose
router# show ip auth-proxy cache	Displays the list of user authentication entries.

The authentication proxy cache lists the host IP address, the source port number, the timeout value for the authentication proxy, and the state of the connection. If the authentication proxy state is HTTP_ESTAB, the user authentication was successful.

```
router# show ip auth-proxy cache
Authentication Proxy Cache
Client IP 192.168.25.215 Port 57882, timeout 1, state HTTP_ESTAB
```

Wait for one minute, which is the timeout value for this named rule, and ask the user to try the connection again. After one minute, the user connection is denied because the authentication proxy has removed the user's authentication entry and any associated dynamic ACLs. The user is presented with a new authentication login page and must log in again to gain access through the firewall.

Establishing User Connections with JavaScript

To verify client connections using the authentication proxy with JavaScript enabled on the client browser, follow this procedure:

- Step 1** From a client host, initiate an HTTP connection through the firewall. This generates the authentication proxy login page.
- Step 2** At the authentication proxy login page, enter a username and password.

Step 3 Click **OK** to submit the username and password to the AAA server.

A popup window appears indicating whether the login attempt succeeded or failed. If the authentication is successful, the connection is completed automatically. If the authentication fails, the authentication proxy reports the failure to the user and prompts the user with multiple retries.

Note

If the authentication attempt is unsuccessful after five attempts, the user must wait two minutes and initiate another HTTP session to trigger authentication proxy.

Establishing User Connections Without JavaScript

To ensure secure authentication, the authentication proxy design requires JavaScript. You can use the authentication proxy without enabling JavaScript on the browser, but this poses a potential security risk if users do not properly establish network connections. The following procedure provides the steps to properly establish a connection with JavaScript disabled. Network administrators are strongly advised to instruct users on how to properly establish connections using the procedure in this section.

Note

Failure to follow this procedure can cause user credentials to be passed to a network web server other than the authentication proxy or can cause the authentication proxy to reject the login attempt.

To verify client connections using the authentication proxy when JavaScript is not enabled on the client browser, follow this procedure:

Step 1 Initiate an HTTP connection through the firewall.

This generates the authentication proxy login page.

Step 2 From the authentication proxy login page at the client, enter the username and password.

Step 3 Click **OK** to submit the username and password to the AAA server.

A popup window appears indicating whether the login attempt succeeded or failed. If the popup window indicates successful authentication, go to [Step 7](#).

Step 4 If the popup window displays a failed authentication message, click **Close** on the browser **File** menu.

Note

Do not click **Reload (Refresh** for Internet Explorer) to close the popup window.

Step 5 From the original authentication login page, click **Reload (Refresh** for Internet Explorer) on the browser toolbar. The user login credentials are cleared from the form.

Note

Do not click **OK**. You must click **Reload** or **Refresh** to clear the username and password and to reload the form before attempting to log in again.

Step 6 Enter the username and password again.

If the authentication is successful, a window appears displaying a successful authentication message. If the window displays a failed authentication message, go to [Step 4](#).

Step 7 Click **Close** on the browser **File** menu.

Step 8 From the original authentication proxy login page, click **Reload (Refresh** for Internet Explorer) on the browser toolbar.

The authentication proxy completes the authenticated connection with the web server.

Monitoring and Maintaining the Authentication Proxy

This section describes how to view dynamic access list entries and how to manually remove authentication entries. This section contains the following sections:

- [Displaying Dynamic ACL Entries](#)
- [Deleting Authentication Proxy Cache Entries](#)

Displaying Dynamic ACL Entries

You can display dynamic access list entries when they are in use. After an authentication proxy entry is cleared by you or by the idle timeout parameter, you can no longer display it. The number of matches displayed indicates the number of times the access list entry was hit.

To view dynamic access lists and any temporary access list entries that are currently established by the authentication proxy, use the **show ip access-lists** command in privileged EXEC mode:

Command	Purpose
router# show ip access-lists	Displays the standard and extended access lists configured on the firewall, including dynamic ACL entries.

Consider the following example where ACL 105 is applied inbound at the input interface where you configure authentication proxy. The initial display shows the contents of the ACLs prior to authentication. The second display shows the same displays after user authentication with the AAA server.

Note

If NAT is configured, the **show ip access list** command might display the translated host IP address for the dynamic ACL entry or the IP address of the host initiating the connection. If the ACL is applied on the NAT outside interface, the translated address is displayed. If the ACL is applied on the NAT inside interface, the IP address of the host initiating the connection is displayed. The **show ip auth-proxy cache** command always displays the IP address of the host initiating the connection.

For example, the following is a list of ACL entries prior to the authentication proxy:

```
Router# show ip access-lists
.
.
.
Extended IP access list 105
deny tcp any any eq telnet
deny udp any any
permit tcp any any (28 matches)
permit ip any any
```

The following sample output shows a list of ACL entries following user authentication:

```
Router# show ip access-lists
.
.
.
Extended IP access list 105
! The ACL entries following user authentication are shown below.
permit tcp host 192.168.25.215 any eq 26
permit icmp host 192.168.25.215 host 60.0.0.2
permit tcp host 192.168.25.215 any eq telnet
permit tcp host 192.168.25.215 any eq ftp
permit tcp host 192.168.25.215 any eq ftp-data
permit tcp host 192.168.25.215 any eq smtp
deny tcp any any eq telnet
deny udp any any
permit tcp any any (76 matches)
permit ip any any
```

Deleting Authentication Proxy Cache Entries

When the authentication proxy is in use, dynamic access lists dynamically grow and shrink as authentication entries are added and deleted. To display the list of authentication entries, use the **show ip auth-proxy cache** command. To manually delete an authentication entry, use the **clear ip auth-proxy cache** command in privileged EXEC mode:

Command	Purpose
router# clear ip auth-proxy cache {* host ip address}	Deletes authentication proxy entries from the firewall before they time out. Use an asterisk to delete all authentication cache entries. Enter a specific IP address to delete an entry for a single host.

Authentication Proxy Configuration Examples

Configuring the authentication proxy feature requires configuration changes on both the router and the AAA server. The following sections provide authentication proxy configuration examples:

- [Authentication Proxy Configuration Example](#)
- [Authentication Proxy, IPSec, and CBAC Configuration Example](#)
- [Authentication Proxy, IPSec, NAT, and CBAC Configuration Example](#)
- [AAA Server User Profile Example](#)

Throughout these examples, the exclamation point (!) indicates a comment line. Comment lines precede the configuration entries being described.

Authentication Proxy Configuration Example

The following examples highlight the specific authentication proxy configuration entries. These examples do not represent a complete router configuration. Complete router configurations using the authentication proxy are included later in this chapter.

This section contains the following examples:

- [AAA Configuration Example](#)
- [HTTP Server Configuration Example](#)
- [Authentication Proxy Configuration Example](#)
- [Interface Configuration Example](#)

AAA Configuration Example

```
aaa new-model
aaa authentication login default group tacacs group radius
! Set up the aaa new model to use the authentication proxy.
aaa authorization auth-proxy default group tacacs group radius
! Define the AAA servers used by the router.
aaa accounting auth-proxy default start-stop group tacacs+
! Set up authentication proxy with accounting.
tacacs-server host 172.31.54.143
tacacs-server key cisco
radius-server host 172.31.54.143
radius-server key cisco
```

HTTP Server Configuration Example

```
! Enable the HTTP server on the router.
ip http server
! Set the HTTP server authentication method to AAA.
ip http authentication aaa
! Define standard access list 61 to deny any host.
access-list 61 deny any
! Use ACL 61 to deny connections from any host to the HTTP server.
ip http access-class 61
```

Authentication Proxy Configuration Example

```
! Set the global authentication proxy timeout value.
ip auth-proxy auth-cache-time 60
! Apply a name to the authentication proxy configuration rule.
ip auth-proxy name HQ_users http
```

Interface Configuration Example

```
! Apply the authentication proxy rule at an interface.
interface e0
 ip address 10.1.1.210 255.255.255.0
 ip auth-proxy HQ_users
```

Authentication Proxy, IPSec, and CBAC Configuration Example

The following example shows a router configuration with the authentication proxy, IPSec, and CBAC features. [Figure 47](#) illustrates the configuration.

**Note**

If you are using this feature with Cisco IOS software release 12.3(8)T or later, see the document [Crypto Access Check on Clear-Text Packets](#) (feature module, release 12.3(8)T).

Figure 47 Authentication Proxy, IPSec, and CBAC Configuration Example

In this example, Host A initiates an HTTP connection with the web server (WWW). The HTTP traffic between Router 1 and Router 2 is encrypted using IPSec. The authentication proxy, IPSec, and CBAC are configured at interface Serial0 on Router 2, which is acting as the firewall. ACL 105 blocks all traffic at interface Serial0. ACL 102 is applied at interface Ethernet0 on Router 2 to block all traffic on that interface except traffic from the AAA server.

When Host A initiates an HTTP connection with the web server, the authentication proxy prompts the user at Host A for a username and password. These credentials are verified with the AAA server for authentication and authorization. If authentication is successful, the per-user ACLs are downloaded to the firewall to permit services.

The following examples provide both the Router 1 and Router 2 configurations for completeness:

- [Router 1 Configuration Example](#)
- [Router 2 Configuration Example](#)

Router 1 Configuration Example

Authentication Proxy, IPSec, NAT, and CBAC Configuration Example

The following example provides a router configuration with the authentication proxy, IPSec, NAT, and CBAC features. [Figure 48](#) illustrates the configuration.

Figure 48 Authentication Proxy, IPSec, and CBAC Configuration Example

In this example, Host A initiates an HTTP connection with the web server (WWW). The HTTP traffic between router 1 (interface BRI0) and router 2 (interface Serial2) is encrypted using IPSec. The authentication proxy is configured on router 2, which is acting as the firewall. The authentication proxy, NAT, and CBAC are configured at interface Serial2, which is acting as the firewall. ACL 105 blocks all traffic at interface Serial2. ACL 102 is applied at interface Ethernet0 on router 2 to block all traffic on that interface except traffic from the AAA server. In this example, the authentication proxy uses standard ACL 10 to specify the hosts using the authentication proxy feature.

When any host in ACL 10 initiates an HTTP connection with the web server, the authentication proxy prompts the user at that host for a username and password. These credentials are verified with AAA server for authentication and authorization. If authentication is successful, the per-user ACLs are downloaded to the firewall to permit services.

The following examples provide both the router 1 and router 2 configurations for completeness:

- [Router 1 Configuration Example](#)

- [Router 2 Configuration Example](#)

AAA Server User Profile Example

This section includes examples of the authentication proxy user profile entries on the AAA servers. The “proxyacl” entries define the user access privileges. After the user has successfully used the authentication proxy to log in, these entries are transferred to the firewall router. Each entry in the profile must specify “permit” access for the service or application. The source address in each entry is set to “any”, which is replaced with the IP address of the authenticating host when the profile is downloaded to the firewall. The privilege level must be set to 15 for all AAA users.

This section contains the following sections:

- [CiscoSecure ACS 2.3 for Windows NT](#)
- [CiscoSecure ACS 2.3 for UNIX](#)
- [TACACS+ Server](#)
- [Livingston Radius Server](#)
- [Ascend Radius Server](#)

CiscoSecure ACS 2.3 for Windows NT

This section describes how to configure authentication proxy on CiscoSecure ACS 2.3 for Windows NT. For detailed information about CiscoSecure ACS, refer to the documentation for that product.

The following sample configuration is for the TACACS+ service of CiscoSecure ACS for Windows NT.

-
- Step 1** Click the Interface Configuration icon and click **TACACS+ (Cisco)**.
- Scroll down to New Services.
 - Add a new service, “auth-proxy”, in the Service field. Leave the Protocol field empty.
 - Select both the User and Group check boxes for the new service.
 - Scroll down to Advance Configuration Options and check the Per-user Advance TACACS+ features.
 - Click **Submit**.
- Step 2** Click the Network Configuration icon.
- Click the Add Entry icon for Network Access Servers and fill in the Network Access Server Hostname, IP address, and key (the key configured on the router) fields.
 - Select TACACS+ (Cisco) for the Authenticate Using option.
 - Click the Submit + Restart icon.
- Step 3** Click the Group Setup icon.
- Select a user group from the drop-down menu.
 - Select the Users in Group check box.
 - Select a user from the user list.
 - In the User Setup list, scroll down to TACACS+ Settings and select the “auth-proxy” check box.
 - Select the Custom Attributes check box.
 - Add the profile entries (do not use single or double quotes around the entries) and set the privilege level to 15.

```
priv-lvl=15  
proxyacl#1=permit tcp any any eq 26
```

```

proxyacl#2=permit icmp any host 60.0.0.2
proxyacl#3=permit tcp any any eq ftp
proxyacl#4=permit tcp any any eq ftp-data
proxyacl#5=permit tcp any any eq smtp
proxyacl#6=permit tcp any any eq telnet

```

g. Click **Submit**.

Step 4 Click the User Setup icon.

- a. Click **List All Users**.
- b. Add a username.
- c. Scroll down to User Setup Password Authentication.
- d. Select SDI SecurID Token Card from the Password Authentication drop-down menu.
- e. Select the previous configured user group 1.
- f. Click **Submit**.

Step 5 Click Group Setup icon again.

- a. Select the user group 1.
- b. Click **Users in Group**.
- c. Click **Edit Settings**.
- d. Click the Submit + Restart icon to make sure the latest configuration is updated and sent to the AAA server.

CiscoSecure ACS 2.3 for UNIX

This section describes how to configure authentication proxy on CiscoSecure ACS 2.3 for UNIX. For detailed information regarding CiscoSecure ACS, refer to the documentation for that product.

To manage the CiscoSecure ACS using the Administrator program, you need a web browser that supports Java and JavaScript. You must enable Java in the browser application. You can start the Java-based CiscoSecure Administrator advanced configuration program from any of the CiscoSecure ACS Administrator web pages.

The following sample configuration procedure is for the TACACS+ service of CiscoSecure ACS 2.3 for UNIX.

Step 1 On the CiscoSecure ACS web menu bar of the CiscoSecure ACS web interface, click **Advanced** and then click **Advanced** again.

The Java-based CiscoSecure Administrator advanced configuration program appears. It might require a few minutes to load.

Step 2 In the CiscoSecure Administrator advanced configuration program, locate and deselect Browse in the Navigator pane of the tabbed Members page.

This displays the Create New Profile icon.

Step 3 In the Navigator pane, do one of the following:

- Locate and click the group to which the user will belong.
- If you do not want the user to belong to a group, click the [Root] folder icon.

- Step 4** Click **Create Profile** to display the New Profile dialog box.
- Step 5** Make sure the Group check box is cleared.
- Step 6** Enter the name of the user you want to create and click **OK**. The new user appears in the tree.
- Step 7** Click the icon for the group or user profile in the tree that is displayed in the Navigator pane of the tabbed Members page.
- Step 8** If necessary, in the Profile pane, click the Profile icon to expand it.
A list or dialog box that contains attributes applicable to the selected profile or service appears in the window at the bottom right of the screen. The information in this window changes depending on what you have selected in the Profile pane.
- Step 9** Click **Service-String**.
- Step 10** Click **string**, enter **auth-proxy** in the text field, and click **Apply**.
- Step 11** Select the **Option** menu.
- Step 12** On the **Option** menu, click **Default Attributes**.
- Step 13** Change the attribute from Deny to **Permit**.
- Step 14** Click **Apply**.
- Step 15** On the **Option** menu, click **Attribute** and enter the privilege level in the text field:
`priv-lvl=15`
- Step 16** On the **Option** menu, click **Attribute** and enter the **proxyacl** entries in the text field:
`proxyacl#1="permit tcp any any eq 26"`

Repeat this step for each additional service or protocol to add:
`proxyacl#2="permit icmp any host 60.0.0.2"`
`proxyacl#3="permit tcp any any eq ftp"`
`proxyacl#4="permit tcp any any eq ftp-data"`
`proxyacl#5="permit tcp any any eq smtp"`
`proxyacl#6="permit tcp any any eq telnet"`
- Step 17** When you have finished making all your changes, click **Submit**.

TACACS+ Server

```
default authorization = permit
key = cisco
user = Brian {
  login = cleartext cisco
  service = auth-proxy
  {
    priv-lvl=15
    proxyacl#1="permit tcp any any eq 26"
    proxyacl#2="permit icmp any host 60.0.0.2"
    proxyacl#3="permit tcp any any eq ftp"
    proxyacl#4="permit tcp any any eq ftp-data"
    proxyacl#5="permit tcp any any eq smtp"
    proxyacl#6="permit tcp any any eq telnet"
  }
}
```

Livingston Radius Server

```

Configuring Port to Application Mapping

This chapter describes the Cisco IOS Firewall Port to Application Mapping (PAM) feature. PAM enables CBAC-supported applications to be run on nonstandard ports. Using PAM, network administrators can customize access control for specific applications and services to meet the distinct needs of their networks.

For a complete description of the PAM commands in this chapter, refer to the chapter “Port to Application Mapping Commands” of the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the “Identifying Supported Platforms” section in the chapter “Using Cisco IOS Software.”

In This Chapter

This chapter contains the following sections:

- [About Port to Application Mapping](#)
- [PAM Configuration Task List](#)
- [Monitoring and Maintaining PAM](#)
- [PAM Configuration Examples](#)

About Port to Application Mapping

Port to Application Mapping (PAM) is a feature of the Cisco IOS Firewall feature set. PAM allows you to customize TCP or UDP port numbers for network services or applications. PAM uses this information to support network environments that run services using ports that are different from the registered or well-known ports associated with an application.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

Using the port information, PAM establishes a table of default port-to-application mapping information at the firewall. The information in the PAM table enables Context-based Access Control (CBAC) supported services to run on nonstandard ports. Previously, CBAC was limited to inspecting traffic using only the well-known or registered ports associated with an application. Now, PAM allows network administrators to customize network access control for specific applications and services.

PAM also supports host or subnet specific port mapping, which allows you to apply PAM to a single host or subnet using standard access control lists (ACLs). Host or subnet specific port mapping is done using standard ACLs.

This section contains the following sections:

- [How PAM Works](#)
- [System-Defined Port Mapping](#)
- [PAM and CBAC](#)
- [When to Use PAM](#)

How PAM Works

PAM generates a table of information that identifies specific applications with specific TCP or UDP port information. When the firewall router first starts up, the PAM table is populated with system-defined mapping information. As you customize the mapping information, the PAM table is modified with the new information. The information in the PAM table serves as the default port mapping for traffic passing through the firewall.

PAM works with CBAC to identify the applications associated with various port numbers, including services running on non-standard ports, as it inspect traffic passing through the firewall. Previously, CBAC was limited to inspecting traffic using only the well-known or registered ports associated with an application.

Entries in the PAM table provide three types of mapping information:

- [System-Defined Port Mapping](#)
- [User-Defined Port Mapping](#)
- [Host-Specific Port Mapping](#)

System-Defined Port Mapping

PAM creates a table, or database, of system-defined mapping entries using the well-known or registered port mapping information set up during the system start-up. The system-defined entries comprise all the services supported by CBAC, which requires the system-defined mapping information to function properly. The system-defined mapping information cannot be deleted or changed; that is, you cannot map HTTP services to port 21 (FTP) or FTP services to port 80 (HTTP).

Note

You can override the system-defined entries for specific hosts using the PAM host-specific option. Refer to the section [“Host-Specific Port Mapping”](#) in this chapter.

[Table 42](#) lists the default system-defined services and applications in the PAM table.

Table 42 **System-Defined Port Mapping**

Application Name	Well-Known or Registered Port Number	Protocol Description
cuseeme	7648	CU-SeeMe Protocol
exec	512	Remote Process Execution
ftp	21	File Transfer Protocol (control port)
http	80	Hypertext Transfer Protocol
h323	1720	H.323 Protocol (for example, MS NetMeeting, Intel Video Phone)
login	513	Remote login
mgcp	2427	Media Gateway Control Protocol
msrpc	135	Microsoft Remote Procedure Call
netshow	1755	Microsoft NetShow
real-audio-video	7070	RealAudio and RealVideo
rtsp	8559	Real Time Streaming Protocol
shell	514	Remote command
sip	5060	Session Initiation Protocol
smtp	25	Simple Mail Transfer Protocol
sqlnet	1521	SQL-NET
streamworks	1558	StreamWorks Protocol
sunrpc	111	SUN Remote Procedure Call
telnet	23	Telnet
tftp	69	Trivial File Transfer Protocol
vdolive	7000	VDOLive Protocol

This section has the following sections:

- [User-Defined Port Mapping](#)
- [Host-Specific Port Mapping](#)

User-Defined Port Mapping

Network services or applications that use non-standard ports require user-defined entries in the PAM table. For example, your network might run HTTP services on the non-standard port 8000 instead of on the system-defined default port (port 80). In this case, you can use PAM to map port 8000 with HTTP services. If HTTP services run on other ports, use PAM to create additional port mapping entries. After you define a port mapping, you can overwrite that entry at a later time by simply mapping that specific port with a different application.

Note

If you try to map an application to a system-defined port, a message appears that warns you of a mapping conflict.

User-defined port mapping information can also specify a range of ports for an application by establishing a separate entry in the PAM table for each port number in the range.

User-defined entries are saved with the default mapping information when you save the router configuration.

Host-Specific Port Mapping

User-defined entries in the mapping table can include host-specific mapping information, which establishes port mapping information for specific hosts or subnets. In some environments, it might be necessary to override the default port mapping information for a specific host or subnet.

With host-specific port mapping, you can use the same port number for different services on different hosts. This means that you can map port 8000 with HTTP services for one host, while mapping port 8000 with Telnet services for another host.

Host-specific port mapping also allows you to apply PAM to a specific subnet when that subnet runs a service that uses a port number that is different from the port number defined in the default mapping information. For example, hosts on subnet 192.168.21.0 might run HTTP services on non-standard port 8000, while other traffic through the firewall uses the default port for HTTP services, which is port 80.

Host-specific port mapping allows you to override a system-defined entry in the PAM table. For example, if CBAC finds an entry in the PAM table that maps port 25 (the system-defined port for SMTP) with HTTP for a specific host, CBAC identifies port 25 as HTTP protocol traffic on that host.

Note

If the host-specific port mapping information is the same as an existing system-defined or user-defined default entries, host-specific port changes have no effect.

PAM and CBAC

CBAC uses the information in the PAM table to identify a service or application from traffic flowing through the firewall. With PAM, CBAC can associate non-standard port numbers with specific protocols. For example, if you use PAM to map port 8000 with HTTP services, CBAC can determine that traffic using port 8000 is an HTTP application.

When to Use PAM

Here are a few examples of when you might want to use PAM:

- Use PAM to apply a non-standard port numbers for a service or application.
- Use PAM when a specific host or subnet uses a port number for an application that is different than the default port number established in the PAM table.
- Use PAM when different hosts use the same port number for different applications.

PAM Configuration Task List

See the following sections for PAM configuration tasks. Each task in the list indicates if it is optional or required:

- [Configuring Standard ACLs](#) (Optional)
- [Configuring PAM](#) (Required)
- [Verifying PAM](#) (Optional)

Configuring Standard ACLs

If you require PAM for a specific host or subnet, use the **access-list** (standard) command in global configuration mode to define an ACL:

Command	Purpose
Router(config)# access-list <i>access-list-number</i> permit <i>source</i> [<i>source-wildcard</i>]	(Optional) Creates a standard ACL that defines the specific host or subnet for host-specific PAM. For complete information on access-list command, refer to the <i>Cisco IOS IP Command Reference, Volume 1 of 3: Addressing and Services</i> .

Configuring PAM

To configure PAM, use the **ip port-map** command in global configuration mode:

Command	Purpose
Router(config)# ip port-map <i>appl_name</i> port <i>port_num</i> [list <i>acl_num</i>]	Establishes a port mapping entry using the TCP or UDP port number and the application name. (Optional) Use the list option to associate this port mapping to the specific hosts in the ACL. (PAM uses standard access lists only.) If an access list is included, the hosts defined in that ACL have the application <i>appl_name</i> running on port <i>port_num</i> .

Verifying PAM

To verify the port mapping information, enter the **show ip port-map** command in privileged EXEC mode and review the entries:

```
Router# show ip port-map
```

This command displays all entries in the PAM table, including the system-defined entries.

For PAM configuration examples using the commands in this chapter, refer to the “[PAM Configuration Examples](#)” section at the end of this chapter.

Monitoring and Maintaining PAM

The following commands can be used to monitor and maintain PAM:

Command	Purpose
Router# show ip port-map [<i>appl_name</i> port <i>port_num</i>]	Displays the port mapping information, including the system-defined entries. Include the application name to display a list of entries by application. Include the port number to display the entries by port.
Router(config)# no ip port-map <i>appl_name</i> port <i>port_num</i> [list <i>acl_num</i>]	Deletes user-defined port mapping information. This command has no effect on the system-defined port mapping information.

PAM Configuration Examples

The following sections provide PAM configuration examples:

- [Mapping an Application to a Non-Standard Port Example](#)
- [Mapping an Application with a Port Range Example](#)
- [Invalid Port Mapping Entry Example](#)
- [Mapping an Application to a Port for a Specific Host Example](#)
- [Mapping an Application to a Port for a Subnet Example](#)
- [Overriding a System-Defined Port Mapping Example](#)
- [Mapping Different Applications to the Same Port Example](#)

Mapping an Application to a Non-Standard Port Example

In this example, non-standard port 8000 is established as the user-defined default port mapping for HTTP services:

```
ip port-map http port 8000
```

Mapping an Application with a Port Range Example

The following PAM entries establish a range of non-standard ports for HTTP services:

```
ip port-map http 8001
ip port-map http 8002
ip port-map http 8003
ip port-map http 8004
```

Invalid Port Mapping Entry Example

This example is not valid because it tries to establish port 21, which is the system-defined default port for FTP, as the user-defined port for HTTP services:

```
ip port-map http port 21
```

Mapping an Application to a Port for a Specific Host Example

In this example, a specific host uses port 8000 for FTP services. ACL 10 identifies the server address (192.168.32.43), while port 8000 is mapped with FTP services.

```
access-list 10 permit 192.168.32.43
ip port-map ftp port 8000 list 10
```

Mapping an Application to a Port for a Subnet Example

In this example, a specific subnet runs HTTP services on port 8080. ACL 50 identifies the subnet, while port 8080 is mapped with HTTP services.

```
access-list 50 permit 192.168.92.0 0.0.0.255
ip port-map http 8080 list 50
```

Overriding a System-Defined Port Mapping Example

In this example, a specific host runs HTTP services on port 25, which is the system-defined port number for SMTP services. This requires a host-specific PAM entry that overrides the system-defined default port mapping for HTTP, which is port 80. ACL 15 identifies the host address (192.168.33.33), while port 25 is mapped with HTTP services.

```
access-list 15 permit 192.168.33.33
ip port-map http port 25 list 15
```

Mapping Different Applications to the Same Port Example

In this example, the same port number is required by different services running on different hosts. Port 8000 is required for HTTP services for host 192.168.3.4, while port 8000 is also required for FTP services for host 192.168.5.6. ACL 10 and ACL 20 identify the specific hosts, while the PAM entries map the ports with the services for each ACL.

```
access-list 10 permit 192.168.3.4
access-list 20 permit 192.168.5.6
ip port-map http port 8000 list 10
ip port-map http ftp 8000 list 20
```

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and

coincidental.

IPSec and IKE

Internet Key Exchange for IPSec VPNs

Configuring Internet Key Exchange for IPSec VPNs

This module describes how to configure the Internet Key Exchange (IKE) protocol for basic IP Security (IPSec) virtual private networks (VPNs). IKE is a key management protocol standard that is used in conjunction with the IPSec standard. IPSec is an IP security feature that provides robust authentication and encryption of IP packets.

IPSec can be configured without IKE, but IKE enhances IPSec by providing additional features, flexibility, and ease of configuration for the IPSec standard.

IKE is a hybrid protocol, which implements the Oakley key exchange and Skeme key exchange inside the Internet Security Association Key Management Protocol (ISAKMP) framework. (ISAKMP, Oakley, and Skeme are security protocols implemented by IKE.)

Module History

This module was first published on May 2, 2005, and last updated on May 2, 2005.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all features. To find information about feature support and configuration, use the [“Feature Information for Configuring IKE for IPSec VPNs”](#) section on page 24.

Prerequisites for IKE Configuration

- You should be familiar with the concepts and tasks explained in the module “Configuring Security for VPNs with IPSec.”
- Ensure that your access control lists (ACLs) are compatible with IKE. Because IKE negotiation uses User Datagram Protocol (UDP) on port 500, your ACLs must be configured so that UDP port 500 traffic is not blocked at interfaces used by IKE and IPSec. In some cases you might need to add a statement to your ACLs to explicitly permit UDP port 500 traffic.

Restrictions for IKE Configuration

The following restrictions are applicable when configuring IKE negotiation:

- The initiating router *must not* have a certificate associated with the remote peer.
- The preshared key *must* be by fully qualified domain name (FQDN) on both peers. (To configure the preshared key, enter the **crypto isakmp key** command.)
- The communicating routers *must* have a FQDN host entry for each other in their configurations.
- The communicating routers *must* be configured to authenticate by hostname, *not* by IP address; thus, you should use the **crypto isakmp identity hostname** command.

Information About Configuring IKE for IPSec VPNs

To configure IKE for IPSec VPNs, you should understand the following concepts:

- [Supported Standards for Use with IKE, page 2](#)
- [IKE Benefits, page 4](#)
- [IKE Main Mode and Aggressive Mode, page 4](#)

Supported Standards for Use with IKE

Cisco implements the following standards:

- IPSec—IP Security Protocol. IPSec is a framework of open standards that provides data confidentiality, data integrity, and data authentication between participating peers. IPSec provides these security services at the IP layer; it uses IKE to handle negotiation of protocols and algorithms based on local policy and to generate the encryption and authentication keys to be used by IPSec. IPSec can be used to protect one or more data flows between a pair of hosts, between a pair of security gateways, or between a security gateway and a host.
- ISAKMP—Internet Security Association and Key Management Protocol. A protocol framework that defines payload formats, the mechanics of implementing a key exchange protocol, and the negotiation of a security association.
- Oakley—A key exchange protocol that defines how to derive authenticated keying material.
- Skeme—A key exchange protocol that defines how to derive authenticated keying material, with rapid key refreshment.

The component technologies implemented for use by IKE include the following:

- **AES**—Advanced Encryption Standard. A cryptographic algorithm that protects sensitive, unclassified information. AES is privacy transform for IPSec and IKE and has been developed to replace the DES. AES is designed to be more secure than DES: AES offers a larger key size, while ensuring that the only known approach to decrypt a message is for an intruder to try every possible key. AES has a variable key length—the algorithm can specify a 128-bit key (the default), a 192-bit key, or a 256-bit key.
- **DES**—Data Encryption Standard. An algorithm that is used to encrypt packet data. IKE implements the 56-bit DES-CBC with Explicit IV standard. Cipher Block Chaining (CBC) requires an initialization vector (IV) to start encryption. The IV is explicitly given in the IPSec packet.

Cisco IOS software also implements Triple DES (168-bit) encryption, depending on the software versions available for a specific platform. Triple DES (3DES) is a strong form of encryption that allows sensitive information to be transmitted over untrusted networks. It enables customers, particularly in the finance industry, to utilize network-layer encryption.

**Note**

Cisco IOS images that have strong encryption (including, but not limited to, 56-bit data encryption feature sets) are subject to United States government export controls, and have a limited distribution. Images that are to be installed outside the United States require an export license. Customer orders might be denied or subject to delay because of United States government regulations. Contact your sales representative or distributor for more information, or send e-mail to export@cisco.com.

- **SEAL**—Software Encryption Algorithm. An alternative algorithm to software-based DES, 3DES, and AES. SEAL encryption uses a 160-bit encryption key and has a lower impact to the CPU when compared to other software-based algorithms.
- **Diffie-Hellman**—A public-key cryptography protocol that allows two parties to establish a shared secret over an unsecure communications channel. Diffie-Hellman is used within IKE to establish session keys. 768-bit (the default), 1024-bit, and 1536-bit Diffie-Hellman groups are supported.
- **MD5 (HMAC variant)**—Message Digest 5. A hash algorithm used to authenticate packet data. HMAC is a variant that provides an additional level of hashing.
- **SHA (HMAC variant)**—Secure Hash Algorithm. A hash algorithm used to authenticate packet data. HMAC is a variant that provides an additional level of hashing.
- **RSA signatures and RSA encrypted nonces**—RSA is the public key cryptographic system developed by Ron Rivest, Adi Shamir, and Leonard Adleman. RSA signatures provide nonrepudiation, and RSA encrypted nonces provide repudiation. (Repudiation and nonrepudiation have to do with traceability.)

IKE interoperates with the following standard:

X.509v3 certificates—Used with the IKE protocol when authentication requires public keys. This certificate support allows the protected network to scale by providing the equivalent of a digital ID card to each device. When two devices intend to communicate, they exchange digital certificates to prove their identity (thus removing the need to manually exchange public keys with each peer or to manually specify a shared key at each peer).

IKE Benefits

IKE automatically negotiates IPSec security associations (SAs) and enables IPSec secure communications without costly manual preconfiguration. Specifically, IKE provides the following benefits:

- Eliminates the need to manually specify all the IPSec security parameters in the crypto maps at both peers.
- Allows you to specify a lifetime for the IPSec SA.
- Allows encryption keys to change during IPSec sessions.
- Allows IPSec to provide anti-replay services.
- Permits certification authority (CA) support for a manageable, scalable IPSec implementation.
- Allows dynamic authentication of peers.

IKE Main Mode and Aggressive Mode

IKE has two phases of key negotiation: phase 1 and phase 2. Phase 1 negotiates a security association (a key) between two IKE peers. The key negotiated in phase 1 enables IKE peers to communicate securely in phase 2. During phase 2 negotiation, IKE establishes keys (security associations) for other applications, such as IPSec.

Phase 1 negotiation can occur using main mode or aggressive mode. Main mode tries to protect all information during the negotiation, meaning that no information is available to a potential attacker. When main mode is used, the identities of the two IKE peers are hidden. Although this mode of operation is very secure, it is relatively costly in terms of the time it takes to complete the negotiation. Aggressive mode takes less time to negotiate keys between peers; however, it gives up some of the security provided by main mode negotiation. For example, the identities of the two parties trying to establish a security association are exposed to an eavesdropper.

The two modes serve different purposes and have different strengths. Main mode is slower than aggressive mode, but main mode is more secure and more flexible because it can offer an IKE peer more security proposals than aggressive mode. Aggressive mode is less flexible and not as secure, but much faster.

In Cisco IOS software, the two modes are not configurable. The default action for IKE authentication (rsa-sig, rsa-encr, or preshared) is to initiate main mode; however, in cases where there is no corresponding information to initiate authentication, and there is a preshared key associated with the hostname of the peer, Cisco IOS software can initiate aggressive mode. Cisco IOS software will respond in aggressive mode to an IKE peer that initiates aggressive mode.

How to Configure IKE for IPSec VPNs

If you do not want IKE to be used with your IPSec implementation, you can disable it at all IPSec peers via the **no crypto isakmp** command, skip the rest of this chapter, and begin your IPSec VPN.

Note

If you disable IKE, you will have to manually specify all the IPSec SAs in the crypto maps at all peers, the IPSec SAs of the peers will never time out for a given IPSec session, the encryption keys will never change during IPSec sessions between the peers, anti-replay services will not be available between the peers, and public key infrastructure (PKI) support cannot be used.

IKE is enabled by default. IKE does not have to be enabled for individual interfaces, but it is enabled globally for all interfaces at the router.

Perform the following tasks to provide authentication of IPSec peers, negotiate IPSec SAs, and establish IPSec keys:

- [Creating IKE Policies: Security Parameters for IKE Negotiation, page 5](#) (required)
- [Configuring IKE Authentication, page 9](#) (required)
- [Configuring IKE Mode Configuration, page 17](#)

Creating IKE Policies: Security Parameters for IKE Negotiation

An IKE policy defines a combination of security parameters to be used during the IKE negotiation. You must create an IKE policy at each peer participating in the IKE exchange.

If you do not configure any IKE policies, your router will use the default policy, which is always set to the lowest priority and which contains the default value of each parameter.

About IKE Policies

Because IKE negotiations must be protected, each IKE negotiation begins by agreement of both peers on a common (shared) IKE policy. This policy states which security parameters will be used to protect subsequent IKE negotiations and mandates how the peers are authenticated.

After the two peers agree upon a policy, the security parameters of the policy are identified by an SA established at each peer, and these SAs apply to all subsequent IKE traffic during the negotiation.

You can configure multiple, prioritized policies on each peer—each with a different combination of parameter values. However, at least one of these policies must contain exactly the same encryption, hash, authentication, and Diffie-Hellman parameter values as one of the policies on the remote peer. For each policy that you create, you assign a unique priority (1 through 10,000, with 1 being the highest priority).

Tip

If you are interoperating with a device that supports only one of the values for a parameter, your choice is limited to the value supported by the other device. Aside from this limitation, there is often a trade-off between security and performance, and many of these parameter values represent such a trade-off. You should evaluate the level of security risks for your network and your tolerance for these risks.

IKE Peers Agreeing Upon a Matching IKE Policy

When the IKE negotiation begins, IKE searches for an IKE policy that is the same on both peers. The peer that initiates the negotiation will send all its policies to the remote peer, and the remote peer will try to find a match. The remote peer looks for a match by comparing its own highest priority policy against the policies received from the other peer. The remote peer checks each of its policies in order of its priority (highest priority first) until a match is found.

A match is made when both policies from the two peers contain the same encryption, hash, authentication, and Diffie-Hellman parameter values, and when the remote peer's policy specifies a lifetime that is less than or equal to the lifetime in the policy being compared. (If the lifetimes are not identical, the shorter lifetime—from the remote peer's policy—will be used.)

If a match is found, IKE will complete negotiation, and IPSec security associations will be created. If no acceptable match is found, IKE refuses negotiation and IPSec will not be established.

**Note**

Depending on which authentication method is specified in a policy, additional configuration might be required (as described in the section “[Configuring IKE Authentication](#)”). If a peer’s policy does not have the required companion configuration, the peer will not submit the policy when attempting to find a matching policy with the remote peer.

Restrictions

If you are configuring an AES IKE policy, note the following restrictions:

- Your router must support IPSec and long keys (the “k9” subsystem).
- AES cannot encrypt IPSec and IKE traffic if an acceleration card is present.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp policy** *priority*
4. **encryption** {**des** | **3des** | **aes** | **aes 192** | **aes 256**}
5. **hash** {**sha** | **md5**}
6. **authentication** {**rsa-sig** | **rsa-encr** | **pre-share**}
7. **group** {**1** | **2** | **5**}
8. **lifetime** *seconds*
9. **exit**
10. **exit**
11. **show crypto isakmp policy**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto isakmp policy <i>priority</i> Example: Router(config)# crypto isakmp policy 10	Defines an IKE policy and enters config-isakmp configuration mode. <i>priority</i>—Uniquely identifies the IKE policy and assigns a priority to the policy. Valid values: 1 to 10,000; 1 is the highest priority.
Step 4	encryption {des 3des aes aes 192 aes 256} Example: Router(config-isakmp)# encryption aes 256	Specifies the encryption algorithm. By default, the des keyword is used. des—56-bit DES-CBC 3des—168-bit DES aes—128-bit AES aes 192—192-bit AES aes 256—256-bit AES
Step 5	hash {sha md5} Example: Router(config-isakmp)# hash sha	Specifies the hash algorithm. By default, SHA-1 (sha) is the used. Note MD5 has a smaller digest and is considered to be slightly faster than SHA-1.
Step 6	authentication {rsa-sig rsa-encr pre-share} Example: Router(config-isakmp)# authentication pre-share	Specifies the authentication method. By default, RSA signatures are used. rsa-sig—RSA signatures require that you configure your peer routers to obtain certificates from a CA. rsa-encr—RSA encrypted nonces require that you ensure each peer has the other peer's RSA public keys. pre-share—Preshared keys require that you separately configure these preshared keys.

	Command or Action	Purpose
Step 7	group {1 2 5} Example: Router(config-isakmp)# group 1	Specifies the Diffie-Hellman group identifier. By default, D-H group 1 is used. 1—768-bit Diffie-Hellman 2—1024-bit Diffie-Hellman 5—1536-bit Diffie-Hellman Note The 1024-bit and 1536-bit Diffie-Hellman options are harder to “crack,” but require more CPU time to execute.
Step 8	lifetime <i>seconds</i> Example: Router(config-isakmp)# lifetime 180	Specifies the lifetime of the IKE SA. <i>seconds</i>—Time, in seconds, before each SA expires. Valid values: 60 to 86,400 seconds; default value: 86,400. Note The shorter the lifetime (up to a point), the more secure your IKE negotiations will be. However, with longer lifetimes, future IPsec SAs can be set up more quickly.
Step 9	exit Example: Router(config-isakmp)# exit	Exits config-isakmp configuration mode.
Step 10	exit Example: Router(config)# exit	Exits the global configuration mode.
Step 11	show crypto isakmp policy Example: Router# show crypto isakmp policy	(Optional) Displays all existing IKE policies.
Step 12	—	Repeat these steps for each policy you want to create.

**Note**

These parameters apply to the IKE negotiations after the IKE SA is established.

Examples

The following sample output from the **show crypto isakmp policy** command displays a warning message after a user tries to configure an IKE encryption method that the hardware does not support:

Router# **show crypto isakmp policy**

```
Protection suite of priority 1
  encryption algorithm: AES - Advanced Encryption Standard (256 bit keys).
WARNING:encryption hardware does not support the configured
encryption method for ISAKMP policy 1
  hash algorithm:          Secure Hash Standard
  authentication method: Pre-Shared Key
```

```
Diffie-Hellman group:  #1 (768 bit)
lifetime:              3600 seconds, no volume limit
```

Troubleshooting Tips

- Clear (and reinitialize) IPSec SAs by using the **clear crypto sa** EXEC command.
Using the **clear crypto sa** command without parameters will clear out the full SA database, which will clear out active security sessions. You may also specify the **peer**, **map**, or **entry** keywords to clear out only a subset of the SA database. For more information, see the **clear crypto sa** command in the *Cisco IOS Security Command Reference*, Release 12.4.
- The default policy and default values for configured policies do not show up in the configuration when you issue the **show running-config** command. To see the default policy and any default values within configured policies, use the **show crypto isakmp policy** command.
- Any IPSec transforms or IKE encryption methods that the current hardware does not support should be disabled; they are ignored whenever an attempt to negotiate with the peer is made.

If a user enters an IPSec transform or an IKE encryption method that the hardware does not support, a warning message will be generated. These warning messages are also generated at boot time. When an encrypted card is inserted, the current configuration is scanned. If any IPSec transforms or IKE encryption methods are found that are not supported by the hardware, a warning message will be generated.

What to Do Next

Depending on which authentication method you specified in your IKE policies (RSA signatures, RSA encrypted nonces, or preshared keys), you must do certain additional configuration tasks before IKE and IPSec can successfully use the IKE policies. For information on completing these additional tasks, refer to the following section “[Configuring IKE Authentication](#).”

To configure an AES-based transform set, see the module “Configuring Security for VPNs with IPSec.”

Configuring IKE Authentication

After you have created at least one IKE policy in which you specified an authentication method (or accepted the default method), you need to configure an authentication method. IKE policies cannot be used by IPSec until the authentication method is successfully configured.

To configure IKE authentication, you should perform one of the following tasks, as appropriate:

- [Configuring RSA Keys Manually for RSA Encrypted Nonces, page 11](#)
- [Configuring Preshared Keys, page 13](#)
- Configuring RSA Keys to Obtain Certificates from a CA. For information on completing this task, see the module “Deploying RSA Keys Within a PKI.”

IKE Authentication Methods: Overview

IKE authentication consists of three options—RSA signatures, RSA encrypted nonces, and preshared keys. Each authentication method requires additional configuration as follows:

RSA Signatures

With RSA signatures, you can configure the peers to obtain certificates from a CA. (The CA must be properly configured to issue the certificates.) Using a CA can dramatically improve the manageability and scalability of your IPSec network. Additionally, RSA signature-based authentication uses only two public key operations, whereas RSA encryption uses four public key operations, making it costlier in terms of overall performance. To properly configure CA support, see the chapter “Implementing and Managing a PKI.”

The certificates are used by each peer to exchange public keys securely. (RSA signatures requires that each peer has the public signature key of the remote peer.) When both peers have valid certificates, they will automatically exchange public keys with each other as part of any IKE negotiation in which RSA signatures are used.

You can also exchange the public keys manually, as described in the section “[Configuring RSA Keys Manually for RSA Encrypted Nonces](#).”

RSA signatures provide nonrepudiation for the IKE negotiation. And, you can prove to a third party after the fact that you did indeed have an IKE negotiation with the remote peer.

RSA Encrypted Nonces

With RSA encrypted nonces, you must ensure that each peer has the public keys of the other peers.

Unlike RSA signatures, the RSA encrypted nonces method can not use certificates to exchange public keys. Instead, you ensure that each peer has the others’ public keys by one of the following methods:

- Manually configuring RSA keys as described in the section “[Configuring RSA Keys Manually for RSA Encrypted Nonces](#).”

or

- Ensuring that an IKE exchange using RSA signatures with certificates has already occurred between the peers. (The peers’ public keys are exchanged during the RSA-signatures-based IKE negotiations if certificates are used.)

To make that the IKE exchange happens, specify two policies: a higher-priority policy with RSA encrypted nonces and a lower-priority policy with RSA signatures. When IKE negotiations occur, RSA signatures will be used the first time because the peers do not yet have each other’s public keys. Then future IKE negotiations can use RSA encrypted nonces because the public keys will have been exchanged.

Note This alternative requires that you already have CA support configured.

RSA encrypted nonces provide repudiation for the IKE negotiation; however, unlike RSA signatures, you cannot prove to a third party that you had an IKE negotiation with the remote peer.

Preshared Keys

With preshared keys, you must configure them as described in the section “[Configuring Preshared Keys](#).”

Preshared keys are clumsy to use if your secured network is large, and they do not scale well with a growing network. However, they do not require use of a CA, as do RSA signatures, and might be easier to set up in a small network with fewer than ten nodes. RSA signatures also can be considered more secure when compared with preshared key authentication.

**Note**

If RSA encryption is configured and signature mode is negotiated (and certificates are used for signature mode), the peer will request both signature and encryption keys. Basically, the router will request as many keys as the configuration will support. If RSA encryption is not configured, it will just request a signature key.

Prerequisites

You must have configured at least one IKE policy, which is where the authentication method was specified (or RSA signatures was accepted by default).

Configuring RSA Keys Manually for RSA Encrypted Nonces

To manually configure RSA keys, perform this task for each IPSec peer that uses RSA encrypted nonces in an IKE policy.

**Note**

This task can be performed only if a CA is not in use.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto key generate rsa** {general-keys | usage-keys} [label *key-label*] [exportable] [modulus *modulus-size*]
4. **exit**
5. **show crypto key mypubkey rsa**
6. **configure terminal**
7. **crypto key pubkey-chain rsa**
8. **named-key** *key-name* [encryption | signature]
- or
- addressed-key** *key-address* [encryption | signature]
9. **address** *ip-address*
10. **key-string** *key-string*
11. **quit**
12. Repeat these steps at each peer that uses RSA encrypted nonces in an IKE policy.
13. **exit**
14. **exit**
15. **show crypto key pubkey-chain rsa** [name *key-name* | address *key-address*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto key generate rsa {general-keys usage-keys} [label key-label] [exportable] [modulus modulus-size] Example: Router(config)# crypto key generate rsa general-keys modulus 360	Generates RSA keys. If a <i>key-label</i> argument is not specified, the default value, which is the fully qualified domain name (FQDN) of the router, is used.
Step 4	exit Example: Router(config)# exit	(Optional) Exits global configuration mode.
Step 5	show crypto key mypubkey rsa Example: Router# show crypto key mypubkey rsa	(Optional) Displays the generated RSA public keys.
Step 6	configure terminal Example: Router# configure terminal	Returns to global configuration mode.
Step 7	crypto key pubkey-chain rsa Example: Router(config)# crypto key pubkey-chain rsa	Enters public key configuration mode (so you can manually specify the RSA public keys of other devices).
Step 8	named-key key-name [encryption signature] Example: Router(config-pubkey-chain)# named-key otherpeer.example.com or addressed-key key-address [encryption signature] Example: Router(config-pubkey-chain)# addressed-key 10.1.1.2 encryption	Indicates which remote peer's RSA public key you are going to specify and enters public key configuration mode. If the remote peer uses its host name as its ISAKMP identity, use the named-key command and specify the remote peer's FQDN, such as somerouter.example.com, as the <i>key-name</i> . If the remote peer uses its IP address as its ISAKMP identity, use the addressed-key command and specify the remote peer's IP address as the <i>key-address</i> .

	Command or Action	Purpose
Step 9	address <i>ip-address</i> Example: Router(config-pubkey-key)# address 10.5.5.1	Specifies the IP address of the remote peer. If you use the named-key command, you need to use this command to specify the IP address of the peer.
Step 10	key-string <i>key-string</i> Example: Router(config-pubkey-key)# key-string Router(config-pubkey)# 00302017 4A7D385B 1234EF29 335FC973 Router(config-pubkey)# 2DD50A37 C4F4B0FD 9DADE748 429618D5 Router(config-pubkey)# 18242BA3 2EDFBDD3 4296142A DDF7D3D8 Router(config-pubkey)# 08407685 2F2190A0 0B43F1BD 9A8A26DB Router(config-pubkey)# 07953829 791FCDE9 A98420F0 6A82045B Router(config-pubkey)# 90288A26 DBC64468 7789F76E EE21	Specifies the RSA public key of the remote peer. (This key was previously viewed by the administrator of the remote peer when the RSA keys of the remote router were generated.)
Step 11	quit Example: Router(config-pubkey-k)# quit	Returns to public key chain configuration mode.
Step 12	—	Repeat these steps at each peer that uses RSA encrypted nonces in an IKE policy.
Step 13	exit Example: Router(config-pubkey-c)# exit	Returns to global configuration mode.
Step 14	exit Example: Router(config)# exit	Returns to EXEC mode.
Step 15	show crypto key pubkey-chain rsa [<i>name key-name</i> <i>address key-address</i>] Example: Router# show crypto key pubkey-chain rsa	(Optional) Displays either a list of all RSA public keys that are stored on your router or details of a particular RSA key that is stored on your router.

Configuring Preshared Keys

To configure preshared keys, perform these steps at each peer that uses preshared keys in an IKE policy.

Setting ISAKMP Identity for Preshared Keys

You should set the ISAKMP identity for each peer that uses preshared keys in an IKE policy.

When two peers use IKE to establish IPSec SAs, each peer sends its identity to the remote peer. Each peer sends either its host name or its IP address, depending on how you have set the ISAKMP identity of the router.

By default, a peer's ISAKMP identity is the IP address of the peer. If appropriate, you could change the identity to be the peer's host name instead. As a general rule, set the identities of all peers the same way—either all peers should use their IP addresses or all peers should use their hostnames. If some peers use their host names and some peers use their IP addresses to identify themselves to each other, IKE negotiations could fail if the identity of a remote peer is not recognized and a DNS lookup is unable to resolve the identity.

Mask Preshared Keys

A mask preshared key allows a group of remote users with the same level of authentication to share an IKE preshared key. The preshared key of the remote peer must match the preshared key of the local peer for IKE authentication to occur.

A mask preshared key is usually distributed through a secure out-of-band channel. In a remote peer-to-local peer scenario, any remote peer with the IKE preshared key configured can establish IKE SAs with the local peer.

If you specify the **mask** keyword with the **crypto isakmp key** command, it is up to you to use a subnet address, which will allow more peers to share the same key. That is, the preshared key is no longer restricted to use between two users.

Note

Using 0.0.0.0 as a subnet address is not recommended because it encourages group preshared keys, which allow all peers to have the same group key, thereby reducing the security of your user authentication.

Disable Xauth on a Specific IPSec Peer

Disabling Extended Authentication (Xauth) for static IPSec peers prevents the routers from being prompted for Xauth information—username and password.

Without the ability to disable Xauth, a user cannot select which peer on the same crypto map should use Xauth. That is, if a user has router-to-router IPSec on the same crypto map as a VPN-client-to-Cisco-IOS IPSec, both peers are prompted for a username and password. In addition, a remote static peer (a Cisco IOS router) cannot establish an IKE SA with the local Cisco IOS router. (Xauth is not an optional exchange, so if a peer does not respond to an Xauth request, the IKE SA is deleted.) Thus, the same interface cannot be used to terminate IPSec to VPN clients (that need Xauth) as well as other Cisco IOS routers (that cannot respond to Xauth) unless this feature is implemented.

Note

Xauth can be disabled only if preshared keys are used as the authentication mechanism for the given crypto map.

Restrictions

- Preshared do not scale well with a growing network.
- Mask preshared keys have the following restrictions:
 - The SA cannot be established between the IPSec peers until all IPSec peers are configured for the same preshared key.

- The mask preshared key must be distinctly different for remote users requiring varying levels of authorization. You must configure a new preshared key for each level of trust and assign the correct keys to the correct parties. Otherwise, an untrusted party may obtain access to protected data.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp identity {address | hostname}**
4. **ip host *hostname* *address1* [*address2*...*address8*]**
5. **crypto isakmp key *keystring* **address** *peer-address* [**mask**] [**no-xauth**]**
or
crypto isakmp key *keystring* **hostname *hostname* [**no-xauth**]**
6. **crypto isakmp key *keystring* **address** *peer-address* [**mask**] [**no-xauth**]**
or
crypto isakmp key *keystring* **hostname *hostname* [**no-xauth**]**
7. Repeat these steps for each peer that uses preshared keys.

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto isakmp identity {address hostname} Example: Router(config)# crypto isakmp identity address	Specifies the peer's ISAKMP identity by IP address or by hostname at the local peer. address—Typically used when there is only one interface (and therefore only one IP address) that will be used by the peer for IKE negotiations, and the IP address is known. hostname—Should be used if there is more than one interface on the peer that might be used for IKE negotiations, or if the interface's IP address is unknown (such as with dynamically assigned IP addresses).
Step 4	ip host hostname address1 [address2...address8] Example: Router(config)# ip host RemoteRouter.example.com 192.168.0.1	If the local peer's ISAKMP identity was specified using a hostname, maps the peer's host name to its IP address(es) at all the remote peers. (This step might be unnecessary if the hostname or address is already mapped in a DNS server.)
Step 5	crypto isakmp key keystring address peer-address [mask] [no-xauth] Example: Router(config)# crypto isakmp key sharedkeystring address 192.168.1.33 no-xauth or crypto isakmp key keystring hostname hostname [no-xauth] Example: Router(config) crypto isakmp key sharedkeystring hostname RemoteRouter.example.com	Specifies at the local peer the shared key to be used with a particular remote peer. If the remote peer specified its ISAKMP identity with an address, use the address keyword in this step; otherwise use the hostname keyword in this step. no-xauth—Prevents the router from prompting the peer for Xauth information. Use this keyword if router-to-router IPSec is on the same crypto map as VPN-client-to-Cisco IOS IPSec. Note According to the design of preshared key authentication in IKE main mode, preshared keys must be based on the IP address of the peers. Although you can send hostname as the identity of preshared key authentication, the key is searched on the IP address of the peer; if the key is not found (based on the IP address) the negotiation will fail.

	Command or Action	Purpose
Step 6	crypto isakmp key <i>keystring</i> address <i>peer-address</i> [<i>mask</i>] [no-xauth] Example: Router(config) crypto isakmp key sharedkeystring address 10.0.0.1 or crypto isakmp key <i>keystring</i> hostname <i>hostname</i> [no-xauth] Example: Router(config) crypto isakmp key sharedkeystring hostname LocalRouter.example.com	Specifies at the remote peer the shared key to be used with the local peer. This is the same key you just specified at the local peer. If the local peer specified its ISAKMP identity with an address, use the address keyword in this step; otherwise use the hostname keyword in this step.
Step 7	—	Repeat these steps at each peer that uses preshared keys in an IKE policy.

Configuring IKE Mode Configuration

Perform the following task to configure IKE mode configuration.

About IKE Mode Configuration

IKE mode configuration, as defined by the Internet Engineering Task Force (IETF) , allows a gateway to download an IP address (and other network level configuration) to the client as part of an IKE negotiation. Using this exchange, the gateway gives IP addresses to the IKE client to be used as an “inner” IP address encapsulated under IPSec. This method provides a known IP address for the client that can be matched against IPSec policy.

To implement IPSec VPNs between remote access clients that have dynamic IP addresses and a corporate gateway, you have to dynamically administer scalable IPSec policy on the gateway once each client is authenticated. With IKE Mode Configuration, the gateway can set up scalable policy for a very large set of clients irrespective of the IP addresses of those clients.

There are two types of IKE Mode Configuration:

- Gateway initiation—Gateway initiates the configuration mode with the client. Once the client responds, the IKE modifies the identity of the sender, the message is processed, and the client receives a response.
- Client initiation—Client initiates the configuration mode with the gateway. The gateway responds with an IP address that it has allocated for the client.

Restrictions

IKE Mode Configuration has the following restrictions:

- Interfaces with crypto maps that are configured for IKE Mode Configuration may experience a slightly longer connection setup time, which is true even for IKE peers that refuse to be configured or do not respond to the configuration mode request. In both cases, the gateway initiates the configuration of the client.
- This feature was not designed to enable the configuration mode for every IKE connection by default. Configure this feature at the global crypto map level.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip local pool** *pool-name start-addr end-addr*
4. **crypto isakmp client configuration address-pool local** *pool-name*
5. **crypto map** *tag* **client configuration address** [**initiate** | **respond**]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip local pool <i>pool-name</i> <i>start-addr</i> <i>end-addr</i> Example: Router(config) ip local pool ire 172.16.23.0 172.16.23.255	Defines an existing local address pool that defines a set of addresses.
Step 4	crypto isakmp client configuration address-pool <i>local pool-name</i> Example: Router(config) crypto isakmp client configuration address-pool local ire	References the local address pool in the IKE configuration.
Step 5	crypto map <i>tag</i> client configuration address [<i>initiate</i> <i>respond</i>] Example: Router(config)# crypto map dyn client configuration address initiate	Configures IKE Mode Configuration in global crypto map configuration mode.

Configuration Examples for an IKE Configuration

This section contains the following configuration examples:

- [Creating IKE Policies: Examples, page 19](#)
- [Configuring IKE Authentication: Example, page 21](#)

Creating IKE Policies: Examples

This section contains the following examples, which show how to configure a 3DES IKE policy and an AES IKE policy:

- [Creating 3DES IKE Policies: Example, page 20](#)
- [Creating an AES IKE Policy: Example, page 20](#)

Creating 3DES IKE Policies: Example

This example creates two IKE policies, with policy 15 as the highest priority, policy 20 as the next priority, and the existing default priority as the lowest priority. It also creates a preshared key to be used with policy 20 with the remote peer whose IP address is 192.168.224.33.

```
crypto isakmp policy 15
  encryption 3des
  hash md5
  authentication rsa-sig
  group 2
  lifetime 5000
!
crypto isakmp policy 20
  authentication pre-share
  lifetime 10000
!
crypto isakmp key 1234567890 address 192.168.224.33
```

In the example, the encryption des of policy 15 would not appear in the written configuration because this is the default value for the encryption algorithm parameter.

If the **show crypto isakmp policy** command is issued with this configuration, the output is as follows:

```
Protection suite priority 15
encryption algorithm:3DES - Triple Data Encryption Standard (168 bit keys)
hash algorithm:Message Digest 5
authentication method:Rivest-Shamir-Adleman Signature
Diffie-Hellman group:#2 (1024 bit)
lifetime:5000 seconds, no volume limit
Protection suite priority 20
encryption algorithm:DES - Data Encryption Standard (56 bit keys)
hash algorithm:Secure Hash Standard
authentication method:preshared Key
Diffie-Hellman group:#1 (768 bit)
lifetime:10000 seconds, no volume limit
Default protection suite
encryption algorithm:DES - Data Encryption Standard (56 bit keys)
hash algorithm:Secure Hash Standard
authentication method:Rivest-Shamir-Adleman Signature
Diffie-Hellman group:#1 (768 bit)
lifetime:86400 seconds, no volume limit
```

Note that although the output shows “no volume limit” for the lifetimes, you can configure only a time lifetime (such as 86,400 seconds); volume-limit lifetimes are not configurable.

Creating an AES IKE Policy: Example

The following example is sample output from the **show running-config** command. In this example, the AES 256-bit key is enabled.

```
Current configuration : 1665 bytes
!
version 12.2
service timestamps debug datetime msec
service timestamps log datetime msec
no service password-encryption
!
hostname "Router1"
!
!
ip subnet-zero
!
```

```

!
no ip domain lookup
!
ip audit notify log
ip audit po max-events 100
!
crypto isakmp policy 10
  encryption aes 256
  authentication pre-share
  lifetime 180
crypto isakmp key cisco123 address 10.0.110.1
!
!
crypto ipsec transform-set aesset esp-aes 256 esp-sha-hmac
  mode transport
!
crypto map aesmap 10 ipsec-isakmp
  set peer 10.0.110.1
  set transform-set aesset
  match address 120
!
.
.
.

```

Configuring IKE Authentication: Example

The following example shows how to manually specify the RSA public keys of two IPSec peer—the peer at 10.5.5.1 uses general-purpose keys, and the other peer uses special-usage keys:

```

crypto key pubkey-chain rsa
  named-key otherpeer.example.com
  address 10.5.5.1
  key-string
005C300D 06092A86 4886F70D 01010105
00034B00 30480241 00C5E23B 55D6AB22
04AEF1BA A54028A6 9ACC01C5 129D99E4
64CAB820 847EDAD9 DF0B4E4C 73A05DD2
BD62A8A9 FA603DD2 E2A8A6F8 98F76E28
D58AD221 B583D7A4 71020301 0001
  quit
exit

  quit
exit

```

```
exit
```

Where to Go Next

After you have successfully configured IKE negotiation, you can begin configuring IPSec. For information on completing these tasks, see the module “Configuring Security for VPNs With IPSec.”

Glossary

anti-replay—Security service in which the receiver can reject old or duplicate packets to protect itself against replay attacks. IPsec provides optional anti-replay services by use of a sequence number and the use of authentication.

data authentication—Verification of the integrity and origin of the data.

Data authentication can refer either to integrity alone or to both of these concepts (although data origin authentication is dependent upon data integrity).

peer—In the context of this chapter, a “peer” is a router or other device that participates in IPsec and IKE.

PFS—perfect forward secrecy. Cryptographic characteristic associated with a derived shared secret value. With PFS, if one key is compromised, previous and subsequent keys are not also compromised, because subsequent keys are not derived from previous keys.

repudiation—Quality that prevents a third party from being able to prove that a communication between two other parties ever took place. Repudiation is a desirable quality if you do not want your communications to be traceable.

nonrepudiation—Quality that allows a third party to prove that a communication between two other parties took place. Nonrepudiation is desirable if you want to be able to trace your communications and prove that they occurred.

SA—security association. How two or more entities utilize security services to communicate securely.

For example, an IPsec SA defines the encryption algorithm (if used), the authentication algorithm, and the shared session key to be used during the IPsec connection. Both IPsec and IKE require and use SAs to identify the parameters of their connections. IKE can negotiate and establish its own SA. The IPsec SA is established either by IKE or by manual user configuration.

Note

Refer to [Internetworking Terms and Acronyms](#) for terms not included in this glossary.

Feature Information for Configuring IKE for IPsec VPNs

[Table 43](#) lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table.

Not all commands may be available in your Cisco IOS software release. For details on when support for a specific command was introduced, see the command reference documentation.

Cisco IOS software images are specific to a Cisco IOS software release, a feature set, and a platform. Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Note

[Table 43](#) lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 43 *Feature Information for Configuring IKE for IPsec VPNs*

Feature Name	Software Releases	Feature Configuration Information
Ability to Disable Extended Authentication for Static IPsec Peers	12.2(4)T	This feature allows a user to disable Xauth while configuring the preshared key for router-to-router IPsec. Thus, the router will not prompt the peer for a username and password, which are transmitted when Xauth occurs for VPN-client-to-Cisco-IOS IPsec. The following section provides information about this feature: • Configuring Preshared Keys The following command was modified by this feature: crypto isakmp key
Advanced Encryption Standard (AES)	12.2(8)T	This feature adds support for the new encryption standard AES, which is a privacy transform for IPsec and IKE and has been developed to replace DES. The following sections provide information about this feature: • Supported Standards for Use with IKE • Creating IKE Policies: Security Parameters for IKE Negotiation The following commands were modified by this feature: crypto ipsec transform-set, encryption (IKE policy), show crypto isakmp policy, show crypto ipsec transform-set
SEAL Encryption	12.3(7)T	This feature adds support for SEAL encryption in IPsec. The following section provides information about this feature: • Supported Standards for Use with IKE The following command was modified by this feature: crypto ipsec transform-set
IKE Extended Authentication (Xauth)	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.
Wildcard Pre-Shared Key	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.
IKE - Diffie-Hellman (768 Bit or 1024 Bit) PKCS #3 Support	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

Table 43 *Feature Information for Configuring IKE for IPsec VPNs (continued)*

Feature Name	Software Releases	Feature Configuration Information
IKE Phase 1 Main Mode and Phase 1 Aggressive Mode	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.
IKE - RSA Signature	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

Call Admission Control for IKE

First Published: May 17, 2004

Last Updated: August 04, 2008

The Call Admission Control for IKE feature describes the application of Call Admission Control (CAC) to the Internet Key Exchange (IKE) protocol in Cisco IOS. CAC limits the number of simultaneous IKE security associations (SAs) (that is, calls to CAC) that a router can establish.

History for the Call Admission Control for IKE Feature

Release	Modification
12.3(8)T	This feature was introduced.
12.2(18)SXD1	This feature was integrated into Cisco IOS Release 12.2(18)SXD1 on the Cisco 6500 and Cisco 7600.
12.4(6)T	This feature was integrated into Cisco IOS Release 12.4(6)T. The ability to configure a limit on the number of in-negotiation IKE connections was added only to this and subsequent T-train releases.
12.2(33)SRA	This feature was integrated into Cisco IOS Release 12.2(33)SRA on the Cisco 7600. The in-negotiation IKE connection feature was not added to this SRA release.
12.2(33)SXH	This feature was integrated into Cisco IOS Release 12.2(33)SXH. The in-negotiation IKE connection feature was not added to this SXH release.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

- [Additional References, page 7](#)
- [Command Reference, page 8](#)

Prerequisites for Call Admission Control for IKE

- Configure IKE on the router. Refer to the *Cisco IOS Security Configuration Guide*, Release 12.3.

Information About Call Admission Control for IKE

To configure CAC for IKE, you need to understand the following concepts:

- [IKE Session, page 2](#)
- [Security Association Limit, page 2](#)
- [System Resource Usage, page 3](#)

IKE Session

There are two ways to limit the number of IKE SAs that a router can establish to or from another router:

- Configure the absolute IKE SA limit by entering the **crypto call admission limit** command. The router drops new IKE SA requests when the value has been reached.
- Configure the system resource limit by entering the **call admission limit** command. The router drops new IKE SA requests when the level of system resources that are configured in the unit of charge is being used.

For information about using these commands, see the [“Command Reference” section on page 8](#).

CAC is applied only to new SAs (that is, when an SA does not already exist between the peers). Every effort is made to preserve existing SAs. Only new SA requests will ever be denied due to a lack of system resources or because the configured IKE SA limit has been reached.

Security Association Limit

An SA is a description of how two or more entities will utilize security services to communicate securely on behalf of a particular data flow. IKE requires and uses SAs to identify the parameters of its connections. IKE can negotiate and establish its own SA. An IKE SA is used by IKE only, and it is bidirectional. An IKE SA cannot limit IPsec.

IKE drops SA requests based on a user-configured SA limit. To configure an IKE SA limit, enter the **crypto call admission limit** command. When there is a new SA request from a peer router, IKE determines if the number of active IKE SAs plus the number of SAs being negotiated meets or exceeds the configured SA limit. If the number is greater than or equal to the limit, the new SA request is rejected and a syslog is generated. This log contains the source destination IP address of the SA request.

Limit on Number of In-negotiation IKE Connections

Effective with Cisco IOS Release 12.4(6)T, a limit on the number of in-negotiation IKE connections can be configured. This type of IKE connection represents either an aggressive mode IKE SA or a main mode IKE SA prior to its authentication and actual establishment.

Using the **crypto call admission limit ike in-negotiation-sa {number}** command allows the configured number of in-negotiation IKE SAs to start negotiation without contributing to the maximum number of IKE SAs allowed.

System Resource Usage

CAC polls a global resource monitor so that IKE knows when the router is running short of CPU cycles or memory buffers. You can configure a resource limit, from 1 to 100000, that represents the level of system resources that are configured in the unit of charge. When that level of resources is being used, IKE drops (will not accept new) SA requests. To configure the system resource usage, enter the **call admission control** command.

How to Configure Call Admission Control for IKE

This section contains the following procedures:

- [Configure the IKE Security Association Limit, page 3](#) (optional)
- [Configure the System Resource Limit, page 4](#) (optional)

Note

You must perform one of the procedures.

Configure the IKE Security Association Limit

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto call admission limit {ike {in-negotiation-sa number | sa number } }**
4. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto call admission limit {ike {in-negotiation-sa number sa number}} Example: Router(config)# crypto call admission limit ike sa 25	Specifies the maximum number of IKE SAs that the router can establish before IKE begins rejecting new SA requests. Note An ISAKMP connection needs to be built in two directions. If you have 500 spokes in your network, you should set this value at a minimum of 1000 (500 x 2).
Step 4	exit Example: Router(config)# exit	Returns to privileged EXEC mode.

Configure the System Resource Limit

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **call admission limit** *charge*
4. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	call admission limit <i>charge</i> Example: Router(config)# call admission limit 90000	Sets the level of the system resources that, when used, causes IKE to stop accepting new SA requests. <i>charge</i>—Valid values are 1 to 100000.
Step 4	exit Example: Router(config)# exit	Returns to privileged EXEC mode.

Verifying the Call Admission Control for IKE Configuration

To verify the CAC for IKE configuration, perform the following steps.

SUMMARY STEPS

1. **show call admission statistics**
2. **show crypto call admission statistics**

DETAILED STEPS

Note

For detailed field descriptions of the command output, see the [“Command Reference” section on page 8](#).

Step 1 show call admission statistics

Use this command to monitor the global CAC configuration parameters and the behavior of CAC.

```
Router# show call admission statistics
```

```
Total Call admission charges: 0, limit 25
Total calls rejected 12, accepted 51
Load metric: charge 0, unscaled 0
```

Step 2 show crypto call admission statistics

Use this command to monitor Crypto CAC statistics.

```
Router# show crypto call admission statistics
```

```
-----
Crypto Call Admission Control Statistics
-----
System Resource Limit: 0    Max IKE SAs 0
Total IKE SA Count:    0    active:    0    negotiating: 0
Incoming IKE Requests: 0    accepted:  0    rejected:   0
Outgoing IKE Requests: 0    accepted:  0    rejected:   0
Rejected IKE Requests: 0    rsrc low:  0    SA limit:   0
-----
```

Configuration Examples for Call Admission Control for IKE

This section provides the following configuration examples:

- [Configuring the IKE Security Association Limit: Example, page 6](#)
- [Configuring the System Resource Limit: Example, page 6](#)

Configuring the IKE Security Association Limit: Example

The following example shows how to specify that there can be a maximum of 25 SAs before IKE starts rejecting new SA requests:

```
Router(config)# crypto call admission limit ike sa 25
```

Configuring the System Resource Limit: Example

The following example shows how to specify that IKE should drop SA requests when the level of system resources that are configured in the unit of charge reaches 90000:

```
Router(config)# call admission limit 90000
```

Certificate to ISAKMP Profile Mapping

First Published: May 17, 2004

Last Updated: August 21, 2007

The Certificate to ISAKMP Profile Mapping feature enables you to assign an Internet Security Association and Key Management Protocol (ISAKMP) profile to a peer on the basis of the contents of arbitrary fields in the certificate. In addition, this feature allows you to assign a group name to those peers that are assigned an ISAKMP profile.

History for Certificate to ISAKMP Profile Mapping Feature

Release	Modification
12.3(8)T	This feature was introduced.
12.2(33)SRA	This feature was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH	This feature was integrated into Cisco IOS Release 12.2(33)SXH.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Prerequisites for Certificate to ISAKMP Profile Mapping

- You should be familiar with configuring certificate maps.
- You should be familiar with configuring ISAKMP profiles.

Restrictions for Certificate to ISAKMP Profile Mapping

This feature will not be applicable if you use Rivest, Shamir, and Adelman- (RSA-) signature or RSA-encryption authentication without certificate exchange. ISAKMP peers must be configured to do RSA-signature or RSA-encryption authentication using certificates.

Information About Certificate to ISAKMP Profile Mapping

To configure the Certificate to ISAKMP Profile Mapping feature, you should understand the following concepts:

- [Certificate to ISAKMP Profile Mapping Overview, page 2](#)
- [How Certificate to ISAKMP Profile Mapping Works, page 2](#)
- [Assigning an ISAKMP Profile and Group Name to a Peer, page 3](#)

Certificate to ISAKMP Profile Mapping Overview

Prior to Cisco IOS Release 12.3(8)T, the only way to map a peer to an ISAKMP profile was as follows. The ISAKMP identity field in the ISAKMP exchange was used for mapping a peer to an ISAKMP profile. When certificates were used for authentication, the ISAKMP identity payload contained the subject name from the certificate. If a certificate authority (CA) did not provide the required group value in the first Organizational Unit (OU) field of a certificate, an ISAKMP profile could not be assigned to a peer.

Effective with Cisco IOS Release 12.3(8)T, a peer can still be mapped as explained above. However, the Certificate to ISAKMP Profile Mapping feature enables you to assign an ISAKMP profile to a peer on the basis of the contents of arbitrary fields in the certificate. You are no longer limited to assigning an ISAKMP profile on the basis of the subject name of the certificate. In addition, this feature allows you to assign a group to a peer to which an ISAKMP profile has been assigned.

How Certificate to ISAKMP Profile Mapping Works

[Figure 1](#) illustrates how certificate maps may be attached to ISAKMP profiles and assigned group names.

Figure 1 *Certificate Maps Mapped for Profile Group Assignment*

A certificate map can be attached to only one ISAKMP profile although an ISAKMP profile can have several certificate maps attached to it.

Certificate maps provide the ability for a certificate to be matched with a given set of criteria. ISAKMP profiles can bind themselves to certificate maps, and if the presented certificate matches the certificate map present in an ISAKMP profile, the peer will be assigned the ISAKMP profile. If the ISAKMP profile contains a client configuration group name, the same group name will be assigned to the peer. This ISAKMP profile information will override the information in the ID_KEY_ID identity or in the first OU field of the certificate.

Assigning an ISAKMP Profile and Group Name to a Peer

To assign an ISAKMP profile to a peer on the basis of arbitrary fields in the certificate, use the **match certificate** command after the ISAKMP profile has been defined.

To associate a group name with an ISAKMP profile that will be assigned to a peer, use the **client configuration group** command, also after the ISAKMP profile has been defined.

How to Configure Certificate to ISAKMP Profile Mapping

This section contains the following procedures:

- [Mapping the Certificate to the ISAKMP Profile, page 4](#) (required)
- [Verifying That the Certificate Has Been Mapped, page 4](#) (optional)
- [Assigning the Group Name to the Peer, page 5](#) (required)
- [Monitoring and Maintaining Your Certificate to ISAKMP Profile Mapping, page 6](#) (optional)

Mapping the Certificate to the ISAKMP Profile

To map the certificate to the ISAKMP profile, perform the following steps. This configuration will enable you to assign the ISAKMP profile to a peer on the basis of the contents of arbitrary fields in the certificate.

SUMMARY STEPS

- 1. `enable`
- 2. `configure terminal`
- 3. `crypto isakmp profile profile-name`
- 4. `match certificate certificate-map`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>enable</code> Example: Router# <code>enable</code>	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	<code>configure terminal</code> Example: Router# <code>configure terminal</code>	Enters global configuration mode.
Step 3	<code>crypto isakmp profile profile-name</code> Example: Router (config)# <code>crypto isakmp profile vpnprofile</code>	Defines an ISAKMP profile and enters into crypto ISAKMP profile configuration mode.
Step 4	<code>match certificate certificate-map</code> Example: Router (conf-isa-prof)# <code>match certificate map1</code>	Accepts the name of a certificate map.

Verifying That the Certificate Has Been Mapped

The following `show` command may be used to verify that the subject name of the certificate map has been properly configured.

SUMMARY

- 1. `enable`
- 2. `show crypto ca certificates`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router# enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	show crypto ca certificates Example: Router# show crypto ca certificates	Displays information about your certificate.

Assigning the Group Name to the Peer

To associate a group name with a peer when the peer is mapped to an ISAKMP profile, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp profile** *profile-name*
4. **client configuration group** *group-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router# enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto isakmp profile <i>profile-name</i> Example: Router (config)# crypto isakmp profile vpnprofile	Defines an ISAKMP profile and enters into isakmp profile configuration mode.
Step 4	client configuration group <i>group-name</i> Example: Router (conf-isa-prof)# client configuration group group1	Accepts the name of a group that will be assigned to a peer when the peer is assigned this crypto ISAKMP profile.

Monitoring and Maintaining Your Certificate to ISAKMP Profile Mapping

To monitor and maintain your certificate to ISAKMP profile mapping, you may use the following **debug** command.

SUMMARY STEPS

1. **enable**
2. **debug crypto isakmp**

DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>enable</code>	Enables privileged EXEC mode. • Enter your password if prompted.
	Example: <code>Router# enable</code>	
Step 2	<code>debug crypto isakmp</code>	Displays output showing that the certificate has gone through certificate map matching and that the certificate matches the ISAKMP profile.
	Example: <code>Router# debug crypto isakmp</code>	The command may also be used to verify that the peer has been assigned a group.

Configuration Examples for Certificate to ISAKMP Profile Mapping

This section contains the following configuration examples:

- [Certificates Mapped to the ISAKMP Profile on the Basis of Arbitrary Fields: Example, page 7](#)
- [Group Name Assigned to a Peer That Is Associated with an ISAKMP Profile: Example, page 7](#)
- [Mapping a Certificate to an ISAKMP Profile Verification: Example, page 8](#)
- [Group Name Assigned to a Peer Verification: Example, page 9](#)

Certificates Mapped to the ISAKMP Profile on the Basis of Arbitrary Fields: Example

The following configuration example shows that whenever a certificate contains “ou = green,” the ISAKMP profile “cert_pro” will be assigned to the peer:

```
crypto pki certificate map cert_map 10
  subject-name co ou = green
!
!
crypto isakmp identity dn
crypto isakmp profile cert_pro
  ca trust-point 2315
  ca trust-point LaBCA
  initiate mode aggressive
  match certificate cert_map
```

Group Name Assigned to a Peer That Is Associated with an ISAKMP Profile: Example

The following example shows that the group “some_group” is to be associated with a peer that has been assigned an ISAKMP profile:

```
crypto isakmp profile id_profile
  ca trust-point 2315
```

```
match identity host domain cisco.com
client configuration group some_group
```

Mapping a Certificate to an ISAKMP Profile Verification: Example

The following examples show that a certificate has been mapped to an ISAKMP profile. The examples include the configurations for the responder and initiator, **show command** output verifying that the subject name of the certificate map has been configured, and **debug** command output showing that the certificate has gone through certificate map matching and been matched to the ISAKMP profile.

Responder Configuration

```
crypto pki certificate map cert_map 10
! The above line is the certificate map definition.
subject-name co ou = green
! The above line shows that the subject name must have "ou = green."
!
crypto isakmp profile certpro
! The above line shows that this is the ISAKMP profile that will match if the certificate
of the peer matches cert_map (shown on third line below).
ca trust-point 2315
ca trust-point LaBCA
match certificate cert_map
initiate mode aggressive
```

Initiator Configuration

```
crypto ca trustpoint LaBCA
enrollment url http://10.76.82.20:80/cgi-bin/openscep
subject-name ou=green,c=IN
! The above line ensures that the subject name "ou = green" is set.
revocation-check none
```

show crypto ca certificates Command Output for the Initiator

```
Router# show crypto ca certificates
```

```
Certificate
Status: Available
Certificate Serial Number: 21
Certificate Usage: General Purpose
Issuer:
  cn=blue-lab CA
  o=CISCO
  c=IN
Subject:
  Name: Router1.cisco.com
  c=IN
  ou=green
! The above line is a double check that "ou = green" has been set as the subject name.
  hostname=Router1.cisco.com
Validity Date:
  start date: 14:34:30 UTC Mar 31 2004
  end   date: 14:34:30 UTC Apr 1 2009
  renew date: 00:00:00 UTC Jan 1 1970
Associated Trustpoints: LaBCA
```

debug crypto isakmp Command Output for the Responder

```
Router# debug crypto isakmp
```

```

6d23h: ISAKMP (0:268435460): received packet from 192.0.0.2 dport 500 sport 500 Global (R)

        FQDN name     : Router1.cisco.com
        protocol      : 17
        port          : 500
        length        : 28
6d23h: ISAKMP:(0:4:HW:2):: peer matches *none* of the profiles
6d23h: ISAKMP:(0:4:HW:2): processing CERT payload. message ID = 0
6d23h: ISAKMP:(0:4:HW:2): processing a CT_X509_SIGNATURE cert
6d23h: ISAKMP:(0:4:HW:2): peer's pubkey isn't cached
6d23h: ISAKMP:(0:4:HW:2): OU = green
6d23h: ISAKMP:(0:4:HW:2): certificate map matches certpro profile
! The above line shows that the certificate has gone through certificate map matching and
that it matches the "certpro" profile.
6d23h: ISAKMP:(0:4:HW:2): Trying to re-validate CERT using new profile
6d23h: ISAKMP:(0:4:HW:2): Creating CERT validation list: 2315, LaBcA,
6d23h: ISAKMP:(0:4:HW:2): CERT validity confirmed.

```

Group Name Assigned to a Peer Verification: Example

The following configuration and debug output show that a group has been assigned to a peer.

Initiator Configuration

```

crypto isakmp profile certpro
  ca trust-point 2315
  ca trust-point LaBcA
  match certificate cert_map
  client configuration group new_group
! The statement on the above line will assign the group "new_group" to any peer that
matches the ISAKMP profile "certpro."
  initiate mode aggressive
!

```

debug crypto isakmp profile Command Output for the Responder

The following debug output example shows that the peer has been matched to the ISAKMP profile named "certpro" and that it has been assigned a group named "new_group."

```

Router# debug crypto isakmp profile
6d23h: ISAKMP (0:268435461): received packet from 192.0.0.2 dport 500 sport 500 Global (R)
MM_KEY_EXCH
6d23h: ISAKMP: Main Mode packet contents (flags 1, len 892):
6d23h:         ID payload
6d23h:         FQDN <Router1.cisco.com> port 500 protocol 17
6d23h:         CERT payload
6d23h:         SIG payload
6d23h:         KEEPALIVE payload

```

```

6d23h:          NOTIFY payload
6d23h: ISAKMP:(0:5:HW:2):Input = IKE_MESG_FROM_PEER, IKE_MM_EXCH
6d23h: ISAKMP:(0:5:HW:2):Old State = IKE_R_MM4 New State = IKE_R_MM5

6d23h: ISAKMP:(0:5:HW:2): processing ID payload. message ID = 0
6d23h: ISAKMP (0:268435461): ID payload
      next-payload : 6
      type          : 2
      FQDN name     : Router1.cisco.com
      protocol      : 17
      port          : 500
      length        : 28
6d23h: ISAKMP:(0:5:HW:2):: peer matches *none* of the profiles

Restrictions for Encrypted Preshared Key

- Old ROM monitors (ROMMONs) and boot images cannot recognize the new type 6 passwords. Therefore, errors are expected if you boot from an old ROMMON.
- For Cisco 836 routers, please note that support for Advanced Encryption Standard (AES) is available only on IP plus images.

Information About Encrypted Preshared Key

Before Using the Encrypted Preshared Key feature, you should understand the following concepts:

- [Using the Encrypted Preshared Key Feature to Securely Store Passwords, page 2](#)
- [How to Configure an Encrypted Preshared Key, page 3](#)

Using the Encrypted Preshared Key Feature to Securely Store Passwords

Using the Encrypted Preshared Key feature, you can securely store plain text passwords in type 6 format in NVRAM using a command-line interface (CLI). Type 6 passwords are encrypted. Although the encrypted passwords can be seen or retrieved, it is difficult to decrypt them to find out the actual password. Use the **key config-key password-encryption** command with the **password encryption aes** command to configure and enable the password (symmetric cipher AES is used to encrypt the keys). The password (key) configured using the **config-key password-encryption** command is the master encryption key that is used to encrypt all other keys in the router.

If you configure the **password encryption aes** command without configuring the **key config-key password-encryption** command, the following message is printed at startup or during any nonvolatile generation (NVGEN) process, such as when the **show running-config** or **copy running-config startup-config** commands have been configured:

```
"Can not encrypt password. Please configure a configuration-key with 'key config-key'"
```

Changing a Password

If the password (master key) is changed, or reencrypted, using the **key config-key password-encryption** command, the list registry passes the old key and the new key to the application modules that are using type 6 encryption.

Deleting a Password

If the master key that was configured using the **key config-key password-encryption** command is deleted from the system, a warning is printed (and a confirm prompt is issued) that states that all type 6 passwords will become useless. As a security measure, after the passwords have been encrypted, they will never be decrypted in the Cisco IOS software. However, passwords can be reencrypted as explained in the previous paragraph.

Caution

If the password configured using the **key config-key password-encryption** command is lost, it cannot be recovered. The password should be stored in a safe location.

Unconfiguring Password Encryption

If you later unconfigure password encryption using the **no password encryption aes** command, all existing type 6 passwords are left unchanged, and as long as the password (master key) that was configured using the **key config-key password-encryption** command exists, the type 6 passwords will be decrypted as and when required by the application.

Storing Passwords

Because no one can “read” the password (configured using the **key config-key password-encryption** command), there is no way that the password can be retrieved from the router. Existing management stations cannot “know” what it is unless the stations are enhanced to include this key somewhere, in which case the password needs to be stored securely within the management system. If configurations are stored using TFTP, the configurations are not standalone, meaning that they cannot be loaded onto a router. Before or after the configurations are loaded onto a router, the password must be manually added (using the **key config-key password-encryption** command). The password can be manually added to the stored configuration but is not recommended because adding the password manually allows anyone to decrypt all passwords in that configuration.

Configuring New or Unknown Passwords

If you enter or cut and paste cipher text that does not match the master key, or if there is no master key, the cipher text is accepted or saved, but an alert message is printed. The alert message is as follows:

“ciphertext>[for username bar>] is incompatible with the configured master key.”

If a new master key is configured, all the plain keys are encrypted and made type 6 keys. The existing type 6 keys are not encrypted. The existing type 6 keys are left as is.

If the old master key is lost or unknown, you have the option of deleting the master key using the **no key config-key password-encryption** command. Deleting the master key using the **no key config-key password-encryption** command causes the existing encrypted passwords to remain encrypted in the router configuration. The passwords will not be decrypted.

Enabling the Encrypted Preshared Key

The **password encryption aes** command is used to enable the encrypted password.

How to Configure an Encrypted Preshared Key

This section contains the following procedures:

- [Configuring an Encrypted Preshared Key, page 4](#) (required)
- [Monitoring Encrypted Preshared Keys, page 5](#) (optional)
- [Configuring an ISAKMP Preshared Key, page 6](#) (optional)
- [Configuring an ISAKMP Preshared Key in ISAKMP Keyrings, page 7](#) (optional)
- [Configuring ISAKMP Aggressive Mode, page 8](#) (optional)
- [Configuring a Unity Server Group Policy, page 9](#) (optional)

- [Configuring an Easy VPN Client, page 10](#) (optional)

Configuring an Encrypted Preshared Key

To configure an encrypted preshared key, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **key config-key password-encryption** *[text]*
4. **password encryption aes**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	key config-key password-encryption <i>[text]</i> Example: Router (config)# key config-key password-encryption	Stores a type 6 encryption key in private NVRAM. • If you want to key in interactively (using the enter key) and an encrypted key already exists, you will be prompted for the following: Old key, New key, and Confirm key. • If you want to key in interactively but an encryption key is not present, you will be prompted for the following: New key and Confirm key. • If you want to remove the password that is already encrypted, you will see the following prompt: “WARNING: All type 6 encrypted keys will become unusable. Continue with master key deletion? [yes/no]:”.
Step 4	password encryption aes Example: Router (config)# password-encryption aes	Enables the encrypted preshared key.

Troubleshooting Tips

If you see the warning message “ciphertext >[for username bar>] is incompatible with the configured master key,” you have entered or cut and pasted cipher text that does not match the master key or there is no master key. (The cipher text will be accepted or saved.) The warning message will allow you to locate the broken configuration line or lines.

Monitoring Encrypted Preshared Keys

To get logging output for encrypted preshared keys, perform the following steps.

1. **enable**
2. **password logging**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	password logging Example: Router# password logging	Provides a log of debugging output for a type 6 password operation.

Examples

The following **password logging** debug output shows that a new master key has been configured and that the keys have been encrypted with the new master key:

```
Router (config)# key config-key password-encrypt
New key:
Confirm key:
Router (config)#
01:40:57: TYPE6_PASS: New Master key configured, encrypting the keys with
the new master keypas

Router (config)# key config-key password-encrypt
Old key:
New key:
Confirm key:
Router (config)#
01:42:11: TYPE6_PASS: Master key change heralded, re-encrypting the keys
with the new master key
01:42:11: TYPE6_PASS: Mac verification successful
01:42:11: TYPE6_PASS: Mac verification successful
01:42:11: TYPE6_PASS: Mac verification successful
```

What To Do Next

You can perform any of the following procedures. Each procedure is independent of the others.

- [Configuring an ISAKMP Preshared Key, page 6](#)
- [Configuring an ISAKMP Preshared Key in ISAKMP Keyrings, page 7](#)
- [Configuring ISAKMP Aggressive Mode, page 8](#)
- [Configuring a Unity Server Group Policy, page 9](#)
- [Configuring an Easy VPN Client, page 10](#)

Configuring an ISAKMP Preshared Key

To configure an ISAKMP preshared key, perform the following procedure.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp key *keystring* address *peer-address***
4. **crypto isakmp key *keystring* hostname *hostname***

DETAILED STEPS

	Command	Description
Step 1	enable Example: Router# enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto isakmp key <i>keystring</i> address <i>peer-address</i> Example: Router (config)# crypto isakmp key cisco address 10.2.3.4	Configures a preshared authentication key. • The <i>peer-address</i> argument specifies the IP address of the remote peer.
Step 4	crypto isakmp key <i>keystring</i> hostname <i>hostname</i> Example: Router (config)# crypto isakmp key foo hostname foo.com	Configures a preshared authentication key. • The <i>hostname</i> argument specifies the fully qualified domain name (FQDN) of the peer.

Example

The following sample output shows that an encrypted preshared key has been configured:

```
crypto isakmp key 6 _Hg[^^ECgLGgPF^RXTQfDDWQ][YAAB address 10.2.3.4
crypto isakmp key 6 `eR\etRaKCUPYYQfDgXRwi_AAB hostname foo.com
```

Configuring an ISAKMP Preshared Key in ISAKMP Keyrings

To configure an ISAKMP preshared key in ISAKMP keyrings, which are used in IPsec Virtual Route Forwarding (VRF) configurations, perform the following procedure.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto keyring** *keyring-name*
4. **pre-shared-key address** *address* **key** *key*
5. **pre-shared-key hostname** *hostname* **key** *key*

DETAILED STEPS

	Command	Description
Step 1	enable Example: Router# enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto keyring <i>keyring-name</i> Example: Router (config)# crypto keyring foo	Defines a crypto keyring to be used during Internet Key Exchange (IKE) authentication and enters keyring configuration mode.
Step 4	pre-shared-key address <i>address</i> key <i>key</i> Example: Router (config-keyring)# pre-shared-key address 10.2.3.5 key cisco	Defines a preshared key to be used for IKE authentication. • The <i>address</i> argument specifies the IP address of the remote peer.
Step 5	pre-shared-key hostname <i>hostname</i> key <i>key</i> Example: Router (config-keyring)# pre-shared-key hostname foo.com key cisco	Defines a preshared key to be used for IKE authentication. • The <i>hostname</i> argument specifies the FQDN of the peer.

Example

The following **show-running-config** sample output shows that an encrypted preshared key in ISAKMP keyrings has been configured.

```
crypto keyring foo
  pre-shared-key address 10.2.3.5 key 6 `WHCJYR_Z]GRPF^RXTQfDcfZ]GPAAB
  pre-shared-key hostname foo.com key 6 aE_REHDcOfYCPF^RXTQfDJYVVNSAAB
```

Configuring ISAKMP Aggressive Mode

To configure ISAKMP aggressive mode, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp peer ip-address** *ip-address*
4. **set aggressive-mode client-endpoint** *client-endpoint*
5. **set aggressive-mode password** *password*

DETAILED STEPS

	Command	Description
Step 1	enable Example: Router# enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto isakmp peer ip-address <i>ip-address</i> Example: Router (config)# crypto isakmp peer ip-address 10.2.3.4	To enable an IP Security (IPSec) peer for IKE querying of authentication, authorization, and accounting (AAA) for tunnel attributes in aggressive mode and to enter ISAKMP peer configuration mode.
Step 4	set aggressive-mode client-endpoint <i>client-endpoint</i> Example: Router (config-isakmp-peer)# set aggressive-mode client-endpoint fqdn cisco.com	Specifies the Tunnel-Client-Endpoint attribute within an ISAKMP peer configuration.
Step 5	set aggressive-mode password <i>password</i> Example: Router (config-isakmp-peer)# set aggressive-mode password cisco	Specifies the Tunnel-Password attribute within an ISAKMP peer configuration.

Example

The following **show-running-config** sample output shows that an encrypted preshared key in ISAKMP aggressive mode has been configured.

```
crypto isakmp peer address 10.2.3.4
  set aggressive-mode password 6 ^aKPIQ_KJE_PPF^RXTQfDTIaLNeAAB
  set aggressive-mode client-endpoint fqdn cisco.com
```

Configuring a Unity Server Group Policy

To configure a unity server group policy, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp client configuration group** *group-name*
4. **pool** *name*
5. **domain** *name*
6. **key** *name*

DETAILED STEPS

	Command	Description
Step 1	enable	Enables privileged EXEC mode. • Enter your password if prompted.
	Example: Router# enable	
Step 2	configure terminal	Enters global configuration mode.
	Example: Router# configure terminal	
Step 3	crypto isakmp client configuration group <i>group-name</i>	Specifies the policy profile of the group that will be defined and enters ISAKMP group configuration mode.
	Example: Router (config)# crypto isakmp client configuration group foo	
Step 4	pool <i>name</i>	Defines a local pool address.
	Example: Router (config-isakmp-group)# pool foopool	

	Command	Description
Step 5	domain <i>name</i>	Specifies the Domain Name Service (DNS) domain to which a group belongs.
	Example: Router (config-isakmp-group)# domain cisco.com	
Step 6	key <i>name</i>	Specifies the IKE preshared key for group policy attribute definition.
	Example: Router (config-isakmp-group)# key cisco	

Example

The following **show-running-config** sample output shows that an encrypted key has been configured for a unity server group policy:

```
crypto isakmp client configuration group foo
key 6 cZZgDZPOE\ddPF^RXTQfDTIaLNeAAB
domain cisco.com
pool foopool
```

Configuring an Easy VPN Client

To configure an Easy VPN client, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec client** *ezvpn name*
4. **peer** *ipaddress*
5. **mode** client
6. **group** *group-name* **key** *group-key*
7. **connect** manual

DETAILED STEPS

	Command	Description
Step 1	enable	Enables privileged EXEC mode. • Enter your password if prompted.
	Example: Router# enable	
Step 2	configure terminal	Enters global configuration mode.
	Example: Router# configure terminal	

	Command	Description
Step 3	crypto ipsec client ezvpn name Example: Router (config)# crypto ipsec client ezvpn foo	Creates a Cisco Easy VPN remote configuration and enters Cisco Easy VPN remote configuration mode.
Step 4	peer ipaddress Example: Router (config-isakmp-peer)# peer 10.2.3.4	Sets the peer IP address for the VPN connection.
Step 5	mode client Example: Router (config-isakmp-ezpvpy)# mode client	Automatically configures the router for Cisco Easy VPNclient mode operation, which uses Network Address Translation (NAT) or Peer Address Translation (PAT) address translations.
Step 6	group group-name key group-key Example: Router (config-isakmp-ezvpn)# group foo key cisco	Specifies the group name and key value for the VPN connection.
Step 7	connect manual Example: Router (config-isakmp-ezvpn)# connect manual	Specifies the manual setting for directing the Cisco Easy VPN remote client to wait for a command or application program interface (API) call before attempting to establish the Cisco Easy VPN remote connection.

Example

The following **show-running-config** sample output shows that an Easy VPN client has been configured. The key has been encrypted.

```
crypto ipsec client ezvpn foo
connect manual
group foo key 6 gdMI`S^^[GicPF^RXTQfDFKEO\RAAB
mode client
peer 10.2.3.4
```

Configuration Examples for Encrypted Preshared Key

This section provides the following configuration examples:

- [Encrypted Preshared Key: Example, page 12](#)
- [No Previous Key Present: Example, page 12](#)
- [Key Already Exists: Example, page 12](#)
- [Key Already Exists But the User Wants to Key In Interactively: Example, page 12](#)
- [No Key Present But the User Wants to Key In Interactively: Example, page 12](#)
- [Removal of the Password Encryption: Example, page 13](#)

Encrypted Preshared Key: Example

The following is an example of a configuration for which a type 6 preshared key has been encrypted. It includes the prompts and messages that a user might see.

```
Router (config)# crypto isakmp key cisco address 10.0.0.2
Router (config)# exit
Router# show running-config | include crypto isakmp key
crypto isakmp key cisco address 10.0.0.2
Router#
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router (config)# password encryption aes
Router (config)# key config-key password-encrypt
New key:
Confirm key:
Router (config)#
01:46:40: TYPE6_PASS: New Master key configured, encrypting the keys with
the new master key
Router (config)# exit
Router # show running-config | include crypto isakmp key
crypto isakmp key 6 CXWdhVTZYB_Vcd^`cIHD0ahiFTa address 10.0.0.2
```

No Previous Key Present: Example

In the following configuration example, no previous key is present:

```
Router (config)# key config-key password-encryption testkey 123
```

Key Already Exists: Example

In the following configuration example, a key already exists:

```
Router (config)# key config-key password-encryption testkey123
Old key:
Router (config)#
```

Key Already Exists But the User Wants to Key In Interactively: Example

In the following configuration example, the user wants to key in interactively, but a key already exists. The Old key, New key, and Confirm key prompts will show on your screen if you enter the **key config-key password-encryption** command and press the enter key to get into interactive mode.

```
Router (config)# key config-key password-encryption
Old key:
New key:
Confirm key:
```

No Key Present But the User Wants to Key In Interactively: Example

In the following example, the user wants to key in interactively, but no key is present. The New key and Confirm key prompts will show on your screen if you are in interactive mode.

```
Router (config)# key config-key password-encryption
New key:
```

Confirm key:

Removal of the Password Encryption: Example

In the following configuration example, the user wants to remove the encrypted password. The “WARNING: All type 6 encrypted keys will become unusable. Continue with master key deletion? [yes/no]:” prompt will show on your screen if you are in interactive mode.

```
Router (config)# no key config-key password-encryption
```

```
WARNING: All type 6 encrypted keys will become unusable. Continue with master key  
deletion ? [yes/no]: y
```

Where to Go Next

Configure any other preshared keys.

Multi-ISA

This feature module describes the Multi-ISA feature and includes the following sections:

- [Feature Overview, page 1](#)
- [Supported Platforms, page 3](#)
- [Supported Standards, MIBs, and RFCs, page 4](#)
- [Prerequisites, page 4](#)
- [Configuration Tasks, page 5](#)
- [Verifying Multi-ISA, page 5](#)
- [Monitoring and Maintaining Multi-ISA, page 5](#)
- [Configuration Examples, page 5](#)
- [Command Reference, page 8](#)
- [Glossary, page 9](#)

Feature Overview

The Multi-ISA feature allows a Cisco IOS router to accommodate more than one hardware crypto engine at a time. This feature allows users to increase the capacity of their routers with multiple Integrated Services Adapters (ISAs) and Integrated Services Module (ISMs).

Note

ISAs are used on Cisco 7200 routers and ISMs are used on Cisco 7100 routers. Hereafter, for purposes of this document and unless otherwise noted, the term ISA will denote both Integrated Services Adapters and Integrated Services Modules.

The multi-ISA layer provides a single interface, which Cisco IOS software can use to send commands to different hardware crypto engines. The multi-ISA layer accepts all commands and packets on behalf of all underlying hardware crypto engines; it distributes all commands and packets in a predefined manner. That is, when you request an Internet Key Exchange-security association (IKE-SA) session, the multi-ISA layer determines which of the two hardware crypto engine contains fewer IKE-SAs, and it assigns the next session to the hardware crypto engine that has fewer IKE-SAs.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

How Multi-ISA Works

When your router has only one ISA in an active state, all IKE and IP Security-SA sessions go to this one ISA. Once you have inserted the second ISA into your router and it becomes active, subsequent IKE-SAs will flow to the second ISA until the first and second ISAs have an equal number of IKE-SA sessions. For example, if ISA-1 has 10 IKE sessions, and then ISA-2 becomes active, the router will send the following 11 through 20 IKE sessions to ISA-2. Thereafter, the multi-ISA layer will maintain a balance of IKE-SA sessions on both ISAs.

Note

The second ISA becomes active through online insertion and removal (OIR) or micro reload.

Benefits

The Multi-ISA feature provides the following benefits:

- Load-sharing of IKE-SAs
- Increased IPSec traffic throughput of your router
- OIR support

Restrictions

System Requirements

Your system should contain at least 128 megabytes of memory to run a single ISA and 256 megabytes of memory to run two ISAs. You need more than 128 megabytes of memory to cross 2,000 bidirectional IPSec tunnels.

Note

All tunnels referenced to in this document are defined as bidirectional IPSec tunnels.

Crypto Capabilities

All ISAs supported by the multi-ISA layer must have the same crypto capabilities. For example, if one ISA supports 3DES, another ISA that does not support 3DES cannot be in the same router under the multi-ISA layer.

Failover Limitations

Keepalives are needed to achieve failover in your router. If you turn on keepalives, you cannot exceed 500 tunnels because of current IKE keepalive limitations in the Cisco IOS software.

Note

This restriction will be lifted in a future release.

MPPE

Multiple Microsoft Point-to-Point Encryption (MPPE) ISA support is not available.

Related Documents

The following documents provide information related to the Multi-ISA feature:

- *Cisco IOS Security Configuration Guide*, Release 12.1
- *Cisco IOS Security Command Reference*, Release 12.1
- ISA and ISM Installation and Configuration
- The chapter “Basic System Management” in *Cisco IOS Configuration Fundamentals Command Reference*, Release 12.1
- The chapter “Performing Basic System Management” in *Cisco IOS Configuration Fundamentals Configuration Guide*

Supported Platforms

The following platforms support the Multi-ISA feature:

- Cisco 7140
- Cisco 7200 with NP300 service module

Determining Platform Support Through Cisco Feature Navigator

Cisco IOS software is packaged in feature sets that are supported on specific platforms. To get updated information regarding platform support for this feature, access Cisco Feature Navigator. Cisco Feature Navigator dynamically updates the list of supported platforms as new platform support is added for the feature.

Cisco Feature Navigator is a web-based tool that enables you to determine which Cisco IOS software images support a specific set of features and which features are supported in a specific Cisco IOS image. You can search by feature or release. Under the release section, you can compare releases side by side to display both the features unique to each software release and the features in common.

To access Cisco Feature Navigator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to cco-locksmith@cisco.com. An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions found at this URL:

<http://www.cisco.com/register>

Cisco Feature Navigator is updated regularly when major Cisco IOS software releases and technology releases occur. For the most current information, go to the Cisco Feature Navigator home page at the following URL:

<http://www.cisco.com/go/fn>

Availability of Cisco IOS Software Images

Platform support for particular Cisco IOS software releases is dependent on the availability of the software images for those platforms. Software images for some platforms may be deferred, delayed, or changed without prior notice. For updated information about platform support and availability of software images for each Cisco IOS software release, refer to the online release notes or, if supported, Cisco Feature Navigator.

Supported Standards, MIBs, and RFCs

Standards

No new or modified standards are supported by this feature.

MIBs

No new or modified MIBs are supported by this feature.

To locate and download MIBs for selected platforms, Cisco IOS releases, and feature sets, use Cisco MIB Locator found at the following URL:

<http://tools.cisco.com/ITDIT/MIBS/servlet/index>

If Cisco MIB Locator does not support the MIB information that you need, you can also obtain a list of supported MIBs and download MIBs from the Cisco MIBs page at the following URL:

<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>

To access Cisco MIB Locator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to cco-locksmith@cisco.com. An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions found at this URL:

<http://www.cisco.com/register>

RFCs

No new or modified RFCs are supported by this feature.

Prerequisites

IPSec Encryption

To use the Multi-ISA feature, you must configure your ISAs to provide IPSec encryption services by performing the following tasks:

- Configure IKE policies.
- Configure IPSec.
- Create crypto map entries.
- Apply a crypto map set to each interface through which IPSec traffic flows.

For information on completing these tasks, refer to *ISA and ISM Installation and Configuration*.

Manual Buffer Tuning

In the 7200 platform, it is recommended that you manually finetune packet buffers to establish more IKE-SA or IPSec tunnels.

To manually configure buffer tuning, enter the following global configuration command:

Command	Purpose
Router# (config) buffers { small middle big verybig large huge <i>type number</i> } { permanent max-free min-free initial } <i>number</i>	Makes adjustments to initial buffer pool settings and to the limits at which temporary buffers are created and destroyed.

For buffer tuning examples, see the “[Configuration Examples](#)” section later in this document.

Configuration Tasks

None

Verifying Multi-ISA

To verify how many active IKE and IPSec sessions are on each hardware crypto engine, how many Diffie-Hellman (DH) keys are in use, and how far your ISA is from reaching its maximum limit, use the **show crypto eli** command in EXEC mode.

Monitoring and Maintaining Multi-ISA

To obtain a snapshot of how many IKE-SAs and IPSec sessions are active and how many DH keys are in use, use the following command in EXEC mode:

Command	Purpose
Router# show crypto eli	Displays a snapshot of how many IKE-SAs and IPSec sessions are active and how many DH keys are in use for each hardware crypto engine.

Configuration Examples

This section provides the following configuration examples:

- [Single ISA Scenario Example](#)
- [Load-Balancing with Multi-ISA Example](#)
- [Manual Buffer Tuning Examples](#)

Single ISA Scenario Example

The following example is sample output from the **show crypto eli** command. In this example, a router has established 1246 IKE sessions; however, all IKE sessions flow to a single ISA because only one ISA is in an active state.

```
P0# show crypto eli
```

```
Encryption Layer : ACTIVE
Number of crypto engines = 1 .
```

```
Slot-3 crypto engine details.
Capability-IPSec :No-IPPCP, 3DES, NoRSA
```

```
IKE-Session   : 1246 active, 2029 max, 0 failed
DH-Key        :      0 active, 1014 max, 0 failed
IPSec-Session : 2712 active, 4059 max, 0 failed
```

Load-Balancing with Multi-ISA Example

The following example is sample output from the **show crypto eli** command. In this example, a router has established 2492 IKE sessions; the IKE sessions are equally distributed between two ISAs (each ISA contains 1246 IKE sessions), allowing you to increase the capacity of your router.

```
P0# show crypto eli
```

```
Encryption Layer : ACTIVE
Number of crypto engines = 2 .
```

```
Slot-3 crypto engine details.
Capability-IPSec :No-IPPCP, 3DES, NoRSA
```

```
IKE-Session   : 1246 active, 2029 max, 0 failed
DH-Key        :      0 active, 1014 max, 0 failed
IPSec-Session : 2676 active, 4059 max, 0 failed
```

```
Slot-5 crypto engine details.
Capability-IPSec :No-IPPCP, 3DES, NoRSA
```

```
IKE-Session   : 1246 active, 2029 max, 0 failed
DH-Key        :      0 active, 1014 max, 0 failed
IPSec-Session : 2678 active, 4059 max, 0 failed
```

[Table 1](#) describes significant fields shown in the display.

Table 1 *show crypto eli summary Field Descriptions*

Field	Description
active	The number of sessions that are active on a given hardware crypto engine.
max	The maximum number of sessions allowed for any given IKE, DH, or IPSec entry.
failed	The number of times that Cisco IOS software attempted to create more sessions than the number specified in “max.”

Manual Buffer Tuning Examples

The following example shows recommended numbers to use, based on available memory, when manually configuring packet buffers on the 7200 platform using the **buffers** command:

Memory (MB)	Non-HUGE Buffers		
	Min-free	Permanent	Max-free
32	64	256	1280
64	128	512	2560
96	192	768	3840
128	256	1024	5120
160	320	1280	6400
192	384	1536	7680
224	448	1792	8960
256	512	2048	10240

Memory (MB)	HUGE Buffers		
	Min-free	Permanent	Max-free
32	4	16	64
64	8	32	128
96	12	48	192
128	16	64	256
160	20	80	320
192	24	96	384
224	28	112	448
256	32	128	512

Table 2 describes significant fields shown in the display.

Table 2 Manual Buffer Tuning Example Descriptions

Field	Description
Memory (MB)	Available memory on your 7200 platform.
Min-free	Minimum number of free or unallocated buffers in a buffer pool.
Permanent	Number of permanent buffers that the system tries to create and keep.
Max-free	Maximum number of free or unallocated buffers in a buffer pool.

The following example shows sample output from the **show buffers** command:

P0# **show buffers**

Buffer elements:

```
500 in free list (500 max allowed)
12666974 hits, 0 misses, 0 created
```

Public buffer pools:

Small buffers, 104 bytes (total 2048, permanent 2048):

```
2039 in free list (512 min, 10240 max allowed)
293 hits, 0 misses, 0 trims, 0 created
0 failures (0 no memory)
```

Middle buffers, 600 bytes (total 2048, permanent 2048, peak 5000 @ 16:34:14):

```
2048 in free list (512 min, 10240 max allowed)
849 hits, 0 misses, 0 trims, 0 created
0 failures (0 no memory)
```

Big buffers, 1524 bytes (total 2048, permanent 2048):

```
2048 in free list (512 min, 10240 max allowed)
84 hits, 0 misses, 0 trims, 0 created
```

```
0 failures (0 no memory)
VeryBig buffers, 4520 bytes (total 2048, permanent 2048):
  2048 in free list (512 min, 10240 max allowed)
  0 hits, 0 misses, 0 trims, 0 created
  0 failures (0 no memory)
Large buffers, 5024 bytes (total 2048, permanent 2048, peak 5000 @ 16:34:25):
  2047 in free list (512 min, 10240 max allowed)
  18 hits, 0 misses, 0 trims, 0 created
  0 failures (0 no memory)
Huge buffers, 18024 bytes (total 128, permanent 128):
  128 in free list (32 min, 512 max allowed)
  0 hits, 0 misses, 0 trims, 0 created
  0 failures (0 no memory)
```

Command Reference

The following commands are introduced or modified in the feature or features

- **show crypto eli**

For information about these commands, see the Cisco IOS Security Command Reference at

http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html.

For information about all Cisco IOS commands, see the Command Lookup Tool at

<http://tools.cisco.com/Support/CLILookup> or the Master Command List.

Glossary

crypto map—A Cisco IOS software configuration entity that performs two primary functions: (1) selecting data flows that need security processing and (2) defining the policy for these flows and the crypto peer to which traffic needs to go. A crypto map is applied to an interface. The concept of a crypto map was introduced in classic crypto but was expanded for IPSec.

DH—See Diffie-Hellman.

Diffie-Hellman—A public-key cryptography protocol that allows two parties to establish a shared secret over an insecure communications channel. Diffie-Hellman is used within IKE to establish session keys and is a component of Oakley.

IKE—Internet Key Exchange. A hybrid protocol that implements Oakley key exchange and Skeme key exchange inside the Internet Security Association and Key Management Protocol framework. IKE can be used with other protocols, but its initial implementation is with IPSec. IKE provides authentication of the IPSec peers, negotiates IPSec keys, and negotiates IPSec security associations.

IKE is used to establish a shared security policy and authenticated keys for services (such as IPSec) that require keys. Before any IPSec traffic can be passed, each router, firewall, or host must be able to verify the identity of its peer. This can be done by manually entering preshared keys into both hosts or by a certification authority (CA) service.

Integrated Services Adapter—See ISA.

Internet Key Exchange—See IKE.

IPSec—IP Security. A framework of open standards that provides data confidentiality, data integrity, and data authentication between participating peers. IPSec provides these security services at the IP layer. IPSec uses IKE to handle negotiation of protocols and algorithms based on local policy and to generate the encryption and authentication keys to be used by IPSec. IPSec can be used to protect one or more data flows between a pair of hosts, between a pair of security gateways, or between a security gateway and a host.

IP Security—See IPSec.

ISA—Integrated Services Adapter. Provides high-performance, hardware-assisted tunneling and encryption services suitable for private WAN and virtual private network (VPN) applications. Within this feature module, ISA includes ISM.

ISM—Integrated Services Module.

OIR—online insertion and removal. A feature that allows you to add, replace, or remove a card from your router without interrupting the system power, entering console commands, or causing other software or interfaces to shut down. This feature is sometimes referred to as “hot swapping” or “power-on servicing.”

online insertion and removal—See OIR.

IKE: Initiate Aggressive Mode

Feature History

Release	Modification
12.2(8)T	This feature was introduced.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

This document describes the IKE: Initiate Aggressive Mode feature in Cisco IOS Release 12.2(8)T. It includes the following sections:

- [Feature Overview, page 1](#)
- [Supported Platforms, page 2](#)
- [Supported Standards, MIBs, and RFCs, page 4](#)
- [Prerequisites, page 4](#)
- [Configuration Tasks, page 4](#)
- [Configuration Examples, page 5](#)
- [Command Reference, page 7](#)

Feature Overview

The IKE: Initiate Aggressive Mode feature allows you to configure Internet Key Exchange (IKE) preshared keys as RADIUS tunnel attributes for IP Security (IPSec) peers. Thus, you can scale your IKE preshared keys in a hub-and-spoke topology.

Although IKE preshared keys are simple to understand and easy to deploy, they do not scale well with an increasing number of users and are therefore prone to security threats. Instead of keeping your preshared keys on the hub router, this feature allows you to scale your preshared keys by storing and retrieving them from an authentication, authorization, and accounting (AAA) server. The preshared keys are stored in the AAA server as Internet Engineering Task Force (IETF) RADIUS tunnel attributes and are retrieved when a user tries to “speak” to the hub router. The hub router retrieves the preshared key

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

from the AAA server and the spokes (the users) initiate aggressive mode to the hub by using the preshared key that is specified in the Internet Security Association Key Management Policy (ISAKMP) peer policy as a RADIUS tunnel attribute.

RADIUS Tunnel Attributes

To initiate an IKE aggressive mode negotiation, the Tunnel-Client-Endpoint (66) and Tunnel-Password (69) attributes must be configured in the ISAKMP peer policy. The Tunnel-Client-Endpoint attribute will be communicated to the server by encoding it in the appropriate IKE identity payload; the Tunnel-Password attribute will be used as the IKE preshared key for the aggressive mode negotiation.

Benefits

The IKE: Initiate Aggressive Mode feature allows you to specify RADIUS tunnel attributes for an IPSec peer and to initiate an IKE aggressive mode negotiation with the tunnel attributes. This feature is best implemented in a crypto hub-and-spoke scenario, by which the spokes initiate IKE aggressive mode negotiation with the hub by using the preshared keys that are specified as tunnel attributes and stored on the AAA server. This scenario is scalable because the preshared keys are kept at a central repository (the AAA server) and more than one hub router and one application can use the information.

Restrictions

TED Restriction

This feature is not intended to be used with a dynamic crypto map that uses Tunnel Endpoint Discovery (TED) to initiate tunnel setup. TED is useful in configuring a full mesh setup, which requires an AAA server at each site to store the preshared keys for the peers; this configuration is not practical for use with this feature.

Tunnel-Client-Endpoint ID Types

Only the following ID types can be used in this feature:

- ID_IPV4 (IPV4 address)
- ID_FQDN (fully qualified domain name, for example “foo.cisco.com”)
- ID_USER_FQDN (e-mail address)

Supported Platforms

This feature runs on all platforms that support IPSec and public key infrastructure (PKI).

- Cisco 800 series

- Cisco 805
- Cisco 806
- Cisco 828
- Cisco 1400 series
- Cisco 1600 series
- Cisco 1600-R series
- Cisco 1710
- Cisco 1720
- Cisco 1750
- Cisco 1751
- Cisco 2400 series
- Cisco 2600 series
- Cisco 3620
- Cisco 3640
- Cisco 3660
- Cisco 3725
- Cisco 3745
- Cisco 7100 series
- Cisco 7200 series
- Cisco 7500 series
- Cisco 7700 series
- Cisco MC3810
- Route Processor Module (RPM)
- Universal Route Module (URM)

Determining Platform Support Through Cisco Feature Navigator

Cisco IOS software is packaged in feature sets that support specific platforms. To get updated information regarding platform support for this feature, access Cisco Feature Navigator. Cisco Feature Navigator dynamically updates the list of supported platforms as new platform support is added for the feature.

Cisco Feature Navigator is a web-based tool that enables you to quickly determine which Cisco IOS software images support a specific set of features and which features are supported in a specific Cisco IOS image. You can search by feature or release. Under the release section, you can compare releases side by side to display both the features unique to each software release and the features in common.

To access Cisco Feature Navigator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to cco-locksmith@cisco.com. An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions at <http://www.cisco.com/register>.

Cisco Feature Navigator is updated regularly when major Cisco IOS software releases and technology releases occur. For the most current information, go to the Cisco Feature Navigator home page at the following URL:

<http://www.cisco.com/go/fn>

Supported Standards, MIBs, and RFCs

Standards

None

MIBs

None

To obtain lists of supported MIBs by platform and Cisco IOS release, and to download MIB modules, go to the Cisco MIB website on Cisco.com at the following URL:

<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>

RFCs

- RFC 2409, *The Internet Key Exchange*
- RFC 2868, *RADIUS Attributes for Tunnel Protocol Support*

Prerequisites

Before configuring the Initiate Aggressive Mode IKE feature, you must perform the following tasks:

- Configure AAA
- Configure an IPSec Transform
- Configure a Static Crypto Map
- Configure an ISAKMP Policy
- Configure a Dynamic Crypto Map

For information on completing these tasks, refer to the chapters “Configuring Authentication,” “Configuring IPSec Network Security,” and “Configuring Internet Key Exchange Security Protocol” in the *Cisco IOS Security Configuration Guide*, Release 12.2.

Configuration Tasks

See the following sections for configuration tasks for the IKE: Initiate Aggressive Mode feature. Each task in the list is identified as either required or optional.

- [Configuring RADIUS Tunnel Attributes](#) (required)
- [Verifying RADIUS Tunnel Attribute Configurations](#) (optional)

Configuring RADIUS Tunnel Attributes

To configure the Tunnel-Client-Endpoint and Tunnel-Password attributes within the ISAKMP peer configuration, use the following commands beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# crypto map <i>map-name</i> isakmp authorization list <i>list-name</i>	Enables IKE querying of AAA for tunnel attributes in aggressive mode.
Step 2	Router(config)# crypto isakmp peer { ip-address <i>ip-address</i> fqdn <i>fqdn</i> }	Enables an IPSec peer for IKE querying of AAA for tunnel attributes in aggressive mode and enters ISAKMP policy configuration mode.
Step 3	Router(config-isakmp)# set aggressive-mode client-endpoint <i>client-endpoint</i>	Specifies the Tunnel-Client-Endpoint attribute within an ISAKMP peer configuration.
Step 4	Router(config-isakmp)# set aggressive-mode password <i>password</i>	Specifies the Tunnel-Password attribute within an ISAKMP peer configuration.

Verifying RADIUS Tunnel Attribute Configurations

To verify that the Tunnel-Client-Endpoint and Tunnel-Password attributes have been configured within the ISAKMP peer policy, use the **show running-config** global configuration command.

Troubleshooting Tips

To troubleshoot the IKE: Initiate Aggressive Mode feature, use the following debug commands in EXEC mode:

Command	Purpose
Router# debug aaa authorization	Displays information on AAA authorization.
Router# debug crypto isakmp	Displays messages about IKE events.
Router# debug radius	Displays information associated with the RADIUS.

Configuration Examples

This section provides the following configuration examples:

- [Hub Configuration Example](#)
- [Spoke Configuration Example](#)
- [RADIUS User Profile Example](#)

Hub Configuration Example

The following example shows how to configure a hub for a hub-and-spoke topology that supports aggressive mode using RADIUS tunnel attributes:

```
!The AAA configurations are as follows:
aaa new-model
aaa authorization network ike group radius
aaa authentication login default group radius
!
! The Radius configurations are as follows:
radius-server host 1.1.1.1 auth-port 1645 acct-port 1646
radius-server key rad123
!
! The IKE configurations are as follows:
crypto isakmp policy 1
 authentication pre-share
!
! The IPsec configurations are as follows:
crypto ipsec transform-set trans1 esp-3des esp-sha-hmac
!
crypto dynamic-map Dmap 10
 set transform-set trans1
!
crypto map Testtag isakmp authorization list ike
crypto map Testtag 10 ipsec-isakmp dynamic Dmap
!
interface Ethernet0
 ip address 4.4.4.1 255.255.255.0
 crypto map Testtag
!
interface Ethernet1
 ip address 2.2.2.1 255.255.255.0
```

Spoke Configuration Example

The following example shows how to configure a spoke for a hub-and-spoke topology that supports aggressive mode using RADIUS tunnel attributes:

```
!The IKE configurations are as follows:
crypto isakmp policy 1
 authentication pre-share
!
! The IPsec configurations are as follows:
crypto ipsec transform-set trans1 esp-3des esp-sha-hmac
 access-list 101 permit ip 3.3.3.0 0.0.0.255 2.2.2.0 0.0.0.255
!
! Initiate aggressive mode using Radius tunnel attributes
crypto isakmp peer address 4.4.4.1
 set aggressive-mode client-endpoint user-fqdn user@cisco.com
 set aggressive-mode password cisco123
!
crypto map Testtag 10 ipsec-isakmp
 set peer 4.4.4.1
 set transform-set trans1
 match address 101
!
interface Ethernet0
 ip address 5.5.5.1 255.255.255.0
 crypto map Testtag
!
```

```
interface Ethernet1
 ip address 3.3.3.1 255.255.255.0
```

RADIUS User Profile Example

The following is an example of a user profile on a RADIUS server that supports the Tunnel-Client-Endpoint and Tunnel-Password attributes:

```
user@cisco.com Password = "cisco", Service-Type = Outbound
Tunnel-Medium-Type = :1:IP,
Tunnel-Type = :1:ESP,
Cisco:Avpair = "ipsec:tunnel-password=cisco123",
Cisco:Avpair = "ipsec:key-exchange=ike"
```

Command Reference

The following commands are introduced or modified in the feature or features

- **crypto isakmp peer**
- **set aggressive-mode client-endpoint**
- **set aggressive-mode password**

For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html.

For information about all Cisco IOS commands, see the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the Master Command List.

Security for VPNs with IPSec

Configuring Security for VPNs with IPSec

This module describes how to configure basic IP Security (IPSec) virtual private networks (VPNs). IPSec is a framework of open standards developed by the Internet Engineering Task Force (IETF). It provides security for transmission of sensitive information over unprotected networks such as the Internet. IPSec acts at the network layer, protecting and authenticating IP packets between participating IPSec devices (“peers”), such as Cisco routers.

Module History

This module was first published on May 2, 2005, and last updated on May 2, 2005.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all features. To find information about feature support and configuration, use the [“Feature Information for Security for VPNs with IPSec” section on page 35](#).

Contents

Prerequisites for Configuring Security for VPNs with IPSec

IKE Configuration

You must configure Internet Key Exchange (IKE) as described in the module “Configuring Internet Key Exchange Security for IPSec VPNs.”

Even if you decide to not use IKE, you still must disable it as described in the module “Configuring Internet Key Exchange for IPSec VPNs.”

Ensure Access Lists Are Compatible with IPSec

IKE uses UDP port 500. The IPSec Encapsulating Security Payload (ESP) and Authentication Header (AH) protocols use protocol numbers 50 and 51. Ensure that your access lists are configured so that protocol 50, 51, and User Datagram Protocol (UDP) port 500 traffic is not blocked at interfaces used by IPSec. In some cases you might need to add a statement to your access lists to explicitly permit this traffic.

Restrictions for Configuring Security for VPNs with IPSec

Unicast IP Datagram Application Only

At this time, IPSec can be applied to unicast IP datagrams only. Because the IPSec Working Group has not yet addressed the issue of group key distribution, IPSec does not currently work with multicasts or broadcast IP datagrams.

NAT Configuration

If you use Network Address Translation (NAT), you should configure static NAT translations so that IPSec works properly. In general, NAT translation should occur before the router performs IPSec encapsulation; in other words, IPSec should be working with global addresses.

Information About Configuring Security for VPNs with IPSec

To configure basic IPSec VPNs, you should understand the following concepts:

- [Supported Standards, page 2](#)
- [Supported Hardware, Switching Paths, and Encapsulation, page 4](#)
- [IPSec Functionality Overview, page 6](#)
- [IPSec Traffic Nested to Multiple Peers, page 8](#)

Supported Standards

Cisco implements the following standards with this feature:

- IPSec—IP Security Protocol. IPSec is a framework of open standards that provides data confidentiality, data integrity, and data authentication between participating peers. IPSec provides these security services at the IP layer; it uses IKE to handle negotiation of protocols and algorithms

based on local policy, and to generate the encryption and authentication keys to be used by IPSec. IPSec can be used to protect one or more data flows between a pair of hosts, between a pair of security gateways, or between a security gateway and a host.

Note The term IPSec is sometimes used to describe the entire protocol of IPSec data services and IKE security protocols and is also sometimes used to describe only the data services.

IPSec is documented in a series of Internet Drafts, all available at <http://www.ietf.org/html.charters/ipsec-charter.html>.

- IKE—A hybrid protocol that implements Oakley and SKEME key exchanges inside the ISAKMP framework. While IKE can be used with other protocols, its initial implementation is with the IPSec protocol. IKE provides authentication of the IPSec peers, negotiates IPSec security associations, and establishes IPSec keys.

The component technologies implemented for IPSec include:

- AES—Advanced Encryption Standard. A cryptographic algorithm that protects sensitive, unclassified information. AES is privacy transform for IPSec and IKE and has been developed to replace the DES. AES is designed to be more secure than DES: AES offers a larger key size, while ensuring that the only known approach to decrypt a message is for an intruder to try every possible key. AES has a variable key length—the algorithm can specify a 128-bit key (the default), a 192-bit key, or a 256-bit key.
- DES—Data Encryption Standard. An algorithm that is used to encrypt packet data. Cisco IOS implements the mandatory 56-bit DES-CBC with Explicit IV. Cipher Block Chaining (CBC) requires an initialization vector (IV) to start encryption. The IV is explicitly given in the IPSec packet. For backwards compatibility, Cisco IOS IPSec also implements the RFC 1829 version of ESP DES-CBC.

Cisco IOS also implements Triple DES (168-bit) encryption, depending on the software versions available for a specific platform. Triple DES (3DES) is a strong form of encryption that allows sensitive information to be transmitted over untrusted networks. It enables customers to utilize network layer encryption.

Note Cisco IOS images with strong encryption (including, but not limited to, 56-bit data encryption feature sets) are subject to United States government export controls, and have a limited distribution. Images to be installed outside the United States require an export license. Customer orders might be denied or subject to delay due to United States government regulations. Contact your sales representative or distributor for more information, or send e-mail to export@cisco.com.

- SEAL—Software Encryption Algorithm. An alternative algorithm to software-based DES, 3DES, and AES. SEAL encryption uses a 160-bit encryption key and has a lower impact to the CPU when compared to other software-based algorithms.
- MD5 (HMAC variant)—MD5 (Message Digest 5) is a hash algorithm. HMAC is a keyed hash variant used to authenticate data.
- SHA (HMAC variant)—SHA (Secure Hash Algorithm) is a hash algorithm. HMAC is a keyed hash variant used to authenticate data.

IPSec as implemented in Cisco IOS software supports the following additional standards:

- AH—Authentication Header. A security protocol which provides data authentication and optional anti-replay services. AH is embedded in the data to be protected (a full IP datagram).

- ESP—Encapsulating Security Payload. A security protocol which provides data privacy services and optional data authentication, and anti-replay services. ESP encapsulates the data to be protected.

Supported Hardware, Switching Paths, and Encapsulation

IPSec has certain requirements for hardware, switching paths, and encapsulation methods as follows:

- [Supported Hardware](#)
- [Supported Switching Paths](#)
- [Supported Encapsulation](#)

Supported Hardware

This section contains the following subsections:

- [VPN Accelerator Module \(VAM\) Support](#)
- [AIMs and NM Support](#)

VPN Accelerator Module (VAM) Support

The VAM is a single-width acceleration module. It provides high-performance, hardware-assisted tunneling and encryption services suitable for VPN remote access, site-to-site intranet, and extranet applications. It also provides platform scalability and security while working with all services necessary for successful VPN deployments—security, quality of service (QoS), firewall and intrusion detection, service-level validation, and management. The VAM off-loads IPSec processing from the main processor, thus freeing resources on the processor engines for other tasks.

The VAM provides hardware-accelerated support for the following multiple encryption functions:

- 56-bit DES standard mode: CBC
- 3-Key Triple DES (168-bit)
- SHA-1 and MD5
- Rivest, Shamir, Adelman (RSA) public-key algorithm
- Diffie-Hellman key exchange RC4-40

For more information on VAMs, see the document “VPN Acceleration Module (VAM).”

AIMs and NM Support

The data encryption Advanced Integration Module (AIM) and Network Module (NM) provide hardware-based encryption.

The data encryption AIMs and NM are hardware Layer 3 (IPSec) encryption modules and provide DES and Triple DES IPSec encryption for multiple T1s or E1s of bandwidth. These products also have hardware support for Diffie-Hellman, RSA, and DSA key generation.

Before using either module, note that RSA manual keying is not supported.

See [Table 44](#) to determine which VPN encryption module to use.

IPPCP Software for Use with AIMS and NMs in Cisco 2600 and Cisco 3600 Series Routers

Software IPPCP with AIMS and NMs allow customers to use Lempel-Ziv-Stac (LZS) software compression with IPSec when a VPN module is in Cisco 2600 and Cisco 3600 series routers, allowing users to effectively increase the bandwidth on their interfaces.

Without IPPCP software, compression is not supported with the VPN encryption hardware AIM and NM; that is, a user had to remove the VPN module from the router and run software encryption with software compression. IPPCP enables all VPN modules to support LZS compression in software when the VPN module is in the router, thereby, allowing users to configure data compression and increase their bandwidth, which is useful for a low data link.

Without IPPCP, compression occurs at Layer 2, and encryption occurs at Layer 3. After a data stream is encrypted, it is passed on for compression services. When the compression engine receives the encrypted data streams, the data expands and does not compress. This feature enables both compression and encryption of the data to occur at Layer 3 by selecting LZS with the IPSec transform set; that is, LZS compression occurs before encryption, and it is able to get better compression ratio.

Table 44 AIM/VPN Encryption Module Support by Cisco IOS Release

	Encryption Module Support by Cisco IOS Release				
Platform	12.2(13)T	12.3(4)T	12.3(5)	12.3(6)	12.3(7)T

Cisco 3745					

For more information on AIMS and NM, see [Installing Advanced Integration Modules in Cisco 2600 Series, Cisco 3600 Series, and Cisco 3700 Series Routers](#).

Supported Switching Paths

Table 45 lists the supported switching paths that work with IPSec.

Table 45 **Supported Switching Paths for IPSec**

Switching Paths	Examples
Process switching	<pre>interface ethernet0/0 no ip route-cache</pre>
Fast switching	<pre>interface ethernet0/0 ip route-cache ! Ensure that you will not hit flow switching. no ip route-cache flow ! Disable CEF for the interface, which supercedes global CEF. no ip route-cache cef</pre>
Cisco Express Forwarding (CEF)	<pre>ip cef interface ethernet0/0 ip route-cache ! Ensure that you will not hit flow switching. no ip route-cache flow</pre>
Fast-flow switching	<pre>interface ethernet0/0 ip route-cache ! Enable flow switching p route-cache flow ! Disable CEF for the interface. no ip route-cache cef</pre>
CEF-flow switching	<pre>! Enable global CEF. ip cef interface ethernet0/0 ip route-cache ip route-cache flow ! Enable CEF for the interface ip route-cache cef</pre>

Supported Encapsulation

IPSec works with the following serial encapsulations: High-Level Data-Links Control (HDLC), PPP, and Frame Relay.

IPSec also works with the Generic Routing Encapsulation (GRE) and IPinIP Layer 3, Layer 2 Forwarding (L2F), Layer 2 Tunneling Protocol (L2TP), Data Link Switching+ (DLSw+), and SRB tunneling protocols; however, multipoint tunnels are not supported. Other Layer 3 tunneling protocols may not be supported for use with IPSec.

Because the IPSec Working Group has not yet addressed the issue of group key distribution, IPSec currently cannot be used to protect group traffic (such as broadcast or multicast traffic).

IPSec Functionality Overview

IPSec provides the following network security services. (In general, local security policy dictates the use of one or more of these services.)

- **Data Confidentiality**—The IPSec sender can encrypt packets before transmitting them across a network.
- **Data Integrity**—The IPSec receiver can authenticate packets sent by the IPSec sender to ensure that the data has not been altered during transmission.

- Data Origin Authentication—The IPSec receiver can authenticate the source of the IPSec packets sent. This service is dependent upon the data integrity service.
- Anti-Replay—The IPSec receiver can detect and reject replayed packets.

IPSec provides secure *tunnels* between two peers, such as two routers. You define which packets are considered sensitive and should be sent through these secure tunnels, and you define the parameters that should be used to protect these sensitive packets, by specifying characteristics of these tunnels. Then, when the IPSec peer recognizes such a sensitive packet, the peer sets up the appropriate secure tunnel and sends the packet through the tunnel to the remote peer. (The use of the term *tunnel* in this chapter does not refer to using IPSec in tunnel mode.)

More accurately, these *tunnels* are sets of security associations (SAs) that are established between two IPSec peers. The SAs define which protocols and algorithms should be applied to sensitive packets and specify the keying material to be used by the two peers. SAs are unidirectional and are established per security protocol (AH or ESP).

With IPSec you define what traffic should be protected between two IPSec peers by configuring access lists and applying these access lists to interfaces by way of crypto map sets. Therefore, traffic may be selected on the basis of source and destination address, and optionally Layer 4 protocol, and port. (The access lists used for IPSec are used only to determine which traffic should be protected by IPSec, not which traffic should be blocked or permitted through the interface. Separate access lists define blocking and permitting at the interface.)

A crypto map set can contain multiple entries, each with a different access list. The crypto map entries are searched in order—the router attempts to match the packet to the access list specified in that entry.

When a packet matches a **permit** entry in a particular access list, and the corresponding crypto map entry is tagged as **cisco**, connections are established if necessary. If the crypto map entry is tagged as **ipsec-isakmp**, IPSec is triggered. If no SA exists that IPSec can use to protect this traffic to the peer, IPSec uses IKE to negotiate with the remote peer to set up the necessary IPSec SAs on behalf of the data flow. The negotiation uses information specified in the crypto map entry as well as the data flow information from the specific access list entry. (The behavior is different for dynamic crypto map entries. See the section “[Creating Dynamic Crypto Maps](#)” section later in this module.)

If the crypto map entry is tagged as **ipsec-manual**, IPSec is triggered. If no SA exists that IPSec can use to protect this traffic to the peer, the traffic is dropped. In this case, the SAs are installed via the configuration, without the intervention of IKE. If the SAs did not exist, IPSec did not have all of the necessary pieces configured.

Once established, the set of SAs (outbound, to the peer) is then applied to the triggering packet and to subsequent applicable packets as those packets exit the router. “Applicable” packets are packets that match the same access list criteria that the original packet matched. For example, all applicable packets could be encrypted before being forwarded to the remote peer. The corresponding inbound SAs are used when processing the incoming traffic from that peer.

Multiple IPSec tunnels can exist between two peers to secure different data streams, with each tunnel using a separate set of SAs. For example, some data streams might be authenticated only while other data streams must both be encrypted and authenticated.

Access lists associated with IPSec crypto map entries also represent which traffic the router requires to be protected by IPSec. Inbound traffic is processed against the crypto map entries—if an unprotected packet matches a **permit** entry in a particular access list associated with an IPSec crypto map entry, that packet is dropped because it was not sent as an IPSec-protected packet.

Crypto map entries also include transform sets. A transform set is an acceptable combination of security protocols, algorithms, and other settings to apply to IPSec protected traffic. During the IPSec SA negotiation, the peers agree to use a particular transform set when protecting a particular data flow.

IPSec Traffic Nested to Multiple Peers

You can nest IPSec traffic to a series of IPSec peers. For example, in order for traffic to traverse multiple firewalls (these firewalls have a policy of not letting through traffic that they have not authenticated), the router must establish IPSec tunnels with each firewall in turn. The “nearer” firewall becomes the “outer” IPSec peer.

In the example shown in [Figure 54](#), Router A encapsulates the traffic destined for Router C in IPSec (Router C is the inner IPSec peer). However, before Router A can send this traffic, it must first reencapsulate this traffic in IPSec in order to send it to Router B (Router B is the “outer” IPSec peer).

It is possible for the traffic between the “outer” peers to have one kind of protection (such as data authentication) and for traffic between the “inner” peers to have different protection (such as both data authentication and encryption).

How to Configure IPSec VPNs

Perform the tasks in the following sections to create IPSec VPNs:

- [Creating Crypto Access Lists, page 8](#)
- [Defining Transform Sets: A Combination of Security Protocols and Algorithms, page 14](#)
- [Creating Crypto Map Sets, page 17](#)
- [Applying Crypto Map Sets to Interfaces, page 30](#)

Creating Crypto Access Lists

To create crypto access lists that define which traffic is protected via IPSec tunnels, you should understand the following concepts:

- [Crypto Access List Overview](#)
- [When to Use the permit and deny Keywords in Crypto Access Lists](#)
- [Mirror Image Crypto Access Lists at Each IPSec Peer](#)
- [When to Use the any Keyword in Crypto Access Lists](#)

Crypto Access List Overview

Crypto access lists are used to define which IP traffic is protected by crypto and which traffic is not protected by crypto. (These access lists are *not* the same as regular access lists, which determine what traffic to forward or block at an interface.) For example, access lists can be created to protect all IP traffic between Subnet A and Subnet Y or Telnet traffic between Host A and Host B.

The access lists themselves are not specific to IPSec. It is the crypto map entry referencing the specific access list that defines whether IPSec processing is applied to the traffic matching a **permit** in the access list.

Crypto access lists associated with IPSec crypto map entries have four primary functions:

- Select outbound traffic to be protected by IPSec (permit = protect).
- Indicate the data flow to be protected by the new SAs (specified by a single **permit** entry) when initiating negotiations for IPSec security associations.
- Process inbound traffic in order to filter out and discard traffic that should have been protected by IPSec.
- Determine whether or not to accept requests for IPSec security associations on behalf of the requested data flows when processing IKE negotiation from the IPSec peer.
- Negotiation is performed only for **ipsec-isakmp** crypto map entries. In order to be accepted, if the peer initiates the IPSec negotiation, it must specify a data flow that is “permitted” by a crypto access list associated with an **ipsec-isakmp** crypto map entry.

If you want certain traffic to receive one combination of IPSec protection (for example, authentication only) and other traffic to receive a different combination of IPSec protection (for example, both authentication and encryption), you need to create two different crypto access lists to define the two different types of traffic. These different access lists are then used in different crypto map entries which specify different IPSec policies.

When to Use the permit and deny Keywords in Crypto Access Lists

Crypto protection can be permitted or denied for certain IP traffic in a crypto access list as follows:

- To protect IP traffic that matches the specified policy conditions in its corresponding crypto map entry, use the **permit** keyword in an access list.
- To refuse protection for IP traffic that matches the specified policy conditions in its corresponding crypto map entry, use the **deny** keyword in an access list.

Note

IP traffic is not protected by crypto if it is refused protection in all of the crypto map entries for an interface.

After the corresponding crypto map entry is defined and the crypto map set is applied to the interface, the defined crypto access list is applied to an interface. Different access lists must be used in different entries of the same crypto map set. However, both inbound and outbound traffic is evaluated against the same “outbound” IPSec access list. Therefore, the access list’s criteria is applied in the forward direction to traffic exiting your router and in the reverse direction to traffic entering your router.

In [Figure 55](#), IPSec protection is applied to traffic between Host 10.0.0.1 and Host 192.168.0.2 as the data exits Router A’s S0 interface en route to Host 192.168.0.2. For traffic from Host 10.0.0.1 to Host 192.168.0.2, the access list entry on Router A is evaluated as follows:

```
source = host 10.0.0.1
dest = host 192.168.0.2
```

For traffic from Host 192.168.0.2 to Host 10.0.0.1, that same access list entry on Router A is evaluated as follows:

```
source = host 192.168.0.2
dest = host 10.0.0.1
```

Figure 55 How Crypto Access Lists Are Applied for Processing IPSec

If you configure multiple statements for a given crypto access list that is used for IPSec, in general the first **permit** statement that is matched is the statement used to determine the scope of the IPSec SA. That is, the IPSec SA is set up to protect traffic that meets the criteria of the matched statement only. Later, if traffic matches a different **permit** statement of the crypto access list, a new, separate IPSec SA is negotiated to protect traffic matching the newly matched access list statement.

Any unprotected inbound traffic that matches a **permit** entry in the crypto access list for a crypto map entry flagged as IPSec is dropped, because this traffic was expected to be protected by IPSec.

Note

If you view your router's access lists by using a command such as **show ip access-lists**, *all* extended IP access lists are shown in the command output. This display output includes extended IP access lists that are used for traffic filtering purposes and those that are used for crypto. The **show** command output does not differentiate between the different uses of the extended access lists.

The following example shows that if overlapping networks are used, then the most specific networks are defined in crypto sequence numbers before less specific networks are defined. In this example, the more specific network is covered by the crypto map sequence number 10, followed by the less specific network in the crypto map, which is sequence number 20.

```
crypto map mymap 10 ipsec-isakmp
  set peer 192.168.1.1
  set transform-set test
  match address 101
crypto map mymap 20 ipsec-isakmp
  set peer 192.168.1.2
  set transform-set test
  match address 102
```

```
access-list 101 permit ip 10.1.1.0 0.0.0.255 172.16.1.0 0.0.0.255  
access-list 102 permit ip 10.0.0.0 0.255.255.255 172.16.0.0 0.15.255.255
```

The following example shows how having a **deny** keyword in one crypto map sequence number and having a **permit** keyword for the same subnet and IP range in another crypto map sequence number is not supported.

```
crypto map mymap 10 ipsec-isakmp  
  set peer 192.168.1.1  
  set transform-set test  
  match address 101  
crypto map mymap 20 ipsec-isakmp  
  set peer 192.168.1.2  
  set transform-set test  
  match address 102  
  
access-list 101 deny ip 10.1.1.0 0.0.0.255 172.16.1.0 0.0.0.255  
access-list 101 permit ip 10.0.0.0 0.255.255.255 172.16.0.0 0.15.255.255  
  
access-list 102 permit ip 10.1.1.0 0.0.0.255 172.16.1.0 0.0.0.255
```

Mirror Image Crypto Access Lists at Each IPSec Peer

Cisco recommends that for every crypto access list specified for a static crypto map entry that you define at the local peer, you define a “mirror image” crypto access list at the remote peer. This ensures that traffic that has IPSec protection applied locally can be processed correctly at the remote peer. (The crypto map entries themselves must also support common transforms and must refer to the other system as a peer.)

[Figure 56](#) shows some sample scenarios when you have mirror image access lists and when you do not have mirror image access lists.

Figure 56 Mirror Image vs. Nonmirror Image Crypto Access Lists (for IPSec)

As Figure 56 indicates, IPSec SAs can be established as expected whenever the two peers' crypto access lists are mirror images of each other. However, an IPSec SA can be established only some of the time when the access lists are not mirror images of each other. This can happen in the case where an entry in one peer's access list is a subset of an entry in the other peer's access list, such as shown in Cases 3 and 4 of Figure 56. IPSec SA establishment is critical to IPSec—without SAs, IPSec does not work, causing any packets matching the crypto access list criteria to be silently dropped instead of being forwarded with IPSec.

In Figure 56, an SA cannot be established in Case 4. This is because SAs are always requested according to the crypto access lists at the initiating packet's end. In Case 4, Router N requests that all traffic between Subnet X and Subnet Y be protected, but this is a superset of the specific flows permitted by the crypto access list at Router M so the request is therefore not permitted. Case 3 works because Router M's request is a subset of the specific flows permitted by the crypto access list at Router N.

Because of the complexities introduced when crypto access lists are not configured as mirror images at peer IPSec devices, Cisco strongly encourages you to use mirror image crypto access lists.

When to Use the **any** Keyword in Crypto Access Lists

When you create crypto access lists, using the **any** keyword could cause problems. Cisco discourages the use of the **any** keyword to specify source or destination addresses.

The **any** keyword in a **permit** statement is discouraged when you have multicast traffic flowing through the IPSec interface; the **any** keyword can cause multicast traffic to fail.

The **permit any any** statement is strongly discouraged, because this causes all outbound traffic to be protected (and all protected traffic sent to the peer specified in the corresponding crypto map entry) and requires protection for all inbound traffic. Then, all inbound packets that lack IPSec protection are silently dropped, including packets for routing protocols, Network Time Protocol (NTP), echo, echo response, and so on.

You need to be sure you define which packets to protect. If you *must* use the **any** keyword in a **permit** statement, you must preface that statement with a series of **deny** statements to filter out any traffic (that would otherwise fall within that **permit** statement) that you do not want to be protected.

Also, use of **any** keyword in access control lists (ACLs) with reverse route injection (RRI) is not supported. (For more information on RRI, see the section “[Creating Crypto Map Sets](#).”)

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **access-list** *access-list-number* {**deny** | **permit**} *protocol source source-wildcard destination destination-wildcard* [**log**]
or
ip access-list extended *name*
4. Repeat Step 3 for each crypto access list you want to create.

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	access-list <i>access-list-number</i> { deny permit } <i>protocol source source-wildcard destination destination-wildcard</i> [log] Example: Router(config)# access-list 100 permit ip 10.0.68.0 0.0.0.255 10.1.1.0 0.0.0.255 or ip access-list extended <i>name</i> Example: Router(config)# ip access-list extended vpn-tunnel	Specifies conditions to determine which IP packets are protected. ¹ Enable or disable crypto for traffic that matches these conditions. Tip Cisco recommends that you configure “mirror image” crypto access lists for use by IPSec and that you avoid using the any keyword.
Step 4	—	Repeat Step 3 for each crypto access list you want to create.

1. You specify conditions using an IP access list designated by either a number or a name. The **access-list** command designates a numbered extended access list; the **ip access-list extended** command designates a named access list.

What to Do Next

After at least one crypto access list is created, a transform set needs to be defined as described in the section [“Defining Transform Sets: A Combination of Security Protocols and Algorithms.”](#)

Next the crypto access lists need to be associated to particular interfaces when you configure and apply crypto map sets to the interfaces are configured and applied (following instructions in the sections [“Creating Crypto Map Sets”](#) and [“Applying Crypto Map Sets to Interfaces”](#)).

Defining Transform Sets: A Combination of Security Protocols and Algorithms

Perform this task to define a transform set that is to be used by the IPSec peers during IPSec security association negotiations with IKE.

Restrictions

If you are specifying SEAL encryption, note the following restrictions:

- Your router and the other peer must not have hardware IPSec encryption.
- Your router and the other peer must support IPSec.
- Your router and the other peer must support the k9 subsystem.
- SEAL encryption is available only on Cisco equipment. Therefore, interoperability is not possible.

About Transform Sets

A transform set represents a certain combination of security protocols and algorithms. During the IPSec SA negotiation, the peers agree to use a particular transform set for protecting a particular data flow.

You can specify multiple transform sets, and then specify one or more of these transform sets in a crypto map entry. The transform set defined in the crypto map entry is used in the IPSec SA negotiation to protect the data flows specified by that crypto map entry’s access list.

During IPSec security association negotiations with IKE, the peers search for a transform set that is the same at both peers. When such a transform set is found, it is selected and is applied to the protected traffic as part of both peers’ IPSec SAs. (With manually established SAs, there is no negotiation with the peer, so both sides must specify the same transform set.)

If you change a transform set definition, the change is only applied to crypto map entries that reference the transform set. The change is not applied to existing security associations, but is used in subsequent negotiations to establish new SAs. If you want the new settings to take effect sooner, you can clear all or part of the SA database by using the **clear crypto sa** command

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec transform-set** *transform-set-name* *transform1* [*transform2* [*transform3*]]

4. **mode** [**tunnel** | **transport**]
5. **exit**
6. **clear crypto sa** [peer {*ip-address* | **peer-name**} | sa map *map-name* | sa entry *destination-address protocol spi*]
7. **show crypto ipsec transform-set** [*tag transform-set-name*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto ipsec transform-set <i>transform-set-name transform1</i> [<i>transform2</i> [<i>transform3</i>]] Example: Router(config)# crypto ipsec transform-set aesset esp-aes 256 esp-sha-hmac	Defines a transform set and enters crypto transform configuration mode. There are complex rules defining which entries you can use for the transform arguments. These rules are explained in the command description for the crypto ipsec transform-set command, and Table 46 provides a list of allowed transform combinations.
Step 4	mode [tunnel transport] Example: Router(cfg-crypto-tran)# mode transport	(Optional) Changes the mode associated with the transform set. The mode setting is applicable only to traffic whose source and destination addresses are the IPSec peer addresses; it is ignored for all other traffic. (All other traffic is in tunnel mode only.)
Step 5	exit Example: Router(config)# exit	Exits global configuration mode.

	Command or Action	Purpose
Step 6	<pre>clear crypto sa [peer {ip-address peer-name} sa map map-name sa entry destination-address protocol spi]</pre> Example: Router# clear crypto sa	(Optional) Clears existing IPsec security associations so that any changes to a transform set takes effect on subsequently established security associations. Manually established SAs are reestablished immediately. - Using the clear crypto sa command without parameters clear out the full SA database, which clears out active security sessions. - You may also specify the peer, map, or entry keywords to clear out only a subset of the SA database.
Step 7	<pre>show crypto ipsec transform-set [tag transform-set-name]</pre> Example: Router# show crypto ipsec transform-set	(Optional) Displays the configured transform sets.

Table 46 shows allowed transform combinations.

Table 46 Allowed Transform Combinations

Transform Type	Transform	Description
AH Transform	ah-md5-hmac	AH with the MD5 (a Hash-based Message Authentication Code [HMAC] variant) authentication algorithm
	ah-sha-hmac	AH with the SHA (an HMAC variant) authentication algorithm
ESP Encryption Transform	esp-aes	ESP with the 128-bit AES encryption algorithm
	esp-aes 192	ESP with the 192-bit AES encryption algorithm
	esp-aes 256	ESP with the 256-bit AES encryption algorithm
	esp-des	ESP with the 56-bit DES encryption algorithm
	esp-3des	ESP with the 168-bit DES encryption algorithm (3DES or Triple DES)
	esp-null	Null encryption algorithm
	esp-seal	ESP with the 160-bit SEAL encryption algorithm.

Table 46 *Allowed Transform Combinations (continued)*

Transform Type	Transform	Description
ESP Authentication Transform	esp-md5-hmac	ESP with the MD5 (HMAC variant) authentication algorithm
	esp-sha-hmac	ESP with the SHA (HMAC variant) authentication algorithm
IP Compression Transform	comp-lzs	IP compression with the LZS algorithm

What to Do Next

After you have defined a transform set, you should create a crypto map as specified in the section [“Creating Crypto Map Sets.”](#)

Creating Crypto Map Sets

See one of the following sections, as appropriate, to help create crypto map sets:

- [Creating Static Crypto Maps](#)
- [Creating Dynamic Crypto Maps](#)
- [Creating Crypto Map Entries to Establish Manual SAs](#)

Prerequisites

Before you create crypto map entries, you should determine which type of crypto map—static, dynamic, or manual—best addresses the needs of your network. You should also understand the following concepts:

- [About Crypto Maps](#)
- [Load Sharing Among Crypto Maps](#)
- [Crypto Map Guidelines](#)

About Crypto Maps

Crypto map entries created for IPSec pull together the various parts used to set up IPSec SAs, including:

- Which traffic should be protected by IPSec (per a crypto access list)
- The granularity of the flow to be protected by a set of SAs
- Where IPSec-protected traffic should be sent (who the remote IPSec peer is)
- The local address to be used for the IPSec traffic (See the section [“Applying Crypto Map Sets to Interfaces”](#) for more details.)
- What IPSec SA should be applied to this traffic (selecting from a list of one or more transform sets)
- Whether SAs are manually established or are established via IKE
- Other parameters that might be necessary to define an IPSec SA

How Crypto Maps Work

Crypto map entries with the same crypto map name (but different map sequence numbers) are grouped into a crypto map set. Later, you apply these crypto map sets to interfaces; then, all IP traffic passing through the interface is evaluated against the applied crypto map set. If a crypto map entry sees outbound IP traffic that should be protected and the crypto map specifies the use of IKE, a SA is negotiated with the remote peer according to the parameters included in the crypto map entry; otherwise, if the crypto map entry specifies the use of manual SAs, an SA should have already been established via configuration. (If a dynamic crypto map entry sees outbound traffic that should be protected and no security association exists, the packet is dropped.)

The policy described in the crypto map entries is used during the negotiation of SAs. If the local router initiates the negotiation, it uses the policy specified in the static crypto map entries to create the offer to be sent to the specified IPSec peer. If the IPSec peer initiates the negotiation, the local router checks the policy from the static crypto map entries, as well as any referenced dynamic crypto map entries to decide whether to accept or reject the peer's request (offer).

For IPSec to succeed between two IPSec peers, both peers' crypto map entries must contain compatible configuration statements.

Compatible Crypto Maps: Establishing an SA

When two peers try to establish a SA, they must each have at least one crypto map entry that is compatible with one of the other peer's crypto map entries. For two crypto map entries to be compatible, they must at least meet the following criteria:

- The crypto map entries must contain compatible crypto access lists (for example, mirror image access lists). In the case where the responding peer is using dynamic crypto maps, the entries in the local crypto access list must be "permitted" by the peer's crypto access list.
- The crypto map entries must each identify the other peer (unless the responding peer is using dynamic crypto maps).
- The crypto map entries must have at least one transform set in common.

Load Sharing Among Crypto Maps

You can define multiple remote peers using crypto maps to allow for load sharing. Load sharing is useful because if one peer fails, there continues to be a protected path. The peer that packets are actually sent to is determined by the last peer that the router heard from (received either traffic or a negotiation request from) for a given data flow. If the attempt fails with the first peer, IKE tries the next peer on the crypto map list.

If you are not sure how to configure each crypto map parameter to guarantee compatibility with other peers, you might consider configuring dynamic crypto maps as described in the section "[Creating Dynamic Crypto Maps](#)." Dynamic crypto maps are useful when the establishment of the IPSec tunnels is initiated by the remote peer (such as in the case of an IPSec router fronting a server). They are not useful if the establishment of the IPSec tunnels is locally initiated, because the dynamic crypto maps are policy templates, not complete statements of policy. (Although the access lists in any referenced dynamic crypto map entry are used for crypto packet filtering.)

Crypto Map Guidelines

You can apply only one crypto map set to a single interface. The crypto map set can include a combination of IPSec/IKE and IPSec/manual entries. Multiple interfaces can share the same crypto map set if you want to apply the same policy to multiple interfaces.

If you create more than one crypto map entry for a given interface, use the *seq-num* argument of each map entry to rank the map entries: the lower the *seq-num* argument, the higher the priority. At the interface that has the crypto map set, traffic is evaluated against higher priority map entries first.

You must create multiple crypto map entries for a given interface if any of the following conditions exist:

- If different data flows are to be handled by separate IPSec peers.
- If you want to apply different IPSec security to different types of traffic (to the same or separate IPSec peers); for example, if you want traffic between one set of subnets to be authenticated, and traffic between another set of subnets to be both authenticated and encrypted. In this case the different types of traffic should have been defined in two separate access lists, and you must create a separate crypto map entry for each crypto access list.
- If you are not using IKE to establish a particular set of security associations, and want to specify multiple access list entries, you must create separate access lists (one per **permit** entry) and specify a separate crypto map entry for each access list.

Creating Static Crypto Maps

When IKE is used to establish SAs, the IPSec peers can negotiate the settings they use for the new security associations. This means that you can specify lists (such as lists of acceptable transforms) within the crypto map entry.

Perform this task to create crypto map entries that use IKE to establish the SAs.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name seq-num ipsec-isakmp*
4. **match address** *access-list-id*
5. **set peer** {*hostname* | *ip-address*}
6. **set transform-set** *transform-set-name1* [*transform-set-name2...transform-set-name6*]
7. **set security-association lifetime** {**seconds** *seconds* | **kilobytes** *kilobytes*}
8. **set security-association level per-host**
9. **set pfs** [**group1** | **group2** | **group5**]
10. **exit**
11. **exit**
12. **show crypto map** [**interface** *interface* | tag *map-name*]

DETAILED STEPS

	Command	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto map <i>map-name seq-num ipsec-isakmp</i> Example: Router(config)# crypto map static-map 1 ipsec-isakmp	Names the crypto map entry to create (or modify), and enters crypto map configuration mode.
Step 4	match address <i>access-list-id</i> Example: Router(config-crypto-m)# match address vpn-tunnel	Names an extended access list. This access list determines which traffic should be protected by IPSec and which traffic should not be protected by IPSec security in the context of this crypto map entry.
Step 5	set peer { <i>hostname</i> <i>ip-address</i> } Example: Router(config-crypto-m)# set-peer 192.168.101.1	Specifies a remote IPSec peer, the peer to which IPSec protected traffic can be forwarded. Repeat for multiple remote peers.
Step 6	set transform-set <i>transform-set-name1</i> [<i>transform-set-name2</i> ... <i>transform-set-name6</i>] Example: Router(config-crypto-m)# set transform-set aesset	Specifies which transform sets are allowed for this crypto map entry. List multiple transform sets in order of priority (highest priority first).
Step 7	set security-association lifetime { seconds <i>seconds</i> kilobytes <i>kilobytes</i> } Example: Router (config-crypto-m)# set security-association lifetime seconds 2700	(Optional) Specifies a SA lifetime for the crypto map entry. By default, the SAs of the crypto map are negotiated according to the global lifetimes.
Step 8	set security-association level per-host Example: Router(config-crypto-m)# set security-association level per-host	(Optional) Specifies that separate SAs should be established for each source and destination host pair. By default, a single IPSec “tunnel” can carry traffic for multiple source hosts and multiple destination hosts.
		 Caution Use this command with care, because multiple streams between given subnets can rapidly consume resources.

	Command	Purpose
Step 9	set pfs [group1 group2 group 5] Example: Router(config-crypto-m)# set pfs group2	(Optional) Specifies that IPSec either should ask for perfect forward secrecy (PFS) when requesting new SAs for this crypto map entry or should demand PFS in requests received from the IPSec peer. By default, PFS is not requested. If no group is specified with this command, group1 is used as the default.
Step 10	exit Example: Router(config-crypto-m)# exit	Exits crypto-map configuration mode.
Step 11	exit Example: Router(config)# exit	Exits global configuration mode.
Step 12	show crypto map [interface <i>interface</i> tag <i>map-name</i>] Example: Router# show crypto map	Displays your crypto map configuration.

Troubleshooting Tips

Certain configuration changes take effect only when negotiating subsequent SAs. If you want the new settings to take immediate effect, you must clear the existing SAs so that they are re-established with the changed configuration. If the router is actively processing IPSec traffic, it is desirable to clear only the portion of the SA database that would be affected by the configuration changes (that is, clear only the SAs established by a given crypto map set). Clearing the full SA database should be reserved for large-scale changes, or when the router is processing very little other IPSec traffic.

To clear IPSec SAs, use the **clear crypto sa** command with appropriate parameters. (Omitting all parameters clears out the full SA database, which clears active security sessions.)

What to Do Next

After you have successfully created a static crypto map, you must apply the crypto map set to each interface through which IPSec traffic flows. To complete this task, see the section “[Applying Crypto Map Sets to Interfaces](#).”

Creating Dynamic Crypto Maps

Dynamic crypto maps can ease IPSec configuration and are recommended for use with networks where the peers are not always predetermined. To create dynamic crypto maps, you should understand the following concepts:

- [Dynamic Crypto Maps Overview](#)
- [Tunnel Endpoint Discovery \(TED\)](#)

Dynamic Crypto Maps Overview

Dynamic crypto maps are only available for use by IKE.

A dynamic crypto map entry is essentially a static crypto map entry without all the parameters configured. It acts as a policy template where the missing parameters are later dynamically configured (as the result of an IPSec negotiation) to match a remote peer's requirements. This allows remote peers to exchange IPSec traffic with the router even if the router does not have a crypto map entry specifically configured to meet all of the remote peer's requirements.

Dynamic crypto maps are not used by the router to initiate new IPSec security associations with remote peers. Dynamic crypto maps are used when a remote peer tries to initiate an IPSec security association with the router. Dynamic crypto maps are also used in evaluating traffic.

A dynamic crypto map set is included by reference as part of a crypto map set. Any crypto map entries that reference dynamic crypto map sets should be the lowest priority crypto map entries in the crypto map set (that is, have the highest sequence numbers) so that the other crypto map entries are evaluated first; that way, the dynamic crypto map set is examined only when the other (static) map entries are not successfully matched.

If the router accepts the peer's request, at the point that it installs the new IPSec security associations it also installs a temporary crypto map entry. This entry is filled in with the results of the negotiation. At this point, the router performs normal processing, using this temporary crypto map entry as a normal entry, even requesting new security associations if the current ones are expiring (based upon the policy specified in the temporary crypto map entry). Once the flow expires (that is, all of the corresponding security associations expire), the temporary crypto map entry is then removed.

For both static and dynamic crypto maps, if unprotected inbound traffic matches a **permit** statement in an access list, and the corresponding crypto map entry is tagged as "IPSec," then the traffic is dropped because it is not IPSec-protected. (This is because the security policy as specified by the crypto map entry states that this traffic must be IPSec-protected.)

For static crypto map entries, if outbound traffic matches a **permit** statement in an access list and the corresponding SA is not yet established, the router initiates new SAs with the remote peer. In the case of dynamic crypto map entries, if no SA existed, the traffic would simply be dropped (because dynamic crypto maps are not used for initiating new SAs).

Note

Use care when using the **any** keyword in **permit** entries in dynamic crypto maps. If it is possible for the traffic covered by such a **permit** entry to include multicast or broadcast traffic, the access list should include **deny** entries for the appropriate address range. Access lists should also include **deny** entries for network and subnet broadcast traffic, and for any other traffic that should not be IPSec protected.

Restrictions for Dynamic Crypto Maps

Dynamic crypto map entries specify crypto access lists that limit traffic for which IPSec SAs can be established. A dynamic crypto map entry that does not specify an access list is ignored during traffic filtering. A dynamic crypto map entry with an empty access list causes traffic to be dropped. If there is only one dynamic crypto map entry in the crypto map set, it must specify acceptable transform sets.

Tunnel Endpoint Discovery (TED)

Defining a dynamic crypto map allows only the receiving router to dynamically determine an IPSec peer. TED allows the initiating router to dynamically determine an IPSec peer for secure IPSec communications.

Dynamic TED helps to simplify IPSec configuration on the individual routers within a large network. Each node has a simple configuration that defines the local network that the router is protecting and the required IPSec transforms.

To have a large, fully-meshed network *without* TED, each peer needs to have static crypto maps to every other peer in the network. For example, if there are 100 peers in a large, fully-meshed network, each router needs 99 static crypto maps for each of its peers. With TED, only a single dynamic crypto map with TED enabled is needed because the peer is discovered dynamically. Thus, static crypto maps do not need to be configured for each peer.

**Note**

TED helps only in discovering peers; otherwise, TED does not function any differently than normal IPSec. TED does not improve the scalability of IPSec (in terms of performance or the number of peers or tunnels).

Figure 57 and the corresponding steps explain a sample TED network topology.

Figure 57 Tunnel Endpoint Discovery Sample Network Topology

- Step 1** Host A sends a packet that is destined for Host B.
- Step 2** Router 1 intercepts and reads the packet. According to the IKE policy, Router 1 contains the following information: the packet must be encrypted, there are no SAs for the packet, and TED is enabled. Thus, Router 1 drops the packet and sends a TED probe into the network. (The TED probe contains the IP address of Host A (as the source IP address) and the IP address of Host B (as the destination IP address) embedded in the payload.
- Step 3** Router 2 intercepts the TED probe and checks the probe against the ACLs that it protects; after the probe matches an ACL, it is recognized as a TED probe for proxies that the router protects. It then sends a TED reply with the IP address of Host B (as the source IP address) and the IP address of Host A (as the destination IP address) embedded in the payload.
- Step 4** Router 1 intercepts the TED reply and checks the payloads for the IP address and half proxy of Router 2. It then combines the source side of its proxy with the proxy found in the second payload and initiates an IKE session with Router 2; thereafter, Router 1 initiates an IPSec session with Router 2.

**Note**

IKE cannot occur until the peer is identified.

TED Versions

The following table lists the available TED versions:

Version	First Available Release	Description
TEDv1	12.0(5)T	Performs basic TED functionality on nonredundant networks.
TEDv2	12.1M	Enhanced to work with redundant networks with paths through multiple security gateways between the source and the destination.
TEDv3	12.2M	Enhanced to allow non-IP-related entries to be used in the access list.

TED Restrictions

TED has the following restrictions:

- It is Cisco proprietary.
- It is available only on dynamic crypto maps. (The dynamic crypto map template is based on the dynamic crypto map performing peer discovery. Although there are no access-list restrictions on the dynamic crypto map template, the dynamic crypto map template should cover data sourced from the protected traffic and the receiving router using the **any** keyword. When using the **any** keyword, include explicit **deny** statements to exempt routing protocol traffic prior to entering the **permit any** command.)
- TED works only in tunnel mode; that is, it does not work in transport mode.
- It is limited by the performance and scalability of limitation of IPsec on each individual platform.

Note

Enabling TED slightly decreases the general scalability of IPsec because of the set-up overhead of peer discovery, which involves an additional “round-trip” of IKE messages (TED probe and reply). Although minimal, the additional memory used to store data structures during the peer discovery stage adversely affects the general scalability of IPsec.

- The IP addresses must be able to be routed within the network.
- The access list used in the crypto map for TED can only contain IP-related entries—TCP, UDP, or any other protocol cannot be used in the access list.

Note

This restriction is no longer applicable in TEDv3.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto dynamic-map** *dynamic-map-name* *dynamic-seq-num*
4. **set transform-set** *transform-set-name1* [*transform-set-name2...transform-set-name6*]
5. **match address** *access-list-id*
6. **set peer** {*hostname* | *ip-address*}
7. **set security-association lifetime** {**seconds** *seconds* | **kilobytes** *kilobytes*}

8. **set pfs** [group1 | group2 | group5]
9. **exit**
10. **exit**
11. **show crypto dynamic-map** [tag map-name]
12. **configure terminal**
13. **crypto map** map-name seq-num ipsec-isakmp dynamic dynamic-map-name [discover]

DETAILED STEPS

	Command	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto dynamic-map dynamic-map-name dynamic-seq-num Example: Router(config)# crypto dynamic-map test-map 1	Creates a dynamic crypto map entry and enters crypto map configuration mode.
Step 4	set transform-set transform-set-name1 [transform-set-name2...transform-set-name6] Example: Router(config-crypto-m)# set transform-set aasset	Specifies which transform sets are allowed for the crypto map entry. List multiple transform sets in order of priority (highest priority first). This is the only configuration statement required in dynamic crypto map entries.

	Command	Purpose
Step 5	match address <i>access-list-id</i> Example: Router(config-crypto-m)# match address 101	(Optional) Accesses list number or name of an extended access list. This access list determines which traffic should be protected by IPSec and which traffic should not be protected by IPSec security in the context of this crypto map entry. Note Although access-lists are optional for dynamic crypto maps, they are highly recommended. If this is configured, the data flow identity proposed by the IPSec peer must fall within a permit statement for this crypto access list. If this is not configured, the router accepts any data flow identity proposed by the IPSec peer. However, if this is configured but the specified access list does not exist or is empty, the router drops all packets. This is similar to static crypto maps because they also require that an access list be specified. Care must be taken if the any keyword is used in the access list, because the access list is used for packet filtering as well as for negotiation. You must configure a match address; otherwise, the behavior is not secure, and you cannot enable TED because packets are sent in the clear (unencrypted.)
Step 6	set peer { <i>hostname</i> <i>ip-address</i> } Example: Router(config-crypto-m)# set peer 192.168.101.1	(Optional) Specifies a remote IPSec peer. Repeat for multiple remote peers. Note This is rarely configured in dynamic crypto map entries. Dynamic crypto map entries are often used for unknown remote peers.
Step 7	set security-association lifetime { <i>seconds seconds</i> <i>kilobytes kilobytes</i> } Example: Router (config-crypto-m)# set security-association lifetime seconds 7200	(Optional) Overrides (for a particular crypto map entry) the global lifetime value, which is used when negotiating IP Security SAs.
Step 8	set pfs [<i>group1</i> <i>group2</i> <i>group5</i>] Example: Router(config-crypto-m)# set pfs group2	(Optional) Specifies that IPSec should ask for PFS when requesting new security associations for this crypto map entry or should demand PFS in requests received from the IPSec peer. By default, PFS is not requested. If no group is specified with this command, group1 is used as the default.
Step 9	exit Example: Router(config-crypto-m)# exit	Exits crypto-map configuration mode and returns to global configuration mode.

	Command	Purpose
Step 10	<code>exit</code> Example: Router(config)# <code>exit</code>	Exits global configuration mode.
Step 11	<code>show crypto dynamic-map</code> [<i>tag map-name</i>] Example: Router# <code>show crypto dynamic-map</code>	(Optional) Displays information about dynamic crypto maps.
Step 12	<code>configure terminal</code> Example: Router# <code>configure terminal</code>	Returns to global configuration mode.
Step 13	<code>crypto map</code> <i>map-name</i> <i>seq-num</i> ipsec-isakmp dynamic <i>dynamic-map-name</i> [discover] Example: Router(config)# <code>crypto map static-map 1 ipsec-isakmp dynamic test-map discover</code>	(Optional) Adds a dynamic crypto map to a crypto map set. You should set the crypto map entries referencing dynamic maps to the lowest priority entries in a crypto map set. Note You must issue the discover keyword to enable TED.

Troubleshooting Tips

Certain configuration changes take effect only when negotiating subsequent SAs. If you want the new settings to take immediate effect, you must clear the existing SAs so that they are reestablished with the changed configuration. If the router is actively processing IPSec traffic, it is desirable to clear only the portion of the SA database that would be affected by the configuration changes (that is, clear only the SAs established by a given crypto map set). Clearing the full SA database should be reserved for large-scale changes, or when the router is processing very little other IPSec traffic.

To clear IPSec SAs, use the **clear crypto sa** command with appropriate parameters. (Omitting all parameters clears the full SA database, which clears active security sessions.)

What to Do Next

After you have successfully created a crypto map set, you must apply the crypto map set to each interface through which IPSec traffic flows. To complete this task, see the section “[Applying Crypto Map Sets to Interfaces](#).”

Creating Crypto Map Entries to Establish Manual SAs

The use of manual security associations is a result of a prior arrangement between the users of the local router and the IPSec peer. The two parties may begin with manual SAs and then move to using SAs established via IKE, or the remote party’s system may not support IKE. If IKE is not used for establishing the SAs, there is no negotiation of SAs, so the configuration information in both systems must be the same in order for traffic to be processed successfully by IPSec.

The local router can simultaneously support manual and IKE-established SAs, even within a single crypto map set.

There is very little reason to disable IKE on the local router (unless the router only supports manual SAs, which is unlikely).

**Note**

Access lists for crypto map entries tagged as **ipsec-manual** are restricted to a single **permit** entry and subsequent entries are ignored. In other words, the SAs established by that particular crypto map entry are only for a single data flow. To be able to support multiple manually established SAs for different kinds of traffic, define multiple crypto access lists, and then apply each one to a separate **ipsec-manual** crypto map entry. Each access list should include one **permit** statement defining what traffic to protect.

To create crypto map entries to establish manual SAs (that is, when IKE is not used to establish the SAs), perform this task.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name seq-num ipsec-manual*
4. **match address** *access-list-id*
5. **set peer** {*hostname* | *ip-address*}
6. **set transform-set** *transform-set-name*
7. **set session-key inbound ah spi** *hex-key-string*
or
set session-key outbound ah spi *hex-key-string*
8. **set session-key inbound esp spi cipher** *hex-key-string* [**authenticator** *hex-key-string*]
or
set session-key outbound esp spi cipher *hex-key-string* [**authenticator** *hex-key-string*]
9. **exit**
10. **exit**
11. **show crypto map** [**interface** *interface* | **tag** *map-name*]

DETAILED STEPS

	Command	Purpose
Step 1	enable	Enables privileged EXEC mode. Enter your password if prompted.
	Example: Router> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example: Router# configure terminal	

	Command	Purpose
Step 3	crypto map <i>map-name seq-num ipsec-manual</i> Example: Router(config)# crypto map mymap 10 ipsec-manual	Specifies the crypto map entry to create or modify and enters crypto map configuration mode.
Step 4	match address <i>access-list-id</i> Example: Router(config-crypto-m)# match address 102	Names an IPSec access list that determines which traffic should be protected by IPSec and which traffic should not be protected by IPSec in the context of this crypto map entry. (The access list can specify only one permit entry when IKE is not used.)
Step 5	set peer { <i>hostname</i> <i>ip-address</i> } Example: Router(config-crypto-m)# set peer 10.0.0.5	Specifies the remote IPSec peer. This is the peer to which IPSec protected traffic should be forwarded. (Only one peer can be specified when IKE is not used.)
Step 6	set transform-set <i>transform-set-name</i> Example: Router(config-crypto-m)# set transform-set someset	Specifies which transform set should be used. This must be the same transform set that is specified in the remote peer's corresponding crypto map entry. Note Only one transform set can be specified when IKE is not used.
Step 7	set session-key inbound ah <i>spi hex-key-string</i> Example: Router(config-crypto-m)# set session-key inbound ah 256 98765432109876549876543210987654 and set session-key outbound ah <i>spi hex-key-string</i> Example: Router(config-crypto-m)# set session-key outbound ah 256 fedcbafedcbafedcfedcbafedcbafedc	Sets the AH security parameter indexes (SPIs) and keys to apply to inbound and outbound protected traffic if the specified transform set includes the AH protocol. (This manually specifies the AH security association to be used with protected traffic.)
Step 8	set session-key inbound esp <i>spi cipher hex-key-string [authenticator hex-key-string]</i> Example: Router(config-crypto-m)# set session-key inbound esp 256 cipher 0123456789012345 and set session-key outbound esp <i>spi cipher hex-key-string [authenticator hex-key-string]</i> Example: Router(config-crypto-m)# set session-key outbound esp 256 cipher abcdefabcdefabcd	Sets the ESP SPIs and keys to apply to inbound and outbound protected traffic if the specified transform set includes the ESP protocol. Specifies the cipher keys if the transform set includes an ESP cipher algorithm. Specifies the authenticator keys if the transform set includes an ESP authenticator algorithm. (This manually specifies the ESP security association to be used with protected traffic.)

	Command	Purpose
Step 9	exit Example: Router(config-crypto-m)# exit	Exits crypto-map configuration mode and returns to global configuration mode.
Step 10	exit Example: Router(config)# exit	Exits global configuration mode.
Step 11	show crypto map [interface <i>interface</i> tag <i>map-name</i>] Example: Router# show crypto map	Displays your crypto map configuration.

Troubleshooting Tips

For manually established SAs, you must clear and reinitialize the SAs for the changes to take effect. To clear IPSec SAs, use the **clear crypto sa** command with appropriate parameters. (Omitting all parameters clears the full SA database, which clears active security sessions.)

What to Do Next

After you have successfully created a crypto map set, you must apply the crypto map set to each interface through which IPSec traffic flows. To complete this task, see the section “[Applying Crypto Map Sets to Interfaces](#).”

Applying Crypto Map Sets to Interfaces

You need to apply a crypto map set to each interface through which IPSec traffic flows. Applying the crypto map set to an interface instructs the router to evaluate all the interface’s traffic against the crypto map set and to use the specified policy during connection or security association negotiation on behalf of traffic to be protected by crypto.

Perform this task to apply a crypto map to an interface.

Redundant Interfaces Sharing the Same Crypto Map

For redundancy, you could apply the same crypto map set to more than one interface. The default behavior is as follows:

- Each interface has its own piece of the security association database.
- The IP address of the local interface is used as the local address for IPSec traffic originating from or destined to that interface.

If you apply the same crypto map set to multiple interfaces for redundancy purposes, you need to specify an identifying interface. One suggestion is to use a loopback interface as the identifying interface. This has the following effects:

- The per-interface portion of the IPSec security association database is established one time and shared for traffic through all the interfaces that share the same crypto map.

- The IP address of the identifying interface is used as the local address for IPSec traffic originating from or destined to those interfaces sharing the same crypto map set.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **crypto map** *map-name*
5. **exit**
6. **crypto map** *map-name* **local-address** *interface-id*
7. **exit**
8. **show crypto map** [*interface interface*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface <i>type number</i> Example: Router(config)# Interface FastEthernet 0/0	Configures an interface and enters interface configuration mode.
Step 4	crypto map <i>map-name</i> Example: Router(config-if)# crypto map mymap	Applies a crypto map set to an interface.
Step 5	exit Example: Router(config-if)# exit	Exits interface configuration mode and returns to global configuration mode.
Step 6	crypto map <i>map-name</i> local-address <i>interface-id</i> Example: Router(config)# crypto map mymap local-address loopback0	(Optional) Permits redundant interfaces to share the same crypto map using the same local identity.

	Command or Action	Purpose
Step 7	exit Example: Router(config)# exit	(Optional) Exits global configuration mode.
Step 8	show crypto map [interface interface] Example: Router# show crypto map	(Optional) Displays your crypto map configuration

Configuration Examples for Configuring an IPsec VPN

This section contains the following configuration example:

Glossary

anti-replay—Security service where the receiver can reject old or duplicate packets to protect itself against replay attacks. IPSec provides this optional service by use of a sequence number combined with the use of data authentication. Cisco IOS IPSec provides this service whenever it provides the data authentication service, except for manually established SAs (that is, SAs established by configuration and not by IKE).

data authentication—Verification of the integrity and origin of the data.

Data authentication can refer either to integrity alone or to both of these concepts (although data origin authentication is dependent upon data integrity).

data confidentiality—Security service in which the protected data cannot be observed.

data flow—Grouping of traffic, identified by a combination of source address or mask; destination address or mask; IP next protocol field, and source and destination ports, where the protocol and port fields can have the values of **any**. IPSec protection is applied to data flows.

peer—In the context of this module, a “peer” is a router or other device that participates in IPSec.

PFS—perfect forward secrecy. Cryptographic characteristic associated with a derived shared secret value. With PFS, if one key is compromised, previous and subsequent keys are not compromised, because subsequent keys are not derived from previous keys.

SA—security association. Description of how two or more entities use security services in the context of a particular security protocol (AH or ESP) to communicate securely on behalf of a particular data flow. The transform and the shared secret keys are used for protecting the traffic.

SPI—security parameter index. A number which, together with a destination IP address and security protocol, uniquely identifies a particular security association. Without IKE, the SPI is manually specified for each security association.

transform—List of operations performed on a dataflow to provide data authentication, data confidentiality, and data compression. For example, one transform is the ESP protocol with the HMAC-MD5 authentication algorithm; another transform is the AH protocol with the 56-bit DES encryption algorithm and the ESP protocol with the HMAC-SHA authentication algorithm.

tunnel—In the context of this module, “tunnel” is a secure communication path between two peers, such as two routers. It does not refer to using IPSec in tunnel mode.

Note

Feature Information for Security for VPNs with IPSec

[Table 47](#) lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table.

Not all commands may be available in your Cisco IOS software release. For details on when support for a specific command was introduced, see the command reference documentation.

Cisco IOS software images are specific to a Cisco IOS software release, a feature set, and a platform. Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

[Table 47](#) lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 47 Feature Information for Configuring Security for IPSec VPNs

Feature Name	Software Releases	Feature Configuration Information
Advanced Encryption Standard (AES)	12.2(8)T	This feature adds support for the new encryption standard AES, which is a privacy transform for IPSec and IKE and has been developed to replace DES. The following sections provide information about this feature: • Supported Standards • Defining Transform Sets: A Combination of Security Protocols and Algorithms The following commands were modified by this feature: crypto ipsec transform-set, encryption (IKE policy), show crypto ipsec transform-set, show crypto isakmp policy
DES/3DES/AES VPN Encryption Module (AIM-VPN/EPII, AIM-VPN/HPII, AIM-VPN/BPII Family)	12.3(7)T	This feature describes which VPN encryption hardware AI) and NM are supported in certain Cisco IOS software releases. The following section provides information about this feature: • AIMs and NM Support
SEAL Encryption	12.3(7)T	This feature adds support for SEAL encryption in IPSec. The following section provides information about this feature: • Supported Standards • Defining Transform Sets: A Combination of Security Protocols and Algorithms The following command was modified by this feature: crypto ipsec transform-set
Software IPPCP (LZS) with Hardware Encryption	12.2(13)T	This feature allows customers to use LZS software compression with IPSec when a VPN module is in Cisco 2600 and Cisco 3600 series routers. The following section provides information about this feature: • AIMs and NM Support
IKE Shared Secret Using AAA Server	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

Crypto Conditional Debug Support

The Crypto Conditional Debug Support feature introduces three new command-line interfaces (CLIs) that allow users to debug an IP Security (IPSec) tunnel on the basis of predefined crypto conditions such as the peer IP address, connection-ID of a crypto engine, and security parameter index (SPI). By limiting debug messages to specific IPSec operations and reducing the amount of debug output, users can better troubleshoot a router with a large number of tunnels.

Feature History for Crypto Conditional Debug Support

Feature History	
Release	Modification
12.3(2)T	This feature was introduced.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

Prerequisites for Crypto Conditional Debug Support

To use the new crypto CLIs, you must be using a crypto image, such as the k8 or k9 subsystem.

Restrictions for Crypto Conditional Debug Support

- This feature does not support debug message filtering for hardware crypto engines.
- Although conditional debugging is useful for troubleshooting peer-specific or functionality related Internet Key Exchange (IKE) and IPSec problems, conditional debugging may not be able to define and check large numbers of debug conditions.

Because extra space is needed to store the debug condition values, additional processing overhead is added to the CPU and memory usage is increased. Thus, enabling crypto conditional debugging on a router with heavy traffic should be used with caution.

Information About Crypto Conditional Debug Support

To enable the conditional crypto debug commands, you should understand the following concept:

- [Supported Condition Types, page 2](#)

Supported Condition Types

The new crypto conditional debug CLIs—**debug crypto condition**, **debug crypto condition unmatched**, and **show crypto debug-condition**—allow you to specify conditions (filter values) in which to generate and display debug messages related only to the specified conditions. [Table 1](#) lists the supported condition types.

Table 1 *Supported Condition Types for Crypto Debug CLI*

Condition Type (Keyword)	Description
connid ¹	An integer between 1–32766. Relevant debug messages will be shown if the current IPSec operation uses this value as the connection ID to interface with the crypto engine.
flowid ¹	An integer between 1–32766. Relevant debug messages will be shown if the current IPSec operation uses this value as the flow-ID to interface with the crypto engine.
FVRF	The name string of a virtual private network (VPN) routing and forwarding (VRF) instance. Relevant debug messages will be shown if the current IPSec operation uses this VRF instance as its front-door VRF (FVRF).

Table 1 **Supported Condition Types for Crypto Debug CLI (continued)**

Condition Type (Keyword)	Description
IVRF	The name string of a VRF instance. Relevant debug messages will be shown if the current IPsec operation uses this VRF instance as its inside VRF (IVRF).
peer group	A Unity group-name string. Relevant debug messages will be shown if the peer is using this group name as its identity.
peer hostname	A fully qualified domain name (FQDN) string. Relevant debug messages will be shown if the peer is using this string as its identity; for example, if the peer is enabling IKE Xauth with this FQDN string.
peer ipaddress	A single IP address. Relevant debug messages will be shown if the current IPsec operation is related to the IP address of this peer.
peer subnet	A subnet and a subnet mask that specify a range of peer IP addresses. Relevant debug messages will be shown if the IP address of the current IPsec peer falls into the specified subnet range.
peer username	A username string. Relevant debug messages will be shown if the peer is using this username as its identity; for example, if the peer is enabling IKE Extended Authentication (Xauth) with this username.
SPI ¹	A 32-bit unsigned integer. Relevant debug messages will be shown if the current IPsec operation uses this value as the SPI.

1. If an IPsec connid, flowid, or SPI is used as a debug condition, the debug messages for a related IPsec flow are generated. An IPsec flow has two connids, flowids, and SPIs—one inbound and one outbound. Both two connids, flowids, and SPIs can be used as the debug condition that triggers debug messages for the IPsec flow.

How to Enable Crypto Conditional Debug Support

This section contains the following procedures:

- [Enabling Crypto Conditional Debug Messages, page 3](#)
- [Enabling Crypto Error Debug Messages, page 5](#)

Enabling Crypto Conditional Debug Messages

To enable crypto conditional debug filtering, you must perform the following tasks.

Performance Considerations

- Before enabling crypto conditional debugging, you must decide what debug condition types (also known as debug filters) and values will be used. The volume of debug messages is dependent on the number of conditions you define.

Note

Specifying numerous debug conditions may consume CPU cycles and negatively affect router performance.

- Your router will perform conditional debugging only after at least one of the global crypto debug commands—**debug crypto isakmp**, **debug crypto ipsec**, and **debug crypto engine**—has been enabled. This requirement helps to ensure that the performance of the router will not be impacted when conditional debugging is not being used.

Disable Crypto Debug Conditions

If you choose to disable crypto conditional debugging, you must first disable any crypto global debug CLIs you have issued; thereafter, you can disable conditional debugging.

Note

The **reset** keyword can be used to disable all configured conditions at one time.

SUMMARY STEPS

1. **enable**
2. **debug crypto condition** [*connid integer engine-id integer*] [*flowid integer engine-id integer*] [*fvr string*] [*ivrf string*] [**peer** [*group string*] [*hostname string*] [*ipv4 ipaddress*] [*subnet subnet mask*] [*username string*]] [*spi integer*] [**reset**]
3. **show crypto debug-condition** {[**peer**] [*connid*] [*spi*] [*fvr*] [*ivrf*] [**unmatched**]}
4. **debug crypto isakmp**
5. **debug crypto ipsec**
6. **debug crypto engine**
7. **debug crypto condition unmatched** [*isakmp* | *ipsec* | *engine*] (optional)

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	debug crypto condition [<i>connid integer</i>] [<i>engine-id integer</i>] [<i>flowid integer</i>] [<i>engine-id integer</i>] [<i>fvrf string</i>] [<i>ivrf string</i>] [<i>peer [group string] [hostname string] [ipv4 ipaddress] [subnet subnet mask] [username string]]</i>] [<i>spi integer</i>] [<i>reset</i>] Example: Router# debug crypto condition connid 2000 engine-id 1	Defines conditional debug filters.
Step 3	show crypto debug-condition {[<i>peer</i>] [<i>connid</i>] [<i>spi</i>] [<i>fvrf</i>] [<i>ivrf</i>] [<i>unmatched</i>]} Example: Router# show crypto debug-condition spi	Displays crypto debug conditions that have already been enabled in the router.
Step 4	debug crypto isakmp Example: Router# debug crypto isakmp	Enables global IKE debugging.
Step 5	debug crypto ipsec Example: Router# debug crypto ipsec	Enables global IPSec debugging.
Step 6	debug crypto engine Example: Router# debug crypto engine	Enables global crypto engine debugging.
Step 7	debug crypto condition unmatched [<i>isakmp</i> <i>ipsec</i> <i>engine</i>] Example: Router# debug crypto condition unmatched ipsec	(Optional) Displays debug conditional crypto messages when no context information is available to check against debug conditions. If none of the optional keywords are specified, all crypto-related information will be shown.

Enabling Crypto Error Debug Messages

To enable crypto error debug messages, you must perform the following tasks.

debug crypto error CLI

Enabling the **debug crypto error** command displays only error-related debug messages, thereby, allowing you to easily determine why a crypto operation, such as an IKE negotiation, has failed within your system.

Note

When enabling this command, ensure that global crypto debug commands are not enabled; otherwise, the global commands will override any possible error-related debug messages.

SUMMARY STEPS

1. **enable**
2. **debug crypto {isakmp | ipsec | engine} error**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	debug crypto {isakmp ipsec engine} error Example: Router# debug crypto ipsec error	Enables only error debugging messages for a crypto area.

Configuration Examples for the Crypto Conditional Debug CLIs

This section includes the following examples:

- [Enabling Crypto Conditional Debugging: Example, page 6](#)
- [Disabling Crypto Conditional Debugging: Example, page 7](#)

Enabling Crypto Conditional Debugging: Example

The following example shows how to display debug messages when the peer IP address is 10.1.1.1, 10.1.1.2, or 10.1.1.3, and when the connection-ID 2000 of crypto engine 0 is used. This example also shows how to enable global debug crypto CLIs and enable the **show crypto debug-condition** command to verify conditional settings.

```
Router# debug crypto condition connid 2000 engine-id 1
Router# debug crypto condition peer ipv4 10.1.1.1
Router# debug crypto condition peer ipv4 10.1.1.2
Router# debug crypto condition peer ipv4 10.1.1.3
Router# debug crypto condition unmatched
! Verify crypto conditional settings.
Router# show crypto debug-condition
```

```
Crypto conditional debug currently is turned ON
IKE debug context unmatched flag:ON
IPsec debug context unmatched flag:ON
Crypto Engine debug context unmatched flag:ON

IKE peer IP address filters:
10.1.1.1 10.1.1.2 10.1.1.3

Connection-id filters:[connid:engine_id]2000:1,
! Enable global crypto CLIs to start conditional debugging.
Router# debug crypto isakmp
Router# debug crypto ipsec
Router# debug crypto engine
```

Disabling Crypto Conditional Debugging: Example

The following example shows how to disable all crypto conditional settings and verify that those settings have been disabled:

```
Router# debug crypto condition reset
! Verify that all crypto conditional settings have been disabled.
Router# show crypto debug-condition
```

```
Crypto conditional debug currently is turned OFF
IKE debug context unmatched flag:OFF
IPsec debug context unmatched flag:OFF
Crypto Engine debug context unmatched flag:OFF
```

Distinguished Name Based Crypto Maps

Feature History

Release	Modification
12.2(4)T	This feature was introduced.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

This feature module describes the Distinguished Name Based Crypto Map feature in Cisco IOS Release 12.2(4)T. It includes the following sections:

- [Feature Overview, page 1](#)
- [Supported Platforms, page 2](#)
- [Supported Standards, MIBs, and RFCs, page 3](#)
- [Prerequisites, page 3](#)
- [Configuration Tasks, page 3](#)
- [Configuration Examples, page 5](#)
- [Command Reference, page 6](#)

Feature Overview

The Distinguished Name Based Crypto Maps feature allows you to configure the router to restrict access to selected encrypted interfaces for those peers with specific certificates, especially certificates with particular Distinguished Names (DNs).

Previously, if the router accepted a certificate or a shared secret from the encrypting peer, Cisco IOS did not have a method of preventing the peer from communicating with any encrypted interface other than the restrictions on the IP address of the encrypting peer. This feature allows you to configure which crypto maps are usable to a peer based on the DN that a peer used to authenticate itself, thereby, enabling you to control which encrypted interfaces a peer with a specified DN can access.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

Benefits

The Distinguished Name Based Crypto Maps feature allows you to set restrictions in the router configuration that prevent peers with specific certificates—especially certificates with particular DNs—from having access to selected encrypted interfaces.

Restrictions

System Requirements

To configure this feature, your router must support IP Security.

Performance Impact

If you restrict access to a large number of DNs, it is recommended that you specify a few number of crypto maps referring to large identity sections instead of specifying a large number of crypto maps referring to small identity sections.

Related Documents

The following documents provide information related to the Distinguished Name Based Crypto Maps feature:

- *Cisco IOS Security Command Reference*, Release 12.2
- *Cisco IOS Security Configuration Guide*, Release 12.2

Supported Platforms

This feature is supported on the following platforms:

- Cisco 1700 series
- Cisco 2600 series
- Cisco 3620
- Cisco 3640
- Cisco 3660
- Cisco 7100 series
- Cisco 7200 series
- Cisco uBR905 Cable Access Router
- Cisco uBR925 Cable Access Router

Determining Platform Support Through Feature Navigator

Cisco IOS software is packaged in feature sets that support specific platforms. To get updated information regarding platform support for this feature, access Feature Navigator. Feature Navigator dynamically updates the list of supported platforms as new platform support is added for the feature.

Feature Navigator is a web-based tool that enables you to quickly determine which Cisco IOS software images support a specific set of features and which features are supported in a specific Cisco IOS image.

To access Feature Navigator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to cco-locksmit@cis.com. An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions at <http://www.cisco.com/register>.

Feature Navigator is updated regularly when major Cisco IOS software releases and technology releases occur. For the most current information, go to the Feature Navigator home page at the following URL: <http://www.cisco.com/go/fn>

Supported Standards, MIBs, and RFCs

Standards

None

MIBs

None

To obtain lists of supported MIBs by platform and Cisco IOS release, and to download MIB modules, go to the Cisco MIB website on Cisco.com at the following URL:

<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>

RFCs

None

Prerequisites

Before configuring a DN based crypto map, you must perform the following tasks:

- Create an Internet Key Exchange (IKE) policy at each peer.
For more information on creating IKE policies, refer to the chapter “Configuring Internet Key Exchange Security Protocol” of the *Cisco IOS Security Configuration Guide*.
- Create crypto map entries for IPsec.
For more information on creating crypto map entries, refer to the chapter “Configuring IPsec Network Security” of the *Cisco IOS Security Configuration Guide*.

Configuration Tasks

See the following sections for configuration tasks for the Distinguished Name Based Crypto Maps feature. Each task in the list is identified as either required or optional.

- [Configuring DN Based Crypto Maps \(authenticated by DN\)](#) (required)
- [Configuring DN Based Crypto Maps \(authenticated by hostname\)](#) (required)
- [Applying Identity to DN Based Crypto Maps](#) (required)
- [Verifying DN Based Crypto Maps](#) (optional)

Configuring DN Based Crypto Maps (authenticated by DN)

To configure a DN based crypto map that can be used only by peers that have been authenticated by a DN, use the following commands beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# crypto identity name	Configures the identity of a router with the given list of DNs in the certificate of the router and enters crypto identity configuration mode.
Step 2	Router(crypto-identity)# dn name=string [,name=string]	Associates the identity of the router with the DN in the certificate of the router. Note The identity of the peer must match the identity in the exchanged certificate.

Configuring DN Based Crypto Maps (authenticated by hostname)

To configure a DN based crypto map that can be used only by peers that have been authenticated by a hostname, use the following commands beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# crypto identity name	Configures the identity of a router with the given list of DNs in the certificate of the router and enters crypto identity configuration mode.
Step 2	Router(crypto-identity)# fqdn name	Associates the identity of the router with the hostname that the peer used to authenticate itself. Note The identity of the peer must match the identity in the exchanged certificate.

Applying Identity to DN Based Crypto Maps

To apply the identity (within the crypto map context), use the following commands beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# crypto map <i>map-name seq-num ipsec-isakmp</i>	Creates or modifies a crypto map entry and enters the crypto map configuration mode.
Step 2	Router(config-crypto-map)# identity <i>name</i>	Applies the identity to the crypto map. When this command is applied, only the hosts that match a configuration listed within the identity <i>name</i> can use the specified crypto map. Note If the identity command does not appear within the crypto map, the encrypted connection does not have any restrictions other than the IP address of the encrypting peer.

Verifying DN Based Crypto Maps

To verify that this functionality is properly configured, use the following command in EXEC mode:

Command	Purpose
Router# show crypto identity	Displays the configured identities.

Troubleshooting Tips

If an encrypting peer attempts to establish a connection that is blocked by the DN based crypto map configuration, the following error message will be logged:

```
<time>: %CRYPTO-4-IKE_QUICKMODE_BAD_CERT: encrypted connection attempted with a peer without the configured certificate attributes.
```

Configuration Examples

This section provides the following configuration example:

- [DN Based Crypto Map Configuration Example](#)

DN Based Crypto Map Configuration Example

The following example shows how to configure DN based crypto maps that have been authenticated by DN and hostname. Comments are included inline to explain various commands.

```
! DN based crypto maps require you to configure an IKE policy at each peer.
crypto isakmp policy 15
  encryption 3des
  hash md5
  authentication rsa-sig
  group 2
  lifetime 5000
crypto isakmp policy 20
```

```

authentication pre-share
lifetime 10000
crypto isakmp key 1234567890 address 171.69.224.33
!
! The following is an IPsec crypto map (part of IPsec configuration). It can be used only
! by peers that have been authenticated by DN and if the certificate belongs to BigBiz.
crypto map map-to-bigbiz 10 ipsec-isakmp
set peer 172.21.114.196
set transform-set my-transformset
match address 124
identity to-bigbiz
!
crypto identity to-bigbiz
dn ou=BigBiz
!
!
! This crypto map can be used only by peers that have been authenticated by hostname
! and if the certificate belongs to little.com.
crypto map map-to-little-com 10 ipsec-isakmp
set peer 172.21.115.119
set transform-set my-transformset
match address 125
identity to-little-com
!
crypto identity to-little-com
fqdn little.com
!

```

Command Reference

The following new commands are pertinent to this feature. To see the command pages for these commands and other commands used with this feature, go to the *Cisco IOS Master Commands List*, Release 12.4, at <http://www.cisco.com/univercd/cc/td/doc/product/software/ios124/124mindx/124index.htm>.

- **crypto identity**
- **dn**
- **fqdn**
- **identity**

For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html.

For information about all Cisco IOS commands, see the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the Master Command List.

Dynamic Multipoint VPN (DMVPN)

First Published: November 25, 2002

Last Updated: December 11, 2006

The Dynamic Multipoint VPN (DMVPN) feature allows users to better scale large and small IP Security (IPsec) Virtual Private Networks (VPNs) by combining generic routing encapsulation (GRE) tunnels, IPsec encryption, and Next Hop Resolution Protocol (NHRP).

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for Dynamic Multipoint VPN \(DMVPN\)” section on page 53](#).

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Americas Headquarters:

Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

Prerequisites for Dynamic Multipoint VPN (DMVPN)

- Before a multipoint GRE (mGRE) and IPsec tunnel can be established, you must define an Internet Key Exchange (IKE) policy by using the **crypto isakmp policy** command.
- For the NAT-Transparency Aware enhancement to work, you must use IPsec transport mode on the transform set. Also, even though NAT-Transparency can support two peers (IKE and IPsec) being translated to the same IP address (using the User Datagram Protocol [UDP] ports to differentiate them [that is, Peer Address Translation (PAT)]), this functionality is not supported for DMVPN. All DMVPN spokes must have a unique IP address after they have been NAT translated. They can have the same IP address before they are NAT translated.
- To enable 2547oDMPVN—Traffic Segmentation Within DMVPN you must configure multiprotocol label switching (MPLS) by using the **mpls ip** command.

Restrictions for Dynamic Multipoint VPN (DMVPN)

- If you use the [Dynamic Creation for Spoke-to-Spoke Tunnels](#) benefit of this feature, you must use IKE certificates or wildcard preshared keys for Internet Security Association Key Management Protocol (ISAKMP) authentication.

**Note**

It is highly recommended that you *do not use* wildcard preshared keys because the attacker will have access to the VPN if one spoke router is compromised.

- GRE tunnel keepalives (that is, the **keepalive** command under a GRE interface) are not supported on point-to-point or multipoint GRE tunnels in a DMVPN Network.
- For best DMVPN functionality, it is recommended that you run the latest Cisco IOS software Release 12.4 mainline, 12.4T, or 12.2(18)SXF.

DMVPN Support on the Cisco 6500 and Cisco 7600

Blade-to-Blade Switchover on the Cisco 6500 and Cisco 7600

- DMVPN does not support blade-to-blade switchover on the Cisco 6500 and Cisco 7600.

Cisco 6500 or Cisco 7600 As a DMVPN Hub

- A Cisco 6500 or Cisco 7600 that is functioning as a DMVPN hub cannot be located behind a NAT router.
- If a Cisco 6500 or Cisco 7600 is functioning as a DMVPN hub, the spoke behind NAT must be a Cisco 6500 or Cisco 7600, respectively, or the router must be upgraded to Cisco IOS software Release 12.3(11)T02 or a later release.

Cisco 6500 or Cisco 7600 As a DMVPN Spoke

- If a Cisco 6500 or Cisco 7600 is functioning as a spoke, the hub cannot be behind NAT.
- If a Cisco 6500 or Cisco 7600 is functioning as a DMVPN spoke behind NAT, the hub must be a Cisco 6500 or Cisco 7600, respectively, or the router must be upgraded to Cisco IOS Release 12.3(11)T02 or a later release.

DMVPN Hub or Spoke Supervisor Engine

- Only a Supervisor Engine 720 can be used as a DMVPN hub or spoke. A Supervisor Engine 2 cannot be used.

Encrypted Multicast with GRE

- Encrypted Multicast with GRE is not supported on the Cisco 6500 nor on the Cisco 7600.

mGRE Interfaces

- If there are two mGRE interfaces on the same DMVPN node and they both do not have a tunnel key, the two mGRE interfaces must each have a unique tunnel source address (or interface) configured.
- On the Cisco 6500 and Cisco 7600, each GRE interface (multipoint or point-to-point) must have a unique tunnel source address (or interface).
- The following commands are not supported under mGRE with DMVPN: **ip tcp adjust-mss**, **qos pre-classify tunnel vrf**, **tunnel path-mtu-discovery**, and **tunnel vrf**.

Quality of Service (QoS)

- You cannot use QoS for DMVPN packets on a Cisco 6500 or Cisco 7600.

Tunnel Key

- The use of a tunnel key on a GRE (multipoint or point-to-point) interface is not supported in the hardware switching ASICs on the Cisco 6500 and Cisco 7600 platforms. If a tunnel key is configured, throughput performance is greatly reduced.
- In Cisco IOS Release 12.3(11)T3 and Release 12.3(14)T, the requirement that a mGRE interface must have a tunnel key was removed. Therefore, in a DMVPN network that includes a Cisco 6500 or Cisco 7600 as a DMVPN node, you should remove the tunnel key from all DMVPN nodes in the DMVPN network, thus preserving the throughput performance on the Cisco 6500 and Cisco 7600 platforms.
- If the tunnel key is not configured on any DMVPN node within a DMVPN network, it must not be configured on all DMVPN nodes with the DMVPN network.

VRF-Aware DMVPN Scenarios

- The **mls mpls tunnel-recv** command must be configured on the provider equipment (PE) DMVPN hub if customer equipment (CE) DMVPN spokes need to “talk” to other CEs across the MPLS cloud.
- The mGRE interface should be configured with a large enough IP maximum transmission unit (1400 packets) to avoid having the route processor doing fragmentation.
- Enhanced Interior Gateway Routing Protocol (EIGRP) should be avoided.

Information About Dynamic Multipoint VPN (DMVPN)

To configure the Dynamic Multipoint VPN (DMVPN) feature, you must understand the following concepts:

- [Benefits of Dynamic Multipoint VPN \(DMVPN\), page 4](#)
- [Feature Design of Dynamic Multipoint VPN \(DMVPN\), page 5](#)
- [IPsec Profiles, page 6](#)

- [VRF Integrated DMVPN, page 6](#)
- [DMVPN—Enabling Traffic Segmentation Within DMVPN, page 7](#)
- [NAT-Transparency Aware DMVPN, page 9](#)
- [Call Admission Control with DMVPN, page 10](#)
- [NHRP Rate-Limiting Mechanism, page 10](#)

Benefits of Dynamic Multipoint VPN (DMVPN)

Hub Router Configuration Reduction

- Currently, for each spoke router, there is a separate block of configuration lines on the hub router that define the crypto map characteristics, the crypto access list, and the GRE tunnel interface. This feature allows users to configure a single mGRE tunnel interface, a single IPsec profile, and no crypto access lists on the hub router to handle all spoke routers. Thus, the size of the configuration on the hub router remains constant even if spoke routers are added to the network.
- DMVPN architecture can group many spokes into a single multipoint GRE interface, removing the need for a distinct physical or logical interface for each spoke in a native IPsec installation.

Automatic IPsec Encryption Initiation

- GRE has the peer source and destination address configured or resolved with NHRP. Thus, this feature allows IPsec to be immediately triggered for the point-to-point GRE tunneling or when the GRE peer address is resolved via NHRP for the multipoint GRE tunnel.

Support for Dynamically Addressed Spoke Routers

- When using point-to-point GRE and IPsec hub-and-spoke VPN networks, the physical interface IP address of the spoke routers must be known when configuring the hub router because IP address must be configured as the GRE tunnel destination address. This feature allows spoke routers to have dynamic physical interface IP addresses (common for cable and DSL connections). When the spoke router comes online, it will send registration packets to the hub router: within these registration packets, is the current physical interface IP address of this spoke.

Dynamic Creation for Spoke-to-Spoke Tunnels

- This feature eliminates the need for spoke-to-spoke configuration for direct tunnels. When a spoke router wants to transmit a packet to another spoke router, it can now use NHRP to dynamically determine the required destination address of the target spoke router. (The hub router acts as the NHRP server, handling the request for the source spoke router.) The two spoke routers dynamically create an IPsec tunnel between them so data can be directly transferred.

VRF Integrated DMVPN

- DMVPNs can be used to extend the Multiprotocol Label Switching (MPLS) networks that are deployed by service providers to take advantage of the ease of configuration of hub and spokes, to provide support for dynamically addressed customer premises equipment (CPEs), and to provide zero-touch provisioning for adding new spokes into a DMVPN.

Feature Design of Dynamic Multipoint VPN (DMVPN)

The Dynamic Multipoint VPN (DMVPN) feature combines GRE tunnels, IPsec encryption, and NHRP routing to provide users an ease of configuration via crypto profiles—which override the requirement for defining static crypto maps—and dynamic discovery of tunnel endpoints.

This feature relies on the following two Cisco enhanced standard technologies:

- NHRP—A client and server protocol where the hub is the server and the spokes are the clients. The hub maintains an NHRP database of the public interface addresses of the each spoke. Each spoke registers its real address when it boots and queries the NHRP database for real addresses of the destination spokes to build direct tunnels.
- mGRE Tunnel Interface —Allows a single GRE interface to support multiple IPsec tunnels and simplifies the size and complexity of the configuration.

The topology shown in [Figure 1](#) and the corresponding bullets explain how this feature works.

- Each spoke has a permanent IPsec tunnel to the hub, not to the other spokes within the network. Each spoke registers as clients of the NHRP server.
- When a spoke needs to send a packet to a destination (private) subnet on another spoke, it queries the NHRP server for the real (outside) address of the destination (target) spoke.
- After the originating spoke “learns” the peer address of the target spoke, it can initiate a dynamic IPsec tunnel to the target spoke.
- The spoke-to-spoke tunnel is built over the multipoint GRE interface.
- The spoke-to-spoke links are established on demand whenever there is traffic between the spokes. Thereafter, packets can bypass the hub and use the spoke-to-spoke tunnel.

Note

After a preconfigured amount of inactivity on the spoke-to-spoke tunnels, the router will tear down those tunnels to save resources (IPsec security associations [SAs]).

IPsec Profiles

IPsec profiles abstract IPsec policy information into a single configuration entity, which can be referenced by name from other parts of the configuration. Therefore, users can configure functionality such as GRE tunnel protection with a single line of configuration. By referencing an IPsec profile, the user does not have to configure an entire crypto map configuration. An IPsec profile contains only IPsec information; that is, it does not contain any access list information or peering information.

VRF Integrated DMVPN

VPN Routing and Forwarding (VRF) Integrated DMVPN enables users to map DMVPN multipoint interfaces into MPLS VPNs. This mapping allows Internet service providers (ISPs) to extend their existing MPLS VPN services by mapping off-network sites (typically a branch office) to their respective MPLS VPNs. Customer equipment (CE) routers are terminated on the DMVPN PE router, and traffic is placed in the VRF instance of an MPLS VPN.

DMVPN can interact with MPLS VPNs in two ways:

1. The **ip vrf forwarding** command is used to inject the data IP packets (those packets inside the mGRE+IPsec tunnel) into the MPLS VPN. The **ip vrf forwarding** command is supported for DMVPN in Cisco IOS Release 12.3(6) and Release 12.3(7)T.
2. The **tunnel vrf** command is used to transport (route) the mGRE+IPsec tunnel packet itself within an MPLS VPN. The **tunnel vrf** command is supported in Cisco IOS Release 12.3(11)T but not in Cisco IOS Release 12.2(18)SXE.

Note

Clear-text data IP packets are forwarded in a VRF using the **ip vrf forwarding** command, and encrypted tunnel IP packets are forwarded in a VRF using the **tunnel vrf** command.

The **ip vrf forwarding** and **tunnel vrf** commands may be used at the same time. If they are used at the same time, the VRF name of each command may be the same or different.

For information about configuring the forwarding of clear-text data IP packets into a VRF, see the section “[Configuring the Forwarding of Clear-Text Data IP Packets into a VRF](#).” For information about configuring the forwarding of encrypted tunnel packets into a VRF, see the section “[Configuring the Forwarding of Encrypted Tunnel Packets into a VRF](#).”

For more information about configuring VRF, see reference in the “[Related Documents](#)” section.

[Figure 2](#) illustrates a typical VRF Integrated DMVPN scenario.

Figure 2 VRF Integrated DMVPN

DMVPN—Enabling Traffic Segmentation Within DMVPN

Cisco IOS Release 12.4(11)T provides an enhancement that allows you to segment VPN traffic within a DMVPN tunnel. VRF instances are labeled, using MPLS, to indicate their source and destination.

The diagram in [Figure 3](#) and the corresponding bullets explain how traffic segmentation within DMVPN works.

Diagram illustrating a Hub-and-Spoke network topology for VPNv4 routes, showing the interaction between the Hub, Spoke, and Service Provider (SP) Network.

Legend:

- VRF red
- ... VRF green
- - - VRF blue

Topology Components and Connections:

- MAN-PE2:** The central Service Provider (SP) Network router.
- Hub:** The central Hub-and-Spoke router, labeled **WAN-PE/RR**.
- Spoke A:** The first spoke router, labeled **Branch PE1**.
- Spoke B:** The second spoke router, labeled **Branch PE2**.
- SP Network:** The central cloud representing the Service Provider Network.

Connections and Protocols:

- GRE:** Connections between the Hub and the Spokes (Spoke A and Spoke B).
- LDP:** Connections between the Hub and MAN-PE2.
- LDP Over GRE:** Connections between the Hub and the Spokes (Spoke A and Spoke B).

Routing Protocol: Multiprotocol BGP (MP-iBGP) for VPNv4 routes.

- The hub shown in the diagram is a WAN-PE and a route reflector, and the spokes (PE routers) are clients.
- There are three VRFs, designated “red,” “green,” and “blue.”
- Each spoke has both a neighbor relationship with the hub (multiprotocol Border Gateway Protocol [MP-iBGP] peering) and a GRE tunnel to the hub.
- Each spoke advertises its routes and VPNv4 prefixes to the hub.
- The hub sets its own IP address as the next-hop route for all the VPNv4 addresses it learns from the spokes and assigns a local MPLS label for each VPN when it advertises routes back to the spokes. As a result, traffic from Spoke A to Spoke B is routed via the hub.

1. Spoke A advertises a VPNv4 route

1. Spoke A advertises a VPNv4 route to the hub, and applies the label *X* to the VPN.
2. The hub changes the label to *Y* when the hub advertises the route to Spoke B.
3. When Spoke B has traffic to send to Spoke A, it applies the *Y* label, and the traffic goes to the hub.
4. The hub swaps the VPN label, by removing the *Y* label and applying an *X* label, and sends the traffic to Spoke A.

NAT-Transparency Aware DMVPN

DMVPN spokes are often situated behind a NAT router (which is often controlled by the ISP for the spoke site) with the outside interface address of the spoke router being dynamically assigned by the ISP using a private IP address (per Internet Engineering Task Force [IETF] RFC 1918).

Prior to Cisco IOS Release 12.3(6) and 12.3(7)T, these spoke routers had to use IPsec tunnel mode to participate in a DMVPN network. In addition, their assigned outside interface private IP address had to be unique across the DMVPN network. Even though ISAKMP and IPsec would negotiate NAT-T and “learn” the correct NAT public address for the private IP address of this spoke, NHRP could only “see” and use the private IP address of the spoke for its mapping entries. Effective with the NAT-Transparency Aware DMVPN enhancement, NHRP can now learn and use the NAT public address for its mappings as long as IPsec transport mode is used (which is the recommended IPsec mode for DMVPN networks). The restriction that the private interface IP address of the spoke must be unique across the DMVPN network has been removed. It is recommended that all DMVPN routers be upgraded to the new code before you try to use the new functionality even though spoke routers that are not behind NAT do not need to be upgraded. In addition, you cannot convert upgraded spoke routers that are behind NAT to the new configuration (IPsec transport mode) until the hub routers have been upgraded.

Also added in Cisco IOS Releases 12.3(9a) and 12.3(11)T is the capability to have the hub DMVPN router behind static NAT. This was a change in the ISAKMP NAT-T support. For this functionality to be used, all the DMVPN spoke routers and hub routers must be upgraded, and IPsec must use transport mode.

For these NAT-Transparency Aware enhancements to work, you must use IPsec transport mode on the transform set. Also, even though NAT-Transparency (IKE and IPsec) can support two peers (IKE and IPsec) being translated to the same IP address (using the UDP ports to differentiate them), this functionality is not supported for DMVPN. All DMVPN spokes must have a unique IP address after they have been NAT translated. They can have the same IP address before they are NAT translated.

Figure 4 illustrates a NAT-Transparency Aware DMVPN scenario.

Note

In Cisco IOS Release 12.4(6)T or earlier, DMVPN spokes behind NAT *will not* participate in dynamic direct spoke-to-spoke tunnels. Any traffic to or from a spoke that is behind NAT will be forwarded using the DMVPN hub routers. DMVPN spokes that are not behind NAT in the same DMVPN network may create dynamic direct spoke-to-spoke tunnels between each other.

In Cisco IOS Release 12.4(6)T or later releases, DMVPN spokes behind NAT *will* participate in dynamic direct spoke-to-spoke tunnels. The spokes must be behind NAT boxes that are performing NAT, not PAT. The NAT box must translate the spoke to the same outside NAT IP address for the spoke-spoke connections as the NAT box does for the spoke-hub connection. If there is more than one DMVPN spoke behind the same NAT box, then the NAT box *must* translate the DMVPN spokes to different outside NAT IP addresses. It is also likely that you may not be able to build a direct spoke-spoke tunnel between these spokes. If a spoke-spoke tunnel fails to form, then the spoke-spoke packets will continue to be forwarded via the spoke-hub-spoke path.

Figure 4 NAT-Transparency Aware DMVPN

Call Admission Control with DMVPN

In a DMVPN network, it is easy for a DMVPN router to become “overwhelmed” with the number of tunnels it is trying to build. Call Admission Control can be used to limit the number of tunnels that can be built at any one time, thus protecting the memory of the router and CPU resources.

It is most likely that Call Admission Control will be used on a DMVPN spoke to limit the total number of ISAKMP sessions (DMVPN tunnels) that a spoke router will attempt to initiate or accept. This limiting is accomplished by configuring an IKE SA limit under Call Admission Control, which configures the router to drop new ISAKMP session requests (inbound and outbound) if the current number of ISAKMP SAs exceeds the limit.

It is most likely that Call Admission Control will be used on a DMVPN hub to rate limit the number of DMVPN tunnels that are attempting to be built at the same time. The rate limiting is accomplished by configuring a system resource limit under Call Admission Control, which configures the router to drop new ISAKMP session requests (new DMVPN tunnels) when the system utilization is above a specified percentage. The dropped session requests allow the DMVPN hub router to complete the current ISAKMP session requests, and when the system utilization drops, it can process the previously dropped sessions when they are reattempted.

No special configuration is required to use Call Admission Control with DMVPN. For information about configuring Call Admission Control, see the reference in the section “[Related Documents](#).”

NHRP Rate-Limiting Mechanism

NHRP has a rate-limiting mechanism that restricts the total number of NHRP packets from any given interface. The default values, which are set using the **ip nhrp max-send** command, are 100 packets every 10 seconds per interface. If the limit is exceeded, you will get the following system message:

```
%NHRP-4-QUOTA: Max-send quota of [int]pkts/[int]Sec. exceeded on [chars]
```

For more information about this system message, see the document [12.4T System Message Guide](#).

How to Configure Dynamic Multipoint VPN (DMVPN)

To enable mGRE and IPsec tunneling for hub and spoke routers, you must configure an IPsec profile that uses a global IPsec policy template and configure your mGRE tunnel for IPsec encryption. This section contains the following procedures:

- [Configuring an IPsec Profile, page 11](#) (required)
- [Configuring the Hub for DMVPN, page 13](#) (required)
- [Configuring the Spoke for DMVPN, page 17](#) (required)
- [Configuring the Forwarding of Clear-Text Data IP Packets into a VRF, page 20](#) (optional)
- [Configuring the Forwarding of Encrypted Tunnel Packets into a VRF, page 21](#) (optional)
- [Configuring DMVPN—Traffic Segmentation Within DMVPN, page 22](#)
- [Troubleshooting Dynamic Multipoint VPN \(DMVPN\), page 27](#) (optional)

Configuring an IPsec Profile

The IPsec profile shares most of the same commands with the crypto map configuration, but only a subset of the commands are valid in an IPsec profile. Only commands that pertain to an IPsec policy can be issued under an IPsec profile; you cannot specify the IPsec peer address or the access control list (ACL) to match the packets that are to be encrypted.

Prerequisites

Before configuring an IPsec profile, you must define a transform set by using the **crypto ipsec transform-set** command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec profile** *name*
4. **set transform-set** *transform-set-name*
5. **set identity**
6. **set security association lifetime** {*seconds seconds* | *kilobytes kilobytes*}
7. **set pfs** [*group1* | *group2*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable	Enables higher privilege levels, such as privileged EXEC mode.
	Example: Router> enable	Enter your password if prompted.
Step 2	configure terminal	Enters global configuration mode.
	Example: Router# configure terminal	
Step 3	crypto ipsec profile <i>name</i>	Defines the IPsec parameters that are to be used for IPsec encryption between “spoke and hub” and “spoke and spoke” routers.
	Example: Router(config)# crypto ipsec profile vpnprof	This command enters crypto map configuration mode. The <i>name</i> argument specifies the name of the IPsec profile.
Step 4	set transform-set <i>transform-set-name</i>	Specifies which transform sets can be used with the IPsec profile.
	Example: Router(config-crypto-map)# set transform-set trans2	The <i>transform-set-name</i> argument specifies the name of the transform set.
Step 5	set identity	(Optional) Specifies identity restrictions to be used with the IPsec profile.
	Example: Router(config-crypto-map)# set identity	
Step 6	set security association lifetime {seconds <i>seconds</i> kilobytes <i>kilobytes</i>}	(Optional) Overrides the global lifetime value for the IPsec profile.
	Example: Router(config-crypto-map)# set security association lifetime seconds 1800	- The seconds <i>seconds</i> option specifies the number of seconds a security association will live before expiring; the kilobytes <i>kilobytes</i> option specifies the volume of traffic (in kilobytes) that can pass between IPsec peers using a given security association before that security association expires. - The default for the <i>seconds</i> argument is 3600 seconds.
Step 7	set pfs [<i>group1</i> <i>group2</i>]	(Optional) Specifies that IPsec should ask for perfect forward secrecy (PFS) when requesting new security associations for this IPsec profile. If this command is not specified, the default (group1) will be enabled.
	Example: Router(config-crypto-map)# set pfs group2	The group1 keyword specifies that IPsec should use the 768-bit Diffie-Hellman (DH) prime modulus group when performing the new DH exchange; the group2 keyword specifies the 1024-bit DH prime modulus group.

What to Do Next

Proceed to the following sections “[Configuring the Hub for DMVPN](#)” and “[Configuring the Spoke for DMVPN](#).”

Configuring the Hub for DMVPN

To configure the hub router for mGRE and IPsec integration (that is, associate the tunnel with the IPsec profile configured in the previous procedure), use the following commands:

**Note**

NHRP network IDs are locally significant and can be different. It makes sense from a deployment and maintenance perspective to use unique network ID numbers (using the **ip nhrp network-id** command) across all routers in a DMVPN network, but it is not necessary that they be the same.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel** *number*
4. **ip address** *ip-address mask [secondary]*
5. **ip mtu** *bytes*
6. **ip nhrp authentication** *string*
7. **ip nhrp map multicast dynamic**
8. **ip nhrp network-id** *number*
9. **tunnel source** {*ip-address* | *type number*}
10. **tunnel key** *key-number*
11. **tunnel mode gre multipoint**
12. **tunnel protection ipsec profile** *name*
13. **bandwidth** *kbps*
14. **ip tcp adjust-mss** *max-segment-size*
15. **ip nhrp holdtime** *seconds*
16. **delay** *number*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables higher privilege levels, such as privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: Router(config)# interface tunnel 5	Configures a tunnel interface and enters interface configuration mode The <i>number</i> argument specifies the number of the tunnel interface that you want to create or configure. There is no limit on the number of tunnel interfaces you can create.
Step 4	ip address <i>ip-address mask [secondary]</i> Example: Router(config-if)# ip address 10.0.0.1 255.255.255.0	Sets a primary or secondary IP address for the tunnel interface. Note All hubs and spokes that are in the same DMVPN network must be addressed in the same IP subnet.
Step 5	ip mtu <i>bytes</i> Example: Router(config-if)# ip mtu 1400	Sets the maximum transmission unit (MTU) size, in bytes, of IP packets sent on an interface.
Step 6	ip nhrp authentication <i>string</i> Example: Router(config-if)# ip nhrp authentication donttell	Configures the authentication string for an interface using NHRP. Note The NHRP authentication string must be set to the same value on all hubs and spokes that are in the same DMVPN network.
Step 7	ip nhrp map multicast dynamic Example: Router(config-if)# ip nhrp map multicast dynamic	Allows NHRP to automatically add spoke routers to the multicast NHRP mappings.
Step 8	ip nhrp network-id <i>number</i> Example: Router(config-if)# ip nhrp network-id 99	Enables NHRP on an interface. The <i>number</i> argument specifies a globally unique 32-bit network identifier from a nonbroadcast multiaccess (NBMA) network. The range is from 1 to 4294967295.
Step 9	tunnel source {<i>ip-address</i> <i>type number</i>} Example: Router (config-if)# tunnel source Ethernet0	Sets source address for a tunnel interface.

	Command or Action	Purpose
Step 10	tunnel key <i>key-number</i> Example: Router(config-if)# tunnel key 100000	(Optional) Enables an ID key for a tunnel interface. The <i>key-number</i> argument specifies a number from 0 to 4,294,967,295 that identifies the tunnel key. Note The key number must be set to the same value on all hubs and spokes that are in the same DMVPN network. Note This command should not be configured if you are using a Cisco 6500 or Cisco 7600 platform.
Step 11	tunnel mode gre multipoint Example: Router(config-if)# tunnel mode gre multipoint	Sets the encapsulation mode to mGRE for the tunnel interface.
Step 12	tunnel protection ipsec profile <i>name</i> Example: Router(config-if)# tunnel protection ipsec profile vpnprof	Associates a tunnel interface with an IPsec profile. The <i>name</i> argument specifies the name of the IPsec profile; this value must match the <i>name</i> specified in the crypto ipsec profile <i>name</i> command.
Step 13	bandwidth <i>kbps</i> Example: Router(config-if)# bandwidth 1000	Sets the current bandwidth value for an interface to higher-level protocols. The <i>kbps</i> argument specifies the bandwidth in kilobits per second. The default value is 9. The recommend bandwidth value is 1000 or greater. Setting the bandwidth value to at least 1000 is critical if EIGRP is used over the tunnel interface. Higher bandwidth values may be necessary depending on the number of spokes supported by a hub.
Step 14	ip tcp adjust-mss <i>max-segment-size</i> Example: Router(config-if)# ip tcp adjust-mss 1360	Adjusts the maximum segment size (MSS) value of TCP packets going through a router. The <i>max-segment-size</i> argument specifies the maximum segment size, in bytes. The range is from 500 to 1460. The recommended value is 1360 when the number of IP MTU bytes is set to 1400. With these recommended settings, TCP sessions quickly scale back to 1400-byte IP packets so the packets will “fit” in the tunnel.

	Command or Action	Purpose
Step 15	ip nhrp holdtime <i>seconds</i> Example: Router(config-if)# ip nhrp holdtime 450	Changes the number of seconds that NHRP NBMA addresses are advertised as valid in authoritative NHRP responses. The <i>seconds</i> argument specifies the time in seconds that NBMA addresses are advertised as valid in positive authoritative NHRP responses. The recommended value ranges from 300 seconds to 600 seconds.
Step 16	delay <i>number</i> Example: Router(config-if)# delay 1000	(Optional) Used to change the EIGRP routing metric for routes learned over the tunnel interface. The <i>number</i> argument specifies the delay time in seconds. The recommend value is 1000.

Configuring the Spoke for DMVPN

To configure spoke routers for mGRE and IPsec integration, use the following commands.

**Note**

NHRP network IDs are locally significant and can be different. It makes sense from a deployment and maintenance perspective to use unique network ID numbers (using the **ip nhrp network-id** command) across all routers in a DMVPN network, but it is not necessary that they be the same.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel** *number*
4. **ip address** *ip-address mask [secondary]*
5. **ip mtu** *bytes*
6. **ip nhrp authentication** *string*
7. **ip nhrp map** *hub-tunnel-ip-address hub-physical-ip-address*
8. **ip nhrp map multicast** *hub-physical-ip-address*
9. **ip nhrp nhs** *hub-tunnel-ip-address*
10. **ip nhrp network-id** *number*
11. **tunnel source** {*ip-address* | *type number*}
12. **tunnel key** *key-number*
13. **tunnel mode gre multipoint**
or
tunnel destination *hub-physical-ip-address*
14. **tunnel protection ipsec profile** *name*
15. **bandwidth** *kbps*
16. **ip tcp adjust-mss** *max-segment-size*
17. **ip nhrp holdtime** *seconds*
18. **delay** *number*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable	Enables higher privilege levels, such as privileged EXEC mode.
	Example: Router> enable	Enter your password if prompted.
Step 2	configure terminal	Enters global configuration mode.
	Example: Router# configure terminal	
Step 3	interface tunnel <i>number</i>	Configures a tunnel interface and enters interface configuration mode.
	Example: Router(config)# interface tunnel 5	The <i>number</i> argument specifies the number of the tunnel interface that you want to create or configure. There is no limit on the number of tunnel interfaces you can create.
Step 4	ip address <i>ip-address mask [secondary]</i>	Sets a primary or secondary IP address for the tunnel interface.
	Example: Router(config-if)# ip address 10.0.0.2 255.255.255.0	Note All hubs and spokes that are in the same DMVPN network must be addressed in the same IP subnet.
Step 5	ip mtu <i>bytes</i>	Sets the MTU size, in bytes, of IP packets sent on an interface.
	Example: Router(config-if)# ip mtu 1400	
Step 6	ip nhrp authentication <i>string</i>	Configures the authentication string for an interface using NHRP.
	Example: Router(config-if)# ip nhrp authentication donttell	Note The NHRP authentication string be set to the same value on all hubs and spokes that are in the same DMVPN network.
Step 7	ip nhrp map <i>hub-tunnel-ip-address hub-physical-ip-address</i>	Statically configures the IP-to-NBMA address mapping of IP destinations connected to an MBMA network.
	Example: Router(config-if)# ip nhrp map 10.0.0.1 172.17.0.1	<i>hub-tunnel-ip-address</i>—Defines the NHRP server at the hub, which is permanently mapped to the static public IP address of the hub. <i>hub-physical-ip-address</i>—Defines the static public IP address of the hub.
Step 8	ip nhrp map multicast <i>hub-physical-ip-address</i>	Enables the use of a dynamic routing protocol between the spoke and hub, and sends multicast packets to the hub router.
	Example: Router(config-if)# ip nhrp map multicast 172.17.0.1	

	Command or Action	Purpose
Step 9	<pre>ip nhrp nhs hub-tunnel-ip-address</pre> Example: Router(config-if)# ip nhrp nhs 10.0.0.1	Configures the hub router as the NHRP next-hop server.
Step 10	<pre>ip nhrp network-id number</pre> Example: Router(config-if)# ip nhrp network-id 99	Enables NHRP on an interface. The <i>number</i> argument specifies a globally unique 32-bit network identifier from a NBMA network. The range is from 1 to 4294967295.
Step 11	<pre>tunnel source {ip-address type number}</pre> Example: Router (config-if)# tunnel source Ethernet0	Sets the source address for a tunnel interface.
Step 12	<pre>tunnel key key-number</pre> Example: Router (config-if)# tunnel key 100000	(Optional) Enables an ID key for a tunnel interface. - The <i>key-number</i> argument specifies a number from 0 to 4,294,967,295 that identifies the tunnel key. - The key number must be set to the same value on all hubs and spokes that are in the same DMVPN network. Note This command should not be configured if you are using a Cisco 6500 or Cisco 7600 platform.
Step 13	<pre>tunnel mode gre multipoint</pre> or <pre>tunnel destination hub-physical-ip-address</pre> Example: Router(config-if)# tunnel mode gre multipoint or <pre>Router(config-if)# tunnel destination 172.17.0.1</pre>	Sets the encapsulation mode to mGRE for the tunnel interface. Use this command if data traffic can use dynamic spoke-to-spoke traffic. Specifies the destination for a tunnel interface. Use this command if data traffic can use hub-and-spoke tunnels.
Step 14	<pre>tunnel protection ipsec profile name</pre> Example: Router(config-if)# tunnel protection ipsec profile vpnprof	Associates a tunnel interface with an IPsec profile. The <i>name</i> argument specifies the name of the IPsec profile; this value must match the <i>name</i> specified in the crypto ipsec profile name command.
Step 15	<pre>bandwidth kbps</pre> Example: Router(config-if)# bandwidth 1000	Sets the current bandwidth value for an interface to higher-level protocols. The <i>kbps</i> argument specifies the bandwidth in kilobits per second. The default value is 9. The recommend bandwidth value is 1000 or greater. The bandwidth setting for the spoke does not need to equal the bandwidth setting for the DMVPN hub. It is usually easier if all of the spokes use the same or similar value.

	Command or Action	Purpose
Step 16	<code>ip tcp adjust-mss <i>max-segment-size</i></code> Example: Router(config-if)# ip tcp adjust-mss 1360	Adjusts the maximum segment size (MSS) value of TCP packets going through a router. The <i>max-segment-size</i> argument specifies the maximum segment size, in bytes. The range is from 500 to 1460. The recommended number value is 1360 when the number of IP MTU bytes is set to 1400. With these recommended settings, TCP sessions quickly scale back to 1400-byte IP packets so the packets will “fit” in the tunnel.
Step 17	<code>ip nhrp holdtime <i>seconds</i></code> Example: Router(config-if)# ip nhrp holdtime 450	Changes the number of seconds that NHRP NBMA addresses are advertised as valid in authoritative NHRP responses. The <i>seconds</i> argument specifies the time in seconds that NBMA addresses are advertised as valid in positive authoritative NHRP responses. The recommended value ranges from 300 seconds to 600 seconds.
Step 18	<code>delay <i>number</i></code> Example: Router(config-if)# delay 1000	(Optional) Used to change the EIGRP routing metric for routes learned over the tunnel interface. The <i>number</i> argument specifies the delay time in seconds. The recommend value is 1000.

Configuring the Forwarding of Clear-Text Data IP Packets into a VRF

To configure the forwarding of clear-text data IP packets into a VRF, perform the following steps. This configuration assumes that the VRF BLUE has already been configured.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **ip vrf forwarding** *vrf-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable	Enables higher privilege levels, such as privileged EXEC mode.
	Example: Router> enable	Enter your password if prompted.
Step 2	configure terminal	Enters global configuration mode.
	Example: Router# configure terminal	
Step 3	interface <i>type number</i>	Configures an interface type and enters interface configuration mode.
	Example: Router (config)# interface tunnel0	
Step 4	ip vrf forwarding <i>vrf-name</i>	Associates a VPN VRF with an interface or subinterface.
	Example: Router (config-if)# ip vrf forwarding BLUE	

Configuring the Forwarding of Encrypted Tunnel Packets into a VRF

To configure the forwarding of encrypted tunnel packets into a VRF, perform the following steps. This configuration assumes that the VRF RED has already been configured.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface *type number***
4. **tunnel vrf *vrf-name***

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable	Enables higher privilege levels, such as privileged EXEC mode.
	Example: Router> enable	Enter your password if prompted.
Step 2	configure terminal	Enters global configuration mode.
	Example: Router# configure terminal	

	Command or Action	Purpose
Step 3	<code>interface type number</code> Example: Router (config)# interface tunnel0	Configures an interface type and enters interface configuration mode.
Step 4	<code>tunnel vrf vrf-name</code> Example: Router (config-if)# tunnel vrf RED	Associates a VPN VRF instance with a specific tunnel destination, interface, or subinterface.

Configuring DMVPN—Traffic Segmentation Within DMVPN

There are no new commands to use for configuring traffic segmentation, but there are tasks you must complete in order to segment traffic within a DMVPN tunnel:

- [Enabling MPLS on the VPN Tunnel, page 22](#)
- [Configuring Multiprotocol BGP on the Hub Router, page 23](#)
- [Configuring Multiprotocol BGP on the Spoke Routers, page 25](#)

Prerequisites

The tasks that follow assume that the DMVPN tunnel and the VRFs “red” and “blue” have already been configured.

For information on configuring a DMVPN tunnel, see the “[Configuring the Hub for DMVPN](#)” section on [page 13](#) and the “[Configuring the Spoke for DMVPN](#)” section on [page 17](#). For details about VRF configuration, see the “[Configuring the Forwarding of Clear-Text Data IP Packets into a VRF](#)” section on [page 20](#) and the “[Configuring the Forwarding of Encrypted Tunnel Packets into a VRF](#)” section on [page 21](#).

Enabling MPLS on the VPN Tunnel

Because traffic segmentation within a DMVPN tunnel depends upon MPLS, you must configure MPLS for each VRF instance in which traffic will be segmented. For detailed information about configuring MPLS, see [Cisco IOS Multiprotocol Label Switching Configuration Guide](#), Release 12.4.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. `interface type number`
4. **mpls ip**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable	Enables higher privilege levels, such as privileged EXEC mode.
	Example: Router> enable	Enter your password if prompted.
Step 2	configure terminal	Enters global configuration mode.
	Example: Router# configure terminal	
Step 3	interface <i>type number</i>	Configures an interface type and enters interface configuration mode.
	Example: Router (config)# interface tunnel0	
Step 4	mpls ip	Enables MPLS tagging of packets on the specified tunnel interface.
	Example: Router (config-if)# mpls ip	

Configuring Multiprotocol BGP on the Hub Router

You must configure multiprotocol iBGP (MP-iBGP) to enable advertisement of VPNv4 prefixes and labels to be applied to the VPN traffic. Use BGP to configure the hub as a route reflector. To force all traffic to be routed via the hub, configure the BGP route reflector to change the next hop to itself when it advertises VPNv4 prefixes to the route reflector clients (spokes).

For more information about the BGP routing protocol, see the “BGP” chapter in the [Cisco IOS IP Routing Protocols Configuration Guide](#), Release 12.4.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **router bgp**
4. **neighbor *ipaddress* remote-as *as-number***
5. **neighbor *ipaddress* update-source *interface***
6. **address-family vpnv4**
7. **neighbor *ipaddress* activate**
8. **neighbor *ipaddress* send-community extended**
9. **neighbor *ipaddress* route-reflector-client**
10. **neighbor *ipaddress* route-map *nexthop* out**
11. **exit-address family**
12. **address-family ipv4 *vrf-name***

13. redistribute connected
14. route-map
15. set ip next-hop *ipaddress*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables higher privilege levels, such as privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	router bgp Example: Router (config)# router bgp	Enters BGP configuration mode.
Step 4	neighbor ipaddress remote-as as-number Example: Router (config)# neighbor 10.0.0.11 remote-as 1	Adds an entry to the BGP or multiprotocol BGP neighbor table.
Step 5	neighbor ipaddress update-source interface Example: Router (config)# neighbor 10.10.10.11 update-source Tunnel1	Configures the Cisco IOS software to allow BGP sessions to use any operational interface for TCP connections.
Step 6	address-family vpnv4 Example: Router (config)# address-family vpnv4	Enters address family configuration mode to configure a routing session using Virtual Private Network (VPN) Version 4 address prefixes.
Step 7	neighbor ipaddress activate Example: Router (config)# neighbor 10.0.0.11 activate	Enables the exchange of information with a BGP neighbor.
Step 8	neighbor ipaddress send-community extended Example: Router (config)# neighbor 10.0.0.11 send-community extended	Specifies that extended community attributes should be sent to a BGP neighbor.

	Command or Action	Purpose
Step 9	neighbor <i>ipaddress</i> route-reflector-client Example: Router (config)# neighbor 10.0.0.11 route-reflector-client	Configures the router as a BGP route reflector and configures the specified neighbor as its client.
Step 10	neighbor <i>ipaddress</i> route-map <i>nexthop out</i> Example: Router (config)# neighbor 10.0.0.11 route-map nexthop out	Forces all traffic to be routed via the hub.
Step 11	exit-address-family Example: Router (config)# exit-address-family	Exits the address family configuration mode for VPNv4.
Step 12	address-family <i>ipv4 vrf-name</i> Example: Router (config)# address-family ipv4 vrf red	Enters address family configuration mode to configure a routing session using standard IP Version 4 address prefixes.
Step 13	redistribute connected Example: Router (config)# redistribute connected	Redistributes routes that are established automatically by virtue of having enabled IP on an interface from one routing domain into another routing domain.
Step 14	route-map Example: Router (config)# route-map nexthop permit 10	Enters route map configuration mode to configure the next-hop that will be advertised to the spokes.
Step 15	set ip next-hop <i>ipaddress</i> Example: Router (config)# set ip next-hop 10.0.0.1	Sets the next hop to be the hub.

Configuring Multiprotocol BGP on the Spoke Routers

Multiprotocol-iBGP (MP-iBGP) must be configured on the spoke routers and the hub. Follow the steps below for each spoke router in the DMVPN.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **router bgp**
4. **neighbor *ipaddress* remote-as *as-number***
5. **neighbor *ipaddress* update-source *interface***
6. **address-family vpnv4**

7. **neighbor ipaddress activate**
8. **neighbor ipaddress send-community extended**
9. **exit-address-family**
10. **address-family ipv4 vrf-name**
11. **redistribute connected**
12. **exit-address-family**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables higher privilege levels, such as privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	router bgp Example: Router (config)# router bgp 1	Enters BGP configuration mode.
Step 4	neighbor ipaddress remote-as as-number Example: Router (config)# neighbor 10.0.0.1 remote-as 1	Adds an entry to the BGP or multiprotocol BGP neighbor table.
Step 5	neighbor ipaddress update-source interface Example: Router (config)# neighbor 10.10.10.1 update-source Tunnel1	Configures the Cisco IOS software to allow BGP sessions to use any operational interface for TCP connections.
Step 6	address-family vpvv4 Example: Router (config)# address-family vpvv4	Enters address family configuration mode to configure a routing session using Virtual Private Network (VPN) Version 4 address prefixes.
Step 7	neighbor ipaddress activate Example: Router (config)# neighbor 10.0.0.1 activate	Enables the exchange of information with a BGP neighbor.
Step 8	neighbor ipaddress send-community extended Example: Router (config)# neighbor 10.0.0.1 send-community extended	Specifies that extended community attributes should be sent to a BGP neighbor.

	Command or Action	Purpose
Step 9	exit-address-family Example: Router (config)# exit-address-family	Exits the address family configuration mode.
Step 10	address-family ipv4 vrf-name Example: Router (config)# address-family ipv4 vrf red	Enters address family configuration mode to configure a routing session using standard IP Version 4 address prefixes.
Step 11	redistribute connected Example: Router (config)# redistribute connected	Redistributes routes that are established automatically by virtue of having enabled IP on an interface from one routing domain into another routing domain.
Step 12	exit-address-family Example: Router (config)# exit-address-family	Exits the address family configuration mode. Note Repeat Steps 10–12 for each VRF.

Troubleshooting Dynamic Multipoint VPN (DMVPN)

After configuring DMVPN, to verify that DMVPN is operating correctly, to clear DMVPN statistics or sessions, or to debug DMVPN, you may perform the following optional steps:

SUMMARY STEPS

1. **clear dmvpn session** [peer {nbma | tunnel} ip-address] [interface {tunnel number}] [vrf vrf-name] [static]
2. **clear dmvpn statistics** [peer {nbma | tunnel} ip-address] [interface {tunnel number}] [vrf vrf-name]
3. **debug dmvpn** {[condition [unmatched] | [peer [nbma | tunnel {ip-address}]] | [vrf {vrf-name}] | [interface {tunnel number}]]} [{error | detail | packet | all} {nhrp | crypto | tunnel | socket | all}]
4. **debug nhrp condition**
5. **debug nhrp error**
6. **logging dmvpn** [rate-limit seconds]
7. **show crypto ipsec sa** [active | standby]
8. **show crypto isakmp sa**
9. **show crypto map**
10. **show dmvpn** [peer [nbma | tunnel {ip-address}] | [network {ip-address} {mask}]] [vrf {vrf-name}] [interface {tunnel number}] [detail] [static] [debug-condition]
11. **show ip nhrp traffic** [interface {tunnel number}]

DETAILED STEPS

-
- Step 1** The **clear dmvpn session** command is used to clear DMVPN sessions.
- The following example clears only dynamic DMVPN sessions:
- ```
Router# clear dmvpn session peer nbma
```
- The following example clears all DMVPN sessions, both static and dynamic, for the specified tunnel:
- ```
Router# clear dmvpn session interface tunnel 100 static
```
- Step 2** The **clear dmvpn statistics** command is used to clear DMVPN related counters. The following example shows how to clear DMVPN related session counters for the specified tunnel interface:
- ```
Router# clear dmvpn statistics peer tunnel 192.0.2.3
```
- Step 3** The **debug dmvpn** command is used to debug DMVPN sessions. You can enable or disable DMVPN debugging based on a specific condition. There are three levels of DMVPN debugging, listed in the order of details from lowest to highest:
- Error level
  - Detail level
  - Packet level
- The following example shows how to enable conditional DMVPN debugging that displays all error debugs for next hop routing protocol (NHRP), sockets, tunnel protection and crypto information:
- ```
Router# debug dmvpn error all
```
- Step 4** The **debug nhrp condition** command enables or disables debugging based on a specific condition. The following example shows how to enable conditional NHRP debugging:
- ```
Router# debug nhrp condition
```
- Step 5** The **debug nhrp error** command displays information about NHRP error activity. The following example shows how to enable debugging for NHRP error messages:
- ```
Router# debug nhrp error
```
- Step 6** The **logging dmvpn** command is used to enable DMVPN system logging. The following command shows how to enable DMVPN system logging at the rate of 1 message every 20 seconds:
- ```
Router(config)# logging dmvpn rate-limit 20
```
- The following example shows a sample system log with DMVPN messages:
- ```
%DMVPN-7-CRYPTO_SS: Tunnel101-192.0.2.1 socket is UP
%DMVPN-5-NHRP_NHS: Tunnel101 192.0.2.251 is UP
%DMVPN-5-NHRP_CACHE: Client 192.0.2.2 on Tunnel1 Registered.
%DMVPN-5-NHRP_CACHE: Client 192.0.2.2 on Tunnel101 came UP.
%DMVPN-3-NHRP_ERROR: Registration Request failed for 192.0.2.251 on Tunnel101
```
- Step 7** The **show crypto ipsec sa** command displays the settings used by the current SAs. The following example output shows the IPsec SA status of only the active device:
- ```
Router# show crypto ipsec sa active

interface: Ethernet0/0
 Crypto map tag: to-peer-outside, local addr 209.165.201.3
 protected vrf: (none)
 local ident (addr/mask/prot/port): (192.168.0.1/255.255.255.255/0/0)
 remote ident (addr/mask/prot/port): (172.16.0.1/255.255.255.255/0/0)
 current_peer 209.165.200.225 port 500

ike_cookies: 9263635C CA4B4E99 C14E908E 8EE2D79C
IV size: 8 bytes
replay detection support: Y
Status: ACTIVE
```

**Step 8** The **show crypto isakmp sa** command displays all current IKE SAs at a peer. For example, the following sample output is displayed after IKE negotiations have successfully completed between two peers.

Router# **show crypto isakmp sa**

| dst           | src           | state   | conn-id | slot |
|---------------|---------------|---------|---------|------|
| 172.17.63.19  | 172.16.175.76 | QM_IDLE | 2       | 0    |
| 172.17.63.19  | 172.17.63.20  | QM_IDLE | 1       | 0    |
| 172.16.175.75 | 172.17.63.19  | QM_IDLE | 3       | 0    |

**Step 9** The **show crypto map** command displays the crypto map configuration.

The following sample output is displayed after a crypto map has been configured:

Router# **show crypto map**

```
Crypto Map "Tunnel5-head-0" 10 ipsec-isakmp
 Profile name: vpnprof
 Security association lifetime: 4608000 kilobytes/3600 seconds
 PFS (Y/N): N
 Transform sets={trans2, }

Crypto Map "Tunnel5-head-0" 20 ipsec-isakmp
 Map is a PROFILE INSTANCE.
 Peer = 172.16.175.75
 Extended IP access list
 access-list permit gre host 172.17.63.19 host 172.16.175.75
 Current peer: 172.16.175.75
 Security association lifetime: 4608000 kilobytes/3600 seconds
 PFS (Y/N): N
 Transform sets={trans2, }

Crypto Map "Tunnel5-head-0" 30 ipsec-isakmp
 Map is a PROFILE INSTANCE.
 Peer = 172.17.63.20
 Extended IP access list
 access-list permit gre host 172.17.63.19 host 172.17.63.20
 Current peer: 172.17.63.20
 Security association lifetime: 4608000 kilobytes/3600 seconds
 PFS (Y/N): N
 Transform sets={trans2, }

Crypto Map "Tunnel5-head-0" 40 ipsec-isakmp
 Map is a PROFILE INSTANCE.
 Peer = 172.16.175.76
```

```

Extended IP access list
 access-list permit gre host 172.17.63.19 host 172.16.175.76
Current peer: 172.16.175.76
Security association lifetime: 4608000 kilobytes/3600 seconds
PFS (Y/N): N
Transform sets={trans2, }
Interfaces using crypto map Tunnel5-head-0:
Tunnel5

```

**Step 10** The **show dmvpn** command displays DMVPN specific session information. The following example shows example summary output:

```
Router# show dmvpn
```

```

Legend: Attrb --> S - Static, D - Dynamic, I - Incomplete
 N - NATed, L - Local, X - No Socket
 # Ent --> Number of NHRP entries with same NBMA peer

```

```

! The line below indicates that the sessions are being displayed for Tunnel1.
! Tunnel1 is acting as a spoke and is a peer with three other NBMA peers.

```

```

Tunnel1, Type: Spoke, NBMA Peers: 3,
Ent Peer NBMA Addr Peer Tunnel Add State UpDn Tm Attrb

 2 192.0.2.21 192.0.2.116 IKE 3w0d D
 1 192.0.2.102 192.0.2.11 NHRP 02:40:51 S

Ent Peer NBMA Addr Peer Tunnel Add State UpDn Tm Attrb

 1 192.0.2.25 192.0.2.171 IKE never S

```

**Step 11** The **show ip nhrp traffic** command displays NHRP statistics. The following example shows output for a specific tunnel, tunnel7:

```
Router# show ip nhrp traffic interface tunnel7
```

```
Tunnel7: Max-send Limit:100Pkts/10Sec, Usage:0%
```

```
Sent: Total 79
```

```

```

## What to Do Next

If you have troubleshooted your DMVPN configuration and proceed to contact technical support, the **show tech-support** command includes information for DMVPN sessions. For more information, see the **show tech-support** command in the Cisco IOS Configuration Fundamentals Command Reference.

# Configuration Examples for Dynamic Multipoint VPN (DMVPN) Feature

This section provides the following comprehensive configuration examples:

- [Hub Configuration for DMVPN: Example, page 31](#)
- [Spoke Configuration for DMVPN: Example, page 32](#)
- [VRF Aware DMVPN: Example, page 33](#)

## Hub Configuration for DMVPN: Example

In the following example, which configures the hub router for multipoint GRE and IPsec integration, no explicit configuration lines are needed for each spoke; that is, the hub is configured with a global IPsec policy template that all spoke routers can talk to. In this example, EIGRP is configured to run over the private physical interface and the tunnel interface.

```
crypto isakmp policy 1
 authentication pre-share
crypto isakmp key cisco47 address 0.0.0.0
!
crypto ipsec transform-set trans2 esp-des esp-md5-hmac
mode transport
!
crypto ipsec profile vpnprof
 set transform-set trans2
!
interface Tunnel0
 bandwidth 1000
 ip address 10.0.0.1 255.255.255.0
 ! Ensures longer packets are fragmented before they are encrypted; otherwise, the
 receiving router would have to do the reassembly.
 ip mtu 1400
 ! The following line must match on all nodes that "want to use" this mGRE tunnel:
 ip nhrp authentication donttell
 ! Note that the next line is required only on the hub.
 ip nhrp map multicast dynamic
 ! The following line must match on all nodes that want to use this mGRE tunnel:
 ip nhrp network-id 99
 ip nhrp holdtime 300
 ! Turns off split horizon on the mGRE tunnel interface; otherwise, EIGRP will not
 advertise routes that are learned via the mGRE interface back out that interface.
 no ip split-horizon eigrp 1
 ! Enables dynamic, direct spoke-to-spoke tunnels when using EIGRP.
 no ip next-hop-self eigrp 1
 ip tcp adjust-mss 1360
 delay 1000
 ! Sets IPsec peer address to Ethernet interface's public address.
 tunnel source Ethernet0
 tunnel mode gre multipoint
 ! The following line must match on all nodes that want to use this mGRE tunnel.
 tunnel key 1000000
 tunnel protection ipsec profile vpnprof
!
interface Ethernet0
 ip address 172.17.0.1 255.255.255.0
!
interface Ethernet1
 ip address 192.168.0.1 255.255.255.0
```

```

!
router eigrp 1
 network 10.0.0.0 0.0.0.255
 network 192.168.0.0 0.0.0.255
!

```

For information about defining and configuring ISAKMP profiles, see the references in the [“Related Documents”](#) section.

## Spoke Configuration for DMVPN: Example

In the following example, all spokes are configured the same except for tunnel and local interface address, thereby, reducing necessary configurations for the user:

```

crypto isakmp policy 1
 authentication pre-share
crypto isakmp key cisco47 address 0.0.0.0
!
crypto ipsec transform-set trans2 esp-des esp-md5-hmac
 mode transport
!
crypto ipsec profile vpnprof
 set transform-set trans2
!
interface Tunnel0
 bandwidth 1000
 ip address 10.0.0.2 255.255.255.0
 ip mtu 1400
! The following line must match on all nodes that want to use this mGRE tunnel:
 ip nhrp authentication donttell
! Definition of NHRP server at the hub (10.0.0.1), which is permanently mapped to the
static public address of the hub (172.17.0.1).
 ip nhrp map 10.0.0.1 172.17.0.1
! Sends multicast packets to the hub router, and enables the use of a dynamic routing
protocol between the spoke and the hub.
 ip nhrp map multicast 172.17.0.1
! The following line must match on all nodes that want to use this mGRE tunnel:
 ip nhrp network-id 99
 ip nhrp holdtime 300
! Configures the hub router as the NHRP next-hop server.
 ip nhrp nhs 10.0.0.1
 ip tcp adjust-mss 1360
 delay 1000
 tunnel source Ethernet0
 tunnel mode gre multipoint
! The following line must match on all nodes that want to use this mGRE tunnel:
 tunnel key 100000
 tunnel protection ipsec profile vpnprof
!
! This is a spoke, so the public address might be dynamically assigned via DHCP.
interface Ethernet0
 ip address dhcp hostname Spoke1
!
interface Ethernet1
 ip address 192.168.1.1 255.255.255.0
!
! EIGRP is configured to run over the inside physical interface and the tunnel.
router eigrp 1
 network 10.0.0.0 0.0.0.255
 network 192.168.1.0 0.0.0.255

```

## VRF Aware DMVPN: Example

When configuring VRF Aware DMVPN, you must create a separate DMVPN network for each VRF instance. In the following example, there are two DMVPN networks: BLUE and RED. In addition, a separate source interface has been used on the hub for each DMVPN tunnel—a must for Cisco IOS Release 12.2(18)SXE. For other Cisco IOS releases, you can configure the same tunnel source for both of the tunnel interfaces, but you must configure the **tunnel key** and **tunnel protection (tunnel protection ipsec profile {name} shared)** commands.

### Note

If you use the **shared** keyword, then you should be running Cisco IOS Release 12.4(5) or Release 12.4(6)T, or a later release. Otherwise the IPsec/GRE tunnels under the two mGRE tunnel interfaces may not function correctly.

### Hub Configuration

```
interface Tunnel0
! Note the next line.
 ip vrf forwarding BLUE
 bandwidth 1000
 ip address 10.0.0.1 255.255.255.0
 ip mtu 1436
 ! Note the next line.
 ip nhrp authentication BLUE!KEY
 ip nhrp map multicast dynamic
 ! Note the next line
 ip nhrp network-id 100000
 ip nhrp holdtime 600
 no ip split-horizon eigrp 1
 no ip next-hop-self eigrp 1
 ip tcp adjust-mss 1360
 delay 1000
 ! Note the next line.
 tunnel source Ethernet0
 tunnel mode gre multipoint
 tunnel protection ipsec profile vpnprof!
interface Tunnel1
! Note the next line.
 ip vrf forwarding RED
 bandwidth 1000
 ip address 10.0.0.1 255.255.255.0
 ip mtu 1436
 ! Note the next line.
 ip nhrp authentication RED!KEY
 ip nhrp map multicast dynamic
 ! Note the next line.
 ip nhrp network-id 20000
 ip nhrp holdtime 600
 no ip split-horizon eigrp 1
 no ip next-hop-self eigrp 1
 ip tcp adjust-mss 1360
 delay 1000
 ! Note the next line.
 tunnel source Ethernet1
 tunnel mode gre multipoint
 tunnel protection ipsec profile vpnprof!
interface Ethernet0
 ip address 172.17.0.1 255.255.255.0
!
interface Ethernet1
```

```
ip address 192.0.2.171 255.255.255.0
```

**Note**

For the hub configuration shown above, a separate DMVPN network is configured for each VPN. The NHRP network ID and authentication keys must be unique on the two mGRE interfaces.

**EIGRP Configuration on the Hub**

```
router eigrp 1
auto-summary
!
address-family ipv4 vrf BLUE
network 10.0.0.0 0.0.0.255
no auto-summary
autonomous-system 1
exit-address-family
!
address-family ipv4 vrf RED
network 10.0.0.0 0.0.0.255
no auto-summary
autonomous-system 1
exit-address-family
```

**Spoke Configurations****Spoke 1:**

```
interface Tunnel0
bandwidth 1000
ip address 10.0.0.2 255.255.255.0
ip mtu 1436
! Note the next line.
ip nhrp authentication BLUE!KEY
ip nhrp map 10.0.0.1 172.17.0.1
ip nhrp network-id 100000
ip nhrp holdtime 300
ip nhrp nhs 10.0.0.1
ip tcp adjust-mss 1360
delay 1000
tunnel mode gre multipoint
tunnel source Ethernet0
tunnel destination 172.17.0.1
tunnel protection ipsec profile vpnprof
```

**Spoke 2:**

```
interface Tunnel0
bandwidth 1000
ip address 10.0.0.2 255.255.255.0
ip mtu 1436

## 2547oDMVPN with Traffic Segmentation (with BGP only): Example

The following example show a traffic segmentation configuration in which traffic is segmented between two spokes that serve as provider edge (PE) devices.

### Hub Configuration

```
hostname hub-pe1

boot-start-marker
boot-end-marker

no aaa new-model

resource policy

clock timezone EST 0
ip cef
no ip domain lookup

!This section refers to the forwarding table for VRF blue:
ip vrf blue
 rd 2:2
 route-target export 2:2
 route-target import 2:2

!This section refers to the forwarding table for VRF red:
ip vrf red
 rd 1:1
 route-target export 1:1
 route-target import 1:1

mpls label protocol ldp

crypto isakmp policy 1
 authentication pre-share
crypto isakmp key cisco address 0.0.0.0 0.0.0.0

crypto ipsec transform-set t1 esp-des
 mode transport

crypto ipsec profile prof
 set transform-set t1

interface Tunnel1
 ip address 10.9.9.1 255.255.255.0
 no ip redirects
 ip nhrp authentication cisco
 ip nhrp map multicast dynamic
 ip nhrp network-id 1

!The command below enables MPLS on the DMVPN network:
mpls ip
 tunnel source Ethernet0/0
 tunnel mode gre multipoint
 tunnel protection ipsec profile prof

interface Loopback0
 ip address 10.0.0.1 255.255.255.255

interface Ethernet0/0
 ip address 172.0.0.1 255.255.255.0
```

!The multiprotocol BGP route reflector (the hub) configuration changes the next-hop information to set itself as the next-hop and assigns a new VPN label for the prefixes learned from the spokes and advertises the VPN prefix:

```
router bgp 1
 no synchronization
 bgp log-neighbor-changes
 neighbor 10.0.0.11 remote-as 1
 neighbor 10.0.0.11 update-source Tunnel1
 neighbor 10.0.0.12 remote-as 1
 neighbor 10.0.0.12 update-source Tunnel1
 no auto-summary

 address-family vpnv4
 neighbor 10.0.0.11 activate
 neighbor 10.0.0.11 send-community extended
 neighbor 10.0.0.11 route-reflector-client
 neighbor 10.0.0.11 route-map NEXTHOP out
 neighbor 10.0.0.12 activate
 neighbor 10.0.0.12 send-community extended
 neighbor 10.0.0.12 route-reflector-client
 neighbor 10.0.0.12 route-map NEXTHOP out
 exit-address-family

 address-family ipv4 vrf red
 redistribute connected
 no synchronization
 exit-address-family

 address-family ipv4 vrf blue
 redistribute connected
 no synchronization
 exit-address-family

 no ip http server
 no ip http secure-server
```

!In this route map information, the hub sets the next hop to itself, and the VPN prefixes are advertised:

```
route-map NEXTHOP permit 10
 set ip next-hop 10.0.0.1
```

```
control-plane
```

```
line con 0
 logging synchronous
line aux 0
line vty 0 4
 no login
```

```
end
```

## Spoke Configurations

### Spoke 2

```
hostname spoke-pe2

boot-start-marker
boot-end-marker

## 2547oDMVPN with Traffic Segmentation (Enterprise Branch): Example

The following example shows a configuration for segmenting traffic between two spokes located at branch offices of an enterprise. In this example, EIGRP is configured to learn routes to reach BGP neighbors within the DMVPN.

### Hub Configuration

```

hostname HUB

boot-start-marker
boot-end-marker

no aaa new-model

resource policy

clock timezone EST 0
ip cef
no ip domain lookup

!This section refers to the forwarding table for VRF blue:
ip vrf blue
rd 2:2
route-target export 2:2
route-target import 2:2

```

```
!This refers to the forwarding table for VRF red:
ip vrf red
 rd 1:1
 route-target export 1:1
 route-target import 1:1

mpls label protocol ldp

crypto isakmp policy 1
 authentication pre-share
crypto isakmp key cisco address 0.0.0.0 0.0.0.0

crypto ipsec transform-set t1 esp-des
 mode transport

crypto ipsec profile prof
 set transform-set t1

interface Tunnel1
 ip address 10.0.0.1 255.255.255.0
 no ip redirects
 ip nhrp authentication cisco
 ip nhrp map multicast dynamic
 ip nhrp network-id 1

!EIGRP is enabled on the DMVPN network to learn the IGP prefixes:
no ip split-horizon eigrp 1

!The command below enables MPLS on the DMVPN network:
mpls ip
 tunnel source Ethernet0/0
 tunnel mode gre multipoint
 tunnel protection ipsec profile prof

!This address is advertised by EIGRP and used as the BGP endpoint:
interface Loopback0
 ip address 10.9.9.1 255.255.255.255

interface Ethernet0/0
 ip address 172.0.0.1 255.255.255.0

!EIGRP is configured to learn the BGP peer addresses (10.9.9.x networks)
router eigrp 1
 network 10.9.9.1 0.0.0.0
 network 10.0.0.0 0.0.0.255
 no auto-summary

!The multiprotocol BGP route reflector (the hub) configuration changes the next-hop
information to set itself as the next-hop and assigns a new VPN label for the prefixes
learned from the spokes and advertises the VPN prefix:
router bgp 1
 no synchronization
 bgp router-id 10.9.9.1
 bgp log-neighbor-changes
 neighbor 10.9.9.11 remote-as 1
 neighbor 10.9.9.11 update-source Loopback0

# Command Reference

The following commands are introduced or modified in the feature or features

- **clear dmvpn session**
- **clear dmvpn statistics**
- **debug dmvpn**
- **debug nhrp condition**
- **debug nhrp error**
- **logging dmvpn**
- **show dmvpn**
- **show ip nhrp traffic**

For information about these commands, see the Cisco IOS Security Command Reference at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html).

For information about all Cisco IOS commands, see the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the Master Command List.

# Feature Information for Dynamic Multipoint VPN (DMVPN)

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1** Feature Information for Dynamic Multipoint VPN (DMVPN)

| Feature Name                                          | Releases                             | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------------------------|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2547oDMVPN—Enabling Traffic Segmentation Within DMVPN | 12.4(11)T                            | The 2547oDMVPN feature allows users to segment VPN traffic within a DMVPN tunnel by applying MPLS labels to VRF instances to indicate the source and destination of each VRF.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Manageability Enhancements for DMVPN                  | 12.4(9)T                             | DMVPN session manageability was expanded with DMVPN specific commands for debugging, show output, session and counter control, and system log information. The following sections provide information about this feature: <ul style="list-style-type: none"> <li><a href="#">Troubleshooting Dynamic Multipoint VPN (DMVPN)</a></li> </ul> The following commands were introduced or modified by this feature: <b>clear dmvpn session</b> , <b>clear dmvpn statistics</b> , <b>debug dmvpn</b> , <b>debug nhrp condition</b> , <b>debug nhrp error</b> , <b>logging dmvpn</b> , <b>show dmvpn</b> , <b>show ip nhrp traffic</b> |
| DMVPN Phase 2                                         | 12.2(18)SXE<br>12.3(9)a<br>12.3(8)T1 | DMVPN Spoke-to-Spoke functionality was made more production ready. If you are using this functionality in a production network, the minimum release is Release 12.3(9a) or Release 12.3(8)T1.<br><br>In Release 12.2(18)SXE, support was added for the Cisco Catalyst 6500 series switch and the Cisco 7600 series router.                                                                                                                                                                                                                                                                                                      |

**Table 1**      **Feature Information for Dynamic Multipoint VPN (DMVPN)**

| Feature Name                           | Releases                 | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| —                                      | 12.3(6)<br>12.3(7)T      | Virtual Route Forwarding Integrated DMVPN and Network Address Translation-Transparency (NAT-T) Aware DMVPN enhancements were added. In addition, DMVPN Hub-to-Spoke functionality was made more production ready. If you are using this functionality in a production network, the minimum release requirement is Cisco IOS Release 12.3(6) or 12.3(7)T.<br><br>The enhancements added in Cisco IOS Release 12.3(6) were integrated into Cisco IOS Release 12.3(7)T. |
| Dynamic Multipoint VPN (DMVPN) Phase 1 | 12.2(13)T                | The Dynamic Multipoint VPN (DMVPN) feature allows users to better scale large and small IPsec Virtual Private Networks (VPNs) by combining generic routing encapsulation (GRE) tunnels, IP security (IPsec) encryption, and Next Hop Resolution Protocol (NHRP).                                                                                                                                                                                                     |
| DMVPN - Phase 2                        | Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers.                                                                                                                                                                                                                                                                                                                                                                                                        |
| Dynamic Multipoint VPN (DMVPN) Phase 1 | Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers.                                                                                                                                                                                                                                                                                                                                                                                                        |

## Glossary

**AM**—aggressive mode. A mode during IKE negotiation. Compared to MM, AM eliminates several steps, making it faster but less secure than MM. Cisco IOS software will respond in aggressive mode to an IKE peer that initiates aggressive mode.

**GRE**—generic routing encapsulation. Tunnels that provide a specific pathway across the shared WAN and encapsulate traffic with new packet headers to ensure delivery to specific destinations. The network is private because traffic can enter a tunnel only at an endpoint. Tunnels do not provide true confidentiality (encryption does) but can carry encrypted traffic.

GRE tunneling can also be used to encapsulate non-IP traffic into IP and send it over the Internet or IP network. The Internet Package Exchange (IPX) and AppleTalk protocols are examples of non-IP traffic.

**IKE**—Internet Key Exchange. A hybrid protocol that implements Oakley key exchange and Skeme key exchange inside the ISAKMP framework. Although IKE can be used with other protocols, its initial implementation is with IPsec. IKE provides authentication of the IPsec peers, negotiates IPsec keys, and negotiates IPsec security associations.

**IPsec**—IP security. A framework of open standards developed by the Internet Engineering Task Force (IETF). IPsec provides security for transmission of sensitive information over unprotected networks such as the Internet. IPsec acts at the network layer, protecting and authenticating IP packets between participating IPsec devices (“peers”), such as Cisco routers.

**ISAKMP**—Internet Security Association Key Management Protocol. A protocol framework that defines payload formats, the mechanics of implementing a key exchange protocol, and the negotiation of a security association.

**MM**—main mode. Mode that is slower than aggressive mode but more secure and more flexible than aggressive mode because it can offer an IKE peer more security proposals. The default action for IKE authentication (rsa-sig, rsa-encr, or preshared) is to initiate main mode.

**NHRP**—Next Hop Resolution Protocol. Routers, access servers, and hosts can use NHRP to discover the addresses of other routers and hosts connected to a NBMA network.

The Cisco implementation of NHRP supports the IETF draft version 11 of *NBMA Next Hop Resolution Protocol (NHRP)*.

The Cisco implementation of NHRP supports IP Version 4, Internet Packet Exchange (IPX) network layers, and, at the link layer, ATM, Ethernet, SMDS, and multipoint tunnel networks. Although NHRP is available on Ethernet, NHRP need not be implemented over Ethernet media because Ethernet is capable of broadcasting. Ethernet support is unnecessary (and not provided) for IPX.

**PFS**—Perfect Forward Secrecy. A cryptographic characteristic associated with a derived shared secret value. With PFS, if one key is compromised, previous and subsequent keys are not compromised, because subsequent keys are not derived from previous keys.

**SA**—security association. Describes how two or more entities will utilize security services to communicate securely. For example, an IPsec SA defines the encryption algorithm (if used), the authentication algorithm, and the shared session key to be used during the IPsec connection.

Both IPsec and IKE require and use SAs to identify the parameters of their connections. IKE can negotiate and establish its own SA. The IPsec SA is established either by IKE or by manual user configuration.

**transform**—The list of operations done on a dataflow to provide data authentication, data confidentiality, and data compression. For example, one transform is the ESP protocol with the HMAC-MD5 authentication algorithm; another transform is the AH protocol with the 56-bit DES encryption algorithm and the ESP protocol with the HMAC-SHA authentication algorithm.

**VPN**—Virtual Private Network. A framework that consists of multiple peers transmitting private data securely to one another over an otherwise public infrastructure. In this framework, inbound and outbound network traffic is protected using protocols that tunnel and encrypt all data. This framework permits networks to extend beyond their local topology, while remote users are provided with the appearance and functionality of a direct network connection.

# Cisco Easy VPN Remote

---

**First Published: November 25, 2002**

**Last Updated: November 4, 2008**

This document provides information on configuring and monitoring the Cisco Easy VPN Remote feature to create IPsec Virtual Private Network (VPN) tunnels between a supported router and an Easy VPN server (Cisco IOS router, VPN 3000 concentrator, or Cisco PIX Firewall) that supports this form of IPsec encryption and decryption.

For the benefits of this feature, see the section “[Benefits of the Cisco Easy VPN Remote Feature](#).”

## Finding Feature Information in This Module

*Your Cisco IOS software release may not support all of the features documented in this module.* To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for Easy VPN Remote](#)” section on page 108.

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

# Prerequisites for Cisco Easy VPN Remote

## Cisco Easy VPN Remote Feature

- A Cisco 800 series router running Cisco IOS Release 12.2(15)T, 12.3(2)T, 12.3(4)T, 12.3(7)T, or 12.3(7)XR2 configured as a Cisco Easy VPN remote.
- A Cisco 1700 series router running Cisco IOS Release 12.2(15)T, 12.3(2)T, 12.3(4)T, 12.3(7)T, or 12.3(7)XR, configured as a Cisco Easy VPN remote.
- A Cisco 1800 series fixed configuration router running Cisco IOS Release 12.3(8)YI.
- A Cisco uBR905 or Cisco uBR925 cable access router running Cisco IOS Release 12.2(15)T, configured as a Cisco Easy VPN remote.
- Another Cisco router or VPN concentrator that supports the Cisco Easy VPN Server feature and that is configured as a Cisco IOS Easy VPN server. See the “[Required Easy VPN Servers](#)” section for a detailed list.

## Reactivate Primary Peer Feature

- An existing Easy VPN remote configuration can be enhanced to accommodate the Reactivate Primary Peer feature using the **peer** command (and **default** keyword) and the **idle-time** command. After the tunnel between the Easy VPN remote and a nondefault peer is working, the Reactivate Primary Peer feature takes effect, that is, the Easy VPN remote periodically tries to check the connectivity with the primary peer. Any time the Easy VPN remote detects that the link is working, the Easy VPN remote tears down the existing connection and brings up the tunnel with the primary peer.

# Restrictions for Cisco Easy VPN Remote

## Required Easy VPN Servers

The Cisco Easy VPN Remote feature requires that the destination peer be a Cisco IOS Easy VPN server or VPN concentrator that supports the Cisco Easy VPN Server feature. At the time of publication, servers or concentrators that support this feature include the following platforms when running the indicated software releases:

- Cisco 806, Cisco 826, Cisco 827, Cisco 828, Cisco 831, Cisco 836, and Cisco 837 routers—Cisco IOS Release 12.2(8)T or later release. Cisco 800 series routers are not supported in Cisco IOS Release 12.3(7)XR, but they are supported in Cisco IOS Release 12.3(7)XR2.
- Cisco 870 series—Cisco IOS Release 12.3(8)YI1.
- Cisco 1700 series—Cisco IOS Release 12.2(8)T or later release.
- Cisco 1800 series fixed configuration router—Cisco IOS Release 12.3(8)YI.
- Cisco 1812 router—Cisco IOS Release 12.3(8)YH.
- Cisco 2600 series—Cisco IOS Release 12.2(8)T or later release.
- Cisco 3620—Cisco IOS Release 12.2(8)T or later release.
- Cisco 3640—Cisco IOS Release 12.2(8)T or later release.
- Cisco 3660—Cisco IOS Release 12.2(8)T or later release.
- Cisco 7100 series VPN routers—Cisco IOS Release 12.2(8)T or later release.
- Cisco 7200 series routers—Cisco IOS Release 12.2(8)T or later release.

- Cisco 7500 series routers—Cisco IOS Release 12.2(8)T or later release.
- Cisco PIX 500 series—Software Release 6.2 or later release.
- Cisco VPN 3000 series—Software Release 3.11 or later release.

### Only ISAKMP Policy Group 2 Supported on Easy VPN Servers

The Unity Protocol supports only Internet Security Association Key Management Protocol (ISAKMP) policies that use group 2 (1024-bit Diffie-Hellman) Internet Key Exchange (IKE) negotiation, so the Easy VPN server being used with the Cisco Easy VPN Remote feature must be configured for a group 2 ISAKMP policy. The Easy VPN server cannot be configured for ISAKMP group 1 or group 5 when being used with a Cisco Easy VPN client.

### Transform Sets Supported

To ensure a secure tunnel connection, the Cisco Easy VPN Remote feature does not support transform sets that provide encryption without authentication (ESP-DES and ESP-3DES) or transform sets that provide authentication without encryption (ESP-NUL ESP-SHA-HMAC and ESP-NUL ESP-MD5-HMAC).

#### Note

The Cisco Unity Client Protocol does not support Authentication Header (AH) authentication, but Encapsulation Security Protocol (ESP) is supported.

### Dial Backup for Easy VPN Remotes

Line-status-based backup is not supported in this feature.

### Network Address Translation Interoperability Support

Network Address Translation (NAT) interoperability is not supported in client mode with split tunneling.

### Multicast and Static NAT

Multicast and static NAT are supported only for Easy VPN remotes using dynamic virtual tunnel interfaces (DVTIs).

### Virtual IPsec Interface Restrictions

- For the Virtual IPsec Interface Support feature to work, virtual templates support is needed.
- If you are using a virtual tunnel interface on the Easy VPN remote device, it is recommended that you configure the server for a virtual tunnel interface.

### Dual Tunnel Support

The following restrictions apply if you are using dual tunnels that share common inside and outside interfaces:

- If dual tunnels are configured, one of the tunnels should have a split tunnel configured on the server.
- Web Intercept can be configured for only one of the tunnels. Web Intercept should not be used for the voice tunnel.
- Web Intercept cannot be used for IP phones until authorization proxy becomes aware of how to bypass the IP phone.
- Some features, such as Pushing a Configuration URL Through a Mode-Configuration Exchange, can be used only through a single tunnel.

**cTCP Support on Easy VPN Clients**

- cTCP listens on only up to 10 ports.
- If there are other applications registered for the port on which cTCP is enabled, those applications will not work.

## Information About Cisco Easy VPN Remote

To configure the Cisco Easy VPN Remote features, you should understand the following concepts:

- [Benefits of the Cisco Easy VPN Remote Feature, page 4](#)
- [Cisco Easy VPN Remote Overview, page 4](#)
- [Modes of Operation, page 5](#)
- [Authentication, page 8](#)
- [Tunnel Activation Options, page 17](#)
- [Dead Peer Detection Stateless Failover Support, page 18](#)
- [Cisco Easy VPN Remote Features, page 19](#)

## Benefits of the Cisco Easy VPN Remote Feature

- Allows dynamic configuration of end-user policy, requiring less manual configuration by end users and field technicians, thus reducing errors and further service calls.
- Allows the provider to change equipment and network configurations as needed, with little or no reconfiguration of the end-user equipment.
- Provides for centralized security policy management.
- Enables large-scale deployments with rapid user provisioning.
- Eliminates the need for end users to purchase and configure external VPN devices.
- Eliminates the need for end users to install and configure Easy VPN Client software on their PCs.
- Offloads the creation and maintenance of the VPN connections from the PC to the router.
- Reduces interoperability problems between the different PC-based software VPN clients, external hardware-based VPN solutions, and other VPN applications.
- Sets up a single IPsec tunnel regardless of the number of multiple subnets that are supported and the size of the split-include list.

## Cisco Easy VPN Remote Overview

Cable modems, xDSL routers, and other forms of broadband access provide high-performance connections to the Internet, but many applications also require the security of VPN connections that perform a high level of authentication and that encrypt the data between two particular endpoints. However, establishing a VPN connection between two routers can be complicated and typically requires tedious coordination between network administrators to configure the VPN parameters of the two routers.

The Cisco Easy VPN Remote feature eliminates much of this tedious work by implementing Cisco Unity Client Protocol, which allows most VPN parameters to be defined at a Cisco IOS Easy VPN server. This server can be a dedicated VPN device, such as a Cisco VPN 3000 concentrator or a Cisco PIX Firewall or a Cisco IOS router that supports the Cisco Unity Client Protocol.

After the Cisco Easy VPN server has been configured, a VPN connection can be created with minimal configuration on an Easy VPN remote, such as a Cisco 800 series router or a Cisco 1700 series router. When the Easy VPN remote initiates the VPN tunnel connection, the Cisco Easy VPN server pushes the IPsec policies to the Easy VPN remote and creates the corresponding VPN tunnel connection.

The Cisco Easy VPN Remote feature provides for automatic management of the following details:

- Negotiating tunnel parameters, such as addresses, algorithms, and lifetime.
- Establishing tunnels according to the parameters that were set.
- Automatically creating the NAT or Port Address Translation (PAT) and associated access lists that are needed, if any.
- Authenticating users, that is, ensuring that users are who they say they are by way of usernames, group names, and passwords.
- Managing security keys for encryption and decryption.
- Authenticating, encrypting, and decrypting data through the tunnel.

## Modes of Operation

The Cisco Easy VPN Remote feature supports three modes of operation: client, network extension, and network extension plus:

- **Client**—Specifies that NAT or PAT be done so that the PCs and other hosts at the remote end of the VPN tunnel form a private network that does not use any IP addresses in the IP address space of the destination server.

An enhancement has been made so that the IP address that is received via mode configuration is automatically assigned to an available loopback interface. The IPsec Security Associations (SAs) for this IP address are automatically created by Easy VPN Remote. The IP address is typically used for troubleshooting (using ping, Telnet, and Secure Shell).

- **Network extension**—Specifies that the PCs and other hosts at the client end of the VPN tunnel should be given IP addresses that are fully routable and reachable by the destination network over the tunneled network so that they form one logical network. PAT is not used, which allows the client PCs and hosts to have direct access to the PCs and hosts at the destination network.
- **Network extension plus (mode network-plus)**—Identical to network extension mode with the additional capability of being able to request an IP address via mode configuration and automatically assign it to an available loopback interface. The IPsec SAs for this IP address are automatically created by Easy VPN Remote. The IP address is typically used for troubleshooting (using ping, Telnet, and Secure Shell).

All modes of operation also optionally support split tunneling, which allows secure access to corporate resources through the VPN tunnel while also allowing Internet access through a connection to an Internet service provider (ISP) or other service—thereby eliminating the corporate network from the path for web access.

## Client Mode and Network Extension Mode Scenarios

Figure 1 illustrates the client mode of operation. In this example, the Cisco 831 router provides access to two PCs, which have IP addresses in the 10.0.0.0 private network space. These PCs connect to the Ethernet interface on the Cisco 831 router, which also has an IP address in the 10.0.0.0 private network space. The Cisco 831 router performs NAT or PAT translation over the VPN tunnel so that the PCs can access the destination network.

**Figure 1** Cisco Easy VPN Remote Connection

### Note

The diagram in Figure 1 could also represent a split tunneling connection, in which the client PCs can access public resources in the global Internet without including the corporate network in the path for the public resources.

Figure 2 also illustrates the client mode of operation, in which a VPN concentrator provides destination endpoints to multiple xDSL clients. In this example, Cisco 800 series routers provide access to multiple small business clients, each of which uses IP addresses in the 10.0.0.0 private network space. The Cisco 800 series routers perform NAT or PAT translation over the VPN tunnel so that the PCs can access the destination network.

**Figure 2** Cisco Easy VPN Remote Connection (using a VPN concentrator)

Figure 3 illustrates the network extension mode of operation. In this example, the Cisco 831 router and Cisco 1700 series router both act as Cisco Easy VPN remote devices, connecting to a Cisco VPN 3000 concentrator.

The client hosts are given IP addresses that are fully routable by the destination network over the tunnel. These IP addresses could be either in the same subnet space as the destination network or in separate subnets, assuming that the destination routers are configured to properly route those IP addresses over the tunnel.

In this example, the PCs and hosts attached to the two routers have IP addresses that are in the same address space as the destination enterprise network. The PCs connect to the Ethernet interface of the Cisco 831 router, which also has an IP address in the enterprise address space. This scenario provides a seamless extension of the remote network.

**Figure 3** Cisco Easy VPN Network Extension Connection

## Authentication

The Cisco Easy VPN Remote feature supports a two-stage process for authenticating the remote router to the central concentrator. The first step is Group Level Authentication and is part of the control channel creation. In this first stage, two types of authentication credentials can be used: either preshared keys or digital certificates. The following paragraphs provide details about these options.

The second authentication step is called Extended Authentication or Xauth. In this step, the remote side (in this case the Easy VPN router) submits a username and password to the central site router. This step is the same process as that which occurs when a user of the Cisco VPN software client on a PC enters his or her username and password to activate his or her VPN tunnel. When using the router, the difference is that the router itself is being authenticated to the network, not a PC with Cisco VPN Client software. Xauth is an optional step (it can be disabled) but is normally enabled to improve security. After Xauth is successful and the tunnel comes up, all PCs behind the Easy VPN remote router have access to the tunnel.

If Xauth is enabled, it is key to decide how to input the username and password. There are two options. The first option is to store the Xauth username and password in the configuration file of the router. This option is typically used if the router is shared between several PCs and the goal is to keep the VPN tunnel up all the time (see the section "[Automatic Activation](#)") or to have the router automatically bring up the tunnel whenever there is data to be sent (see the section "[Traffic-Triggered Activation](#)"). An example of this application is a branch office situation, in which the users in the branch office want the VPN tunnel to be available whenever they have data to send and do not want to have to do anything special to activate the VPN tunnel. If the PCs in the branch office must be individually authenticated on the basis of the ID of each user, the correct configuration is to put the Easy VPN router in Automatic Activation mode to keep the tunnel "up" all the time and to use Cisco IOS Authentication Proxy or 802.1x to authenticate the individual PCs. Because the tunnel is always up, Authentication Proxy or 802.1x can access a central site user database such as AAA/RADIUS to authenticate the individual user requests as they are submitted by PC users. (See the "[Related Documents](#)" sections "General information on IPsec and VPN" for a reference to configuring Authentication Proxy and "802.1x authentication" for a reference to configuring 802.1x authentication.)

The second option for entry of the Xauth username and password is not to store it on the router. Instead, a PC user who is connected to the router is presented with a special web page that allows the user to manually enter the username and password (see the section “[Manual Activation](#)”). The router sends the username and password to the central site concentrator, and if the username and password are correct, the tunnel comes up. The typical application for this configuration is a teleworker network. The teleworker wants to control when the tunnel is up and has to enter his or her personal user credentials (which could include one-time passwords) to activate the tunnel. Also, the network administrator may want teleworker tunnels up only when someone is using them to conserve resources on the central concentrators. (See the section “[Web-Based Activation](#)” for details about this configuration.)

The Xauth username and password can also be manually entered from the command-line interface (CLI) of the router. This method is not recommended for most situations because the user must first log in to the router (and needs a user ID on the router to do so). However, it can be useful for network administrators during troubleshooting.

## Using Preshared Keys

Using preshared keys, each peer is aware of the key of the other peer. Preshared keys are displayed in running configurations, so they can be seen by anyone (referred to as clear format). When a more secure type of authentication is required, Cisco software also supports another type of preshared key: the encrypted preshared key.

Using an encrypted preshared key for authentication allows you to securely store plain-text passwords in type 6 (encrypted) format in NVRAM. A group preshared key can be preconfigured on both VPN-tunnel peers. The encrypted form of the keyword can be seen in the running configuration, but the actual keyword is not visible. (For more information about encrypted preshared keys, see [Encrypted Preshared Key](#).)

## Using Digital Certificates

Digital certificates provide for the support of Rivest, Shamir, and Adelman (RSA) signatures on Easy VPN remote devices. The support is provided through a RSA certificate that can be stored on or off the remote device.

### Note

The recommended timeout for Easy VPN using digital certificates is 40 seconds.

For more information about digital certificates, see the [Easy VPN Remote RSA Signature Support](#) feature guide, Release 12.3(7)T1.

## Using Xauth

Xauth is an additional level of authentication that can be used. Xauth is applicable when either group preshared keys or digital certificates are used. Xauth credentials can be entered using a web interface manager, such as Security Device Manager (SDM), or using the CLI. (See the section “[Cisco Easy VPN Remote Web Managers](#).”)

The Save Password feature allows the Xauth username and password to be saved in the Easy VPN Remote configuration so that you are not required to enter the username and password manually. One-Time Passwords (OTPs) are not supported by the Save Password feature and must be entered manually when Xauth is requested. The Easy VPN server must be configured to “Allow Saved Passwords.” (For more information about how to configure the Save Password feature, see the section “[Dead Peer Detection Periodic Message Option](#).”)

Xauth is controlled by the Easy VPN server. When the Cisco IOS Easy VPN server requests Xauth authentication, the following messages are displayed on the console of the router:

```
EZVPN: Pending XAuth Request, Please enter the following command:
crypto ipsec client ezvpn xauth
```

When you see this message, you can provide the necessary user ID, password, and other information by entering the **crypto ipsec client ezvpn connect** command and responding to the prompts that follow.

The recommended Xauth timeout is 50 seconds or fewer.

#### Note

The timeout for entering the username and password is determined by the configuration of the Cisco IOS Easy VPN server. For servers running Cisco IOS software, this timeout value is specified by the **crypto isakmp xauth timeout** command.

## Web-Based Activation

Web-Based Activation provides a user-friendly method for a remote teleworker to authenticate the VPN tunnel between his or her remote Easy VPN router and the central site router. This feature allows administrators to set up their remote LANs so that the initial HTTP request that is coming from any of the remote PCs is intercepted by the remote Easy VPN router. A login page is returned to the user, whereby the user may enter credentials to authenticate the VPN tunnel. After the VPN tunnel comes up, all users behind this remote site can access the corporate LAN without being reprompted for the username and password. Alternatively, the user may choose to bypass the VPN tunnel and connect only to the Internet, in which case a password is not required.

A typical application for web-based activation is a home teleworker who brings up the Easy VPN tunnel only when he or she needs to connect to the corporate LAN. If the remote teleworker is not present, other members of the household (such as a spouse or children) can use the Internet Only option to browse the Internet without activating the VPN tunnel. [Figure 4](#) shows a typical scenario for web-based activation.

**Figure 4** Typical Web-Based Activation Scenario

#### Note

Entering the Xauth credentials brings up the tunnel for all users who are behind this remote site. After the tunnel is up, any additional PCs that are behind the remote site do not get prompted for Xauth credentials. Web-Based Activation is an authentication to bring up the VPN tunnel for all remote PCs and cannot be considered individual user authentication. Individual user authentication for VPN tunnel access is available using the Cisco IOS Authentication Proxy or 802.1x features, which can be

configured on the remote Easy VPN router. (See the “[Related Documents](#)” sections “General information on IPsec and VPN” for a reference to configuring Authentication Proxy and “802.1x authentication” for a reference to configuring 802.1x authentication.)

To configure web-based activation, see the section “[Configuring Web-Based Activation](#).”

The following sections show the various screen shots that a remote teleworker sees when the Web-Based Activation feature is turned on:

- [Web-Based Activation Portal Page, page 11](#)
- [VPN Authentication Bypass, page 12](#)
- [VPN Tunnel Authentication, page 13](#)
- [Successful Authentication, page 14](#)
- [Deactivation, page 15](#)

## Web-Based Activation Portal Page

[Figure 5](#) is an example of a web-based activation portal page. The user may choose to connect to the corporate LAN by clicking Connect Now or he or she may choose to connect only to the Internet by clicking Internet Only.

**Note**

If the user chooses to connect only to the Internet, a password is not required.

**Figure 5**      **Portal Page**

127240

## VPN Authentication Bypass

Figure 6 is an example of a web-based activation in which the user chose to connect only to the Internet by clicking the Internet Only option. This option is most useful for household members who need to browse the Internet while the remote teleworker is not available to authenticate the VPN tunnel for corporate use.

**Figure 6** VPN Authentication Bypass Page

**Note**

If the Web-Based Activation window is mistakenly closed, to connect again, a user should follow this two-step process:

1. In a browser, type “http://routeripaddress/ezvpn/bypass” and try to connect to the URL. Entering this URL clears the bypass state that was created for your IP address (when the “Internet only” button was pressed). If you get a message saying that no such page is found, it does not matter because the only purpose of accessing the URL is to clear the bypass state.
2. After clearing the bypass state, you can browse to any external site. The Connect and Bypass page appears again. You can connect to VPN by pressing the Connect button.

## VPN Tunnel Authentication

[Figure 7](#) is an example of a web-based activation in which the user chose to connect to the corporate LAN by entering a username and password. After the user is successfully authenticated, the Easy VPN tunnel is brought up for this remote site. If there are multiple PCs behind this remote site, none of the additional users who are connecting to the corporate LAN will be requested for the Xauth credentials because the tunnel is already up.

**Figure 7** VPN Tunnel Authentication

### Successful Authentication

Figure 8 is an example of a successful activation. If the user chooses to deactivate the VPN tunnel, he or she should click the Disconnect button. After the IKE security association (SA) times out (the default value is 24 hours), the remote teleworker has to enter the Xauth credentials to bring up the tunnel.

**Figure 8**      **Successful Activation**

## Deactivation

Figure 9 is an example of a VPN tunnel that has been deactivated successfully. The page automatically closes in 5 seconds.

**Figure 9** *VPN Tunnel Deactivated Successfully*

## 802.1x Authentication

The 802.1x Authentication feature allows you to combine Easy VPN client mode operation with 802.1x authentication on Cisco IOS routers. For more information about this feature, see “802.1x Authentication” in the section “[Additional References](#).”

## Tunnel Activation Options

There are three tunnel activation options:

- Automatic activation
- Manual activation
- Traffic-triggered activation (not available in Cisco IOS Release 12.3(11)T)

Tunnel connect and disconnect options are available with SDM.

### Automatic Activation

The Cisco Easy VPN tunnel is automatically connected when the Cisco Easy VPN Remote feature is configured on an interface. If the tunnel times out or fails, the tunnel automatically reconnects and retries indefinitely.

To specify automatic tunnel control on a Cisco Easy VPN remote device, you need to configure the **crypto ipsec client ezvpn** command and then the **connect auto** subcommand. However, you do not need to use these two commands when you are creating a new Easy VPN remote configuration because the default is “automatic.”

To disconnect or reset a particular tunnel, you should use the **clear crypto ipsec client ezvpn** command, or you can use SDM.

### Manual Activation

The Cisco Easy VPN Remote software implements manual control of the Cisco Easy VPN tunnels so that you can establish and terminate the tunnel on demand.

To specify manual tunnel control on a Cisco Easy VPN remote device, you need to input the **crypto ipsec client ezvpn** command and then the **connect manual** command.

The manual setting means that the Cisco Easy VPN remote will wait for a command before attempting to establish the Cisco Easy VPN Remote connection. When the tunnel times out or fails, subsequent connections will also have to wait for the command.

If the configuration is manual, the tunnel is connected only after you issue the command **crypto ipsec client ezvpn connect**.

To disconnect or reset a particular tunnel, you should use the **clear crypto ipsec client ezvpn** command, or you can use SDM.

See the “[Configuring Manual Tunnel Control](#)” section for specific information on how to configure manual control of a tunnel.

### Traffic-Triggered Activation

#### Note

This feature is not available in Cisco IOS Release 12.3(11)T.

The Traffic-Triggered Activation feature is recommended for transactional-based VPN applications. It is also recommended for use with the Easy VPN dial backup feature for the backup Easy VPN configuration so that backup is activated only when there is traffic to send across the tunnel.

To use Access Control List (ACL) tunnel control, you must first describe the traffic that is considered “interesting.” For more information about ACLs, see the chapter “[Access Control Lists: Overview and Guidelines](#)” in the “Traffic Filtering and Firewalls” section of the *Cisco IOS Security Configuration Guide, Release 12.3*. To actually configure an ACL-triggered tunnel, use the **crypto ipsec client ezvpn** command with the **connect acl** subcommand.

## Dead Peer Detection Stateless Failover Support

Two options are available for configuring Dead Peer Detection Stateless Failover Support:

- Backup Server List Local Configuration
- Backup Server List Auto Configuration

### Backup Server List Local Configuration

Backup Server List Local Configuration allows users to enter multiple peer statements. With this feature configured, if the client is connecting to a peer and the negotiation fails, Easy VPN fails over to the next peer. This failover continues through the list of peers. When the last peer is reached, Easy VPN rolls over to the first peer. The IKE and IPsec SAs to the previous peer are deleted. Multiple peer statements work for both IP addresses as well as for hostnames. Setting or unsetting the peer statements will not affect the order of the peer statements.

To use this feature, use the **peer** subcommand of the **crypto ipsec client ezvpn** command.

### Backup Server List Auto Configuration

Easy VPN remote that is based on Cisco IOS software can have up to 10 backup servers configured for redundancy. The Backup Server feature allows the Easy VPN server to “push” the backup server list to the Easy VPN remote.

The backup list allows the administrator to control the backup servers to which a specific Easy VPN remote will connect in case of failure, retransmissions, or dead peer detection (DPD) messages.

**Note**

Before the backup server feature can work, the backup server list has to be configured on the server.

#### How a Backup Server Works

If remote A goes to server A and the connection fails, remote A goes to server B. If server B has a backup list configured, that list will override the backup server list of server A. If the connection to server B fails, remote A will continue through the backup servers that have been configured.

**Note**

If you are in auto mode and you have a failure, you will transition automatically from server A to server B. However, if you are in manual mode, you have to configure the transition manually. To configure the transition manually, use the **crypto ipsec client ezvpn** command with the **connect** keyword.

No new configuration is required at the Easy VPN remote to enable this feature. If you want to display the current server, you can use the **show crypto ipsec client ezvpn** command. If you want to find out which peers were pushed by the Easy VPN server, you can use the same command.

To troubleshoot this feature, use the **debug crypto ipsec client ezvpn** command. If more information is needed for troubleshooting purposes, use the **debug crypto isakmp** command. The **show crypto ipsec client ezvpn** command may also be used for troubleshooting.

## Cisco Easy VPN Remote Features

The Cisco Easy VPN Remote feature is a collection of features that improves the capabilities of the Cisco Easy VPN Remote feature introduced in Cisco IOS Release 12.2(4)YA. The Cisco Easy VPN Remote feature includes the following:

- [Default Inside Interface, page 20](#)—This feature supports the autoconfiguration of the default Easy VPN inside interface for Cisco 800 series routers.
- [Multiple Inside Interfaces, page 21](#)—This feature allows you to configure up to eight inside interfaces on the Cisco Easy VPN remote.
- [Multiple Outside Interfaces, page 21](#)—This feature allows you to configure up to four outside tunnels for outside interfaces.
- [VLAN Support, page 21](#)—This feature allows VLANs to be configured as valid Easy VPN inside interfaces.
- [Multiple Subnet Support, page 22](#)—This feature allows multiple subnets from the Easy VPN inside interface to be included in the Easy VPN tunnel.
- [NAT Interoperability Support, page 22](#)—This feature automatically restores the NAT configuration when the IPsec VPN tunnel is disconnected.
- [Local Address Support, page 22](#)—The Cisco Easy VPN Remote feature is enhanced to support an additional **local-address** attribute that specifies which interface is used to determine the IP address used to source the Easy VPN tunnel traffic.
- [Peer Hostname, page 23](#)—When a peer is defined as a hostname, the hostname is stored and the Domain Name System (DNS) lookup is done at the time of tunnel connection.
- [Proxy DNS Server Support, page 23](#)—This feature allows you to configure the router in a Cisco Easy VPN remote configuration to act as a proxy DNS server for LAN-connected users.
- [Cisco IOS Firewall Support, page 23](#)—This feature supports Cisco IOS Firewall configurations on all platforms.
- [Easy VPN Remote and Server on the Same Interface, page 23](#)—The Easy VPN remote and Easy VPN server are supported on the same interface, which makes it possible to establish a tunnel to another Easy VPN server and terminate the Easy VPN software client on the same interface simultaneously.
- [Easy VPN Remote and Site to Site on the Same Interface, page 23](#)—The Easy VPN Remote and site to site (crypto map) are supported on the same interface, which makes it possible to establish a tunnel to another Easy VPN server and have another site to site on the same interface simultaneously.
- [Cisco Easy VPN Remote Web Managers, page 24](#)—Users can manage the Cisco Easy VPN Remote feature on the Cisco uBR905 and Cisco uBR925 cable access routers using a built-in web interface.
- [Dead Peer Detection Periodic Message Option, page 24](#)—This feature allows you to configure your router to query the liveliness of its IKE peer at regular intervals.
- [Load Balancing, page 24](#)—If a remote device is loaded and unable to accept more traffic, the VPN 3000 will send a notify message that contains an IP address that represents the new IKE server to which the remote should connect.

- [Management Enhancements, page 25](#)—This feature allows for remote management of the VPN remote.
- [PFS Support, page 25](#)—The PFS configuration mode attribute is sent by the server if requested by the VPN remote device.
- [Dial Backup, page 25](#)—This feature allows you to configure a dial backup tunnel connection on your remote device.
- [Virtual IPsec Interface Support, page 27](#)—This feature allows you to selectively send traffic to different Easy VPN concentrators as well as to the Internet (includes a reference to the IPsec Virtual Tunnel Interface feature.)
- [Dual Tunnel Support, page 29](#)—This feature allows you to configure multiple Easy VPN tunnels that share common inside and outside interfaces to connect two peers to two different VPN servers simultaneously.
- [Banner, page 32](#)—The EasyVPN remote device can download a banner that has been pushed by the Easy VPN server. The banner can be used for Xauth and web-based activation. The banner is displayed when the Easy VPN tunnel is “up” on the Easy VPN remote console or as an HTML page in the case of web-based activation.
- [Configuration Management Enhancements \(Pushing a Configuration URL Through a Mode-Configuration Exchange\), page 33](#)—The Easy VPN remote device can download a URL that is pushed by the Easy VPN server, allowing the Easy VPN remote device to download configuration content and apply it to the running configuration.
- [Reactivate Primary Peer, page 33](#)—This feature allows you to designate a primary peer. When an Easy VPN device fails over from the primary peer to a backup peer and the primary peer is again available, connections with the backup peer are torn down and a connection is made with the primary peer.
- [Identical Addressing Support, page 33](#)—This feature integrates Network Address Translation (NAT) with Easy VPN to allow remotes with overlapping internal IP addressing to connect to the Easy VPN server.
- [cTCP Support on Easy VPN Clients, page 34](#)—When cTCP is enabled on a remote device (client) and headend device, IKE and ESP (Protocol 50) traffic is encapsulated in the TCP header so that the firewalls in between the client and the headend device permit this traffic (considering it the same as TCP traffic).

## Default Inside Interface

Easy VPN Remote supports the autoconfiguration of the default Easy VPN inside interface for Cisco 800 series routers. The interface Ethernet 0 is the default inside interface.

If you want to disable the default inside interface and configure another inside interface on the Cisco 800 series router, you must configure the other inside interface first and then disable the default inside interface. You can use the following command to disable the default inside interface:

```
no crypto ipsec client ezvpn name inside
```

If you did not configure the other inside interface first before disabling the default inside interface, you will receive a message such as the following (see lines three and four):

```
Router (config)# interface ethernet0
Router (config-if)# no crypto ipsec client ezvpn hw-client inside
Cannot remove the single interface unless
one other inside interface is configured
```

## Multiple Inside Interfaces

Inside interface support is enhanced in the Cisco Easy VPN Remote feature to support multiple inside interfaces for all platforms. Inside interfaces can be configured manually with the enhanced command and subcommand:

```
interface interface-name
 crypto ipsec client ezvpn name [outside | inside]
```

See the “[Configuring Multiple Inside Interfaces](#)” section for information on how to configure more than one inside interface.

Multiple inside interfaces offer the following capabilities:

- Up to eight inside interfaces are supported on the Cisco 800 and Cisco 1700 series routers.
- At least one inside interface must be configured for each outside interface; otherwise, the Cisco Easy VPN Remote feature does not establish a connection.
- Adding a new inside interface or removing an existing inside interface automatically resets the Cisco Easy VPN Remote connection (the currently established tunnel). You must reconnect a manually configured tunnel, and if Xauth is required by the Cisco Easy VPN server, the user is reprompted. If you have set the Cisco Easy VPN Remote configuration to connect automatically and no Xauth is required, no user input is required.
- Inside interfaces that are configured or the default setting can be shown by using the **show crypto ipsec client ezvpn** command.

## Multiple Outside Interfaces

The Easy VPN Remote feature supports one Easy VPN tunnel per outside interface. You can configure up to four Easy VPN tunnels per Cisco router. Each Easy VPN tunnel can have multiple inside interfaces configured, but they cannot overlap with another Easy VPN tunnel unless dial backup is configured. For more information about dial backup, see the section “[Dial Backup](#).” To configure multiple outside interfaces, use the **crypto ipsec client ezvpn** command and **outside** keyword.

To disconnect or clear a specific tunnel, the **clear crypto ipsec client ezvpn** command specifies the IPsec VPN tunnel name. If there is no tunnel name specified, all existing tunnels are cleared.

See the “[Configuring Multiple Outside Interfaces](#)” section for more information on configuring more than one outside interface.

## VLAN Support

Inside interface support on VLANs makes it possible to have valid Easy VPN inside interface support on a VLAN, which was not possible before Cisco IOS Release 12.3(7)XR. With this feature, SAs can be established at connection using the VLAN subnet address or mask as a source proxy.

For the inside interface support on VLANs to work, you must define each VLAN as an Easy VPN inside interface. In addition, IPsec SAs should be established for each inside interface in the same manner as for other inside interfaces. For more information about inside and outside interfaces, see the sections “[Multiple Inside Interfaces](#)” and “[Multiple Outside Interfaces](#).”

Inside interface support on VLANs is supported only on Cisco routers that support VLANs.

## Multiple Subnet Support

For situations in which you have multiple subnets connected to an Easy VPN inside interface, you can optionally include these subnets in the Easy VPN tunnel. First, you must specify the subnets that should be included by defining them in an ACL. To configure an ACL, see “Access control lists, configuring” in the [“Additional References”](#) section. Next, you have to use the **acl** subcommand of the **crypto ipsec client ezvpn** (global) command to link your ACL to the Easy VPN configuration. Easy VPN Remote will automatically create the IPsec SAs for each subnet that is defined in the ACL as well as for the subnets that are defined on the Easy VPN inside interface.

**Note**

---

Multiple subnet support is not supported in client mode.

---

## NAT Interoperability Support

Cisco Easy VPN Remote supports interoperability with NAT. You can have a NAT configuration and a Cisco Easy VPN Remote configuration that coexist. When an IPsec VPN tunnel is down, the NAT configuration works.

In the Cisco Easy VPN Remote feature, the router automatically restores the previous NAT configuration when the IPsec VPN tunnel is torn down. The user-defined access lists are not disturbed. Users can continue to access nontunnel areas of the Internet when the tunnel times out or disconnects.

**Note**

---

NAT interoperability is not supported in client mode with split tunneling.

---

## Local Address Support

The Cisco Easy VPN Remote feature is enhanced to support an additional **local-address** attribute. This attribute specifies which interface is used to determine the IP address that is used to source the Easy VPN Remote tunnel traffic. After specifying the interface with the **local-address** subcommand, you can manually assign a static IP address to the interface or use the **cable-modem dhcp-proxy interface** command to automatically configure the specified interface with a public IP address. See the [“Configuring Proxy DNS Server Support”](#) section for configuration information.

Local Address Support is available for all platforms, but it is more applicable to the Cisco uBR905 and Cisco uBR925 cable access routers in conjunction with the **cable-modem dhcp-proxy interface** command. Typically, the loopback interface is the interface used to source tunnel traffic for the Cisco uBR905 and Cisco uBR925 cable access routers.

In a typical DOCSIS network, the Cisco uBR905 and Cisco uBR925 cable access routers are normally configured with a private IP address on the cable modem interface. In the initial Cisco Easy VPN Remote feature, a public IP address was required on the cable modem interface to support the Easy VPN remote.

In the Cisco Easy VPN Remote feature, cable providers can use the Cable DHCP Proxy feature to obtain a public IP address and assign it to the cable modem interface, which is usually the loopback interface.

For more information on the **cable-modem dhcp-proxy interface** command, see the [“Cable CPE Commands”](#) chapter in the [Cisco Broadband Cable Command Reference Guide](#).

**Note**

---

The **cable-modem dhcp-proxy interface** command is supported only for the Cisco uBR905 and Cisco uBR925 cable access routers.

---

## Peer Hostname

The peer in a Cisco Easy VPN Remote configuration can be defined as an IP address or a hostname. Typically, when a peer is defined as a hostname, a DNS lookup is done immediately to get an IP address. In the Cisco Easy VPN Remote feature, the peer hostname operation is enhanced to support DNS entry changes. The text string of the hostname is stored so that the DNS lookup is done at the time of the tunnel connection, not when the peer is defined as a hostname.

See the “[Configuring and Assigning the Easy VPN Remote Configuration](#)” section for information on enabling the peer hostname functionality.

## Proxy DNS Server Support

When the Easy VPN tunnel is down, the DNS addresses of the ISP or cable provider should be used to resolve DNS requests. When the WAN connection is up, the DNS addresses of the enterprise should be used.

As a way of implementing use of the DNS addresses of the cable provider when the WAN connection is down, the router in a Cisco Easy VPN Remote configuration can be configured to act as a proxy DNS server. The router, acting as a proxy DNS server for LAN-connected users, receives DNS queries from local users on behalf of the real DNS server. The DHCP server then can send out the LAN address of the router as the IP address of the DNS server. After the WAN connection comes up, the router forwards the DNS queries to the real DNS server and caches the DNS query records.

See the “[Configuring Proxy DNS Server Support](#)” section for information on enabling the proxy DNS server functionality.

## Cisco IOS Firewall Support

The Cisco Easy VPN Remote feature works in conjunction with Cisco IOS Firewall configurations on all platforms.

## Easy VPN Remote and Server on the Same Interface

This feature allows the Easy VPN remote and Easy VPN server to be supported on the same interface, making it possible to both establish a tunnel to another Easy VPN server and terminate the Easy VPN software client on the same interface simultaneously. A typical application would be a geographically remote location for which Easy VPN Remote is being used to connect to a corporate Easy VPN server and also to terminate local software client users.

For more information about the Easy VPN Remote and Server on the Same Interface feature, see “Easy VPN Remote and Server on the Same Interface” in the section “[Additional References](#).”

## Easy VPN Remote and Site to Site on the Same Interface

This feature allows the Easy VPN remote and site to site (crypto map) to be supported on the same interface, making it possible to both establish a tunnel to another Easy VPN server and have another site to site on the same interface simultaneously. A typical application would be a third-party VPN service provider that is managing a remote router via the site-to-site tunnel and using Easy VPN Remote to connect the remote site to a corporate Easy VPN server.

For more information about the Easy VPN Remote and Site to Site on the Same Interface feature, see “Easy VPN Remote and Site to Site on the Same Interface” in the section “[Additional References](#).”

## Cisco Easy VPN Remote Web Managers

Web interface managers may be used to manage the Cisco Easy VPN Remote feature. One such web interface manager is SDM, which is supported on the Cisco 830 series, Cisco 1700 series, Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers. SDM enables you to connect or disconnect the tunnel and provides a web interface for Xauth. For more information about SDM, see [Cisco Security Device Manager](#).

A second web interface manager is the Cisco Router Web Setup (CRWS) tool, which is supported on the Cisco 806 router. The CRWS provides a similar web interface as SDM.

A third web interface manager, Cisco Easy VPN Remote Web Manager, is used to manage the Cisco Easy VPN Remote feature for Cisco uBR905 and Cisco uBR925 cable access routers. You do not need access to the CLI to manage the Cisco Easy VPN remote connection.

The web interface managers allow you to do the following:

- See the current status of the Cisco Easy VPN remote tunnel.
- Connect a tunnel that is configured for manual control.
- Disconnect a tunnel that is configured for manual control or reset a tunnel configured for automatic connection.
- Be prompted for Xauth information, if needed.

See the [“Troubleshooting the VPN Connection”](#) section for more information about Cisco Easy VPN Remote Web Manager.

## Dead Peer Detection Periodic Message Option

The dead peer detection periodic message option allows you to configure your router to query the liveness of its IKE peer at regular intervals. The benefit of this approach over the default approach (on-demand dead peer detection) is earlier detection of dead peers. For more information about the dead peer detection periodic message option, see *“Dead peer detection”* in the section [“Additional References.”](#)

## Load Balancing

When the Cisco VPN 3000 concentrator is configured for load balancing, the VPN 3000 will accept an incoming IKE request from the VPN remote on its virtual IP address. If the device is loaded and unable to accept more traffic, the VPN 3000 will send a notify message that contains an IP address that represents the new IKE server to which the remote should connect. The old connection will be torn down and a new connection established to the redirected VPN gateway.

There is no configuration required for load balancing to occur. If the VPN gateway is configured for load balancing, and it notifies the VPN remote that it is performing load balancing, the VPN remote has access to the load balancing feature.

To verify whether load balancing is occurring, use the **debug crypto isakmp**, **debug crypto ipsec client ezvpn**, and **show crypto ipsec** commands. To troubleshoot the load balancing process, use the **show crypto ipsec** command.

## Management Enhancements

Management enhancements for Easy VPN remotes allow for the remote management of the VPN remote. The feature provides for the IPv4 address to be pushed by configuration mode to the VPN remote. The IPv4 address is assigned to the first available loopback interface on the VPN remote, and any existing statically defined loopbacks are not overridden. On disconnect, the address and loopback interface are removed from the list of active interfaces.

After the VPN remote is connected, the loopback interface should be accessible from the remote end of the tunnel. All PAT activities will be translated through this interface IP address.

If a loopback exists, and an IP address is associated with it and its state is unassigned, the interface is a good candidate for mode configuration address management.

**Note**

After you assign an address to the loopback interface, if you save the configuration to NVRAM and reboot the VPN remote, the configuration address is permanently contained in the configuration. If you saved the configuration to NVRAM and rebooted the VPN remote, you must enter configuration mode and remove the IP address from the loopback interface manually.

You can use the **show ip interface** command with the **brief** keyword to verify that a loopback has been removed. The output of this **show** command also displays the interface.

## PFS Support

The PFS configuration mode attribute is sent by the server if requested by the VPN remote device. If any subsequent connection by the remote device shows that PFS is not received by the remote, PFS will not be sent in IPsec proposal suites.

**Note**

The PFS group that will be proposed in the IPsec proposal suites is the same as the group used for IKE.

You can use the **show crypto ipsec client ezvpn** command to display the PFS group and to verify that you are using PFS.

## Dial Backup

**Note**

The Dial Backup feature is not available in Cisco IOS Release 12.3(11)T.

Dial backup for Easy VPN remotes allows you to configure a dial backup tunnel connection on your remote device. The backup feature is “brought up” only when real data has to be sent, eliminating the need for expensive dialup or ISDN links that must be created and maintained even when there is no traffic.

[Figure 10](#) illustrates a typical Easy VPN remote-with-dial-backup scenario. In this scenario, a Cisco 1751 remote device is attempting to connect to another Cisco 1751 (acting as a server). There is a failure in the primary Easy VPN tunnel, and the connection is rerouted through the Easy VPN backup tunnel to the Cisco 1751 server.

**Figure 10** *Dial Backup for Easy VPN Scenario*

## Dial Backup Using a Dial-on-Demand Solution

IP static route tracking enable Cisco IOS software to identify when a Point-to-Point Protocol over Ethernet (PPPoE) or IPsec VPN tunnel “goes down” and initiates a Dial-on-Demand (DDR) connection to a preconfigured destination from any alternative WAN or LAN port (for example, a T1, ISDN, analog, or auxiliary port). The failure may be caused by several catastrophic events (for example, by Internet circuit failures or peer device failure). The remote route has only a static route to the corporate network. The IP static-route-tracking feature allows an object to be tracked (using an IP address or hostname) using Internet Control Message Protocol (ICMP), TCP, or other protocols, and it installs or removes the static route on the basis of the state of the tracked object. If the tracking feature determines that Internet connectivity is lost, the default route for the primary interface is removed, and the floating static route for the backup interface is enabled.

## Dial Backup Using Object Tracking

IP static route tracking must be configured for dial backup on an Easy VPN remote device to work. The object tracking configuration is independent of the Easy VPN remote dial backup configuration. (For more information about object tracking, see the feature guide [Reliable Static Routing Backup Using Object Tracking](#).)

## Easy VPN Remote Dial Backup Support Configuration

You can configure dial backup for your Easy VPN remote using two Easy VPN remote options that allow a connection to the backup Easy VPN configuration and a connection to the tracking system.

- To specify the Easy VPN configuration that will be activated when backup is triggered, use the **backup** subcommand of the **crypto ipsec client ezvpn** (global) command.
- The Easy VPN remote device registers to the tracking system to get the notifications for change in the state of the object. Use the **track** subcommand to inform the tracking process that the Easy VPN remote device is interested in tracking an object, which is identified by the object number. The tracking process, in turn, informs the Easy VPN remote device when the state of this object changes. This notification prompts the Easy VPN remote device when the state of this object changes. This notification prompts the Easy VPN remote device to bring up the backup connection when the tracked object state is DOWN. When the tracked object is UP again, the backup connection is torn down and the Easy VPN remote device will switch back to using the primary connection.

**Note**

Only one backup configuration is supported for each primary Easy VPN configuration. Each inside interface must specify the primary and backup Easy VPN configuration.

## Dynamically Addressed Environments

To allow dial backup to be deployed in dynamically addressed environments, use the IP SLA Pre-Routed ICMP Echo Probe feature. (For more information about this feature, see [Cisco 1700 Series- Cisco IOS Release 12.3\(7\)XR](#) release notes. To use the IP SLA Pre-Routed ICMP Echo Probe feature, use the **icmp-echo** command with the **source-interface** keyword.

## Dial Backup Examples

For examples of dial backup configurations, see the section “[Dial Backup: Examples](#).”

## Virtual IPsec Interface Support

The Virtual IPsec Interface Support feature provides a routable interface to selectively send traffic to different Easy VPN concentrators as well as to the Internet.

Before Cisco IOS Release 12.4(4)T, at the tunnel-up/tunnel-down transition, attributes that were pushed during the mode configuration had to be parsed and applied. When such attributes resulted in the configurations being applied on the interface, the existing configuration had to be overridden. With the Virtual IPsec Interface Support feature, the tunnel-up configuration can be applied to separate interfaces, making it easier to support separate features at tunnel-up time. Features that are applied to the traffic going into the tunnel can be separate from the features that are applied to traffic that is not going through the tunnel (for example, split-tunnel traffic and traffic leaving the device when the tunnel is not up). When the Easy VPN negotiation is successful, the line protocol state of the virtual-access interface gets changed to up. When the Easy VPN tunnel goes down because the security association (SA) expires or is deleted, the line protocol state of the virtual-access interfaces changes to down.

Routes act as traffic selectors in an Easy VPN virtual interface, that is, the routes replace the access list on the crypto map. In a virtual-interface configuration, Easy VPN negotiates a single IPsec SA if the Easy VPN server has been configured with a dynamic virtual IPsec interface. This single SA is created irrespective of the Easy VPN mode that is configured.

After the SA is established, routes that point to the virtual-access interface are added to direct traffic to the corporate network. Easy VPN also adds a route to the VPN concentrator so that IPsec-encapsulated packets get routed to the corporate network. A default route that points to the virtual-access interface is added in the case of a nonsplit mode. When the Easy VPN server “pushes” the split tunnel, the split tunnel subnet becomes the destination to which the routes that point to the virtual access are added. In either case, if the peer (VPN concentrator) is not directly connected, Easy VPN adds a route to the peer.

**Note**

- Most routers that run the Cisco Easy VPN Client software have a default route configured. The default route that is configured should have a metric value greater than 1. The metric value must be greater than 1 because Easy VPN adds a default route that has a metric value of 1. The route points to the virtual-access interface so that all traffic is directed to the corporate network when the concentrator does not “push” the split tunnel attribute.

For more information about the IPsec Virtual Tunnel Interface feature, see the document *IPSec Virtual Tunnel Interface* (URL link provided in the “[Related Documents](#)” section of this document [*General Information on IPsec and VPN*]).

[Table 1](#) presents the different methods of configuring a remote device and the corresponding headend IPsec aggregator configurations. Each row represents a way to configure a remote device. The third column shows the different headend configurations that can be used with IPsec interfaces. See [Table 2](#) for a description of terms that are used in [Table 1](#) and [Table 3](#).

**Table 1** *How Different Remote Device Configurations Interact with Various Headends and Configurations*

| Remote Device Configurations | IOS Headend – Using Crypto Maps                                                                                                                                                                                                                                           | IOS Headend – Using IPsec Interfaces                                                                                                                                                                                                                                         | VPN3000/ASA                                                                                                        |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|

|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ASA                                                                     | Cisco Adaptive Security Appliance, a threat-management security appliance.                                                                                                                                                                                                                                                                                                           |
| Crypto maps                                                             | Commonly used for configuring IPsec tunnels. The crypto map is attached to an interface. For more information on crypto maps, see the section “Creating Crypto Map Sets” of the “Configuring Security for VPNs with IPsec” chapter of the <i>Cisco IOS Security Configuration Guide</i> . (URL link provided in the “ <a href="#">Related Documents</a> ” section of this document.) |
| Easy VPN dual tunnel remote device                                      | Two Easy VPN remote device configurations in which both are using a dynamic IPsec virtual tunnel interface.                                                                                                                                                                                                                                                                          |
| Easy VPN virtual interface remote device (Easy VPN virtual interface)   | Easy VPN remote configuration that configures the usage of a dynamic IPsec virtual tunnel interface.                                                                                                                                                                                                                                                                                 |
| IPsec interface                                                         | Consists of static and dynamic IPsec virtual interfaces.                                                                                                                                                                                                                                                                                                                             |
| IPsec Virtual Tunnel Interface                                          | Tunnel interface that is created from a virtual template tunnel interface using mode IPsec. For more information on virtual tunnel interface configurations, see the document <i>IPSec Virtual Tunnel Interface</i> (URL link provided in the “ <a href="#">Related Documents</a> ” section of this document [ <i>General Information on IPsec and VPN</i> ]).                       |
| Legacy Easy VPN                                                         | Easy VPN remote device configuration that uses crypto maps and does not use IPsec interfaces.                                                                                                                                                                                                                                                                                        |
| Static IPsec virtual tunnel interface (static virtual tunnel interface) | Tunnel interface used with mode IPsec that proposes and accepts only an “ipv4 any any” selector. For more information on static virtual tunnel interface configurations, see the document <i>IPSec Virtual Tunnel Interface</i> (URL link provided in the “ <a href="#">Related Documents</a> ” section of this document [ <i>General Information on IPsec and VPN</i> ]).           |
| VPN 3000                                                                | Cisco VPN 3000 series routers.                                                                                                                                                                                                                                                                                                                                                       |

## Dual Tunnel Support

Easy VPN now supports the ability to configure two easy VPN tunnels that have the same inside and outside interfaces. The feature is called the Easy VPN Dual Tunnel. Configuring multiple tunnels on a single remote device can be accomplished in a number of ways, which are listed below in [Table 3](#) along with their configuration and usage considerations. Further discussion in this section refers to only one such method of configuring dual tunnels using Easy VPN tunnels that have virtual interfaces. This method will be referred to as Dual Tunnel Support.

In a dual-tunnel Easy VPN setup, each Easy VPN tunnel is configured using virtual IPsec interface support, as shown in the section “[Virtual IPsec Interface Support](#).” Each Easy VPN tunnel has its unique virtual interface, which is created when the Easy VPN configuration is complete.

There are two possible combinations in which the dual tunnels can be used.

- Dual Easy VPN tunnels that have one tunnel using a nonsplit tunnel policy and the other tunnel using a split tunnel policy that has been pushed from the respective headend.

- Dual Easy VPN tunnel in which both tunnels are using an independent split tunnel policy that has been pushed from the respective headend.

**Note**

It is not permitted to have dual Easy VPN tunnels in which both tunnels are using a nonsplit tunnel policy.

The Easy VPN dual tunnel makes use of route injections to direct the appropriate traffic through the correct Easy VPN virtual tunnel interface. When the Easy VPN tunnel on the remote device “comes up,” it “learns” the split or nonsplit policy from the headend. The Easy VPN remote device injects routes in its routing table that correspond to the nonsplit networks that have been learned. If the headend pushes a nonsplit tunnel policy to the Easy VPN remote device, the Easy VPN remote device installs a default route in its routing table that directs all traffic out of the Easy VPN virtual interface that corresponds to this Easy VPN tunnel. If the headend pushes split-tunnel networks to the remote device, the remote device installs specific routes to the split networks in its routing table, directing the traffic to these networks out of the virtual tunnel interface.

**Note**

Dual Tunnel Easy VPN uses destination-based routing to send traffic to the respective tunnels.

Output features can be applied to this virtual interface. Examples of such output features are Cisco IOS Quality of Service and Cisco IOS Firewall. These features must be configured on the virtual template that is configured in the Easy VPN client configuration.

[Table 3](#) explains how this feature should be used. See [Table 2](#) for a description of terms that are used in [Table 1](#) and [Table 3](#).

**Table 3**      **Dual Tunnel Usage Guidelines**

| <b>Dual Tunnel Combinations</b>                             | <b>Headends Supported</b> | <b>Configuration and Usage Considerations on the Easy VPN Remote Device and Headend</b>                                                                                                                                                                                                                                                                             |
|-------------------------------------------------------------|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Two legacy Easy VPN tunnels                                 | IOS, ASA, and VPN 3000    | <ul style="list-style-type: none"> <li>Two tunnels cannot share a common outside interface.</li> <li>Two tunnels cannot share a common inside interface.</li> <li>The two tunnels should use separate inside and outside interfaces.</li> <li>Traffic from an inside interface that belongs to one Easy VPN tunnel cannot be pushed into another tunnel.</li> </ul> |
| One legacy Easy VPN tunnel and one crypto map               | IOS, ASA, and VPN 3000    | The crypto map can share the same outside interface as the legacy Easy VPN client configuration. However, the behavior of the two remote devices depends on the mode of Easy VPN as well as the IPsec selectors of the crypto map and the Easy VPN remote device. This is not a recommended combination.                                                            |
| One legacy Easy VPN tunnel and one static virtual interface | IOS                       | Both tunnels cannot terminate on the same headend. The static virtual interface remote device tunnel has to be terminated on a static virtual interface on the headend router. The legacy Easy VPN remote device tunnel can terminate on the virtual tunnel interface or crypto map that is configured on the headend.                                              |

**Table 3**      **Dual Tunnel Usage Guidelines (continued)**

| <b>Dual Tunnel Combinations</b>                                 | <b>Headends Supported</b> | <b>Configuration and Usage Considerations on the Easy VPN Remote Device and Headend</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------------------|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| One legacy Easy VPN tunnel and one Easy VPN virtual interface   | IOS, ASA, and VPN 3000    | <ul style="list-style-type: none"> <li>Both tunnels cannot terminate on the same headend.</li> <li>The legacy Easy VPN tunnel and the Easy VPN virtual interface can share a common inside and outside interface.</li> <li>An Easy VPN virtual interface should be used only with split tunneling.</li> <li>Legacy Easy VPN can use a split tunnel or no split tunnel.</li> <li>The Web-Based Activation feature cannot be applied on both Easy VPN tunnels.</li> <li>Using two Easy VPN virtual interfaces is preferable to using this combination.</li> </ul> |
| One Easy VPN virtual interface and one static virtual interface | IOS                       | <ul style="list-style-type: none"> <li>Both tunnels cannot terminate on the same peer. The static virtual interface and the Easy VPN virtual interface can use the same outside interface.</li> <li>The Easy VPN virtual interface should use split tunneling.</li> </ul>                                                                                                                                                                                                                                                                                       |
| Two Easy VPN virtual interfaces                                 | IOS, ASA, and VPN 3000    | <ul style="list-style-type: none"> <li>Both tunnels cannot terminate on the same peer.</li> <li>At least one of the tunnels should use split tunneling.</li> <li>Web-Based Activation cannot be applied to both Easy VPN tunnels.</li> </ul>                                                                                                                                                                                                                                                                                                                    |

## Banner

The Easy VPN server pushes a banner to the Easy VPN remote device. The Easy VPN remote device can use the banner during Xauth and web-based activation. The Easy VPN remote device displays the banner the first time that the Easy VPN tunnel is brought up.

The banner is configured under global configuration on the Easy VPN server.

## Configuration Management Enhancements (Pushing a Configuration URL Through a Mode-Configuration Exchange)

After this feature has been configured on the server using the commands **configuration url** and **configuration version** (subcommands under the **crypto isakmp client configuration group** command), the server can “push” the configuration URL and configuration version number to the Easy VPN remote device. With this information, the Easy VPN remote device can download the configuration content and apply it to its running configuration. For more information about this feature, see the section “Configuration Management Enhancements” in the *Easy VPN Server* feature module.

## Reactivate Primary Peer

The Reactivate Primary Peer feature allows a default primary peer to be defined. The default primary peer (a server) is one that is considered better than other peers for reasons such as lower cost, shorter distance, or more bandwidth. With this feature configured, if Easy VPN fails over during Phase 1 SA negotiations from the primary peer to the next peer in its backup list, and if the primary peer is again available, the connections with the backup peer are torn down and the connection is again made with the primary peer.

Dead Peer Detection is one of the mechanisms that acts as a trigger for primary peer reactivation. Idle timers that are configured under Easy VPN is another triggering mechanism. When configured, the idle timer detects inactivity on the tunnel and tears it down. A subsequent connect (which is immediate in auto mode) is attempted with the primary preferred peer rather than with the peer last used.

**Note**

---

Only one primary peer can be defined.

---

## Identical Addressing Support

The Identical Addressing Support feature supports identically addressed LANs on Easy VPN remotes. Network resources, such as printers and web servers on the LAN side of the EasyVPN remotes, that have overlapping addressing with other Easy VPN remotes are now reachable. The Easy VPN Remote feature was enhanced to work with NAT to provide this functionality.

- The Easy VPN server requires no changes to support the Identical Addressing Support feature.
- The Identical Addressing Support feature is supported only in network extension modes (network-extension and network-plus).
- Virtual tunnel interfaces must be configured on the Easy VPN remote before using the Identical Addressing Support feature.

Figure 11 shows an example of the Identical Addressing Support feature configuration.

**Figure 11 Identical Addressing Support**

The Identical Addressing Support feature can be configured with the following command and enhanced subcommands:

```
crypto ipsec client ezvpn <name>
```

#### Enhanced subcommands

- **nat acl** {*acl-name* | *acl-number*}—Enables split tunneling for the traffic specified by the ACL name or the ACL number.
  - The *acl-name* argument is the name of the ACL.
  - The *acl-number* argument is the number of the ACL.
- **nat allow**—Allows NAT to be integrated with Cisco Easy VPN.

For detailed steps on how to configure Identical Addressing Support, see “[Configuring Identical Addressing Support](#).”

## cTCP Support on Easy VPN Clients

The Cisco Tunneling Control Protocol (cTCP) feature can be used for situations in which an Easy VPN client (remote device) is operating in an environment in which standard IPsec does not function or in which it does not function transparently without modification to existing firewall rules. These situations include the following:

- Small office or home office router performing Network Address Translation (NAT) or Port Address Translation (PAT)
- PAT-provided IP address behind a larger router (for example, in a corporation)
- Non-NAT firewall (packet filtering or stateful)
- Proxy server

Figure 12 illustrates how IPsec traffic that is tunneled inside the cTCP traverses Network Address Translation (NAT) and the firewall (see the dashed line).

**Figure 12** *cTCP on an Easy VPN Remote Device*

For detailed steps on how to configure cTCP on Easy VPN remote devices, see the section “[Configuring cTCP on an Easy VPN Client](#).”

For more information about cTCP support on Easy VPN remote devices, including configuration and troubleshooting examples, see “cTCP on Cisco Easy VPN remote devices” in the section “[Related Documents](#).”

## How to Configure Cisco Easy VPN Remote

This section includes the following required and optional tasks.

### Remote Tasks

- [Configuring and Assigning the Easy VPN Remote Configuration, page 36](#) (required)
- [Verifying the Cisco Easy VPN Configuration, page 38](#) (optional)
- [Configuring Save Password, page 39](#) (optional)
- [Configuring Manual Tunnel Control, page 40](#) (optional)
- [Configuring Automatic Tunnel Control, page 42](#) (optional)
- [Configuring Multiple Inside Interfaces, page 43](#) (optional)
- [Configuring Multiple Outside Interfaces, page 44](#) (optional)
- [Configuring Multiple Subnet Support, page 45](#) (optional)
- [Configuring Proxy DNS Server Support, page 47](#) (optional)
- [Configuring Dial Backup, page 47](#) (optional)
- [Configuring the DHCP Server Pool, page 48](#) (required)
- [Resetting a VPN Connection, page 48](#) (optional)
- [Monitoring and Maintaining VPN and IKE Events, page 49](#) (optional)
- [Configuring a Virtual Interface, page 50](#) (optional)
- [Troubleshooting Dual Tunnel Support, page 51](#) (optional)
- [Configuring Reactivate \(a Default\) Primary Peer, page 52](#) (optional)
- [Configuring Identical Addressing Support, page 53](#) (optional)
- [Configuring cTCP on an Easy VPN Client, page 56](#) (optional)
- [Restricting Traffic When a Tunnel Is Down, page 57](#) (optional)

**Easy VPN Server Tasks**

- [Configuring a Cisco IOS Easy VPN Server, page 58](#) (required)
- [Configuring an Easy VPN Server on a VPN 3000 Series Concentrator, page 58](#) (optional)
- [Configuring an Easy VPN Server on a Cisco PIX Firewall, page 60](#) (optional)

**Web Interface Tasks**

- [Configuring Web-Based Activation, page 61](#) (optional)
- [Monitoring and Maintaining Web-Based Activation, page 61](#) (optional)
- [Using SDM As a Web Manager, page 65](#) (optional)

**Troubleshooting the VPN Connection**

- [Troubleshooting the Client Mode of Operation, page 65](#) (optional)
- [Troubleshooting Remote Management, page 66](#) (optional)
- [Troubleshooting Dead Peer Detection, page 66](#) (optional)

## Remote Tasks

### Configuring and Assigning the Easy VPN Remote Configuration

The router acting as the Easy VPN remote must create a Cisco Easy VPN Remote configuration and assign it to the outgoing interface. To configure and assign the remote configuration, perform the following steps.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **crypto ipsec client ezvpn *name***
4. **group *group-name* key *group-key***
5. **peer [*ip-address* | *hostname*]**
6. **mode {*client* | *network-extension*}**
7. **exit**
8. **interface *interface***
9. **crypto ipsec client ezvpn *name* [*outside*]**
10. **exit**
11. **exit**

## DETAILED STEPS

|        | Command                                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                     | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                             | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Step 3 | <b>crypto ipsec client ezvpn name</b><br><br><b>Example:</b><br>Router (config)# crypto ipsec client ezvpn easy client remote                              | Creates a remote configuration and enters Cisco Easy VPN Remote configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Step 4 | <b>group group-name key group-key</b><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# group easy-vpn-remote-groupname key easy-vpn-remote-password | Specifies the IPsec group and IPsec key value to be associated with this configuration. <p><b>Note</b> The value of the <i>group-name</i> argument must match the group defined on the Easy VPN server. On Cisco IOS routers, use the <b>crypto isakmp client configuration group</b> and <b>crypto map dynmap isakmp authorization list</b> commands.</p> <p><b>Note</b> The value of the <i>group-key</i> argument must match the key defined on the Easy VPN server. On Cisco IOS routers, use the <b>crypto isakmp client configuration group</b> command.</p> |
| Step 5 | <b>peer [ip-address   hostname]</b><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# peer 192.185.0.5                                               | Specifies the IP address or hostname for the destination peer (typically the IP address on the outside interface of the destination route). <ul style="list-style-type: none"> <li>Multiple peers may be configured.</li> </ul> <p><b>Note</b> You must have a DNS server configured and available to use the <i>hostname</i> option.</p>                                                                                                                                                                                                                          |
| Step 6 | <b>mode {client   network-extension}</b><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# mode client                                               | Specifies the type of VPN connection that should be made. <ul style="list-style-type: none"> <li><b>client</b>—Specifies that the router is configured for VPN client operation, using NAT or PAT address translation. Client operation is the default if the type of VPN connection is not specified</li> <li><b>network-extension</b>—Specifies that the router is to become a remote extension of the enterprise network at the destination of the VPN connection.</li> </ul>                                                                                   |
| Step 7 | <b>exit</b><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# exit                                                                                   | Exits Cisco Easy VPN Remote configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|         | Command                                                                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                               |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 8  | <b>interface</b> <i>interface</i><br><br><b>Example:</b><br>Router (config)# interface Ethernet1                                                 | Enters interface configuration mode for the interface.<br><ul style="list-style-type: none"><li>This interface will become the outside interface for the NAT or PAT translation.</li></ul>                                                                                                                                                                            |
| Step 9  | <b>crypto ipsec client ezvpn name [outside]</b><br><br><b>Example:</b><br>Router (config-if)# crypto ipsec client ezvpn easy_vpn_remote1 outside | Assigns the Cisco Easy VPN Remote configuration to the interface.<br><ul style="list-style-type: none"><li>This configuration automatically creates the necessary NAT or PAT translation parameters and initiates the VPN connection (if you are in client mode).</li></ul><br><b>Note</b> The inside interface must be specified on Cisco 1700 and higher platforms. |
| Step 10 | <b>exit</b><br><br><b>Example:</b><br>Router (config-if)# exit                                                                                   | Exits interface configuration mode.                                                                                                                                                                                                                                                                                                                                   |
| Step 11 | <b>exit</b><br><br><b>Example:</b><br>Router (config)# exit                                                                                      | Exits global configuration mode.                                                                                                                                                                                                                                                                                                                                      |

## Verifying the Cisco Easy VPN Configuration

To verify that the Cisco Easy VPN Remote configuration has been correctly configured, that the configuration has been assigned to an interface, and that the IPsec VPN tunnel has been established, perform the following steps.

### SUMMARY STEPS

1. **show crypto ipsec client ezvpn**
2. **show ip nat statistics**

### DETAILED STEPS

- Step 1** Display the current state of the Cisco Easy VPN Remote connection using the **show crypto ipsec client ezvpn** command. The following is typical output for a Cisco 1700 series router using client mode:

```
Router# show crypto ipsec client ezvpn
```

```
Tunnel name : hw1
Inside interface list: FastEthernet0/0, Serial0/0,
Outside interface: Serial1/0
Current State: IPSEC_ACTIVE
Last Event: SOCKET_UP
Address: 10.0.0.5
Mask: 255.255.255.255
Default Domain: cisco.com
Tunnel name : hw2
Inside interface list: Serial0/1,
Outside interface: Serial1/1
Current State: IPSEC_ACTIVE
```

```
Last Event: SOCKET_UP
Default Domain: cisco.com
```

- Step 2** Display the NAT or PAT configuration that was automatically created for the VPN connection using the **show ip nat statistics** command. The “Dynamic mappings” field of this display gives the details for the NAT or PAT translation that is occurring on the VPN tunnel.

```
Router# show ip nat statistics
```

```
Total active translations: 0 (0 static, 0 dynamic; 0 extended)
Outside interfaces:
 cable-modem0
Inside interfaces:
 Ethernet0
Hits: 1489 Misses: 1
Expired translations: 1
Dynamic mappings:
-- Inside Source
access-list 198 pool enterprise refcount 0
 pool enterprise: netmask 255.255.255.0
 start 192.168.1.90 end 192.168.1.90
 type generic, total addresses 1, allocated 0 (0%), misses 0\
```

If you are seeing IPSEC\_ACTIVE in your output at this point, everything is operating as expected.

---

## Configuring Save Password

To configure the Save Password feature, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **password encryption aes**
4. **crypto ipsec client ezvpn *name***
5. **username *name* password {0 | 6} {*password*}**
6. **exit**
7. **show running-config**

## DETAILED STEPS

|        | Command                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                              |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                     | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>Enter your password if prompted.</li></ul>                                                                                                                                                                                                                                       |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                             | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                    |
| Step 3 | <b>password encryption aes</b><br><br><b>Example:</b><br>Router (config)# password encryption aes                                          | Enables a type 6 encrypted preshared key.                                                                                                                                                                                                                                                                                                            |
| Step 4 | <b>crypto ipsec client ezvpn name</b><br><br><b>Example:</b><br>Router (config)# crypto ipsec client ezvpn ezvpn1                          | Creates a Cisco Easy VPN remote configuration and enters the Cisco Easy VPN remote configuration mode.                                                                                                                                                                                                                                               |
| Step 5 | <b>username name password {0   6} {password}</b><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# username server_1 password 0 blue | Allows you to save your Xauth password locally on the PC. <ul style="list-style-type: none"><li>The <b>0</b> keyword specifies that an unencrypted password will follow.</li><li>The <b>6</b> keyword specifies that an encrypted password will follow.</li><li>The <i>password</i> argument is the unencrypted (cleartext) user password.</li></ul> |
| Step 6 | <b>exit</b><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# exit                                                                   | Exits the Cisco Easy VPN remote configuration mode.                                                                                                                                                                                                                                                                                                  |
| Step 7 | <b>show running-config</b><br><br><b>Example:</b><br>Router (config)# show running-config                                                  | Displays the contents of the configuration file that is currently running.                                                                                                                                                                                                                                                                           |

## Configuring Manual Tunnel Control

To configure control of IPsec VPN tunnels manually so that you can establish and terminate the IPsec VPN tunnels on demand, perform the following steps.

### Note

CLI is one option for connecting the tunnel. The preferred method is via the web interface (using SDM).

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec client ezvpn *name***
4. **connect [auto | manual]**
5. **exit**
6. **exit**
7. **crypto ipsec client ezvpn connect *name***

## DETAILED STEPS

|        | Command                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                      |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                    | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                             |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                            | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                            |
| Step 3 | <b>crypto ipsec client ezvpn <i>name</i></b><br><br><b>Example:</b><br>Router (config)# crypto ipsec client ezvpn easy vpn remote1        | Assigns a Cisco Easy VPN remote configuration to an interface and enters Cisco Easy VPN Remote configuration mode. <ul style="list-style-type: none"> <li>The <i>name</i> argument specifies the configuration name to be assigned to the interface.</li> </ul>                                                                                                              |
| Step 4 | <b>connect [ auto   manual]</b><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# connect manual                                    | Connects the VPN tunnel. Specify <b>manual</b> to configure manual tunnel control. <ul style="list-style-type: none"> <li>Automatic is the default; you do not need to use the <b>manual</b> keyword if your configuration is automatic.</li> </ul>                                                                                                                          |
| Step 5 | <b>exit</b><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# exit                                                                  | Exits Cisco Easy VPN Remote configuration mode.                                                                                                                                                                                                                                                                                                                              |
| Step 6 | <b>exit</b><br><br><b>Example:</b><br>Router (config)# exit                                                                               | Exits global configuration mode and enters privileged EXEC mode.                                                                                                                                                                                                                                                                                                             |
| Step 7 | <b>crypto ipsec client ezvpn connect <i>name</i></b><br><br><b>Example:</b><br>Router# crypto ipsec client ezvpn connect easy vpn remote1 | Connects a given Cisco Easy VPN remote configuration. <ul style="list-style-type: none"> <li>The <i>name</i> argument specifies the IPsec VPN tunnel name.</li> </ul> <b>Note</b> If the tunnel name is not specified, the active tunnel is connected. If there is more than one active tunnel, the command fails with an error requesting that you specify the tunnel name. |

## Configuring Automatic Tunnel Control

To configure automatic tunnel control, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec client ezvpn** *name*
4. **connect** [auto | manual]
5. **exit**
6. **exit**
7. **crypto ipsec client ezvpn connect** *name*

### DETAILED STEPS

|        | Command                                                                                                                               | Purpose                                                                                                                                                                                                                                       |
|--------|---------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                                                                                                           |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                        | Enters global configuration mode.                                                                                                                                                                                                             |
| Step 3 | <b>crypto ipsec client ezvpn</b> <i>name</i><br><br><b>Example:</b><br>Router (config)# crypto ipsec client<br>ezvpn easy vpn remote1 | Assigns a Cisco Easy VPN remote configuration to an interface and enters Cisco Easy VPN Remote configuration mode.<br><ul style="list-style-type: none"><li>• Specify the configuration name to be assigned to the interface.</li></ul>       |
| Step 4 | <b>connect</b> [auto   manual]<br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# connect<br>auto                                | Connects the VPN tunnel.<br><ul style="list-style-type: none"><li>• Specify <b>auto</b> to configure automatic tunnel control. Automatic is the default; you do not need to use this subcommand if your configuration is automatic.</li></ul> |
| Step 5 | <b>exit</b><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# exit                                                              | Exits Cisco Easy VPN Remote configuration mode.                                                                                                                                                                                               |
| Step 6 | <b>exit</b><br><br><b>Example:</b><br>Router (config)# exit                                                                           | Exits global configuration mode and enters privileged EXEC mode.                                                                                                                                                                              |

|               | Command                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 7</b> | <b>crypto ipsec client ezvpn connect <i>name</i></b><br><br><b>Example:</b><br>Router# crypto ipsec client ezvpn connect<br>easy vpn remote1 | Connects a given Cisco Easy VPN remote configuration. <ul style="list-style-type: none"> <li>The <i>name</i> argument specifies the IPsec VPN tunnel name.</li> </ul> <b>Note</b> If the tunnel name is not specified, the active tunnel is connected. If there is more than one active tunnel, the command fails with an error requesting that you specify the tunnel name. |

## Configuring Multiple Inside Interfaces

You can configure up to three inside interfaces for all platforms. You need to manually configure each inside interface using the following procedure.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface *interface-name***
4. **exit**
5. **crypto ipsec client ezvpn *name* [outside | inside]**
6. **interface *interface-name***
7. **exit**
8. **crypto ipsec client ezvpn *name* [outside | inside]**

### DETAILED STEPS

|               | Command                                                                                               | Purpose                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>      |
| <b>Step 2</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                        | Enters global configuration mode.                                                                                     |
| <b>Step 3</b> | <b>interface <i>interface-name</i></b><br><br><b>Example:</b><br>Router (config)# interface Ethernet0 | Selects the interface you want to configure by specifying the interface name and enters interface configuration mode. |
| <b>Step 4</b> | <b>exit</b><br><br><b>Example:</b><br>Router (config-if)# exit                                        | Exits interface configuration mode.                                                                                   |

|        | Command                                                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                    |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 5 | <b>crypto ipsec client ezvpn <i>name</i> [outside   inside]</b><br><br><b>Example:</b><br>Router (config)# crypto ipsec client ezvpn easy vpn remote 1 inside | Specifies the Cisco Easy VPN remote configuration name to be assigned to the first inside interface. <ul style="list-style-type: none"> <li>You must specify <b>inside</b> for each inside interface.</li> </ul>                                                                           |
| Step 6 | <b>interface <i>interface-name</i></b><br><br><b>Example:</b><br>Router (config)# interface Ethernet1                                                         | Selects the next interface you want to configure by specifying the next interface name and enters interface configuration mode.                                                                                                                                                            |
| Step 7 | <b>exit</b><br><br><b>Example:</b><br>Router (config-if)# exit                                                                                                | Exits interface configuration mode.                                                                                                                                                                                                                                                        |
| Step 8 | <b>crypto ipsec client ezvpn <i>name</i> [outside   inside]</b><br><br><b>Example:</b><br>Router (config)# crypto ipsec client ezvpn easy vpn remote2 inside  | Specifies the Cisco Easy VPN remote configuration name to be assigned to the next inside interface. <ul style="list-style-type: none"> <li>You must specify <b>inside</b> for each inside interface.</li> </ul> Repeat Step 3 through Step 4 to configure an additional tunnel if desired. |

## Configuring Multiple Outside Interfaces

You can configure multiple tunnels for outside interfaces, setting up a tunnel for each outside interface. You can configure a maximum of four tunnels using the following procedure for each outside interface.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface *interface-name***
4. **exit**
5. **crypto ipsec client ezvpn *name* [outside | inside]**
6. **interface *interface-name***
7. **exit**
8. **crypto ipsec client ezvpn *name* [outside | inside]**

## DETAILED STEPS

|        | Command                                                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                 | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                         |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                         | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                        |
| Step 3 | <b>interface</b> <i>interface-name</i><br><br><b>Example:</b><br>Router (config)# interface Ethernet0                                                                  | Selects the first outside interface you want to configure by specifying the interface name and enters interface configuration mode.                                                                                                                                                                                                                                                                      |
| Step 4 | <b>exit</b><br><br><b>Example:</b><br>Router (config-if)# exit                                                                                                         | Exits interface configuration mode.                                                                                                                                                                                                                                                                                                                                                                      |
| Step 5 | <b>crypto ipsec client ezvpn name</b> [ <b>outside</b>   <b>inside</b> ]<br><br><b>Example:</b><br>Router (config)# crypto ipsec client ezvpn easy vpn remote1 outside | Specifies the Cisco Easy VPN remote configuration name to be assigned to the first outside interface. <ul style="list-style-type: none"> <li>Specify <b>outside</b> (optional) for each outside interface. If neither <b>outside</b> nor <b>inside</b> is specified for the interface, the default is <b>outside</b>.</li> </ul>                                                                         |
| Step 6 | <b>interface</b> <i>interface-name</i><br><br><b>Example:</b><br>Router (config)# interface Ethernet1                                                                  | Selects the next outside interface you want to configure by specifying the next interface name.                                                                                                                                                                                                                                                                                                          |
| Step 7 | <b>exit</b><br><br><b>Example:</b><br>Router (config-if)# exit                                                                                                         | Exits interface configuration mode.                                                                                                                                                                                                                                                                                                                                                                      |
| Step 8 | <b>crypto ipsec client ezvpn name</b> [ <b>outside</b>   <b>inside</b> ]<br><br><b>Example:</b><br>Router (config)# crypto ipsec client ezvpn easy vpn remote2 outside | Specifies the Cisco Easy VPN remote configuration name to be assigned to the next outside interface. <ul style="list-style-type: none"> <li>Specify <b>outside</b> (optional) for each outside interface. If neither <b>outside</b> nor <b>inside</b> is specified for the interface, the default is <b>outside</b>.</li> </ul> Repeat Step 3 through Step 4 to configure additional tunnels if desired. |

## Configuring Multiple Subnet Support

When configuring multiple subnet support, you must first configure an access list to define the actual subnets to be protected. Each source subnet or mask pair indicates that all traffic that is sourced from this network to any destination is protected by IPsec. For information about configuring ACLs, see “Access control lists, configuring” in the section “[Additional References](#).”

After you have defined the subnets, you must configure the crypto IPsec client EZVPN profile to use the ACLs.

**Note**

Multiple subnets are not supported in client mode.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **interface** *interface-name*
4. **exit**
5. **crypto ipsec client ezvpn** *name*
6. **acl** {*acl-name* | *acl-number*}

**DETAILED STEPS**

|        | Command                                                                                                                  | Purpose                                                                                                               |
|--------|--------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                   | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>   |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                           | Enters global configuration mode.                                                                                     |
| Step 3 | <b>interface</b> <i>interface-name</i><br><br><b>Example:</b><br>Router (config)# interface Ethernet1                    | Selects the interface you want to configure by specifying the interface name and enters interface configuration mode. |
| Step 4 | <b>exit</b><br><br><b>Example:</b><br>Router (config-if)# exit                                                           | Exits interface configuration mode.                                                                                   |
| Step 5 | <b>crypto ipsec client ezvpn</b> <i>name</i><br><br><b>Example:</b><br>Router (config)# crypto ipsec client ezvpn ez1    | Creates a Cisco Easy VPN remote configuration and enters crypto Easy VPN configuration mode.                          |
| Step 6 | <b>acl</b> { <i>acl-name</i>   <i>acl-number</i> }<br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# acl acl-list1 | Specifies multiple subnets in a VPN tunnel.                                                                           |

## Configuring Proxy DNS Server Support

As a way of implementing the use of the DNS addresses of the ISP when the WAN connection is down, the router in a Cisco Easy VPN remote configuration can be configured to act as a proxy DNS server. To enable the proxy DNS server functionality with the **ip dns server** command, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip dns server**

### DETAILED STEPS

|        | Command                                                                        | Purpose                                                                                                             |
|--------|--------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                         | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal | Enters global configuration mode.                                                                                   |
| Step 3 | <b>ip dns server</b><br><br><b>Example:</b><br>Router (config)# ip dns server  | Enables the router to act as a proxy DNS server.<br><br><b>Note</b> This definition is IOS specific.                |

### What to Do Next

After configuring the router, you configure the Cisco IOS Easy VPN server as follows:

- Under the **crypto isakmp client configuration group** command, configure the *dns* subcommand as in the following example:

```
dns A.B.C.D A1.B1.C1.D1
```

These DNS server addresses should be pushed from the server to the Cisco Easy VPN remote and dynamically added to or deleted from the running configuration of the router.

For information about general DNS server functionality in Cisco IOS software applications, see [Configuring DNS](#) and [Configuring DNS on Cisco Routers](#).

## Configuring Dial Backup

### Note

The Dial Backup feature is not available in Cisco IOS Release 12.3(11)T.

To configure dial backup, perform the following steps.

## SUMMARY STEPS

1. Create the Easy VPN backup configuration.
2. Add the backup subcommand details to the primary configuration.
3. Apply the backup Easy VPN configuration to the dial backup outside interface.
4. Apply the Easy VPN profile to the inside interfaces.

## DETAILED STEPS

|               | Command                                                                                                               | Purpose                                                                                                                                                                |
|---------------|-----------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Create the Easy VPN dial backup configuration.                                                                        | For details about the backup configuration, see the section “ <a href="#">Dial Backup</a> .”                                                                           |
| <b>Step 2</b> | Add the backup subcommand details to the primary configuration.                                                       | Use the <b>backup</b> subcommand and <b>track</b> keyword of the <b>crypto ipsec client ezvpn</b> command.                                                             |
| <b>Step 3</b> | Apply the backup Easy VPN configuration to the dial backup outside interface (for example, serial, async, or dialer). | For details about applying the backup configuration to the dial backup outside interface, see the section “ <a href="#">Configuring Multiple Outside Interfaces</a> .” |
| <b>Step 4</b> | Apply the Easy VPN profile to the inside interfaces (there can be more than one).                                     | For details about applying the Easy VPN profile to the inside interfaces, see the section “ <a href="#">Configuring Multiple Inside Interfaces</a> .”                  |

## Configuring the DHCP Server Pool

To configure the Dynamic Host Configuration Protocol (DHCP) server pool, see the chapter “[Configuring DHCP](#)” in the *Cisco IOS IP Configuration Guide*, Release 12.3.

## Resetting a VPN Connection

To reset the VPN connection, perform the following steps. The **clear** commands can be configured in any order or independent of one another.

## SUMMARY STEPS

1. **enable**
2. **clear crypto ipsec client ezvpn**
3. **clear crypto sa**
4. **clear crypto isakmp**

**DETAILED STEPS**

|        | Command                                                                                                  | Purpose                                                                                                                                                 |
|--------|----------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                   | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                        |
| Step 2 | <b>clear crypto ipsec client ezvpn</b><br><br><b>Example:</b><br>Router# clear crypto ipsec client ezvpn | Resets the Cisco Easy VPN remote state machine and brings down the Cisco Easy VPN remote connection on all interfaces or on a given interface (tunnel). |
| Step 3 | <b>clear crypto sa</b><br><br><b>Example:</b><br>Router# clear crypto sa                                 | Deletes IPsec SAs.                                                                                                                                      |
| Step 4 | <b>clear crypto isakmp</b><br><br><b>Example:</b><br>Router# clear crypto isakmp                         | Clears active IKE connections.                                                                                                                          |

**Monitoring and Maintaining VPN and IKE Events**

To monitor and maintain VPN and IKE events, perform the following steps.

**SUMMARY STEPS**

1. **enable**
2. **debug crypto ipsec client ezvpn**
3. **debug crypto ipsec**
4. **debug crypto isakmp**

**SUMMARY STEPS**

|        | Command                                                                                                  | Purpose                                                                                                          |
|--------|----------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                   | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>debug crypto ipsec client ezvpn</b><br><br><b>Example:</b><br>Router# debug crypto ipsec client ezvpn | Displays information showing the configuration and implementation of the Cisco Easy VPN Remote feature.          |

|        | Command                                                                          | Purpose                             |
|--------|----------------------------------------------------------------------------------|-------------------------------------|
| Step 3 | <b>debug crypto ipsec</b><br><br><b>Example:</b><br>Router# debug crypto ipsec   | Displays IPsec events.              |
| Step 4 | <b>debug crypto isakmp</b><br><br><b>Example:</b><br>Router# debug crypto isakmp | Displays messages about IKE events. |

## Configuring a Virtual Interface

To configure a virtual interface, perform the following steps.

### Note

Before the virtual interface is configured, ensure that the Easy VPN profile is not applied on any outside interface. Remove the Easy VPN profile from the outside interface and then configure the virtual interface.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface virtual-template** *number* **type** *type-of-virtual-template*
4. **tunnel mode ipsec ipv4**
5. **exit**
6. **crypto ipsec client ezvpn** *name*
7. **virtual-interface** *virtual-template-number*

## DETAILED STEPS

|        | Command                                                                                                                                                                        | Purpose                                                                                                                                                                                                                                      |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                         | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                           |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                 | Enters global configuration mode.                                                                                                                                                                                                            |
| Step 3 | <b>interface virtual-template</b> <i>number</i> <b>type</b> <i>type-of-virtual-template</i><br><br><b>Example:</b><br>Router (config)# interface virtual-template1 type tunnel | (Optional) Creates a virtual template of the type tunnel and enters interface configuration mode. <ul style="list-style-type: none"> <li>• Steps 3, 4, and 5 are optional, but if one is configured, they must all be configured.</li> </ul> |

|        | Command                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                           |
|--------|---------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 4 | <b>tunnel mode ipsec ipv4</b><br><br><b>Example:</b><br>Router (if-config)# tunnel mode ipsec<br>ipv4                           | (Optional) Configures the tunnel that does the IPsec tunneling.                                                                                                                                                                                                                                                                   |
| Step 5 | <b>exit</b><br><br><b>Example:</b><br>Router (if-config)# exit                                                                  | (Optional) Exits interface (virtual-tunnel) configuration mode.                                                                                                                                                                                                                                                                   |
| Step 6 | <b>crypto ipsec client ezvpn name</b><br><br><b>Example:</b><br>Router (config)# crypto ipsec client<br>ezvpn EasyVPN1          | Creates a Cisco Easy VPN remote configuration and enters the Cisco Easy VPN remote configuration mode.                                                                                                                                                                                                                            |
| Step 7 | <b>virtual-interface virtual-template-number</b><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)#<br>virtual-interface 3 | Instructs the Easy VPN remote to create a virtual interface to be used as an outside interface. If the virtual template number is specified, the virtual-access interface is derived from the virtual interface that was specified. If a virtual template number is not specified, a generic virtual-access interface is created. |

## Troubleshooting Dual Tunnel Support

The following **debug** and **show** commands may be used to troubleshoot your dual-tunnel configuration.

### SUMMARY STEPS

1. **enable**
2. **debug crypto ipsec client ezvpn**
3. **debug ip policy**
4. **show crypto ipsec client ezvpn**
5. **show ip interface**

### DETAILED STEPS

|        | Command                                                                                                  | Purpose                                                                                                            |
|--------|----------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                   | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>debug crypto ipsec client ezvpn</b><br><br><b>Example:</b><br>Router# debug crypto ipsec client ezvpn | Displays information about Cisco Easy VPN remote connections.                                                      |

|        | Command                                                                                                | Purpose                                                                 |
|--------|--------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| Step 3 | <b>debug ip policy</b><br><br><b>Example:</b><br>Router# debug ip policy                               | Displays IP policy routing packet activity.                             |
| Step 4 | <b>show crypto ipsec client ezvpn</b><br><br><b>Example:</b><br>Router# show crypto ipsec client ezvpn | Displays the Cisco Easy VPN Remote configuration.                       |
| Step 5 | <b>show ip interface</b><br><br><b>Example:</b><br>Router# show ip interface                           | Displays the usability status of interfaces that are configured for IP. |

## Configuring Reactivate (a Default) Primary Peer

To configure a default primary peer, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec client ezvpn** *name*
4. **peer** {*ip-address* | *hostname*} [**default**]
5. **idle-time** *idle-time*

### DETAILED STEPS

|        | Command                                                                                                               | Purpose                                                                                                            |
|--------|-----------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                        | Enters global configuration mode.                                                                                  |
| Step 3 | <b>crypto ipsec client ezvpn</b> <i>name</i><br><br><b>Example:</b><br>Router (config)# crypto ipsec client ezvpn ez1 | Creates a Cisco Easy VPN remote configuration and enters crypto Easy VPN configuration mode.                       |

|        | Command                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 4 | <b>peer</b> { <i>ip-address</i>   <i>hostname</i> } [ <b>default</b> ]<br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# peer 10.2.2.2 default | Sets the peer IP address or hostname for the VPN connection. <ul style="list-style-type: none"> <li>A hostname can be specified only when the router has a DNS server available for hostname resolution.</li> <li>The peer subcommand may be input multiple times. However, only one default or primary peer entry can exist at a time (for example, 10.2.2.2 default).</li> <li>The <b>default</b> keyword defines the peer as the primary peer.</li> </ul> |
| Step 5 | <b>idle-time</b> <i>idle-time</i><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# idle-time 60                                               | (Optional) Idle time in seconds after which an Easy VPN tunnel is brought down. <ul style="list-style-type: none"> <li>Idle time=60 through 86400 seconds.</li> </ul> <b>Note</b> If idle time is configured, the tunnel for the primary server is not brought down.                                                                                                                                                                                         |

## Configuring Identical Addressing Support

Configuring Identical Addressing Support comprises the following tasks:

- Defining the Easy VPN remote in network-extension mode and enabling **nat allow**.
- Assigning the Cisco Easy VPN Remote configuration to the Outside interface.
- Creating a loopback interface and assigning the Cisco Easy VPN Remote configuration to the Inside interface of the loopback interface.
- Configuring a one-to-one static NAT translation for each host that needs to be accessible from the EasyVPN server-side network or from other client locations.
- Configuring dynamic overloaded NAT or PAT using an access list for all the desired VPN traffic. The NAT or PAT traffic is mapped to the Easy VPN inside interface IP address.
- And, if split-tunneling is required, using the **nat acl** command to enable split-tunneling for the traffic specified by the *acl-name* or the *acl-number* argument. The ACL is the same as the ACL used by the NAT or PAT mapping in the preceding bullet item.

To configure Identical Addressing Support, perform the following steps on your router.

### Prerequisites

Easy VPN Remote must be configured in network extension mode before you can configure the Identical Addressing Support feature.

### SUMMARY STEPS

- enable**
- configure terminal**
- crypto ipsec client ezvpn** *name*
- mode network-extension**
- nat allow**
- exit**
- interface** *interface*

8. **crypto ipsec client ezvpn name** *outside*
9. **exit**
10. **interface** *interface*
11. **ip address** *ip mask*
12. **crypto ipsec client ezvpn name** *inside*
13. **exit**
14. **ip nat inside source static** *local-ip global-ip*
15. **ip nat inside source list** {*acl-name* | *acl-number*} **interface** *interface* **overload**
16. **crypto ipsec client ezvpn name**
17. **nat acl** {*acl-name* | *acl-number*}
18. **exit**
19. **exit**

## DETAILED STEPS

|        | Command                                                                                                               | Purpose                                                                                                             |
|--------|-----------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                        | Enters global configuration mode.                                                                                   |
| Step 3 | <b>crypto ipsec client ezvpn name</b><br><br><b>Example:</b><br>Router (config)# crypto ipsec client ezvpn easyclient | Creates a remote configuration and enters Cisco Easy VPN Remote configuration mode.                                 |
| Step 4 | <b>mode network-extension</b><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# mode network-extension          | Configures Easy VPN client in network-extension mode.                                                               |
| Step 5 | <b>nat allow</b><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# nat allow                                    | Allows NAT to be integrated with Easy VPN and enables the Identical Addressing feature.                             |
| Step 6 | <b>exit</b><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# exit                                              | Exits Cisco Easy VPN Remote configuration mode.                                                                     |

|         | Command                                                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                          |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 7  | <b>interface</b> <i>interface</i><br><br><b>Example:</b><br>Router (config)# interface Ethernet1                                                                                            | Enters interface configuration mode for the interface. <ul style="list-style-type: none"><li>This interface will become the outside interface for the NAT or PAT translation.</li></ul>                                                                                                                                                          |
| Step 8  | <b>crypto ipsec client ezvpn name outside</b><br><br><b>Example:</b><br>Router (config-if)# crypto ipsec client ezvpn easyclient outside                                                    | Assigns the Cisco Easy VPN Remote configuration to the outside interface. <ul style="list-style-type: none"><li>This configuration automatically creates the necessary NAT or PAT translation parameters and initiates the VPN connection (if you are in client mode).</li></ul>                                                                 |
| Step 9  | <b>exit</b><br><br><b>Example:</b><br>Router (config-if)# exit                                                                                                                              | Exits interface configuration mode.                                                                                                                                                                                                                                                                                                              |
| Step 10 | <b>interface</b> <i>interface</i><br><br><b>Example:</b><br>Router (config)# interface Loopback0                                                                                            | Enters interface configuration mode for the loopback interface. <ul style="list-style-type: none"><li>This interface will become the inside interface for the NAT or PAT translation.</li></ul>                                                                                                                                                  |
| Step 11 | <b>ip address ip mask</b><br><br><b>Example:</b><br>Router (config-if)# ip address 10.1.1.1 255.255.255.252                                                                                 | Assigns the IP address and mask to the loopback interface.                                                                                                                                                                                                                                                                                       |
| Step 12 | <b>crypto ipsec client ezvpn name inside</b><br><br><b>Example:</b><br>Router (config-if)# crypto ipsec client ezvpn easyclient inside                                                      | Assigns the Cisco Easy VPN Remote configuration to the inside interface.                                                                                                                                                                                                                                                                         |
| Step 13 | <b>exit</b><br><br><b>Example:</b><br>Router (config-if)# exit                                                                                                                              | Exits interface configuration mode.                                                                                                                                                                                                                                                                                                              |
| Step 14 | <b>ip nat inside source static local-ip global-ip</b><br><br><b>Example:</b><br>Router (config)# ip nat inside source static 10.10.10.10 5.5.5.5                                            | Configure a one-to-one static NAT translation for each host that needs to be accessible from the Easy VPN server side network, or from other client locations.                                                                                                                                                                                   |
| Step 15 | <b>ip nat inside source list {acl-name   acl-number} interface interface overload</b><br><br><b>Example:</b><br>Router (config)# ip nat inside source list 100 interface Loopback0 overload | Configure dynamic overloaded NAT or PAT, which uses an ACL for all the desired VPN traffic. The NAT and PAT traffic is mapped to the Easy VPN inside interface IP address. <ul style="list-style-type: none"><li>The <i>acl-name</i> argument is the name of the ACL.</li><li>The <i>acl-number</i> argument is the number of the ACL.</li></ul> |

|         | Command                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|-----------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 16 | <b>crypto ipsec client ezvpn name</b><br><br><b>Example:</b><br>Router (config)# crypto ipsec client ezvpn easyclient | (Optional, if using split tunneling) Enters Cisco Easy VPN Remote configuration mode.                                                                                                                                                                                                                                                                                                                    |
| Step 17 | <b>nat acl {acl-name   acl-number}</b><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# nat acl 100            | (Optional, if using split tunneling) Enables split-tunneling for the traffic specified by the <i>acl-name</i> or the <i>acl-number</i> argument. The ACL is the same as the ACL used by the NAT or PAT mapping in the Step 15. <ul style="list-style-type: none"><li>• The <i>acl-name</i> argument is the name of the ACL.</li><li>• The <i>acl-number</i> argument is the number of the ACL.</li></ul> |
| Step 18 | <b>exit</b><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# exit                                              | Exits Cisco Easy VPN Remote configuration mode.                                                                                                                                                                                                                                                                                                                                                          |
| Step 19 | <b>exit</b><br><br><b>Example:</b><br>Router (config)# exit                                                           | Exits global configuration mode.                                                                                                                                                                                                                                                                                                                                                                         |

## Configuring cTCP on an Easy VPN Client

To configure cTCP on an Easy VPN client (remote device), perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ctcp [keepalive number-of-seconds | port port-number]**
4. **crypto ipsec client ezvpn name**
5. **ctcp port port-number**

### DETAILED STEPS

|        | Command                                                                        | Purpose                                                                                                          |
|--------|--------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                         | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal | Enters global configuration mode.                                                                                |

|               | Command                                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 3</b> | <b>crypto ctcp</b> [ <b>keepalive</b> <i>number-of-seconds</i>   <b>port</b> <i>port-number</i> ]<br><br><b>Example:</b><br>Router (config)# crypto ctcp keepalive 15 | Sets cTCP keepalive interval for the remote device. <ul style="list-style-type: none"> <li><i>number-of-seconds</i>—Number of seconds between keepalives. Value = 5 through 3600.</li> <li><b>port</b> <i>port-number</i>—Port number that cTCP listens to. Up to 10 numbers can be configured.</li> </ul> <b>Note</b> The cTCP client has to send periodic keepalives to the server to keep NAT or firewall sessions alive. |
| <b>Step 4</b> | <b>crypto ipsec client ezvpn</b> <i>name</i><br><br><b>Example:</b><br>Router (config)# crypto ipsec client ezvpn ezvpn1                                              | Creates a Cisco Easy VPN remote configuration and enters Cisco Easy VPN remote configuration mode.                                                                                                                                                                                                                                                                                                                           |
| <b>Step 5</b> | <b>ctcp port</b> <i>port-number</i><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# ctcp port 200                                                             | Sets the port number for cTCP encapsulation for Easy VPN. <ul style="list-style-type: none"> <li><i>port-number</i>—Port number on the hub. Value = 1 through 65535.</li> </ul>                                                                                                                                                                                                                                              |

## Restricting Traffic When a Tunnel Is Down

To restrict the client from sending traffic in clear text when a tunnel is down, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec client ezvpn** *name*
4. **flow allow acl** [*name* | *number*]

### DETAILED STEPS

|               | Command                                                                        | Purpose                                                                                                          |
|---------------|--------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><br><b>Example:</b><br>Router> enable                         | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| <b>Step 2</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal | Enters global configuration mode.                                                                                |

|        | Command                                                                                                                 | Purpose                                                                                                                                                                                                                                       |
|--------|-------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <code>crypto ipsec client ezvpn name</code><br><br><b>Example:</b><br>Router (config)# crypto ipsec client ezvpn ezvpn1 | Creates a Cisco Easy VPN remote configuration and enters Cisco Easy VPN remote configuration mode.                                                                                                                                            |
| Step 4 | <code>flow allow acl [name   number]</code><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)#flow allow acl 102   | Restricts the client from sending traffic in clear text when the tunnel is down.<br><br><ul style="list-style-type: none"> <li><i>name</i>— Access list name.</li> <li><i>number</i>— Access list number. Value = 100 through 199.</li> </ul> |

## Easy VPN Server Tasks

### Configuring a Cisco IOS Easy VPN Server

For information about configuring the Easy VPN Server, see the following document:

- [Easy VPN Server](#)

### Configuring an Easy VPN Server on a VPN 3000 Series Concentrator

This section describes the guidelines required to configure the Cisco VPN 3000 series concentrator for use with the Cisco Easy VPN Remote feature. As a general rule, you can use the default configuration except for IP addresses, server addresses, routing configurations, and for the following parameters and options:

- [Peer Configuration on a Cisco Easy VPN Remote Using the Hostname](#), page 59
- [Interactive Hardware Client Authentication Version 3.5](#), page 59
- [IPsec Tunnel Protocol](#), page 59
- [IPsec Group](#), page 59
- [Group Lock](#), page 59
- [Xauth](#), page 59
- [Split Tunneling](#), page 60
- [IKE Proposals](#), page 60
- [New IPsec SA](#), page 60

#### Note

You must be using Cisco VPN 3000 series concentrator software Release 3.11 or later to support Cisco Easy VPN software clients and remotes.

## Peer Configuration on a Cisco Easy VPN Remote Using the Hostname

After you have configured the Cisco Easy VPN server on the VPN 3000 concentrator to use hostname as its identity, you must configure the peer on the Cisco Easy VPN remote using the hostname. You can either configure DNS on the client to resolve the peer hostname or configure the peer hostname locally on the client using the **ip host** command. As an example, you can configure the peer hostname locally on an Easy VPN remote as follows:

```
ip host crypto-gw.cisco.com 10.0.0.1
```

Or you can configure the Easy VPN remote to use the hostname with the **peer** command and *hostname* argument, as follows:

```
peer crypto-gw.cisco.com.
```

## Interactive Hardware Client Authentication Version 3.5

The Cisco Easy VPN Remote feature does not support the Interactive Hardware Client Authentication Version 3.5 feature. This feature must be disabled. You can disable the feature on the VPN 3000 series concentrator by clicking the **HW Client** tab on the **Configuration | User Management | Base Group** screen.

## IPsec Tunnel Protocol

IPsec Tunnel Protocol enables the IPsec tunnel protocol so that it is available for users. The IPsec Tunnel Protocol is configured on the Cisco VPN 3000 series concentrator by clicking the **General** tab on the **Configuration | User Management | Base Group** screen.

## IPsec Group

IPsec group configures the Cisco VPN 3000 series concentrator with a group name and password that match the values configured for the Cisco Easy VPN remote configuration on the router. These values are configured on the router with the **group group-name key group-key** subcommand and arguments. The values are configured on the Cisco VPN 3000 series concentrator using the **Configuration | User Management | Groups** screen.

## Group Lock

If you are defining multiple users in multiple groups on the VPN 3000 series concentrator, you must check the **Group Lock** box in the IPsec tab to prevent users in one group from logging in with the parameters of another group. For example, if you have configured one group for split tunneling access and another group without split tunneling access, clicking the **Group Lock** box prevents users in the second group from gaining access to the split tunneling features. The Group Lock checkbox appears in the **IPsec** tab in the **Configuration | User Management | Base Group** screen and in the **IPsec** tab in the **Configuration | User Management | Groups | Add/Modify** screens.

## Xauth

To use Xauth, set the **Authentication** parameter to **None**. The Authentication parameter appears in the **IPsec** tab in the **Configuration | User Management | Base Group** screen and in the **IPsec** tab in the **Configuration | User Management | Groups | Add/Modify** screens.

## Split Tunneling

The **Configuration | User Management | Base Group, Mode Configuration Parameters Tab** screen includes a **Split Tunnel** option with a checkbox that says “Allow the networks in the list to bypass the tunnel.”

## IKE Proposals

The Cisco VPN 3000 series concentrator is preconfigured with a default IKE proposal, CiscoVPNClient-3DES-MD5, that can be used with Cisco Easy VPN remotes. This IKE proposal supports preshared keys with Xauth using the MD5/HMAC-128 algorithm and Diffie-Hellman Group 2.

This IKE proposal is active by default, but you should verify that it is still an active proposal using the **Configuration | System | Tunneling Protocols | IPsec | IKE Proposals** screen.

In addition, as part of configuring the Cisco VPN 3000 series concentrator—for the Cisco Easy VPN Remote image, you do not need to create a new IPsec SA. Use the default IKE and Easy VPN remote lifetime configured on the Cisco VPN 3000 series concentrator.

### Note

You can also use the default IKE proposals IKE-DES-MD5 and IKE-3DES-MD5, but they do not enable Xauth support by default.

## New IPsec SA

You can create a new IPsec SA. Cisco Easy VPN clients use a SA having the following parameters:

- Authentication Algorithm=ESP/MD5/HMAC-128
- Encryption Algorithm=DES-56 or 3DES-168 (recommended)
- Encapsulation Mode=Tunnel
- IKE Proposal=CiscoVPNClient-3DES-MD5 (preferred)

The Cisco VPN 3000 series concentrator is preconfigured with several default security associations (SAs), but they do not meet the IKE proposal requirements. To use an IKE proposal of CiscoVPNClient-3DES-MD5, copy the ESP/IKE-3DES-MD5 SA and modify it to use CiscoVPNClient-3DES-MD5 as its IKE proposal. An IKE proposal is configured on the VPN 3000 series concentrator using the **Configuration | Policy Management | Traffic Management | Security Associations** screen.

For information about configuring an Easy VPN Server on a Cisco PIX Firewall, see the following document:

- [Easy VPN Server](#)

## Web Interface Tasks

### Configuring Web-Based Activation

To configure a LAN so that any HTTP requests coming from any of the PCs on the private LAN are intercepted, providing corporate users with access to the corporate Web page, perform the following steps.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec client ezvpn *name***
4. **xauth userid mode {http-intercept | interactive | local}**

#### DETAILED STEPS

|        | Command                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                              |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                      | Enables privileged EXEC mode.<br><ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                                                |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                              | Enters global configuration mode.                                                                                                                                                                                                                                    |
| Step 3 | <b>crypto ipsec client ezvpn <i>name</i></b><br><br><b>Example:</b><br>Router (config)# crypto ipsec client<br>ezvpn easy vpn remote1                       | Assigns a Cisco Easy VPN remote configuration to an interface and enters Cisco Easy VPN Remote configuration mode.<br><ul style="list-style-type: none"> <li>• The <i>name</i> argument specifies the configuration name to be assigned to the interface.</li> </ul> |
| Step 4 | <b>xauth userid mode {http-intercept   interactive   local}</b><br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# xauth<br>userid mode http-intercept | Specifies how the VPN device handles Xauth requests or prompts from the server.                                                                                                                                                                                      |

### Monitoring and Maintaining Web-Based Activation

To monitor and maintain web-based activation, perform the following steps. (The **debug** and **show** commands may be used independently, or they may all be configured.)

#### SUMMARY STEPS

1. **enable**
2. **debug crypto ipsec client ezvpn**

3. **debug ip auth-proxy ezvpn**
4. **show crypto ipsec client ezvpn**
5. **show ip auth-proxy config**

## DETAILED STEPS

|        | Command                                                                                                  | Purpose                                                                                                                                                   |
|--------|----------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                   | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                       |
| Step 2 | <b>debug crypto ipsec client ezvpn</b><br><br><b>Example:</b><br>Router# debug crypto ipsec client ezvpn | Displays information about the Cisco Easy VPN connection.                                                                                                 |
| Step 3 | <b>debug ip auth-proxy ezvpn</b><br><br><b>Example:</b><br>Router# debug ip auth-proxy ezvpn             | Displays information related to proxy authentication behavior for web-based activation.                                                                   |
| Step 4 | <b>show crypto ipsec client ezvpn</b><br><br><b>Example:</b><br>Router# show crypto ipsec client ezvpn   | Shows that the username and password used for user credentials during Xauth negotiations will be obtained by intercepting HTTP connections from the user. |
| Step 5 | <b>show ip auth-proxy config</b><br><br><b>Example:</b><br>Router# show ip auth-proxy config             | Displays the auth-proxy rule that has been created and applied by Easy VPN.                                                                               |

## Examples

### Debug Output

The following is sample **debug** output for a typical situation in which a user has opened a browser and connected to the corporate website:

Router# **debug ip auth-proxy ezvpn**

```
Dec 10 12:41:13.335: AUTH-PROXY: New request received by EzVPN WebIntercept
! The following line shows the ip address of the user.
from 10.4.205.205
Dec 10 12:41:13.335: AUTH-PROXY:GET request received
Dec 10 12:41:13.335: AUTH-PROXY:Normal auth scheme in operation
Dec 10 12:41:13.335: AUTH-PROXY:Ezvpn is NOT active. Sending connect-bypass page to user
```

At this point, the user chooses “connect” on his or her browser:

```
Dec 10 12:42:43.427: AUTH-PROXY: New request received by EzVPN WebIntercept
from 10.4.205.205
Dec 10 12:42:43.427: AUTH-PROXY:POST request received
Dec 10 12:42:43.639: AUTH-PROXY:Found attribute <connect> in form
Dec 10 12:42:43.639: AUTH-PROXY:Sending POST data to EzVPN
Dec 10 12:42:43.639: EZVPN(tunnel22): Communication from Interceptor
application.
```

```
Request/Response from 10.4.205.205, via Ethernet0
Dec 10 12:42:43.639: connect: Connect Now
Dec 10 12:42:43.639: EZVPN(tunnel22): Received CONNECT from 10.4.205.205!
Dec 10 12:42:43.643: EZVPN(tunnel22): Current State: CONNECT_REQUIRED
Dec 10 12:42:43.643: EZVPN(tunnel22): Event: CONNECT
Dec 10 12:42:43.643: EZVPN(tunnel22): ezvpn_connect_request
```

Easy VPN contacts the server:

```
Dec 10 12:42:43.643: EZVPN(tunnel22): Found valid peer 192.168.0.1
Dec 10 12:42:43.643: EZVPN(tunnel22): Added PSK for address 192.168.0.1

Dec 10 12:42:43.643: EZVPN(tunnel22): New State: READY
Dec 10 12:42:44.815: EZVPN(tunnel22): Current State: READY
Dec 10 12:42:44.815: EZVPN(tunnel22): Event: IKE_PFS
Dec 10 12:42:44.815: EZVPN(tunnel22): No state change
Dec 10 12:42:44.819: EZVPN(tunnel22): Current State: READY
Dec 10 12:42:44.819: EZVPN(tunnel22): Event: CONN_UP
Dec 10 12:42:44.819: EZVPN(tunnel22): ezvpn_conn_up B8E86EC7 E88A8A18 D0D51422
8AFF32B7
```

The server requests Xauth information:

```
Dec 10 12:42:44.823: EZVPN(tunnel22): No state change
Dec 10 12:42:44.827: EZVPN(tunnel22): Current State: READY
Dec 10 12:42:44.831: EZVPN(tunnel22): Event: XAUTH_REQUEST
Dec 10 12:42:44.831: EZVPN(tunnel22): ezvpn_xauth_request
Dec 10 12:42:44.831: EZVPN(tunnel22): ezvpn_parse_xauth_msg
Dec 10 12:42:44.831: EZVPN: Attributes sent in xauth request message:
Dec 10 12:42:44.831: XAUTH_TYPE_V2(tunnel22): 0
Dec 10 12:42:44.831: XAUTH_USER_NAME_V2(tunnel22):
Dec 10 12:42:44.831: XAUTH_USER_PASSWORD_V2(tunnel22):
Dec 10 12:42:44.831: XAUTH_MESSAGE_V2(tunnel22) <Enter Username and
Password.>
Dec 10 12:42:44.831: EZVPN(tunnel22): Requesting following info for xauth
Dec 10 12:42:44.831: username:(Null)
Dec 10 12:42:44.835: password:(Null)
Dec 10 12:42:44.835: message:Enter Username and Password.
Dec 10 12:42:44.835: EZVPN(tunnel22): New State: XAUTH_REQ
```

The username and password prompt are displayed in the browser of the user:

```
Dec 10 12:42:44.835: AUTH-PROXY: Response to POST is CONTINUE
Dec 10 12:42:44.839: AUTH-PROXY: Displayed POST response successfully
Dec 10 12:42:44.843: AUTH-PROXY:Served POST response to the user
```

When the user enters his or her username and password, the following is sent to the server:

```
Dec 10 12:42:55.343: AUTH-PROXY: New request received by EzVPN WebIntercept
from 10.4.205.205
Dec 10 12:42:55.347: AUTH-PROXY:POST request received
Dec 10 12:42:55.559: AUTH-PROXY:No of POST parameters is 3
Dec 10 12:42:55.559: AUTH-PROXY:Found attribute <username> in form
Dec 10 12:42:55.559: AUTH-PROXY:Found attribute <password> in form
Dec 10 12:42:55.559: AUTH-PROXY:Found attribute <ok> in form
Dec 10 12:42:55.563: AUTH-PROXY:Sending POST data to EzVPN
Dec 10 12:42:55.563: EZVPN(tunnel22): Communication from Interceptor application.
Request/Response from 10.4.205.205, via Ethernet0
Dec 10 12:42:55.563: username:http
Dec 10 12:42:55.563: password:<omitted>
Dec 10 12:42:55.563: ok:Continue
Dec 10 12:42:55.563: EZVPN(tunnel22): Received username|password from 10.4.205.205!
Dec 10 12:42:55.567: EZVPN(tunnel22): Current State: XAUTH_PROMPT
Dec 10 12:42:55.567: EZVPN(tunnel22): Event: XAUTH_REQ_INFO_READY
Dec 10 12:42:55.567: EZVPN(tunnel22): ezvpn_xauth_reply
```

```

Dec 10 12:42:55.567: XAUTH_TYPE_V2(tunnel22): 0
Dec 10 12:42:55.567: XAUTH_USER_NAME_V2(tunnel22): http
Dec 10 12:42:55.567: XAUTH_USER_PASSWORD_V2(tunnel22): <omitted>
Dec 10 12:42:55.567: EZVPN(tunnel22): New State: XAUTH_REPLIED
Dec 10 12:42:55.891: EZVPN(tunnel22): Current State: XAUTH_REPLIED
Dec 10 12:42:55.891: EZVPN(tunnel22): Event: XAUTH_STATUS
Dec 10 12:42:55.891: EZVPN(tunnel22): xauth status received: Success

```

After using the tunnel, the user chooses “Disconnect”:

```

Dec 10 12:48:17.267: EZVPN(tunnel22): Received authentic disconnect credential
Dec 10 12:48:17.275: EZVPN(): Received an HTTP request: disconnect
Dec 10 12:48:17.275: %CRYPTO-6-EZVPN_CONNECTION_DOWN: (Client) User=
 Group=tunnel22 Client_public_addr=192.168.0.13 Server_public_addr=192.168.0.1
 Assigned_client_addr=10.3.4.5

```

### Show Output Before the User Is Connected to the Tunnel

The following output from the two **show** commands (**show crypto ipsec client ezvpn** and **show ip auth-proxy config**) displays what you might see before a user is connected to a VPN tunnel:

Router# **show crypto ipsec client ezvpn tunnel22**

```

Tunnel name : tunnel22
Inside interface list: Ethernet0
Outside interface: Ethernet1
Current State: CONNECT_REQUIRED
Last Event: RESET
Save Password: Disallowed
! Note the next line.
 XAuth credentials: HTTP intercepted
 HTTP return code : 200
 IP addr being prompted: 0.0.0.0
Current EzVPN Peer: 192.168.0.1

```

Router# **show ip auth-proxy config**

```

Authentication global cache time is 60 minutes
Authentication global absolute time is 0 minutes
Authentication Proxy Watch-list is disabled

Authentication Proxy Rule Configuration
! Note that the next line is the Easy VPN-defined internal rule.
 Auth-proxy name ezvpn401***
 Applied on Ethernet0
 http list not specified inactivity-timer 60 minutes

```

### Show Output After the User Is Connected to the Tunnel

The following output from the two **show** commands (**show crypto ipsec client ezvpn** and **show ip auth-proxy config**) displays what you might see after the user has been connected to the tunnel:

Router# **show crypto ipsec client ezvpn tunnel22**

```

Tunnel name : tunnel22
Inside interface list: Ethernet0
Outside interface: Ethernet1
Current State: IPSEC_ACTIVE
Last Event: SOCKET_UP
Address: 10.3.4.5
Mask: 255.255.255.255
Save Password: Disallowed
 XAuth credentials: HTTP intercepted
 HTTP return code : 200
 IP addr being prompted: 192.168.0.0

```

Current EzVPN Peer: 192.168.0.1

Router# **show ip auth-proxy config**

Authentication global cache time is 60 minutes  
Authentication global absolute time is 0 minutes  
Authentication Proxy Watch-list is disabled

Auth-proxy name ezvpnWeb\*\*\* (EzVPN-defined internal rule)  
http list not specified inactivity-timer 60 minutes

## Using SDM As a Web Manager

For information about the SDM web manager, see the following document:

- [Cisco Security Device Manager](#)

## Troubleshooting the VPN Connection

### Troubleshooting a VPN Connection Using the Cisco Easy VPN Remote Feature

To troubleshoot a VPN connection created using the Cisco Easy VPN Remote feature, use the following suggested techniques.

- Be aware that any changes to an active Cisco Easy VPN remote configuration or IP address changes to the involved interfaces, such as adding or removing an inside interface, result in a reset of the Cisco Easy VPN Remote connection.
- Enable debugging of the Cisco Easy VPN Remote feature using the **debug crypto ipsec client ezvpn** command.
- Enable debugging of IKE events using the **debug crypto ipsec** and **debug crypto isakmp** commands.
- Display the active IPsec VPN connections using the **show crypto engine connections active** command.
- To reset the VPN connection, use the **clear crypto ipsec client ezvpn** command. If you have debugging enabled, you might prefer to use the **clear crypto sa** and **clear crypto isakmp** commands.

## Troubleshooting the Client Mode of Operation

The following information may be used to troubleshoot the Easy VPN Remote configuration for the client mode of operation.

In client mode, the Cisco Easy VPN Remote feature automatically configures the NAT or PAT translation and access lists that are needed to implement the VPN tunnel. These configurations are automatically created when the IPsec VPN connection is initiated. When the tunnel is torn down, the NAT or PAT and access list configurations are automatically deleted.

The NAT or PAT configuration is created with the following assumptions:

- The **ip nat inside** command is applied to all inside interfaces, including default inside interfaces. The default inside interface is the Ethernet 0 interface (for the Cisco 806, Cisco 826, Cisco 827, Cisco 828, Cisco 831, Cisco 836, and Cisco 837 routers).

- The **ip nat outside** command is applied to the interface that is configured with the Cisco Easy VPN Remote configuration. On the Cisco 800 series and Cisco 1700 series routers, the outside interface is configured with the Cisco Easy VPN Remote configuration. On the Cisco 1700 series routers, Cisco 2600 series routers, Cisco 3600 series routers, and Cisco 3700 series routers, multiple outside interfaces can be configured.

**Tip**

The NAT or PAT translation and access list configurations that are created by the Cisco Easy VPN Remote feature are not written to either the startup configuration or running configuration files. These configurations, however, can be displayed using the **show ip nat statistics** and **show access-list** commands.

## Troubleshooting Remote Management

To troubleshoot remote management of the VPN remote, use the **show ip interface** command. Using the **brief** keyword, you can verify that the loopback has been removed and that the interface is shown correctly.

### Examples

Following is a typical example of output from the **show ip interface** command.

Router# **show ip interface brief**

| Interface | IP-Address  | OK? | Method | Status                | Protocol |
|-----------|-------------|-----|--------|-----------------------|----------|
| Ethernet0 | unassigned  | YES | NVRAM  | administratively down | down     |
| Ethernet1 | 10.0.0.11   | YES | NVRAM  | up                    | up       |
| Loopback0 | 192.168.6.1 | YES | manual | up                    | up       |
| Loopback1 | 10.12.12.12 | YES | NVRAM  | up                    | up       |

Router# **show ip interface brief**

| Interface | IP-Address  | OK? | Method | Status                | Protocol |
|-----------|-------------|-----|--------|-----------------------|----------|
| Ethernet0 | unassigned  | YES | NVRAM  | administratively down | down     |
| Ethernet1 | 10.0.0.11   | YES | NVRAM  | up                    | up       |
| Loopback1 | 10.12.12.12 | YES | NVRAM  | up                    | up       |

## Troubleshooting Dead Peer Detection

To troubleshoot dead peer detection, use the **show crypto ipsec client ezvpn** command.

### Examples

The following typical output displays the current server and the peers that have been pushed by the Easy VPN server:

Router# **show crypto ipsec client ezvpn**

```
Easy VPN Remote Phase: 4
Tunnel name : ez1
Inside interface list: Loopback1,
Outside interface: Ethernet1
```

```
Current State: IPSEC_ACTIVE
Last Event: CONNECT
Address: 192.168.6.5
Mask: 255.255.255.255
DNS Primary: 10.2.2.2
DNS Secondary: 10.2.2.3
NBMS/WINS Primary: 10.6.6.6
Default Domain: cisco.com
Save Password: Allowed
Current EzVPN Peer:10.0.0.110
Backup Gateways
(0): green.cisco.com
(1): blue
```

# Easy VPN Remote Configuration Examples

## Client Mode Configuration: Examples

The examples in this section show configurations for the Cisco Easy VPN Remote feature in client mode. Also shown are the Cisco IOS Easy VPN server configurations that correspond to these client configurations.

- [Cisco Easy VPN Client in Client Mode \(Cisco 831\): Example, page 68](#)
- [Cisco Easy VPN Client in Client Mode \(Cisco 837\): Example, page 69](#)
- [Cisco Easy VPN Client in Client Mode \(Cisco 1700 Series\): Example, page 71](#)

For more client-mode configuration examples, see [IPSec VPN](#) (under the “Technical Documents” and “Cisco IOS IPSec Configuration Documents” sections) and to [Cisco Easy VPN Solutions](#).

### Note

Typically, users configure the Cisco 800 series routers with the SDM or CRWS web interface, not by entering CLI commands. However, the configurations shown here for the Cisco 800 series routers display typical configurations that can be used if manual configuration is desired.

### Cisco Easy VPN Client in Client Mode (Cisco 831): Example

In the following example, a Cisco 831 router is configured as an Easy VPN remote using the Cisco Easy VPN Remote feature in client mode. This example shows the following components of the Cisco Easy VPN Remote configuration:

- DHCP server pool—The **ip dhcp pool** command creates a pool of IP addresses to be assigned to the PCs connected to the Ethernet 0 interface of the router. The pool assigns addresses in the class C private address space (192.168.100.0) and configures each PC so that its default route is 192.168.100.1, which is the IP address assigned to the Ethernet interface of the router. The DHCP lease period is one day.
- Cisco Easy VPN remote configuration—The first **crypto ipsec client ezvpn easy vpn remote** command (global configuration mode) creates a Cisco Easy VPN remote configuration named “easy vpn remote.” This configuration specifies the group name “easy vpn remote-groupname” and the shared key value “easy vpn remote-password,” and it sets the peer destination to the IP address **192.185.0.5** (which is the address assigned to the interface connected to the Internet on the destination peer router). The Cisco Easy VPN Remote configuration is configured for the default **client** mode.

### Note

If DNS is also configured on the router, the **peer** keyword option also supports a hostname instead of an IP address.

- The second **crypto ipsec client ezvpn easy vpn remote** command (interface configuration mode) assigns the Cisco Easy VPN Remote configuration to the Ethernet 1 interface so that all traffic that is received and transmitted on that interface is sent through the VPN tunnel.

### Cisco Easy VPN Client in Client Mode (Cisco 837): Example

In the following example, a Cisco 837 router is configured as an Easy VPN remote using the Cisco Easy VPN Remote feature in the client mode of operation. This example shows the following components of the Cisco Easy VPN remote configuration:

- PPPoE configuration—The ATM 0 interface is configured to support PPPoE connections over the Dialer 1 virtual interface. Because the interfaces use PPPoE, a DHCP IP address pool is not required to provide IP addresses to the connected PCs.
- Cisco Easy VPN Remote configuration—The first **crypto ipsec client ezvpn** command (global configuration mode) creates a Cisco Easy VPN remote configuration named “easy vpn remote.” This configuration specifies the group name “easy vpn remote-groupname” and the shared key value of “easy vpn remote-password,” and it sets the peer destination to the IP address 10.0.0.5 (which is the address assigned to the interface connected to the Internet on the destination peer router). The Cisco Easy VPN remote configuration is configured for the default client mode.

**Note** If DNS is also configured on the router, the **peer** keyword option also supports a hostname instead of an IP address.

- The second **crypto ipsec client ezvpn** command (interface configuration mode) assigns the Cisco Easy VPN remote configuration to the Dialer 1 interface so that all traffic received and transmitted on that interface is sent through the VPN tunnel.

### Cisco Easy VPN Client in Client Mode (Cisco 1700 Series): Example

In the following example, a Cisco 1753 router is configured as an Easy VPN remote using the Cisco Easy VPN Remote feature in the client mode of operation. This example shows a running configuration of a Cisco 1753 that has two inside interfaces and one outside interface on one tunnel. The **connect auto** subcommand manually establishes the IPsec VPN tunnel.

## Local Address Support for Easy VPN Remote: Example

The following example shows that the **local-address** command is used to specify the loopback 0 interface for sourcing tunnel traffic:

```

Router# configure terminal
Router(config)# crypto ipsec client ezvpn telecommuter-client
Router(config-crypto-ezvpn)# local-address loopback0

```

## Network Extension Mode Configuration: Examples

In this section, the following examples demonstrate how to configure the Cisco Easy VPN Remote feature in the network extension mode of operation. Also shown are the Cisco IOS Easy VPN server configurations that correspond to these client configurations.

- [Cisco Easy VPN Client in Network Extension Mode \(Cisco 831\): Example, page 74](#)
- [Cisco Easy VPN Client in Network Extension Mode \(Cisco 837\): Example, page 75](#)
- [Cisco Easy VPN Client in Network Extension Mode \(Cisco 1700 Series\): Example, page 77](#)

For more network extension mode configuration examples, see [IPSec VPN](#) (under the “Technical Documents” and “Cisco IOS IPSec Configuration Documents” sections) and to [Cisco Easy VPN Solutions](#).

### Cisco Easy VPN Client in Network Extension Mode (Cisco 831): Example

In the following example, a Cisco 831 router is configured as an Easy VPN remote using the Cisco Easy VPN Remote feature. This example shows the following components of the Cisco Easy VPN remote configuration:

- The Ethernet 0 interface is assigned an address in the network address space of the Cisco IOS Easy VPN server. The **ip route** command directs all traffic for this network space from the Ethernet 1 interface to the destination server.
- Cisco Easy VPN Remote configuration—The first **crypto ipsec client ezvpn** command (global configuration mode) creates a Cisco Easy VPN remote configuration named “easy vpn remote.” This configuration specifies the group name “easy vpn remote-groupname” and the shared key value “easy vpn remote-password,” and it sets the peer destination to the IP address 192.185.0.5 (which is the address assigned to the interface connected to the Internet on the destination peer router). The Cisco Easy VPN remote configuration is configured for network extension mode.

**Note** If DNS is also configured on the router, the **peer** keyword option also supports a hostname instead of an IP address.

- The second **crypto ipsec client ezvpn** command (interface configuration mode) assigns the Cisco Easy VPN Remote configuration to the Ethernet 1 interface so that all traffic that is received and transmitted on that interface is sent through the VPN tunnel.

### Cisco Easy VPN Client in Network Extension Mode (Cisco 1700 Series): Example

In the following example, a Cisco 1700 series router is configured as an Easy VPN remote using the Cisco Easy VPN Remote feature in the network extension mode of operation. This example shows the following components of the Cisco Easy VPN remote configuration:

- Cisco Easy VPN Remote configuration—The first **crypto ipsec client ezvpn** command (global configuration mode) creates a Cisco Easy VPN remote configuration that is named “easy vpn remote.” This configuration specifies the group name “easy vpn remote-groupname” and the shared key value “easy vpn remote-password,” and it sets the peer destination to the IP address 10.0.0.2 (which is the address assigned to the interface connected to the Internet on the destination peer router). The Cisco Easy VPN remote configuration is configured for network extension mode.

**Note** If DNS is also configured on the router, the **peer** keyword option also supports a hostname instead of an IP address.

- The second **crypto ipsec client ezvpn easy vpn remote** command (interface configuration mode) assigns the Cisco Easy VPN remote configuration to the Ethernet 0 interface so that all traffic that is received and transmitted on that interface is sent through the VPN tunnel.

## PFS Support: Examples

The following **show crypto ipsec client ezvpn** command output shows the group name (“2”) and that PFS is being used:

```
Router# show crypto ipsec client ezvpn
```

```
Easy VPN Remote Phase: 4
```

```
Tunnel name : ez1
Inside interface list: Loopback1,
Outside interface: Ethernet1
Current State: IPSEC_ACTIVE
Last Event: SOCKET_UP
Address: 192.168.6.6
Mask: 255.255.255.255
Using PFS Group: 2
Save Password: Allowed
Current EzVPN Peer:10.0.0.110
```

Note that on a Cisco IOS EasyVPN server, PFS must be included in IPsec proposals by adding to the crypto map, as in the following example:

```
crypto dynamic-map mode 1
 set security-association lifetime seconds 180
 set transform-set client
 set pfs group2
 set isakmp-profile fred
reverse-route
```

## Dial Backup: Examples

### DHCP Configured on Primary Interface and PPP Async As Backup

The following example shows that a Cisco 1711 router has been configured so that DHCP is configured on the primary interface and PPP asynchronous mode is configured as the backup:

Router# **show running-config**

```

Building configuration...

Current configuration : 3427 bytes

## Web-Based Activation: Example

The following example shows that HTTP connections from the user are to be intercepted and that the user can do web-based authentication (192.0.0.13 is the VPN client device and 192.0.0.1 is the server device):

```
crypto ipsec client ezvpn tunnel22
 connect manual
 group tunnel22 key 22tunnel
 mode client
 peer 192.168.0.1
 xauth userid mode http-intercept
!
!
interface Ethernet0
 ip address 10.4.23.15 255.0.0.0
 crypto ipsec client ezvpn tunnel22 inside!
interface Ethernet1
 ip address 192.168.0.13 255.255.255.128
 duplex auto
 crypto ipsec client ezvpn tunnel22
!
```

## Easy VPN Remote with Virtual IPsec Interface Support Configuration: Examples

The following examples indicate that Virtual IPsec Interface Support has been configured on the Easy VPN remote devices.

## Virtual IPsec Interface: Generic Virtual Access

The following example shows an Easy VPN remote device with virtual-interface support using a generic virtual-access IPsec interface.

```

!
version 12.4
service timestamps debug datetime msec
service timestamps log datetime msec
no service password-encryption
!
hostname Router
!

## Virtual IPsec Interface: Virtual Access Derived from Virtual Template

The following example shows an Easy VPN remote device with virtual-interface support using a virtual-template-derived virtual-access IPsec interface:

```
!
version 12.4
service timestamps debug datetime msec
service timestamps log datetime msec
no service password-encryption
!
hostname Router
!
boot-start-marker
boot-end-marker
!
!
no aaa new-model
!
resource policy
!
clock timezone IST 0
ip subnet-zero
no ip dhcp use vrf connected
!
!
crypto ipsec client ezvpn ez
 connect manual
 group easy key cisco
 mode client
 peer 10.3.0.2
 virtual-interface 1
 xauth userid mode interactive
!
!
interface Ethernet0/0
 ip address 10.1.0.2 255.255.255.0
 no keepalive
 no cdp enable
 crypto ipsec client ezvpn ez inside
!
interface Ethernet1/0
 ip address 10.2.0.1 255.255.255.0
 no keepalive
 no cdp enable
 crypto ipsec client ezvpn ez
!
interface Virtual-Template1 type tunnel
 no ip address
 tunnel mode ipsec ipv4
!
!
ip classless
ip route 0.0.0.0 0.0.0.0 10.2.0.2 2
no ip http server
no ip http secure-server
!
!
line con 0
line aux 0
line vty 0 4
 login
!
end
```

## When the Tunnel Is Down

The result of a virtual-interface configuration on an Easy VPN profile is the creation of a virtual-access interface. This interface provides IPsec encapsulation. The output below shows the configuration of a virtual-access interface when Easy VPN is “down.”

```
Router# show running-config interface virtual-access 2
```

```
Building configuration...
```

```
Current configuration : 99 bytes
```

```
!
interface Virtual-Access2
 no ip address
 tunnel source Ethernet1/0
 tunnel mode ipsec ipv4
end
```

A virtual-interface configuration results in the creation of a virtual-access interface. This virtual-access interface is made automatically outside the interface of the Easy VPN profile. The routes that are added later when the Easy VPN tunnels come up point to this virtual interface for sending the packets to the corporate network. If **crypto ipsec client ezvpn name outside (crypto ipsec client ezvpn name** command and **outside** keyword) is applied on a real interface, that interface is used as the IKE (IPsec) endpoint (that is, IKE and IPsec packets use the address on the interface as the source address).

```
Router# show crypto ipsec client ezvpn
```

```
Easy VPN Remote Phase: 5
```

```
Tunnel name : ez
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access2 (bound to Ethernet1/0)
Current State: CONNECT_REQUIRED
Last Event: TRACKED_OBJECT_UP
Save Password: Disallowed
Current EzVPN Peer: 10.3.0.2
```

Because a virtual interface, or for that matter any interface, is routable, routes act like traffic selectors. When the Easy VPN tunnel is “down,” there are no routes pointing to the virtual interface, as shown in the following example:

```
Router# show ip route
```

```
Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
 D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
 N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
 E1 - OSPF external type 1, E2 - OSPF external type 2
 i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
 ia - IS-IS inter area, * - candidate default, U - per-user static route
 o - ODR, P - periodic downloaded static route
```

```
Gateway of last resort is 10.2.0.2 to network 0.0.0.0
```

```
10.0.0.0/24 is subnetted, 2 subnets
C 10.2.0.0 is directly connected, Ethernet1/0
C 10.1.0.0 is directly connected, Ethernet0/0
S* 0.0.0.0/0 [2/0] via 10.2.0.2
```

## When the Tunnel Is Up

In the case of client or network plus mode, Easy VPN creates a loopback interface and assigns the address that is pushed in mode configuration. To assign the address of the loopback to the interface, use the **ip unnumbered** command (**ip unnumbered loopback**). In the case of network extension mode, the virtual access will be configured as **ip unnumbered ethernet0** (the bound interface).

```
Router# show running-config interface virtual-access 2
```

```
Building configuration...
```

```
Current configuration : 138 bytes
```

```
!
interface Virtual-Access2
 ip unnumbered Loopback0
 tunnel source Ethernet1/0
 tunnel destination 10.3.0.2
 tunnel mode ipsec ipv4
end
```

```
Router# show crypto ipsec client ezvpn
```

```
Easy VPN Remote Phase: 5
```

```
Tunnel name : ez
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access2 (bound to Ethernet1/0)
Current State: IPSEC_ACTIVE
Last Event: SOCKET_UP
Address: 10.5.0.2
Mask: 255.255.255.255
DNS Primary: 10.6.0.2
NBMS/WINS Primary: 10.7.0.1
Default Domain: cisco.com
Using PFS Group: 2
Save Password: Disallowed
Split Tunnel List: 1
 Address : 10.4.0.0
 Mask : 255.255.255.0
 Protocol : 0x0
 Source Port : 0
 Dest Port : 0
Current EzVPN Peer: 10.3.0.2
```

When the tunnels come up, Easy VPN adds either a default route that points to the virtual-access interface or adds routes for all the split attributes of the subnets that point to the virtual-access interface. Easy VPN also adds a route to the peer (destination or concentrator) if the peer is not directly connected to the Easy VPN device.

The following **show ip route** command output examples are for virtual IPsec interface situations in which a split tunnel attribute was sent by the server and a split tunnel attribute was not sent, respectively.

### Split Tunnel Attribute Has Been Sent by the Server

```
Router# show ip route
```

```
Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
 D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
 N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
 E1 - OSPF external type 1, E2 - OSPF external type 2
 i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
 ia - IS-IS inter area, * - candidate default, U - per-user static route
```

```

o - ODR, P - periodic downloaded static route

Gateway of last resort is 10.2.0.2 to network 0.0.0.0

10.0.0.0/8 is variably subnetted, 5 subnets, 2 masks
C 10.2.0.0/24 is directly connected, Ethernet1/0
S 10.3.0.2/32 [1/0] via 10.2.0.2, Ethernet1/0 <<< Route to
peer (EzVPN server)
C 10.1.0.0/24 is directly connected, Ethernet0/0
C 10.5.0.2/32 is directly connected, Loopback0
S 10.4.0.0/24 [1/0] via 0.0.0.0, Virtual-Access2 <<< Split
tunnel attr sent by the server
S* 10.0.0.0/0 [2/0] via 10.2.0.2

```

### Split Tunnel Attribute Has Not Been Sent by the Server

All networks in the split attribute should be shown, as in the following example:

Router# **show ip route**

```

Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
 D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
 N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
 E1 - OSPF external type 1, E2 - OSPF external type 2
 i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
 ia - IS-IS inter area, * - candidate default, U - per-user static route
 o - ODR, P - periodic downloaded static route

```

```

Gateway of last resort is 0.0.0.0 to network 0.0.0.0

10.0.0.0/8 is variably subnetted, 4 subnets, 2 masks
C 10.2.0.0/24 is directly connected, Ethernet1/0
! The following line is the route to the peer (the Easy VPN server).
S 10.3.0.2/32 [1/0] via 10.2.0.2, Ethernet1/0
C 10.1.0.0/24 is directly connected, Ethernet0/0
C 10.5.0.3/32 is directly connected, Loopback0
! The following line is the default route.
S* 10.0.0.0/0 [1/0] via 10.0.0.0, Virtual-Access2

```

## Dual Tunnel Configuration: Example

The following is an example of a typical dual-tunnel configuration:

```

version 12.4

!
end

```

## Dual Tunnel Show Output: Examples

The following **show** command examples display information about three phases of a dual tunnel that is coming up:

- First Easy VPN tunnel is up
- Second Easy VPN tunnel is initiated
- Both of the Easy VPN tunnels are up

### Before the EzVPN Tunnels Are Up

Router# **show crypto ipsec client ezvpn**

Easy VPN Remote Phase: 6

```

Tunnel name : ezvpn1
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access2 (bound to Ethernet1/0)
Current State: CONNECT_REQUIRED
Last Event: TRACKED OBJECT UP
Save Password: Disallowed
Current EzVPN Peer: 10.75.1.2

```

```

Tunnel name : ezvpn2
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access3 (bound to Serial2/0)
Current State: CONNECT_REQUIRED
Last Event: TRACKED OBJECT UP
Save Password: Disallowed
Current EzVPN Peer: 10.75.2.2

```

Router# **show ip route**

```

Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
 D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
 N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
 E1 - OSPF external type 1, E2 - OSPF external type 2
 i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
 ia - IS-IS inter area, * - candidate default, U - per-user static route
 o - ODR, P - periodic downloaded static route

```

The gateway of last resort is 10.76.1.1 to network 0.0.0.0.

```

10.0.0.0/24 is subnetted, 2 subnets
C 10.76.2.0 is directly connected, Serial2/0
C 10.76.1.0 is directly connected, Ethernet1/0
C 192.168.1.0/24 is directly connected, Ethernet0/0
S* 0.0.0.0/0 [2/0] via 10.76.1.1

```

#### Note

The metric of the default route should be greater than 1 so that the default route that is added later by Easy VPN takes precedence and the traffic goes through the Easy VPN virtual-access interface.

**Easy VPN “ezvpn2” Tunnel Is Up**

```
Router# show crypto ipsec client ezvpn
```

```
Easy VPN Remote Phase: 6
```

```
Tunnel name : ezvpn1
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access2 (bound to Ethernet1/0)
Current State: CONNECT_REQUIRED
Last Event: TRACKED_OBJECT_UP
Save Password: Disallowed
Current EzVPN Peer: 10.75.1.2
```

```
Tunnel name : ezvpn2
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access3 (bound to Serial2/0)
Current State: IPSEC_ACTIVE
Last Event: SOCKET_UP
DNS Ezvpn1: 10.6.0.2
NBMS/WINS Ezvpn1: 10.7.0.1
Default Domain: cisco.com
Save Password: Disallowed
Current EzVPN Peer: 10.75.2.2
```

```
Router# show ip route
```

```
Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
 D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
 N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
 E1 - OSPF external type 1, E2 - OSPF external type 2
 i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
 ia - IS-IS inter area, * - candidate default, U - per-user static route
 o - ODR, P - periodic downloaded static route
```

The gateway of last resort is 0.0.0.0 to network 0.0.0.0.

```
10.0.0.0/8 is variably subnetted, 3 subnets, 2 masks
! The next line is the Easy VPN route.
S 10.75.2.2/32 [1/0] via 10.76.1.1
C 10.76.2.0/24 is directly connected, Serial2/0
C 10.76.1.0/24 is directly connected, Ethernet1/0
C 192.168.1.0/24 is directly connected, Ethernet0/0
! The next line is the Easy VPN route.
S* 0.0.0.0/0 [1/0] via 0.0.0.0, Virtual-Access3
```

One default route and one route to the peer is added as shown above.

**Easy VPN “ezvpn2” Is Up and Easy VPN “ezvpn1” Is Initiated**

```
Router# crypto ipsec client ezvpn connect ezvpn1
```

```
Router# show crypto ipsec client ezvpn
```

```
Easy VPN Remote Phase: 6
```

```
Tunnel name : ezvpn1
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access2 (bound to Ethernet1/0)
Current State: READY
```

```
Last Event: CONNECT
Save Password: Disallowed
Current EzVPN Peer: 10.75.1.2
```

```
Tunnel name : ezvpn2
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access3 (bound to Serial2/0)
Current State: IPSEC_ACTIVE
Last Event: SOCKET_UP
DNS Ezvpn1: 10.6.0.2
NBMS/WINS Ezvpn1: 10.7.0.1
Default Domain: cisco.com
Save Password: Disallowed
Current EzVPN Peer: 10.75.2.2
```

Router# **show ip route**

```
Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
 D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
 N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
 E1 - OSPF external type 1, E2 - OSPF external type 2
 i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
 ia - IS-IS inter area, * - candidate default, U - per-user static route
 o - ODR, P - periodic downloaded static route
```

The gateway of last resort is 10.0.0.0 to network 10.0.0.0.

```
10.0.0.0/8 is variably subnetted, 4 subnets, 2 masks
S 10.75.2.2/32 [1/0] via 10.76.1.1
! The next line is the Easy VPN router.
S 10.75.1.2/32 [1/0] via 10.76.1.1
C 10.76.2.0/24 is directly connected, Serial2/0
C 10.76.1.0/24 is directly connected, Ethernet1/0
C 192.168.1.0/24 is directly connected, Ethernet0/0
S* 10.0.0.0/0 [1/0] via 10.0.0.0, Virtual-Access3
```

The route to 10.75.1.2 is added before the Easy VPN “ezvpn1” tunnel has come up. This route is for reaching the Easy VPN “ezvpn1” peer 10.75.1.2.

### Both Tunnels Are Up

Router# **show crypto ipsec client ezvpn**

```
Easy VPN Remote Phase: 6

Tunnel name : ezvpn1
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access2 (bound to Ethernet1/0)
Current State: IPSEC_ACTIVE
Last Event: SOCKET_UP
DNS Ezvpn1: 10.6.0.2
NBMS/WINS Ezvpn1: 10.7.0.1
Default Domain: cisco.com
Save Password: Disallowed
Split Tunnel List: 1
 Address : 192.168.3.0
 Mask : 255.255.255.255

```

## cTCP on an Easy VPN Client (Remote Device): Examples

For configuration and troubleshooting examples, see the topic “cTCP on Cisco Easy VPN remote devices” in the [“Related Documents” section on page 102](#).

## Easy VPN Server Configuration Examples

This section describes basic Cisco Easy VPN server configurations that support the Cisco Easy VPN remote configurations given in the previous sections. For complete information on configuring these servers, see [Easy VPN Server](#) for Cisco IOS Release 12.3(7)T, available on Cisco.com.

- [Cisco Easy VPN Server Without Split Tunneling: Example, page 97](#)
- [Cisco Easy VPN Server Configuration with Split Tunneling: Example, page 98](#)
- [Cisco Easy VPN Server Configuration with Xauth: Example, page 100](#)
- [Easy VPN Server Interoperability Support: Example, page 102](#)

## Cisco Easy VPN Server Without Split Tunneling: Example

The following example shows the Cisco Easy VPN server that is the destination peer router for the Cisco Easy VPN remote network extension mode configurations shown earlier in this section. In addition to the other IPsec configuration commands, the **crypto isakmp client configuration group** command defines the attributes for the VPN group that was assigned to the Easy VPN remote router. This includes a matching key value (easy vpn remote password), and the appropriate routing parameters, such as DNS server, for the Easy VPN remotes.

To support the network extension mode of operation, the **ip route** command instructs that incoming packets for the 172.168.0.0 network be directed from the cable modem interface to the Cisco Easy VPN remote. Other **ip route** commands might be needed, depending on the topology of your network.

### Note

This example shows a Cisco uBR925 cable access router, but typically the destination Easy VPN remote is a router, such as a Cisco VPN 3000 concentrator or a Cisco IOS router, that supports the Easy VPN Server feature.

## Cisco Easy VPN Server Configuration with Split Tunneling: Example

The following example shows a Cisco Easy VPN server that is configured for a split tunneling configuration with a Cisco Easy VPN remote. This example is identical to that shown in the “[Cisco Easy VPN Server Without Split Tunneling: Example](#)” except for access list 150, which is assigned as part of the **crypto isakmp client configuration group** command. This access list allows the Cisco Easy VPN remote to use the server to access one additional subnet that is not part of the VPN tunnel without compromising the security of the IPsec connection.

To support network extension mode, the **ip route** command instructs that incoming packets for the 172.168.0.0 network be directed from the cable modem interface to the Cisco Easy VPN remote. Other **ip route** commands might be necessary, depending on the topology of your network.

### Note

This example shows a Cisco uBR925 cable access router, but typically the destination Easy VPN remote will be a router, such as a VPN 3000 concentrator or a Cisco IOS router, that supports the Easy VPN Server feature.

```

## Cisco Easy VPN Server Configuration with Xauth: Example

The following example shows a Cisco Easy VPN server configured to support Xauth with the Cisco Easy VPN Remote feature. This example is identical to that shown in the “[Cisco Easy VPN Server Configuration with Split Tunneling: Example](#)” except for the following commands that enable and configure Xauth:

- **aaa authentication login userlist local**—Specifies the local username database for authentication at login time. You could also specify the use of RADIUS servers by first using the **aaa authentication login userlist group radius** command and then by specifying the RADIUS servers using the **aaa group server radius** command.
- **crypto isakmp xauth timeout**—Specifies the amount of time, in seconds, that the user has to enter the appropriate username and password to authenticate the session.
- **crypto map dynmap client authentication list userlist**—Creates a crypto map named “**dynmap**” that enables Xauth.
- **username cisco password 7 cisco**—Creates an entry in the local username database for a user with the username of “**cisco**” and an encrypted password of “**cisco**.” This command should be repeated for each separate user that accesses the server.

The following commands, which are also present in the non-Xauth configurations, are also required for Xauth use:

- **aaa authorization network easy vpn remote-groupname local**—Requires authorization for all network-related service requests for users in the group named “**easy vpn remote-groupname**” using the local username database.
- **aaa new-model**—Specifies that the router should use the new AAA authentication commands.
- **aaa session-id common**—Specifies that a unique and common session ID should be used for AAA sessions.
- **crypto map dynmap 1 ipsec-isakmp dynamic dynmap**—Specifies that IKE should be used to establish the IPsec SAs, using the crypt map named “**dynmap**” as the policy template.
- **crypto map dynmap client configuration address respond**—Enables IKE negotiation, accepting requests from any requesting peers.
- **crypto map dynmap isakmp authorization list easy vpn remote-groupname**—Configures the crypto map named “**dynmap**” to use IKE Shared Secret using the group named “**easy vpn remote-groupname**.”

### Tip

This configuration shows the server configured for split tunneling, but Xauth can also be used with nonsplit tunnel configurations as well.

**Note**

This example shows a Cisco uBR925 cable access router, but typically the destination Easy VPN server is a router such as a VPN 3000 concentrator or a Cisco IOS router that supports the Easy VPN Server feature.

- **type echo protocol ipIcmpEcho**
- **xauth userid mode**

# Feature Information for Easy VPN Remote

Table 4 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Cisco IOS software images are specific to a Cisco IOS software release, a feature set, and a platform. Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

## Note

Table 4 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 4** Feature Information for Easy VPN Remote

| Feature Name    | Releases                                 | Feature Information                                                                                                                                                                                                                                                                                                                                                               |

# Glossary

**AAA**—authentication, authorization, and accounting. Framework of security services that provide the method for identifying users (authentication); for remote access control (authorization); and for collecting and sending security server information used for billing, auditing, and reporting (accounting).

**aggressive mode**—Mode that eliminates several steps during Internet Key Exchange (IKE) authentication negotiation between two or more IPsec peers. Aggressive mode is faster than main mode but is not as secure.

**authorization**—Method for remote access control, including one-time authorization or authorization for each service; per-user account list and profile; user group support; and support of IP, IPX, ARA, and Telnet. AAA authorization works by assembling a set of attributes that describe what the user is authorized to perform. These attributes are compared to the information contained in a database for a given user and the result is returned to AAA to determine the actual capabilities and restrictions of the user. The database can be located locally on the access server or router, or it can be hosted remotely on a RADIUS or TACACS+ security server. Remote security servers, such as RADIUS and TACACS+, authorize users for specific rights by associating attribute-value (AV) pairs, which define those rights, with the appropriate user. All authorization methods must be defined through AAA.

**CA**—certificate authority. An entity in a network that issues and manages security credentials and public keys (in the form of X509v3 certificates) for message encryption. As part of a public key infrastructure (PKI), a CA checks with a registration authority (RA) to verify information provided by the requestor of a digital certificate. If the RA verifies the information of the requestor, the CA can then issue a certificate. Certificates generally include the public key of the owner, the expiration date of the certificate, the name of the owner, and other information about the public key owner.

**CRWS**—Cisco Router Web Setup Tool. Tool that provides web interface capabilities.

**cTCP**—Cisco Tunneling Control Protocol. When cTCP is enabled on a remote device (client) and headend device, IKE and ESP (Protocol 50) traffic is encapsulated in the TCP header so that the firewalls in between the client and the headend device permits this traffic (considering it the same as TCP traffic).

**DPD**—dead peer detection. Queries the liveliness of the Internet Key Exchange (IKE) peer of a router at regular intervals.

**DSLAM**—digital subscriber line access multiplexer. A device that connects many digital subscriber lines to a network by multiplexing the DSL traffic onto one or more network trunk lines.

**IKE**—Internet Key Exchange. Key management protocol standard that is used in conjunction with the IP Security (IPsec) standard. IPsec is an IP security feature that provides robust authentication and encryption of IP packets. IPsec can be configured without IKE, but IKE enhances IPsec by providing additional features, flexibility, and ease of configuration for the IPsec standard. IKE is a hybrid protocol that implements the Oakley key exchange and Skeme key exchange inside the Internet Security Association and Key Management Protocol (ISAKMP) framework. ISAKMP, Oakley, and Skeme are security protocols implemented by IKE.

**IPsec**—IP Security Protocol. Framework of open standards that provides data confidentiality, data integrity, and data authentication between participating peers. IPsec provides these security services at the IP layer. IPsec uses IKE to handle negotiation of protocols and algorithms based on local policy and to generate the encryption and authentication keys to be used by IPsec. IPsec can be used to protect one or more data flows between a pair of hosts, between a pair of security gateways, or between a security gateway and a host.

**main mode**—Mode that ensures the highest level of security when two or more IPsec peers are negotiating IKE authentication. It requires more processing time than aggressive mode.

**MIB**—Management Information Base. Database of network management information that is used and maintained by a network management protocol, such as Simple Network Management Protocol (SNMP) or Common Management Information Protocol (CMIP). The value of a MIB object can be changed or retrieved using SNMP or CMIP commands, usually through a graphical user interface (GUI) network management system (NMS). MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

**peer**—Router or device that participates as an endpoint in IPsec and IKE.

**preshared key**—Shared, secret key that uses IKE for authentication.

**QoS**—quality of service. Capability of a network to provide better service to selected network traffic over various technologies, including Frame Relay; Asynchronous Transfer Mode (ATM); Ethernet; and 802.1 networks, SONET, and IP-routed networks that may use any or all of these underlying technologies.

**RADIUS**—Remote Authentication Dial-In User Service. Distributed client or server system that secures networks against unauthorized access. RADIUS clients run on Cisco routers and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.

**SA**—security association. Instance of security policy and keying material applied to a data flow. Both IKE and IPsec use SAs, although SAs are independent of one another. IPsec SAs are unidirectional, and they are unique in each security protocol. An IKE SA is used by IKE only, and unlike the IPsec SA, it is bi-directional. IKE negotiates and establishes SAs on behalf of IPsec. A user can also establish IPsec SAs manually.

A set of SAs are needed for a protected data pipe, one per direction per protocol. For example, if you have a pipe that supports encapsulating security payload (ESP) between peers, one ESP SA is required for each direction. SAs are uniquely identified by destination (IPsec endpoint) address, security protocol (AH or ESP), and security parameter index (SPI).

**SDM**—Security Device Manager. Web interface manager that enables you to connect or disconnect a VPN tunnel and that provides a web interface for extended authentication (Xauth).

**SNMP**—Simple Network Management Protocol. Application-layer protocol that provides a message format for communication between SNMP managers and agents.

**trap**—Message sent by an SNMP agent to a network management system, console, or terminal to indicate the occurrence of a significant event, such as a specifically defined condition or a threshold that was reached.

**VPN**—virtual private network. Enables IP traffic to travel securely over a public TCP/IP network by encrypting all traffic from one network to another. A VPN uses tunnels to encrypt all information at the IP level.

# Easy VPN Remote RSA Signature Support

---

**First Published: March 1, 2004**

**Last Updated: August 21, 2007**

The Easy VPN Remote RSA Signature Support feature provides for the support of Rivest, Shamir, and Adelman (RSA) signatures on Easy VPN remote devices. The support is provided through RSA certificates that can be stored on or off the remote device.

## Finding Feature Information in This Module

*Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for Easy VPN Remote RSA Signature Support](#)” section on page 6.*

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Contents

- [Prerequisites for Easy VPN Remote RSA Signature Support, page 1](#)
- [Restrictions for Easy VPN Remote RSA Signature Support, page 2](#)
- [Information About Easy VPN Remote RSA Signature Support, page 2](#)
- [How to Configure Easy VPN Remote RSA Signature Support, page 2](#)
- [Additional References, page 3](#)

## Prerequisites for Easy VPN Remote RSA Signature Support

- You must have a Cisco Virtual Private Network (VPN) remote device and be familiar with configuring the device.

---

**Americas Headquarters:**

**Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA**

© 2007 Cisco Systems, Inc. All rights reserved.

- You must have a certification authority (CA) available to your network before you configure this interoperability feature. The CA must support the public key infrastructure (PKI) protocol of Cisco Systems, which is the Simple Certificate Enrollment Protocol (SCEP) (formerly called certificate enrollment protocol [CEP]).
- You should be familiar with IP Security (IPSec) and PKI.
- You should be familiar with configuring RSA key pairs.
- You should be familiar with configuring CAs.

## Restrictions for Easy VPN Remote RSA Signature Support

- This feature should be configured only when you also configure both IPSec and Internet Key Exchange (IKE) in your network.
- The Cisco IOS software does not support CA server public keys greater than 2048 bits.

## Information About Easy VPN Remote RSA Signature Support

To configure the Easy VPN Remote RSA Signature Support feature, you should understand the following concept:

- [Easy VPN Remote RSA Signature Support Overview, page 2](#)

## Easy VPN Remote RSA Signature Support Overview

The Easy VPN Remote RSA Signature Support feature allows you to configure RSA signatures on your Easy VPN remote device. The signatures can be stored on or off your remote device.

## How to Configure Easy VPN Remote RSA Signature Support

This section contains the following procedure:

- [Configuring Easy VPN Remote RSA Signature Support, page 2](#)

## Configuring Easy VPN Remote RSA Signature Support

The RSA signatures for an Easy VPN remote device are configured the same way that you would configure RSA signatures for any other Cisco device. (For information about configuring RSA signatures, refer to the “Configuring Certification Authority Interoperability” chapter of the “IP Security and Encryption” section of the *Cisco IOS Security Configuration Guide*, Release 12.4.)

To enable the RSA signatures, when you are configuring the Easy VPN remote and assigning the configuration to the outgoing interface, you must omit the **group** command. The content of the first Organizational Unit (OU) field will be used as the group. (For information about configuring Cisco Easy VPN remote devices, refer to the feature document “[Cisco Easy VPN Remote](#),” Release 12.4(11)T.)

To troubleshoot your Easy VPN remote RSA signature configuration, you can use the following **debug** commands. The **debug** commands can be used in any order or individually.

## SUMMARY STEPS

1. `enable`
2. `debug crypto ipsec client ezvpn`
3. `debug crypto isakmp`

## DETAILED STEPS

|        | Command or Action                                                                                                           | Purpose                                                                                                          |
|--------|-----------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <code>enable</code><br><br><b>Example:</b><br>Router> <code>enable</code>                                                   | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul> |
| Step 2 | <code>debug crypto ipsec client ezvpn</code><br><br><b>Example:</b><br>Router# <code>debug crypto ipsec client ezvpn</code> | Displays information about the VPN tunnel as it relates to the Easy VPN remote configuration.                    |
| Step 3 | <code>debug crypto isakmp</code><br><br><b>Example:</b><br>Router# <code>debug crypto isakmp</code>                         | Displays messages about IKE events.                                                                              |

# Feature Information for Easy VPN Remote RSA Signature Support

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1** Feature Information for Easy VPN Remote RSA Signature Support

| Feature Name                            | Releases                                | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

# Easy VPN Server

---

**First Published: February 25, 2002**

**Last Updated: November 4, 2008**

The Easy VPN Server feature introduces server support for the Cisco VPN Client Release 3.x and later software clients and Cisco VPN hardware clients (such as the Cisco 800, Cisco 900, Cisco 1700, VPN 3002, and PIX 501 devices). This feature allows a remote end user to communicate using IP Security (IPsec) with any Cisco IOS Virtual Private Network (VPN) gateway. Centrally managed IPsec policies are “pushed” to the client device by the server, minimizing configuration by the end user.

## Finding Feature Information in This Module

*Your Cisco IOS software release may not support all of the features documented in this module.* To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for Easy VPN Server](#)” section on [page 75](#).

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

# Restrictions for Easy VPN Server

## Nonsupported Protocols

Table 1 outlines IPsec protocol options and attributes that currently are *not* supported by Cisco VPN clients, so these options and attributes should not be configured on the router for these clients.

**Table 1** *Nonsupported IPsec Protocol Options and Attributes*

| Options                     | Attributes                                                                    |
|-----------------------------|-------------------------------------------------------------------------------|
| Authentication Types        | Authentication with public key encryption<br>Digital Signature Standard (DSS) |
| Diffie-Hellman (D-H) groups | 1                                                                             |
| IPsec Protocol Identifier   | IPSEC_AH                                                                      |
| IPsec Protocol Mode         | Transport mode                                                                |
| Miscellaneous               | Manual keys<br>Perfect Forward Secrecy (PFS)                                  |

## Cisco Secure VPN Client 1.x Restrictions

When used with this feature, the Cisco Secure VPN Client 1.x has the following restrictions:

- It does not support dead peer detection (DPD) or any other keepalive scheme.
- It does not support initial contact.

This feature cannot use per-group attribute policy profiles such as IP addresses, and Domain Name Service (DNS). Thus, customers must continue to use existing, globally defined parameters for IP address assignment, Windows Internet Naming Service (WINS) and DNS, and preshared keys.

## Multicast and Static NAT

Multicast and static NAT are supported only for Easy VPN servers using dynamic virtual tunnel interfaces (DVTIs).

## Virtual IPsec Interface Restrictions

The Virtual IPsec Interface Support feature works only with a Cisco software VPN Client that is version 4.x or later, and an Easy VPN remote device that is configured to use a virtual interface.

## cTCP Restrictions

- If a port is being used for Cisco Tunnel Control Protocol (cTCP), it cannot be used for other applications.
- cTCP can be used on only ten ports at a time.
- cTCP is supported on only Cisco IOS Easy VPN servers.
- If a cTCP connection is set up on a port, cTCP cannot be disabled on that port because doing so would cause the existing connection to stop receiving traffic.
- High Availability of cTCP is not currently supported on the Easy VPN server.

# Information About Easy VPN Server

Before using the Easy VPN Server Enhancements feature, you should understand the following concepts:

- [How It Works, page 3](#)
- [RADIUS Support for Group Profiles, page 4](#)
- [RADIUS Support for User Profiles, page 7](#)
- [Supported Protocols, page 8](#)
- [Functions Supported by Easy VPN Server, page 9](#)

## How It Works

When the client initiates a connection with a Cisco IOS VPN device, the “conversation” that occurs between the peers consists of device authentication via Internet Key Exchange (IKE), followed by user authentication using IKE Extended Authentication (Xauth), VPN policy push (using Mode Configuration), and IPsec security association (SA) creation. An overview of this process is as follows:

- The client initiates IKE Phase 1 via aggressive mode (AM) if a preshared key is to be used for authentication; the client initiates main mode (MM) if digital certificates are used. If the client identifies itself with a preshared key, the accompanying group name entered in the configuration GUI (ID\_KEY\_ID) is used to identify the group profile associated with this client. If digital certificates are used, the organizational unit (OU) field of a distinguished name (DN) is used to identify the group profile.

**Note**

Because the client may be configured for preshared key authentication, which initiates IKE AM, it is recommended that the administrator change the identity of the Cisco IOS VPN device via the **crypto isakmp identity hostname** command. This will not affect certificate authentication via IKE MM.

- The client attempts to establish an IKE SA between its public IP address and the public IP address of the Cisco IOS VPN device. To reduce the amount of manual configuration on the client, every combination of encryption and hash algorithms, in addition to authentication methods and D-H group sizes, is proposed.
- Depending on its IKE policy configuration, the Cisco IOS VPN device will determine which proposal is acceptable to continue negotiating Phase 1.

**Tip**

IKE policy is global for the Cisco IOS VPN device and can consist of several proposals. In the case of multiple proposals, the Cisco IOS VPN device will use the first match, so you should always list your most secure policies first.

**Note**

Device authentication ends and user authentication begins at this point.

- After the IKE SA is successfully established, and if the Cisco IOS VPN device is configured for Xauth, the client waits for a “username/password” challenge and then responds to the challenge of the peer. The information that is entered is checked against authentication entities using

authentication, authorization, and accounting (AAA) protocols such as RADIUS and TACACS+. Token cards may also be used via AAA proxy. During Xauth, it is also possible for a user-specific attribute to be retrieved if the credentials of that user are validated via RADIUS.

**Note** VPN devices that are configured to handle remote clients should always be configured to enforce user authentication.

- If the Cisco IOS VPN device indicates that authentication was successful, the client requests further configuration parameters from the peer. The remaining system parameters (for example, IP address, DNS, and split tunnel attributes) are pushed to the client at this time using Mode Configuration.

**Note** The IP address pool and group preshared key (if Rivest, Shamir, and Adelman [RSA] signatures are not being used) are the only required parameter in a group profile, all other parameters are optional.

- After each client is assigned an internal IP address via Mode Configuration, it is important that the Cisco IOS VPN device knows how to route packets through the appropriate VPN tunnel. Reverse route injection (RRI) will ensure that a static route is created on the Cisco IOS VPN device for each client internal IP address.

**Note** It is recommended that you enable RRI on the crypto map (static or dynamic) for the support of VPN clients unless the crypto map is being applied to a Generic Routing Encapsulation (GRE) tunnel that is already being used to distribute routing information.

- After the configuration parameters have been successfully received by the client, IKE quick mode is initiated to negotiate IPsec SA establishment.
- After IPsec SAs are created, the connection is complete.

## RADIUS Support for Group Profiles

Group policy information is stored in a profile that can be defined locally in the router configuration or on a RADIUS server that is accessible by the Cisco IOS VPN device. If RADIUS is used, you must configure access to the server and allow the Cisco IOS VPN device to send requests to the server.

To define group policy attributes for RADIUS, you must do the following task on your RADIUS server:

- Define a user that has a name equal to the group name as defined in the client graphical user interface (GUI). For example, if users will be connecting to the Cisco IOS VPN device using the group name “sales,” you will need a user whose name is “sales.” The password for this user is “cisco,” which is a special identifier that is used by the router for RADIUS purposes. The username must then be made a member of a group in which the correct policy is defined. For simplicity, it is recommended that the group name be the same as the username.

## For a Cisco Secure Access Control Server

If you are using a Cisco Secure access control server (ACS), you may configure your remote access VPN group profiles on this server. To perform this task, you must ensure that Internet Engineering Task Force (IETF) RADIUS attributes are selected for group configuration as shown in [Figure 1](#). (This figure also

shows the compulsory attributes required for a remote access VPN group.) All values must be entered except the Tunnel-Password attribute, which is actually the preshared key for IKE purposes; if digital certificates are preferred, this attribute may be omitted.

**Figure 1** IETF RADIUS Attributes Selection for Group Configuration

The screenshot displays the Cisco Systems Group Setup web interface. On the left is a navigation menu with icons and labels for: User Setup, Group Setup (highlighted), Network Configuration, System Configuration, Interface Configuration, Administration Control, External User Databases, Reports and Activity, and Online Documentation. The main content area is titled "Group Setup" and contains a tabbed interface with three tabs: "Access Restrictions", "Enable Options", and "IP Address Assignment". The "Enable Options" tab is active, showing a sub-tabbed interface with "TACACS+", "IETF Radius" (selected), and "Cisco IOS/PIX Radius". Below these tabs is the "IETF RADIUS Attributes" section, which includes a list of attributes with checkboxes and input fields:

- ☒ [006] Service-Type: Outbound (dropdown)
- ☐ [027] Session-Timeout: 0 (text input)
- ☐ [028] Idle-Timeout: 0 (text input)
- ☒ [064] Tunnel-Type:
  - Tag 1: 1, Value: IP ESP (dropdown)
  - Tag 2: 2, Value: (dropdown)
- ☐ [065] Tunnel-Medium-Type:
  - Tag 1: 1, Value: (dropdown)
  - Tag 2: 2, Value: (dropdown)
- ☒ [069] Tunnel-Password:
  - Tag 1: 1, Value: cisco (text input)
  - Tag 2: 2, Value: (text input)

At the bottom of the form are three buttons: "Submit", "Submit + Restart", and "Cancel".

In addition to the compulsory attributes shown in [Figure 1](#), other values can be entered that represent the group policy that is pushed to the remote client via Mode Configuration. [Figure 2](#) shows an example of a group policy. All attributes are optional except the addr-pool, key-exchange=preshared-key, and key-exchange=ike attributes. The values of the attributes are the same as the setting that is used if the policy is defined locally on the router rather than in a RADIUS server. (These values are explained in the section [“Defining Group Policy Information for Mode Configuration Push”](#) later in this document.)

**Figure 2** CiscoSecure ACS Group Policy Setup

After the group profile is created, a user who is a member of the group should be added. (Remember that the username that is defined maps to the group name as defined on the remote client, and the password defined for the username in the RADIUS database must be “cisco.”) If digital certificates are the preferred method of IKE authentication, the username should reflect the OU field in the certificate presented by the remote client.

## For All Other RADIUS Servers

Ensure that your RADIUS server allows you to define attribute-value (AV) pairs. (For an example, see the section “[Configuring Cisco IOS for Easy VPN Server: Example](#)” later in this document).

**Note**

If digital certificates are used, the username defined in RADIUS must be equal to the OU field of the DN of the certificate of the client.

## RADIUS Support for User Profiles

Attributes may also be applied on a per-user basis. If you apply attributes on a per-user basis, you can override a group attribute value with an individual user attribute. The attributes are retrieved at the time that user authentication via Xauth occurs. The attributes are then combined with group attributes and applied during Mode Configuration.

User-based attributes are available only if RADIUS is being used for user authentication.

To define user policy attributes for RADIUS, you must do the following task on your RADIUS server:

- Define a user or add attributes to the existing profile of a user in your RADIUS database. The password for the user will be used during Xauth user authentication, or you may proxy to a third-party server, such as a token card server.

[Figure 3](#) shows how CiscoSecure ACS may be used for user authentication and for the assignment of a Framed-IP-Address attribute that may be pushed to the client. The presence of this attribute means that the local address pool defined for the group to which that user belongs will be overridden.

**Figure 3** CiscoSecure ACS User Profile Setup

## For All Other RADIUS Servers

Ensure that your RADIUS server allows you to define AV pairs. (For an example, see the [“Configuring Cisco IOS for Easy VPN Server: Example”](#) section later in this document.)

## Supported Protocols

[Table 2](#) outlines supported IPsec protocol options and attributes that can be configured for this feature. (See [Table 1](#) for nonsupported options and attributes.)

**Table 2** Supported IPsec Protocol Options and Attributes

| Options                   | Attributes                                                                                                                                                               |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Authentication Algorithms | <ul style="list-style-type: none"> <li>Hashed Message Authentication Codes with Message Digest 5 (HMAC-MD5)</li> <li>HMAC-Secure Hash Algorithm 1 (HMAC-SHA1)</li> </ul> |
| Authentication Types      | <ul style="list-style-type: none"> <li>Preshared keys</li> <li>RSA digital signatures</li> </ul>                                                                         |

**Table 2**      **Supported IPsec Protocol Options and Attributes (continued)**

| Options                       | Attributes                                                                                                                           |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| D-H groups                    | <ul style="list-style-type: none"> <li>• 2</li> <li>• 5</li> </ul>                                                                   |
| Encryption Algorithms (IKE)   | <ul style="list-style-type: none"> <li>• Data Encryption Standard (DES)</li> <li>• Triple Data Encryption Standard (3DES)</li> </ul> |
| Encryption Algorithms (IPsec) | <ul style="list-style-type: none"> <li>• DES</li> <li>• 3DES</li> <li>• NULL</li> </ul>                                              |
| IPsec Protocol Identifiers    | <ul style="list-style-type: none"> <li>• Encapsulating Security Payload (ESP)</li> <li>• IP LZS compression (IPCOMP-LZS)</li> </ul>  |
| IPsec Protocol Mode           | Tunnel mode                                                                                                                          |

## Mode Configuration Version 6 Support

Mode Configuration version 6 is now supported for more attributes (as described in an IETF draft submission).

## Xauth Version 6 Support

Cisco IOS has been enhanced to support version 6 of Xauth. Xauth for user authentication is based on an IETF draft submission.

## IKE DPD

The client implements a new keepalives scheme—IKE DPD.

DPD allows two IPsec peers to determine whether the other is still “alive” during the lifetime of a VPN connection. DPD is useful because a host may reboot, or the dialup link of a remote user may disconnect without notifying the peer that the VPN connection has gone away. When an IPsec host determines that a VPN connection no longer exists, the host can notify a user, attempt to switch to another IPsec host, or clean up valuable resources that were allocated for the peer that no longer exists.

A Cisco IOS VPN device can be configured to send and reply to DPD messages. DPD messages are sent if no other traffic is being passed through the VPN tunnel. If a configured amount of time has lapsed since the last inbound data was received, DPD will send a message (“DPD R-U-THERE”) the next time it sends outbound IPsec data to the peer. DPD messages are unidirectional and are automatically sent by Cisco VPN clients. DPD *must* be configured on the router *only* if the router wishes to send DPD messages to the VPN client to determine the health of the client.

## Split Tunneling Control

Remote clients can support split tunneling, which enables a client to have intranet and Internet access at the same time. If split tunneling is not configured, the client will direct all traffic through the tunnel, even traffic destined for the Internet.

## Initial Contact

If a client is suddenly disconnected, the gateway may not be notified. Consequently, removal of connection information (IKE and IPsec SAs) for that client will not immediately occur. Thus, if the client attempts to reconnect to the gateway again, the gateway will refuse the connection because the previous connection information is still valid.

To avoid such a scenario, a new capability called initial contact has been introduced; it is supported by all Cisco VPN products. If a client or router is connecting to another Cisco gateway for the first time, an initial contact message is sent that tells the receiver to ignore and delete any old connection information that has been maintained for that newly connecting peer. Initial contact ensures that connection attempts are not refused because of SA synchronization problems, which are often identified via invalid security parameter index (SPI) messages and which require devices to have their connections cleared.

## Group-Based Policy Control

Policy attributes such as IP addresses, DNS, and split tunnel access can be provided on a per-group or per-user basis.

## User-Based Policy Control

Attributes may also be applied on a per-user basis. You can override a group attribute value with an individual user attribute. The attributes are retrieved at the time that user authentication via Xauth occurs. They are then combined with group attributes and applied during Mode Configuration.

From Cisco IOS Release 12.3(4)T forward, attributes can be applied on a per-user basis after the user has been authenticated. These attributes can override any similar group attributes. User-based attributes are available only if RADIUS is used as the database.

### Framed-IP-Address

To select the Framed-IP-Address attribute for CiscoSecure for NT, do the following: Under the user profile, choose the “use this IP address” option under addressing and manually enter the address. (You should check the method of configuring a framed IP address with your own RADIUS server because this procedure will vary.)

**Note**

If a framed IP address is present, and there is also a local pool address configured for the group that the user belongs to, the framed IP address will override the local pool setting.

### DHCP Client Proxy

Easy VPN servers currently assign an IP address to a remote device using either a local pool that is configured on the router or the framed IP address attribute that is defined in RADIUS. Effective with Cisco IOS Release 12.4(9)T, the DHCP Client Proxy feature provides the option of configuring an Easy VPN server to obtain an IP address from a DHCP server. The IP address is pushed to the remote device using mode configuration.

**Note**

This feature does not include functionality for the DHCP server to push the DNS, WINS server, or domain name to the remote client.

To configure DHCP Client Proxy, see the section [“Configuring an Easy VPN Server to Obtain an IP Address from a DHCP Server.”](#)

#### Benefits of DHCP Client Proxy

- The functionality provided with this feature helps in the creation of DDNS (dynamic Domain Name System) entries when a DNS server exists in conjunction with the DHCP server.
- The user is not restricted to IP address pools.

### User-Save-Password

As per the group description, the User-Save-Password attribute can be received in addition to the group variant (Save-Password), but if it is received, it will override the value asserted by the group.

The following is an output example of a RADIUS AV pair for the User-Save-Password attribute:

```
ipsec:user-save-password=1
```

### User-Include-Local-LAN

As per the group description, the User-Include-Local-LAN attribute can be received in addition to the group variant (Include-Local-LAN), but if it is received, it will override the value asserted by the group.

The following is an output example of a RADIUS AV pair for the User-Include-Local LAN attribute:

```
ipsec:user-include-local-lan=1
```

## User-VPN-Group

The User-VPN-Group attribute is a replacement for the [Group-Lock](#) attribute. It allows support for both preshared key and RSA signature authentication mechanisms such as certificates.

If you need to check that the group a user is attempting to connect to is indeed the group the user belongs to, use the User-VPN-Group attribute. The administrator sets this attribute to a string, which is the group that the user belongs to. The group the user belongs to is matched against the VPN group as defined by group name (ID\_KEY\_ID) for preshared keys or by the OU field of a certificate. If the groups do not match, the client connection is terminated.

This feature works only with AAA RADIUS. Local Xauth authentication must still use the Group-Lock attribute.

The following is an output example of a RADIUS AV pair for the User-VPN-Group attribute:

```
ipsec:user-vpn-group=cisco
```

## Group-Lock

If you are only using pre-shared keys (no certificates or other RSA signature authentication mechanisms) with RADIUS or local AAA, you can continue to use the Group-Lock attribute. If you are only using pre-shared keys (no certificates or other RSA signature authentication mechanisms) with RADIUS, you can either continue to use the Group-Lock attribute or you can use the new [User-VPN-Group](#) attribute.

### Caution

Do not use the Group-Lock attribute if you are using RSA signature authentication mechanisms such as certificates. Use the [User-VPN-Group](#) attribute instead.

## Session Monitoring for VPN Group Access

It is possible to mimic the functionality provided by some RADIUS servers for limiting the maximum number of connections to a specific server group and also for limiting the number of simultaneous logins for users in that group. After user-defined thresholds are defined in each VPN group, connections will be denied until counts drop below these thresholds.

If you use a RADIUS server, such as CiscoSecure ACS, it is recommended that you enable this session control on the RADIUS server if the functionality is provided. In this way, usage can be controlled across a number of servers by one central repository. When enabling this feature on the router itself, only connections to groups on that specific device are monitored. Load-sharing scenarios are not accurately accounted for.

To configure session monitoring using command-line interface (CLI), use the **crypto isakmp client configuration group** command and the **max-users** and **max-logins** subcommands.

The following is an output example of RADIUS AV pairs that have been added to the relevant group:

```
ipsec:max-users=1000
ipsec:max-logins=1
```

## Virtual IPsec Interface Support on a Server

Virtual IPsec Interface Support on a Server allows you to selectively send traffic to different Easy VPN concentrators (servers) as well as to the Internet.

Before Cisco IOS Release 12.4(4)T, at the tunnel-up/tunnel-down transition, attributes that were pushed during the mode configuration had to be parsed and applied. When such attributes resulted in the configurations being applied on the interface, the existing configuration had to be overridden.

With the Virtual Ipsec Interface Support feature, the tunnel-up configuration can be applied to separate interfaces, making it easier to support separate features at tunnel-up. Features that are applied to the traffic going into the tunnel can be separate from the features that are applied to traffic that is not going through the tunnel (for example, split-tunnel traffic and traffic leaving the device when the tunnel is not up). When the Easy VPN negotiation is successful, the line protocol state of the virtual-access interface gets changed to up. When the Easy VPN tunnel goes down because the SA expires or is deleted, the line protocol state of the virtual-access interfaces changes to down.

**Note**

---

This feature does not support multicast.

---

For more information about this feature, see the document [Cisco Easy VPN Remote](#). (This feature is configured on the Easy VPN remote device.)

For information about the IPsec Virtual Tunnel Interface feature, see the document “IPSec Virtual Tunnel Interface” (link in the “[Related Documents](#)” section of this document).

## Virtual Tunnel Interface Per-User Attribute Support

Effective with Cisco IOS Release 12.4(9)T, Virtual Tunnel Interface provides per-user attribute support for Easy VPN servers.

For more information about this feature, see the document [IPsec Virtual Tunnel Interface](#).

## Banner, Auto-Update, and Browser Proxy

The following features provide support for attributes that aid in the management of the Cisco Easy VPN remote device.

### Banner

An Easy VPN server can be configured to push the banner to the Easy VPN remote device. A banner is needed for the web-based activation feature. The banner is displayed when the Easy VPN tunnel is up on the Easy VPN remote console or as a HTML page in the case of web-based activation.

### Auto-Update

An Easy VPN server can be configured to provide an automated mechanism for software and firmware upgrades on an Easy VPN remote device.

### Browser Proxy

An Easy VPN server can be configured so that an Easy VPN remote device can access resources on the corporate network. Using this feature, the user does not have to manually modify the proxy settings of his or her web browser when connecting to the corporate network using Cisco IOS VPN Client or manually revert the proxy settings upon disconnecting.

## Configuration Management Enhancements

### Pushing a Configuration URL Through a Mode-Configuration Exchange

When remote devices connect to a corporate gateway for creating an IPsec VPN tunnel, some policy and configuration information has to be applied to the remote device when the VPN tunnel is active to allow the remote device to become a part of the corporate VPN.

The Pushing a Configuration URL Through a Mode-Configuration Exchange feature provides for a mode-configuration attribute that “pushes” a URL from the concentrator (server) to the Cisco IOS Easy VPN remote device. The URL contains the configuration information that the remote device has to download and apply to the running configuration, and it contains the Cisco IOS CLI listing. (For more information about a Cisco IOS CLI listing, see Cisco IOS documentation for the **configuration url** command.) The CLI for this feature is configured on the concentrator.

The configuration that is pushed to the remote device is persistent by default. That is, the configuration is applied when the IPsec tunnel is “up,” but it is not withdrawn when the IPsec tunnel goes “down.” However, it is possible to write a section of configuration that is transient in nature, in which case the configuration of the section is reverted when the tunnel is disconnected.

There are no restrictions on where the configuration distribution server is physically located. However, it is recommended that a secure protocol such as HTTPS (Secure HTTP) be used to retrieve the configuration. The configuration server can be located in the corporate network, so because the transfer happens through the IPsec tunnel, insecure access protocols (HTTP) can be used.

Regarding backward compatibility: the remote device asks for the CONFIGURATION-URL and CONFIGURATION-VERSION attributes. Because the CONFIGURATION-URL and CONFIGURATION-VERSION attributes are not mandatory attributes, the server sends them only if it has them configured for the group. There is no built-in restriction to push the configuration, but bootstrap configurations (such as for the IP address) cannot be sent because those configurations are required to set up the Easy VPN tunnel, and the CONFIGURATION-URL comes into effect only after the Easy VPN tunnel comes up.

### After the Configuration Has Been Acquired by the Easy VPN Remote Device

After the configuration has been acquired by the Easy VPN remote device, the remote device sends a new ISAKMP notification to the Easy VPN server. The notification contains several manageability information messages about the client (remote device). The Easy VPN server takes two actions when this information is received:

- The Easy VPN server caches the information in its peer database. The information can be displayed by using the **show crypto isakmp peer config** command. This command output displays all manageability information that is sent by the client (remote device).
- If accounting is enabled, the Easy VPN server sends an accounting update record that contains the manageability information messages about the remote device to the accounting RADIUS server. This accounting update is later available in the accounting log of the RADIUS server.

### How to Configure This Feature

The commands that are used to configure this feature and the attributes CONFIGURATION-URL and CONFIGURATION-VERSION are described in the **crypto isakmp client configuration group** command documentation.

## Per User AAA Policy Download with PKI

With the Support of Per User AAA Policy Download with PKI feature, user attributes are obtained from the AAA server and pushed to the remote device through mode configuration. The username that is used to get the attributes is retrieved from the remote device certificate.

## Per-User Attribute Support for Easy VPN Servers

The Per-User Attribute Support for Easy VPN Servers feature provides users with the ability to support per-user attributes on Easy VPN servers. These attributes are applied on the virtual access interface.

### Local Easy VPN AAA Server

For a local Easy VPN AAA server, the per-user attributes can be applied at the group level or at the user level using the command-line interface (CLI).

To configure per-user attributes for a local Easy VPN server, see “[Configuring Per-User Attributes on a Local Easy VPN AAA Server](#).”

### Remote Easy VPN AAA Server

Attribute value (AV) pairs can be defined on a remote Easy VPN AAA server as shown in this example:

```
cisco-avpair = "ip:outacl#101=permit tcp any any established"
```

### Per-User Attributes

The following per-user attributes are currently defined in the AAA server and are applicable to IPsec:

- inacl
- interface-config
- outacl
- route
- rte-fltr-in
- rte-fltr-out
- sub-policy-In
- sub-policy-Out
- policy-route
- prefix

## Syslog Message Enhancements

Some new syslog messages have been added for Easy VPN in Cisco IOS Release 12.4(4)T. The syslog messages can be enabled on your server by using the command-line interface (CLI). The format of the syslog messages is as follows:

```
timestamp: %CRYPTO-6-VPN_TUNNEL_STATUS: (Server) <event message> User=<username>
Group=<groupname> Client_public_addr=<ip_addr> Server_public_addr=<ip addr>
```

For an authentication-passed event, the syslog message looks like the following:

```
Jul 25 23:33:06.847: %CRYPTO-6-VPN_TUNNEL_STATUS: (Server) Authentication PASS
ED User=blue Group=Cisco1760group Client_public_addr=10.20.20.1
Server_public_addr=10.20.20.2
```

Three of the messages (Max users, Max logins, and Group does not exist) are authorization issues and are printed only with the group name in the format. The reason for only the group name being printed is that authorization check happens much before mode configuration happens. Therefore, the peer information is not yet present and cannot be printed. The following is an example of a “Group does not exist” message.

```
*Jun 30 18:02:58.107: %CRYPTO-6-VPN_TUNNEL_STATUS: Group: group_1 does not exist
```

## Easy VPN Syslog Messages That Are Supported

Both ezvpn\_connection\_up and ezvpn\_connection\_down were already supported in a previous release of syslog messages. The enhancements in Cisco IOS Release 12.4(4)T follow the same format, but new syslogs are introduced. The added syslogs are as follows:

- Authentication Passed
- Authentication Rejected
  - Group Lock Enabled
  - Incorrect Username or Password
  - Max Users exceeded/Max Logins exceeded
  - No. of Retries exceeded
- Authentication Failed (AAA Not Contactable)
- IP Pool Not present/No Free IP Address available in the pool
- ACL associated with Ezvpn policy but NOT defined (hence, no split tunneling possible)
- Save password Turned ON
- Incorrect firewall record being sent by Client (incorrect vendor | product | capability)
- Authentication Rejected
  - Access restricted via incoming interface
  - Group does not exist

## Network Admission Control Support for Easy VPN

Network Admission Control was introduced in Cisco IOS Release 12.3(8)T as a way to determine whether a PC client should be allowed to connect to the LAN. Network Admission Control uses Extensible Authentication Protocol over UDP (EAPoUDP) to query the Cisco trust agent on the PC and allows a PC to access the network if the client status is healthy. Different policies can be applied on the server to deny or limit access of PCs that are infected.

Effective with Cisco IOS Release 12.4(4)T, Network Admission Control can now be used to monitor the status of remote PC clients as well. After the Easy VPN tunnel comes up and the PC starts to send traffic, the traffic is intercepted at the Easy VPN server, and the posture validation process starts. The posture validation process consists of sending an EAPoUDP request over the Easy VPN tunnel and querying the Cisco trust agent. The authentication server is configured inside the trusted network, behind the IPsec aggregator.

The configuration of an Easy VPN server that has Network Admission Control enabled is shown in the output in [Network Admission Control: Example, page 64](#).

## Central Policy Push Firewall Policy Push

The Easy VPN server supports Central Policy Push (CPP) Firewall Policy Push. This feature allows administrators to push policies that enforce security to the Cisco Easy VPN (software) Client and related firewall software.

A split tunnel enables access to corporate networks, but it also allows a remote device to be exposed to attacks from the Internet. This feature enables the server to determine whether to allow or deny a tunnel if the remote device does not have a required firewall, thereby reducing exposure to attacks.

The following firewall types are supported:

- Cisco-Integrated-firewall (central-policy-push)
- Cisco-Security-Agent (check-presence)
- Zonelabs-Zonealarm (both)
- Zonelabs-ZonealarmPro (both)

The server can be used either to check the presence of a firewall on the client (remote device) using the check-presence option or to specify the specifics of the firewall policies that must be applied by the client using the central-policy-push.

### Note

The **policy check-presence** command and keyword, which are used with this feature, replace the **firewall are-u-there** command functionality that was supported before Cisco IOS Release 12.4(6)T. The **firewall are-u-there** command will continue to be supported for backward compatibility.

To enable this feature, see the sections “[Defining a CPP Firewall Policy Push Using a Local AAA Server](#)” and “[Applying a CPP Firewall Policy Push to the Configuration Group](#).”

## Syslog Support for CPP Firewall Policy Push

Syslog support can be enabled using the **crypto logging ezvpn** command on your router. CPP syslog messages will be printed for the following error conditions:

- If policy is configured on a group configuration (using the **firewall policy** command), but a global policy with the same name is not defined (using the **crypto isakmp client firewall** command). The syslog message is as follows:

Policy enabled on group configuration but not defined

Tunnel setup proceeds as normal (with the firewall).

- If an incorrect firewall request (vendor/product/cap incorrect order) is received, the syslog message is as follows:

Incorrect firewall record received from client

- If a policy mismatch occurs between the Cisco VPN Client and the server, the syslog is as follows:

CPP policy mismatch between client and headend

## Password Aging

Prior to Cisco IOS Release 12.4(6)T, EasyVPN remote devices (clients) sent username and password values to the Easy VPN server, which in turn sent them to the AAA subsystem. The AAA subsystem generated an authentication request to the RADIUS server. If the password had expired, the RADIUS

server replied with an authentication failure. The reason for the failure was not passed back to the AAA subsystem. The user was denied access due to authentication failure, but he or she did not know that the failure was due to password expiration.

Effective with Cisco IOS Release 12.4(6)T, if you have configured the Password Aging feature, the EasyVPN client is notified when a password has expired, and you are prompted to enter a new password. To configure the Password Aging feature, see the section “[Configuring Password Aging](#).”

For more information about Password Aging, see the reference for “Password Aging” in the section [Additional References](#) (subsection “Related Documents”).

## Split DNS

Effective with Cisco IOS Release 12.4(9)T, split DNS functionality is available on Easy VPN servers. This feature enables the Easy VPN hardware client to use primary and secondary DNS values to resolve DNS queries. These values are pushed by the Easy VPN server to the Easy VPN remote device. To configure this feature on your server, use the **split-dns** command (see the section “[Defining Group Policy Information for Mode Configuration Push](#)”). Configuring this command adds the split-dns attribute to the policy group. The attribute will include the list of domain names that you configured. All other names will be resolved using the public DNS server.

For more information about configuring split DNS, see “Configuring Split and Dynamic DNS on the Cisco VPN 3000” at the following URL:

[http://www.cisco.com/warp/public/471/dns\\_split\\_dynam.pdf](http://www.cisco.com/warp/public/471/dns_split_dynam.pdf)

## cTCP

The Cisco Tunneling Control Protocol (cTCP) feature can be used for situations in which an Easy VPN remote device is operating in an environment in which standard IPsec does not function or in which it does not function transparently without modification to existing firewall rules. These situations include the following:

- Small or home office router performing Network Address Translation (NAT) or Port Address Translation (PAT)
- PAT-provided IP address behind a larger router (for example, in a corporation)
- Non-NAT firewall (packet filtering or stateful)
- Proxy server

The firewall should be configured to allow the headend to accept cTCP connections on the configured cTCP port. This configuration is enabled on the Easy VPN server. If the firewall is not configured, it will not allow the cTCP traffic.

### Note

cTCP traffic is actually Transmission Control Protocol (TCP) traffic. cTCP packets are IKE or Encapsulating Security Payload (ESP) packets that are being transmitted over TCP.

## VRF Assignment by a AAA Server

To assign VRF to Easy VPN users, the following attributes should be enabled on a AAA server:

```
Cisco-avpair "ip:interface-config=ip vrf forwarding example1"
Cisco-avpair "ip:interface-config=ip unnumbered loopback10"
```

# How to Configure Easy VPN Server

This section includes the following procedures:

- [Enabling Policy Lookup via AAA, page 20](#) (required)
- [Defining Group Policy Information for Mode Configuration Push, page 21](#) (required)
- [Enabling VPN Session Monitoring, page 24](#) (optional)
- [Verifying a VPN Session, page 25](#) (optional)
- [Applying Mode Configuration and Xauth, page 26](#) (required)
- [Enabling Reverse Route Injection for the Client, page 27](#) (optional)
- [Enabling IKE Dead Peer Detection, page 28](#) (optional)
- [Configuring RADIUS Server Support, page 29](#) (optional)
- [Verifying Easy VPN Server, page 30](#) (optional)
- [Configuring a Banner, page 30](#) (optional)
- [Configuring Auto Upgrade, page 31](#) (optional)
- [Configuring Browser Proxy, page 32](#) (optional)
- [Configuring the Pushing of a Configuration URL Through a Mode-Configuration Exchange, page 33](#) (optional)
- [Configuring Per User AAA Download with PKI—Configuring the Crypto PKI Trustpoint, page 34](#) (optional)
- [Configuring the Actual Per User AAA Download with PKI, page 36](#) (optional)
- [Configuring Per-User Attributes on a Local Easy VPN AAA Server, page 38](#)

## Enabling Policy Lookup via AAA

To enable policy lookup via AAA, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa new-model**
4. **aaa authentication password-prompt** *text-string*
5. **aaa authentication username prompt** *text-string*
6. **aaa authentication login** [*list-name method1*] [*method2...*]
7. **aaa authorization network** *list-name* **local group radius**
8. **username** *name* **password** *encryption-type* *encrypted-password*

### DETAILED STEPS

|        | Command                                                                                                                                                               | Purpose                                                                                                             |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                        | Enters global configuration mode.                                                                                   |
| Step 3 | <b>aaa new-model</b><br><br><b>Example:</b><br>Router (config)# aaa new-model                                                                                         | Enables AAA.                                                                                                        |
| Step 4 | <b>aaa authentication password-prompt</b> <i>text-string</i><br><br><b>Example:</b><br>Router (config)# aaa authentication password-prompt "Enter your password now:" | (Optional) Changes the text displayed when users are prompted for a password.                                       |
| Step 5 | <b>aaa authentication username-prompt</b> <i>text-string</i><br><br><b>Example:</b><br>Router (config)# aaa authentication username-prompt "Enter your name here:"    | (Optional) Changes the text displayed when users are prompted to enter a username.                                  |

|        | Command                                                                                                                                                                               | Purpose                                                                                                                                                                                                                   |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 6 | <b>aaa authentication login</b> [ <i>list-name method1</i> ] [ <i>method2...</i> ]<br><br><b>Example:</b><br>Router (config)# aaa authentication login<br>userlist local group radius | Sets AAA authentication at login. <ul style="list-style-type: none"> <li>A local and RADIUS server may be used together and will be tried in order.</li> </ul> <b>Note</b> This command must be enabled to enforce Xauth. |
| Step 7 | <b>aaa authorization network</b> <i>list-name</i> <b>local group radius</b><br><br><b>Example:</b><br>Router (config)# aaa authorization<br>network group list local group radius     | Enables group policy lookup. <ul style="list-style-type: none"> <li>A local and RADIUS server may be used together and will be tried in order.</li> </ul>                                                                 |
| Step 8 | <b>username</b> <i>name</i> <b>password</b> <i>encryption-type encrypted-password</i><br><br><b>Example:</b><br>Router (config)# username server_r<br>password 7 121F0A18             | (Optional) Defines local users for Xauth if RADIUS or TACACS+ is not used.<br><br><b>Note</b> Use this command only if no external validation repository will be used.                                                    |

## Defining Group Policy Information for Mode Configuration Push

Although users can belong to only one group per connection, they may belong to specific groups with different policy requirements. Thus, users may decide to connect to the client using a different group ID by changing their client profile on the VPN device. To define the policy attributes that are pushed to the client via Mode Configuration, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp client configuration group** {*group-name* | **default**}
4. **key** *name*
5. **dns** *primary-server secondary-server*
6. **wins** *primary-server secondary-server*
7. **domain** *name*
8. **pool** *name*
9. **netmask** *name*
10. **acl** *number*
11. **access-restrict** {*interface-name*}
12. **policy check-presence**  
or  
**firewall are-u-there**
13. **group-lock**

14. `include-local-lan`
15. `save-password`
16. `backup-gateway`
17. `pfs`

## DETAILED STEPS

|        | Command                                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                            |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                               | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                   |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                       | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                  |
| Step 3 | <b>crypto isakmp client configuration group</b><br>{group-name   default}<br><br><b>Example:</b><br>Router (config)# crypto isakmp client configuration group group1 | Specifies the policy profile of the group that will be defined and enters Internet Security Association Key Management Protocol (ISAKMP) group configuration mode. <ul style="list-style-type: none"> <li>If no specific group matches and a default group is defined, users will automatically be given the policy of a default group.</li> </ul> |
| Step 4 | <b>key name</b><br><br><b>Example:</b><br>Router (config-isakmp-group)# key group1                                                                                   | Specifies the IKE preshared key for group policy attribute definition. <p><b>Note</b> This command <i>must</i> be enabled if the client identifies itself with a preshared key.</p>                                                                                                                                                                |
| Step 5 | <b>dns primary-server secondary-server</b><br><br><b>Example:</b><br>Router (config-isakmp-group)# dns 10.2.2.2 10.3.3.3                                             | (Optional) Specifies the primary and secondary DNS servers for the group.                                                                                                                                                                                                                                                                          |
| Step 6 | <b>wins primary-server secondary-server</b><br><br><b>Example:</b><br>Router (config-isakmp-group)# wins 10.10.10.10 10.12.12.12                                     | (Optional) Specifies the primary and secondary WINS servers for the group.                                                                                                                                                                                                                                                                         |
| Step 7 | <b>domain name</b><br><br><b>Example:</b><br>Router (config-isakmp-group)# domain domain.com                                                                         | (Optional) Specifies the DNS domain to which a group belongs.                                                                                                                                                                                                                                                                                      |

|         | Command                                                                                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 8  | <p><b>pool</b> <i>name</i></p> <p><b>Example:</b><br/>Router (config-isakmp-group)# pool green</p>                                                                                                                                  | <p>Defines a local pool address.</p> <ul style="list-style-type: none"> <li>Although a user must define at least one pool name, a separate pool may be defined for each group policy.</li> </ul> <p><b>Note</b> This command <i>must</i> be defined and refer to a valid IP local pool address or the client connection will fail.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Step 9  | <p><b>netmask</b> <i>name</i></p> <p><b>Example:</b><br/>Router (config-isakmp-group)# netmask 255.255.255.255</p>                                                                                                                  | <p>(Optional) Specifies that a subnet mask be downloaded to the client for local connectivity.</p> <p><b>Note</b> Some VPN clients use the default mask for their particular classes of address. However, for a router, the host-based mask is typically used (/32). If you want to override the default mask, use the <b>netmask</b> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Step 10 | <p><b>acl</b> <i>number</i></p> <p><b>Example:</b><br/>Router (config-isakmp-group)# acl 199</p>                                                                                                                                    | <p>(Optional) Configures split tunneling.</p> <ul style="list-style-type: none"> <li>The <i>number</i> argument specifies a group of access control list (ACL) rules that represent protected subnets for split tunneling purposes.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Step 11 | <p><b>access-restrict</b> {<i>interface-name</i>}</p> <p><b>Example:</b><br/>Router (config-isakmp-group)# access-restrict fastethernet0/0</p>                                                                                      | <p>Restricts clients in a group to an interface.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Step 12 | <p><b>policy check-presence</b></p> <p>or</p> <p><b>firewall are-u-there</b></p> <p><b>Example:</b><br/>Router (config-isakmp-group)# policy check-presence</p> <p>or</p> <p>Router (config-isakmp-group)# firewall are-u-there</p> | <p>(Optional) Denotes that the server should check for the presence of the specified firewall (as shown as the firewall type on the client).</p> <p>or</p> <p>Adds the firewall are-u-there attribute to the server group if your PC is running the Black Ice or Zone Alarm personal firewalls.</p> <p><b>Note</b> The <b>policy</b> command and <b>check-presence</b> keyword were added to Cisco IOS documentation in Cisco IOS 12.4(6)T. It is recommended that the <b>policy</b> command be used instead of the <b>firewall are-u-there</b> command because the <b>policy</b> command is supported in local AAA and remote AAA configurations. The <b>firewall are-u-there</b> command can be figured only locally, but it is still supported for backward compatibility.</p> |
| Step 13 | <p><b>group-lock</b></p> <p><b>Example:</b><br/>Router (config-isakmp-group)# group-lock</p>                                                                                                                                        | <p>Enforces the group lock feature.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Step 14 | <p><b>include-local-lan</b></p> <p><b>Example:</b><br/>Router (config-isakmp-group)# include-local-lan</p>                                                                                                                          | <p>(Optional) Configures the Include-Local-LAN attribute to allow a nonsplit-tunneling connection to access the local subnetwork at the same time as the client.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|         | Command                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------|-------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 15 | <b>save-password</b><br><br><b>Example:</b><br>Router (config-isakmp-group)#<br>save-password   | (Optional) Saves your Xauth password locally on your PC.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Step 16 | <b>backup-gateway</b><br><br><b>Example:</b><br>Router (config-isakmp-group)# backup<br>gateway | (Optional) Rather than have backup gateways added to client configurations manually, it is possible to have the server “push down” a list of backup gateways to the client device. <ul style="list-style-type: none"> <li>These gateways are tried in order in the case of a failure of the previous gateway. The gateways may be specified using IP addresses or host names.</li> </ul>                                                                                                        |
| Step 17 | <b>pfs</b><br><br><b>Example:</b><br>Router (config-isakmp-group)# pfs                          | (Optional) Notifies the client of the central-site policy regarding whether PFS is required for any IPsec SA. <ul style="list-style-type: none"> <li>Because the client device does not have a user interface option to enable or disable PFS negotiation, the server will notify the client device of the central site policy using this parameter. The Diffie-Hellman (D-H) group that is proposed for PFS will be the same that was negotiated in Phase 1 of the IKE negotiation.</li> </ul> |

## Enabling VPN Session Monitoring

If you wish to set restrictions on the maximum number of connections to the router per VPN group and the maximum number of simultaneous logins per user, add the following attributes to the VPN group.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp client configuration group *group-name***
4. **exit**
5. **max-logins *number-of-logins***
6. **max-users *number-of-users***

### DETAILED STEPS

|        | Command                                                | Purpose                                                                                                          |
|--------|--------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |

|        | Command                                                                                                                                                      | Purpose                                                                                                                                                                                                                                             |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                               | Enters global configuration mode.                                                                                                                                                                                                                   |
| Step 3 | <b>crypto isakmp client configuration group</b> <i>group-name</i><br><br><b>Example:</b><br>Router (config)# crypto isakmp client configuration group group1 | Specifies the policy profile of the group that will be defined and enters ISAKMP group configuration mode. <ul style="list-style-type: none"> <li><i>group-name</i>—Group definition that identifies which policy is enforced for users.</li> </ul> |
| Step 4 | <b>exit</b><br><br><b>Example:</b><br>Router (config-isakmp-group)# exit                                                                                     | Exits ISAKMP group configuration mode.                                                                                                                                                                                                              |
| Step 5 | <b>max-logins</b> <i>number-of-logins</i><br><br><b>Example:</b><br>Router (config-isakmp-group)# max-logins 10                                              | (Optional) Limits the number of simultaneous logins for users in a specific server group.                                                                                                                                                           |
| Step 6 | <b>max-users</b> <i>number-of-users</i><br><br><b>Example:</b><br>Router (config)# max-users 1000                                                            | (Optional) Limits the number of connections to a specific server group.                                                                                                                                                                             |

## Verifying a VPN Session

To verify a VPN session, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **show crypto session group**
3. **show crypto session summary**

### DETAILED STEPS

|        | Command                                                                                          | Purpose                                                                                                                |
|--------|--------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| Step 2 | <b>show crypto session group</b><br><br><b>Example:</b><br>Router# show crypto session group     | Displays groups that are currently active on the VPN device.                                                           |
| Step 3 | <b>show crypto session summary</b><br><br><b>Example:</b><br>Router# show crypto session summary | Displays groups that are currently active on the VPN device and the users that are connected for each of those groups. |

## Applying Mode Configuration and Xauth

Mode Configuration and Xauth must be applied to a crypto map to be enforced. To apply Mode Configuration and Xauth to a crypto map, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map tag client configuration address [initiate | respond]**
4. **crypto map map-name isakmp authorization list list-name**
5. **crypto map map-name client authentication list list-name**

### DETAILED STEPS

|        | Command                                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                           |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                  | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                                                                                                                                                                                               |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                          | Enters global configuration mode.                                                                                                                                                                                                                                                                                                 |
| Step 3 | <b>crypto map tag client configuration address [initiate   respond]</b><br><br><b>Example:</b><br>Router (config)# crypto map dyn client configuration address initiate | Configures the router to initiate or reply to Mode Configuration requests.<br><br><b>Note</b> Cisco clients require the <b>respond</b> keyword to be used; however, if the Cisco Secure VPN Client 1.x is used, the <b>initiate</b> keyword must be used; <b>initiate</b> and <b>respond</b> keywords may be used simultaneously. |

|        | Command                                                                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                       |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Step 5 | <b>crypto map <i>map-name</i> client authentication list <i>list-name</i></b><br><br><b>Example:</b><br>Router (config)# crypto map xauthmap<br>client authentication list xauthlist     | Enforces Xauth. <ul style="list-style-type: none"> <li>The <i>list-name</i> argument is used to determine the appropriate username and password storage location (local or RADIUS) as defined in the <b>aaa authentication login</b> command.</li> </ul>                                                      |

## Enabling Reverse Route Injection for the Client

To enable RRI on the crypto map (static or dynamic) for VPN client support, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto dynamic *map-name seq-num***  
or  
**crypto map *map-name seq-num* ipsec-isakmp**
4. **set peer *ip-address***
5. **set transform-set *transform-set-name***
6. **reverse-route**
7. **match-address**

### DETAILED STEPS

|        | Command                                                                        | Purpose                                                                                                         |
|--------|--------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                         | Enables privileged EXEC mode <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal | Enters global configuration mode.                                                                               |

|               | Command                                                                                                                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                               |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 3</b> | <b>crypto dynamic</b> <i>map-name seq-num</i><br>or<br><b>crypto map</b> <i>map-name seq-num ipsec-isakmp</i><br><br><b>Example:</b><br>Router (config)# <b>crypto dynamic</b> mymap 10<br><br>or<br>Router (config)# <b>crypto map</b> yourmap 15<br>ipsec-isakmp | Creates a dynamic crypto map entry and enters crypto map configuration mode.<br><br>or<br><br>Adds a dynamic crypto map set to a static crypto map set and enters crypto map configuration mode.                                                                                                      |
| <b>Step 4</b> | <b>set peer</b> <i>ip-address</i><br><br><b>Example:</b><br>Router (config-crypto-map)# <b>set peer</b> 10.20.20.20                                                                                                                                                | Specifies an IPsec peer IP address in a crypto map entry. <ul style="list-style-type: none"> <li>This step is optional when configuring dynamic crypto map entries.</li> </ul>                                                                                                                        |
| <b>Step 5</b> | <b>set transform-set</b> <i>transform-set-name</i><br><br><b>Example:</b><br>Router (config-crypto-map)# <b>set transform-set</b> dessha                                                                                                                           | Specifies which transform sets are allowed for the crypto map entry. <ul style="list-style-type: none"> <li>Lists multiple transform sets in order of priority (highest priority first).</li> </ul> <b>Note</b> This list is the only configuration statement required in dynamic crypto map entries. |
| <b>Step 6</b> | <b>reverse-route</b><br><br><b>Example:</b><br>Router (config-crypto-map)# <b>reverse-route</b>                                                                                                                                                                    | Creates source proxy information.                                                                                                                                                                                                                                                                     |
| <b>Step 7</b> | <b>match address</b><br><br><b>Example:</b><br>Router (config-crypto-map)# <b>match address</b>                                                                                                                                                                    | Specifies an extended access list for a crypto map entry. <ul style="list-style-type: none"> <li>This step is optional when configuring dynamic crypto map entries.</li> </ul>                                                                                                                        |

## Enabling IKE Dead Peer Detection

To enable a Cisco IOS VPN gateway (instead of the client) to send IKE DPD messages, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp keepalive secs retries**

## DETAILED STEPS

|        | Command                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                             |
|--------|----------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                               | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                    |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                       | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                   |
| Step 3 | <b>crypto isakmp keepalive secs retries</b><br><br><b>Example:</b><br>Router (config)# crypto isakmp keepalive 20 10 | Allows the gateway to send DPD messages to the router. <ul style="list-style-type: none"> <li>The <i>secs</i> argument specifies the number of seconds between DPD messages (the range is from 1 to 3600 seconds); the <i>retries</i> argument specifies the number of seconds between retries if DPD messages fail (the range is from 2 to 60 seconds).</li> </ul> |

## Configuring RADIUS Server Support

To configure access to the server and allow the Cisco IOS VPN device to send requests to the server, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **radius server host ip-address [auth-port port-number] [acct-port port-number] [key string]**

### DETAILED STEPS

|        | Command                                                | Purpose                                                                                                          |
|--------|--------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |

|        | Command                                                                                                                                                                                                                                                                                                                         | Purpose                                                                                                                                      |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Step 2 | <b>configure terminal</b>                                                                                                                                                                                                                                                                                                       | Enters global configuration mode.                                                                                                            |
| Step 3 | <b>Example:</b><br>Router# configure terminal<br><br><b>radius server host</b> <i>ip-address</i> [ <b>auth-port</b> <i>port-number</i> ] [ <b>acct-port</b> <i>port-number</i> ] [ <b>key</b> <i>string</i> ]<br><br><b>Example:</b><br>Router (config)# radius server host 192.168.1.1. auth-port 1645 acct-port 1646 key XXXX | Specifies a RADIUS server host.<br><br><b>Note</b> This step is required if you choose to store group policy information in a RADIUS server. |

## Verifying Easy VPN Server

To verify your configurations for this feature, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **show crypto map** [*interface interface* | **tag** *map-name*]

### DETAILED STEPS

|        | Command                                                                                                                                                   | Purpose                                                                                                             |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                    | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul> |

## Configuring Browser Proxy

To configure an EasyVPN server so that the Easy VPN remote device can access resources on the corporate network when using Cisco IOS VPN Client software, perform the following steps. With this configuration, the user does not have to manually modify the proxy settings of his or her web browser when connecting and does not have to manually revert the proxy settings when disconnecting.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp client configuration browser-proxy** {browser-proxy-name}
4. **proxy** {proxy-parameter}

## DETAILED STEPS

|        | Command                                                                                                                                                                         | Purpose                                                                                                               |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                          | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>      |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                  | Enters global configuration mode.                                                                                     |
| Step 3 | <b>crypto isakmp client configuration browser-proxy {browser-proxy-name}</b><br><br><b>Example:</b><br>Router (config)# crypto isakmp client configuration browser-proxy bproxy | Configures browser-proxy parameters for an Easy VPN remote device and enters ISAKMP Browser Proxy configuration mode. |
| Step 4 | <b>proxy {proxy-parameter}</b><br><br><b>Example:</b><br>Router (config-ikmp-browser-proxy)# proxy auto-detect                                                                  | Configures proxy parameters for an Easy VPN remote device.                                                            |

## Configuring the Pushing of a Configuration URL Through a Mode-Configuration Exchange

To configure an Easy VPN server to push a configuration URL through a Mode-Configuration Exchange, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp client configuration group {group-name}**
4. **configuration url {url}**
5. **configuration version {version-number}**

## DETAILED STEPS

|        | Command                                                                                                                                                        | Purpose                                                                                                                                                                                                                                                 |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                         | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                        |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                 | Enters global configuration mode.                                                                                                                                                                                                                       |
| Step 3 | <b>crypto isakmp client configuration group</b> <i>{group-name}</i><br><br><b>Example:</b><br>Router (config)# crypto isakmp client configuration group Group1 | Specifies to which group a policy profile will be defined and enters crypto ISAKMP group configuration mode.                                                                                                                                            |
| Step 4 | <b>configuration url</b> <i>{url}</i><br><br><b>Example:</b><br>Router (config-isakmp-group)# configuration url http://10.10.88.8/easy.cfg                     | Specifies the URL the remote device must use to get the configuration from the server. <ul style="list-style-type: none"> <li>The URL must be a non-NULL terminated ASCII string that specifies the complete path of the configuration file.</li> </ul> |
| Step 5 | <b>configuration version</b> <i>{version-number}</i><br><br><b>Example:</b><br>Router (config-isakmp-group)# configuration version 10                          | Specifies the version of the configuration. <ul style="list-style-type: none"> <li>The version number will be an unsigned integer in the range 1 through 32767.</li> </ul>                                                                              |

## Configuring Per User AAA Download with PKI—Configuring the Crypto PKI Trustpoint

To configure a AAA server to push user attributes to a remote device, perform the following steps.

### Prerequisites

Before configuring a AAA server to push user attributes to a remote device, you must have configured AAA. The crypto PKI trustpoint must also be configured (see the first configuration task below). It is preferable that the trustpoint configuration contain the **authorization username** command.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto pki trustpoint** *name*
4. **enrollment url** *url*

5. **revocation-check none**
6. **rsa-keypair** *key-label*
7. **authorization username** {**subjectname** *subjectname*}
8. **exit**

## DETAILED STEPS

|        | Command                                                                                                                                                                                         | Purpose                                                                                                          |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                          | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                  | Enters global configuration mode.                                                                                |
| Step 3 | <b>crypto pki trustpoint</b> <i>name</i><br><br><b>Example:</b><br>Router (config)# crypto pki trustpoint<br>ca-server                                                                          | Declares the trustpoint that your router should use and enters ca-trustpoint configuration mode.                 |
| Step 4 | <b>enrollment url</b> <i>url</i><br><br><b>Example:</b><br>Router (config-ca-trustpoint)# enrollment<br>url http://10.7.7.2:80                                                                  | Specifies the URL of the certification authority (CA) server to which to send enrollment requests.               |
| Step 5 | <b>revocation-check none</b><br><br><b>Example:</b><br>Router (config-ca-trustpoint)#<br>revocation-check none                                                                                  | Checks the revocation status of a certificate.                                                                   |
| Step 6 | <b>rsa-keypair</b> <i>key-label</i><br><br><b>Example:</b><br>Router (config-ca-trustpoint)# rsa-keypair<br>rsa-pair                                                                            | Specifies which key pair to associate with the certificate.                                                      |
| Step 7 | <b>authorization username</b> { <b>subjectname</b> <i>subjectname</i> }<br><br><b>Example:</b><br>Router (config-ca-trustpoint)# authorization<br>username <i>subjectname</i> <i>commonname</i> | Specifies the parameters for the different certificate fields that are used to build the AAA username.           |
| Step 8 | <b>exit</b><br><br><b>Example:</b><br>Router (config-ca-trustpoint)# exit                                                                                                                       | Exits ca-trustpoint configuration mode.                                                                          |

## Configuring the Actual Per User AAA Download with PKI

To configure the actual per-user download with PKI, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp policy** *priority*
4. **group** {1 | 2}
5. **exit**
6. **crypto isakmp profile** *profile-name*
7. **match certificate** *certificate-map*
8. **client pki authorization list** *listname*
9. **client configuration address** {*initiate* | *respond*}
10. **virtual-template** *template-number*
11. **exit**
12. **crypto ipsec transform-set** [*transform-set-name transform1*] [*transform2*] [*transform3*] [*transform4*]
13. **crypto ipsec profile** *name*
14. **set transform-set** *transform-set-name*

### DETAILED STEPS

|        | Command                                                                                                        | Purpose                                                                                                             |
|--------|----------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                         | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                 | Enters global configuration mode.                                                                                   |
| Step 3 | <b>crypto isakmp policy</b> <i>priority</i><br><br><b>Example:</b><br>Router (config)# crypto isakmp policy 10 | Defines an IKE policy and enters ISAKMP policy configuration mode.                                                  |
| Step 4 | <b>group</b> {1   2}<br><br><b>Example:</b><br>Router (config-isakmp-policy)# group 2                          | Specifies the Diffie-Hellman group identifier within an IKE policy.                                                 |

|         | Command                                                                                                                                                                                                                           | Purpose                                                                                                                                                                |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 5  | <b>exit</b><br><br><b>Example:</b><br>Router (config-isakmp-policy)# exit                                                                                                                                                         | Exits ISAKMP policy configuration mode.                                                                                                                                |
| Step 6  | <b>crypto isakmp profile</b> <i>profile-name</i><br><br><b>Example:</b><br>Router (config)# crypto isakmp profile<br>ISA-PROF                                                                                                     | Defines an ISAKMP profile and audits IPsec user sessions and enters crypto ISAKMP profile configuration mode.                                                          |
| Step 7  | <b>match certificate</b> <i>certificate-map</i><br><br><b>Example:</b><br>Router (config-isakmp-profile)# match<br>certificate cert_map                                                                                           | Assigns an ISAKMP profile to a peer on the basis of the contents of arbitrary fields in the certificate.                                                               |
| Step 8  | <b>client pki authorization list</b> <i>listname</i><br><br><b>Example:</b><br>Router (config-isakmp-profile)# client pki<br>authorization list usrgrp                                                                            | Specifies the authorization list of AAA servers that will be used for obtaining per-user AAA attributes on the basis of the username constructed from the certificate. |
| Step 9  | <b>client configuration address</b> {initiate   respond}<br><br><b>Example:</b><br>Router (config-isakmp-profile)# client<br>configuration address respond                                                                        | Configures IKE configuration mode in the ISAKMP profile.                                                                                                               |
| Step 10 | <b>virtual-template</b> <i>template-number</i><br><br><b>Example:</b><br>Router(config-isakmp-profile)#<br>virtual-template 2                                                                                                     | Specifies which virtual template will be used to clone virtual access interfaces.                                                                                      |
| Step 11 | <b>exit</b><br><br><b>Example:</b><br>Router(config-isakmp-profile)# exit                                                                                                                                                         | Exits crypto ISAKMP profile configuration mode.                                                                                                                        |
| Step 12 | <b>crypto ipsec transform-set</b><br><i>transform-set-name transform1 [transform2]</i><br><i>[transform3] [transform4]</i><br><br><b>Example:</b><br>Router (config)# crypto ipsec transform-set<br>trans2 esp-3des esp-sha-hmac1 | Defines a transform set—an acceptable combination of security protocols and algorithms.                                                                                |

|         | Command                                                                                                                | Purpose                                                                                          |
|---------|------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| Step 13 | <b>crypto ipsec profile</b> <i>name</i><br><br><b>Example:</b><br>Router (config)# crypto ipsec profile<br>IPSEC_PROF  | Defines the IPsec parameters that are to be used for IPsec encryption between two IPsec routers. |
| Step 14 | <b>set transform-set</b> <i>transform-set-name</i><br><br><b>Example:</b><br>Router (config)# set transform-set trans2 | Specifies which transform sets can be used with the crypto map entry.                            |

## Configuring Per-User Attributes on a Local Easy VPN AAA Server

To configure per-user attributes on a local Easy VPN AAA server, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa attribute list** *list-name*
4. **attribute type** *name value* [**service** *service*] [**protocol** *protocol*]
5. **exit**
6. **crypto isakmp client configuration group** *group-name*
7. **crypto aaa attribute list** *list-name*

### DETAILED STEPS

|        | Command or Action                                                                                             | Purpose                                                                                                            |
|--------|---------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                        | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                | Enters global configuration mode.                                                                                  |
| Step 3 | <b>aaa attribute list</b> <i>list-name</i><br><br><b>Example:</b><br>Router(config)# aaa attribute list list1 | Defines a AAA attribute list locally on a router and enters attribute list configuration mode.                     |

|        | Command or Action                                                                                                                                                                             | Purpose                                                                                               |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|
| Step 4 | <b>attribute type name value [service service]</b><br><b>[protocol protocol]</b><br><br><b>Example:</b><br>Router(config-attr-list)# attribute type<br>attribute xxxx service ike protocol ip | Defines an attribute type that is to be added to an attribute list locally on a router.               |
| Step 5 | <b>exit</b><br><br><b>Example:</b><br>Router(config-attr-list)# exit                                                                                                                          | Exits attribute list configuration mode.                                                              |
| Step 6 | <b>crypto isakmp client configuration group</b><br><b>group-name</b><br><br><b>Example:</b><br>Router (config)# crypto isakmp client<br>configuration group group1                            | Specifies to which group a policy profile will be defined and enters ISAKMP group configuration mode. |
| Step 7 | <b>crypto aaa attribute list list-name</b><br><br><b>Example:</b><br>Router (config-isakmp-group)# crypto aaa<br>attribute list listname1                                                     | Defines a AAA attribute list locally on a router.                                                     |

## Enabling Easy VPN Syslog Messages

To enable Easy VPN syslog messages on a server, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto logging ezvpn group group-name**

### DETAILED STEPS

|        | Command                                                | Purpose                                                                                                            |
|--------|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |

|        | Command                                                                            | Purpose                                                                                                                                                                                                                                                                                                                   |
|--------|------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 2 | <code>configure terminal</code>                                                    | Enters global configuration mode.                                                                                                                                                                                                                                                                                         |
|        | <b>Example:</b><br>Router# <code>configure terminal</code>                         |                                                                                                                                                                                                                                                                                                                           |
| Step 3 | <code>crypto logging ezvpn [group group-name]</code>                               | Enables Easy VPN syslog messages on a server.                                                                                                                                                                                                                                                                             |
|        | <b>Example:</b><br>Router (config)# <code>crypto logging ezvpn group group1</code> | <ul style="list-style-type: none"> <li>The <b>group</b> keyword and <i>group-name</i> argument are optional. If a group name is not provided, syslog messages are enabled for all Easy VPN connections to the server. If a group name is provided, syslog messages are enabled for that particular group only.</li> </ul> |

## Defining a CPP Firewall Policy Push Using a Local AAA Server

To define a CPP firewall policy push on a server to allow or deny a tunnel on the basis of whether a remote device has a required firewall for a local AAA server, perform the following steps.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `crypto isakmp client firewall {policy-name} {required | optional} {firewall-type}`
4. `policy {check-presence | central-policy-push {access-list {in | out} access-list-name | access-list-number}}`

### DETAILED STEPS

|        | Command                                                    | Purpose                                                                            |
|--------|------------------------------------------------------------|------------------------------------------------------------------------------------|
| Step 1 | <code>enable</code>                                        | Enables privileged EXEC mode.                                                      |
|        | <b>Example:</b><br>Router> <code>enable</code>             | <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <code>configure terminal</code>                            | Enters global configuration mode.                                                  |
|        | <b>Example:</b><br>Router# <code>configure terminal</code> |                                                                                    |

|        | Command                                                                                                                                                                                                                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <p><b>crypto isakmp client firewall</b> {<i>policy-name</i>} {<b>required</b>   <b>optional</b>} {<i>firewall-type</i>}</p> <p><b>Example:</b><br/>Router (config)# crypto isakmp client<br/>firewall hw-client-g-cpp required<br/>Cisco-Security-Agent</p>                                                                                                         | <p>Defines the CPP firewall push policy on a server and enters ISAKMP client firewall configuration mode.</p> <p>The arguments and keywords are as follows:</p> <ul style="list-style-type: none"> <li>• <b>policy-name</b>—Uniquely identifies a policy. A policy name can be associated with the Easy VPN client group configuration of the server (local group configuration) or on the AAA server.</li> <li>• <b>required</b>—Policy is mandatory. If the CPP policy is defined as mandatory and is included in the Easy VPN server configuration, the tunnel setup is allowed only if the client confirms this policy. Otherwise, the tunnel is terminated.</li> <li>• <b>optional</b>—Policy is optional. If the CPP policy is defined as optional, and is included in the Easy VPN server configuration, the tunnel setup is continued even if the client does not confirm the defined policy.</li> <li>• <b>firewall-type</b>—Type of firewall (see the <b>crypto isakmp client firewall</b> command for a list of firewall types).</li> </ul> |
| Step 4 | <p><b>policy</b> {<b>check-presence</b>   <b>central-policy-push</b>} {<b>access-list</b> {<b>in</b>   <b>out</b>} <i>access-list-name</i>   <i>access-list-number</i>}}</p> <p><b>Example:</b><br/>Router (config-ikmp-client-fw)# policy<br/>central-policy-push access-list out acl1</p> <p>or<br/>Router (config-ikmp-client-fw)# policy<br/>check-presence</p> | <p>Defines the CPP firewall policy push.</p> <p>The arguments and keywords are as follows:</p> <ul style="list-style-type: none"> <li>• <b>check-presence</b>—Denotes that the server should check for the presence of the specified firewall as shown by the value of the <i>firewall-type</i> argument on the client.</li> <li>• <b>central-policy-push</b>—The configuration following this keyword specifies the actual policy, such as the input and output access lists that have to be applied by the client firewall, which is of the type specified by the value of the <i>firewall-type</i> argument.</li> <li>• <b>access-list {in   out}</b>—Defines the inbound and outbound access lists.</li> <li>• <b>access-list-name   access-list-number</b>—Name or number of the access list.</li> </ul>                                                                                                                                                                                                                                          |

## What to Do Next

Apply the CPP firewall policy push to the configured group.

## Applying a CPP Firewall Policy Push to the Configuration Group

Now that the CPP firewall policy push has been defined, it must be applied to the configuration group by performing the following steps.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp client configuration group** *{group-name}*
4. **firewall policy** *{policy-name}*

## DETAILED STEPS

|        | Command                                                                                                                                                             | Purpose                                                                                                                             |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                              | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                 |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                      | Enters global configuration mode.                                                                                                   |
| Step 3 | <b>crypto isakmp client configuration group</b> <i>{group-name}</i><br><br><b>Example:</b><br>Router (config)# crypto isakmp client configuration group hw-client-g | Specifies to which group a policy profile will be defined and enters ISAKMP group configuration mode.                               |
| Step 4 | <b>firewall policy</b> <i>{policy-name}</i><br><br><b>Example:</b><br>Router (crypto-isakmp-group)# firewall policy hw-client-g-cpp                                 | Specifies the CPP firewall push policy name for the crypto ISAKMP client configuration group on a local authentication, AAA server. |

## Defining a CPP Firewall Policy Push Using a Remote AAA Server

To define a CPP firewall policy push using a remote AAA server, see the section “[Defining a CPP Firewall Policy Push Using a Local AAA Server](#).” The steps are the same for this configuration.

## What to Do Next

After defining the CPP firewall policy push, you should add the VSA cpp-policy under the group definition.

## Adding the VSA CPP-Policy Under the Group Definition

To add the the VSA cpp-policy under the group definition that is defined in RADIUS, perform the following step.

## SUMMARY STEPS

1. Add the VSA cpp-policy under the group definition that is defined in RADIUS.

## DETAILED STEPS

|        | Command                                                                                                                                         | Purpose                                                   |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------|
| Step 1 | Add the VSA “cpp-policy” under the group definition that is defined in RADIUS.<br><br><b>Example:</b><br>ipsec:cpp-policy=”Enterprise Firewall” | Defines the CPP firewall push policy for a remote server. |

## Verifying CPP Firewall Policy Push

To verify the CPP firewall push policy on a local or remote AAA server, perform the following steps.

## SUMMARY STEPS

1. `enable`
2. `debug crypto isakmp`

## DETAILED STEPS

|        | Command                                                                                             | Purpose                                                                                                               |
|--------|-----------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| Step 1 | <code>enable</code><br><br><b>Example:</b><br>Router> <code>enable</code>                           | Enables privileged EXEC mode.<br><ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <code>debug crypto isakmp</code><br><br><b>Example:</b><br>Router# <code>debug crypto isakmp</code> | Displays messages about IKE events.                                                                                   |

## Configuring Password Aging

To configure Password Aging so that the Easy VPN client is notified if the password has expired, perform the following steps.

## Restrictions

The following restrictions apply to the Password Aging feature:

- It works only with VPN software clients. It does not work with VPN client hardware.
- It works only with RADIUS servers.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa new-model**
4. **aaa authentication login {list-name} password-expiry method1 [method2...]**
5. **radius-server host {ip-address} auth-port port-number acct-port port-number key string}**
6. Configure the ISAKMP profile
7. **client authentication list {list-name}**

## DETAILED STEPS

|        | Command                                                                                                                                                                                                                                                                | Purpose                                                                                                             |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                                                                                 | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                                                                                         | Enters global configuration mode.                                                                                   |
| Step 3 | <b>aaa new-model</b><br><br><b>Example:</b><br>Router (config)# aaa new-model                                                                                                                                                                                          | Enables AAA.                                                                                                        |
| Step 4 | <b>aaa authentication login {list-name} password-expiry method1 [method2...]</b><br><br><b>Example:</b><br>Router (config)# aaa authentication login userauth paswd-expiry group radius                                                                                | Configures the authentication list so that the Password Aging feature is enabled.                                   |
| Step 5 | <b>radius-server host {ip-address} auth-port port-number acct-port port-number key string}</b><br><br><b>Example:</b><br>Router (config)# radius-server host 172.19.217.96 255.255.255.0 auth-port 1645 acct-port 1646 key cisco radius-server vsa send authentication | Configures the RADIUS server.                                                                                       |

|        | Command                                                                                                                                           | Purpose                                                                                                                                               |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 6 | Configure the ISAKMP profile.<br><br><b>Example:</b><br>see the section “ <a href="#">Configuring Password Aging: Example</a> ”                   | Configures the ISAKMP profile and enters ISAKMP profile configuration mode (see the section “ <a href="#">Configuring Password Aging: Example</a> ”). |
| Step 7 | <code>client authentication list {list-name}</code><br><br><b>Example:</b><br>Router (config-isakmp-profile)# client authentication list userauth | Configures IKE extended authentication (Xauth) in an ISAKMP profile and includes the authentication list that was defined above.                      |

## Configuring Split DNS

To configure Split DNS, perform the following steps.

### Prerequisites

Before the Split DNS feature can work, the following commands should have been configured on the Easy VPN remote:

- `ip dns server`
- `ip domain-lookup`

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `crypto isakmp client configuration group group-name`
4. `dns primary-server secondary-server`
5. `split-dns domain-name`

### DETAILED STEPS

|        | Command                                                                              | Purpose                                                                                                             |
|--------|--------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Step 1 | <code>enable</code><br><br><b>Example:</b><br>Router> enable                         | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul> |
| Step 2 | <code>configure terminal</code><br><br><b>Example:</b><br>Router# configure terminal | Enters global configuration mode.                                                                                   |

|        | Command                                                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                    |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <b>crypto isakmp client configuration group</b> <i>{group-name   default}</i><br><br><b>Example:</b><br>Router (config)# crypto isakmp client configuration group group1 | Specifies the policy profile of the group that will be defined and enters ISAKMP group configuration mode. <ul style="list-style-type: none"> <li>If no specific group matches and a default group is defined, users will automatically be given the policy of a default group.</li> </ul> |
| Step 4 | <b>dns primary-server secondary-server</b><br><br><b>Example:</b><br>Router (config-isakmp-group)# dns 10.2.2.2 10.3.3.3                                                 | Specifies the primary and secondary DNS servers for the group.                                                                                                                                                                                                                             |
| Step 5 | <b>split-dns domain-name</b><br><br><b>Example:</b><br>Router (config-isakmp-group)# split-dns green.com                                                                 | Specifies a domain name that must be tunneled or resolved to the private network.                                                                                                                                                                                                          |

## Verifying Split DNS

To verify a split DNS configuration, perform the following steps (the **show** commands can be used one at a time or together).

### SUMMARY STEPS

1. **enable**
2. **show ip dns name-list** *[name-list-number]*
3. **show ip dns view** *[vrf vrf-name] [default | view-name]*
4. **show ip dns view-list** *[view-list-name]*

### DETAILED STEPS

|        | Command                                                                                                          | Purpose                                                                                                          |
|--------|------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                           | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>show ip dns name-list</b> <i>[name-list-number]</i><br><br><b>Example:</b><br>Router# show ip dns name-list 1 | Displays information about DNS name lists.                                                                       |

|        | Command                                                                                                                                          | Purpose                                    |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------|
| Step 3 | <b>show ip dns view</b> [ <i>vrf vrf-name</i> ] [ <b>default</b>   <i>view-name</i> ]<br><br><b>Example:</b><br>Router# show ip dns view default | Displays information about DNS views.      |
| Step 4 | <b>show ip dns view-list</b> [ <i>view-list-name</i> ]<br><br><b>Example:</b><br>Router# show ip dns view-list<br>ezvpn-internal-viewlist        | Displays information about DNS view lists. |

## Monitoring and Maintaining Split DNS

To monitor and maintain the split DNS configuration on Easy VPN remote devices, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **debug ip dns name-list**
3. **debug ip dns view**
4. **debug ip dns view-list**

### DETAILED STEPS

|        |                                                                                        |                                                                                                                    |
|--------|----------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                 | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>debug ip dns name-list</b><br><br><b>Example:</b><br>Router# debug ip dns name-list | Enables debugging output for Domain Name System (DNS) name-list events.                                            |
| Step 3 | <b>debug ip dns view</b><br><br><b>Example:</b><br>Router# debug ip dns view           | Enables debugging output for DNS view events.                                                                      |
| Step 4 | <b>debug ip dns view-list</b><br><br><b>Example:</b><br>Router# debug ip dns view-list | Enables debugging output for DNS view-list events.                                                                 |

## Configuring an Easy VPN Server to Obtain an IP Address from a DHCP Server

When the Easy VPN server selects the method for address assignment, it does so in the following order of precedence:

1. Selects the Framed IP address
2. Uses the IP address from the authentication server (group/user)
3. Uses the global IKE address pools
4. Uses DHCP

### Note

To enable the Easy VPN server to obtain an IP address from a DHCP server, remove other address assignments.

To configure an Easy VPN server to obtain an IP address from a DHCP server, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp client configuration group *group-name***
4. **dhcp server {*ip-address* | *hostname*}**
5. **dhcp timeout *time***
6. **dhcp giaddr *scope***

### DETAILED STEPS

|        |                                                                                                                                                              |                                                                                                                                                                                                                                                 |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                       | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                               | Enters global configuration mode.                                                                                                                                                                                                               |
| Step 3 | <b>crypto isakmp client configuration group <i>group-name</i></b><br><br><b>Example:</b><br>Router (config)# crypto isakmp client configuration group group1 | Specifies to which group a policy profile will be defined.<br><br><b>Note</b> Entering this command places the CLI in ISAKMP group configuration mode. From this mode, you can use subcommands to specify characteristics for the group policy. |
| Step 4 | <b>dhcp server {<i>ip-address</i>   <i>hostname</i>}</b><br><br><b>Example:</b><br>Router (config-isakmp-group)# dhcp server 10.10.1.2                       | Specifies a primary (and backup) DHCP server to allocate IP addresses to MS users entering a particular public data network (PDN) access point.                                                                                                 |

|               |                                                                                                             |                                                                                 |
|---------------|-------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| <b>Step 5</b> | <code>dhcp timeout time</code><br><br><b>Example:</b><br>Router (config-isakmp-group)# dhcp timeout 6       | Sets the wait time in seconds before the next DHCP server on the list is tried. |
| <b>Step 6</b> | <code>dhcp giaddr scope</code><br><br><b>Example:</b><br>Router (config-isakmp-group)# dhcp giaddr 10.1.1.4 | Specifies the giaddr for the DHCP scope.                                        |

## Verifying DHCP Client Proxy

To verify your DHCP client proxy configuration, perform the following steps (use the **show** commands one at a time or together).

### SUMMARY STEPS

1. **enable**
2. **show dhcp lease**
3. **show ip dhcp pool**
4. **show ip dhcp binding**

### DETAILED STEPS

|               |                                                                                          |                                                                                                                                                                                                                                               |
|---------------|------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <code>enable</code><br><br><b>Example:</b><br>Router> enable                             | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                            |
| <b>Step 1</b> | <code>show dhcp lease</code><br><br><b>Example:</b><br>Router# show dhcp lease           | Displays information about the DHCP address pools.<br><br><b>Note</b> Use this command when an external DHCP is used.                                                                                                                         |
| <b>Step 2</b> | <code>show ip dhcp pool</code><br><br><b>Example:</b><br>Router# show ip dhcp pool       | Displays information about the DHCP address pools.<br><br><b>Note</b> This command is applicable only when the Easy VPN server is also the DHCP server (generally not the case because in most cases, the DHCP server is an external server). |
| <b>Step 3</b> | <code>show ip dhcp binding</code><br><br><b>Example:</b><br>Router# show ip dhcp binding | Displays address bindings on the DHCP server.<br><br><b>Note</b> This command is applicable only when the Easy VPN server is also the DHCP server (generally not the case because in most cases, the DHCP server is an external server).      |

## Monitoring and Maintaining DHCP Client Proxy

To monitor and maintain your DHCP client proxy configuration, perform the following steps (use the **debug** commands one at a time or together).

### SUMMARY STEPS

1. **enable**
2. **debug crypto isakmp**
3. **debug dhcp**
4. **debug dhcp detail**
5. **debug ip dhcp server events**

### DETAILED STEPS

|               |                                                                                                  |                                                                                                                                                                                                                                                                  |
|---------------|--------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                           | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                 |
| <b>Step 2</b> | <b>debug crypto isakmp</b><br><br><b>Example:</b><br>Router# debug crypto isakmp                 | Displays messages about Internet Key Exchange (IKE) event.                                                                                                                                                                                                       |
| <b>Step 3</b> | <b>debug dhcp</b><br><br><b>Example:</b><br>Router# debug dhcp                                   | Reports server events, like address assignments and database updates.                                                                                                                                                                                            |
| <b>Step 4</b> | <b>debug dhcp detail</b><br><br><b>Example:</b><br>Router# debug dhcp detail                     | Displays detailed DHCP debugging information.                                                                                                                                                                                                                    |
| <b>Step 5</b> | <b>debug ip dhcp server events</b><br><br><b>Example:</b><br>Router# debug ip dhcp server events | Reports server events, like address assignments and database updates.<br><br><b>Note</b> This command is applicable only when the Easy VPN server is also the DHCP server (generally not the case because in most cases, the DHCP server is an external server). |

## Configuring cTCP

To enable cTCP, perform the following steps on your Easy VPN server.

### Prerequisites

Before configuring cTCP, you should have configured crypto IPsec.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ctcp port [port-number]**

## DETAILED STEPS

|               |                                                                                                       |                                                                                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                                                                                                              |
| <b>Step 2</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                        | Enters global configuration mode.                                                                                                                                                                                                             |
| <b>Step 3</b> | <b>crypto ctcp port [port-number]</b><br><br><b>Example:</b><br>Router (config)# crypto ctcp port 120 | Configures cTCP encapsulation for Easy VPN. <ul style="list-style-type: none"><li>• Up to 10 port numbers can be configured.</li><li>• If the <i>port-number</i> argument is not configured, cTCP is enabled on port 80 by default.</li></ul> |

## Verifying cTCP

To verify your cTCP configuration, perform the following steps (the **show** commands can be used one at a time or together).

## SUMMARY STEPS

1. **enable**
2. **show crypto ctcp [peer ip-address]**

## DETAILED STEPS

|               |                                                                                                                |                                                                                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                         | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul> |
| <b>Step 2</b> | <b>show crypto ctcp [peer ip-address]</b><br><br><b>Example:</b><br>Router# show crypto ctcp peer 10.76.235.21 | Displays information about a specific cTCP peer.                                                                 |

## Monitoring and Maintaining a cTCP Configuration

To monitor and maintain your cTCP configuration, perform the following steps.

## SUMMARY STEPS

1. **enable**
2. **debug crypto ctcp**

## DETAILED STEPS

|               |                                                                              |                                                                                                                    |
|---------------|------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><br><b>Example:</b><br>Router> enable                       | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| <b>Step 2</b> | <b>debug crypto ctcp</b><br><br><b>Example:</b><br>Router# debug crypto ctcp | Displays information about a cTCP session.                                                                         |

## Clearing a cTCP Configuration

To clear a cTCP configuration, perform the following steps.

## SUMMARY STEPS

1. **enable**
2. **clear crypto ctcp [peer ip-address]**

## DETAILED STEPS

|               |                                                                                                                 |                                                                                                                    |
|---------------|-----------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                          | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| <b>Step 2</b> | <b>clear crypto ctcp [peer ip-address]</b><br><br><b>Example:</b><br>Router# clear crypto ctcp peer 10.76.23.21 | Displays information about a cTCP session.                                                                         |

## Troubleshooting a cTCP Configuration

To troubleshoot a cTCP configuration, perform the following steps.

### SUMMARY STEPS

1. Ensure that the cTCP session is in the CTCP\_ACK\_RECEIVED state.
2. If the cTCP session is not in the CTCP\_ACK\_RECEIVED state, enable the **debug crypto ctcp** command.
3. If no cTCP bugs are seen, ensure that the firewall is allowing the cTCP packets to get to the server.
4. If the firewall configuration is correct, debugging is enabled, and you do not see any cTCP debugs on your console, you must find out why the cTCP port on the router is not receiving packets.

### DETAILED STEPS

- 
- |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | To ensure that the cTCP session is in the CTCP_ACK_RECEIVED state, use the <b>show crypto ctcp</b> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Step 2</b> | If the cTCP session is not in the CTCP_ACK_RECEIVED state, enable the <b>debug crypto ctcp</b> command and then try using the <b>show crypto ctcp</b> command again.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 3</b> | If no cTCP bugs are seen, ensure that the firewall is allowing the cTCP packets to get to the server (check the firewall configuration).                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 4</b> | If the firewall configuration is correct, debugging is enabled, and you do not see any cTCP debugs on your console, you must find out why the cTCP port on the router is not receiving packets. If you do not see any cTCP debugs and a cTCP session has not been set up, there is a possibility that cTCP packets that are actually TCP packets could have been delivered to a TCP stack instead of to the cTCP port. By enabling the <b>debug ip packet</b> and <b>debug ip tcp packet</b> commands, you may be able to determine whether the packet is being given to the TCP stack. |

## Configuration Examples for Easy VPN Server

This section provides the following configuration examples:

- [Configuring Cisco IOS for Easy VPN Server: Example, page 54](#)
- [RADIUS Group Profile with IPsec AV Pairs: Example, page 55](#)
- [RADIUS User Profile with IPsec AV Pairs: Example, page 56](#)
- [Backup Gateway with Maximum Logins and Maximum Users: Example, page 56](#)
- [Easy VPN with an IPsec Virtual Tunnel Interface: Example, page 56](#)
- [Pushing a Configuration URL Through a Mode-Configuration Exchange: Examples, page 58](#)
- [Per User AAA Policy Download with PKI: Example, page 58](#)
- [Per-User Attributes on an Easy VPN Server: Example, page 62](#)
- [Network Admission Control: Example, page 64](#)
- [Configuring Password Aging: Example, page 66](#)

- [Split DNS: Examples, page 68](#)
- [DHCP Client Proxy: Examples, page 69](#)
- [cTCP Session: Example, page 70](#)
- [VRF Assignment by a AAA Server: Example, page 71](#)

## Configuring Cisco IOS for Easy VPN Server: Example

The following example shows how to define group policy information locally for mode configuration. In this example, a group name is named “cisco” and another group name is named “default.” The policy is enforced for all users who do not offer a group name that matches “cisco.”

```
! Enable policy look-up via AAA. For authentication and authorization, send requests to
! RADIUS first, then try local policy.
aaa new-model
aaa authentication login userlist group radius local
aaa authorization network grouplist group radius local
enable password XXXX
!
username cisco password 0 cisco
clock timezone PST -8
ip subnet-zero
! Configure IKE policies, which are assessed in order so that the first policy that
! matches the proposal of the client will be used.
crypto isakmp policy 1
 group 2
!
crypto isakmp policy 3
 hash md5
 authentication pre-share
 group 2
crypto isakmp identity hostname
!
! Define “cisco” group policy information for mode config push.
crypto isakmp client configuration group cisco
 key cisco
 dns 10.2.2.2 10.2.2.3
 wins 10.6.6.6
 domain cisco.com
 pool green
 acl 199
! Define default group policy for mode config push.
crypto isakmp client configuration group default
 key cisco
 dns 10.2.2.2 10.3.2.3
 pool green
 acl 199
!
!
crypto ipsec transform-set dessha esp-des esp-sha-hmac
!
crypto dynamic-map mode 1
 set transform-set dessha
!
! Apply mode config and xauth to crypto map “mode.” The list names that are defined here
! must match the list names that are defined in the AAA section of the config.
crypto map mode client authentication list userlist
crypto map mode isakmp authorization list grouplist
