## RADIUS Group Profile with IPsec AV Pairs: Example

The following is an example of a standard RADIUS group profile that includes RADIUS IPsec AV pairs. To get the group authorization attributes, “cisco” must be used as the password.

```

client_r Password = "cisco"
Service-Type = Outbound

cisco-avpair = "ipsec:tunnel-type=ESP"
cisco-avpair = "ipsec:key-exchange=ike"
cisco-avpair = "ipsec:tunnel-password=lab"
cisco-avpair = "ipsec:addr-pool=pool1"
cisco-avpair = "ipsec:default-domain=cisco"
cisco-avpair = "ipsec:inac1=101"
cisco-avpair = "ipsec:access-restrict=fastethernet 0/0"
cisco-avpair = "ipsec:group-lock=1"
cisco-avpair = "ipsec:dns-servers=10.1.1.1 10.2.2.2"
cisco-avpair = "ipsec:firewall=1"
cisco-avpair = "ipsec:include-local-lan=1"
cisco-avpair = "ipsec:save-password=1"
cisco-avpair = "ipsec:wins-servers=10.3.3.3 10.4.4.4"

```

```

cisco-avpair = "ipsec:split-dns=green.com"
cisoc-avpair = "ipsec:ipsec-backup-gateway=10.1.1.1"
cisoc-avpair = "ipsec:ipsec-backup-gateway=10.1.1.2"
cisoc-avpair = "ipsec:pfs=1"
cisco-avpair = "ipsec:cpp-policy="Enterprise Firewall"
cisco-avpair = "ipsec:auto-update="Win http://abc.com 4.0.1"
cisco-avpair = "ipsec:browser-proxy=bproxy_profile_A"
cisco-avpair = "ipsec:xauth-banner="Xauth banner text here"

```

## RADIUS User Profile with IPsec AV Pairs: Example

The following is an example of a standard RADIUS user profile that includes RADIUS IPsec AV pairs. These user attributes will be obtained during Xauth.

```

ualluall Password = "uall1234"
 cisco-avpair = "ipsec:user-vpn-group=unity"
 cisco-avpair = "ipsec:user-include-local-lan=1"
 cisco-avpair = "ipsec:user-save-password=1"
 Framed-IP-Address = 10.10.10.10

```

## Backup Gateway with Maximum Logins and Maximum Users: Example

The following example shows that five backup gateways have been configured, that the maximum users have been set to 250, and that maximum logins have been set to 2:

```

crypto isakmp client configuration group sdm
key 6 RMZPPMRQMSdiZNJg`EBbCWTkSTi\`d[
pool POOL1
acl 150
backup-gateway 172.16.12.12
backup-gateway 172.16.12.13
backup-gateway 172.16.12.14
backup-gateway 172.16.12.130
backup-gateway 172.16.12.131
max-users 250
max-logins 2

```

## Easy VPN with an IPsec Virtual Tunnel Interface: Example

## Pushing a Configuration URL Through a Mode-Configuration Exchange: Examples

The following **show crypto ipsec client ezvpn** command output displays the mode configuration URL location and version:

```
Router# show crypto ipsec client ezvpn
```

```
Easy VPN Remote Phase: 5
```

```

Tunnel name : branch
Inside interface list: Vlan1
Outside interface: FastEthernet0
Current State: IPSEC_ACTIVE
Last Event: SOCKET_UP
Address: 172.16.1.209
Mask: 255.255.255.255
Default Domain: cisco.com
Save Password: Allowed
Configuration URL [version]: tftp://172.16.30.2/branch.cfg [11]
Config status: applied, Last successfully applied version: 11
Current EzVPN Peer: 192.168.10.1

```

The following **show crypto isakmp peers config** command output displays all manageability information that is sent by the remote device.

```
Router# show crypto isakmp peers config
```

```

## Network Admission Control: Example

The following is output for an Easy VPN server that has been enabled with Network Admission Control.

### Note

Network Admission Control is supported on an Easy VPN server only when the server uses IPsec virtual interfaces. Network Admission Control is enabled on the virtual template interface and applies to all PC clients that use this virtual template interface.

```
Router# show running-config

!
!
! Note 1: EAPoUDP packets will use the IP address of the loopback interface when sending
the EAPoUDP hello to the Easy VPN client. Using the IP address ensures that the returning
EAPoUDP packets come back encrypted and are associated with the correct virtual access
interface. The ip admission (ip admission source-interface Loopback10) command is
optional. Instead of using this command, you can specify the IP address of the virtual
template to be an address in the inside network space as shown in the configuration of the
virtual template below in Note 2.

! Note2: Use the IP address of the loopback10. This ensures that the EAPoUDP packets that
are attached to virtual-access interfaces that are cloned from this virtual template carry
the source address of the loopback address and that response packets from the VPN client
come back encrypted.

## Split DNS: Examples

In the following example, the split tunnel list named “101” contains the 10.168.0.0/16 network. It is necessary to include this network information so that the DNS requests to the internal DNS server of 10.168.1.1 are encrypted.

```
crypto isakmp client configuration group home
 key abcd
 acl 101
 dns 10.168.1.1. 10.168.1.2
```

### show Output

The following **show** command output example shows that www.ciscoexample1.com and www.ciscoexample2.com have been added to the policy group:

Router# **show running-config | security group**

```
crypto isakmp client configuration group 831server
 key abcd
 dns 10.104.128.248
 split-dns www.ciscoexample1.com
 split-dns www.ciscoexample2.com
 group home2 key abcd
```

The following **show** command output example displays currently configured DNS views:

Router# **show ip dns view**

```
DNS View default parameters:
Logging is off
DNS Resolver settings:
 Domain lookup is enabled
 Default domain name: cisco.com
 Domain search list:
 Lookup timeout: 3 seconds
 Lookup retries: 2
 Domain name-servers:
 172.16.168.183
DNS Server settings:
 Forwarding of queries is enabled
 Forwarder addresses:

DNS View ezvpn-internal-view parameters:
Logging is off
DNS Resolver settings:
 Domain lookup is enabled
 Default domain name:
 Domain search list:
 Lookup timeout: 3 seconds
 Lookup retries: 2
 Domain name-servers:
 10.104.128.248
DNS Server settings:
 Forwarding of queries is enabled
 Forwarder addresses:
```

The following **show** command output example displays currently configured DNS view lists.

Router# **show ip dns view-list**

```
View-list ezvpn-internal-viewlist:
View ezvpn-internal-view:
 Evaluation order: 10
```

```

Restrict to ip dns name-list: 1
View default:
Evaluation order: 20

```

The following **show** command output displays DNS name lists.

```
Router# show ip dns name-list
```

```

ip dns name-list 1
 permit www.ciscoexample1.com
 permit www.ciscoexample2.com

```

## DHCP Client Proxy: Examples

The following examples display DHCP client proxy output information using **show** and **debug** commands.

### show Output

#### Note

To use the **show ip dhcp** command, the DHCP server must be a Cisco IOS server.

The following **show ip dhcp pool** command output provides information about the DHCP parameters:

```
Router# show ip dhcp pool
```

```

Pool dynpool :
 Utilization mark (high/low) : 100 / 0
 Subnet size (first/next) : 0 / 0
 Total addresses : 254
 Leased addresses : 1
 Pending event : none
 1 subnet is currently in the pool:
 Current index IP address range Leased addresses
 10.3.3.1 - 10.3.3.254 1
 No relay targets associated with class aclass

```

The following **show ip dhcp** command output provides information about the DHCP bindings:

```
Router# show ip dhcp binding
```

```

Bindings from all pools not associated with VRF:
IP address Client-ID/ Lease expiration Type
 Hardware address/User name
10.3.3.5 0065.7a76.706e.2d63. Apr 04 2006 06:01 AM Automatic
6c69.656e.74

```

### debug Output

The following example shows how the **debug crypto isakmp** and **debug ip dhcp server events** commands can be used to troubleshoot your DHCP client proxy support configuration:

```

```

## cTCP Session: Example

The following **debug crypto ctcp** command output displays information about a cTCP session, and it includes comments about the output:

```
Router# debug crypto ctcp
```

```

! In the following two lines, a cTCP SYN packet is received from the client, and the cTCP
connection is created.
*Sep 26 11:14:37.135: cTCP: Connection[648B50C0] 10.76.235.21:3519 10.76.248.239:10000:
created
*Sep 26 11:14:37.135: cTCP: SYN from 10.76.235.21:3519
! In the following line, the SYN acknowledgement is sent to the client.
*Sep 26 11:14:37.135: cTCP: Sending SYN(680723B2)ACK(100C637) to 10.76.235.21:3519
! In the following two lines, an acknowledgement is received, and connection setup is
complete. IKE packets should now be received on this newly created cTCP session.
*Sep 26 11:14:37.135: cTCP: Connection[648B50C0] 10.76.235.21:3519 10.76.248.239:10000:
found
*Sep 26 11:14:37.135: cTCP: ACK from 10.76.235.21:3519
*Sep 26 11:14:37.727: cTCP: Connection[648B50C0] 10.76.235.21:3519 10.76.248.239:10000:
found

```

```

*Sep 26 11:14:37.731: cTCP: updating PEER Seq number to 168288031
*Sep 26 11:14:37.731: cTCP: Pak with contiguous buffer
*Sep 26 11:14:37.731: cTCP: mangling IKE packet from peer: 10.76.235.21:500->3519
 10.76.248.239:500->500
*Sep 26 11:14:37.731: cTCP: Connection[648B50C0] 10.76.235.21:3519 10.76.248.239:10000:
found
*Sep 26 11:14:37.799: cTCP: demangling outbound IKE packet: 10.76.248.239:500->500
 10.76.235.21:3519->500
*Sep 26 11:14:37.799: cTCP: encapsulating IKE packet
*Sep 26 11:14:37.799: cTCP: updating LOCAL Seq number to 17452987271
! The above lines show that after the required number of IKE packets are exchanged, IKE
and IPsec SAs are created.
*Sep 26 11:14:40.335: cTCP: updating PEER Seq number to 168304311
*Sep 26 11:14:40.335: cTCP: Pak with particles
*Sep 26 11:14:40.335: cTCP: encapsulating pak
*Sep 26 11:14:40.339: cTCP: datagramstart 0xF2036D8, network_start 0xF2036D8, size 112
*Sep 26 11:14:40.339: cTCP: Pak with contiguous buffer
*Sep 26 11:14:40.339: cTCP: allocated new buffer
*Sep 26 11:14:40.339: cTCP: updating LOCAL Seq number to 17452995351
*Sep 26 11:14:40.339: IP: s=10.76.248.239 (local), d=10.76.235.21 (FastEthernet1/1), len
148, cTCP
! The above lines show that Encapsulating Security Payload (ESP) packets are now being
sent and received.

```

## VRF Assignment by a AAA Server: Example

The following output example shows that neither a VRF nor an IP address has been defined:

```

## Command Reference

The following commands are introduced or modified in the feature or features.

- **aaa authentication login**
- **access-restrict**
- **acl (ISAKMP)**
- **auto-update client**
- **backup-gateway**
- **banner**
- **browser-proxy**
- **clear crypto ctp**
- **clear crypto session**
- **client authentication list**
- **client pki authorization list**
- **configuration url**
- **configuration version**
- **crypto aaa attribute list**
- **crypto ctp**
- **crypto ipsec server send-update**

- **crypto isakmp client configuration browser-proxy**
- **crypto isakmp client configuration group**
- **crypto isakmp client firewall**
- **crypto logging ezvpn**
- **debug crypto ctcp**
- **debug crypto condition**
- **debug ip dns name-list**
- **debug ip dns view**
- **debug ip dns view-list**
- **dhcp server (isakmp)**
- **dhcp timeout**
- **domain (isakmp-group)**
- **firewall are-u-there**
- **firewall policy**
- **group-lock**
- **include-local-lan**
- **key (isakmp-group)**
- **max-logins**
- **max-users**
- **pfs**
- **policy**
- **pool (isakmp-group)**
- **proxy**
- **save-password**
- **show crypto ctcp**
- **show crypto debug-condition**
- **show crypto isakmp peers**
- **show crypto isakmp profile**
- **show crypto isakmp sa**
- **show crypto session**
- **show crypto session group**
- **show crypto session summary**
- **show ip dns name-list**
- **show ip dns view**
- **show ip dns view-list**
- **split-dns**
- **wins**
- **Glossary**

For information about these commands, see the Cisco IOS Security Command Reference at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html).

For information about all Cisco IOS commands, see the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the Master Command List.

## Feature Information for Easy VPN Server

Table 3 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Cisco IOS software images are specific to a Cisco IOS software release, a feature set, and a platform. Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

### Note

Table 3 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 3** Feature Information for Easy VPN Server

| Feature Name    | Releases                | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Easy VPN Server | 12.2(8)T                | The Easy VPN Server feature introduces server support for the Cisco VPN Client Release 3.x and later software clients and Cisco VPN hardware clients (such as the Cisco 800, Cisco 900, Cisco 1700, VPN 3002, and PIX 501 devices). This feature allows a remote end user to communicate using IP Security (IPsec) with any Cisco IOS Virtual Private Network (VPN) gateway. Centrally managed IPsec policies are “pushed” to the client device by the server, minimizing configuration by the end user. |
|                 | 12.3(2)T                | RADIUS support for user profiles, user-based policy control, session monitoring for VPN group access, backup-gateway list, and PFS were added.                                                                                                                                                                                                                                                                                                                                                           |
|                 | 12.3(7)T                | The <b>netmask</b> command was integrated for use on the Easy VPN server.<br><br>For information about configuring this command, see the following section: <ul style="list-style-type: none"> <li>Defining Group Policy Information for Mode Configuration Push, page 21</li> </ul>                                                                                                                                                                                                                     |

# Glossary

**AAA**—authentication, authorization, and accounting. Framework of security services that provides the method for identifying users (authentication), for remote access control (authorization), and for collecting and sending security server information used for billing, auditing, and reporting (accounting).

**aggressive mode (AM)**—Mode during Internet Key Exchange negotiation. Compared to main mode (MM), AM eliminates several steps, which makes it faster but less secure than MM. Cisco IOS software will respond in aggressive mode to an Internet Key Exchange (IKE) peer that initiates aggressive mode.

**AV pair**—attribute-value pair. Additional authentication and authorization information in the following format: Cisco:AVPair="protocol:attribute=value".

**IKE**—Internet Key Exchange. Hybrid protocol that implements Oakley key exchange and Skeme key exchange inside the ISAKMP framework. Although IKE can be used with other protocols, its initial implementation is with IPsec. IKE provides authentication of the IPsec peers, negotiates IPsec keys, and negotiates IPsec security associations.

**IPsec**—IP Security Protocol. Framework of open standards that provides data confidentiality, data integrity, and data authentication between participating peers. IPsec provides these security services at the IP layer. IPsec uses IKE to handle negotiation of protocols and algorithms based on local policy and to generate the encryption and authentication keys to be used by IPsec. IPsec can be used to protect one or more data flows between a pair of hosts, between a pair of security gateways, or between a security gateway and a host.

**ISAKMP**—Internet Security Association Key Management Protocol. Protocol framework that defines payload formats, the mechanics of implementing a key exchange protocol, and the negotiation of a security association.

**MM**—main mode. Mode that is slower than aggressive mode but more secure and more flexible than aggressive mode because it can offer an IKE peer more security proposals. The default action for IKE authentication (Rivest, Shamir, and Adelman signature (rsa-sig), RSA encryption (rsa-encr), or preshared) is to initiate main mode.

**policy push**—Allows administrators to push policies that enforce security to the Cisco Easy VPN (software) Client and related firewall software.

**reverse route injection (RRI)**—Simplified network design for VPNs on which there is a requirement for redundancy or load balancing. RRI works with both dynamic and static crypto maps.

In the dynamic case, as remote peers establish IPsec security associations with an RRI enabled router, a static route is created for each subnet or host protected by that remote peer. For static crypto maps, a static route is created for each destination of an extended access-list rule.

**SA**—security association. Description of how two or more entities will utilize security services to communicate securely. For example, an IPsec SA defines the encryption algorithm (if used), the authentication algorithm, and the shared session key to be used during the IPsec connection.

Both IPsec and IKE require and use SAs to identify the parameters of their connections. IKE can negotiate and establish its own SA. The IPsec SA is established either by IKE or by manual user configuration.

**VPN**—Virtual Private Network. Framework that consists of multiple peers transmitting private data securely to one another over an otherwise public infrastructure. In this framework, inbound and outbound network traffic is protected using protocols that tunnel and encrypt all data. This framework permits networks to extend beyond their local topology, while remote users are provided with the appearance and functionality of a direct network connection.

# Invalid Security Parameter Index Recovery

---

When an invalid security parameter index error (shown as “Invalid SPI”) occurs in IP Security (IPSec) packet processing, the feature allows for an Internet Key Exchange (IKE) security association (SA) to be established. The “IKE” module sends notification of the “Invalid SPI” error to the originating IPSec peer so that Security Association Databases (SADBs) can be resynchronized and successful packet processing can be resumed.

## Finding Feature Information in This Module

*Your Cisco IOS software release may not support all of the features documented in this module.* To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for” section on page 17](#).

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for

Before configuring the feature, you must have enabled Internet Key Exchange (IKE) and IPsec on your router.

## Restrictions for

If an IKE SA is being initiated to notify an IPsec peer of an “Invalid SPI” error, there is the risk that a denial-of-service (DoS) attack can occur. The feature has a built-in mechanism to minimize such a risk, but because there is a risk, the feature is not enabled by default. You must enable the command using command-line interface (CLI).

## Information About

To use the feature, you should understand the following concept.

- [How the Feature Works, page 2](#)

## How the Feature Works

An IPsec “black hole” occurs when one IPsec peer “dies” (for example, a peer can “die” if a reboot occurs or if an IPsec peer somehow gets reset). Because one of the peers (the receiving peer) is completely reset, it loses its IKE SA with the other peer. Generally, when an IPsec peer receives a packet for which it cannot find an SA, it tries to send an IKE “INVALID SPI NOTIFY” message to the data originator. This notification is sent using the IKE SA. If there is no IKE SA available, the receiving peer drops the packet.

### Note

---

A single security association (SA) has only two peers. However, a SADB can have multiple SAs, whereby each SA has an association with a different peer.

---

When an invalid security parameter index (SPI) is encountered, the Invalid Security Parameter Index feature provides for the setting up of an IKE SA with the originator of the data, and the IKE “INVALID SPI NOTIFY” message is sent. The peer that originated the data “sees” the “INVALID SPI NOTIFY” message and deletes the IPsec SA that has the invalid SPI. If there is further traffic from the originating peer, there will not be any IPsec SAs, and new SAs will be set up. Traffic will flow again. The default behavior (that is, without configuring the feature) is that the data packet that caused the invalid SPI error is dropped. The originating peer keeps on sending the data using the IPsec SA that has the invalid SPI, and the receiving peer keeps dropping the traffic (thus creating the “black hole”).

The IPsec module uses the IKE module to send an IKE “INVALID SPI NOTIFY” message to the other peer. Once the invalid SPI recovery is in place, there should not be any significant dropping of packets although the IPsec SA setup can itself result in the dropping of a few packets.

To configure your router for the feature, use the **crypto isakmp invalid-spi-recovery** command. The IKE SA will not be initiated unless you have configured this command.

# How to Configure

This section contains the following procedure.

- [Configuring, page 3](#)

## Configuring

To configure the feature, perform the following steps.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `crypto isakmp invalid-spi-recovery`

### DETAILED STEPS

|        | Command or Action                                                                                                                          | Purpose                                                                                                                       |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <code>enable</code><br><br><b>Example:</b><br>Router> <code>enable</code>                                                                  | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>              |
| Step 2 | <code>configure terminal</code><br><br><b>Example:</b><br>Router# <code>configure terminal</code>                                          | Enters global configuration mode.                                                                                             |
| Step 3 | <code>crypto isakmp invalid-spi-recovery</code><br><br><b>Example:</b><br>Router (config)# <code>crypto isakmp invalid-spi-recovery</code> | Initiates the IKE module process whereby the IKE module notifies the receiving peer that an “Invalid SPI” error has occurred. |

# Verifying an Configuration

To determine the status of the IPSec SA for traffic between two peers, you can use the **show crypto ipsec sa** command. If the IPSec SA is available on one peer and not on the other, there is a “black hole” situation, in which case you will see the invalid SPI errors being logged for the receiving peer. If you turn console logging on or check the syslog server, you will see that these errors are also being logged. [Figure 1](#) shows the topology of a typical preshared configuration setup. Host 1 is the initiating peer (initiator), and Host 2 is the receiving peer (responder).

**Figure 1** Preshared Configuration Topology

## SUMMARY STEPS

To verify the preshared configuration, perform the following steps.

- 1. Initiate the IKE and IPSec SAs between Host 1 and Host 2
- 2. Clear the IKE and IPSec SAs on Router B
- 3. Send traffic from Host 1 to Host 2 and ensure that IKE and IPSec SAs are correctly established
- 4. Check for an invalid SPI message on Router B

## DETAILED STEPS

**Step 1** Initiate the IKE and IPSec SAs between Host 1 and Host 2

**Router A**

Router# show crypto isakmp sa

| f_vrf/i_vrf | dst      | src      | state   | conn-id | slot |
|-------------|----------|----------|---------|---------|------|
| /           | 10.2.2.2 | 10.1.1.1 | QM_IDLE | 1       | 0    |

**Router B**

Router# show crypto isakmp sa

| f_vrf/i_vrf | dst      | src      | state   | conn-id | slot |
|-------------|----------|----------|---------|---------|------|
| /           | 10.1.1.1 | 10.2.2.2 | QM_IDLE | 1       | 0    |

**Router A**

Router# show crypto ipsec sa interface fastethernet0/0

interface: FastEthernet0/0

### Step 3 Send traffic from Host 1 to Host 2 and ensure that new IKE and IPSec SAs are correctly established

```
ping
```

```
Protocol [ip]: ip
```

```
Target IP address: 10.0.2.2
```

```
Repeat count [5]: 30
```

```
Datagram size [100]: 100
```

```
Timeout in seconds [2]:
```

```
Extended commands [n]: no
```

```
Sweep range of sizes [n]: n
```

```
Type escape sequence to abort.
```

```
Sending 30, 100-byte ICMP Echos to 10.0.2.2, timeout is 2 seconds:
```

```
..!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
```

```
Success rate is 93 percent (28/30), round-trip min/avg/max = 1/3/8 ms
```

```
RouterB# show crypto isakmp sa
```

| f_vrf/i_vrf | dst      | src      | state       | conn-id | slot |             |

# Command Reference

The following commands are introduced or modified in the feature or features

- **crypto isakmp invalid-spi-recovery**

For information about these commands, see the Cisco IOS Security Command Reference at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html).

For information about all Cisco IOS commands, see the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the Master Command List.

## Feature Information for

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

**Note**

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1**      **Feature Information for**

| Feature Name                                   | Releases                 | Feature Information                                             |
|------------------------------------------------|--------------------------|-----------------------------------------------------------------|
|                                                | 12.3(2)T                 | This feature was introduced.                                    |
|                                                | 12.2(18)SXE              | This feature was integrated into Cisco IOS Release 12.2(18)SXE. |
| Invalid Special Parameter Index (SPI) Recovery | Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers.   |

# IP Security VPN Monitoring

---

The IP Security VPN Monitoring feature provides VPN session monitoring enhancements that will allow you to troubleshoot the Virtual Private Network (VPN) and monitor the end-user interface. Session monitoring enhancements include the following:

- Ability to specify an Internet Key Exchange (IKE) peer description in the configuration file
- Summary listing of crypto session status
- Syslog notification for crypto session up or down status
- Ability to clear both IKE and IP Security (IPSec) security associations (SAs) using one command-line interface (CLI)

## Feature History for IP Security VPN Monitoring

| Release                  | Modification                                                  |
|--------------------------|---------------------------------------------------------------|
| 12.3(4)T                 | This feature was introduced.                                  |
| Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers. |

## Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

- [Additional References, page 7](#)
- [Command Reference, page 8](#)

## Prerequisites for IP Security VPN Monitoring

- You should be familiar with IPSec and encryption.
- Your router must support IPSec, and before using the IP Security VPN Monitoring feature, you must have configured IPSec on your router.

## Restrictions for IP Security VPN Monitoring

- You must be running Cisco IOS k8 or k9 crypto images on your router.

## Information About IPSec VPN Monitoring

To troubleshoot the IPSec VPN and monitor the end-user interface, you should understand the following concepts:

- [Background: Crypto Sessions, page 2](#)
- [Per-IKE Peer Description, page 2](#)
- [Summary Listing of Crypto Session Status, page 3](#)
- [Syslog Notification for Crypto Session Up or Down Status, page 3](#)
- [IKE and IPSec Security Exchange Clear Command, page 3](#)

## Background: Crypto Sessions

A crypto session is a set of IPSec connections (flows) between two crypto endpoints. If the two crypto endpoints use IKE as the keying protocol, they are IKE peers to each other. Typically, a crypto session consists of one IKE security association (for control traffic) and at least two IPSec security associations (for data traffic—one per each direction). There may be duplicated IKE security associations (SAs) and IPSec SAs or duplicated IKE SAs or IPSec SAs for the same session in the duration of rekeying or because of simultaneous setup requests from both sides.

## Per-IKE Peer Description

The Per-IKE Peer Description function allows you to enter a description of your choosing for an IKE peer. (Before Cisco IOS Release 12.3(4)T, you could use only the IP address or fully qualified domain name [FQDN] to identify the peer; there was no way to configure a description string.) The unique peer description, which can include up to 80 characters, can be used whenever you are referencing that particular IKE peer. To add the peer description, use the **description** command.

**Note**

IKE peers that “sit” behind a Network Address Translation (NAT) device cannot be uniquely identified; therefore, they have to share the same peer description.

The primary application of this description field is for monitoring purposes (for example, when using **show** commands or for logging [syslog messages]). The description field is purely informational (for example, it cannot act as a substitute for the peer address or FQDN when defining crypto maps).

## Summary Listing of Crypto Session Status

You can get a list of all the active VPN sessions by entering the **show crypto session** command. The listing will include the following:

- Interface
- IKE peer description, if available
- IKE SAs that are associated with the peer by whom the IPsec SAs are created
- IPsec SAs serving the flows of a session

Multiple IKE or IPsec SAs may be established for the same peer (for the same session), in which case IKE peer descriptions will be repeated with different values for the IKE SAs that are associated with the peer and for the IPsec SAs that are serving the flows of the session.

You can also use the **show crypto session detail** variant of this command to obtain more detailed information about the sessions.

## Syslog Notification for Crypto Session Up or Down Status

The Syslog Notification for Crypto Session Up or Down Status function provides syslog notification every time the crypto session comes up or goes down.

The following is a sample syslog notification showing that a crypto session is up:

```
%CRYPTO-5-SESSION_STATUS: Crypto session is UP. Peer 10.6.6.1:500 fvrf=name10 ivrf=name20
Description: SJC24-2-VPN-Gateway Id: 10.5.5.2
```

The following is a sample syslog notification showing that a crypto session is down:

```
%CRYPTO-5-SESSION_STATUS: Crypto session is DOWN. Peer 10.6.6.1:500 fvrf=name10
ivrf=name20 Description: SJC24-2-VPN-Gateway Id: 10.5.5.2
```

## IKE and IPsec Security Exchange Clear Command

In previous IOS versions, there was no single command to clear both IKE and IPsec connections (that is, SAs). Instead, you had to use the **clear crypto isakmp** command to clear IKE and the **clear crypto ipsec** command to clear IPsec. The new **clear crypto session** command allows you to clear both IKE and IPsec with a single command. To clear a specific crypto session or a subset of all the sessions (for example, a single tunnel to one remote site), you need to provide session-specific parameters, such as a local or remote IP address, a local or remote port, a front door VPN routing and forwarding (FVRF) name, or an inside VRF (IVRF) name. Typically, the remote IP address will be used to specify a single tunnel to be deleted.

If a local IP address is provided as a parameter when you use the **clear crypto session** command, all the sessions (and their IKE SAs and IPSec SAs) that share the IP address as a local crypto endpoint (IKE local address) will be cleared. If you do not provide a parameter when you use the **clear crypto session** command, all IPSec SAs and IKE SAs that are in the router will be deleted.

## How to Configure IP Security VPN Monitoring

See the following sections for configuration tasks for this feature. Each task in the list is identified as either required or optional.

- [Adding the Description of an IKE Peer, page 4](#) (optional)
- [Verifying Peer Descriptions, page 5](#) (optional)
- [Clearing a Crypto Session, page 6](#) (optional)

### Adding the Description of an IKE Peer

To add the description of an IKE peer to an IPSec VPN session, perform the following steps.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp peer {ip-address ip-address}**
4. **description**

#### DETAILED STEPS

|        | Command or Action                                                              | Purpose                                                                                                            |
|--------|--------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                         | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal | Enters global configuration mode.                                                                                  |

|        | Command or Action                                                                                                                | Purpose                                                                                                                                                                           |
|--------|----------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <b>crypto isakmp peer {ip-address ip-address}</b><br><br><b>Example:</b><br>Router (config)# crypto isakmp peer address 10.2.2.9 | Enables an IPSec peer for IKE querying of authentication, authorization, and accounting (AAA) for tunnel attributes in aggressive mode and enters ISAKMP peer configuration mode. |
| Step 4 | <b>description</b><br><br><b>Example:</b><br>Router (config-isakmp-peer)# description connection from site A                     | Adds a description for an IKE peer.                                                                                                                                               |

## Verifying Peer Descriptions

To verify peer descriptions, use the **show crypto isakmp peer** command.

### SUMMARY STEPS

1. **enable**
2. **show crypto isakmp peer**

### DETAILED STEPS

|        | Command or Action                                                                        | Purpose                                                                                                            |
|--------|------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                   | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>show crypto isakmp peer</b><br><br><b>Example:</b><br>Router# show crypto isakmp peer | Displays peer descriptions.                                                                                        |

## Examples

The following output example verifies that the description “connection from site A” has been added for IKE peer 10.2.2.9:

```
Router# show crypto isakmp peer
```

```
Peer: 10.2.2.9 Port: 500
Description: connection from site A
flags: PEER_POLICY
```

When the peer at address 10.2.2.9 connects and the session comes up, the syslog status will be shown as follows:

```
%CRYPTO-5-SESSION_STATUS: Crypto tunnel is UP. Peer 10.2.2.9:500 Description: connection from site A Id: ezvpn
```

## Clearing a Crypto Session

To clear a crypto session, use the **clear crypto session** command from the router command line. No configuration statements are required in the configuration file to use this command.

### SUMMARY STEPS

1. **enable**
2. **clear crypto session**

### DETAILED STEPS

|        | Command or Action                                                                  | Purpose                                                                                                          |
|--------|------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                             | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>clear crypto session</b><br><br><b>Example:</b><br>Router# clear crypto session | Deletes crypto sessions (IPSec and IKE SAs).                                                                     |

## Configuration Examples for IP Security VPN Monitoring

This section provides the following configuration example:

- [show crypto session Command Output: Examples, page 6](#)

### show crypto session Command Output: Examples

The following is sample output for the **show crypto session** output without the **detail** keyword:

```
Router# show crypto session
```

```
Crypto session current status
```

```
Interface: FastEthernet0/1
```

```
Session status: UP-ACTIVE
```

```
Peer: 172.0.0.2/500
```

```
 IKE SA: local 172.0.0.1/500 remote 172.0.0.2/500 Active
```

```
 IPSEC FLOW: permit ip 10.10.10.0/255.255.255.0 10.30.30.0/255.255.255.0
```

```
 Active SAs: 2, origin: crypto map
```

The following is sample output using the **show crypto session command and the detail** keyword:

```
Router# show crypto session detail
```

```
Interface: Tunnel0
```

```
Session status: UP-ACTIVE
```

```
Peer: 10.1.1.3 port 500 fvrf: (none) ivrf: (none)
```

```
 Desc: this is my peer at 10.1.1.3:500 Green
```

```
Phase1_id: 10.1.1.3
IKE SA: local 10.1.1.4/500 remote 10.1.1.3/500 Active
 Capabilities:(none) connid:3 lifetime:22:03:24
IPSEC FLOW: permit 47 host 10.1.1.4 host 10.1.1.3
 Active SAs: 0, origin: crypto map
 Inbound: #pkts dec'ed 0 drop 0 life (KB/Sec) 0/0
 Outbound: #pkts enc'ed 0 drop 0 life (KB/Sec) 0/0
IPSEC FLOW: permit ip host 10.1.1.4 host 10.1.1.3
 Active SAs: 4, origin: crypto map
 Inbound: #pkts dec'ed 4 drop 0 life (KB/Sec) 4605665/2949
 Outbound: #pkts enc'ed 4 drop 1 life (KB/Sec) 4605665/2949
```

# IPsec Anti-Replay Window: Expanding and Disabling

---

**First Published: February 28, 2005**  
**Last Updated: September 12, 2006**

Cisco IP security (IPsec) authentication provides anti-replay protection against an attacker duplicating encrypted packets by assigning a unique sequence number to each encrypted packet. The decryptor keeps track of which packets it has seen on the basis of these numbers. Currently, the default window size is 64 packets. Generally, this number (window size) is sufficient, but there are times when you may want to expand this window size. The IPsec Anti-Replay Window: Expanding and Disabling feature allows you to expand the window size, allowing the decryptor to keep track of more than 64 packets.

## History for the IPsec Anti-Replay Window: Expanding and Disabling Feature

| Release                  | Modification                                                     |
|--------------------------|------------------------------------------------------------------|
| 12.3(14)T                | This feature was introduced.                                     |
| 12.2(33)SRA              | This feature was integrated into Cisco IOS Release 12.2(33)SRA.  |
| 12.2(18)SXF6             | This feature was integrated into Cisco IOS Release 12.2(18)SXF6. |
| Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers.    |

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for IPsec Anti-Replay Window: Expanding and Disabling

- Before configuring this feature, you should have already created a crypto map or crypto profile.

## Information About IPsec Anti-Replay Window: Expanding and Disabling

To configure the IPsec Anti-Replay Window: Expanding and Disabling feature, you should understand the following concept:

- [IPsec Anti-Replay Window, page 2](#)

### IPsec Anti-Replay Window

Cisco IPsec authentication provides anti-replay protection against an attacker duplicating encrypted packets by assigning a unique sequence number to each encrypted packet. (Security association [SA] anti-replay is a security service in which the receiver can reject old or duplicate packets to protect itself against replay attacks.) The decryptor checks off the sequence numbers that it has seen before. The encryptor assigns sequence numbers in an increasing order. The decryptor remembers the value X of the highest sequence number that it has already seen. N is the window size, and the decryptor also remembers whether it has seen packets having sequence numbers from X-N+1 through X. Any packet with the sequence number X-N is discarded. Currently, N is set at 64, so only 64 packets can be tracked by the decryptor.

At times, however, the 64-packet window size is not sufficient. For example, Cisco quality of service (QoS) gives priority to high-priority packets, which could cause some low-priority packets to be discarded even though they could be one of the last 64 packets received by the decryptor. The IPsec Anti-Replay Window: Expanding and Disabling feature allows you to expand the window size, allowing the decryptor to keep track of more than 64 packets.

Increasing the anti-replay window size has no impact on throughput and security. The impact on memory is insignificant because only an extra 128 bytes per incoming IPsec SA is needed to store the sequence number on the decryptor. It is recommended that you use the full 1024 window size to eliminate any future anti-replay problems.

# How to Configure IPsec Anti-Replay Window: Expanding and Disabling

This section contains the following procedures:

- [Configuring IPsec Anti-Replay Window: Expanding and Disabling Globally, page 3](#) (optional)
- [Configuring IPsec Anti-Replay Window: Expanding and Disabling on a Crypto Map, page 4](#) (optional)

## Configuring IPsec Anti-Replay Window: Expanding and Disabling Globally

To configure IPsec Anti-Replay Window: Expanding and Disabling globally (so that it affects all SAs that are created— except for those that are specifically overridden on a per-crypto map basis), perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec security-association replay window-size [N]**
4. **crypto ipsec security-association replay disable**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                   | Purpose                                                                                                                                                                                                           |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                              | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>Enter your password if prompted.</li></ul>                                                                                                 |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                      | Enters global configuration mode.                                                                                                                                                                                 |
| Step 3 | <b>crypto ipsec security-association replay window-size [N]</b><br><br><b>Example:</b><br>Router (config)# crypto ipsec security-association replay window-size 256 | Sets the size of the SA replay window globally.<br><br><b>Note</b> Configure this command or the <b>crypto ipsec security-association replay disable</b> command. The two commands are not used at the same time. |
| Step 4 | <b>crypto ipsec security-association replay disable</b><br><br><b>Example:</b><br>Router (config)# crypto ipsec security-association replay disable                 | Disables checking globally.<br><br><b>Note</b> Configure this command or the <b>crypto ipsec security-association replay window-size</b> command. The two commands are not used at the same time.                 |

## Configuring IPsec Anti-Replay Window: Expanding and Disabling on a Crypto Map

To configure IPsec Anti-Replay Window: Expanding and Disabling on a crypto map so that it affects those SAs that have been created using a specific crypto map or profile, perform the following steps.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name seq-num* [**ipsec-isakmp**]
4. **set security-association replay window-size [N]**
5. **set security-association replay disable**

## DETAILED STEPS

|        | Command or Action                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                  |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                         |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                        | Enters global configuration mode.                                                                                                                                                                                                                                                        |
| Step 3 | <b>crypto map map-name seq-num [ipsec-isakmp]</b><br><br><b>Example:</b><br>Router (config)# crypto map ETH0 17 ipsec-isakmp                          | Enters crypto map configuration mode and creates a crypto profile that provides a template for configuration of dynamically created crypto maps.                                                                                                                                         |
| Step 4 | <b>set security-association replay window-size [N]</b><br><br><b>Example:</b><br>Router (crypto-map)# set security-association replay window-size 128 | Controls the SAs that are created using the policy specified by a particular crypto map, dynamic crypto map, or crypto profile.<br><br><b>Note</b> Configure this command or the <b>set security-association replay disable</b> command. The two commands are not used at the same time. |
| Step 5 | <b>set security-association replay disable</b><br><br><b>Example:</b><br>Router (crypto-map)# set security-association replay disable                 | Disables replay checking for a particular crypto map, dynamic crypto map, or crypto profile.<br><br><b>Note</b> Configure this command or the <b>set security-association replay window-size</b> command. The two commands are not used at the same time.                                |

## Troubleshooting Tips

- If your replay window size has not been set to a number that is high enough for the number of packets received, you will receive a system message such as the following:

```
*Nov 17 19:27:32.279: %CRYPTO-4-PKT_REPLAY_ERR: decrypt: replay check failed
connection id=1
```

The above message is generated when a received packet is judged to be outside the anti-replay window.

## Configuration Examples for IPsec Anti-Replay Window: Expanding and Disabling

This section includes the following configuration examples:

- [Global Expanding and Disabling of an Anti-Replay Window: Example, page 6](#)

- [Expanding and Disabling of an Anti-Replay Window for a Particular Crypto Map, Dynamic Crypto Map, or Crypto Profile: Example, page 7](#)

## Global Expanding and Disabling of an Anti-Replay Window: Example

The following example shows that the anti-replay window size has been set globally to 1024:

## Expanding and Disabling of an Anti-Replay Window for a Particular Crypto Map, Dynamic Crypto Map, or Crypto Profile: Example

The following example shows that anti-replay checking is disabled for IPsec connections to 172.17.150.2 but enabled (and the default window size is 64) for IPsec connections to 172.17.150.3 and 172.17.150.4:

# Command Reference

The following commands are introduced or modified in the feature or features

- **crypto ipsec security-association replay disable**
- **crypto ipsec security-association replay window-size**
- **set security-association replay disable**
- **set security-association replay window-size**

For information about these commands, see the Cisco IOS Security Command Reference at

[http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html).

For information about all Cisco IOS commands, see the Command Lookup Tool at

<http://tools.cisco.com/Support/CLILookup> or the Master Command List.

# IPSec Dead Peer Detection Periodic Message Option

---

**First Published: May 1, 2004**

**Last Updated: August 21, 2007**

The IPSec Dead Peer Detection Periodic Message Option feature allows you to configure your router to query the liveliness of its Internet Key Exchange (IKE) peer at regular intervals. The benefit of this approach over the default approach (on-demand dead peer detection) is earlier detection of dead peers.

## History for IPSec Dead Peer Detection Periodic Message Option Feature

| Release                  | Modification                                                    |
|--------------------------|-----------------------------------------------------------------|
| 12.3(7)T                 | This feature was introduced.                                    |
| 12.2(33)SRA              | This feature was integrated into Cisco IOS Release 12.2(33)SRA. |
| 12.2(33)SXH              | This feature was integrated into Cisco IOS Release 12.2(33)SXH. |
| Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers.   |

## Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

## Prerequisites for IPSec Dead Peer Detection Periodic Message Option

Before configuring the IPSec Dead Peer Detection Periodic Message Option feature, you should have the following:

- Familiarity with configuring IP Security (IPSec).
- An IKE peer that supports DPD (dead peer detection). Implementations that support DPD include the Cisco VPN 3000 concentrator, Cisco PIX Firewall, Cisco VPN Client, and Cisco IOS software in all modes of operation—site-to-site, Easy VPN remote, and Easy VPN server.

## Restrictions for IPSec Dead Peer Detection Periodic Message Option

Using periodic DPD potentially allows the router to detect an unresponsive IKE peer with better response time when compared to on-demand DPD. However, use of periodic DPD incurs extra overhead. When communicating to large numbers of IKE peers, you should consider using on-demand DPD instead.

## Information About IPSec Dead Peer Detection Periodic Message Option

To configure IPSec Dead Peer Detection Periodic Message Option, you should understand the following concepts:

- [How DPD and Cisco IOS Keepalive Features Work, page 2](#)
- [Using the IPSec Dead Peer Detection Periodic Message Option, page 3](#)
- [Using DPD and Cisco IOS Keepalive Features with Multiple Peers in the Crypto Map, page 3](#)
- [Using DPD in an Easy VPN Remote Configuration, page 3](#)

## How DPD and Cisco IOS Keepalive Features Work

DPD and Cisco IOS keepalives function on the basis of the timer. If the timer is set for 10 seconds, the router will send a “hello” message every 10 seconds (unless, of course, the router receives a “hello” message from the peer). The benefit of IOS keepalives and periodic DPD is earlier detection of dead peers. However, IOS keepalives and periodic DPD rely on periodic messages that have to be sent with considerable frequency. The result of sending frequent messages is that the communicating peers must encrypt and decrypt more packets.

DPD also has an on-demand approach. The contrasting on-demand approach is the default. With on-demand DPD, messages are sent on the basis of traffic patterns. For example, if a router has to send outbound traffic and the liveliness of the peer is questionable, the router sends a DPD message to query the status of the peer. If a router has no traffic to send, it never sends a DPD message. If a peer is dead, and the router never has any traffic to send to the peer, the router will not find out until the IKE or IPSec security association (SA) has to be rekeyed (the liveliness of the peer is unimportant if the router is not trying to communicate with the peer). On the other hand, if the router has traffic to send to the peer, and the peer does not respond, the router will initiate a DPD message to determine the state of the peer.

## Using the IPSec Dead Peer Detection Periodic Message Option

With the IPSec Dead Peer Detection Periodic Message Option feature, you can configure your router so that DPD messages are “forced” at regular intervals. This forced approach results in earlier detection of dead peers. For example, if a router has no traffic to send, a DPD message is still sent at regular intervals, and if a peer is dead, the router does not have to wait until the IKE SA times out to find out.

If you want to configure the DPD periodic message option, you should use the **crypto isakmp keepalive** command with the **periodic** keyword. If you do not configure the **periodic** keyword, the router defaults to the on-demand approach.

### Note

When the **crypto isakmp keepalive** command is configured, the Cisco IOS software negotiates the use of Cisco IOS keepalives or DPD, depending on which protocol the peer supports.

## Using DPD and Cisco IOS Keepalive Features with Multiple Peers in the Crypto Map

DPD and IOS keepalive features can be used in conjunction with multiple peers in the crypto map to allow for stateless failover. DPD allows the router to detect a dead IKE peer, and when the router detects the dead state, the router deletes the IPSec and IKE SAs to the peer. If you configure multiple peers, the router will switch over to the next listed peer for a stateless failover.

## Using DPD in an Easy VPN Remote Configuration

DPD can be used in an Easy VPN remote configuration. See the section [“Configuring DPD for an Easy VPN Remote” section on page 5](#).

## How to Configure IPSec Dead Peer Detection Periodic Message Option

This section contains the following procedures:

- [Configuring a Periodic DPD Message, page 4](#)
- [Configuring DPD and Cisco IOS Keepalives with Multiple Peers in the Crypto Map, page 4](#)
- [Configuring DPD for an Easy VPN Remote, page 5](#)
- [Verifying That DPD Is Enabled, page 6](#)

## Configuring a Periodic DPD Message

To configure a periodic DPD message, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp keepalive *seconds* [*retries*] [**periodic** | **on-demand**]**

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Step 3 | <b>crypto isakmp keepalive <i>seconds</i> [<i>retries</i>] [<b>periodic</b>   <b>on-demand</b>]</b><br><br><b>Example:</b><br>Router (config)# crypto isakmp keepalive 10 periodic | Allows the gateway to send DPD messages to the peer.<br><ul style="list-style-type: none"> <li>• <i>seconds</i>—Number of seconds between DPD messages.</li> <li>• <i>retries</i>—(Optional) Number of seconds between DPD retries if the DPD message fails.</li> <li>• <b>periodic</b>—(Optional) DPD messages are sent at regular intervals.</li> <li>• <b>on-demand</b>—(Optional) DPD retries are sent on demand. This is the default behavior.</li> </ul> |

## Configuring DPD and Cisco IOS Keepalives with Multiple Peers in the Crypto Map

To configure DPD and IOS keepalives to be used in conjunction with the crypto map to allow for stateless failover, perform the following steps. This configuration will cause a router to cycle through the peer list when it detects that the first peer is dead.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map *map-name seq-num ipsec-isakmp***
4. **set peer {*host-name* [**dynamic**] | *ip-address*}**

5. **set transform-set** *transform-set-name*
6. **match address** [*access-list-id* | *name*]

## DETAILED STEPS

|        | Command or Action                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                      |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                 | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                             |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                         | Enters global configuration mode.                                                                                                                                                                                                                                                            |
| Step 3 | <b>crypto map</b> <i>map-name</i> <i>seq-num</i> <b>ipsec-isakmp</b><br><br><b>Example:</b><br>Router (config)# crypto map green 1 ipsec-isakmp        | Enters crypto map configuration mode and creates or modifies a crypto map entry. <ul style="list-style-type: none"> <li>The <b>ipsec-isakmp</b> keyword indicates that IKE will be used to establish the IPSec SAs for protecting the traffic specified by this crypto map entry.</li> </ul> |
| Step 4 | <b>set peer</b> { <i>host-name</i> [ <b>dynamic</b> ]   <i>ip-address</i> }<br><br><b>Example:</b><br>Router (config-crypto-map)# set peer 10.12.12.12 | Specifies an IPSec peer in a crypto map entry. <ul style="list-style-type: none"> <li>You can specify multiple peers by repeating this command.</li> </ul>                                                                                                                                   |
| Step 5 | <b>set transform-set</b> <i>transform-set-name</i><br><br><b>Example:</b><br>Router (config-crypto-map)# set transform-set txfm                        | Specifies which transform sets can be used with the crypto map entry. <ul style="list-style-type: none"> <li>You can specify more than one transform set name by repeating this command.</li> </ul>                                                                                          |
| Step 6 | <b>match address</b> [ <i>access-list-id</i>   <i>name</i> ]<br><br><b>Example:</b><br>Router (config-crypto-map)# match address 101                   | Specifies an extended access list for a crypto map entry.                                                                                                                                                                                                                                    |

## Configuring DPD for an Easy VPN Remote

To configure DPD in an Easy VPN remote configuration, perform the following steps. This configuration also will cause a router to cycle through the peer list when it detects that the first peer is dead.

### Note

IOS keepalives are not supported for Easy VPN remote configurations.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**

3. **crypto ipsec client ezvpn** *name*
4. **connect** {**auto** | **manual**}
5. **group** *group-name* **key** *group-key*
6. **mode** {**client** | **network-extension**}
7. **peer** {*ipaddress* | *hostname*}

## DETAILED STEPS

|               |                                                                                                                                                 |                                                                                                                                                                                                                                                                          |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                          | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>Enter your password if prompted.</li></ul>                                                                                                                                                           |

| <b>Step 6</b> | <b>mode</b> { <b>client</b>   <b>network-extension</b> }<br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# mode client                    | Specifies the VPN mode of operation of the router.                                                                                                                                                                                                                       |
| <b>Step 7</b> | <b>peer</b> { <i>ipaddress</i>   <i>hostname</i> }<br><br><b>Example:</b><br>Router (config-crypto-ezvpn)# peer 10.10.10.10                     | Sets the peer IP address or host name for the VPN connection. <ul style="list-style-type: none"><li>A hostname can be specified only when the router has a DNS server available for host-name resolution.</li><li>This command can be repeated multiple times.</li></ul> |

## Verifying That DPD Is Enabled

DPD allows the router to clear the IKE state when a peer becomes unreachable. If DPD is enabled and the peer is unreachable for some time, you can use the **clear crypto session** command to manually clear IKE and IPSec SAs.

The **debug crypto isakmp** command can be used to verify that DPD is enabled.

## SUMMARY STEPS

1. **enable**
2. **clear crypto session** [**local** *ip-address* [**port** *local-port*]] [**remote** *ip-address* [**port** *remote-port*]] | [**fvr** *vrf-name*] [**ivrf** *vrf-name*]
3. **debug crypto isakmp**

## DETAILED STEPS

# Configuration Examples for IPSec Dead Peer Detection Periodic Message Option

This section provides the following configuration examples:

- [Site-to-Site Setup with Periodic DPD Enabled: Example, page 7](#)
- [Easy VPN Remote with DPD Enabled: Example, page 8](#)
- [Verifying DPD Configuration Using the debug crypto isakmp Command: Example, page 8](#)
- [DPD and Cisco IOS Keepalives Used in Conjunction with Multiple Peers in a Crypto Map: Example, page 11](#)
- [DPD Used in Conjunction with Multiple Peers for an Easy VPN Remote: Example, page 11](#)

## Site-to-Site Setup with Periodic DPD Enabled: Example

The following configurations are for a site-to-site setup with no periodic DPD enabled. The configurations are for the IKE Phase 1 policy and for the IKE preshared key.

### IKE Phase 1 Policy

```
crypto isakmp policy 1
 encryption 3des
```

```

 authentication pre-share
 group 2
!

IKE Preshared Key
crypto isakmp key kd94j1ksldz address 10.2.80.209 255.255.255.0
crypto isakmp keepalive 10 periodic
crypto ipsec transform-set esp-3des-sha esp-3des esp-sha-hmac
crypto map test 1 ipsec-isakmp
 set peer 10.2.80.209
 set transform-set esp-3des-sha
 match address 101
!
!
interface FastEthernet0
 ip address 10.1.32.14 255.255.255.0
 speed auto
 crypto map test
!

```

## Easy VPN Remote with DPD Enabled: Example

The following configuration tells the router to send a periodic DPD message every 30 seconds. If the peer fails to respond to the DPD R\_U\_THERE message, the router will resend the message every 20 seconds (four transmissions altogether).

```

crypto isakmp keepalive 30 20 periodic
crypto ipsec client ezvpn ezvpn-config
 connect auto
 group unity key preshared
 mode client
 peer 10.2.80.209
!
!
interface Ethernet0
 ip address 10.2.3.4 255.255.255.0
 half-duplex
 crypto ipsec client ezvpn ezvpn-config inside
!
interface FastEthernet0
 ip address 10.1.32.14 255.255.255.0
 speed auto
 crypto ipsec client ezvpn ezvpn-config outside

```

## Verifying DPD Configuration Using the debug crypto isakmp Command: Example

The following sample output from the **debug crypto isakmp** command verifies that IKE DPD is enabled:

```
*Mar 25 15:17:14.131: ISAKMP:(0:1:HW:2):IKE_DPD is enabled, initializing timers
```

To see that IKE DPD is enabled (and that the peer supports DPD): when periodic DPD is enabled, you should see the following debug messages at the interval specified by the command:

```
*Mar 25 15:18:52.107: ISAKMP:(0:1:HW:2): sending packet to 10.2.80.209 my_port
500 peer_port 500 (I) QM_IDLE
*Mar 25 15:18:52.107: ISAKMP:(0:1:HW:2):purging node 899852982 *Mar 25 15:18:52.111:
ISAKMP:(0:1:HW:2):Input = IKE_MSG_FROM_TIMER,
IKE_TIMER_IM_ALIVE
*Mar 25 15:18:52.111: ISAKMP:(0:1:HW:2):Old State = IKE_P1_COMPLETE New State =
IKE_P1_COMPLETE
```

The above message corresponds to sending the DPD R\_U\_THERE message.

```
*Mar 25 15:18:52.123: ISAKMP (0:268435457): received packet from 10.2.80.209
dport 500 sport 500 Global (I) QM_IDLE
*Mar 25 15:18:52.123: ISAKMP: set new node -443923643 to QM_IDLE *Mar 25 15:18:52.131:
ISAKMP:(0:1:HW:2): processing HASH payload. message ID =
-443923643
*Mar 25 15:18:52.131: ISAKMP:(0:1:HW:2): processing NOTIFY R_U_THERE_ACK protocol 1
spi 0, message ID = -443923643, sa = 81BA4DD4
*Mar 25 15:18:52.135: ISAKMP:(0:1:HW:2): DPD/R_U_THERE_ACK received from peer
10.2.80.209, sequence 0x9
*Mar 25 15:18:52.135: ISAKMP:(0:1:HW:2):deleting node -443923643 error FALSE
reason "informational (in) state 1"
*Mar 25 15:18:52.135: ISAKMP:(0:1:HW:2):Input = IKE_MSG_FROM_PEER, IKE_INFO_NOTIFY *Mar
25 15:18:52.135: ISAKMP:(0:1:HW:2):Old State = IKE_P1_COMPLETE New State =
IKE_P1_COMPLETE
```

The above message corresponds to receiving the acknowledge (ACK) message from the peer.

```

The above message shows what happens when the remote peer is unreachable. The router sends one DPD R\_U\_THERE message and four retransmissions before it finally deletes the IPsec and IKE SAs.

## DPD and Cisco IOS Keepalives Used in Conjunction with Multiple Peers in a Crypto Map: Example

The following example shows that DPD and Cisco IOS keepalives are used in conjunction with multiple peers in a crypto map configuration when IKE will be used to establish the security associations (SAs). In this example, an SA could be set up to the IPsec peer at 10.0.0.1, 10.0.0.2, or 10.0.0.3.

```
crypto map green 1 ipsec-isakmp
 set peer 10.0.0.1
 set peer 10.0.0.2
 set peer 10.0.0.3
 set transform-set txfm
 match address 101
```

## DPD Used in Conjunction with Multiple Peers for an Easy VPN Remote: Example

The following example shows that DPD is used in conjunction with multiple peers in an Easy VPN remote configuration. In this example, an SA could be set up to the IPsec peer at 10.10.10.10, 10.2.2.2, or 10.3.3.3.

```
crypto ipsec client ezvpn ezvpn-config
 connect auto
 group unity key preshared
 mode client
 peer 10.10.10.10
 peer 10.2.2.2
 peer 10.3.3.3
```

# IPsec Preferred Peer

---

**First Published: March 28, 2005**

**Last Updated: August 21, 2007**

The IP Security (IPsec) Preferred Peer feature allows you to control the circumstances by which multiple peers on a crypto map are tried in a failover scenario.

This feature includes the following capabilities:

- Default peer configuration
- IPsec idle-timer usage with default peer

## **Finding Feature Information in This Module**

*Your Cisco IOS software release may not support all of the features documented in this module.* To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for IPsec Preferred Peer” section on page 9](#).

## **Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images**

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

- [Glossary, page 10](#)

## Prerequisites for IPsec Preferred Peer

- You must have a properly defined, complete crypto map.

## Restrictions for IPsec Preferred Peer

Default peer:

- This feature must be used in conjunction with Dead Peer Detection (DPD). It is most effective on a remote site running DPD in periodic mode. DPD detects the failure of a device quickly and resets the peer list so that the default peer is tried for the next attempted connection.
- Only one peer can be designated as the default peer in a crypto map.
- The default peer must be the first peer in the peer list.

IPsec idle-timer usage with default peer:

- This feature works only on the crypto map for which it is configured. You cannot configure the capability globally for all crypto maps.
- If there is a global idle timer, the crypto map idle-timer value must be different from the global value; otherwise, the idle timer is not added to the crypto map.

## Information About IPsec Preferred Peer

To configure IPsec Preferred Peer, you need to understand the following concepts:

- [IPsec, page 2](#)
- [Dead Peer Detection, page 3](#)
- [Default Peer Configuration, page 3](#)
- [Idle Timers, page 4](#)
- [IPsec Idle-Timer Usage with Default Peer, page 4](#)
- [Peers on Crypto Maps, page 4](#)

## IPsec

IPsec is a framework of open standards developed by the Internet Engineering Task Force (IETF). IPsec provides security for transmission of sensitive information over unprotected networks such as the Internet. IPsec acts at the network layer, protecting and authenticating Internet Protocol (IP) packets between participating IPsec devices (peers), such as Cisco routers.

IPsec provides the following network security services. These services are optional. In general, local security policy dictates the use of one or more of these services:

- **Data Confidentiality**—The IPsec sender can encrypt packets before transmitting them across a network.

- **Data Integrity**—The IPsec receiver can authenticate packets sent by the IPsec sender to ensure that the data has not been altered during transmission.
- **Data Origin Authentication**—The IPsec receiver can authenticate the source of the IPsec packets sent.
- **Anti-Replay**—The IPsec receiver can detect and reject replayed packets.

With IPsec, data can be transmitted across a public network without fear of observation, modification, or spoofing. This enables applications such as Virtual Private Networks (VPNs), including intranets, extranets, and remote user access.

IPsec provides secure tunnels between two peers, such as two routers. You define which packets are considered sensitive and should be sent through these secure tunnels, and you define the parameters that should be used to protect these sensitive packets, by specifying characteristics of these tunnels. When the IPsec peer sees such a sensitive packet, it sets up the appropriate secure tunnel and sends the packet through the tunnel to the remote peer.

## Dead Peer Detection

The VPN Client uses a keepalive mechanism called Dead Peer Detection (DPD) to check the availability of the VPN device on the other side of an IPsec tunnel. If the network is unusually busy or unreliable, you can increase the number of seconds that the VPN Client will wait before deciding whether the peer is no longer active.

Keepalive packets are not sent if traffic is received. This lowers the overhead associated with DPD, because on a heavily loaded network very few keepalive packets will be sent because traffic is being received on the tunnels. In addition, DPD sends keepalive packets only if there is user traffic to send (and no user traffic is received).

You can configure Internet Key Exchange (IKE) DPD so that DPD sends the keepalive packets whether or not there is outbound user data. That is, as long as there is no inbound user data, the keepalive packets are sent at the configured keepalive interval.

## Default Peer Configuration

If a connection timeout occurs, the connection to the current peer is closed. The **set peer** command allows you to configure the first peer as the default peer. If there is a default peer, the next time a connection is initiated, the connection is directed to the default peer instead of to the next peer in the peer list. If the default peer is unresponsive, the next peer in the peer list becomes the current peer and future connections through the crypto map try that peer.

This capability is useful when traffic on a physical link stops due to the failure of a remote peer. DPD indicates that the remote peer is unavailable, but that peer remains the current peer.

A default peer facilitates the failover to a preferred peer that was previously unavailable, but has returned to service. Users can give preference to certain peers in the event of a failover. This is useful if the original failure was due to a network connectivity problem rather than failure of the remote peer.

## Idle Timers

When a router running Cisco IOS software creates an IPsec security association (SA) for a peer, resources must be allocated to maintain the SA. The SA requires both memory and several managed timers. For idle peers, these resources are wasted. If enough resources are wasted by idle peers, the router could be prevented from creating new SAs with other peers.

IPsec SA idle timers increase the availability of resources by deleting SAs associated with idle peers. Because IPsec SA idle timers prevent the wasting of resources by idle peers, more resources are available to create new SAs when required.

If IPsec SA idle timers are not configured, only the global lifetimes for IPsec SAs are applied. SAs are maintained until the global timers expire, regardless of peer activity.

## IPsec Idle-Timer Usage with Default Peer

If all connections to the current peer time out, the next time a connection is initiated it is directed to the default peer configured in the **set peer** command. If a default peer is not configured and there is a connection timeout, the current peer remains the one that timed out.

This enhancement helps facilitate a failover to a preferred peer that was previously unavailable but is in service now.

## Peers on Crypto Maps

A crypto map set can contain multiple entries, each with a different access list. The router searches the crypto map entries in order, and attempts to match the packet to the access list specified in that entry.

When a packet matches a **permit** entry in a particular access list, and the corresponding crypto map entry is tagged as Cisco, connections are established with the remote peer as specified in the set peer statements within the crypto map.

## How to Configure IPsec Preferred Peer

This section contains the following procedures:

- [Configuring a Default Peer, page 4](#) (required)
- [Configuring the Idle Timer, page 5](#) (optional)

## Configuring a Default Peer

To configure a default peer, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name seq-num* [**ipsec-isakmp**] [**dynamic** *dynamic-map-name*] [**discover**] [**profile** *profile-name*]

4. **set peer** {*host-name* [dynamic] [default] | *ip-address* [default] }
5. **exit**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                       | Purpose                                                                                                                                                                                                                       |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                                  | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                              |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                                          | Enters global configuration mode.                                                                                                                                                                                             |
| Step 3 | <b>crypto map</b> <i>map-name</i> <i>seq-num</i> [ipsec-isakmp] [dynamic <i>dynamic-map-name</i> ] [discover] [profile <i>profile-name</i> ]<br><br><b>Example:</b><br>Router(config)# crypto map mymap 10 ipsec-isakmp | Enters crypto map configuration mode. Creates or modifies a crypto map entry, creates a crypto profile that provides a template for configuration of dynamically created crypto maps, or configures a client accounting list. |
| Step 4 | <b>set peer</b> { <i>host-name</i> [dynamic] [default]   <i>ip-address</i> [default] }<br><br><b>Example:</b><br>Router(config-crypto-map)# set peer 10.0.0.2 default                                                   | Specifies an IPsec peer in a crypto map entry. Ensures that the first peer specified is defined as the default peer.                                                                                                          |
| Step 5 | <b>exit</b><br><br><b>Example:</b><br>Router(config-crypto-map)# exit                                                                                                                                                   | Exits crypto map configuration mode and returns to global configuration mode.                                                                                                                                                 |

## Configuring the Idle Timer

To configure the idle timer, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name* *seq-num* [ipsec-isakmp] [dynamic *dynamic-map-name*] [discover] [profile *profile-name*]
4. **set security-association idletime** *seconds* [default]
5. **exit**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                | Purpose                                                                                                                                                                                                                       |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                           | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                              |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                   | Enters global configuration mode.                                                                                                                                                                                             |
| Step 3 | <b>crypto map</b> <i>map-name seq-num [ipsec-isakmp] [dynamic dynamic-map-name] [discover] [profile profile-name]</i><br><br><b>Example:</b><br>Router(config)# crypto map mymap 10 ipsec-isakmp | Enters crypto map configuration mode. Creates or modifies a crypto map entry, creates a crypto profile that provides a template for configuration of dynamically created crypto maps, or configures a client accounting list. |
| Step 4 | <b>set security-association idletime</b> <i>seconds [default]</i><br><br><b>Example:</b><br>Router(config-crypto-map)# set security-association idletime 120 default                             | Specifies the maximum amount of time for which the current peer can be idle before the default peer is used.                                                                                                                  |
| Step 5 | <b>exit</b><br><br><b>Example:</b><br>Router(config-crypto-map)# exit                                                                                                                            | Exits crypto map configuration mode and returns to global configuration mode.                                                                                                                                                 |

## Configuration Examples for IPsec Preferred Peer

- [Configuring a Default Peer: Example, page 6](#)
- [Configuring the IPsec Idle Timer: Example, page 6](#)

### Configuring a Default Peer: Example

The following example shows that the first peer, at IP address 10.1.1.1, is the default peer:

```
crypto map tohub 1 ipsec-isakmp
 set peer 10.1.1.1 default
 set peer 10.2.2.2
```

### Configuring the IPsec Idle Timer: Example

In the following example, if the current peer is idle for 120 seconds, the default peer 10.1.1.1 (which was specified in the **set peer** command) is used for the next attempted connection:

```
crypto map tohub 1 ipsec-isakmp
```

```
set peer 10.1.1.1 default
set peer 10.2.2.2
set security-association idletime 120 default
```

## Command Reference

The following commands are introduced or modified in the feature or features

- **set peer (IPsec)**
- **set security-association idle-time**

For information about these commands, see the Cisco IOS Security Command Reference at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html).

For information about all Cisco IOS commands, see the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the Master Command List.

## Feature Information for IPsec Preferred Peer

[Table 1](#) lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Note

[Table 1](#) lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1** *Feature Information for IPsec Preferred Peer*

| Feature Name         | Releases                                | Feature Information                                                                                                                                                                                                                                                                                                                                                         |

## Glossary

**crypto access list**—A list that defines which IP traffic will be protected by crypto and which traffic will not be protected by crypto.

**crypto map**—A map that specifies which traffic should be protected by IPsec, where IPsec-protected traffic should be sent, and what IPsec transform sets should be applied to this traffic.

**dead peer detection**—A feature that allows the router to detect an unresponsive peer.

**keepalive message**—A message sent by one network device to inform another network device that the virtual circuit between the two is still active.

**peer**—Router or other device that participates in IPsec and IKE. In IPsec, peers are devices or entities that communicate securely either through the exchange of keys or the exchange of digital certificates.

**SA**—security association. An instance of security policy and keying material applied to a data flow. Both IKE and IPsec use SAs, although SAs are independent of one another. IPsec SAs are unidirectional and are unique in each security protocol. An IKE SA is used by IKE only, and unlike the IPsec SA, it is bidirectional. IKE negotiates and establishes SAs on behalf of IPsec. A user also can establish IPsec SAs manually. A set of SAs are needed for a protected data pipe, one per direction per protocol. For example, if you have a pipe that supports Encapsulating Security Payload (ESP) between peers, one ESP SA is required for each direction. SAs are identified uniquely by destination (IPsec endpoint) address, security protocol (AH or ESP), and security parameter index (SPI).

**transform set**—An acceptable combination of security protocols, algorithms, and other settings to apply to IPsec-protected traffic. During the IPsec security association negotiation, the peers agree to use a particular transform set when protecting a particular data flow.

## IPSec Security Association Idle Timers

When a router running the Cisco IOS software creates an IPsec security association (SA) for a peer, resources must be allocated to maintain the SA. The SA requires both memory and several managed timers. For idle peers, these resources are wasted. If enough resources are wasted by idle peers, the router could be prevented from creating new SAs with other peers. The IPsec Security Association Idle Timers feature introduces a configurable idle timer to monitor SAs for activity, allowing SAs for idle peers to be deleted. Benefits of this feature include:

- Increased availability of resources
- Improved scalability of Cisco IOS IPsec deployments

### Feature Specifications for IPsec Security Association Idle Timers

#### Feature History

| Release                  | Modification                                                                                                                                       |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 12.2(15)T                | This feature was introduced.                                                                                                                       |
| 12.3(14)T                | The <b>set security-association idle-time</b> command was added, allowing for the configuration of an IPsec idle timer for a specified crypto map. |
| Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers.                                                                                      |

#### Supported Platforms

Cisco 1700 series access routers, Cisco 2400 series integrated access devices, Cisco 2600 series multiservice platforms, Cisco 3600 series multiservice platforms, Cisco 3700 series multiservice access routers, Cisco 7100 series VPN routers, Cisco 7200 series routers, Cisco 7400 series routers, Cisco 7500 series routers, Cisco 801–804 ISDN routers, Cisco 805 serial router, Cisco 806 broadband router, Cisco 811, Cisco 813, Cisco 820, Cisco 827 ADSL router, Cisco 828 G.SHDSL router, Cisco 8850-RPM, Cisco 950, Cisco AS5350 universal gateway, Cisco AS5400 series universal gateways, Cisco integrated communications system 7750, Cisco MC3810 series multiservice access concentrators, Cisco ubr7200, Cisco ubr900 series cable access routers

### Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

## Prerequisites for IPsec Security Association Idle Timers

You must configure Internet Key Exchange (IKE) as described in the “[Configuring Internet Key Exchange Security Protocol](#)” chapter of the *Cisco IOS Security Configuration Guide*, Release 12.2.

## Information About IPsec Security Association Idle Timers

To configure the IPsec Security Association Idle Timers feature, you must understand the following concepts:

- [Lifetimes for IPsec Security Associations, page 2](#)
- [IPsec Security Association Idle Timers, page 2](#)
- [Benefits of IPsec Security Association Idle Timers, page 3](#)

## Lifetimes for IPsec Security Associations

The Cisco IOS software currently allows the configuration of lifetimes for IPsec SAs. Lifetimes can be configured globally or per crypto map. There are two lifetimes: a “timed” lifetime and a “traffic-volume” lifetime. A security association expires after the first of these lifetimes is reached.

## IPsec Security Association Idle Timers

The IPsec SA idle timers are different from the global lifetimes for IPsec SAs. The expiration of the global lifetime is independent of peer activity. The IPsec SA idle timer allows SAs associated with inactive peers to be deleted before the global lifetime has expired.

If the IPsec SA idle timers are not configured, only the global lifetimes for IPsec SAs are applied. SAs are maintained until the global timers expire, regardless of peer activity.

**Note**

If the last IPsec SA to a given peer is deleted due to idle timer expiration, the Internet Key Exchange (IKE) SA to that peer will also be deleted.

## Benefits of IPsec Security Association Idle Timers

### Increased Availability of Resources

Configuring the IPsec Security Association Idle Timers feature increases the availability of resources by deleting SAs associated with idle peers.

### Improved Scalability of Cisco IOS IPsec Deployments

Because the IPsec Security Association Idle Timers feature prevents the wasting of resources by idle peers, more resources will be available to create new SAs as required.

## How to Configure IPsec Security Association Idle Timers

- [Configuring the IPsec SA Idle Timer Globally, page 3](#)
- [Configuring the IPsec SA Idle Timer per Crypto Map, page 4](#)

### Configuring the IPsec SA Idle Timer Globally

This task configures the IPsec SA idle timer globally. The idle timer configuration will be applied to all SAs.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec security-association idle-time *seconds***

#### DETAILED STEPS

|        | Command or Action                                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                   |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                      | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                                                                                                                                                          |

| Step 3 | <b>crypto ipsec security-association idle-time <i>seconds</i></b><br><br><b>Example:</b><br>Router(config)# crypto ipsec security-association idle-time 600 | Configures the IPsec SA idle timer. <ul style="list-style-type: none"><li>• The <i>seconds</i> argument specifies the time, in seconds, that the idle timer will allow an inactive peer to maintain an SA. Valid values for the <i>seconds</i> argument range from 60 to 86400.</li></ul> |

# Configuring the IPSec SA Idle Timer per Crypto Map

This task configures the IPSec SA idle timer for a specified crypto map. The idle timer configuration will be applied to all SAs under the specified crypto map.

**Note**

This configuration task was available effective with Cisco IOS Release 12.3(14)T.

## SUMMARY STEPS

- enable**
- configure terminal**
- crypto map** *map-name seq-number ipsec-isakmp*
- set security-association idle-time** *seconds*

## DETAILED STEPS

|        | Command or Action                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                   |

| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                               | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                          |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                       | Enters global configuration mode.                                                                                                                                                                                                                                                                                         |
| Step 3 | <b>crypto map</b> <i>map-name seq-number ipsec-isakmp</i><br><br><b>Example:</b><br>Router(config)# crypto map test 1 ipsec-isakmp                   | Creates or modifies a crypto map entry and enters crypto map configuration mode.                                                                                                                                                                                                                                          |
| Step 4 | <b>set security-association idle-time</b> <i>seconds</i><br><br><b>Example:</b><br>Router(config-crypto-map)# set security-association idle-time 600 | Specifies the maximum amount of time for which the current peer can be idle before the default peer is used. <ul style="list-style-type: none"> <li>The <i>seconds</i> argument is the number of seconds for which the current peer can be idle before the default peer is used. Valid values are 60 to 86400.</li> </ul> |

# Configuration Examples for IPSec Security Association Idle Timers

- [Configuring the IPSec SA Idle Timer Globally Example, page 5](#)
- [Configuring the IPSec SA Idle Timer per Crypto Map Example, page 5](#)

## Configuring the IPSec SA Idle Timer Globally Example

The following example globally configures the IPSec SA idle timer to drop SAs for inactive peers after 600 seconds:

```
crypto ipsec security-association idle-time 600
```

## Configuring the IPSec SA Idle Timer per Crypto Map Example

The following example configures the IPSec SA idle timer for the crypto map named test to drop SAs for inactive peers after 600 seconds:

```
crypto map test 1 ipsec-isakmp
set security-association idle-time 600
```

**Note**

---

The above configuration was not available until Cisco IOS Release 12.3(14)T.

# IPSec VPN Accounting

The IPSec VPN Accounting feature allows for a session to be accounted for by indicating when the session starts and when it stops.

A VPN session is defined as an Internet Key Exchange (IKE) security association (SA) and the one or more SA pairs that are created by the IKE SA. The session starts when the first IP Security (IPSec) pair is created and stops when all IPSec SAs are deleted.

Session identifying information and session usage information is passed to the Remote Authentication Dial-In User Service (RADIUS) server via standard RADIUS attributes and vendor-specific attributes (VSAs).

## Feature Specifications for IPSec VPN Accounting

### Feature History

| Release                  | Modification                                                  |
|--------------------------|---------------------------------------------------------------|
| 12.2(15)T                | This feature was introduced.                                  |
| Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers. |

### Supported Platforms

Cisco 2610–2613, Cisco 2620–Cisco 2621, Cisco 2650–Cisco 2651, Cisco 3620, Cisco 3640, Cisco 3660, Cisco 3725, Cisco 3745, Cisco 7100, Cisco 7200, Cisco 7400, Cisco ubr7100, Cisco ubr7200.

## Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

## Prerequisites for IPsec VPN Accounting

You need to understand how to configure RADIUS and authentication, authorization, and accounting (AAA) accounting. For information about configuring RADIUS and AAA, refer to the following documents:

- *Configuring Basic AAA RADIUS for Dial-In Clients*
- [How Does RADIUS Work?](#)
- The chapter “[Configuring RADIUS](#)” in the *Cisco IOS Security Configuration Guide*
- The chapter “[RADIUS Commands](#)” in the *Cisco IOS Security Command Reference*, Release 12.2
- The chapter “[Configuring Accounting](#)” in the *Cisco IOS Security Configuration Guide*, Release 12.2

You also need to know how to configure IPsec accounting. For information about configuring IPsec accounting, refer to the chapter “[Configuring IPsec Network Security](#)” in the *Cisco IOS Security Configuration Guide*, Release 12.2.

## Information About IPsec VPN Accounting

To configure IPsec VPN accounting, you must understand the following concepts:

- [RADIUS Accounting](#), page 2
- [IKE and IPsec Subsystem Interaction](#), page 4

## RADIUS Accounting

For many large networks, it is required that user activity be recorded for auditing purposes. The method that is used most is RADIUS accounting.

RADIUS accounting allows for a session to be accounted for by indicating when the session starts and when it stops. Additionally, session identifying information and session usage information will be passed to the RADIUS server via RADIUS attributes and VSAs.

## RADIUS Start Accounting

The RADIUS Start packet contains many attributes that generally identify who is requesting the service and of what the property of that service consists. [Table 1](#) represents the attributes required for the start.

**Table 1** *RADIUS Accounting Start Packet Attributes*

| <b>RADIUS Attributes Value</b> | <b>Attribute</b>    | <b>Description</b>                                                                                                                                              |
|--------------------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1                              | user-name           | Username used in extended authentication (XAUTH). The username may be NULL when XAUTH is not used.                                                              |
| 4                              | nas-ip-address      | Identifying IP address of the network access server (NAS) that serves the user. It should be unique to the NAS within the scope of the RADIUS server.           |
| 5                              | nas-port            | Physical port number of the NAS that serves the user.                                                                                                           |
| 8                              | framed-ip-address   | Private address allocated for the IP Security (IPSec) session.                                                                                                  |
| 40                             | acct-status-type    | Status type. This attribute indicates whether this accounting request marks the beginning (start), the end (stop), or an update of the session.                 |
| 41                             | acct-delay-time     | Number of seconds the client has been trying to send a particular record.                                                                                       |
| 44                             | acct-session-id     | Unique accounting identifier that makes it easy to match start and stop records in a log file.                                                                  |
| 26                             | vrf-id              | String that represents the name of the Virtual Route Forwarder (VRF).                                                                                           |
| 26                             | isakmp-initiator-ip | Endpoint IP address of the remote Internet Key Exchange (IKE) initiator (V4).                                                                                   |
| 26                             | isakmp-group-id     | Name of the VPN group profile used for accounting.                                                                                                              |
| 26                             | isakmp-phase1-id    | Phase 1 identification (ID) used by IKE (for example, domain name [DN], fully qualified domain name [FQDN], IP address) to help identify the session initiator. |

## RADIUS Stop Accounting

The RADIUS Stop packet contains many attributes that identify the usage of the session. Table 2 represents the additional attributes required for the RADIUS stop packet. It is possible that only the stop packet will be sent without the start if configured to do so. If only the stop packet is sent, this allows an easy way to reduce the number of records going to the AAA server.

**Table 2** *RADIUS Accounting Stop Packet Attributes*

| <b>RADIUS Attributes Value</b> | <b>Attribute</b>   | <b>Description</b>                                                                                                    |
|--------------------------------|--------------------|-----------------------------------------------------------------------------------------------------------------------|
| 42                             | acct-input-octets  | Number of octets that have been received from the Unity client over the course of the service that is being provided. |
| 43                             | acct-output-octets | Number of octets that have been sent to the Unity client in the course of delivering this service.                    |

**Table 2** *RADIUS Accounting Stop Packet Attributes (continued)*

| <b>RADIUS Attributes Value</b> | <b>Attribute</b>      | <b>Description</b>                                                                                                                  |
|--------------------------------|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| 46                             | acct-session-time     | Length of time (in seconds) that the Unity client has received service.                                                             |
| 47                             | acct-input-packets    | Quantity of packets that have been received from the Unity client in the course of delivering this service.                         |
| 48                             | acct-output-packets   | Quantity of packets that have been sent to the Unity client in the course of delivering this service.                               |
| 49                             | acct-terminate-cause  | For future use.                                                                                                                     |
| 52                             | acct-input-gigawords  | How many times the Acct-Input-Octets counter has wrapped around the $2^{32}$ (2 to the 32nd power) over the course of this service. |
| 52                             | acct-output-gigawords | How many times the Acct-Input-Octets counter has wrapped around the $2^{32}$ (2 to the 32nd power) over the course of this service. |

## RADIUS Update Accounting

RADIUS accounting updates are supported. Packet and octet counts are shown in the updates. To learn more about AAA, refer to the following documents:

- [Configuring Basic AAA RADIUS for Dial-In Clients](#)
- The chapter “[RADIUS Commands](#)” in the *Cisco IOS Security Command Reference*, Release 12.2 T
- [How to Assign Privilege Levels with TACACS+ and RADIUS](#)
- Other AAA documentation at the [Cisco.com](#) website

## IKE and IPsec Subsystem Interaction

### Accounting Start

If IPsec accounting is configured, after IKE phases are complete, an accounting start record is generated for the session. New accounting records are not generated during a rekeying.

The following is an account start record that was generated on a router and that is to be sent to the AAA server that is defined:

```
*Aug 23 04:06:20.131: RADIUS(00000002): sending
*Aug 23 04:06:20.131: RADIUS(00000002): Send Accounting-Request to 10.1.1.4:1646 id 4, len 220
*Aug 23 04:06:20.131: RADIUS: authenticator 38 F5 EB 46 4D BE 4A 6F - 45 EB EF 7D B7 19 FB 3F
*Aug 23 04:06:20.135: RADIUS: Acct-Session-Id [44] 10 "00000001"
*Aug 23 04:06:20.135: RADIUS: Vendor, Cisco [26] 31
*Aug 23 04:06:20.135: RADIUS: Cisco AVpair [1] 25 "isakmp-group-id=cclient"
*Aug 23 04:06:20.135: RADIUS: Framed-IP-Address [8] 6 10.13.13.1
*Aug 23 04:06:20.135: RADIUS: Vendor, Cisco [26] 20
*Aug 23 04:06:20.135: RADIUS: Cisco AVpair [1] 14 "vrf-id=cisco"
*Aug 23 04:06:20.135: RADIUS: Vendor, Cisco [26] 35
```

```
*Aug 23 04:06:20.135: RADIUS: Cisco AVpair [1] 29 "isakmp-initator-ip=11.1.2.2"
*Aug 23 04:06:20.135: RADIUS: Vendor, Cisco [26] 36
*Aug 23 04:06:20.135: RADIUS: Cisco AVpair [1] 30 "connect-progress=No
Progress"
*Aug 23 04:06:20.135: RADIUS: User-Name [1] 13 "joe@cclient"
*Aug 23 04:06:20.135: RADIUS: Acct-Status-Type [40] 6 Start [1]
*Aug 23 04:06:20.135: RADIUS: Vendor, Cisco [26] 25
*Aug 23 04:06:20.135: RADIUS: cisco-nas-port [2] 19 "FastEthernet0/0.1"
*Aug 23 04:06:20.135: RADIUS: NAS-Port [5] 6 0
*Aug 23 04:06:20.135: RADIUS: NAS-IP-Address [4] 6 10.1.1.147
*Aug 23 04:06:20.135: RADIUS: Acct-Delay-Time [41] 6 0
*Aug 23 04:06:20.139: RADIUS: Received from id 21645/4 10.1.1.4:1646, Accounting-response,
len 20
*Aug 23 04:06:20.139: RADIUS: authenticator B7 E3 D0 F5 61 9A 89 D8 - 99 A6 8A 8A 98 79
9D 5D
```

## Accounting Stop

An accounting stop packet is generated when there are no more flows (IPSec SA pairs) with the remote peer.

The accounting stop records contain the following information:

- Packets out
- Packets in
- Octets out
- Gigawords in
- Gigawords out

Below is an account start record that was generated on a router. The account start record is to be sent to the AAA server that is defined.

```
*Aug 23 04:20:16.519: RADIUS(00000003): Using existing nas_port 0
*Aug 23 04:20:16.519: RADIUS(00000003): Config NAS IP: 100.1.1.147
*Aug 23 04:20:16.519: RADIUS(00000003): sending
*Aug 23 04:20:16.519: RADIUS(00000003): Send Accounting-Request to 100.1.1.4:1646 id 19,
len 238
*Aug 23 04:20:16.519: RADIUS: authenticator 82 65 5B 42 F0 3F 17 C3 - 23 F3 4C 35 A2 8A
3E E6
*Aug 23 04:20:16.519: RADIUS: Acct-Session-Id [44] 10 "00000002"
*Aug 23 04:20:16.519: RADIUS: Vendor, Cisco [26] 20
*Aug 23 04:20:16.519: RADIUS: Cisco AVpair [1] 14 "vrf-id=cisco"
*Aug 23 04:20:16.519: RADIUS: Vendor, Cisco [26] 35
*Aug 23 04:20:16.519: RADIUS: Cisco AVpair [1] 29 "isakmp-initator-ip=11.1.1.2"
*Aug 23 04:20:16.519: RADIUS: Vendor, Cisco [26] 36

*Aug 23 04:20:16.519: RADIUS: Acct-Delay-Time [41] 6 0
*Aug 23 04:20:16.523: RADIUS: Received from id 21645/19 100.1.1.4:1646,
Accounting-response, len 20
*Aug 23 04:20:16.523: RADIUS: authenticator F1 CA C1 28 CE A0 26 C9 - 3E 22 C9 DA EA B8
22 A0
```

## Accounting Updates

If accounting updates are enabled, accounting updates are sent while a session is “up.” The update interval is configurable. To enable the accounting updates, use the **aaa accounting update** command.

The following is an accounting update record that is being sent from the router:

```
Router#
*Aug 23 21:46:05.263: RADIUS(00000004): Using existing nas_port 0
*Aug 23 21:46:05.263: RADIUS(00000004): Config NAS IP: 100.1.1.147
*Aug 23 21:46:05.263: RADIUS(00000004): sending
*Aug 23 21:46:05.263: RADIUS(00000004): Send Accounting-Request to 100.1.1.4:1646 id 22,
len 200
*Aug 23 21:46:05.263: RADIUS: authenticator 30 FA 48 86 8E 43 8E 4B - F9 09 71 04 4A F1
52 25
*Aug 23 21:46:05.263: RADIUS: Acct-Session-Id [44] 10 "00000003"
*Aug 23 21:46:05.263: RADIUS: Vendor, Cisco [26] 20
*Aug 23 21:46:05.263: RADIUS: Cisco AVpair [1] 14 "vrf-id=cisco"

## How to Configure IPSec VPN Accounting

This section contains the following procedures:

- [Configuring IPSec VPN Accounting, page 7](#)
- [Configuring Accounting Updates, page 10](#)
- [Troubleshooting for IPSec VPN Accounting, page 11](#)

# Configuring IPSec VPN Accounting

To enable IPSec VPN Accounting, you need to perform the following required task:

## Prerequisites

Before configuring IPSec VPN accounting, you must first configure IPSec. To learn about configuring IPSec, refer to the following documents:

- The chapter “[Configuring IPSec Network Security](#)” in the *Cisco IOS Security Configuration Guide*, Release 12.2
- Other IPSec documentation at the [Cisco.com](#) website

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa new-model**
4. **aaa authentication login** *list-name method*
5. **aaa authorization network** *list-name method*
6. **aaa accounting network** *list-name start-stop [broadcast] group group-name*
7. **aaa session-id** common
8. **crypto isakmp profile** *profile-name*
9. **vrf** *ivrif*
10. **match identity group** *group-name*
11. **client authentication list** *list-name*
12. **isakmp authorization list** *list-name*
13. **client configuration address** [**initiate** | **respond**]
14. **accounting** *list-name*
15. **exit**
16. **crypto dynamic-map** *dynamic-map-name dynamic-seq-num*
17. **set transform-set** *transform-set-name*
18. **set isakmp-profile** *profile-name*
19. **reverse-route** [**remote-peer**]
20. **exit**
21. **crypto map** *map-name ipsec-isakmp dynamic dynamic-template-name*
22. **radius-server host** *ip-address* [**auth-port** *port-number*] [**acct-port** *port-number*]
23. **radius-server key** *string*
24. **radius-server vsa send accounting**
25. **interface** *interface-id*
26. **crypto map** *map-name*

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                          | Purpose                                                                                                                                                                                   |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                     | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                          |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                             | Enters global configuration mode.                                                                                                                                                         |
| Step 3 | <b>aaa new-model</b><br><br><b>Example:</b><br>Router (config)# aaa new-model                                                                                                              | Enables periodic interim accounting records to be sent to the accounting server.                                                                                                          |
| Step 4 | <b>aaa authentication login list-name method</b><br><br><b>Example:</b><br>Router (config)# aaa authentication login<br>cisco-client group radius                                          | Enforces authentication, authorization, and accounting (AAA) authentication for extended authorization (XAUTH) via RADIUS or local.                                                       |
| Step 5 | <b>aaa authorization network list-name method</b><br><br><b>Example:</b><br>Router (config)# aaa authorization network<br>cisco-client group radius                                        | Sets AAA authorization parameters on the remote client from RADIUS or local.                                                                                                              |
| Step 6 | <b>aaa accounting network list-name start-stop [broadcast] group group-name</b><br><br><b>Example:</b><br>Router (config)# aaa accounting network acc<br>start-stop broadcast group radius | Enables AAA accounting of requested services for billing or security purposes when you use RADIUS or TACACS+.                                                                             |
| Step 7 | <b>aaa session-id common</b><br><br><b>Example:</b><br>Router (config)# aaa session-id common                                                                                              | Specifies whether the same session ID will be used for each AAA accounting service type within a call or whether a different session ID will be assigned to each accounting service type. |
| Step 8 | <b>crypto isakmp profile profile-name</b><br><br><b>Example:</b><br>Route (config)# crypto isakmp profile cisco                                                                            | Audits IP security (IPSec) user sessions and enters isakmp-profile submode.                                                                                                               |
| Step 9 | <b>vrf ivrf</b><br><br><b>Example:</b><br>Router (conf-isa-prof)# vrf cisco                                                                                                                | Associates the on-demand address pool with a Virtual Private Network (VPN) routing and forwarding (VRF) instance name.                                                                    |

|         | Command or Action                                                                                                                                           | Purpose                                                                                                                                                                                                          |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 10 | <b>match identity group</b> <i>group-name</i><br><br><b>Example:</b><br>Router(conf-isa-prof)# match identity group cisco                                   | Matches an identity from a peer in an ISAKMP profile.                                                                                                                                                            |
| Step 11 | <b>client authentication list</b> <i>list-name</i><br><br><b>Example:</b><br>Router(conf-isa-prof)# client authentication list cisco                        | Configures Internet Key Exchange (IKE) extended authentication (XAUTH) in an Internet Security Association and Key Management Protocol (ISAKMP) profile.                                                         |
| Step 12 | <b>isakmp authorization list</b> <i>list-name</i><br><br><b>Example:</b><br>Router(conf-isa-prof)# isakmp authorization list cisco-client                   | Configures an IKE shared secret and other parameters using the AAA server in an ISAKMP profile. The shared secret and other parameters are generally pushed to the remote peer via mode configuration (MODECFG). |
| Step 13 | <b>client configuration address</b> [initiate   respond]<br><br><b>Example:</b><br>Router(conf-isa-prof)# client configuration address respond              | Configures IKE mode configuration (MODECFG) in the ISAKMP profile.                                                                                                                                               |
| Step 14 | <b>accounting</b> <i>list-name</i><br><br><b>Example:</b><br>Router(conf-isa-prof)# accounting acc                                                          | Enables AAA accounting services for all peers that connect via this ISAKMP profile.                                                                                                                              |
| Step 15 | <b>exit</b><br><br><b>Example:</b><br>Router(conf-isa-prof)# exit                                                                                           | Exits isakmp-profile submode.                                                                                                                                                                                    |
| Step 16 | <b>crypto dynamic-map</b> <i>dynamic-map-name</i> <i>dynamic-seq-num</i><br><br><b>Example:</b><br>Router(config)# crypto dynamic-map mymap 10 ipsec-isakmp | Creates a dynamic crypto map template and enters the crypto map configuration command mode.                                                                                                                      |
| Step 17 | <b>set transform-set</b> <i>transform-set-name</i><br><br><b>Example:</b><br>Router(config-crypto-map)# set transform-set aswan                             | Specifies which transform sets can be used with the crypto map template.                                                                                                                                         |
| Step 18 | <b>set isakmp-profile</b> <i>profile-name</i><br><br><b>Example:</b><br>Router(config-crypto-map)# set isakmp-profile cisco                                 | Sets the ISAKMP profile name.                                                                                                                                                                                    |

|         | Command or Action                                                                                                                                                                                   | Purpose                                                                                                                                                                                                            |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 19 | <b>reverse-route</b> [ <b>remote-peer</b> ]<br><br><b>Example:</b><br>Router(config-crypto-map)# reverse-route                                                                                      | Allows routes (ip addresses) to be injected for destinations behind the VPN remote tunnel endpoint and may include a route to the tunnel endpoint itself (using the <b>remote-peer</b> keyword for the crypto map. |
| Step 20 | <b>exit</b><br><br><b>Example:</b><br>Router(config-crypto-map)# exit                                                                                                                               | Exits dynamic crypto map configuration mode.                                                                                                                                                                       |
| Step 21 | <b>crypto map</b> <i>map-name</i> ipsec-isakmp dynamic <i>dynamic-template-name</i><br><br><b>Example:</b><br>Router(config)# crypto map mymap ipsec-isakmp dynamic dmap                            | Enters crypto map configuration mode                                                                                                                                                                               |
| Step 22 | <b>radius-server host</b> <i>ip-address</i> [ <b>auth-port</b> <i>port-number</i> ] [ <b>acct-port</b> <i>port-number</i> ]<br><br><b>Example:</b><br>Router(config)# radius-server host 172.16.1.4 | Specifies a RADIUS server host.                                                                                                                                                                                    |
| Step 23 | <b>radius-server key</b> <i>string</i><br><br><b>Example:</b><br>Router(config)# radius-server key nsite                                                                                            | Sets the authentication and encryption key for all RADIUS communications between the router and the RADIUS daemon.                                                                                                 |
| Step 24 | <b>radius-server vsa send accounting</b><br><br><b>Example:</b><br>Router(config)# radius-server vsa send accounting                                                                                | Configures the network access server to recognize and use vendor-specific attributes.                                                                                                                              |
| Step 25 | <b>interface</b> <i>type slot/port</i><br><br><b>Example:</b><br>Router(config)# interface FastEthernet 1/0                                                                                         | Configures an interface type and enters interface configuration mode.                                                                                                                                              |
| Step 26 | <b>crypto map</b> <i>map-name</i><br><br><b>Example:</b><br>Router(config-if)# crypto map mymap                                                                                                     | Applies a previously defined crypto map set to an interface.                                                                                                                                                       |

## Configuring Accounting Updates

To send accounting updates while a session is “up,” perform the following optional task:

### Prerequisites

Before you configure accounting updates, you must first configure IPSec VPN accounting. See the section “[Configuring IPSec VPN Accounting](#).”

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa accounting update periodic *number***

## DETAILED STEPS

|        | Command or Action                                                               | Purpose                                                                                     |
|--------|---------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b>                                                                   | Enables privileged EXEC mode.                                                               |
|        | <b>Example:</b><br>Router> enable                                               | <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>        |
| Step 2 | <b>configure terminal</b>                                                       | Enters global configuration mode.                                                           |
|        | <b>Example:</b><br>Router# configure terminal                                   |                                                                                             |
| Step 3 | <b>aaa accounting update periodic <i>number</i></b>                             | (Optional) Enables periodic interim accounting records to be sent to the accounting server. |
|        | <b>Example:</b><br>Router (config)# aaa accounting update periodic 1-2147483647 |                                                                                             |

## Troubleshooting for IPSec VPN Accounting

To display messages about IPSec accounting events, perform the following optional task:

## SUMMARY STEPS

1. **enable**
2. **debug crypto isakmp aaa**

## DETAILED STEPS

|        | Command or Action                                  | Purpose                                                                                                 |
|--------|----------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b>                                      | Enables privileged EXEC mode.                                                                           |
|        | <b>Example:</b><br>Router> enable                  | <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                    |
| Step 2 | <b>debug crypto isakmp aaa</b>                     | Displays messages about Internet Key Exchange (IKE) events.                                             |
|        | <b>Example:</b><br>Router# debug crypto isakmp aaa | <ul style="list-style-type: none"> <li>• The <b>aaa</b> keyword specifies accounting events.</li> </ul> |

# Configuration Examples for IPsec VPN Accounting

- [Accounting and ISAKMP-Profile Example, page 12](#)
- [Accounting Without ISAKMP Profiles Example, page 14](#)

## Accounting and ISAKMP-Profile Example

The following example shows a configuration for supporting remote access clients with accounting and ISAKMP profiles:

```
version 12.2
service timestamps debug datetime msec
service timestamps log datetime msec
no service password-encryption
!
hostname sheep
!
aaa new-model
!
!
aaa accounting network ipsecaaa start-stop group radius
aaa accounting update periodic 1
aaa session-id common
ip subnet-zero
ip cef
!
!
no ip domain lookup
ip domain name cisco.com
ip name-server 172.29.2.133
ip name-server 172.29.11.48
!
!
crypto isakmp policy 1
authentication pre-share
group 2
!
crypto isakmp policy 10
hash md5
authentication pre-share
lifetime 200
crypto isakmp key cisco address 172.31.100.2

crypto iakmp client configuration group cclient
key jegjegjhrj
pool addressA

crypto-isakmp profile groupA
vrf cisco
match identity group cclient
client authentication list cisco-client
isakmp authorization list cisco-client
client configuration address respond
accounting acc
!
!
crypto ipsec transform-set esp-des-md5 esp-des esp-md5-hmac
!
crypto dynamic-map remotes 1
set peer 172.31.100.2

## Command Reference

The following commands are introduced or modified in the feature or features

- **client authentication list**
- **client configuration address**
- **crypto isakmp profile**
- **crypto map (global IPSec)**
- **debug crypto isakmp**
- **isakmp authorization list**
- **match identity**
- **set isakmp-profile**
- **vrf**

For information about these commands, see the Cisco IOS Security Command Reference at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html).

For information about all Cisco IOS commands, see the Command Lookup Tool at

<http://tools.cisco.com/Support/CLILookup> or the Master Command List.

# Glossary

**IKE**—Internet Key Exchange. IKE establishes a shared security policy and authenticates keys for services (such as IP security [IPSec]) that require keys. Before any IPSec traffic can be passed, each router, firewall, and host must verify the identity of its peer. This can be done by manually entering preshared keys into both hosts or by a certification authority (CA) service.

**IPSec**—IP security. IPSec is A framework of open standards that provides data confidentiality, data integrity, and data authentication between participating peers. IPSec provides these security services at the IP layer. IPSec uses IKE to handle the negotiation of protocols and algorithms based on local policy and to generate the encryption and authentication keys to be used by IPSec. IPSec can protect one or more data flows between a pair of hosts, between a pair of security gateways, or between a security gateway and a host.

**ISAKMP**—Internet Security Association and Key Management Protocol. ISAKMP is an Internet IPSec protocol (RFC 2408) that negotiates, establishes, modifies, and deletes security associations. It also exchanges key generation and authentication data (independent of the details of any specific key generation technique), key establishment protocol, encryption algorithm, or authentication mechanism.

**L2TP session**—Layer 2 Transport Protocol. L2TP are communications transactions between the L2TP access concentrator (LAC) and the L2TP network server (LNS) that support tunneling of a single PPP connection. There is a one-to-one relationship among the PPP connection, L2TP session, and L2TP call.

**NAS**—network access server. A NAS is a Cisco platform (or collection of platforms, such as an AccessPath system) that interfaces between the packet world (for example, the Internet) and the circuit world (for example, the public switched telephone network [PSTN]).

**PFS**—**perfect forward secrecy. PFS is a cryptographic characteristic associated with a derived shared secret value. With PFS, if one key is compromised, previous and subsequent keys are not compromised because subsequent keys are not derived from previous keys.**

**QM**—Queue Manager. The Cisco IP Queue Manager (IP QM) is an intelligent, IP-based, call-treatment and routing solution that provides powerful call-treatment options as part of the Cisco IP Contact Center (IPCC) solution.

**RADIUS**—Remote Authentication Dial-In User Service. RADIUS is a database for authenticating modem and ISDN connections and for tracking connection time.

**RSA**—Rivest, Shamir, and Adelman. Rivest, Shamir, and Adelman are the inventors of the Public-key cryptographic system that can be used for encryption and authentication.

**SA**—security association. A SA is an instance of security policy and keying material that is applied to a data flow.

**TACACS+**—Terminal Access Controller Access Control System Plus. TACACS+ is a security application that provides centralized validation of users attempting to gain access to a router or network access server.

**TED**—Tunnel Endpoint Discovery. TED is a Cisco IOS software feature that allows routers to discover IPSec endpoints.

**VPN**—Virtual Private Network. A VPN enables IP traffic to travel securely over a public TCP/IP network by encrypting all traffic from one network to another. A VPN uses "tunneling" to encrypt all information at the IP level.

**VRF**—A VPN routing/forwarding instance. A VRF consists of an IP routing table, a derived forwarding table, a set of interfaces that use the forwarding table, and a set of rules and routing protocols that determine what goes into the forwarding table. In general, a VRF includes the routing information that defines a customer VPN site that is attached to a PE router.

**VSA**—vendor-specific attribute. A VSA is an attribute that has been implemented by a particular vendor. It uses the attribute Vendor-Specific to encapsulate the resulting AV pair: essentially, Vendor-Specific = protocol:attribute = value.

**XAUTH**—Extended authentication. XAUTH is an optional exchange between IKE Phase 1 and IKE Phase 2, in which the router demands additional authentication information in an attempt to authenticate the actual user (as opposed to authenticating the peer).

**Note**

| 12.2(11)T | This feature was integrated into Cisco IOS Release 12.2(11)T and support was added for the Cisco AS5300 and Cisco AS5800 platforms. |
| 12.2(9)YE | This feature was integrated into Cisco IOS Release 12.2(9)YE.                                                                       |
| 12.2(14)S | This feature was integrated into Cisco IOS Release 12.2(14)S.                                                                       |

This feature module describes the IPSec VPN High Availability Enhancements. It includes the following sections:

- [Feature Overview, page 1](#)
- [Supported Platforms, page 4](#)
- [Supported Standards, MIBs, and RFCs, page 5](#)
- [Configuration Tasks, page 6](#)
- [Configuration Examples, page 8](#)
- [Command Reference, page 10](#)

## Feature Overview

The IPSec VPN High Availability Enhancements feature consists of two new features—[Reverse Route Injection](#) (RRI) and [Hot Standby Router Protocol and IPSec](#) (HSRP)—that work together to provide users with a simplified network design for VPNs, and reduced configuration complexity on remote peers with respect to defining gateway lists. When used together, RRI and HSRP provide a more reliable network design for VPNs and reduce configuration complexity on remote peers.

## Reverse Route Injection

Reverse Route Injection (RRI) is a feature designed to simplify network design for Virtual Private Networks (VPNs) in which there is a requirement for redundancy or load balancing. RRI works with both dynamic and static crypto maps.

In the dynamic case, as remote peers establish IPSec security associations (SAs) with an RRI-enabled router, a static route is created for each subnet or host protected by that remote peer. For static crypto maps, a static route is created for each destination of an extended access list rule. When RRI is used on a static crypto map with an access control list (ACL), routes will always exist, even without the negotiation of IPSec SAs.

### Note

Use of any keyword in ACLs with RRI is not supported.

When routes are created, they are injected into any dynamic routing protocol and distributed to surrounding devices. This traffic flows, requiring IPSec to be directed to the appropriate RRI router for transport across the correct SAs to avoid IPSec policy mismatches and possible packet loss.

Figure 87 shows a RRI configuration functionality topology. Remote A is being serviced by Router A and Remote B connected to Router B, providing load balancing across VPN gateways at the central site. RRI on the central site devices will ensure that the other router on the inside of the network can automatically make the correct forwarding decision. RRI also eliminates the need to administer static routes on the inside router.

**Figure 87**      **Topology Showing Reverse Route Injection Configuration Functionality**

## Hot Standby Router Protocol and IPSec

Hot Standby Router Protocol (HSRP) is designed to provide high network availability by routing IP traffic from hosts on Ethernet networks without relying on the availability of any single router. HSRP is particularly useful for hosts that do not support a router discovery protocol, such as ICMP Router Discovery Protocol (IRDP), and do not have the functionality to switch to a new router when their selected router reloads or loses power. Without this functionality, a router that loses its default gateway because of a router failure is unable to communicate with the network.

HSRP is configurable on LAN interfaces using standby command-line interface (CLI) commands. It is now possible to use the standby IP address from an interface as the local IPSec identity, or local tunnel endpoint.

By using the standby IP address as the tunnel endpoint, failover can be applied to VPN routers by using HSRP. Remote VPN gateways connect to the local VPN router via the standby address that belongs to the *active* device in the HSRP group. In the event of failover, the *standby* device takes over ownership of the standby IP address and begins to service remote VPN gateways.

Figure 88 shows the enhanced HSRP functionality topology. Traffic is serviced by the active Router P, the active device in the standby group. In the event of failover, traffic is diverted to Router S, the original standby device. Router S assumes the role of the new active router and takes ownership of the standby IP address.

**Figure 88** Topology Showing Hot Standby Router Protocol Functionality

### Note

In case of a failover, HSRP does not facilitate IPSec state information transference between VPN routers. This means that without this state transference, SAs to remotes will be deleted requiring Internet Key Exchange (IKE) and IPSec SAs to be reestablished. To make IPSec failover more efficient, it is recommended that IKE keepalives be enabled on all routers.

## Benefits

### Reverse Route Injection

- Enables routing of IPSec traffic to a specific VPN headend device in environments that have multiple (redundant) VPN headend devices.

- Ensures predictable failover time of remote sessions between headend devices when using IKE keepalives, especially in environments in which remote device route flapping is common (not taking into consideration the effects of route convergence, which may vary depending on the routing protocol used and the size of the network).
- Eliminates the need for the administration of static routes on upstream devices as routes are dynamically learned by these devices.

#### Hot Standby Router Protocol with IPSec

Failover can be applied to VPN routers through the use of HSRP. Remote VPN gateways connect to the local VPN router through the standby address that belongs to the active device in the HSRP group. This functionality reduces configuration complexity on remote peers with respect to defining gateway lists because only the HSRP standby address needs to be defined.

**Finding Support Information for Platforms and Cisco IOS Software Images**

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

## Supported Standards, MIBs, and RFCs

**Standards**

- No new or modified standards are supported by this feature.

**MIBs**

- No new or modified standards are supported by this feature.

To locate and download MIBs for selected platforms, Cisco IOS releases, and feature sets, use Cisco MIB Locator found at the following URL:

<http://tools.cisco.com/ITDIT/MIBS/servlet/index>

If Cisco MIB Locator does not support the MIB information that you need, you can also obtain a list of supported MIBs and download MIBs from the Cisco MIBs page at the following URL:

<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>

To access Cisco MIB Locator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to [cco-locksmith@cisco.com](mailto:cco-locksmith@cisco.com). An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions found at this URL:

<http://www.cisco.com/register>

**RFCs**

- No new or modified RFCs are supported by this feature.

## Configuration Tasks

See the following sections for configuration tasks for the IPSec VPN High Availability Enhancements feature. Each task in the list is identified as either required or optional.

- [Configuring Reverse Route Injection on a Dynamic Crypto Map](#) (required)
- [Configuring Reverse Route Injection on a Static Crypto Map](#) (required)
- [Configuring HSRP with IPSec](#) (required)
- [Verifying VPN IPSec Crypto Configuration](#) (optional)

### Configuring Reverse Route Injection on a Dynamic Crypto Map

Dynamic crypto map entries, like regular static crypto map entries, are grouped into sets. A set is a group of dynamic crypto map entries all with the same dynamic map name but each with a different dynamic sequence number. Each member of the set may be configured for RRI.

To create a dynamic crypto map entry and enable RRI, use the following commands beginning in global configuration mode:

|        | Command                                                 | Purpose                                                                                                                                                                                                                                         |
|--------|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | Router (config)# <b>crypto dynamic</b> map-name seq-num | Creates a dynamic crypto map entry and enters crypto map configuration mode.                                                                                                                                                                    |
| Step 2 | Router (config-crypto-m)# <b>set transform-set</b>      | Specifies which transform sets are allowed for the crypto map entry. Lists multiple transform sets in order of priority (highest priority first).<br><br>This entry is the only configuration statement required in dynamic crypto map entries. |
| Step 3 | Router (config-crypto-m)# <b>reverse-route</b>          | Creates source proxy information.                                                                                                                                                                                                               |

### Configuring Reverse Route Injection on a Static Crypto Map

Before configuring RRI on a static crypto map, please note the following items:

- Routes are not created based on access list 102 as reverse-route is not enabled on mymap 2. RRI is not enabled by default and is not displayed in the router configuration.
- Enable a routing protocol to distribute the VPN routes to upstream devices.
- If Cisco Express Forwarding (CEF) is run on a VPN router configured for RRI, adjacencies need to be formed for each RRI injected network through the next hop device. As the next hop is not explicitly defined in the routing table for these routes, proxy-ARP should be enabled on the next hop router which allows the CEF adjacency to be formed using the layer two addresses of that device. In cases where there are many RRI injected routes, adjacency tables may become quite large as an entry is created for each device from each of the subnets represented by the RRI route. This issue is to be resolved in a future release.

To add RRI to a static crypto map set, use the following commands beginning in global configuration mode:

|               | Command                                                                    | Purpose                                                                                                                                           |
|---------------|----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Router (config)# <b>crypto map</b> map-name seq-num<br><b>ipsec-isakmp</b> | Adds a dynamic crypto map set to a static crypto map set and enters interface configuration mode.                                                 |
| <b>Step 2</b> | Router (config-if)# <b>set peer ip address</b>                             | Specifies an IPSec peer IP address in a crypto map entry.                                                                                         |
| <b>Step 3</b> | Router (config-if)# <b>reverse-route</b>                                   | Creates dynamically static routes based on crypto access control lists (ACLs).                                                                    |
| <b>Step 4</b> | Router (config-if)# <b>match address</b>                                   | Specifies an extended access list for a crypto map entry.                                                                                         |
| <b>Step 5</b> | Router (config-if)# <b>set transform-set</b>                               | Specifies which transform sets are allowed for the crypto map entry. Lists multiple transform sets in order of priority (highest priority first). |

## Configuring HSRP with IPSec

When configuring HSRP with IPSec, the following conditions may apply:

- When HSRP is applied to a crypto map on an interface, the crypto map must be reapplied if the standby IP address or the standby name is changed on that interface.
- If HSRP is applied to a crypto map on an interface, and the user deletes the standby IP address or the standby name from that interface, the crypto tunnel endpoint is reinitialized to the actual IP address of that interface.
- If a user adds the standby IP address and the standby name to an interface with the requirement IPSec failover, the crypto map must be reapplied with the appropriate redundancy information.
- Standby priorities should be equal on active and standby routers. If they are not, the higher priority router takes over as the active router. When that occurs, the active router goes into a cycle where it continuously goes down and comes back up.
- The IP addresses on the HSRP-tracked interfaces on the standby and active routers should both be either lower or higher on one router than the other. In the case of equal priorities (an HA requirement), HSRP will assign the active state-based IP address. If an addressing scheme exists so that the public IP address of router A is lower than the public IP address of router B, but the opposite is true for their private interfaces, an active/standby-standby/active split condition could exist which will break connectivity.

### Note

To configure HSRP without IPSec refer to the “[Configuring IP Services](#)” chapter of the *Cisco IOS IP Configuration Guide*, Release 12.2.

To apply a crypto map set to an interface, use the following commands beginning in global configuration mode:

|               | Command                                                                                         | Purpose                                                                                |
|---------------|-------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| <b>Step 1</b> | Router (config)# <b>interface</b> <i>type slot/port</i>                                         | Specifies an interface and enters interface configuration mode.                        |
| <b>Step 2</b> | Router (config-if)# <b>standby name</b> <i>group-name</i>                                       | Specifies the standby group name (required).                                           |
| <b>Step 3</b> | Router (config-if)# <b>standby ip</b> <i>ip-address</i>                                         | Specifies the IP address of the standby groups (required for one device in the group). |
| <b>Step 4</b> | Router (config-if)# <b>crypto map</b> <i>map-name</i> <b>redundancy</b> [ <i>standby-name</i> ] | Specifies IP redundancy address as the tunnel endpoint for IPSec.                      |

## Verifying VPN IPSec Crypto Configuration

To verify your VPN IPSec crypto configuration, use the following EXEC commands:

| Command                                                                                                          | Purpose                                         |
|------------------------------------------------------------------------------------------------------------------|-------------------------------------------------|
| Router# <b>show crypto ipsec transform-set</b>                                                                   | Displays your transform set configuration.      |
| Router# <b>show crypto map</b> [ <i>interface interface</i>   <b>tag</b> <i>map-name</i> ]                       | Displays your crypto map configuration.         |
| Router# <b>show crypto ipsec sa</b> [ <i>map map-name</i>   <i>address</i>   <i>identity</i> ] [ <i>detail</i> ] | Displays information about IPSec SAs.           |
| Router# <b>show crypto dynamic-map</b> [ <b>tag</b> <i>map-name</i> ]                                            | Displays information about dynamic crypto maps. |

## Configuration Examples

This section provides the following configuration examples:

- [Reverse Route Injection on a Dynamic Crypto Map Example](#)
- [Reverse Route Injection on a Static Crypto Map Example](#)
- [HSRP and IPSec Example](#)

### Reverse Route Injection on a Dynamic Crypto Map Example

In the following example, using the reverse route crypto map subcommand in the definition of the dynamic crypto map template ensures that routes are created for any remote proxies (subnets or hosts), protected by the connecting remote IPSec peers.

```
crypto dynamic mydynmap 1
 set transform-set esp-3des-sha
 reverse-route
```

This template is then associated with a “parent” crypto map statement and then applied to an interface.

```
crypto map mymap 3 ipsec-isakmp dynamic mydynmap
```

```
interface FastEthernet 0/0
crypto map mymap
```

## Reverse Route Injection on a Static Crypto Map Example

RRI is a good solution for topologies that require encrypted traffic to be diverted to a VPN router and all other traffic to a different router.

In these scenarios, RRI eliminates the need to manually define static routes on devices.

RRI is not required if a single VPN router is used and all traffic passes through the VPN router during its path in and out of the network.

If the user chooses to manually define static routes on the VPN router for remote proxies, and have these routes permanently installed in the routing table, RRI should not be enabled on the crypto map instance that covers the same remote proxies. In this case, there is no possibility of user defined static routes being removed by RRI.

Routing convergence can affect the success of a failover based on the routing protocol used to advertise routes (link state versus periodic update). It is recommended that a link state routing protocol such as OSPF be used to help speed convergence time by ensuring that routing updates are sent as soon as a change in routing state is detected.

In the following example, RRI is enabled for mymap 1, but not for mymap 2. Upon the application of the crypto map to the interface, a route is created based on access-list 101 analogous to the following:

```
IP route 172.17.11.0 255.255.255.0 FastEthernet 0/0
```

```
crypto map mymap 1 ipsec-isakmp
 set peer 172.17.11.1
 reverse-route
 set transform-set esp-3des-sha
 match address 101
crypto map mymap 2 ipsec-isakmp
 set peer 10.1.1.1
 set transform-set esp-3des-sha
 match address 102
```

```
access-list 101 permit ip 192.168.1.0 0.0.0.255 172.17.11.0 0.0.0.255
access-list 102 permit ip 192.168.1.0 0.0.0.255 10.0.0.0 0.0.255.255
```

```
interface FastEthernet 0/0
crypto map mymap
```

## HSRP and IPSec Example

The following example shows how all remote VPN gateways connect to the router via 192.168.0.3. The crypto map on the interface binds this standby address as the local tunnel endpoint for all instances of *mymap* and at the same time ensures that HSRP failover is facilitated between an active and standby device belonging to the same standby group, group1.

Note that RRI is also enabled to provide the ability for only the *active* device in the HSRP group to be advertising itself to inside devices as the next hop VPN gateway to the remote proxies. If there is a failover, routes are deleted on the formerly active device and created on the newly active device.

```
crypto map mymap 1 ipsec-isakmp
 set peer 10.1.1.1
 reverse-route
 set transform-set esp-3des-sha
 match address 102

Interface FastEthernet 0/0
 ip address 192.168.0.2 255.255.255.0
 standby name group1
 standby ip 192.168.0.3
 crypto map mymap redundancy group1

access-list 102 permit ip 192.168.1.0 0.0.0.255 10.0.0.0 0.0.255.255
```

The standby name needs to be configured on all devices in the standby group and the standby address needs to be configured on at least one member of the group. If the standby name is removed from the router, the IPSec SAs will be deleted. If the standby name is added again, regardless of whether the same name or a different name is used, the crypto map (using the redundancy option) will have to be reapplied to the interface.

## Command Reference

The following commands are introduced or modified in the feature or features:  
documented in this module:

- [crypto map \(interface IPSec\)](#)
- [reverse-route](#)

For information about these commands, see the Cisco IOS Security Command Reference at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html).

For information about all Cisco IOS commands, see the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the Master Command List.

# IPsec Virtual Tunnel Interface

---

**First Published: October 18, 2004**

**Last Updated: June 11, 2008**

IP security (IPsec) virtual tunnel interfaces (VTIs) provide a routable interface type for terminating IPsec tunnels and an easy way to define protection between sites to form an overlay network. IPsec VTIs simplify configuration of IPsec for protection of remote links, support multicast, and simplify network management and load balancing.

## Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for IPsec Virtual Tunnel Interface](#)” section on [page 24](#).

## Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

# Restrictions for IPsec Virtual Tunnel Interface

## IPsec Transform Set

The IPsec transform set must be configured in tunnel mode only.

## IKE Security Association

The Internet Key Exchange (IKE) security association (SA) is bound to the VTI. Because IKE SA is bound to the VTI, the same IKE SA cannot be used for a crypto map.

## IPsec SA Traffic Selectors

Static VTIs support only a single IPsec SA that is attached to the VTI interface. The traffic selector for the IPsec SA is always “IP any any.”

A dynamic VTI also is a point-point interface that supports only a single IPsec SA, but the dynamic VTI is flexible in that it can accept the IPsec selectors that are proposed by the initiator.

## IPv4 and IPv6 Packets

This feature supports static VTIs that are configured to encapsulate IPv4 packets or IPv6 packets, but IPv4 packets cannot carry IPv6 packets, and IPv6 packets cannot carry IPv4 packets.

## Proxy

Static VTIs support only the “IP any any” proxy.

Dynamic VTIs support only one proxy, which can be “IP any any” or any subset of it.

## QoS Traffic Shaping

The shaped traffic is process switched.

## Stateful Failover

IPsec stateful failover is not supported with IPsec VTIs.

## Tunnel Protection

The **shared** keyword is not required and must not be configured when using the **tunnel mode ipsec ipv4** command for IPsec IPv4 mode.

## Static VTIs Versus GRE Tunnels

The IPsec VTI is limited to IP unicast and multicast traffic only, as opposed to GRE tunnels, which have a wider application for IPsec implementation.

## VRF-Aware IPsec Configuration

In VRF-aware IPsec configurations with either static or dynamic VTIs (DVTIs), the VRF must *not* be configured in the Internet Security Association and Key Management Protocol (ISAKMP) profile. Instead, the VRF must be configured on the tunnel interface for static VTIs. For DVTIs, you must apply VRF to the vtemplate using the **ip vrf forwarding** command.

# Information About IPsec Virtual Tunnel Interface

The use of IPsec VTIs both greatly simplifies the configuration process when you need to provide protection for remote access and provides a simpler alternative to using generic routing encapsulation (GRE) or Layer 2 Tunneling Protocol (L2TP) tunnels for encapsulation and crypto maps with IPsec. A major benefit associated with IPsec VTIs is that the configuration does not require a static mapping of IPsec sessions to a physical interface. The IPsec tunnel endpoint is associated with an actual (virtual) interface. Because there is a routable interface at the tunnel endpoint, many common interface capabilities can be applied to the IPsec tunnel.

The IPsec VTI allows for the flexibility of sending and receiving both IP unicast and multicast encrypted traffic on any physical interface, such as in the case of multiple paths. Traffic is encrypted or decrypted when it is forwarded from or to the tunnel interface and is managed by the IP routing table. Using IP routing to forward the traffic to the tunnel interface simplifies the IPsec VPN configuration compared to the more complex process of using access control lists (ACLs) with the crypto map in native IPsec configurations. DVTIs function like any other real interface so that you can apply quality of service (QoS), firewall, and other security services as soon as the tunnel is active.

Without Virtual Private Network (VPN) Acceleration Module2+ (VAM2+) accelerating virtual interfaces, the packet traversing an IPsec virtual interface is directed to the router processor (RP) for encapsulation. This method tends to be slow and has limited scalability. In hardware crypto mode, all the IPsec VTIs are accelerated by the VAM2+ crypto engine, and all traffic going through the tunnel is encrypted and decrypted by the VAM2+.

The following sections provide details about the IPsec VTI:

- [Benefits of Using IPsec Virtual Tunnel Interfaces, page 3](#)
- [Routing with IPsec Virtual Tunnel Interfaces, page 5](#)
- [Static Virtual Tunnel Interfaces, page 3](#)
- [Dynamic Virtual Tunnel Interfaces, page 4](#)
- [Dynamic Virtual Tunnel Interface Life Cycle, page 5](#)
- [Traffic Encryption with the IPsec Virtual Tunnel Interface, page 6](#)

## Benefits of Using IPsec Virtual Tunnel Interfaces

IPsec VTIs allow you to configure a virtual interface to which you can apply features. Features for clear-text packets are configured on the VTI. Features for encrypted packets are applied on the physical outside interface. When IPsec VTIs are used, you can separate the application of features such as NAT, ACLs, and QoS and apply them to clear-text or encrypted text, or both. When crypto maps are used, there is no simple way to apply encryption features to the IPsec tunnel.

There are two types of VTI interfaces: static VTIs (SVTIs) and dynamic VTIs (DVTIs).

## Static Virtual Tunnel Interfaces

SVTI configurations can be used for site-to-site connectivity in which a tunnel provides always-on access between two sites. The advantage of using SVTIs as opposed to crypto map configurations is that users can enable dynamic routing protocols on the tunnel interface without the extra 4 bytes required for GRE headers, thus reducing the bandwidth for sending encrypted data.

Additionally, multiple Cisco IOS software features can be configured directly on the tunnel interface and on the physical egress interface of the tunnel interface. This direct configuration allows users to have solid control on the application of the features in the pre- or post-encryption path.

Figure 1 illustrates how a static VTI is used.

**Figure 1** *IPsec Static VTI*

The IPsec VTI supports native IPsec tunneling and exhibits most of the properties of a physical interface.

## Dynamic Virtual Tunnel Interfaces

DVTIs can provide highly secure and scalable connectivity for remote-access VPNs. The DVTI technology replaces dynamic crypto maps and the dynamic hub-and-spoke method for establishing tunnels.

Dynamic VTIs can be used for both the server and remote configuration. The tunnels provide an on-demand separate virtual access interface for each VPN session. The configuration of the virtual access interfaces is cloned from a virtual template configuration, which includes the IPsec configuration and any Cisco IOS software feature configured on the virtual template interface, such as QoS, NetFlow, or ACLs.

Dynamic VTIs function like any other real interface so that you can apply QoS, firewall, other security services as soon as the tunnel is active. QoS features can be used to improve the performance of various applications across the network. Any combination of QoS features offered in Cisco IOS software can be used to support voice, video, or data applications.

Dynamic VTIs provide efficiency in the use of IP addresses and provide secure connectivity. Dynamic VTIs allow dynamically downloadable per-group and per-user policies to be configured on a RADIUS server. The per-group or per-user definition can be created using extended authentication (Xauth) User or Unity group, or it can be derived from a certificate. Dynamic VTIs are standards based, so interoperability in a multiple-vendor environment is supported. IPsec DVTIs allow you to create highly secure connectivity for remote access VPNs and can be combined with Cisco Architecture for Voice, Video, and Integrated Data (AVVID) to deliver converged voice, video, and data over IP networks. The DVTI simplifies Virtual Private Network (VRF) routing and forwarding- (VRF-) aware IPsec deployment. The VRF is configured on the interface.

A DVTI requires minimal configuration on the router. A single virtual template can be configured and cloned.

The DVTI creates an interface for IPsec sessions and uses the virtual template infrastructure for dynamic instantiation and management of dynamic IPsec VTIs. The virtual template infrastructure is extended to create dynamic virtual-access tunnel interfaces. Dynamic VTIs are used in hub-and-spoke configurations. A single DVTI can support several static VTIs. [Figure 2](#) illustrates the DVTI authentication path.

**Figure 2**      *Dynamic IPsec VTI*

The authentication shown in [Figure 2](#) follows this path:

1. User 1 calls the router.
2. Router 1 authenticates User 1.
3. IPsec clones virtual access interface from virtual template interface.

## Dynamic Virtual Tunnel Interface Life Cycle

IPsec profiles define policy for dynamic VTIs. The dynamic interface is created at the end of IKE Phase 1 and IKE Phase 1.5. The interface is deleted when the IPsec session to the peer is closed. The IPsec session is closed when both IKE and IPsec SAs to the peer are deleted.

## Routing with IPsec Virtual Tunnel Interfaces

Because VTIs are routable interfaces, routing plays an important role in the encryption process. Traffic is encrypted only if it is forwarded out of the VTI, and traffic arriving on the VTI is decrypted and routed accordingly. VTIs allow you to establish an encryption tunnel using a real interface as the tunnel endpoint. You can route to the interface or apply services such as QoS, firewalls, network address translation, and Netflow statistics as you would to any other interface. You can monitor the interface, route to it, and it has an advantage over crypto maps because it is a real interface and provides the benefits of any other regular Cisco IOS interface.

**Note**

Dynamic routing can be used with SVTIs. Routing with DVTIs is **not** supported or recommended.

## Traffic Encryption with the IPsec Virtual Tunnel Interface

When an IPsec VTI is configured, encryption occurs in the tunnel. Traffic is encrypted when it is forwarded to the tunnel interface. Traffic forwarding is handled by the IP routing table, and dynamic or static routing can be used to route traffic to the SVTI. DVTI uses reverse route injection to further simplify the routing configurations. Using IP routing to forward the traffic to encryption simplifies the IPsec VPN configuration because the use of ACLs with a crypto map in native IPsec configurations is not required. The IPsec virtual tunnel also allows you to encrypt multicast traffic with IPsec.

IPsec packet flow into the IPsec tunnel is illustrated in [Figure 3](#).

**Figure 3** Packet Flow into the IPsec Tunnel

After packets arrive on the inside interface, the forwarding engine switches the packets to the VTI, where they are encrypted. The encrypted packets are handed back to the forwarding engine, where they are switched through the outside interface.

[Figure 4](#) shows the packet flow out of the IPsec tunnel.

**Figure 4** Packet Flow out of the IPsec Tunnel

## How to Configure IPsec Virtual Tunnel Interface

- [Configuring Static IPsec Virtual Tunnel Interfaces, page 7](#)
- [Configuring Dynamic IPsec Virtual Tunnel Interfaces, page 9](#)

### Configuring Static IPsec Virtual Tunnel Interfaces

This configuration shows how to configure a static IPsec VTI.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto IPsec profile** *profile-name*
4. **set transform-set** *transform-set-name*
5. **interface** *type number*
6. **ip address** *address mask*
7. **tunnel mode ipsec ipv4**
8. **tunnel source** *interface*
9. **tunnel destination** *ip-address*
10. **tunnel protection IPsec profile** *profile-name* [**shared**]

## DETAILED STEPS

|        | Command or Action                                                                                                                                                             | Purpose                                                                                                          |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                        | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                | Enters global configuration mode.                                                                                |
| Step 3 | <b>crypto IPsec profile <i>profile-name</i></b><br><br><b>Example:</b><br>Router(config)# crypto IPsec profile PROF                                                           | Defines the IPsec parameters that are to be used for IPsec encryption between two IPsec routers.                 |
| Step 4 | <b>set transform-set <i>transform-set-name</i> [<i>transform-set-name2</i>...<i>transform-set-name6</i>]</b><br><br><b>Example:</b><br>Router(config)# set transform-set tset | Specifies which transform sets can be used with the crypto map entry.                                            |
| Step 5 | <b>interface <i>type number</i></b><br><br><b>Example:</b><br>Router(config)# interface tunnel0                                                                               | Specifies the interface on which the tunnel will be configured and enters interface configuration mode.          |
| Step 6 | <b>ip address <i>address mask</i></b><br><br><b>Example:</b><br>Router(config-if)# ip address 10.1.1.1 255.255.255.0                                                          | Specifies the IP address and mask.                                                                               |
| Step 7 | <b>tunnel mode ipsec ipv4</b><br><br><b>Example:</b><br>Router(config-if)# tunnel mode ipsec ipv4                                                                             | Defines the mode for the tunnel.                                                                                 |

|         | Command or Action                                                                                                                                           | Purpose                                              |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|
| Step 9  | <b>tunnel destination</b> <i>ip-address</i><br><br><b>Example:</b><br>Router(config-if)# tunnel destination<br>172.16.1.1                                   | Identifies the IP address of the tunnel destination. |
| Step 10 | <b>tunnel protection IPsec profile</b> <i>profile-name</i><br>[shared]<br><br><b>Example:</b><br>Router(config-if)# tunnel protection IPsec<br>profile PROF | Associates a tunnel interface with an IPsec profile. |

## Configuring Dynamic IPsec Virtual Tunnel Interfaces

This task shows how to configure a dynamic IPsec VTI.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto IPsec profile** *profile-name*
4. **set transform-set** *transform-set-name*
5. **interface virtual-template** *number*
6. **tunnel mode** *mode*
7. **tunnel protection IPsec profile** *profile-name* [shared]
8. **exit**
9. **crypto isakamp profile** *profile-name*
10. **virtual-template** *template-number*

### DETAILED STEPS

|        | Command or Action                                                              | Purpose                                                                                                            |
|--------|--------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                         | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal | Enters global configuration mode.                                                                                  |

|         | Command or Action                                                                                                                                                                 | Purpose                                                                                          |

| Step 4  | <b>set transform-set</b> <i>transform-set-name</i> [ <i>transform-set-name2</i> ... <i>transform-set-name6</i> ]<br><br><b>Example:</b><br>Router(config)# set transform-set tset | Specifies which transform sets can be used with the crypto map entry.                            |
| Step 5  | <b>interface virtual-template</b> <i>number</i><br><br><b>Example:</b><br>Router(config)# interface virtual-template 2                                                            | Defines a virtual-template tunnel interface and enters interface configuration mode.             |
| Step 6  | <b>tunnel mode ipsec ipv4</b><br><br><b>Example:</b><br>Router(config-if)# tunnel mode ipsec ipv4                                                                                 | Defines the mode for the tunnel.                                                                 |
| Step 7  | <b>tunnel protection IPsec profile</b> <i>profile-name</i> [ <i>shared</i> ]<br><br><b>Example:</b><br>Router(config-if)# tunnel protection IPsec profile PROF                    | Associates a tunnel interface with an IPsec profile.                                             |
| Step 8  | <b>exit</b><br><br><b>Example:</b><br>Router(config-if)# exit                                                                                                                     | Exits interface configuration mode.                                                              |
| Step 9  | <b>crypto isakamp profile</b> <i>profile-name</i><br><br><b>Example:</b><br>Router(config)# crypto isakamp profile red                                                            | Defines the ISAKAMP profile to be used for the virtual template.                                 |
| Step 10 | <b>virtual-template</b> <i>template-number</i><br><br><b>Example:</b><br>Router(config)# virtual-template 1                                                                       | Specifies the virtual template attached to the ISAKAMP profile.                                  |

## Configuration Examples for IPsec Virtual Tunnel Interface

The following examples are provided to illustrate configuration scenarios for IPsec VTIs:

- [Static Virtual Tunnel Interface with IPsec: Example, page 11](#)
- [VRF-Aware Static Virtual Tunnel Interface: Example, page 14](#)
- [Static Virtual Tunnel Interface with QoS: Example, page 14](#)
- [Static Virtual Tunnel Interface with Virtual Firewall: Example, page 15](#)

- [Dynamic Virtual Tunnel Interface Easy VPN Server: Example, page 16](#)
- [Dynamic Virtual Tunnel Interface Easy VPN Client: Example, page 18](#)
- [VRF-Aware IPsec with Dynamic VTI: Example, page 20](#)
- [Dynamic Virtual Tunnel Interface with Virtual Firewall: Example, page 20](#)
- [Dynamic Virtual Tunnel Interface with QoS: Example, page 21](#)

## Static Virtual Tunnel Interface with IPsec: Example

The following example configuration uses a preshared key for authentication between peers. VPN traffic is forwarded to the IPsec VTI for encryption and then sent out the physical interface. The tunnel on subnet 10 checks packets for IPsec policy and passes them to the Crypto Engine (CE) for IPsec encapsulation. [Figure 5](#) illustrates the IPsec VTI configuration.

**Figure 5** VTI with IPsec

## Verifying the Results for the IPsec Static Virtual Tunnel Interface: Example

This section provides information that you can use to confirm that your configuration is working properly. In this display, Tunnel 0 is “up,” and the line protocol is “up.” If the line protocol is “down,” the session is not active.

### Verifying the C7206 Status

```
Router# show interface tunnel 0
```

```
Tunnel0 is up, line protocol is up
Hardware is Tunnel
Internet address is 10.0.51.203/24
MTU 1514 bytes, BW 9 Kbit, DLY 500000 usec,
reliability 255/255, txload 103/255, rxload 110/255
Encapsulation TUNNEL, loopback not set
Keepalive not set
Tunnel source 10.0.149.203, destination 10.0.149.217
Tunnel protocol/transport IPsec/IP, key disabled, sequencing disabled
Tunnel TTL 255
```

```
Checksumming of packets disabled, fast tunneling enabled
Tunnel transmit bandwidth 8000 (kbps)
Tunnel receive bandwidth 8000 (kbps)
Tunnel protection via IPsec (profile "P1")
Last input never, output never, output hang never
Last clearing of "show interface" counters never
Input queue: 1/75/0/0 (size/max/drops/flushes); Total output drops: 0
Queueing strategy: fifo
Output queue: 0/0 (size/max)
30 second input rate 13000 bits/sec, 34 packets/sec
30 second output rate 36000 bits/sec, 34 packets/sec
191320 packets input, 30129126 bytes, 0 no buffer
Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
59968 packets output, 15369696 bytes, 0 underruns
0 output errors, 0 collisions, 0 interface resets
0 output buffer failures, 0 output buffers swapped out
```

```
Router# show crypto session
```

```

## VRF-Aware Static Virtual Tunnel Interface: Example

To add VRF to the static VTI example, include the **ip vrf** and **ip vrf forwarding** commands to the configuration as shown in the following example.

### C7206 Router Configuration

```
hostname c7206
.
.
ip vrf sample-vti1
 rd 1:1
 route-target export 1:1
 route-target import 1:1
!
.
.
interface Tunnel0
 ip vrf forwarding sample-vti1
 ip address 10.0.51.217 255.255.255.0
 tunnel source 10.0.149.217
 tunnel destination 10.0.149.203
 tunnel mode ipsec ipv4
 tunnel protection ipsec profile P1
.
.
!
end
```

## Static Virtual Tunnel Interface with QoS: Example

You can apply any QoS policy to the tunnel endpoint by including the **service-policy** statement under the tunnel interface. The following example is policing traffic out the tunnel interface.

### C7206 Router Configuration

```
hostname c7206
.
.
class-map match-all VTI
 match any
!
policy-map VTI
 class VTI
 police cir 2000000
 conform-action transmit
 exceed-action drop
!
.
.
interface Tunnel0
 ip address 10.0.51.217 255.255.255.0
 tunnel source 10.0.149.217
 tunnel destination 10.0.149.203
 tunnel mode ipsec ipv4
 tunnel protection ipsec profile P1
```

```

service-policy output VTI
!
.
.
!
end

```

## Static Virtual Tunnel Interface with Virtual Firewall: Example

Applying the virtual firewall to the static VTI tunnel allows traffic from the spoke to pass through the hub to reach the internet. [Figure 6](#) illustrates a static VTI with the spoke protected inherently by the corporate firewall.

**Figure 6** Static VTI with Virtual Firewall

The basic static VTI configuration has been modified to include the virtual firewall definition.

### C7206 Router Configuration

```

hostname c7206
.
.
ip inspect max-incomplete high 1000000
ip inspect max-incomplete low 800000
ip inspect one-minute high 1000000
ip inspect one-minute low 800000
ip inspect tcp synwait-time 60
ip inspect tcp max-incomplete host 100000 block-time 2
ip inspect name IOSFW1 tcp timeout 300
ip inspect name IOSFW1 udp
!
.
.
interface GigabitEthernet0/1
description Internet Connection
ip address 172.18.143.246 255.255.255.0
ip access-group 100 in
ip nat outside
!
interface Tunnel0
ip address 10.0.51.217 255.255.255.0
ip nat inside

```

```

ip inspect IOSFW1 in
tunnel source 10.0.149.217
tunnel destination 10.0.149.203
tunnel mode ipsec ipv4
tunnel protection ipsec profile P1
!
ip classless

!
end

```

## Dynamic Virtual Tunnel Interface Easy VPN Server: Example

The following example illustrates the use of the DVTI Easy VPN server, which serves as an IPsec remote access aggregator. The client can be a home user running a Cisco VPN client or it can be a Cisco IOS router configured as an Easy VPN client.

### C7206 Router Configuration

```

hostname c7206
!
aaa new-model
aaa authentication login local_list local
aaa authorization network local_list local
aaa session-id common
!
ip subnet-zero
ip cef
!
username cisco password 0 cisco123
!
controller ISA 1/1
!
crypto isakmp policy 1
 encr 3des
 authentication pre-share
 group 2
!
crypto isakmp client configuration group group1
 key cisco123
 pool group1pool
 save-password
!
crypto isakmp profile vpn1-ra
 match identity group group1
 client authentication list local_list

```

```

isakmp authorization list local_list
client configuration address respond
virtual-template 1
!
crypto ipsec transform-set VTI-TS esp-3des esp-sha-hmac
!
crypto ipsec profile test-vti1
set transform-set VTI-TS
!
interface GigabitEthernet0/1
description Internet Connection
ip address 172.18.143.246 255.255.255.0
!
interface GigabitEthernet0/2
description Internal Network
ip address 10.2.1.1 255.255.255.0
!
interface Virtual-Template1 type tunnel
ip unnumbered GigabitEthernet0/1
ip virtual-reassembly
tunnel mode ipsec ipv4
tunnel protection ipsec profile test-vti1
!
ip local pool group1pool 192.168.1.1 192.168.1.4
ip classless
ip route 0.0.0.0 0.0.0.0 172.18.143.1
!
end

```

## Verifying the Results for the Dynamic Virtual Tunnel Interface Easy VPN Server: Example

The following examples show that a dynamic VTI has been configured for an Easy VPN server.

Router# **show running-config interface Virtual-Access2**

Building configuration...

```

Current configuration : 250 bytes
!
interface Virtual-Access2
ip unnumbered GigabitEthernet0/1
ip virtual-reassembly
tunnel source 172.18.143.246
tunnel destination 172.18.143.208
tunnel mode ipsec ipv4
tunnel protection ipsec profile test-vti1
no tunnel protection ipsec initiate
end

```

Router# **show ip route**

```

Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
 D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
 N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
 E1 - OSPF external type 1, E2 - OSPF external type 2
 i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
 ia - IS-IS inter area, * - candidate default, U - per-user static route
 o - ODR, P - periodic downloaded static route

```

Gateway of last resort is 10.2.1.10 to network 0.0.0.0

```

 172.18.0.0/24 is subnetted, 1 subnets
C 172.18.143.0 is directly connected, GigabitEthernet0/1

```

```

 192.168.1.0/32 is subnetted, 1 subnets
S 192.168.1.1 [1/0] via 0.0.0.0, Virtual-Access2
 10.0.0.0/24 is subnetted, 1 subnets
C 10.2.1.0 is directly connected, GigabitEthernet0/2
S* 0.0.0.0/0 [1/0] via 172.18.143.1

```

## Dynamic Virtual Tunnel Interface Easy VPN Client: Example

The following example shows how you can set up a router as the Easy VPN client. This example uses basically the same idea as the Easy VPN client that you can run from a PC to connect. In fact, the configuration of the Easy VPN server will work for the software client or the Cisco IOS client.

```

hostname c1841
!
no aaa new-model
!
ip cef
!
username cisco password 0 cisco123
!
crypto ipsec client ezvpn CLIENT
 connect manual
 group group1 key cisco123
 mode client
 peer 172.18.143.246
 virtual-interface 1
 username cisco password cisco123
 xauth userid mode local
!
interface Loopback0
 ip address 10.1.1.1 255.255.255.255
!
interface FastEthernet0/0
 description Internet Connection
 ip address 172.18.143.208 255.255.255.0
 crypto ipsec client ezvpn CLIENT
!
interface FastEthernet0/1
 ip address 10.1.1.252 255.255.255.0
 crypto ipsec client ezvpn CLIENT inside
!
interface Virtual-Template1 type tunnel
 ip unnumbered Loopback0
!
ip route 0.0.0.0 0.0.0.0 172.18.143.1 254
!
end

```

The client definition can be set up in many different ways. The mode specified with the **connect** command can be automatic or manual. If the connect mode is set to manual, the IPsec tunnel has to be initiated manually by a user.

Also note use of the **mode** command. The mode can be client, network-extension, or network-extension-plus. This example indicates client mode, which means that the client is given a private address from the server. Network-extension mode is different from client mode in that the client specifies for the server its attached private subnet. Depending on the mode, the routing table on either end will be slightly different. The basic operation of the IPsec tunnel remains the same, regardless of the specified mode.

## Verifying the Results for the Dynamic Virtual Tunnel Interface Easy VPN Client: Example

The following examples illustrate different ways to display the status of the DVTI.

```
Router# show running-config interface Virtual-Access2
```

```
Building configuration...
```

```
Current configuration : 148 bytes
!
interface Virtual-Access2
 ip unnumbered Loopback1
 tunnel source FastEthernet0/0
 tunnel destination 172.18.143.246
 tunnel mode ipsec ipv4
end
```

```
Router# show running-config interface Loopback1
```

```
Building configuration...
```

```
Current configuration : 65 bytes
!
interface Loopback1
 ip address 192.168.1.1 255.255.255.255
end
```

```
Router# show ip route
```

```
Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
 D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
 N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
 E1 - OSPF external type 1, E2 - OSPF external type 2
 i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
 ia - IS-IS inter area, * - candidate default, U - per-user static route
 o - ODR, P - periodic downloaded static route
```

```
Gateway of last resort is 172.18.143.1 to network 0.0.0.0
```

```
 10.0.0.0/32 is subnetted, 1 subnets
C 10.1.1.1 is directly connected, Loopback0
 172.18.0.0/24 is subnetted, 1 subnets
C 172.18.143.0 is directly connected, FastEthernet0/0
 192.168.1.0/32 is subnetted, 1 subnets
C 192.168.1.1 is directly connected, Loopback1
S* 0.0.0.0/0 [1/0] via 0.0.0.0, Virtual-Access2
```

```
Router# show crypto ipsec client ezvpn
```

```
Easy VPN Remote Phase: 6
```

```
Tunnel name : CLIENT
Inside interface list: FastEthernet0/1
Outside interface: Virtual-Access2 (bound to FastEthernet0/0)
Current State: IPSEC_ACTIVE
Last Event: SOCKET_UP
Address: 192.168.1.1
Mask: 255.255.255.255
Save Password: Allowed
Current EzVPN Peer: 172.18.143.246
```

## VRF-Aware IPsec with Dynamic VTI: Example

This example shows how to configure VRF-Aware IPsec to take advantage of the dynamic VTI:

```
hostname c7206
.
.
ip vrf test-vti1
 rd 1:1
 route-target export 1:1
 route-target import 1:1
!
.
.
interface Virtual-Template1 type tunnel
 ip vrf forwarding test-vti1
 ip unnumbered Loopback0
 ip virtual-reassembly
 tunnel mode ipsec ipv4
 tunnel protection ipsec profile test-vti1
!
.
.
end
```

## Dynamic Virtual Tunnel Interface with Virtual Firewall: Example

The DVTI Easy VPN server can be configured behind a virtual firewall. Behind-the-firewall configuration allows users to enter the network, while the network firewall is protected from unauthorized access. The virtual firewall uses Context-Based Access Control (CBAC) and NAT applied to the Internet interface as well as to the virtual template.

```
hostname c7206
.
.
ip inspect max-incomplete high 1000000
ip inspect max-incomplete low 800000
ip inspect one-minute high 1000000
ip inspect one-minute low 800000
ip inspect tcp synwait-time 60
ip inspect tcp max-incomplete host 100000 block-time 2
ip inspect name IOSFW1 tcp timeout 300
ip inspect name IOSFW1 udp
!
.
.
interface GigabitEthernet0/1
 description Internet Connection
 ip address 172.18.143.246 255.255.255.0
 ip access-group 100 in
 ip nat outside
!
interface GigabitEthernet0/2
 description Internal Network
 ip address 10.2.1.1 255.255.255.0
!
interface Virtual-Template1 type tunnel
 ip unnumbered Loopback0
 ip nat inside
 ip inspect IOSFW1 in
```

```

 tunnel mode ipsec ipv4
 tunnel protection ipsec profile test-vti1
 !
ip classless
ip route 0.0.0.0 0.0.0.0 172.18.143.1
 !
ip nat translation timeout 120
ip nat translation finrst-timeout 2
ip nat translation max-entries 300000
ip nat pool test1 10.2.100.1 10.2.100.50 netmask 255.255.255.0
ip nat inside source list 110 pool test1 vrf test-vti1 overload
 !
access-list 100 permit esp any any
access-list 100 permit udp any eq isakmp any
access-list 100 permit udp any eq non500-isakmp any
access-list 100 permit icmp any any
access-list 110 deny esp any any
access-list 110 deny udp any eq isakmp any
access-list 110 permit ip any any
access-list 110 deny udp any eq non500-isakmp any
 !
end

```

## Dynamic Virtual Tunnel Interface with QoS: Example

You can add QoS to the DVTI tunnel by applying the service policy to the virtual template. When the template is cloned to make the virtual-access interface, the service policy will be applied there. The following example shows the basic DVTI configuration with QoS added.

```

hostname c7206
.
.
class-map match-all VTI
 match any
 !
policy-map VTI
 class VTI
 police cir 2000000
 conform-action transmit
 exceed-action drop
 !
.
.
interface Virtual-Template1 type tunnel
 ip vrf forwarding test-vti1
 ip unnumbered Loopback0
 ip virtual-reassembly
 tunnel mode ipsec ipv4
 tunnel protection ipsec profile test-vti1
 service-policy output VTI
 !
.
.
!
end

```

## Additional References

The following sections provide references related to IPsec virtual tunnel interface.

## Command Reference

The following commands are introduced or modified in the feature or features

- **crypto isakmp profile**
- **interface virtual-template**
- **show vtemplate**
- **tunnel mode**
- **virtual-template**

For information about these commands, see the Cisco IOS Security Command Reference at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html). For information about all Cisco IOS commands, see the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the Master Command List.

# Feature Information for IPsec Virtual Tunnel Interface

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Cisco IOS software images are specific to a Cisco IOS software release, a feature set, and a platform. Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click Cancel at the login dialog box and follow the instructions that appear.

## Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1** Feature Information for IPsec Virtual Tunnel Interface

| Feature Name                   | Releases                                            | Feature Configuration Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------|-----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Static IPsec VTIs              | 12.3(7)T<br>12.3(14)T<br>12.2(33)SRA<br>12.2(33)SXH | IPsec VTIs (VTIs) provide a routable interface type for terminating IPsec tunnels and an easy way to define protection between sites to form an overlay network. IPsec VTIs simplify configuration of IPsec for protection of remote links, support multicast, and simplify network management and load balancing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Dynamic IPsec VTIs             | 12.3(7)T<br>12.3(14)T                               | Dynamic VTIs provide efficiency in the use of IP addresses and provide secure connectivity. Dynamic VTIs allow dynamically downloadable per-group and per-user policies to be configured on a RADIUS server. The per-group or per-user definition can be created using Xauth User or Unity group, or it can be derived from a certificate. Dynamic VTIs are standards based, so interoperability in a multiple-vendor environment is supported. IPsec dynamic VTIs allow you to create highly secure connectivity for remote access VPNs and can be combined with Cisco Architecture for Voice, Video, and Integrated Data (AVVID) to deliver converged voice, video, and data over IP networks. The dynamic VTI simplifies VRF-aware IPsec deployment. The VRF is configured on the interface. |
| IPSec Virtual Tunnel Interface | Cisco IOS<br>XE<br>Release 2.1                      | This feature was introduced on Cisco ASR 1000 Series Routers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

# Low Latency Queueing (LLQ) for IPSec Encryption Engines

---

## Feature History

| Release   | Modification                                                  |
|-----------|---------------------------------------------------------------|
| 12.2(13)T | This feature was introduced.                                  |
| 12.2(14)S | This feature was integrated into Cisco IOS Release 12.2(14)S. |

This feature module describes the Low Latency Queueing (LLQ) for IPSec encryption engines feature in Cisco IOS Release 12.2(13)T and 12.2(14)S. It includes the following sections:

- [Feature Overview, page 1](#)
- [Supported Platforms, page 3](#)
- [Supported Standards, MIBs, and RFCs, page 4](#)
- [Prerequisites, page 4](#)
- [Configuration Tasks, page 4](#)
- [Monitoring and Maintaining LLQ for IPSec Encryption Engines, page 8](#)
- [Configuration Examples, page 8](#)
- [Command Reference, page 9](#)
- [Glossary, page 9](#)

## Feature Overview

Low Latency Queueing (LLQ) for IPSec encryption engines helps reduce packet latency by introducing the concept of queueing before crypto engines. Prior to this, the crypto processing engine gave data traffic and voice traffic equal status. Administrators now designate voice traffic as priority. Data packets arriving at a router interface are directed into a data packet inbound queue for crypto engine processing. This queue is called the best effort queue. Voice packets arriving on a router interface are directed into

a priority packet inbound queue for crypto engine processing. This queue is called the priority queue. The crypto engine undertakes packet processing in a favorable ratio for voice packets. Voice packets are guaranteed a minimum processing bandwidth on the crypto engine.

## Benefits

The Low Latency Queueing (LLQ) for IPSec encryption engines feature guarantees a certain level of crypto engine processing time for priority designated traffic.

### Note

On the Cisco 2600 platform, with the exception of the Cisco 2691 router, the CPU utilization maximizes out before the crypto engine becomes congested, so latency is not improved.

### Better Voice Performance

Voice packets can be identified as priority, allowing the crypto engine to guarantee a certain percentage of processing bandwidth. This feature impacts the end user experience by assuring voice quality if voice traffic is directed onto a congested network.

### Improved Latency and Jitters

Predictability is a critical component of network performance. The Low Latency Queueing (LLQ) for IPSec encryption engines feature delivers network traffic predictability relating to VPN. With this feature disabled, an end user employing an IP phone over VPN might experience jitter or latency, both symptoms of overall network latency and congestion. With this feature enabled, these undesirable characteristics are dissipated.

## Restrictions

- No per-tunnel QoS policy. An interface QoS policy represents all tunnels.
- Assume the same IP precedence/DSCP marking for inbound and outbound voice packets.
- Assume the IP precedence/DSCP marking for voice packets are done at the source.
- Limited match criteria for voice traffic in the interface QoS policy.
- Assume call admission control is enforced within the enterprise.
- No strict error checking when aggregate policy's bandwidth exceeds crypto engine bandwidth. Only a warning is displayed but configuration is allowed.
- Assume voice packets are either all encrypted or unencrypted.

## Related Features and Technologies

- CBWFQ
- Priority Queueing
- Weighted Fair Queueing

## Related Documents

## Supported Platforms

### 12.2(14)S and higher

The LLQ for IPSec encryption engines feature is supported on the following platform:

- Cisco 7200 series

### 12.2(13)T

The LLQ for IPSec encryption engines feature is supported on all platforms using Cisco IOS Release 12.2(13)T or later, including:

- Cisco 2600 series
- Cisco 3600 series
- Cisco 7100 series
- Cisco 7200 series

## Determining Platform Support Through Cisco Feature Navigator

Cisco IOS software is packaged in feature sets that are supported on specific platforms. To get updated information regarding platform support for this feature, access Cisco Feature Navigator. Cisco Feature Navigator dynamically updates the list of supported platforms as new platform support is added for the feature.

Cisco Feature Navigator is a web-based tool that enables you to quickly determine which Cisco IOS software images support a specific set of features and which features are supported in a specific Cisco IOS image. You can search by feature or release. Under the release section, you can compare releases side-by-side to display both the features unique to each software release and the features in common.

To access Cisco Feature Navigator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to [cco-locksmith@cisco.com](mailto:cco-locksmith@cisco.com). An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions found at this URL:

<http://www.cisco.com/register>

Cisco Feature Navigator is updated regularly when major Cisco IOS software releases and technology releases occur. For the most current information, go to the Cisco Feature Navigator home page at the following URL:

<http://www.cisco.com/go/fn>

## Availability of Cisco IOS Software Images

Platform support for particular Cisco IOS software releases is dependent on the availability of the software images for those platforms. Software images for some platforms may be deferred, delayed, or changed without prior notice. For updated information about platform support and availability of software images for each Cisco IOS software release, refer to the online release notes or, if supported, Cisco Feature Navigator.

## Supported Standards, MIBs, and RFCs

### Standards

- No new or modified standards are supported by this feature.

### MIBs

- No new or modified standards are supported by this feature.

To locate and download MIBs for selected platforms, Cisco IOS releases, and feature sets, use Cisco MIB Locator found at the following URL:

<http://tools.cisco.com/ITDIT/MIBS/servlet/index>

If Cisco MIB Locator does not support the MIB information that you need, you can also obtain a list of supported MIBs and download MIBs from the Cisco MIBs page at the following URL:

<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>

To access Cisco MIB Locator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to [cco-locksmith@cisco.com](mailto:cco-locksmith@cisco.com). An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions found at this URL:

<http://www.cisco.com/register>

### RFCs

- No new or modified RFCs are supported by this feature.

## Prerequisites

To use this feature, you should be familiar with the following:

- Access control lists
- Bandwidth management
- CBWFQ

## Configuration Tasks

To configure LLQ for IPSec encryption engines, perform the tasks described in the following section.

**Note**

See the [Quality of Service Solutions Command Reference](#), Cisco IOS Release 12.2, to learn more about configuring server policies on interfaces.

- [Defining Class Maps](#) (required)
- [Configuring Class Policy in the Policy Map](#) (required)
- [Configuring Class Policy for a Priority Queue](#) (required)
- [Configuring Class Policy Using a Specified Bandwidth](#) (optional)
- [Configuring the Class-Default Class Policy](#) (optional)
- [Attaching the Service Policy](#) (required)
- [Verifying Configuration of Policy Maps and Their Classes](#) (optional)

## Defining Class Maps

To create a class map containing match criteria against which a packet is checked to determine if it belongs to a class, use the following commands beginning in global configuration mode:

|               | Command                                                                                                                                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Router(config)# <b>class-map</b> class-map-name                                                                                                                                                                                               | Specifies the name of the class map to be created.                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Step 2</b> | Router(config-cmap)# <b>match access-group</b> {access-group   name access-group-name}<br><br>or<br><br>Router(config-cmap)# <b>match input-interface</b> interface-name<br><br>or<br><br>Router(config-cmap)# <b>match protocol</b> protocol | Specifies the name of the access control list (ACL) against whose contents packets are checked to determine if they belong to the class.<br><br>Specifies the name of the input interface used as a match criterion against which packets are checked to determine if they belong to the class.<br><br>Specifies the name of the protocol used as a match criterion against which packets are checked to determine if they belong to the class. |

## Configuring Class Policy in the Policy Map

To configure a policy map and create class policies that make up the service policy, begin with the **policy-map** command to specify the policy map name. Then use one or more of the following commands to configure the policy for a standard class or the default class:

- **priority**
- **bandwidth**
- **queue-limit** or **random-detect**
- **fair-queue** (for class-default class only)

For each class that you define, you can use one or more of the commands listed to configure the class policy. For example, you might specify bandwidth for one class and both bandwidth and queue limit for another class.

The default class of the policy map (commonly known as the class-default class) is the class to which traffic is directed if that traffic does not satisfy the match criteria of the other classes defined in the policy map.

You can configure class policies for as many classes as are defined on the router, up to the maximum of 64. However, the total amount of bandwidth allocated for all classes in a policy map must not exceed the minimum committed information rate (CIR) configured for the virtual circuit (VC) minus any bandwidth reserved by the **frame-relay voice bandwidth** and **frame-relay ip rtp priority** commands. If the minimum CIR is not configured, the bandwidth defaults to one half of the CIR. If all of the bandwidth is not allocated, the remaining bandwidth is allocated proportionally among the classes on the basis of their configured bandwidth.

To configure class policies in a policy map, perform the tasks described in the following sections. The task in the first section is required; the tasks in the remaining sections are optional.

## Configuring Class Policy for a Priority Queue

To configure a policy map and give priority to a class within the policy map, use the following commands beginning in global configuration mode:

|               | Command                                               | Purpose                                                                                                      |
|---------------|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Router(config)# <b>policy-map</b> policy-map          | Specifies the name of the policy map to be created or modified.                                              |
| <b>Step 2</b> | Router(config-cmap)# <b>class</b> class-name          | Specifies the name of a class to be created and included in the service policy.                              |
| <b>Step 3</b> | Router(config-pmap-c)# <b>priority</b> bandwidth-kbps | Creates a strict priority class and specifies the amount of bandwidth, in kbps, to be assigned to the class. |

## Configuring Class Policy Using a Specified Bandwidth

To configure a policy map and create class policies that make up the service policy, use the following commands beginning in global configuration mode:

|               | Command                                                | Purpose                                                                                                                                                                                                                                                                 |
|---------------|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Router(config)# <b>policy-map</b> policy-map           | Specifies the name of the policy map to be created or modified.                                                                                                                                                                                                         |
| <b>Step 2</b> | Router(config-cmap)# <b>class</b> class-name           | Specifies the name of a class to be created and included in the service policy.                                                                                                                                                                                         |
| <b>Step 3</b> | Router(config-pmap-c)# <b>bandwidth</b> bandwidth-kbps | Specifies the amount of bandwidth to be assigned to the class, in kbps, or as a percentage of the available bandwidth. Bandwidth must be specified in kbps or as a percentage consistently across classes. (Bandwidth of the priority queue must be specified in kbps.) |

To configure more than one class in the same policy map, repeat [Step 2](#) and [Step 3](#).

## Configuring the Class-Default Class Policy

The class-default class is used to classify traffic that does not fall into one of the defined classes. Even though the class-default class is predefined when you create the policy map, you still have to configure it. If a default class is not configured, then traffic that does not match any of the configured classes is given best-effort treatment, which means that the network will deliver the traffic if it can, without any assurance of reliability, delay prevention, or throughput.

To configure a policy map and the class-default class, use the following commands beginning in global configuration mode:

|               | Command                                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Router(config)# <b>policy-map</b> policy-map                                                                                                               | Specifies the name of the policy map to be created or modified.                                                                                                                                                                                                                        |
| <b>Step 2</b> | Router(config-cmap)# <b>class class-default</b><br><i>default-class-name</i>                                                                               | Specifies the default class so that you can configure or modify its policy.                                                                                                                                                                                                            |
| <b>Step 3</b> | Router(config-pmap-c)# <b>bandwidth</b><br>bandwidth-kbps<br><br>or<br><br>Router(config-pmap-c)# <b>fair-queue</b><br>[ <i>number-of-dynamic-queues</i> ] | Specifies the amount of bandwidth, in kbps, to be assigned to the class.<br><br><br><br><br>Specifies the number of dynamic queues to be reserved for use by flow-based WFQ running on the default class. The number of dynamic queues is derived from the bandwidth of the interface. |

## Attaching the Service Policy

To attach a service policy to the output interface and enable LLQ for IPsec encryption engines, use the following command in map-class configuration mode:

|               | Command                                                       | Purpose                                                                                                         |
|---------------|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Router(config)# <b>interface</b> type number                  | Specifies the interface using the LLQ for IPsec encryption engines.                                             |
| <b>Step 2</b> | Router(config-if)# <b>service-policy output</b><br>policy-map | Attaches the specified service policy map to the output interface and enables LLQ for IPsec encryption engines. |

## Verifying Configuration of Policy Maps and Their Classes

To display the contents of a specific policy map or all policy maps configured on an interface, use the following commands in EXEC mode, as needed:

|               | Command                                  | Purpose                                                                                                                                        |
|---------------|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Router# <b>show frame-relay pvc dlci</b> | Displays statistics about the PVC and the configuration of classes for the policy map on the specified data-link connection identifier (DLCI). |

|        | Command                                                                  | Purpose                                                                                                 |
|--------|--------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| Step 2 | Router# <b>show policy-map interface</b> <i>interface-name</i>           | When LLQ is configured, displays the configuration of classes for all policy maps.                      |
| Step 3 | Router# <b>show policy-map interface</b> <i>interface-name dlci dlci</i> | When LLQ is configured, displays the configuration of classes for the policy map on the specified DLCI. |

## Monitoring and Maintaining LLQ for IPsec Encryption Engines

To monitor and maintain LLQ for IPsec encryption engines, use the following command in EXEC mode:

|        | Command                            | Purpose                                                                               |
|--------|------------------------------------|---------------------------------------------------------------------------------------|
| Step 1 | Router# <b>show crypto eng qos</b> | Displays quality of service queueing statistics for LLQ for IPsec encryption engines. |

For a more detailed list of commands that can be used to monitor LLQ for IPsec encryption engines, see the section [“Verifying Configuration of Policy Maps and Their Classes”](#)

## Configuration Examples

This section provides the following configuration example:

- [LLQ for IPsec Encryption Engines Example](#)

### LLQ for IPsec Encryption Engines Example

In the following example, a strict priority queue with a guaranteed allowed bandwidth of 50 kbps is reserved for traffic that is sent from the source address 10.10.10.10 to the destination address 10.10.10.20, in the range of ports 16384 through 20000 and 53000 through 56000.

First, the following commands configure access list 102 to match the desired voice traffic:

```
Router(config)# access-list 102 permit udp host 10.10.10.10 host 10.10.10.20 range 16384 20000
Router(config)# access-list 102 permit udp host 10.10.10.10 host 10.10.10.20 range 53000 56000
```

Next, the class map voice is defined, and the policy map called policy1 is created; a strict priority queue for the class voice is reserved, a bandwidth of 20 kbps is configured for the class bar, and the default class is configured for WFQ. The service-policy command then attaches the policy map to the fas0/0.

```
Router(config)# class-map voice
Router(config-cmap)# match access-group 102
Router(config)# policy-map policy1
Router(config-pmap)# class voice
Router(config-pmap-c)# priority 50
Router(config-pmap)# class bar
Router(config-pmap-c)# bandwidth 20
Router(config-pmap)# class class-default
Router(config-pmap-c)# fair-queue
Router(config)# interface fas0/0
```

```
Router(config-if)# service-policy output policy1
```

## Command Reference

The following new command is pertinent to this feature. To see the command pages for this command and other commands used with this feature, go to the *Cisco IOS Master Commands List*, Release 12.4, at <http://www.cisco.com/univercd/cc/td/doc/product/software/ios124/124mindx/124index.htm>.

- **show crypto eng qos**

For information about these commands, see the Cisco IOS Security Command Reference at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html).

For information about all Cisco IOS commands, see the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the Master Command List.

## Glossary

**IKE**—Internet Key Exchange. IKE establishes a shared security policy and authenticates keys for services (such as IPSec). Before any IPSec traffic can be passed, each router/firewall/host must verify the identity of its peer. This can be done by manually entering preshared keys into both hosts or by a CA service.

**IPSec**—IP Security. A framework of open standards that provides data confidentiality, data integrity, and data authentication between participating peers. IPSec provides these security services at the IP layer. IPSec uses IKE to handle the negotiation of protocols and algorithms based on local policy and to generate the encryption and authentication keys to be used by IPSec. IPSec can protect one or more data flows between a pair of hosts, between a pair of security gateways, or between a security gateway and a host.

# Pre-Fragmentation for IPSec VPNs

## Feature History

| Release                  | Modification                                                  |
|--------------------------|---------------------------------------------------------------|
| 12.1(11b)E               | This feature was introduced.                                  |
| 12.2(13)T                | This feature was integrated into Cisco IOS Release 12.2(13)T. |
| 12.2(14)S                | This feature was integrated into Cisco IOS Release 12.2(14)S. |
| Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers. |

This feature module describes the Pre-fragmentation for IPSec VPNs feature in Cisco IOS Release 12.2(13)T and 12.2(14)S. It includes the following sections:

- [Feature Overview, page 1](#)
- [Supported Platforms, page 4](#)
- [Configuration Tasks, page 6](#)
- [Configuration Tasks, page 6](#)
- [Configuration Examples, page 8](#)
- [Command Reference, page 9](#)

## Feature Overview

When a packet is nearly the size of the maximum transmission unit (MTU) of the outbound link of the encrypting router, and it is encapsulated with IPSec headers, it is likely to exceed the MTU of the outbound link. This causes packet fragmentation after encryption, which makes the decrypting router reassemble in the process path. Pre-fragmentation for IPSec VPNs increases the decrypting router's performance by enabling it to operate in the high performance CEF path instead of the process path.

This feature allows an encrypting router to predetermine the encapsulated packet size from information available in transform sets, which are configured as part of the IPSec security association (SA). If it is predetermined that the packet will exceed the MTU of the output interface, the packet is fragmented before encryption. This function avoids process level reassembly before decryption and helps improve decryption performance and overall IPSec traffic throughput.

**Americas Headquarters:**  
**Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA**

© 2007 Cisco Systems, Inc. All rights reserved.

**Note**

---

The pre-fragmentation feature is turned off by default for tunnel interfaces. To receive pre-fragmentation performance benefits, turn pre-fragmentation on after insuring that the tunnel interfaces have the same MTU on both ends.

---

## Benefits

### Increased Performance

Delivers encryption throughput at maximum encryption hardware accelerator speeds. This performance increase is for near MTU-sized packets.

### Uniform Fragmentation

Packets are fragmented into equally sized units to prevent further downstream fragmentation.

### Interoperability

This feature is interoperable with all Cisco IOS platforms and a number of Cisco VPN clients.

## Restrictions

Take the following information into consideration before this feature is configured:

- Pre-fragmentation for IPsec VPNs operates in IPsec tunnel mode and IPsec tunnel mode with GRE, but not with IPsec transport mode.
- Pre-fragmentation for IPsec VPNs configured on the decrypting router in a unidirectional traffic scenario does not improve the performance or change the behavior of either of the peers.
- Pre-fragmentation for IPsec VPNs occurs before the transform is applied if compression is turned on for outgoing packets.
- Pre-fragmentation for IPsec VPNs functionality depends on the egress interface **crypto ipsec df-bit** configuration and the incoming packet “do not fragment” (DF) bit state. See [Table 1](#).

**Table 1** Pre-Fragmentation for IPsec VPNs Dependencies

| Pre-Fragmentation for IPsec VPNs Feature State (Enabled/Disabled) | Egress Interface “crypto ipsec df-bit” Configuration | Incoming Packet DF Bit State | Result                                                                               |
|-------------------------------------------------------------------|------------------------------------------------------|------------------------------|--------------------------------------------------------------------------------------|
| Enabled                                                           | crypto ipsec df-bit clear                            | 0                            | Fragmentation occurs before encryption.                                              |
| Enabled                                                           | crypto ipsec df-bit clear                            | 1                            | Fragmentation occurs before encryption.                                              |
| Disabled                                                          | crypto ipsec df-bit clear                            | 0                            | Fragmentation occurs after encryption and packets are reassembled before decryption. |
| Disabled                                                          | crypto ipsec df-bit clear                            | 1                            | Fragmentation occurs after encryption and packets are reassembled before decryption. |
| Enabled                                                           | crypto ipsec df-bit set                              | 0                            | Fragmentation occurs before encryption.                                              |

**Table 1** *Pre-Fragmentation for IPsec VPNs Dependencies (continued)*

| <b>Pre-Fragmentation for IPsec VPNs Feature State (Enabled/Disabled)</b> | <b>Egress Interface "crypto ipsec df-bit" Configuration</b> | <b>Incoming Packet DF Bit State</b> | <b>Result</b>                                                                        |
|--------------------------------------------------------------------------|-------------------------------------------------------------|-------------------------------------|--------------------------------------------------------------------------------------|
| Enabled                                                                  | crypto ipsec df-bit set                                     | 1                                   | Packets are dropped.                                                                 |
| Disabled                                                                 | crypto ipsec df-bit set                                     | 0                                   | Fragmentation occurs after encryption and packets are reassembled before decryption. |
| Disabled                                                                 | crypto ipsec df-bit set                                     | 1                                   | Packets are dropped.                                                                 |
| Enabled                                                                  | crypto ipsec df-bit copy                                    | 0                                   | Fragmentation occurs before encryption.                                              |
| Enabled                                                                  | crypto ipsec df-bit copy                                    | 1                                   | Packets are dropped.                                                                 |
| Disabled                                                                 | crypto ipsec df-bit copy                                    | 0                                   | Fragmentation occurs after encryption and packets are reassembled before decryption. |
| Disabled                                                                 | crypto ipsec df-bit copy                                    | 1                                   | Packets are dropped.                                                                 |

## Supported Platforms

### 12.2(14)S and higher

The Pre-fragmentation for IPsec VPN feature is supported on the following platforms:

- Cisco 7200 series
- Cisco 7400 series

### 12.2(13)T

The Pre-fragmentation for IPsec VPN feature is supported on all platforms using Cisco IOS Release 12.2(13)T or higher, including:

- Cisco 1710
- Cisco 1720
- Cisco 1721
- Cisco 1751
- Cisco 1760
- Cisco 2600
- Cisco 2691
- Cisco 3620
- Cisco 3640
- Cisco 3660

- Cisco 3725
- Cisco 3745
- Cisco 7100 series
- Cisco 7200 series
- Cisco 7400 series

#### 12.1(11b)E

The Pre-fragmentation for IPSec VPN feature is supported on all platforms using Cisco IOS Release 12.1(11b)E or higher, including:

- Cisco 7100 series

#### Determining Platform Support Through Cisco Feature Navigator

Cisco IOS software is packaged in feature sets that are supported on specific platforms. To get updated information regarding platform support for this feature, access Cisco Feature Navigator. Cisco Feature Navigator dynamically updates the list of supported platforms as new platform support is added for the feature.

Cisco Feature Navigator is a web-based tool that enables you to determine which Cisco IOS software images support a specific set of features and which features are supported in a specific Cisco IOS image. You can search by feature or release. Under the release section, you can compare releases side by side to display both the features unique to each software release and the features in common.

To access Cisco Feature Navigator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to [cco-locksmith@cisco.com](mailto:cco-locksmith@cisco.com). An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions found at this URL:

<http://www.cisco.com/register>

Cisco Feature Navigator is updated regularly when major Cisco IOS software releases and technology releases occur. For the most current information, go to the Cisco Feature Navigator home page at the following URL:

<http://www.cisco.com/go/fn>

#### Availability of Cisco IOS Software Images

Platform support for particular Cisco IOS software releases is dependent on the availability of the software images for those platforms. Software images for some platforms may be deferred, delayed, or changed without prior notice. For updated information about platform support and availability of software images for each Cisco IOS software release, refer to the online release notes or, if supported, Cisco Feature Navigator.

# Supported Standards, MIBs, and RFCs

## Standards

- No new or modified standards are supported by this feature.

## MIBs

- No new or modified standards are supported by this feature.

To locate and download MIBs for selected platforms, Cisco IOS releases, and feature sets, use Cisco MIB Locator found at the following URL:

<http://tools.cisco.com/ITDIT/MIBS/servlet/index>

If Cisco MIB Locator does not support the MIB information that you need, you can also obtain a list of supported MIBs and download MIBs from the Cisco MIBs page at the following URL:

<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>

To access Cisco MIB Locator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to [cco-locksmith@cisco.com](mailto:cco-locksmith@cisco.com). An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions found at this URL:

<http://www.cisco.com/register>

## RFCs

- No new or modified RFCs are supported by this feature.

## Configuration Tasks

See the following sections for configuration tasks for the Pre-fragmentation for IPSec VPNs feature. Each task in the list is identified as either required or optional.

- [Configuring Pre-Fragmentation For IPSec VPNs](#) (required)
- [Verifying Pre-Fragmentation For IPSec VPNs](#) (optional)

## Configuring Pre-Fragmentation For IPSec VPNs

Pre-fragmentation for IPSec VPNs is globally enabled by default. To enable or disable pre-fragmentation for IPSec VPNs while in interface configuration mode, enter the commands in the following table. Use the **no** form of the commands to revert back to the default configuration, or use the commands themselves to enable configuration of the pre-fragmentation IPSec VPNs.

### Note

Manually enabling or disabling this feature will override the global configuration.

| Command                                                                | Purpose                                                     |
|------------------------------------------------------------------------|-------------------------------------------------------------|
| Router(config-if)# <b>crypto ipsec fragmentation before-encryption</b> | Enables pre-fragmentation for IPsec VPNs on the interface.  |
| Router(config-if)# <b>crypto ipsec fragmentation after-encryption</b>  | Disables pre-fragmentation for IPsec VPNs on the interface. |
| Router(config)# <b>crypto ipsec fragmentation before-encryption</b>    | Enables pre-fragmentation for IPsec VPNs globally.          |
| Router(config)# <b>crypto ipsec fragmentation after-encryption</b>     | Disables pre-fragmentation for IPsec VPNs globally.         |

## Verifying Pre-Fragmentation For IPsec VPNs

To verify that this feature is enabled, consult the interface statistics on the encrypting router and the decrypting router. If fragmentation occurs on the encrypting router, and no reassembly occurs on the decrypting router, fragmentation is happening before encryption, and thus the packets are not being reassembled before decryption. This means that the feature is enabled.

### Note

This method of verification does not apply to packets destined for the decrypting router.

- Step 1** Enter the **show running-configuration** command on the encrypting router. If the feature is enabled, you will observe output similar to the following:

```
Router# show running-configuration
crypto isakmp policy 10
 authentication pre-share
crypto isakmp key abcd123 address 25.0.0.7
!
!
crypto ipsec transform-set fooprime esp-3des esp-sha-hmac
!
crypto map bar 10 ipsec-isakmp
 set peer 25.0.0.7
 set transform-set fooprime
 match address 102
```

If the feature has been disabled, you will observe output similar to the following:

```
Router# show running-configuration
crypto isakmp policy 10
 authentication pre-share
crypto isakmp key abcd123 address 25.0.0.7
!
!
crypto ipsec transform-set fooprime esp-3des esp-sha-hmac
crypto ipsec fragmentation after-encryption
!
crypto map bar 10 ipsec-isakmp
 set peer 25.0.0.7
 set transform-set fooprime
 match address 102
```

- Step 2** Enter the **show running-configuration interface type number** command to display statistics for the encrypting router egress interface. If the feature is enabled, you will observe output similar to the following:

```
Router# show running-configuration interface fastethernet 0/0
interface FastEthernet0/0
 ip address 25.0.0.6 255.0.0.0
 no ip mroute-cache
 load-interval 30
 duplex full
 speed 100
 crypto map bar
```

If the feature has been disabled, you will observe output similar to the following:

```
Router# show running-configuration interface fastethernet 0/0

interface FastEthernet0/0
 ip address 25.0.0.6 255.0.0.0
 no ip mroute-cache
 load-interval 30
 duplex full
 speed 100
 crypto map bar
 crypto ipsec fragmentation after-encryption
```

---

## Configuration Examples

This section provides the following configuration example:

- [Enabling Pre-Fragmentation For IPSec VPNs Example](#)

### Enabling Pre-Fragmentation For IPSec VPNs Example

The following configuration example shows how to configure the Pre-Fragmentation for IPSec VPNs feature:

#### Note

This feature does not show up in the running configuration in this example because the default global pre-fragmentation for IPSec VPNs feature is enabled. Pre-fragmentation for IPSec VPNs shows in the running configuration only when you explicitly enable the feature on the interface.

---

```
crypto isakmp policy 10
 authentication pre-share
 crypto isakmp key abcd123 address 25.0.0.7
 !
 !
 crypto ipsec transform-set fooprime esp-3des esp-sha-hmac
 !
 crypto map bar 10 ipsec-isakmp
 set peer 25.0.0.7
 set transform-set fooprime
 match address 102
```

# Command Reference

The following commands are introduced or modified in the feature or features

- **crypto ipsec fragmentation**
- **crypto ipsec fragmentation (interface configuration)**

For information about these commands, see the Cisco IOS Security Command Reference at

[http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html).

For information about all Cisco IOS commands, see the Command Lookup Tool at

<http://tools.cisco.com/Support/CLILookup> or the Master Command List.

## Real-Time Resolution for IPSec Tunnel Peer

---

After a user specifies a host name (instead of an IP address) for remote IP Security (IPSec) peer, the Real-Time Resolution for IPSec Tunnel Peer feature allows the host name to be domain name server (DNS) resolved before the router establishes the IPSec tunnel. Thus, the router can immediately discover whether the IP address of the peer has changed.

### Feature History for Real-Time Resolution for IPSec Tunnel Peer

| Release                  | Modification                                                  |
|--------------------------|---------------------------------------------------------------|
| 12.3(4)T                 | This feature was introduced.                                  |
| Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers. |

### Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

# Restrictions for Real-Time Resolution for IPsec Tunnel Peer

## Secure DNS Requirement

It is recommended that you use this feature only with secure DNS and when the DNS responses can be authenticated. Otherwise, an attacker can spoof or forge DNS responses and have access to Internet Key Exchange (IKE) authentication data, such as a certificate. If an attacker has a certificate that is trusted by the initiating host, the attacker can successfully establish Phase 1 IKE security association (SA), or the attacker can try to guess the preshared key that is shared between the initiator and the actual responder.

## DNS Initiator

DNS names resolution for remote IPsec peers will work only if they are used as an initiator. The first packet that is to be encrypted will trigger a DNS lookup; after the DNS lookup is complete, subsequent packets will trigger IKE.

# Information About Real-Time Resolution for IPsec Tunnel Peer

To configure real-time resolution for your IPsec peer, you should understand the following concept:

- [Benefits of Real-Time Resolution Via Secure DNS, page 2](#)

## Benefits of Real-Time Resolution Via Secure DNS

When specifying the host name of a remote IPsec peer via the **set peer** command, you can also issue the **dynamic** keyword, which defers DNS resolution of the host name until right before the IPsec tunnel has been established. Deferring resolution enables the Cisco IOS software to detect whether the IP address of the remote IPsec peer has changed. Thus, the software can contact the peer at the new IP address.

If the **dynamic** keyword is not issued, the host name is resolved immediately after it is specified. So, the Cisco IOS software cannot detect an IP address change and, therefore, attempts to connect to the IP address that it previously resolved.

DNS resolution assures users that their established IPsec tunnel is secure and authenticated.

# How to Configure Real-Time Resolution

This section contains the following procedure:

- [Configuring Real-Time Resolution for IPsec Peers, page 2](#)

## Configuring Real-Time Resolution for IPsec Peers

Use this task to configure a router to perform real-time DNS resolution with a remote IPsec peer; that is, the host name of peer is resolved via a DNS lookup right before the router establishes a connection (an IPsec tunnel) with the peer.

## Prerequisites

Before creating a crypto map, you should perform the following tasks:

- Define Internet Security Association Key Management Protocol (ISAKMP) policies.
- Define IPSec transform sets.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name seq-num ipsec-isakmp*
4. **match address** *access-list-id*
5. **set peer** {*host-name [dynamic]* | *ip-address*}
6. **set transform-set** *transform-set-name1 [transform-set-name2...transform-set-name6]*

## DETAILED STEPS

|        | Command or Action                                                         | Purpose                                                                                                                                                            |
|--------|---------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b>                                                             | Enables privileged EXEC mode.                                                                                                                                      |
|        | <b>Example:</b><br>Router> enable                                         | <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                               |
| Step 2 | <b>configure terminal</b>                                                 | Enters global configuration mode.                                                                                                                                  |
|        | <b>Example:</b><br>Router# configure terminal                             |                                                                                                                                                                    |
| Step 3 | <b>crypto map</b> <i>map-name seq-num ipsec-isakmp</i>                    | Specifies the crypto map entry to create (or modify) and enters crypto map configuration mode.                                                                     |
|        | <b>Example:</b><br>Router(config)# crypto map secure_b 10<br>ipsec-isakmp |                                                                                                                                                                    |
| Step 4 | <b>match address</b> <i>access-list-id</i>                                | Names an extended access list.                                                                                                                                     |
|        | <b>Example:</b><br>Router(config-crypto-m)# match address 140             | This access list determines which traffic should be protected by IPSec and which traffic should not be protected by IPSec in the context of this crypto map entry. |

|        | Command or Action                                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 5 | <b>set peer</b> { <i>host-name</i> [ <b>dynamic</b> ]   <i>ip-address</i> }<br><br><b>Example:</b><br>Router(config-crypto-m)# set peer b.cisco.com dynamic                                  | Specifies a remote IPSec peer.<br><br>This is the peer to which IPSec-protected traffic can be forwarded. <ul style="list-style-type: none"> <li><b>dynamic</b>—Allows the host name to be resolved via a DNS lookup just before the router establishes the IPSec tunnel with the remote peer. If this keyword is not specified, the host name will be resolved immediately after the host name is specified.</li> </ul> Repeat for multiple remote peers. |
| Step 6 | <b>set transform-set</b> <i>transform-set-name1</i> [ <i>transform-set-name2</i> ... <i>transform-set-name6</i> ]<br><br><b>Example:</b><br>Router(config-crypto-m)# set transform-set myset | Specifies which transform sets are allowed for this crypto map entry. List multiple transform sets in order of priority (highest priority first).                                                                                                                                                                                                                                                                                                          |

## Troubleshooting Tips

To display crypto map configuration information, use the **show crypto map** command.

## What to Do Next

You need to apply a crypto map set to each interface through which IPSec traffic will flow. Applying the crypto map set to an interface instructs the router to evaluate all the interface's traffic against the crypto map set and to use the specified policy during connection or security association (SA) negotiation on behalf of traffic to be protected by crypto.

# Configuration Examples for Real-Time Resolution

This section provides the following configuration example:

- [Configuring Real-Time Resolution for an IPSec Peer: Example, page 4](#)

## Configuring Real-Time Resolution for an IPSec Peer: Example

[Figure 1](#) and the following example illustrate how to create a crypto map that configures the host name of a remote IPSec peer to DNS resolved via a DNS lookup right before the Cisco IOS software attempts to establish a connection with that peer.

**Figure 1**      **Real-Time Resolution Sample Topology**

```

! Configure the initiating router.
hostname a.cisco.com
ip domain name cisco.com
ip name server 10.0.0.1
!
crypto map secure_b 10 ipsec-isakmp
 match address 140
 set peer b.cisco.com dynamic
 set transform-set xset
interface serial1
 ip address 30.0.0.1
 crypto map secure_b
access-list 140 permit ...
!
! Configure the responding router (the remote IPsec peer).
hostname b.cisco.com
!
crypto map secure_a 10 ipsec-isakmp
 match address 150
 set peer 30.0.0.1
 set transform-set
interface serial0/1
 ip address 40.0.0.1
 crypto map secure_a
access-list 150 ...

! DNS server configuration

b.cisco.com 40.0.0.1 # the address of serial0/1 of b.cisco.com

```

# Reverse Route Injection

---

**First Published: August 16, 2001**

**Last Updated: November 5, 2007**

Reverse route injection (RRI) is the ability for static routes to be automatically inserted into the routing process for those networks and hosts protected by a remote tunnel endpoint. These protected hosts and networks are known as remote proxy identities.

Each route is created on the basis of the remote proxy network and mask, with the next hop to this network being the remote tunnel endpoint. By using the remote Virtual Private Network (VPN) router as the next hop, the traffic is forced through the crypto process to be encrypted.

Enhancements to the default behavior of RRI, the addition of a route tag value, and enhancements to how RRI is configured were added to the Reverse Route Injection feature in Cisco IOS Release 12.3(14)T.

An enhancement was added in Cisco IOS Release 12.4(15)T that allows a distance metric to be set for routes that are created by a VPN process so that the dynamically learned route on a router can take precedence over a locally configured static route.

## Finding Feature Information in This Module

*Your Cisco IOS software release may not support all of the features documented in this module.* To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for Reverse Route Injection”](#) section on page 18.

## Finding Support Information for Platforms and Cisco IOS Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

- [Command Reference, page 17](#)
- [Feature Information for Reverse Route Injection, page 26](#)

## Prerequisites for Reverse Route Injection

- IP routing should be enabled and static routes should be redistributed if dynamic routing protocols are to be used to propagate RRI-generated static routes.

## Restrictions for Reverse Route Injection

- If RRI is applied to a crypto map, that map must be unique to one interface on the router. In other words, the same crypto map cannot be applied to multiple interfaces. If more than one crypto map is applied to multiple interfaces, routes may not be cleaned up correctly. If multiple interfaces require a crypto map, each must use a uniquely defined map. This restriction applies only to RRI before Cisco IOS Release 12.3(14)T.
- For static crypto maps, routes are always present if RRI is configured on an applied crypto map. In Cisco IOS Release 12.3(14)T, the default behavior—of routes always being present for a static map—will not apply unless the **static keyword** is added to the **reverse-route** command.

## Information About Reverse Route Injection

To configure the Reverse Route Injection enhancements, you should understand the following concepts:

- [Reverse Route Injection, page 2](#)
- [Enhancements to Reverse Route Injection in Cisco IOS Release 12.4\(15\)T, page 3](#)

## Reverse Route Injection

RRI is the ability for static routes to be automatically inserted into the routing process for those networks and hosts that are protected by a remote tunnel endpoint. These protected hosts and networks are known as remote proxy identities.

Each route is created on the basis of the remote proxy network and mask, with the next hop to this network being the remote tunnel endpoint. By using the remote VPN router as the next hop, the traffic is forced through the crypto process to be encrypted.

After the static route is created on the VPN router, this information is propagated to upstream devices, allowing them to determine the appropriate VPN router to which to send returning traffic in order to maintain IPsec state flows. Being able to determine the appropriate VPN router is particularly useful if multiple VPN routers are used at a site to provide load balancing or failover or if the remote VPN devices are not accessible via a default route. Routes are created in either the global routing table or the appropriate virtual route forwarding (VRF) table.

RRI is applied on a per-crypto map basis, whether this is via a static crypto map or a dynamic crypto map template. The default behavior for the two map types is as follows:

- In the case of a dynamic crypto map, routes are created upon the successful establishment of IPsec security associations (SAs) for those remote proxies. The next hop back to those remote proxies is via the remote VPN router whose address is learned and applied during the creation of the dynamic crypto map template. The routes are deleted after the SAs are deleted. In Cisco IOS Release 12.3(14)T, the creation of routes on the basis of IPsec source proxies on static crypto maps was added. This behavior became the default behavior on static maps and overrode the creation of routes on the basis of crypto ACLs (see the next bullet).
- For static crypto maps, routes are created on the basis of the destination information defined in the crypto access list. The next hop is taken from the first set peer statement that is attached to the crypto map. If at any time, RRI, the peer, or the access list is removed from the crypto map, routes will be deleted. This behavior changes with the addition of the RRI enhancements, as explained in the sections below.

## Enhancements to Reverse Route Injection in Cisco IOS Release 12.4(15)T

The following enhancements have been added to the Reverse Route Injection feature in Cisco IOS Release 12.4(15)T:

- [RRI Distance Metric, page 3](#)
- [Gateway Option, page 3](#)
- [Support for RRI on IPsec Profiles, page 4](#)
- [Tag Option Configuration Changes, page 4](#)
- [show crypto route Command, page 4](#)

### RRI Distance Metric

In general, a static route is created having an administrative distance of 1, which means that static routes always have precedence in the routing table. In some scenarios, however, it is required that dynamically learned routes take precedence over static routes, with the static route being used in the absence of a dynamically learned route. The addition of the **set reverse-route distance** command under either a crypto map or IPsec profile allows you to specify a different distance metric for VPN-created routes so that those routes will be in effect only if a dynamic or more favored route becomes unavailable.

### Gateway Option

This RRI gateway option is relevant to the crypto map only.

This option allows you to configure unique next hops or gateways for remote tunnel endpoints. The option is identical to the way the **reverse-route remote-peer** {*ip-address*} command worked prior to Cisco IOS Release 12.3(14)T in that two routes are created for each VPN tunnel. The first route is to the destination-protected subnet via the remote tunnel endpoint. The second route specifies the next hop to be taken to reach this tunnel endpoint. This RRI gateway option allows specific default paths to be specified for specific groups of VPN connections on platforms that support recursive route lookups.

#### Note

In 12.4(15)T and later releases, the **gateway** keyword option replaces the **reverse-route remote-peer** command (with no *ip-address*). Due to changes to Cisco Express Forwarding (CEF), an interface as a next-hop cannot be used without also adding a next-hop IP address.

## Support for RRI on IPsec Profiles

Previously RRI was available for crypto map configurations only. Cisco IOS Release 12.4(15)T introduces support for relevant RRI options on IPsec profiles that are predominantly used for virtual tunnel interfaces. On tunnel interfaces, only the distance metric and tag options are useful with the generic RRI capability.

**Note**

It is not necessary to specifically enable RRI on dynamic virtual interfaces for Easy VPN clients. Route support is enabled by default. It is necessary to specify tag or distance metric values if these are required.

## Tag Option Configuration Changes

The tag option was introduced in 12.3(14)T for crypto maps. This option is now supported with IPsec profiles under the **set reverse-route tag** command syntax. The **set reverse-route tag** command is also available under the crypto map for uniformity although the legacy **reverse-route tag** command is no longer supported.

## show crypto route Command

The **show crypto route** command displays routes that are created through IPsec via RRI or Easy VPN virtual tunnel interfaces (VTIs). The routes are displayed in one table. To see sample output for the **show crypto route** command, see the section “[show crypto route Command Output: Example](#).”

# How to Configure Reverse Route Injection

The following sections show how to configure reverse route injection for Cisco IOS software before Release 12.4(15)T and for Release 12.4(15)T.

- [Configuring RRI on Crypto Maps for Cisco IOS Releases Prior to 12.4\(15\)T, page 4](#)
- [Configuring RRI with Enhancements Added in Cisco IOS Release 12.4\(15\)T, page 6](#)

## Configuring RRI on Crypto Maps for Cisco IOS Releases Prior to 12.4(15)T

This section includes the following tasks:

- [Configuring RRI Under a Static Crypto Map, page 4](#)
- [Configuring RRI Under a Dynamic Map Template, page 5](#)

## Configuring RRI Under a Static Crypto Map

To configure RRI under a static crypto map for Cisco IOS software prior to Release 12.4(15)T, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**

3. **crypto map {map-name} {seq-name} ipsec-isakmp**
4. **reverse-route [static | tag tag-id [static] | remote-peer [static] | remote-peer ip-address [static]]**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                        | Purpose                                                                                                          |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                   | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                           | Enters global configuration mode.                                                                                |
| Step 3 | <b>crypto map {map-name} {seq-name} ipsec-isakmp</b><br><br><b>Example:</b><br>Router (config)# crypto map mymap 1<br>ipsec-isakmp                                                                       | Creates or modifies a crypto map entry and enters crypto map configuration mode.                                 |
| Step 4 | <b>reverse-route [static   tag tag-id [static]   remote-peer [static]   remote-peer ip-address [static]]</b><br><br><b>Example:</b><br>Router (config-crypto-map)# reverse-route<br>remote peer 10.1.1.1 | Creates source proxy information for a crypto map entry.                                                         |

## Configuring RRI Under a Dynamic Map Template

To configure RRI under a dynamic map template for Cisco IOS software prior to Release 12.4(15)T, perform the following steps.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto dynamic-map dynamic-map-name dynamic-seq-name**
4. **reverse-route [static | tag tag-id [static] | remote-peer [static] | remote-peer ip-address [static]]**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                                        | Purpose                                                                                                           |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                                                                                   | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>Enter your password if prompted.</li></ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                                                                                           | Enters global configuration mode.                                                                                 |
| Step 3 | <b>crypto dynamic-map</b> <i>dynamic-map-name</i> <i>dynamic-seq-name</i><br><br><b>Example:</b><br>Router (config)# crypto dynamic-map mymap 1                                                                                                                          | Creates a dynamic crypto map entry and enters the crypto map configuration command mode.                          |
| Step 4 | <b>reverse-route</b> [ <b>static</b>   <b>tag</b> <i>tag-id</i> [ <b>static</b>   <b>remote-peer</b> [ <b>static</b>   <b>remote-peer</b> <i>ip-address</i> [ <b>static</b> ]]]<br><br><b>Example:</b><br>Router (config-crypto-map)# reverse-route remote peer 10.1.1.1 | Creates source proxy information for a crypto map entry.                                                          |

## Configuring RRI with Enhancements Added in Cisco IOS Release 12.4(15)T

The following sections show how to configure RRI with the enhancements that were added in Cisco IOS Release 12.4(15)T:

- [Configuring RRI with Enhancements Under a Static Crypto Map, page 6](#)
- [Configuring RRI with Enhancements Under a Dynamic Map Template, page 7](#)
- [Configuring a RRI Distance Metric Under an IPsec Profile, page 8](#)
- [Verifying Routes That Are Created Through IPsec via RRI or Easy VPN VTIs, page 9](#)

## Configuring RRI with Enhancements Under a Static Crypto Map

To configure RRI with enhancements under a static crypto map (for Cisco IOS Release 12.4(15)T and later releases), perform the following steps.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name* *seq-name* **ipsec-isakmp**
4. **reverse-route** [**static** | **remote-peer** *ip-address* [**gateway** ] [**static**]]
5. **set reverse-route** [**distance** *number* | **tag** *tag-id*]

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                     | Purpose                                                                                                                                                                             |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                                                 |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                        | Enters global configuration mode.                                                                                                                                                   |
| Step 3 | <b>crypto map</b> <i>map-name seq-name ipsec-isakmp</i><br><br><b>Example:</b><br>Router (config)# crypto map mymap 1<br>ipsec-isakmp                                                 | Creates or modifies a crypto map entry and enters crypto map configuration mode.                                                                                                    |
| Step 4 | <b>reverse-route</b> [ <b>static</b>   <b>remote-peer</b> <i>ip-address</i> [ <b>gateway</b> ] [ <b>static</b> ]]<br><br><b>Example:</b><br>Router (config-crypto-map)# reverse-route | Creates source proxy information for a crypto map entry.<br><b>Note</b> The <b>gateway</b> keyword can be added to enable the dual route functionality for default gateway support. |
| Step 5 | <b>set reverse-route</b> [ <b>distance</b> <i>number</i>   <b>tag</b> <i>tag-id</i> ]<br><br><b>Example:</b><br>Router (config-crypto-map)# set reverse-route<br>distance 20          | Specifies a distance metric to be used or a tag value to be associated with these routes.                                                                                           |

## Configuring RRI with Enhancements Under a Dynamic Map Template

To configure RRI with enhancements under a dynamic map template (for Cisco IOS Release 12.4(15)T and later releases), perform the following steps.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto dynamic-map** *dynamic-map-name dynamic-seq-name*
4. **reverse-route** [**static** | **remote-peer** *ip-address* [**gateway** ] [**static**]]
5. **set reverse-route** [**distance** *number* | **tag** *tag-id*]

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                        | Purpose                                                                                                          |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                                   | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                                           | Enters global configuration mode.                                                                                |
| Step 3 | <b>crypto dynamic-map</b> <i>dynamic-map-name</i><br><i>dynamic-seq-name</i><br><br><b>Example:</b><br>Router (config)# crypto dynamic-map mymap 1                                                                       | Creates a dynamic crypto map entry and enters the crypto map configuration command mode.                         |
| Step 4 | <b>reverse-route</b> [ <b>static</b>   <b>remote-peer</b> <i>ip-address</i><br>[ <i>gateway</i> ] [ <b>static</b> ]]<br><br><b>Example:</b><br>Router (config-crypto-map)# reverse-route<br>remote peer 10.1.1.1 gateway | Creates source proxy information for a crypto map entry.                                                         |
| Step 5 | <b>set reverse-route</b> [ <b>distance</b> <i>number</i>   <b>tag</b><br><i>tag-id</i> ]<br><br><b>Example:</b><br>Router (config-crypto-map)# set reverse-route<br>distance 20                                          | Specifies a distance metric to be used or a tag value to be associated with these routes.                        |

## Configuring a RRI Distance Metric Under an IPsec Profile

To configure a RRI distance metric under an IPsec profile for Cisco IOS Release 12.4(15)T and later releases, perform the following steps:

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec profile** *name*
4. **set reverse-route** [**distance** *number* | **tag** *tag-id*]

## DETAILED STEPS

|        | Command or Action                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                             |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                        | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                    |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                   |
| Step 3 | <b>crypto ipsec profile <i>name</i></b><br><br><b>Example:</b><br>Router (config)# crypto ipsec profile myprofile                                             | Creates or modifies an IPsec profile and enters IPsec profile configuration mode.                                                                                                                                                                                                                                                                   |
| Step 4 | <b>set reverse-route [<i>distance number</i>   <i>tag tag-id</i>]</b><br><br><b>Example:</b><br>Router (config-crypto-profile)# set reverse-route distance 20 | Defines a distance metric for each static route or tags a reverse route injection- (RRI-) created route. <ul style="list-style-type: none"> <li><b>distance</b>—Defines a distance metric for each static route.</li> <li><b>tag</b>—Sets a tag value that can be used as a “match” value for controlling distribution using route maps.</li> </ul> |

## Verifying Routes That Are Created Through IPsec via RRI or Easy VPN VTIs

To display routes that are created through IPsec via RRI or Easy VPN VTIs, perform the following steps.

## SUMMARY STEPS

1. **enable**
2. **show crypto route**

## DETAILED STEPS

|        | Command or Action                                                            | Purpose                                                                                                          |
|--------|------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                       | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |

## Troubleshooting Tips

To observe the behavior of RRI and its relationship to the creation and deletion of an IPsec SA, you can use the **debug crypto ipsec** command (see the [Cisco IOS Debug Command Reference](#), Release 12.4T).

# Configuration Examples for Reverse Route Injection

This section contains the following sections:

- [Configuring RRI Prior to Cisco IOS Release 12.3\(14\)T: Examples, page 10](#)
- [Configuring RRI with Enhancements Added in Cisco IOS Release 12.3\(14\)T: Examples, page 11](#)
- [Configuring RRI with Enhancements Added in Cisco IOS Release 12.4\(15\)T: Examples, page 12](#)

## Configuring RRI Prior to Cisco IOS Release 12.3(14)T: Examples

The following are examples of RRI configurations and output before Cisco IOS Release 12.3(14)T:

- [Configuring RRI When Crypto ACLs Exist: Example, page 10](#)
- [Configuring RRI When Two Routes Are Created, One for the Remote Endpoint and One for Route Recursion: Example, page 11](#)

### Configuring RRI When Crypto ACLs Exist: Example

The following example shows that all remote VPN gateways connect to the router via 192.168.0.3. RRI is added on the static crypto map, which creates routes on the basis of the source network and source netmask that are defined in the crypto access control list (ACL):

```
crypto map mymap 1 ipsec-isakmp
 set peer 10.1.1.1
 reverse-route
 set transform-set esp-3des-sha
 match address 102
```

```
Interface FastEthernet 0/0
 ip address 192.168.0.2 255.255.255.0
 standby name group1
 standby ip 192.168.0.3
 crypto map mymap redundancy group1
```

```
access-list 102 permit ip 192.168.1.0 0.0.0.255 10.0.0.0 0.0.255.255
```

In Cisco IOS Release 12.3(14)T and later releases, for the static map to retain this same behavior of creating routes on the basis of crypto ACL content, the **static** keyword is required, that is, **reverse-route static**.

#### Note

The **reverse-route** command in this situation creates routes that are analogous to the following static route command-line interface (CLI) commands (**ip route**):

#### Remote Tunnel Endpoint

```
ip route 10.1.1.1 255.255.255.255 192.168.1.1
```

**VPNSM**

```
ip route 10.1.1.1 255.255.255.255 vlan0.1
```

---

## Configuring RRI When Two Routes Are Created, One for the Remote Endpoint and One for Route Recursion: Example

In the following example, two routes are created, one for the remote endpoint and one for route recursion to the remote endpoint via the interface on which the crypto map is configured:

```
reverse-route remote-peer
```

## Configuring RRI with Enhancements Added in Cisco IOS Release 12.3(14)T: Examples

The following are examples of configurations and output for RRI enhancements that were added in Cisco IOS Release 12.3(14)T.

- [Configuring RRI When Crypto ACLs Exist: Example, page 11](#)
- [Configuring RRI with Route Tags: Example, page 11](#)
- [Configuring RRI for One Route to the Remote Proxy via a User-Defined Next Hop: Example, page 12](#)

### Configuring RRI When Crypto ACLs Exist: Example

The following example shows that RRI has been configured for a situation in which there are existing ACLs:

```
crypto map mymap 1 ipsec-isakmp
 set peer 172.17.11.1
 reverse-route static
 set transform-set esp-3des-sha
 match address 101

access-list 101 permit ip 192.168.1.0 0.0.0.255 172.17.11.0 0.0.0.255
```

### Configuring RRI with Route Tags: Example

The following example shows how RRI-created routes can be tagged with a tag number and then used by a routing process to redistribute those tagged routes via a route map:

```
crypto dynamic-map ospf-clients 1
 reverse-route tag 5

router ospf 109
 redistribute rip route-map rip-to-ospf

route-map rip-to-ospf permit
 match tag 5
 set metric 5
 set metric-type type1

Router# show ip ospf topology
```

```
P 10.81.7.48/29, 1 successors, FD is 2588160, tag is 5
 via 192.168.82.25 (2588160/2585600), FastEthernet0/1
```

## Configuring RRI for One Route to the Remote Proxy via a User-Defined Next Hop: Example

**Note** This option is applicable only to crypto maps.

The preceding example shows that one route has been created to the remote proxy via a user-defined next hop. This next hop should not require a recursive route lookup unless it will recurse to a default route.

```
reverse-route remote-peer 10.4.4.4
```

The preceding example yields the following prior to Cisco IOS Release 12.3(14)T:

```
10.0.0.0/24 via 10.1.1.1 (in the VRF table if VRFs are configured)
10.1.1.1/32 via 10.4.4.4 (in the global route table)
```

And this result occurs with RRI enhancements:

```
10.0.0.0/24 via 10.4.4.4 (in the VRF table if VRFs are configured, otherwise in the global
table)
```

## Configuring RRI with Enhancements Added in Cisco IOS Release 12.4(15)T: Examples

The following are examples of configurations and output for RRI enhancements that were added in Cisco IOS Release 12.4(15)T.

- [Configuring a RRI Distance Metric Under a Crypto Map: Example, page 12](#)
- [Configuring RRI with Route Tags: Example, page 11](#)
- [debug and show Command Output for a RRI Distance Metric Configuration Under a Crypto Map: Example, page 13](#)
- [Configuring a RRI Distance Metric for a VTI: Example, page 14](#)
- [debug and show Command Output for a RRI Metric Configuration Having a VTI: Example, page 14](#)
- [show crypto route Command Output: Example, page 15](#)

## Configuring a RRI Distance Metric Under a Crypto Map: Example

The following configuration shows a server and client configuration for which a RRI distance metric has been set under a crypto map:

### Server

```
crypto dynamic-map mymap
 set security-association lifetime seconds 300
 set transform-set 3dessha
 set isakmp-profile profile1
 set reverse-route distance 20
reverse-route
```

### Client

```
crypto ipsec client ezvpn ez
 connect auto
 group cisco key cisco
```

```

mode client
peer 10.0.0.119
username XXX password XXX
xauth userid mode local

```

## Configuring RRI with Route Tags: Example

The following example shows how RRI-created routes can be tagged with a tag number and then used by a routing process to redistribute those tagged routes via a route map:

```

crypto dynamic-map ospf-clients 1
 set reverse-route tag 5

router ospf 109
 redistribute rip route-map rip-to-ospf

route-map rip-to-ospf permit
 match tag 5
 set metric 5
 set metric-type type1

Router# show ip ospf topology

P 10.81.7.48/29, 1 successors, FD is 2588160, tag is 5
 via 192.168.82.25 (2588160/2585600), FastEthernet0/1

```

## debug and show Command Output for a RRI Distance Metric Configuration Under a Crypto Map: Example

The following are **debug** and **show** command output for a RRI distance metric configuration under a crypto map on a server:

```

Router# debug crypto ipsec

00:23:37: IPSEC(validate_proposal_request): proposal part #1,
 (key eng. msg.) INBOUND local= 10.0.0.119, remote= 10.0.0.14,

C 10.15.0.0 is directly connected, Loopback6
S* 0.0.0.0/0 [1/0] via 10.0.0.14

```

## Configuring a RRI Distance Metric for a VTI: Example

The following configuration shows a server and client configuration in which a RRI distance metric has been set for a VTI:

### Server Configuration

```

crypto isakmp profile profile1
 keyring mykeyring
 match identity group cisco
 client authentication list authenlist
 isakmp authorization list autholist
 client configuration address respond
 virtual-template 1
crypto ipsec profile vi
 set transform-set 3dessa
 set reverse-route distance 20
 set isakmp-profile profile1
!
interface Virtual-Template1 type tunnel
 ip unnumbered
 tunnel mode ipsec ipv4
 tunnel protection ipsec profile vi

```

### Client Configuration

```

crypto ipsec client ezvpn ez
 connect auto
 group cisco key cisco
 mode client
 peer 10.0.0.119
 username XXX password XXX
 virtual-interface 1

```

## debug and show Command Output for a RRI Metric Configuration Having a VTI: Example

The following are **debug** and **show** command output for a RRI metric configuration for a VTI on a server:

Router# **debug crypto ipsec**

```

00:47:56: IPSEC(key_engine): got a queue event with 1 KMI message(s)
00:47:56: Crypto mapdb : proxy_match

00:47:56: %LINEPROTO-5-UPDOWN: Line protocol on Interface Virtual-Access2, changed state to up
00:47:56: IPSEC(key_engine): got a queue event with 1 KMI message(s)
00:47:56: IPSEC(key_engine_enable_outbound): rec'd enable notify from ISAKMP
00:47:56: IPSEC(key_engine_enable_outbound): enable SA with spi 182227141/50
00:47:56: IPSEC(update_current_outbound_sa): updated peer 10.0.0.14 current outbound sa to SPI ADC90C5

```

Router# **show ip route**

```

Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
ia - IS-IS inter area, * - candidate default, U - per-user static route
o - ODR, P - periodic downloaded static route

```

Gateway of last resort is 10.0.0.14 to network 0.0.0.0

```

C 192.200.200.0/24 is directly connected, Loopback0
 10.20.20.20/24 is subnetted, 1 subnets
C 10.30.30.30 is directly connected, Loopback4
C 192.168.5.0/24 is directly connected, Loopback3
 10.20.20.20/24 is subnetted, 2 subnets
S 10.3.1.0 [1/0] via 10.0.0.113
C 10.20.20.20 is directly connected, FastEthernet0/0
 192.168.6.0/32 is subnetted, 1 subnets
S 192.168.6.1 [20/0] via 0.0.0.0, Virtual-Access2
C 192.168.3.0/24 is directly connected, Loopback2
 10.15.0.0/24 is subnetted, 1 subnets
C 10.15.0.0 is directly connected, Loopback6
S* 0.0.0.0/0 [1/0] via 10.0.0.14

```

## show crypto route Command Output: Example

The following output example displays routes, in one table, that are created through IPsec via RRI or Easy VPN VTIs:

Router# **show crypto route**

```

VPN Routing Table: Shows RRI and VTI created routes
Codes: RRI - Reverse-Route, VTI- Virtual Tunnel Interface
S - Static Map ACLs

```

```

Routes created in table GLOBAL DEFAULT
192.168.6.2/255.255.255.255 [0/0] via 10.0.0.133
 on Virtual-Access3 RRI
10.1.1.0/255.255.255.0 [10/0] via Virtual-Access2 VTI
192.168.6.1/255.255.255.255 [0/0] via Virtual-Access2 VTI

```

## Additional References

The following sections provide references related to Reverse Route Injection enhancements.

## Command Reference

The following commands are introduced or modified in the feature or features

- **reverse-route**
- **set reverse-route**
- **show crypto route**

For information about these commands, see the Cisco IOS Security Command Reference at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html).

For information about all Cisco IOS commands, see the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the Master Command List.

# Feature Information for Reverse Route Injection

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1** Feature Information for Reverse Route Injection

| Feature Name                      | Releases                          | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Reverse Route Injection           | 12.1(9)E<br>12.2(8)T<br>12.2(8)YE | Reverse route injection (RRI) is the ability for static routes to be automatically inserted into the routing process for those networks and hosts protected by a remote tunnel endpoint. These protected hosts and networks are known as remote proxy identities.<br><br>Each route is created on the basis of the remote proxy network and mask, with the next hop to this network being the remote tunnel endpoint. By using the remote Virtual Private Network (VPN) router as the next hop, the traffic is forced through the crypto process to be encrypted.<br><br>The following sections provide information about this feature: <ul style="list-style-type: none"> <li>“Reverse Route Injection” section on page 2</li> </ul> The following commands were introduced or modified by this feature: <b>reverse-route</b> . |
| Reverse Route Remote Peer Options | 12.2(13)T<br>12.2(14)S            | An enhancement was added to RRI to allow you to specify an interface or address as the explicit next hop to the remote VPN device. This functionality allows the overriding of a default route to properly direct outgoing encrypted packets.<br><br>The following sections provide information about the remote peer options: <ul style="list-style-type: none"> <li>“Enhancements to Reverse Route Injection in Cisco IOS Release 12.4(15)T” section on page 3.</li> </ul>                                                                                                                                                                                                                                                                                                                                                     |

# SafeNet IPSec VPN Client Support

---

The SafeNet IPSec VPN Client Support feature allows you to limit the scope of an Internet Security Association and Key Management Protocol (ISAKMP) profile or ISAKMP keyring configuration to a local termination address or interface. The benefit of this feature is that different customers can use the same peer identities and ISAKMP keys by using different local termination addresses.

## History for the SafeNet IPSec VPN Client Support Feature

| Release     | Modification                                                    |
|-------------|-----------------------------------------------------------------|
| 12.3(14)T   | This feature was introduced.                                    |
| 12.2(18)SXE | This feature was integrated into Cisco IOS Release 12.2(18)SXE. |

## Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

## Prerequisites for SafeNet IPSec VPN Client Support

- You must understand how to configure ISAKMP profiles and ISAKMP keyrings.

## Restrictions for SafeNet IPSec VPN Client Support

- The local address option works only for the primary address of an interface.
- If an IP address is provided, the administrator has to ensure that the connection of the peer terminates to the address that is provided.
- If the IP address does not exist on the device, or if the interface does not have an IP address, the ISAKMP profile or ISAKMP keyring will be effectively disabled.

## Information About SafeNet IPSec VPN Client Support

Before configuring SafeNet IPSec VPN Client Support, you should understand the following concepts:

- [ISAKMP Profile and ISAKMP Keyring Configurations: Background, page 2](#)
- [Local Termination Address or Interface, page 2](#)

## ISAKMP Profile and ISAKMP Keyring Configurations: Background

Prior to Cisco IOS Release 12.3(14)T, ISAKMP-profile and ISAKMP-keyring configurations could be only global, meaning that the scope of these configurations could not be limited by any locally defined parameters (VRF instances were an exception). For example, if an ISAKMP keyring contained a preshared key for address 10.11.12.13, the same key would be used if the peer had the address 10.11.12.13, irrespective of the interface or local address to which the peer was connected. There are situations, however, in which users prefer that associate keyrings be bound not only with virtual route forwarding (VRF) instances but also to a particular interface. For example, if instead of VRF instances, there are virtual LANS, and the Internet Key Exchange (IKE) is negotiated with a group of peers using one fixed virtual LAN (VLAN) interface. Such a group of peers uses a single preshared key, so if keyrings could be bound to an interface, it would be easy to define a wildcard key without risking that the keys would also be used for other customers.

Sometimes the identities of the peer are not in the control of the administrator, and even if the same peer negotiates for different customers, the local termination address is the only way to distinguish the peer. After such a distinction is made, if the traffic is sent to different VRF instances, configuring an ISAKMP profile is the only way to distinguish the peer. Unfortunately, when the peer uses an identical identity for all such situations, the ISAKMP profile cannot distinguish among the negotiations. For such scenarios, it would be beneficial to bind ISAKMP profiles to a local termination address. If a local termination address could be assigned, identical identities from the peer would not be a problem.

## Local Termination Address or Interface

Effective with Cisco IOS Release 12.3(14)T, the SafeNet IPSec VPN Client Support feature allows you to limit the scope of ISAKMP profiles and ISAKMP keyrings to a local termination address or interface.

## Benefit of SafeNet IPSec VPN Client Support

The benefit of this feature is that different customers can use the same peer identities and ISAKMP keys by using different local termination addresses.

## How to Configure SafeNet IPSec VPN Client Support

This section contains the following procedures. The first two configurations are independent of each other.

- [Limiting an ISAKMP Profile to a Local Termination Address or Interface, page 3](#) (required)
- [Limiting a Keyring to a Local Termination Address or Interface, page 4](#) (required)
- [Monitoring and Maintaining SafeNet IPSec VPN Client Support, page 5](#) (optional)
- [Examples, page 6](#) (optional)

### Limiting an ISAKMP Profile to a Local Termination Address or Interface

To configure an ISAKMP profile and limit it to a local termination address or interface, perform the following steps.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp profile** *profile-name*
4. **keyring** *keyring-name*
5. **match identity address** *address*
6. **local-address** {*interface-name* | *ip-address* [*vrf-tag*]}

#### DETAILED STEPS

|        | Command or Action                             | Purpose                                                                                                          |
|--------|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b>                                 | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul> |
|        | <b>Example:</b><br>Router> enable             |                                                                                                                  |
| Step 2 | <b>configure terminal</b>                     | Enters global configuration mode.                                                                                |
|        | <b>Example:</b><br>Router# configure terminal |                                                                                                                  |

|        | Command or Action                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                                            |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <b>crypto isakmp profile</b> <i>profile-name</i><br><br><b>Example:</b><br>Router (config)# crypto isakmp profile profile1                                        | Defines an ISAKMP profile and enters ISAKMP profile configuration mode.                                                                                                                                                                                                            |
| Step 4 | <b>keyring</b> <i>keyring-name</i><br><br><b>Example:</b><br>Router (conf-isa-profile)# keyring keyring1                                                          | (Optional) Configures a keyring with an ISAKMP profile. <ul style="list-style-type: none"> <li>A keyring is not needed inside an ISAKMP profile for local termination to work. Local termination works even if Rivest, Shamir, and Adelman (RSA) certificates are used.</li> </ul> |
| Step 5 | <b>match identity address</b> <i>address</i><br><br><b>Example:</b><br>Router (conf-isa-profile)# match identity address 10.0.0.0 255.0.0.0                       | Matches an identity from a peer in an ISAKMP profile.                                                                                                                                                                                                                              |
| Step 6 | <b>local-address</b> { <i>interface-name</i>   <i>ip-address</i> [ <i>vrf-tag</i> ]}<br><br><b>Example:</b><br>Router (conf-isa-profile)# local-address serial2/0 | Limits the scope of an ISAKMP profile or an ISAKMP keyring configuration to a local termination address or interface.                                                                                                                                                              |

## Limiting a Keyring to a Local Termination Address or Interface

To configure an ISAKMP keyring and limit its scope to a local termination address or interface, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto keyring** *keyring-name*
4. **local-address** {*interface-name* | *ip-address* [*vrf-tag*]}
5. **pre-shared-key** *address address*

## DETAILED STEPS

|        | Command or Action                                                                                                                                          | Purpose                                                                                                               |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                     | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>      |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                             | Enters global configuration mode.                                                                                     |
| Step 3 | <b>crypto keyring <i>keyring-name</i></b><br><br><b>Example:</b><br>Router (config)# crypto keyring keyring1                                               | Defines a crypto keyring to be used during IKE authentication and enters keyring configuration mode.                  |
| Step 4 | <b>local-address {<i>interface-name</i>   <i>ip-address</i> [<i>vrf-tag</i>]}</b><br><br><b>Example:</b><br>Router (conf-keyring)# local-address serial2/0 | Limits the scope of an ISAKMP profile or an ISAKMP keyring configuration to a local termination address or interface. |
| Step 5 | <b>pre-shared-key address <i>address</i></b><br><br><b>Example:</b><br>Router (conf-keyring)# pre-shared-key address 10.0.0.1                              | Defines a preshared key to be used for IKE authentication.                                                            |

## Monitoring and Maintaining SafeNet IPSec VPN Client Support

The following **debug** and **show** commands may be used to monitor and maintain the configuration in which you limited the scope of an ISAKMP profile or ISAKMP keyring to a local termination address or interface.

### SUMMARY STEPS

1. **enable**
2. **debug crypto isakmp**
3. **show crypto isakmp profile**

## DETAILED STEPS

|        | Command or Action                                                                              | Purpose                                                                                                          |
|--------|------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                         | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>debug crypto isakmp</b><br><br><b>Example:</b><br>Router# debug crypto isakmp               | Displays messages about IKE events.                                                                              |
| Step 3 | <b>show crypto isakmp profile</b><br><br><b>Example:</b><br>Router# show crypto isakmp profile | Lists all the ISAKMP profiles that are defined on a router.                                                      |

## Examples

### debug crypto isakmp Command Output for an ISAKMP Keyring That Is Bound to Local Termination Addresses: Example

You have an ISAKMP configuration as follows (the address of serial2/0 is 10.0.0.1, and the address of serial2/1 is 10.0.0.2),

```
crypto keyring keyring1
! Scope of the keyring is limited to interface serial2/0.
 local-address serial2/0
 ! The following is the key string used by the peer.
 pre-shared-key address 10.0.0.3 key somerandomkeystring
crypto keyring keyring2
 local-address serial2/1
 ! The following is the keystring used by the peer coming into serial2/1.
 pre-shared-key address 10.0.0.3 key someotherkeystring
```

and if the connection is coming into serial2/0, keyring1 is chosen as the source of the preshared key (and keyring2 is ignored because it is bound to serial2/1), you would see the following output:

```
Router# debug crypto isakmp

*Feb 11 15:01:29.595: ISAKMP:(0:0:N/A:0):Keyring keyring2 is bound to
 10.0.0.0, skipping
*Feb 11 15:01:29.595: ISAKMP:(0:0:N/A:0):Looking for a matching key for
 10.0.0.3 in keyring1
*Feb 11 15:01:29.595: ISAKMP:(0:0:N/A:0): : success
*Feb 11 15:01:29.595: ISAKMP:(0:0:N/A:0):found peer pre-shared key
 matching 10.0.0.3
*Feb 11 15:01:29.595: ISAKMP:(0:0:N/A:0): local preshared key found
```

### debug crypto isakmp Command Output for an ISAKMP Profile That Is Bound to a Local Termination Address: Example

If you have the following configuration,  
crypto isakmp profile profile1

```
keyring keyring1
match identity address 10.0.0.0 255.0.0.0
local-address serial2/0
crypto isakmp profile profile2
keyring keyring1
keyring keyring2
self-identity fqdn
match identity address 10.0.0.1 255.255.255.255
local-address serial2/1
```

and the connection is coming through the local terminal address serial2/0, you will see the following output:

```
Router# debug crypto isakmp
```

```
*Feb 11 15:01:29.935: ISAKMP:(0:0:N/A:0):
```

```
Profile profile2 bound to 10.0.0.0 skipped
```

```
*Feb 11 15:01:29.935: ISAKMP:(0:1:SW:1):: peer matches profile1 profile
```

### show crypto isakmp profile Command Output: Example

The following is an example of typical **show** command output for an ISAKMP profile that is bound to serial2/0:

```
Router# show crypto isakmp profile
```

```
ISAKMP PROFILE profile1
Identities matched are:
 ip-address 10.0.0.0 255.0.0.0
Certificate maps matched are:
keyring(s): keyring1
trustpoint(s): <all>
Interface binding: serial2/0 (10.20.0.1:global)
```

## Troubleshooting SafeNet IPSec VPN Client Support

If an ISAKMP profile or ISAKMP keyring fails to be selected, you should double-check the local-address binding in the ISAKMP profile or ISAKMP keyring configuration and follow the output of the IKE debugs to determine whether the peer is correctly terminating on the address. You may remove the local-address binding (to make the scope of the profile or keyring global) and check to determine whether the profile or keyring is selected to confirm the situation.

## Configuration Examples for SafeNet IPSec VPN Client Support

This section contains the following configuration, **debug** command, and **show** command examples.

- [ISAKMP Profile Bound to a Local Interface: Example, page 8](#)
- [ISAKMP Keyring Bound to a Local Interface: Example, page 8](#)
- [ISAKMP Keyring Bound to a Local IP Address: Example, page 8](#)
- [ISAKMP Keyring Bound to an IP Address and Limited to a VRF: Example, page 8](#)

## ISAKMP Profile Bound to a Local Interface: Example

The following example shows that the ISAKMP profile is bound to a local interface:

```
crypto isakmp profile profile1
 keyring keyring1
 match identity address 10.0.0.0 255.0.0.0
 local-address serial2/0
```

## ISAKMP Keyring Bound to a Local Interface: Example

The following example shows that the ISAKMP keyring is bound only to interface serial2/0:

```
crypto keyring
 local-address serial2/0
 pre-shared-key address 10.0.0.1
```

## ISAKMP Keyring Bound to a Local IP Address: Example

The following example shows that the ISAKMP keyring is bound only to IP address 10.0.0.2:

```
crypto keyring keyring1
 local-address 10.0.0.2
 pre-shared-key address 10.0.0.2 key
```

## ISAKMP Keyring Bound to an IP Address and Limited to a VRF: Example

The following example shows that an ISAKMP keyring is bound to IP address 10.34.35.36 and that the scope is limited to VRF examplevrf1:

```
ip vrf examplevrf1
 rd 12:3456
crypto keyring ring1
 local-address 10.34.35.36 examplevrf1
interface ethernet2/0
 ip vrf forwarding examplevrf1
 ip address 10.34.35.36 255.255.0.0
```

## VRF-Aware IPSec

---

The VRF-Aware IPSec feature introduces IP Security (IPSec) tunnel mapping to Multiprotocol Label Switching (MPLS) Virtual Private Networks (VPNs). Using the VRF-Aware IPSec feature, you can map IPSec tunnels to Virtual Routing and Forwarding (VRF) instances using a single public-facing address.

### Feature Specifications for VRF-Aware IPSec

---

#### Feature History

| Release   | Modification                 |
|-----------|------------------------------|
| 12.2(15)T | This feature was introduced. |

---

#### Supported Platforms

---

Cisco 1710, Cisco 1760, Cisco 2610-Cisco 2613, Cisco 2620-Cisco 2621, Cisco 2650-Cisco 2651, Cisco 3620, Cisco 3640, Cisco 3660, Cisco 7100, Cisco 7200, Cisco 7400, Cisco 870 Series

---

### Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

## Restrictions for VRF-Aware IPsec

- If you are configuring VRF-Aware IPsec using a crypto map configuration and the Inside VRF (IVRF) is not the same as the Front Door VRF (FVRF), this feature is not interoperable with unicast reverse path forwarding (uRPF) if uRPF is enabled on the crypto map interface. If your network requires uRPF, it is recommended that you use Virtual Tunnel Interface (VTI) for IPsec instead of crypto maps.
- The VRF-Aware IPsec feature does not allow IPsec tunnel mapping between VRFs. For example, it does not allow IPsec tunnel mapping from VRF vpn1 to VRF vpn2.

## Information About VRF-Aware IPsec

The VRF-Aware IPsec feature maps an IPsec tunnel to a MPLS VPN. To configure and use the feature, you need to understand the following concepts:

- [VRF Instance, page 2](#)
- [MPLS Distribution Protocol, page 2](#)
- [VRF-Aware IPsec Functional Overview, page 2](#)

### VRF Instance

A VRF instance is a per-VPN routing information repository that defines the VPN membership of a customer site attached to the Provider Edge (PE) router. A VRF comprises an IP routing table, a derived Cisco Express Forwarding (CEF) table, a set of interfaces that use the forwarding table, and a set of rules and routing protocol parameters that control the information that is included in the routing table. A separate set of routing and CEF tables is maintained for each VPN customer.

### MPLS Distribution Protocol

The MPLS distribution protocol is a high-performance packet-forwarding technology that integrates the performance and traffic management capabilities of data link layer switching with the scalability, flexibility, and performance of network-layer routing.

### VRF-Aware IPsec Functional Overview

Front Door VRF (FVRF) and Inside VRF (IVRF) are central to understanding the feature.

Each IPsec tunnel is associated with two VRF domains. The outer encapsulated packet belongs to one VRF domain, which we shall call the FVRF, while the inner, protected IP packet belongs to another domain called the IVRF. Another way of stating the same thing is that the local endpoint of the IPsec tunnel belongs to the FVRF while the source and destination addresses of the inside packet belong to the IVRF.

One or more IPsec tunnels can terminate on a single interface. The FVRF of all these tunnels is the same and is set to the VRF that is configured on that interface. The IVRF of these tunnels can be different and depends on the VRF that is defined in the Internet Security Association and Key Management Protocol (ISAKMP) profile that is attached to a crypto map entry.

Figure 96 is an illustration of a scenario showing IPSec to MPLS and Layer 2 VPNs.

**Figure 96** *IPSec to MPLS and Layer 2 VPNs*

## Packet Flow into the IPSec Tunnel

- A VPN packet arrives from the Service Provider MPLS backbone network to the PE and is routed through an interface facing the Internet.
- The packet is matched against the Security Policy Database (SPD), and the packet is IPSec encapsulated. The SPD includes the IVRF and the access control list (ACL).
- The IPSec encapsulated packet is then forwarded using the FVRF routing table.

## Packet Flow from the IPSec Tunnel

- An IPSec-encapsulated packet arrives at the PE router from the remote IPSec endpoint.
- IPSec performs the Security Association (SA) lookup for the Security Parameter Index (SPI), destination, and protocol.
- The packet is decapsulated using the SA and is associated with IVRF.
- The packet is further forwarded using the IVRF routing table.

# How to Configure VRF-Aware IPSec

This section contains the following procedures:

- [Configuring Crypto Keyrings, page 4](#) (Optional)
- [Configuring ISAKMP Profiles, page 6](#) (Required)
- [Configuring an ISAKMP Profile on a Crypto Map, page 10](#) (Required)
- [Configuring to Ignore Extended Authentication During IKE Phase 1 Negotiation, page 11](#) (Optional)
- [Verifying VRF-Aware IPSec, page 12](#)
- [Clearing Security Associations, page 13](#)
- [Troubleshooting VRF-Aware IPSec, page 13](#)

## Configuring Crypto Keyrings

A crypto keyring is a repository of preshared and Rivest, Shamir, and Adelman (RSA) public keys. There can be zero or more keyrings on the Cisco IOS router.

Perform the following optional task to configure a crypto keyring.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto keyring** *keyring-name* [**vrf** *vrf-name*]
4. **description** *string* (Optional)
5. **pre-shared-key** {**address** *address* [*mask*] | **hostname** *hostname*} **key** *key* (Optional)
6. **rsa-pubkey** {**address** *address* | **name** *fqdn*} [**encryption** | **signature**] (Optional)
7. **address** *ip-address* (Optional)
8. **serial-number** *serial-number* (Optional)
9. **key-string**
10. **text**
11. **quit**
12. **exit**
13. **exit**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                             |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                        | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Step 3 | <b>crypto keyring <i>keyring-name</i> [<i>vrf fvr-f-name</i>]</b><br><br><b>Example:</b><br>Router (config)# crypto keyring VPN1                                                                      | Defines a keyring with <i>keyring-name</i> as the name of the keyring and enters keyring configuration mode. <ul style="list-style-type: none"> <li>(Optional) The <b>vrf</b> keyword and <i>fvr-f-name</i> argument imply that the keyring is bound to Front Door Virtual Routing and Forwarding (FVRF). The key in the keyring is searched if the local endpoint is in FVRF. If <b>vrf</b> is not specified, the keyring is bound to the global.</li> </ul>                |
| Step 4 | <b>description <i>string</i></b><br><br>Router (config-keyring)# description The keys for VPN1                                                                                                        | (Optional) Specifies a one-line description of the keyring.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Step 5 | <b>pre-shared-key {<i>address address</i> [<i>mask</i>]   <i>hostname hostname</i>} key <i>key</i></b><br><br><b>Example:</b><br>Router (config-keyring)# pre-shared-key address 10.72.23.11 key VPN1 | (Optional) Defines a preshared key by address or host name.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Step 6 | <b>rsa-pubkey {<i>address address</i>   <i>name fqdn</i>} [<i>encryption</i>   <i>signature</i>]</b><br><br><b>Example:</b><br>Router(config-keyring)# rsa-pubkey name host.vpn.com                   | (Optional) Defines a Rivest, Shamir, and Adelman (RSA) public key by address or host name and enters rsa-pubkey configuration mode. <ul style="list-style-type: none"> <li>By default, the key is used for signature.</li> <li>The optional <b>encryption</b> keyword specifies that the key should be used for encryption. The optional <b>signature</b> keyword specifies that the key should be used for signature. By default, the key is used for signature.</li> </ul> |
| Step 7 | <b>address <i>ip-address</i></b><br><br><b>Example:</b><br>Router(config-pubkey-key)# address 10.5.5.1                                                                                                | (Optional) Defines the RSA public key IP address.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Step 8 | <b>serial-number <i>serial-number</i></b><br><br><b>Example:</b><br>Router(config-pubkey-key)# serial-number 1000000                                                                                  | (Optional) Specifies the serial number of the public key. The value is from 0 through infinity.                                                                                                                                                                                                                                                                                                                                                                              |

|         | Command or Action                                                                                 | Purpose                                                                                 |
|---------|---------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| Step 9  | <b>key-string</b><br><br><b>Example:</b><br>Router (config-pubkey-key)# key-string                | Enters into the text mode in which you define the public key.                           |
| Step 10 | <b>text</b><br><br><b>Example:</b><br>Router (config-pubkey)# 00302017 4A7D385B 1234EF29 335FC973 | Specifies the public key.<br><b>Note</b> Only one public key may be added in this step. |
| Step 11 | <b>quit</b><br><br><b>Example:</b><br>Router (config-pubkey)# quit                                | Quits to the public key configuration mode.                                             |
| Step 12 | <b>exit</b><br><br><b>Example:</b><br>Router (config-pubkey)# exit                                | Exits to the keyring configuration mode.                                                |
| Step 13 | <b>exit</b><br><br><b>Example:</b><br>Router(config-keyring)# exit#                               | Exits to global configuration mode.                                                     |

## Configuring ISAKMP Profiles

An ISAKMP profile is a repository for IKE Phase 1 and IKE Phase 1.5 configuration for a set of peers. An ISAKMP profile defines items such as keepalive, trustpoints, peer identities, and XAUTH AAA list during the IKE Phase 1 and Phase 1.5 exchange. There can be zero or more ISAKMP profiles on the Cisco IOS router.

### Note

- If traffic from the router to a certification authority (CA) (for authentication, enrollment, or for obtaining a certificate revocation list [CRL]) or to an Lightweight Directory Access Protocol (LDAP) server (for obtaining a CRL) needs to be routed via a VRF, the **vrf** command must be added to the trustpoint. Otherwise, such traffic will use the default routing table.
- If a profile does not specify one or more trustpoints, all trustpoints in the router will be used to attempt to validate the certificate of the peer (Internet Key Exchange (IKE) main mode or signature authentication). If one or more trustpoints are specified, only those trustpoints will be used.

## Restriction

A router initiating IKE and a router responding to the IKE request should have symmetrical trustpoint configurations. For example, a responding router (in IKE Main Mode) performing RSA signature encryption and authentication might use trustpoints that were defined in the global configuration when sending the CERT-REQ payloads. However, the router might use a restricted list of trustpoints that were defined in the ISAKMP profile for the certificate verification. If the peer (the IKE initiator) is configured

to use a certificate whose trustpoint is in the global list of the responding router but not in ISAKMP profile of the responding router, the certificate will be rejected. (However, if the initiating router does not know about the trustpoints in the global configuration of the responding router, the certificate can still be authenticated.)

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp profile** *profile-name*
4. **description** *string* (Optional)
5. **vrf** *ivrf-name* (Optional)
6. **keepalive** *seconds* **retry** *retry-seconds* (Optional)
7. **self-identity** {**address** | **fqdn** | **user-fqdn** *user-fqdn*} (Optional)
8. **keyring** *keyring-name* (Optional)
9. **ca trust-point** *trustpoint-name* (Optional)
10. **match identity** {**group** *group-name* | **address** *address* [*mask*] [*fvr*] | **host** *host-name* | **host domain** *domain-name* | **user** *user-fqdn* | **user domain** *domain-name*}
11. **client configuration address** {**initiate** | **respond**} (Optional)
12. **client authentication list** *list-name* (Optional)
13. **isakmp authorization list** *list-name* (Optional)
14. **initiate mode aggressive**
15. **exit**

## DETAILED STEPS

|        | Command or Action                                                                                                               | Purpose                                                                                                                                  |
|--------|---------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                          | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                      |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                  | Enters global configuration mode.                                                                                                        |
| Step 3 | <b>crypto isakmp profile</b> <i>profile-name</i><br><br><b>Example:</b><br>Router (config)# crypto isakmp profile<br>vpnprofile | Defines an Internet Security Association and Key Management Protocol (ISAKMP) profile and enters into isakmp profile configuration mode. |

|        | Command or Action                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 4 | <b>description</b> <i>string</i><br><br><b>Example:</b><br>Router (conf-isa-prof)# description<br>configuration for VPN profile                                   | (Optional) Specifies a one-line description of an ISAKMP profile.                                                                                                                                                                                                                                                                                                                                                                                     |
| Step 5 | <b>vrf</b> <i>ivrf-name</i><br><br><b>Example:</b><br>Router (conf-isa-prof)# vrf VPN1                                                                            | (Optional) Maps the IPSec tunnel to a Virtual Routing and Forwarding (VRF) instance.<br><br><b>Note</b> The VRF also serves as a selector for matching the Security Policy Database (SPD). If the VRF is not specified in the ISAKMP profile, the IVRF of the IPSec tunnel will be the same as its FVRF.                                                                                                                                              |
| Step 6 | <b>keepalive</b> <i>seconds</i> <b>retry</b> <i>retry-seconds</i><br><br><b>Example:</b><br>Router (conf-isa-prof)# keepalive 60 retry 5                          | (Optional) Allows the gateway to send dead peer detection (DPD) messages to the peer. <ul style="list-style-type: none"> <li>If not defined, the gateway uses the global configured value.</li> <li><b>seconds</b>—Number of seconds between DPD messages. The range is from 10 to 3600 seconds.</li> <li><b>retry</b> <i>retry-seconds</i>—Number of seconds between retries if the DPD message fails. The range is from 2 to 60 seconds.</li> </ul> |
| Step 7 | <b>self-identity</b> { <i>address</i>   <i>fqdn</i>   <b>user-fqdn</b> <i>user-fqdn</i> }<br><br><b>Example:</b><br>Router (conf-isa-prof)# self-identity address | (Optional) Specifies the identity that the local Internet Key Exchange (IKE) should use to identify itself to the remote peer. <ul style="list-style-type: none"> <li>If not defined, IKE uses the global configured value.</li> <li><b>address</b>—Uses the IP address of the egress interface.</li> <li><b>fqdn</b>—Uses the fully qualified domain name (FQDN) of the router.</li> <li><b>user-fqdn</b>—Uses the specified value.</li> </ul>       |
| Step 8 | <b>keyring</b> <i>keyring-name</i><br><br><b>Example:</b><br>Router (conf-isa-prof)# keyring VPN1                                                                 | (Optional) Specifies the keyring to use for Phase 1 authentication. <ul style="list-style-type: none"> <li>If the keyring is not specified, the global key definitions are used.</li> </ul>                                                                                                                                                                                                                                                           |
| Step 9 | <b>ca trust-point</b> { <i>trustpoint-name</i> }<br><br><b>Example:</b><br>Router (conf-isa-prof)# ca trustpoint<br>VPN1-trustpoint                               | (Optional) Specifies a trustpoint to validate a Rivest, Shamir, and Adelman (RSA) certificate. <ul style="list-style-type: none"> <li>If no trustpoint is specified in the ISAKMP profile, all the trustpoints that are configured on the Cisco IOS router are used to validate the certificate.</li> </ul>                                                                                                                                           |

|         | Command or Action                                                                                                                                                                                                                                                                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 10 | <p><b>match identity</b> {<b>group</b> <i>group-name</i>   <b>address</b> <i>address</i> [<i>mask</i>] [<i>fvr</i>f]   <b>host</b> <i>host-name</i>   <b>host domain</b> <i>domain-name</i>   <b>user</b> <i>user-fqdn</i>   <b>user domain</b> <i>domain-name</i>}</p> <p><b>Example:</b><br/>Router (conf-isa-prof)# match identity address 10.1.1.1</p> | <p>Specifies the client IKE Identity (ID) that is to be matched.</p> <ul style="list-style-type: none"> <li>• <b>group</b> <i>group-name</i>—Matches the <i>group-name</i> with the ID type ID_KEY_ID. It also matches the <i>group-name</i> with the Organizational Unit (OU) field of the Distinguished Name (DN).</li> <li>• <b>address</b> <i>address</i> [<i>mask</i>] <i>fvr</i>f—Matches the <i>address</i> with the ID type ID_IPV4_ADDR. The <i>mask</i> argument can be used to specify a range of addresses. The <i>fvr</i>f <i>argument</i> specifies that the address is in Front Door Virtual Routing and Forwarding (FVRF)</li> <li>• <b>host</b> <i>hostname</i>—Matches the <i>hostname</i> with the ID type ID_FQDN.</li> <li>• <b>host domain</b> <i>domainname</i>—Matches the <i>domainname</i> to the ID type ID_FQDN whose domain name is the same as the <i>domainname</i>. Use this command to match all the hosts in the domain.</li> <li>• <b>user</b> <i>username</i>—Matches the <i>username</i> with the ID type ID_USER_FQDN.</li> <li>• <b>user domain</b> <i>domainname</i>—Matches the ID type ID_USER_FQDN whose domain name matches the <i>domainname</i>.</li> </ul> |
| Step 11 | <p><b>client configuration address</b> {<b>initiate</b>   <b>respond</b>}</p> <p><b>Example:</b><br/>Router (conf-isa-prof)# client configuration address initiate</p>                                                                                                                                                                                     | <p>(Optional) Specifies whether to initiate the mode configuration exchange or responds to mode configuration requests.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Step 12 | <p><b>client authentication list</b> <i>list-name</i></p> <p><b>Example:</b><br/>Router (conf-isa-prof)# client authentication list xauthlist</p>                                                                                                                                                                                                          | <p>(Optional) Authentication, authorization, and accounting (AAA) to use for authenticating the remote client during the extended authentication (XAUTH) exchange.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Step 13 | <p><b>isakmp authorization list</b> <i>list-name</i></p> <p><b>Example:</b><br/>Router (conf-isa-prof)# isakmp authorization list ikessaaalist</p>                                                                                                                                                                                                         | <p>(Optional) Network authorization server for receiving the Phase 1 preshared key and other attribute-value (AV) pairs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## What to Do Next

Go to the section “[Configuring an ISAKMP Profile on a Crypto Map](#).”

## Configuring an ISAKMP Profile on a Crypto Map

An ISAKMP profile must be applied to the crypto map. The IVRF on the ISAKMP profile is used as a selector when matching the VPN traffic. If there is no IVRF on the ISAKMP profile, the IVRF will be equal to the FVRF. Perform this required task to configure an ISAKMP profile on a crypto map.

## Prerequisites

Before configuring an ISAKMP profile on a crypto map, you must first have configured your router for basic IPSec.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name* **isakmp-profile** *isakmp-profile-name* (Optional)
4. **set isakmp-profile** *profile-name* (Optional)
5. **exit**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                |

## Configuring to Ignore Extended Authentication During IKE Phase 1 Negotiation

To ignore XAUTH during an IKE Phase 1 negotiation, use the **no crypto xauth** command. Use the **no crypto xauth** command if you do not require extended authentication for the Unity clients.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no crypto xauth** *interface*

### DETAILED STEPS

|--------|-------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                      | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                            |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                              | Enters global configuration mode.                                                                                                                             |
| Step 3 | <b>no crypto xauth</b> <i>interface</i><br><br><b>Example:</b><br>Router(config)# no crypto xauth ethernet0 | Ignores XAUTH proposals for requests that are destined to the IP address of the interface. By default, Internet Key Exchange (IKE) processes XAUTH proposals. |

## Verifying VRF-Aware IPSec

To verify your VRF-Aware IPSec configurations, use the following **show** commands. These **show** commands allow you to list configuration information and security associations (SAs):

### SUMMARY STEPS

- **enable**
- **show crypto ipsec sa** [**map** *map-name* | **address** | **identity** | **interface** *interface* | **peer** [**vrf** *fvrfrf-name*] **address** | **vrf** *ivrf-name*] [**detail**]
- **show crypto isakmp key**
- **show crypto isakmp profile**
- **show crypto key pubkey-chain rsa**

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                                                                                | Purpose                                                                                                                                                                                                                           |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                                                                                                                           | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                                                                                                  |
| Step 2 | <b>show crypto ipsec sa</b> [ <b>map</b> <i>map-name</i>   <b>address</b>   <b>identity</b>   <b>interface</b> <i>interface</i>   <b>peer</b> [ <b>vrf</b> <i>fvrfrf-name</i> ] <b>address</b>   <b>vrf</b> <i>ivrf-name</i> ] [ <b>detail</b> ]<br><br><b>Example:</b><br>Router# show crypto ipsec sa vrf vpn1 | Allows you to view the settings used by current security associations (SAs).                                                                                                                                                      |
| Step 3 | <b>show crypto isakmp key</b><br><br><b>Example:</b><br>Router# show crypto isakmp key                                                                                                                                                                                                                           | Lists all the keyrings and their preshared keys. <ul style="list-style-type: none"><li>• Use this command to verify your crypto keyring configuration.</li></ul>                                                                  |
| Step 4 | <b>show crypto isakmp profile</b><br><br><b>Example:</b><br>Router# show crypto isakmp profile                                                                                                                                                                                                                   | Lists all ISAKMP profiles and their configurations.                                                                                                                                                                               |
| Step 5 | <b>show crypto key pubkey-chain rsa</b><br><br><b>Example:</b><br>Router# show crypto key pubkey-chain rsa                                                                                                                                                                                                       | Views the Rivest, Shamir, and Adelman (RSA) public keys of the peer that are stored on your router. <ul style="list-style-type: none"><li>• The output is extended to show the keyring to which the public key belongs.</li></ul> |

## Clearing Security Associations

The following **clear** commands allow you to clear SAs.

### SUMMARY STEPS

- **enable**
- **clear crypto sa** [**counters** | **map** *map-name* | **peer** [**vrf** *fvrfrf-name*] *address* | **spi** *address* {**ah** | **esp**} *spi* | **vrf** *ivrf-name*]

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                                                                 | Purpose                                                                                                            |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                                                                                                            | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>clear crypto sa</b> [ <b>counters</b>   <b>map</b> <i>map-name</i>   <b>peer</b> [ <b>vrf</b> <i>fvrfrf-name</i> ] <i>address</i>   <b>spi</b> <i>address</i> { <b>ah</b>   <b>esp</b> } <i>spi</i>   <b>vrf</b> <i>ivrf-name</i> ]<br><br><b>Example:</b><br>Router# clear crypto sa vrf VPN1 | Clears the IPSec security associations (SAs).                                                                      |

## Troubleshooting VRF-Aware IPSec

To troubleshoot VRF-Aware IPSec, use the following **debug** commands:

### SUMMARY STEPS

1. **enable**
2. **debug crypto ipsec**
3. **debug crypto isakmp**

## DETAILED STEPS

|        | Command or Action                                                                        | Purpose                                                                                                          |
|--------|------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                   | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>debug crypto ipsec</b><br><br><b>Example:</b><br>Router# debug crypto ipsec           | Displays IP security (IPSec) events.                                                                             |
| Step 3 | <b>debug crypto isakmp</b><br><br><b>Example:</b><br>Router(config)# debug crypto isakmp | Displays messages about Internet Key Exchange (IKE) events.                                                      |

## Debug Examples for VRF-Aware IPSec

The following sample debug outputs are for a VRF-aware IPSec configuration:

**IPSec PE**

Router# **debug crypto ipsec**

```

Crypto IPSEC debugging is on
IPSEC-PE#debug crypto isakmp
Crypto ISAKMP debugging is on

## Configuration Examples for VRF-Aware IPSec

The following examples show how to configure VRF-Aware IPSec:

- [Static IPSec-to-MPLS VPN Example, page 22](#)
- [IPSec-to-MPLS VPN Using RSA Encryption Example, page 24](#)
- [IPSec-to-MPLS VPN with RSA Signatures Example, page 25](#)
- [Upgrade from Previous Versions of the Cisco Network-Based IPSec VPN Solution, page 28](#)

### Static IPSec-to-MPLS VPN Example

The following sample shows a static configuration that maps IPSec tunnels to MPLS VPNs. The configurations map IPSec tunnels to MPLS VPNs “VPN1” and “VPN2.” Both of the IPSec tunnels terminate on a single public-facing interface.

#### IPSec PE Configuration

```
ip vrf vpn1
 rd 100:1
 route-target export 100:1
 route-target import 100:1
!
ip vrf vpn2

## Upgrade from Previous Versions of the Cisco Network-Based IPSec VPN Solution

The VRF-Aware IPSec feature in the Cisco network-based IPSec VPN solution release 1.5 requires that you change your existing configurations.

The sample configurations that follow indicate the changes you must make to your existing configurations. These samples include the following:

- [Site-to-Site Configuration Upgrade, page 28](#)
- [Remote Access Configuration Upgrade, page 29](#)
- [Combination Site-to-Site and Remote Access Configuration Upgrade, page 31](#)

### Site-to-Site Configuration Upgrade

The following configurations show the changes that are necessary for a site-to-site configuration upgrade from a previous version of the network-based IPSec VPN solution to the Cisco network-based IPSec VPN solution release 1.5:

#### Previous Version Site-to-Site Configuration

```

crypto isakmp key VPN1 address 172.21.25.74
crypto isakmp key VPN2 address 172.21.21.74
!
crypto ipsec transform-set VPN1 esp-des esp-sha-hmac
crypto ipsec transform-set VPN2 esp-3des esp-sha-hmac
!
crypto map VPN1 10 ipsec-isakmp
 set peer 172.21.25.74
 set transform-set VPN1
 match address 101
!
crypto map VPN2 10 ipsec-isakmp
 set peer 172.21.21.74
 set transform-set VPN2
 match address 102
!
interface FastEthernet0/0.1
 encapsulation dot1Q 1 native
 ip vrf forwarding VPN1
 ip address 172.21.25.73 255.255.255.0
 crypto map VPN1
!
interface FastEthernet0/0.2
 encapsulation dot1Q 2 native
 ip vrf forwarding VPN2
 ip address 172.21.21.74 255.255.255.0
 crypto map VPN2

```

## New Version Site-to-Site Configuration

The following is an upgraded version of the same site-to-site configuration to the Cisco network-based IPSec VPN solution release 1.5 solution:

### Note

You must change to keyrings. The VRF-Aware IPSec feature requires that keys be associated with a VRF if the IKE local endpoint is in the VRF.

```
crypto keyring VPN1-KEYS vrf VPN1
pre-shared-key address 172.21.25.74 key VPN1
!
crypto keyring VPN2-KEYS vrf VPN2

## Remote Access Configuration Upgrade

The following configurations show the changes that are necessary for a remote access configuration upgrade from a previous version of the network-based IPSec VPN solution to the Cisco network-based IPSec VPN solution release 1.5:

### Previous Version Remote Access Configuration

```
crypto isakmp client configuration group VPN1-RA-GROUP
key VPN1-RA
pool VPN1-RA
!
crypto isakmp client configuration group VPN2-RA-GROUP
key VPN2-RA
pool VPN2-RA
!
crypto ipsec transform-set VPN1-RA esp-3des esp-sha-hmac
crypto ipsec transform-set VPN2-RA esp-3des esp-md5-hmac
!
crypto dynamic-map VPN1-RA 1
```

```

 set transform-set VPN1-RA
reverse-route
!
crypto dynamic-map VPN2-RA 1
set transform-set VPN2-RA
reverse-route
!
!
crypto map VPN1 client authentication list VPN1-RA-LIST
crypto map VPN1 isakmp authorization list VPN1-RA-LIST
crypto map VPN1 client configuration address initiate
crypto map VPN1 client configuration address respond
crypto map VPN1 10 ipsec-isakmp dynamic VPN1-RA
!
crypto map VPN2 client authentication list VPN2-RA-LIST
crypto map VPN2 isakmp authorization list VPN2-RA-LIST
crypto map VPN2 client configuration address initiate
crypto map VPN2 client configuration address respond
crypto map VPN2 10 ipsec-isakmp dynamic VPN2-RA
!
interface FastEthernet0/0.1
encapsulation dot1Q 1 native
ip vrf forwarding VPN1
ip address 172.21.25.73 255.255.255.0
crypto map VPN1
!
interface FastEthernet0/0.2

ip vrf forwarding VPN2
ip address 172.21.21.74 255.255.255.0
crypto map VPN2

```

## New Version Remote Access Configuration

In the following instance, there is no upgrade; it is recommended that you change to the following configuration:

```

crypto isakmp client configuration group VPN1-RA-GROUP
key VPN1-RA
pool VPN1-RA
!
crypto isakmp client configuration group VPN2-RA-GROUP
key VPN2-RA
pool VPN2-RA
!
crypto isakmp profile VPN1-RA
match identity group VPN1-RA-GROUP
client authentication list VPN1-RA-LIST
isakmp authorization list VPN1-RA-LIST
client configuration address initiate
client configuration address respond
!
crypto isakmp profile VPN2-RA
match identity group VPN2-RA-GROUP
client authentication list VPN2-RA-LIST
isakmp authorization list VPN2-RA-LIST
client configuration address initiate
client configuration address respond
!
crypto ipsec transform-set VPN1-RA esp-3des esp-sha-hmac
crypto ipsec transform-set VPN2-RA esp-3des esp-md5-hmac
!
crypto dynamic-map VPN1-RA 1

```

```

set transform-set VPN1-RA
set isakmp-profile VPN1-RA
reverse-route
!
crypto dynamic-map VPN2-RA 1
set transform-set VPN2-RA
set isakmp-profile VPN2-RA
reverse-route
!
crypto map VPN1 10 ipsec-isakmp dynamic VPN1-RA
!
crypto map VPN2 10 ipsec-isakmp dynamic VPN2-RA
!
interface FastEthernet0/0.1
encapsulation dot1Q 1 native
ip vrf forwarding VPN1
ip address 172.21.25.73 255.255.255.0
crypto map VPN1
!
interface FastEthernet0/0.2
encapsulation dot1Q 2 native
ip vrf forwarding VPN2
ip address 172.21.21.74 255.255.255.0
crypto map VPN2

```

## Combination Site-to-Site and Remote Access Configuration Upgrade

The following configurations show the changes that are necessary for a site-to-site and remote access configuration upgrade from a previous version of the network-based IPSec VPN solution to the Cisco network-based IPSec VPN solution release 1.5:

### Previous Version Site-to-Site and Remote Access Configuration

```

crypto isakmp key VPN1 address 172.21.25.74 no-xauth
crypto isakmp key VPN2 address 172.21.21.74 no-xauth
!
crypto isakmp client configuration group VPN1-RA-GROUP
key VPN1-RA
pool VPN1-RA
!
crypto isakmp client configuration group VPN2-RA-GROUP
key VPN2-RA
pool VPN2-RA
!
crypto ipsec transform-set VPN1 esp-des esp-sha-hmac
crypto ipsec transform-set VPN2 esp-3des esp-sha-hmac
!
crypto ipsec transform-set VPN1-RA esp-3des esp-sha-hmac
crypto ipsec transform-set VPN2-RA esp-3des esp-md5-hmac
!
crypto dynamic-map VPN1-RA 1
set transform-set VPN1-RA
reverse-route
!
crypto dynamic-map VPN2-RA 1
set transform-set VPN2-RA
reverse-route
!
crypto map VPN1 client authentication list VPN1-RA-LIST
crypto map VPN1 isakmp authorization list VPN1-RA-LIST
crypto map VPN1 client configuration address initiate

```

```

crypto map VPN1 client configuration address respond
crypto map VPN1 10 ipsec-isakmp
set peer 172.21.25.74
set transform-set VPN1
match address 101
crypto map VPN1 20 ipsec-isakmp dynamic VPN1-RA
!
crypto map VPN2 client authentication list VPN2-RA-LIST
crypto map VPN2 isakmp authorization list VPN2-RA-LIST
crypto map VPN2 client configuration address initiate
crypto map VPN2 client configuration address respond
crypto map VPN2 10 ipsec-isakmp
set peer 172.21.21.74
set transform-set VPN2
match address 102
crypto map VPN2 20 ipsec-isakmp dynamic VPN2-RA
!
interface FastEthernet0/0.1
encapsulation dot1Q 1 native
ip vrf forwarding VPN1
ip address 172.21.25.73 255.255.255.0
crypto map VPN1
!
interface FastEthernet0/0.2
encapsulation dot1Q 2 native
ip vrf forwarding VPN2
ip address 172.21.21.74 255.255.255.0
crypto map VPN2

```

## New Version Site-to-Site and Remote Access Configuration

You must upgrade to this configuration:

### Note

For site-to-site configurations that do not require XAUTH, configure an ISAKMP profile without XAUTH configuration. For remote access configurations that require XAUTH, configure an ISAKMP profile with XAUTH.

```

crypto keyring VPN1-KEYS vrf VPN1
pre-shared-key address 172.21.25.74 key VPN1
!
crypto keyring VPN2-KEYS vrf VPN2
pre-shared-key address 172.21.21.74 key VPN2
!
crypto isakmp client configuration group VPN1-RA-GROUP
key VPN1-RA
pool VPN1-RA
!
crypto isakmp client configuration group VPN2-RA-GROUP
key VPN2-RA
pool VPN2-RA
!
crypto isakmp profile VPN1
keyring VPN1-KEYS
match identity address 172.21.25.74 VPN1

| <ul style="list-style-type: none"> <li>No new or modified MIBs are supported by this feature, and support for existing MIBs has not been modified by this feature.</li> </ul> | <p>To obtain lists of supported MIBs by platform and Cisco IOS release, and to download MIB modules, go to the Cisco MIB website on Cisco.com at the following URL:</p> <p><a href="http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml">http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml</a></p> |

1. Not all supported MIBs are listed.

To locate and download MIBs for selected platforms, Cisco IOS releases, and feature sets, use Cisco MIB Locator found at the following URL:

<http://tools.cisco.com/ITDIT/MIBS/servlet/index>

If Cisco MIB Locator does not support the MIB information that you need, you can also obtain a list of supported MIBs and download MIBs from the Cisco MIBs page at the following URL:

<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>

To access Cisco MIB Locator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to [cco-locksmith@cisco.com](mailto:cco-locksmith@cisco.com). An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions found at this URL:

<http://www.cisco.com/register>

## Command Reference

The following commands are introduced or modified in the feature or features documented in this module:

### New Commands

- **address**
- **ca trust-point**
- **client authentication list**
- **client configuration address**
- **crypto isakmp profile**
- **crypto keyring**
- **crypto map isakmp-profile**
- **initiate-mode**
- **isakmp authorization list**
- **keepalive (isakmp profile)**

- **keyring**
- **key-string**
- **match identity**
- **no crypto xauth**
- **pre-shared-key**
- **quit**
- **rsa-pubkey**
- **self-identity**
- **serial-number**
- **set isakmp-profile**
- **show crypto isakmp key**
- **show crypto isakmp profile**
- **vrf**

**Modified Commands**

- **clear crypto sa**
- **crypto isakmp peer**
- **crypto map isakmp-profile**
- **show crypto dynamic-map**
- **show crypto ipsec sa**
- **show crypto isakmp sa**
- **show crypto map (IPSec)**

For information about these commands, see the *Cisco IOS Security Command Reference* at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html).

For information about all Cisco IOS commands, see the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the Master Command List.

# Glossary

**CA**—certification authority. CA is an entity that issues digital certificates (especially X.509 certificates) and vouches for the binding between the data items in a certificate.

**CLI**—command-line-interface. CLI is an interface that allows the user to interact with the operating system by entering commands and optional arguments. The UNIX operating system and DOS provide CLIs.

**client**—Corresponding IPSec IOS peer of the UUT in the Multi Protocol Label Switching (MPLS) network.

**dead peer**—IKE peer that is no longer reachable.

**DN**—Distinguished Name. A DN is the global, authoritative name of an entry in the Open System Interconnection (OSI Directory [X.500]).

**FQDN**—fully qualified domain name. A FQDN is the full name of a system rather than just its host name. For example, aldebaran is a host name, and aldebaran.interop.com is an FQDN.

**FR**—Frame Relay. FR is an industry-standard, switch-data-link-layer protocol that handles multiple virtual circuits using high-level data link (HDLC) encapsulation between connected devices. Frame Relay is more efficient than X.25, the protocol for which it generally is considered a replacement.

**FVRF**—Front Door Virtual Routing and Forwarding (VRF) repository. FVRF is the VRF used to route the encrypted packets to the peer.

**IDB**—Interface descriptor block. An IDB subblock is an area of memory that is private to an application. This area stores private information and states variables that an application wants to associate with an IDB or an interface. The application uses the IDB to register a pointer to its subblock, not to the contents of the subblock itself.

**IKE**—Internet Key Exchange. IKE establishes a shared security policy and authenticates keys for services (such as IPSec) that require keys. Before any IPSec traffic can be passed, each router, firewall, and host must verify the identity of its peer. This can be done by manually entering preshared keys into both hosts or by a CA service.

**IKE keepalive**—Bidirectional mechanism for determining the liveliness of an IKE peer.

**IPSec**—Security protocol for IP.

**IVRF**—Inside Virtual Routing and Forwarding. IVRF is the VRF of the plaintext packets.

**MPLS**—Multiprotocol Label Switching. MPLS is a switching method that forwards IP traffic using a label. This label instructs the routers and the switches in the network where to forward the packets based on preestablished IP routing information.

**RSA**—Rivest, Shamir, and Adelman are the inventors of the RSA technique. The RSA technique is a public-key cryptographic system that can be used for encryption and authentication.

**SA**—Security Association. SA is an instance of security policy and keying material applied to a data flow.

**VPN**—Virtual Private Network. A VPN enables IP traffic to travel securely over a public TCP or IP network by encrypting all traffic from one network to another. A VPN uses "tunneling" to encrypt all information at the IP level.

**VRF**—Virtual Route Forwarding. VRF is A VPN routing and forwarding instance. A VRF consists of an IP routing table, a derived forwarding table, a set of interfaces that use the forwarding table, and a set of rules and routing protocols that determine what goes into the forwarding table. In general, a VRF includes the routing information that defines a customer VPN site that is attached to a PE router.

**XAUTH**—Extended authentication. XAUTH is an optional exchange between IKE Phase 1 and IKE Phase 2, in which the router demands additional authentication information in an attempt to authenticate the actual user (as opposed to authenticating the peer).

**Note**

## VPN Acceleration Module (VAM)

---

### Feature History

| Release         | Modification                                                                                                                                       |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 12.1(9)E        | This feature was introduced on the Cisco 7200 series routers on NPE-225, NPE-400, and NSE-1                                                        |
| 12.1(14)E       | This feature was integrated into Cisco IOS Release 12.1(14)E and support for dual VAMs <sup>1</sup> on the Cisco 7200 series with NPE-G1 was added |
| 12.2(9)YE       | Support for this feature was added to the Cisco 7401ASR router <sup>2</sup>                                                                        |
| 12.2(13)T       | This feature was integrated into Cisco IOS Release 12.2(13)T                                                                                       |
| 12.2(15)T       | This feature was integrated into Cisco IOS Release 12.2(15)T                                                                                       |
| 12.3(1)Mainline | This feature was integrated into Cisco IOS Release 12.3(1) Mainline                                                                                |

1. Support for dual VAMs is available on a Cisco 7200 series router with NPE-G1 on Cisco IOS Release 12.2(15)T, 12.1(14)E, and 12.3 Mainline only.
2. The Cisco 7401ASR router is no longer sold.

This feature module describes the VPN Acceleration Module (VAM) feature. It includes the following sections:

- [Feature Overview, page 2](#)
- [Supported Platforms, page 5](#)
- [Supported Standards, MIBs, and RFCs, page 6](#)
- [Prerequisites, page 6](#)
- [Configuration Tasks, page 6](#)
- [Monitoring and Maintaining the VPN Acceleration Module, page 12](#)
- [Configuration Examples, page 13](#)
- [Command Reference, page 15](#)
- [Glossary, page 15](#)

# Feature Overview

The VPN Acceleration Module (VAM) is a single-width acceleration module. It provides high-performance, hardware-assisted tunneling and encryption services suitable for Virtual Private Network (VPN) remote access, site-to-site intranet, and extranet applications. It also provides platform scalability and security while working with all services necessary for successful VPN deployments — security, quality of service (QoS), firewall and intrusion detection, service-level validation, and management. The VAM off-loads IPSec processing from the main processor, thus freeing resources on the processor engines for other tasks.

The VAM provides hardware-accelerated support for the following multiple encryption functions:

- 56-bit Data Encryption Standard (DES) standard mode: Cipher Block Chaining (CBC)
- 3-Key Triple DES (168-bit)
- Secure Hash Algorithm (SHA)-1 and Message Digest 5 (MD5)
- Rivest, Shamir, Adelman (RSA) public-key algorithm
- Diffie-Hellman key exchange RC4-40

## Benefits

The VAM provides the following benefits:

- 10 tunnels per second
- The following number of tunnels based on the corresponding memory of the NPE:
  - 800 tunnels for 64 MB
  - 1600 tunnels for 128 MB
  - 3200 tunnels for 256 MB
  - 5000 tunnels for 512 MB
- RSA encryption
- Accelerated Crypto performance
- Accelerated Internet Key Exchange (IKE)
- Certificate support for automatic authentication using digital certificates
- Dual VAM support

**Note**

Support for dual VAMs is available on a Cisco 7200 series router with an NPE-G1, on Cisco IOS Release 12.2(15)T, 12.1(14)E, and 12.3 Mainline.

- Encryption services to any port adapter installed in the router. The interface on the port adapter must be configured with a crypto map to support IPSec.
- Full-duplex data transmission of over 100 Mbps with various encryption and compression schemes for 300 byte packages
- Hardware-based IPCCP LZS compression
- Network traffic compression that reduces bandwidth utilization
- Online Insertion and Removal (OIR)

- QoS, multiprotocol, and multicast feature interoperation
- Support for full Layer 3 routing, such as Enhanced Interior Gateway Routing Protocol (EIGRP), Open Shortest Path First (OSPF), and Border Gateway Protocol (BGP) across the IPsec VPN
- Up to 145 Mbps throughput using 3DES
- VPN initialization improvements

#### Performance Results for Single VAM

The following two tables provide performance results for a single VAM on a Cisco 7206VXR with an NPE-G1 processor, an onboard GE, and FE port adapters in slots 3 and 4.

| clear_packet_size       | crypto_packet_size | out_packet_size |
|-------------------------|--------------------|-----------------|
| 64                      | 96                 | 114             |
| 300                     | 336                | 354             |
| 1400                    | 1432               | 1450            |
| Mixed packet size - 344 | 378                | 396             |

| pkt_size (bytes)  | # of tunnels | measured_pps (pps) | meas_clear_ndr (Mbps) | meas_crypto_ndr (Mbps) | meas_out_ndr (Mbps) |
|-------------------|--------------|--------------------|-----------------------|------------------------|---------------------|
| 64                | 4            | 65,224             | 33.39                 | 50.09                  | 59.48               |
|                   | 500          | 41,888             | 21.44                 | 32.17                  | 38.20               |
|                   | 1,000        | 40,480             | 20.73                 | 31.09                  | 36.92               |
|                   | 5,000        | 39,408             | 20.18                 | 30.27                  | 35.94               |
| 300               | 4            | 38,032             | 91.28                 | 102.23                 | 107.71              |
|                   | 500          | 37,184             | 89.24                 | 99.95                  | 105.31              |
|                   | 1,000        | 36,064             | 86.55                 | 96.94                  | 102.13              |
|                   | 5,000        | 36,016             | 86.44                 | 96.81                  | 101.99              |
| 1400              | 4            | 9,984              | 111.82                | 114.38                 | 115.81              |
|                   | 500          | 9,848              | 110.29                | 112.82                 | 114.24              |
|                   | 1,000        | 9,648              | 108.06                | 110.53                 | 111.92              |
|                   | 5,000        | 9,616              | 107.70                | 110.16                 | 111.55              |
| Mixed packet size | 4            | 31,472             | 86.61                 | 95.17                  | 99.70               |
|                   | 500          | 31,056             | 85.47                 | 93.91                  | 98.39               |
|                   | 1,000        | 30,128             | 82.91                 | 91.11                  | 95.45               |
|                   | 5,000        | 29,264             | 80.53                 | 88.49                  | 92.71               |

### Performance Results for Dual VAMs

The following two tables provide performance results for dual VAMs on a Cisco 7206VXR with an NPE-G1 processor, an onboard GE, and FE port adapters in slots 3 and 4.

| clear_packet_size       | crypto_packet_size | out_packet_size |
|-------------------------|--------------------|-----------------|
| 64                      | 96                 | 114             |
| 300                     | 336                | 354             |
| 1400                    | 1432               | 1450            |
| Mixed packet size - 344 | 378                | 396             |

| pkt_size (bytes)  | # of tunnels | measured_pps (pps) | meas_clear_ndr (Mbps) | meas_crypto_ndr (Mbps) | meas_out_ndr (Mbps) |
|-------------------|--------------|--------------------|-----------------------|------------------------|---------------------|
| 64                | 4            | 135,544            | 69.40                 | 104.10                 | 123.61              |
|                   | 500          | 61,520             | 31.50                 | 47.25                  | 56.11               |
|                   | 1,000        | 56,928             | 29.15                 | 43.72                  | 51.92               |
|                   | 5,000        | 43,744             | 22.40                 | 33.60                  | 39.89               |
| 300               | 4            | 71,336             | 171.21                | 191.75                 | 202.02              |
|                   | 500          | 60,416             | 145.00                | 162.40                 | 171.10              |
|                   | 1,000        | 56,016             | 134.44                | 150.57                 | 158.64              |
|                   | 5,000        | 42,496             | 101.99                | 114.23                 | 120.35              |
| 1400              | 4            | 18,736             | 209.84                | 214.64                 | 217.34              |
|                   | 500          | 18,424             | 206.35                | 211.07                 | 213.72              |
|                   | 1000         | 18,352             | 205.54                | 210.24                 | 212.88              |
|                   | 5,000        | 18,352             | 205.54                | 210.24                 | 212.88              |
| Mixed packet size | 4            | 60,416             | 166.26                | 182.70                 | 191.40              |
|                   | 500          | 57,888             | 159.31                | 175.05                 | 183.40              |
|                   | 1,000        | 55,488             | 152.70                | 167.80                 | 175.79              |
|                   | 5,000        | 34,272             | 94.32                 | 103.64                 | 108.57              |

## Related Features and Technologies

The following features and technologies are related to the VAM:

- Internet Key Exchange (IKE)
- IP Security (IPSec)

## Related Documents

The following document describes the VAM hardware:

- [VPN Acceleration Module Installation and Configuration](#)

# Supported Platforms

The VAM feature is supported on the following platforms:

- Cisco 7200 series routers with NPE-225, NPE-400, NSE-1, and NPE-G1
- Dual VAM support is available on a Cisco 7200 series router with an NPE-G1, on Cisco IOS Release 12.2(15)T, 12.1(14)E, and 12.3M.
- Cisco 7401ASR router

## Determining Platform Support Through Cisco Feature Navigator

Cisco IOS software is packaged in feature sets that support specific platforms. To get updated information regarding platform support for this feature, access Cisco Feature Navigator. Cisco Feature Navigator dynamically updates the list of supported platforms as new platform support is added for the feature.

Cisco Feature Navigator is a web-based tool that enables you to determine which Cisco IOS software images support a specific set of features and which features are supported in a specific Cisco IOS image. You can search by feature or release. Under the release section, you can compare releases side by side to display both the features unique to each software release and the features in common.

To access Cisco Feature Navigator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to [cco-locksmith@cisco.com](mailto:cco-locksmith@cisco.com). An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions at <http://www.cisco.com/register>.

Cisco Feature Navigator is updated regularly when major Cisco IOS software releases and technology releases occur. For the most current information, go to the Cisco Feature Navigator home page at the following URL:

<http://www.cisco.com/go/fn>

## Availability of Cisco IOS Software Images

**Platform support for particular Cisco IOS software releases is dependent on the availability of the software images for those platforms. Software images for some platforms may be deferred, delayed, or changed without prior notice. For updated information about platform support and availability of software images for each Cisco IOS software release, refer to the online release notes or, if supported, Cisco Feature Navigator.**

# Supported Standards, MIBs, and RFCs

## Standards

- No new or modified standards are supported by this feature.

## MIBs

The following MIBs were introduced or modified in this feature:

- CISCO-IPSEC-FLOW-MONITOR-MIB
- CISCO-IPSEC-MIB
- CISCO-IPSEC-POLICY-MAP-MIB

To locate and download MIBs for selected platforms, Cisco IOS releases, and feature sets, use Cisco MIB Locator found at the following URL:

<http://tools.cisco.com/ITDIT/MIBS/servlet/index>

If Cisco MIB Locator does not support the MIB information that you need, you can also obtain a list of supported MIBs and download MIBs from the Cisco MIBs page at the following URL:

<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>

To access Cisco MIB Locator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to [cco-locksmith@cisco.com](mailto:cco-locksmith@cisco.com). An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions found at this URL:

<http://www.cisco.com/register>

## RFCs

- IPPCP: RFC 2393, 2395
- IPSec/IKE: RFCs 2401-2411, 2451

## Prerequisites

You must configure IPSec and IKE on the router and a crypto map to all interfaces that require encryption service from the VAM. See the [“Configuration Examples” section on page 13](#) for configuration procedures.

## Configuration Tasks

On power up if the enabled LED is on, the VAM is fully functional and does not require any configuration commands. However, for the VAM to provide encryption services, you must complete the following tasks:

- [Configuring an IKE Policy](#) (required)
- [Configuring IPSec](#) (required)

## Configuring an IKE Policy

If you do not specify a value for a parameter, the default value is assigned. For information on default values, refer to the “IP Security and Encryption” chapter of the *Security Command Reference* publication.

To configure an IKE policy, use the following commands beginning in global configuration mode:

|               | Command                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|---------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Router(config)# <b>crypto isakmp policy</b> <i>priority</i>                     | Defines an IKE policy and enters Internet Security Association Key Management Protocol (ISAKMP) policy configuration (config-isakmp) mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Step 2</b> | Router(config-isakmp)# <b>encryption</b> {des   3des   aes   aes 192   aes 256} | Specifies the encryption algorithm within an IKE policy. <ul style="list-style-type: none"> <li>des—Specifies 56-bit DES as the encryption algorithm.</li> <li>3des—Specifies 168-bit DES as the encryption algorithm.</li> <li>aes—Specifies 128-bit AES as the encryption algorithm.</li> <li>aes 192—Specifies 192-bit AES as the encryption algorithm.</li> <li>aes 256—Specifies 256-bit AES as the encryption algorithm.</li> </ul>                                                                                                                                                                                                                                                                                              |
| <b>Step 3</b> | Router(config-isakmp)# <b>authentication</b> {rsa-sig   rsa-encr   pre-share}   | <p>(Optional) Specifies the authentication method within an IKE policy.</p> <ul style="list-style-type: none"> <li>rsa-sig—Specifies Rivest, Shamir, and Adelman (RSA) signatures as the authentication method.</li> <li>rsa-encr—Specifies RSA encrypted nonces as the authentication method.</li> </ul> <div>  <p><b>Note</b> Beginning with Cisco IOS Release 12.3(10), rsa-encr is now enabled for VAM crypto cards.</p> </div> <ul style="list-style-type: none"> <li>pre-share—Specifies preshared keys as the authentication method.</li> </ul> <p><b>Note</b> If this command is not enabled, the default value (rsa-sig) will be used.</p> |
| <b>Step 4</b> | Router(config-isakmp)# <b>lifetime</b> <i>seconds</i>                           | <p>(Optional) Specifies the lifetime of an IKE security association (SA).</p> <p><i>seconds</i>—Number of seconds that each SA should exist before expiring. Use an integer from 60 to 86,400 seconds.</p> <p><b>Note</b> If this command is not enabled, the default value (86,400 seconds [one day]) will be used.</p>                                                                                                                                                                                                                                                                                                                                                                                                               |

|               | Command                                                                | Purpose                                                                                                                                                                                                                                                                                                                                             |
|---------------|------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 5</b> | Router(config-isakmp)# <b>hash</b> { <b>sha</b>   <b>md5</b> }         | (Optional) Specifies the hash algorithm within an IKE policy. <ul style="list-style-type: none"> <li><b>sha</b>—Specifies SHA-1 (HMAC variant) as the hash algorithm.</li> <li><b>md5</b>—Specifies MD5 (HMAC variant) as the hash algorithm.</li> </ul> <b>Note</b> If this command is not enabled, the default value ( <b>sha</b> ) will be used. |
| <b>Step 6</b> | Router(config-isakmp)# <b>group</b> { <b>1</b>   <b>2</b>   <b>5</b> } | (Optional) Specifies the Diffie-Hellman (DH) group identifier within an IKE policy. <p><b>1</b>—Specifies the 768-bit DH group.</p> <p><b>2</b>—Specifies the 1024-bit DH group.</p> <p><b>5</b>—Specifies the 1536-bit DH group.</p> <b>Note</b> If this command is not enabled, the default value (768-bit) will be used.                         |

For detailed information on creating IKE policies, refer to the “[Configuring Internet Key Exchange Security Protocol](#)” chapter in the *Security Configuration Guide* publication.

## Configuring IPSec

After you have completed IKE configuration, configure IPSec at each participating IPSec peer. This section contains basic steps to configure IPSec and includes the tasks discussed in the following sections:

- [Creating Crypto Access Lists, page 8](#)
- [Defining Transform Sets, page 9](#)

### Creating Crypto Access Lists

To create crypto access lists, use the following commands in global configuration mode:

|               | Command                                                                                                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                              |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Router(config)# <b>access-list</b> <i>access-list-number</i> { <b>deny</b>   <b>permit</b> } <i>protocol source source-wildcard destination destination-wildcard</i> [ <b>log</b> ]<br><br>or<br><b>ip access-list extended</b> <i>name</i> | Specifies conditions to determine which IP packets are protected. <sup>1</sup> (Enable or disable encryption for traffic that matches these conditions.)<br><br>We recommend that you configure “mirror image” crypto access lists for use by IPSec and that you avoid using the <b>any</b> keyword. |
| <b>Step 2</b> | Router(config-if)# Add <b>permit</b> and <b>deny</b> statements as appropriate.                                                                                                                                                             | Adds permit or deny statements to access lists.                                                                                                                                                                                                                                                      |
| <b>Step 3</b> | Router(config-if)# <b>end</b>                                                                                                                                                                                                               | Exits the configuration command mode.                                                                                                                                                                                                                                                                |

1. You specify conditions using an IP access list designated by either a number or a name. The **access-list** command designates a numbered extended access list; the **ip access-list extended** command designates a named access list.

For detailed information on configuring access lists, refer to the “[Configuring IPSec Network Security](#)” chapter in the *Security Configuration Guide* publication.

## Defining Transform Sets

To define a transform set, use the following commands, starting in global configuration mode:

| Command                                                                                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router# <b>crypto ipsec transform-set</b><br><i>transform-set-name transform1 [transform2</i><br><i>[transform3]]</i>                                                                                                                        | Defines a transform set and enters crypto transform configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Router# <b>mode</b> [ <b>tunnel</b>   <b>transport</b> ]                                                                                                                                                                                     | Changes the mode associated with the transform set. The mode setting is applicable only to traffic whose source and destination addresses are the IPSec peer addresses; it is ignored for all other traffic. (All other traffic is in tunnel mode only.)                                                                                                                                                                                                                                       |
| Router# <b>end</b>                                                                                                                                                                                                                           | Exits the crypto transform configuration mode to enabled mode.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Router# <b>clear crypto sa</b><br>or<br><b>clear crypto sa peer</b> { <i>ip-address</i>   <i>peer-name</i> }<br>or<br><b>clear crypto sa map</b> <i>map-name</i><br>or<br><b>clear crypto sa spi</b> <i>destination-address protocol spi</i> | Clears existing IPSec security associations so that any changes to a transform set take effect on subsequently established security associations (SAs). (Manually established SAs are reestablished immediately.)<br><br>Using the <b>clear crypto sa</b> command without parameters clears out the full SA database, which clears out active security sessions. You might also specify the <b>peer</b> , <b>map</b> , or <b>entry</b> keywords to clear out only a subset of the SA database. |

To create crypto map entries that use IKE to establish the security associations, use the following commands, starting in global configuration mode:

| Command                                                                                                           | Purpose                                                                                                                                            |
|-------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Router# <b>crypto map</b> <i>map-name seq-num ipsec-isakmp</i>                                                    | Creates the crypto map and enters crypto map configuration mode.                                                                                   |
| Router# <b>match address</b> <i>access-list-id</i>                                                                | Specifies an extended access list. This access list determines which traffic is protected by IPSec and which is not.                               |
| Router# <b>set peer</b> { <i>hostname</i>   <i>ip-address</i> }                                                   | Specifies a remote IPSec peer. This is the peer to which IPSec-protected traffic can be forwarded.<br><br>Repeat for multiple remote peers.        |
| Router# <b>set transform-set</b> <i>transform-set-name1</i><br><i>[transform-set-name2...transform-set-name6]</i> | Specifies which transform sets are allowed for this crypto map entry. Lists multiple transform sets in order of priority (highest priority first). |
| Router# <b>end</b>                                                                                                | Exits crypto map configuration mode.                                                                                                               |

Repeat these steps to create additional crypto map entries as required.

For detailed information on configuring crypto maps, refer to the “[Configuring IPSec Network Security](#)” chapter in the *Security Configuration Guide* publication.

## Verifying the Configuration

The following steps provide information on verifying your configurations:

- Step 1** Enter the **show crypto ipsec transform-set** command to view your transform set configuration:

```
Router# show crypto ipsec transform-set
Transform set combined-des-md5: {esp-des esp-md5-hmac}
 will negotiate = {Tunnel},
Transform set t1: {esp-des esp-md5-hmac}
 will negotiate = {Tunnel},
Transform set t100: {ah-sha-hmac}
 will negotiate = {Transport},
Transform set t2: {ah-sha-hmac}
 will negotiate = {Tunnel},
 {esp-des}
 will negotiate = {Tunnel},
```

- Step 2** Enter the **show crypto map [interface interface | tag map-name]** command to view your crypto map configuration:

```
outer# show crypto map
Crypto Map: "router-alice" idb: Ethernet0 local address: 172.21.114.123
Crypto Map "router-alice" 10 ipsec-isakmp
 Peer = 172.21.114.67
 Extended IP access list 141
 access-list 141 permit ip
 source: addr = 172.21.114.123/0.0.0.0
 dest: addr = 172.21.114.67/0.0.0.0
 Current peer: 172.21.114.67
 Security-association lifetime: 4608000 kilobytes/120 seconds
 PFS (Y/N): N
 Transform sets={t1,}
```

- Step 3** Enter the **show crypto ipsec sa [map map-name | address | identity | detail | interface]** command to view information about IPSec security associations.

```
Router# show crypto ipsec sa
interface: Ethernet0
 Crypto map tag: router-alice, local addr. 172.21.114.123
 local ident (addr/mask/prot/port): (172.21.114.123/255.255.255.255/0/0)
 remote ident (addr/mask/prot/port): (172.21.114.67/255.255.255.255/0/0)
 current_peer: 172.21.114.67
 PERMIT, flags={origin_is_acl,}
 #pkts encaps: 10, #pkts encrypt: 10, #pkts digest 10
 #pkts decaps: 10, #pkts decrypt: 10, #pkts verify 10
 #send errors 10, #recv errors 0

 outbound ah sas:

```

## Troubleshooting Tips

To verify that Cisco IOS software has recognized VAM, enter the **show diag** command and check the output. For example, when the router has the VAM in slot 1, the following output appears:

```

Router# show diag 1
Slot 1:
 VAM Encryption/Compression engine. Port adapter
 Port adapter is analyzed
 Port adapter insertion time 00:04:45 ago
 EEPROM contents at hardware discovery:
 Hardware Revision :1.0
 PCB Serial Number :15485660
 Part Number :73-5953-04
 Board Revision :
 RMA Test History :00
 RMA Number :0-0-0-0
 RMA History :00
 Deviation Number :0-0
 Product Number :CLEO

```

```

Top Assy. Part Number :800-10496-04
CLEI Code :
EEPROM format version 4
EEPROM contents (hex):
0x00:04 FF 40 02 8A 41 01 00 C1 8B 31 35 34 38 35 36
0x10:36 30 00 00 00 82 49 17 41 04 42 FF FF 03 00 81
0x20:00 00 00 00 04 00 80 00 00 00 00 CB 94 43 4C 45
0x30:4F 20 20 20 20 20 20 20 20 20 20 20 20 20 20
0x40:20 C0 46 03 20 00 29 00 04 C6 8A FF FF FF FF FF
0x50:FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF
0x60:FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF
0x70:FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF

```

To see if the VAM is currently processing crypto packets, enter the **show pas vam interface** command. The following is sample output:

```

Router# show pas vam interface

Interface VAM 1/1 :
ds:0x632770C8 idb:0x62813728
Statistics of packets and bytes that through this interface:
 18 packets in 18 packets out
 2268 bytes in 2268 bytes out
 0 paks/sec in 0 paks/sec out
 0 Kbits/sec in 0 Kbits/sec out
 83 commands out 83 commands acknowledged
ppq_full_err :0 ppq_rx_err :0
cmdq_full_err :0 cmdq_rx_err :0
no_buffer :0 fallback :0
dst_overflow :0 nr_overflow :0
sess_expired :0 pkt_fragmented :0
out_of_mem :0 access_denied :0
invalid_fc :0 invalid_param :0
invalid_handle :0 output_overrun :0
input_underrun :0 input_overrun :0
key_invalid :0 packet_invalid :0
decrypt_failed :0 verify_failed :0
attr_invalid :0 attr_val_invalid :0
attr_missing :0 obj_not_wrap :0
bad_imp_hash :0 cant_fragment :0
out_of_handles :0 compr_cancelled :0
rng_st_fail :0 other_errors :0
633 seconds since last clear of counters

```

When the VAM processes packets, the “packet in” and “packet out” counters change. Counter “packets out” represents the number of packets directed to the VAM. Counter “packets in” represents the number of packets received from the VAM.

#### Note

In versions prior to Cisco IOS Release 12.2(5)T and Cisco IOS Release 12.1(10)E, upon reboot trap configurations are lost and need to be re-entered.

## Monitoring and Maintaining the VPN Acceleration Module

Use the commands below to monitor and maintain the VPN Acceleration Module:

| Command                                | Purpose                                                        |
|----------------------------------------|----------------------------------------------------------------|
| Router# <b>show pas isa interface</b>  | Displays the ISA interface configuration.                      |
| Router# <b>show pas isa controller</b> | Displays the ISA controller configuration.                     |
| Router# <b>show pas vam interface</b>  | Verifies the VAM is currently processing crypto packets.       |
| Router# <b>show pas vam controller</b> | Displays the VAM controller configuration.                     |
| Router# <b>Show version</b>            | Displays integrated service adapter as part of the interfaces. |

## Configuration Examples

This section provides the following configuration examples:

- [Configuring IKE Policies Example, page 13](#)
- [Configuring IPSec Configuration Example, page 13](#)

### Configuring IKE Policies Example

In the following example, two IKE policies are created, with policy 15 as the highest priority, policy 20 as the next priority, and the existing default priority as the lowest priority. It also creates a preshared key to be used with policy 20 with the remote peer whose IP address is 192.168.224.33.

```
crypto isakmp policy 15
 encryption 3des
 hash md5
 authentication rsa-sig
 group 2
 lifetime 5000
crypto isakmp policy 20
 authentication pre-share
 lifetime 10000
crypto isakmp key 1234567890 address 192.168.224.33
```

### Configuring IPSec Configuration Example

The following example shows a minimal IPSec configuration where the security associations will be established via IKE:

An IPSec access list defines which traffic to protect:

```
access-list 101 permit ip 10.0.0.0 0.0.0.255 10.2.2.0 0.0.0.255
```

A transform set defines how the traffic will be protected. In this example, transform set "myset1" uses DES encryption and SHA for data packet authentication:

```
crypto ipsec transform-set myset1 esp-des esp-sha
```

Another transform set example is "myset2," which uses Triple DES encryption and MD5 (HMAC variant) for data packet authentication:

```
crypto ipsec transform-set myset2 esp-3des esp-md5-hmac
```

A crypto map joins together the IPsec access list and transform set and specifies where the protected traffic is sent (the remote IPsec peer):

```
crypto map toRemoteSite 10 ipsec-isakmp
match address 101
set transform-set myset2
set peer 10.2.2.5
```

The crypto map is applied to an interface:

```
interface Serial0
ip address 10.0.0.2
crypto map toRemoteSite
```

**Note**

---

In this example, IKE must be enabled.

---

# Command Reference

The following commands are introduced or modified in the feature or features

- **show pas vam interface**
- **show pas vam controller**
- **crypto engine sw ipsec**

For information about these commands, see the Cisco IOS Security Command Reference at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html).

For information about all Cisco IOS commands, see the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the Master Command List.

## Glossary

**VAM**—VPN Acceleration Module.

**IKE**—Internet Key Exchange. IKE establishes a shared security policy and authenticates keys for services (such as IPSec) that require keys. Before any IPSec traffic can be passed, each router/firewall/host must verify the identity of its peer. This can be done by manually entering preshared keys into both hosts or by a CA service.

**IPSec**—IP Security. A framework of open standards that provides data confidentiality, data integrity, and data authentication between participating peers. IPSec provides these security services at the IP layer. IPSec uses IKE to handle the negotiation of protocols and algorithms based on local policy and to generate the encryption and authentication keys to be used by IPSec. IPSec can protect one or more data flows between a pair of hosts, between a pair of security gateways, or between a security gateway and a host.

## **Public Key Infrastructure (PKI)**

# Implementing and Managing PKI Features Roadmap

---

This roadmap lists the features documented in the *Cisco IOS Security Configuration Guide* and maps them to the modules in which they appear.

## Roadmap History

This roadmap was first published on May 2, 2005, and last updated on May 2, 2005.

## Feature and Release Support

[Table 56](#) lists public key infrastructure (PKI) feature support for the following Cisco IOS software release trains:

- [Cisco IOS Releases 12.2T, 12.3, and 12.3T](#)

Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table. *Not all features may be supported in your Cisco IOS software release.*

Cisco IOS software images are specific to a Cisco IOS software release, a feature set, and a platform. Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

## Note

[Table 56](#) lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

| <b>Cisco IOS Releases 12.2T, 12.3, and 12.3T</b> |                                                            |                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                 |
| 12.3(14)T                                        | Administrative Secure Device Provisioning Introducer       | This feature allows you to act as an administrative introducer to introduce a device into a PKI network and then provide a username as the device name for the record locator in the AAA database.                                                                                                                                                          | “Setting Up Secure Device Provisioning (SDP) for Enrollment in a PKI”                                                           |
| 12.3(14)T                                        | Persistent Self-Signed Certificates                        | This feature allows users the HTTPS server to generate and save a self-signed certificate in the router’s startup configuration. Thus, future SSL handshakes between the client and the HTTPS server can use the same self-signed certificate without user intervention.                                                                                    | “Configuring Certificate Enrollment for a PKI”                                                                                  |
| 12.3(14)T                                        | Secure Device Provisioning Certificate-Based Authorization | This feature allows certificates issued by other authority (CA) servers to be used for SDP introductions.                                                                                                                                                                                                                                                   | “Setting Up Secure Device Provisioning (SDP) for Enrollment in a PKI”                                                           |
| 12.3(14)T                                        | Subordinate Certificate Server                             | This enhancement allows you to configure a subordinate certificate server to grant all or certain SCEP or manual certificate requests.                                                                                                                                                                                                                      | “Configuring and Managing a Cisco IOS Certificate Server for PKI Deployment”                                                    |
| 12.3(14)T                                        | USB Storage                                                | This feature explains how to store RSA keys on a device external to the router via a USB eToken. The SmartCard technology (which is owned by Aladdin Knowledge Systems) in a USB key form factor (also referred to as a USB eToken) provides secure configuration distribution and allows users to store PKI credentials, such as RSA keys, for deployment. | “Storing PKI Credentials External to the Router”                                                                                |
| 12.3(11)T                                        | The Certificate Server Auto Archive enhancement            | This enhancement enables the CA certificate and CA key to be backed up automatically just once after they are generated by the certificate server. As a result, it is not necessary to generate an exportable CA key if CA backup is desirable.                                                                                                             | “Configuring and Managing a Cisco IOS Certificate Server for PKI Deployment”                                                    |
| 12.3(11)T                                        | PKI AAA Authorization Using the Entire Subject Name        | This feature provides users with the ability to query the AAA server using the entire subject name from the certificate as a unique AAA username.                                                                                                                                                                                                           | “Configuring Revocation and Authorization of Certificates in a PKI”                                                             |
| 12.3(11)T                                        | PKI Status                                                 | This enhancement added the <b>status</b> keyword to the <b>show crypto pki trustpoints</b> command, which allows you to view the current status of the trustpoint. Prior to this enhancement, you had to issue the <b>show crypto pki certificates</b> and the <b>show crypto pki timers</b> commands for the current status.                               | “Configuring Certificate Enrollment for a PKI” and “Configuring and Managing a Cisco IOS Certificate Server for PKI Deployment” |
| 12.3(11)T                                        | Reenroll Using Existing Certificates                       | This feature allows users to reenroll a router with a Cisco IOS CA via existing certificates from a third-party vendor CA.                                                                                                                                                                                                                                  | “Configuring Certificate Enrollment for a PKI”                                                                                  |
| 12.3(8)T                                         | Easy Secure Device Deployment                              | This feature introduces support for SDP (formerly called EzSDD), which offers a web-based enrollment interface that enables network administrators to deploy new devices in large networks.                                                                                                                                                                 | “Setting Up Secure Device Provisioning (SDP) for Enrollment in a PKI”                                                           |

**Table 56**      **Supported PKI Features (continued)**

| Release  | Feature Name                                                               | Feature Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Where Documented                                                                     |
|----------|----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| 12.3(8)T | Easy Secure Device Deployment AAA Integration                              | This feature integrates an external AAA database, allowing the introducer to be authenticated against a AAA database instead of having to use the enable password of the local Cisco certificate server.                                                                                                                                                                                                                                                                                                                                                                                                | “Setting Up Secure Device Provisioning (SDP) for Enrollment in a PKI”                |
| 12.3(7)T | The Certificate Server Registration Authority (RA) Mode enhancement        | A certificate server can be configured to run in RA mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | “Configuring and Managing a Cisco IOS Certificate Server for PKI Deployment”         |
| 12.3(7)T | The “crypto pki” commands should be a synonym for “crypto ca” commands     | This enhancement changes all commands that begin as “crypto ca” to “crypto pki.” Although the router will still accept crypto ca, all output will be read back as crypto pki.                                                                                                                                                                                                                                                                                                                                                                                                                           | All modules that contain crypto ca commands.                                         |
| 12.3(7)T | Key Rollover for Certificate Renewal                                       | This feature allows the certificate renewal request to be made before the certificate expires and retains the old key and certificate until the new certificate is available.                                                                                                                                                                                                                                                                                                                                                                                                                           | “Configuring Certificate Enrollment for a PKI”                                       |
| 12.3(7)T | PKI: Query Multiple Servers During Certificate Revocation Check            | This feature introduces the ability for Cisco IOS software to make multiple attempts to retrieve the CRL, allowing operations to continue when a particular server is not available. In addition, the ability to override the CDPs in a certificate with a manually configured CDP has been introduced. Manually overriding the CDPs in a certificate can be advantageous when a particular server is unavailable for an extended period of time. The certificate’s CDPs can be replaced with a URL or directory specification without reissuing all of the certificates that contain the original CDP. | “Configuring Revocation and Authorization of Certificates in a PKI”                  |
| 12.3(7)T | Protected Private Key Storage                                              | This feature allows a user to encrypt and lock the RSA private keys that are used on a Cisco IOS router, thereby, preventing unauthorized use of the private keys.                                                                                                                                                                                                                                                                                                                                                                                                                                      | “Deploying RSA Keys Within a PKI”                                                    |
| 12.3(4)T | Import of RSA Key Pair and Certificates in PEM Format                      | This feature allows customers to use PEM-formatted files to import or export RSA key pairs. PEM-formatted files allow customers to directly use existing RSA key pairs on their Cisco IOS routers instead of generating new keys. Also, customers can issue certificate requests and receive issued certificates in PEM-formatted files.                                                                                                                                                                                                                                                                | “Deploying RSA Keys Within a PKI” and “Configuring Certificate Enrollment for a PKI” |
| 12.3(4)T | Using Certificate ACLs to Ignore Revocation Check and Expired Certificates | This feature allows a certificate that meets specified criteria to be accepted regardless of the validity period of the certificate, or if the certificate meets the specified criteria, revocation checking does not have to be performed. Certificate ACLs are used to specify the criteria that the certificate must meet to be accepted or to avoid revocation checking. In addition, if AAA communication is protected by a certificate, this feature provides for the AAA checking of the certificate to be ignored.                                                                              | “Configuring Revocation and Authorization of Certificates in a PKI”                  |

**Table 56**      **Supported PKI Features (continued)**

| Release   | Feature Name                                        | Feature Description                                                                                                                                                                                                                                                                                                                                                                                                                 | Where Documented                                                             |
|-----------|-----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|
| 12.3(4)T  | Cisco IOS Certificate Server                        | This feature introduces support for the Cisco IOS CS, which offers users a CA that is directly integrated with Cisco IOS software to more easily deploy basic PKI networks.                                                                                                                                                                                                                                                         | “Configuring and Managing a Cisco IOS Certificate Server for PKI Deployment” |
| 12.3(4)T  | Direct HTTP Enrollment with CA Servers              | This feature allows users to configure an enrollment profile if their CA server does not support SCEP and they do not want to use an RA as a proxy. The enrollment profile allows users to send HTTP requests directly to the CA server instead of the RA proxy.                                                                                                                                                                    | “Configuring Certificate Enrollment for a PKI”                               |
| 12.3(2)T  | Online Certificate Status Protocol (OCSP)           | This feature allows users to enable OCSP instead of CRLs to check certificate status. Unlike CRLs, which provide only periodic certificate status, OCSP can provide timely information regarding the status of a certificate.                                                                                                                                                                                                       | “Configuring Revocation and Authorization of Certificates in a PKI”          |
| 12.3(1)   | PKI Integration with AAA Server                     | This feature provides additional scalability for authorization by generating a AAA username from the certificate presented by the peer. A AAA server is queried to determine whether the certificate is authorized for use by the internal component. The authorization is indicated by a component-specified label that must be present in the AV pair for the user.                                                               | “Configuring Revocation and Authorization of Certificates in a PKI”          |
| 12.2(15)T | Certificate Security Attribute-Based Access Control | Under the IPsec protocol, CA interoperability permits Cisco IOS devices and a CA to communicate so that the Cisco IOS device can obtain and use digital certificates from the CA. Certificates contain several fields that are used to determine whether a device or user is authorized to perform a specified action. This feature adds fields to the certificate that allow specifying an ACL, to create a certificate-based ACL. | “Configuring Revocation and Authorization of Certificates in a PKI”          |
| 12.2(15)T | Exporting and Importing RSA Keys                    | This feature allows you to transfer security credentials between devices by exporting and importing RSA keys. The key pair that is shared between two devices will allow one device to immediately and transparently take over the functionality of the other router.                                                                                                                                                               | “Deploying RSA Keys Within a PKI”                                            |
| 12.2(15)T | Multiple-Tier CA Hierarchy                          | This enhancement enables users to set up a PKI in a hierarchical framework to support multiple CAs. Within a hierarchical PKI, all enrolled peers can validate the certificate of one another as long as the peers share a trusted root CA certificate or a common subordinate CA.                                                                                                                                                  | “Configuring Certificate Enrollment for a PKI”                               |
| 12.2(13)T | Manual Certificate Enrollment (TFTP Cut-and-Paste)  | This feature allows users to generate a certificate request and accept CA certificates as well as the router’s certificates via a TFTP server or manual cut-and-paste operations.                                                                                                                                                                                                                                                   | “Configuring Certificate Enrollment for a PKI”                               |
| 12.2(8)T  | Certificate Autoenrollment                          | This feature introduces certificate autoenrollment, which allows the router to automatically request a certificate from the CA that is using the parameters in the configuration.                                                                                                                                                                                                                                                   | “Configuring Certificate Enrollment for a PKI”                               |

**Table 56**      *Supported PKI Features (continued)*

| Release  | Feature Name                        | Feature Description                                                                                                                                                                                                        | Where Documented                               |
|----------|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------|
| 12.2(8)T | Certificate Enrollment Enhancements | This feature introduces five new <b>crypto ca trustpoint</b> subcommands that provide new options for certificate requests and allow users to specify fields in the configuration instead of having to go through prompts. | “Configuring Certificate Enrollment for a PKI” |
| 12.2(8)T | Multiple RSA Key Pair Support       | This feature allows a user to configure a router to have multiple RSA key pairs. Thus, the Cisco IOS software can maintain a different key pair for each identity certificate.                                             | “Deploying RSA Keys Within a PKI”              |
| 12.2(8)T | Trustpoint CLI                      | This feature introduces the <b>crypto ca trustpoint</b> command, which adds support for trustpoint CAs.                                                                                                                    | “Configuring Certificate Enrollment for a PKI” |

# Cisco IOS PKI Overview: Understanding and Planning a PKI

---

Cisco IOS public key infrastructure (PKI) provides certificate management to support security protocols such as IP Security (IPSec), secure shell (SSH), and secure socket layer (SSL).

This module identifies and describes concepts that are needed to understand, plan for, and implement a PKI.

## Module History

This module was first published on May 2, 2005, and last updated on July 17, 2008.

## Contents

- [Information About Cisco IOS PKI, page 1](#)
- [Planning for a PKI, page 5](#)
- [Where to Go Next, page 6](#)
- [Additional References, page 6](#)

## What Is Cisco IOS PKI?

A PKI is composed of the following entities:

- Peers communicating on a secure network
- At least one certification authority (CA) that grants and maintains certificates
- Digital certificates, which contain information such as the certificate validity period, peer identity information, encryption keys that are used for secure communications, and the signature of the issuing CA
- An optional registration authority (RA) to offload the CA by processing enrollment requests
- A distribution mechanism (such as Lightweight Directory Access Protocol [LDAP] or HTTP) for certificate revocation lists (CRLs)

PKI provides customers with a scalable, secure mechanism for distributing, managing, and revoking encryption and identity information in a secured data network. Every entity (a person or a device) participating in the secured communication is enrolled in the PKI in a process where the entity generates an Rivest, Shamir, and Adelman (RSA) key pair (one private key and one public key) and has their identity validated by a trusted entity (also known as a CA or trustpoint).

After each entity enrolls in a PKI, every peer (also known as an end host) in a PKI is granted a digital certificate that has been issued by a CA. When peers must negotiate a secured communication session, they exchange digital certificates. Based on the information in the certificate, a peer can validate the identity of another peer and establish an encrypted session with the public keys contained in the certificate.

Although you can plan for and set up your PKI in a number of different ways, [Figure 97](#) shows the major components that make up a PKI and suggests an order in which each decision within a PKI can be made. [Figure 97](#) is a suggested approach; you can choose to set up your PKI from a different perspective.

**Figure 97**      **Deciding How to Set Up Your PKI**

## RSA Keys Overview

An RSA key pair consists of a public key and a private key. When setting up your PKI, you must include the public key in the certificate enrollment request. After the certificate has been granted, the public key will be included in the certificate so that peers can use it to encrypt data that is sent to the router. The private key is kept on the router and used both to decrypt the data sent by peers and to digitally sign transactions when negotiating with peers.

RSA key pairs contain a key modulus value. The modulus determines the size of the RSA key. The larger the modulus, the more secure the RSA key. However, keys with large modulus values take longer to generate, and encryption and decryption operations take longer with larger keys.

## What Are CAs?

A CA, also known as a trustpoint, manages certificate requests and issues certificates to participating network devices. These services (managing certificate requests and issuing certificates) provide centralized key management for the participating devices and are explicitly trusted by the receiver to validate identities and to create digital certificates. Before any PKI operations can begin, the CA generates its own public key pair and creates a self-signed CA certificate; thereafter, the CA can sign certificate requests and begin peer enrollment for the PKI.

You can use a CA provided by a third-party CA vendor, or you can use an “internal” CA, which is the Cisco IOS Certificate Server.

## Hierarchical PKI: Multiple CAs

PKI can be set up in a hierarchical framework to support multiple CAs. At the top of the hierarchy is a root CA, which holds a self-signed certificate. The trust within the entire hierarchy is derived from the RSA key pair of the root CA. The subordinate CAs within the hierarchy can be enrolled with either the root CA or with another subordinate CA. These enrollment options are how multiple tiers of CAs are configured. Within a hierarchical PKI, all enrolled peers, can validate the certificate of one another if the peers share a trusted root CA certificate or a common subordinate CA.

Figure 98 shows the enrollment relationships among CAs within a three-tiered hierarchy.

**Figure 98** *Three-Tiered CA Hierarchy Sample Topology*

117375

Each CA corresponds to a trustpoint. For example, CA11 and CA12 are subordinate CAs, holding CA certificates that have been issued by CA1; CA111, CA112, and CA113 are also subordinate CAs, but their CA certificates have been issued by CA11.

### When to Use Multiple CAs

Multiple CAs provide users with added flexibility and reliability. For example, subordinate CAs can be placed in branch offices while the root CA is at the office headquarters. Also, different granting policies can be implemented per CA, so you can set up one CA to automatically grant certificate requests while another CA within the hierarchy requires each certificate request to be manually granted.

Scenarios in which at least a two-tier CA is recommended are as follows:

- Large and very active networks in which a large number of certificates are revoked and reissued. A multiple tier CA helps to control the size of the CRLs.
- When online enrollment protocols are used, the root CA can be kept offline with the exception of issuing subordinate CA certificates. This scenario provides added security for the root CA.

## Certificate Enrollment: How It Works

Certificate enrollment is the process of obtaining a certificate from a CA. Each end host that wants to participate in the PKI must obtain a certificate. Certificate enrollment occurs between the end host requesting the certificate and the CA. [Figure 99](#) and the following steps describe the certificate enrollment process.

**Figure 99** *Certificate Enrollment Process*

1. The end host generates an RSA key pair.
2. The end host generates a certificate request and forwards it to the CA (or the RA, if applicable).
3. The CA receives the certificate enrollment request, and, depending on your network configuration, one of the following options occurs:
  - c. Manual intervention is required to approve the request.
  - d. The end host is configured to automatically request a certificate from the CA. Thus, operator intervention is no longer required at the time the enrollment request is sent to the CA server.

**Note**

If you configure the end host to automatically request certificates from the CA, you should have an additional authorization mechanism.

4. After the request is approved, the CA signs the request with its private key and returns the completed certificate to the end host.
5. The end host writes the certificate to a storage area such as NVRAM.

## Certificate Enrollment Via Secure Device Provisioning

Secure Device Provisioning (SDP) is a web-based certificate enrollment interface that can be used to easily deploy PKI between two end devices, such as a Cisco IOS client and a Cisco IOS certificate server.

SDP (also referred to as Trusted Transitive Introduction [TTI]) is a communication protocol that provides a bidirectional introduction between two end entities, such as a new network device and a Virtual Private Network (VPN). SDP involves the following three entities:

- **Introducer**—A mutually trusted device that introduces the petitioner to the registrar. The introducer can be a device user, such as a system administrator.
- **Petitioner**—A new device that is joined to the secure domain.
- **Registrar**—A certificate server or other server that authorizes the petitioner.

SDP is implemented over a web browser in three phases—welcome, introduction, and completion. Each phase is shown to the user via a web page. For more information on each phase and how SDP works, see the “Setting Up Secure Device Provisioning (SDP) for Enrollment in a PKI” module.

## Certificate Revocation: Why It Occurs

After each participant has successfully enrolled in the PKI, the peers are ready to begin negotiations for a secure connection with each other. Thus, the peers present their certificates for validation followed by a revocation check. After the peer verifies that the other peer’s certificate was issued by an authenticated CA, the CRL or Online Certificate Status Protocol (OCSP) server is checked to ensure that the certificate has not been revoked by the issuing CA. The certificate usually contains a certificate distribution point (CDP) in the form of a URL. Cisco IOS software uses the CDP to locate and retrieve the CRL. If the CDP server does not respond, the Cisco IOS software reports an error, which may result in the peer’s certificate being rejected.

## Planning for a PKI

Planning for a PKI requires evaluating the requirements and expected use for each of the PKI components shown in [Figure 97](#). It is recommended that you (or the network administrator) thoroughly plan the PKI before beginning any PKI configuration.

Although there are a number of approaches to consider when planning the PKI, this document begins with peer-to-peer communication and proceeds as shown in [Figure 97](#). However you or the network administrator choose to plan the PKI, understand that certain decisions influence other decisions within the PKI. For example, the enrollment and deployment strategy could influence the planned CA hierarchy. Thus, it is important to understand how each component functions within the PKI and how certain component options are dependent upon decisions made earlier in the planning process.

## Where to Go Next

As suggested in [Figure 97](#), you begin to configure a PKI by setting up and deploying RSA keys. For more information, see the module “Deploying RSA Keys Within a PKI.”

## Additional References

The following sections provide references related to Cisco IOS PKI.

## Glossary

**CDP**—certificate distribution point. Field within a digital certificate containing information that describes how to retrieve the CRL for the certificate. The most common CDPs are HTTP and LDAP URLs. A CDP may also contain other types of URLs or an LDAP directory specification. Each CDP contains one URL or directory specification.

**certificates**—Electronic documents that bind a user's or device's name to its public key. Certificates are commonly used to validate a digital signature.

**CRL**—certificate revocation list. Electronic document that contains a list of revoked certificates. The CRL is created and digitally signed by the CA that originally issued the certificates. The CRL contains dates for when the certificate was issued and when it expires. A new CRL is issued when the current CRL expires.

**CA**—certification authority. Service responsible for managing certificate requests and issuing certificates to participating IPSec network devices. This service provides centralized key management for the participating devices and is explicitly trusted by the receiver to validate identities and to create digital certificates.

**peer certificate**—Certificate presented by a peer, which contains the peer's public key and is signed by the trustpoint CA.

**PKI**—public key infrastructure. System that manages encryption keys and identity information for components of a network that participate in secured communications.

**RA**—registration authority. Server that acts as a proxy for the CA so that CA functions can continue when the CA is offline. Although the RA is often part of the CA server, the RA could also be an additional application, requiring an additional device to run it.

**RSA keys**—Public key cryptographic system developed by Ron Rivest, Adi Shamir, and Leonard Adleman. An RSA key pair (a public and a private key) is required before you can obtain a certificate for your router.

# Deploying RSA Keys Within a PKI

---

**First Published: May 2, 2005**

**Last Updated: November 17, 2006**

This module explains how to set up and deploy Rivest, Shamir, and Adelman (RSA) keys within a public key infrastructure (PKI). An RSA key pair (a public and a private key) is required before you can obtain a certificate for your router; that is, the end host must generate a pair of RSA keys and exchange the public key with the certification authority (CA) to obtain a certificate and enroll in a PKI.

## Finding Feature Information in This Module

*Your Cisco IOS software release may not support all of the features documented in this module.* To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for RSA Keys Within a PKI” section on page 20](#).

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

# Prerequisites for Configuring RSA Keys for a PKI

- Before setting up and deploying RSA keys for a PKI, you should be familiar with the module “Cisco IOS PKI Overview: Understanding and Planning a PKI.”
- As of Cisco IOS Release 12.3(7)T, all commands that begin as “crypto ca” have been changed to begin as “crypto pki.” Although the router will still accept crypto ca commands, all output will be read back as crypto pki.

## Information About RSA Keys Configuration

To deploy RSA keys within a PKI, you should understand the following concepts:

- [RSA Keys Overview, page 2](#)
- [Reasons to Store Multiple RSA Keys on a Router, page 3](#)
- [Benefits of Exportable RSA Keys, page 3](#)
- [Passphrase Protection While Importing and Exporting RSA Keys, page 4](#)

## RSA Keys Overview

An RSA key pair consists of a public key and a private key. When setting up your PKI, you must include the public key in the certificate enrollment request. After the certificate has been granted, the public key will be included in the certificate so that peers can use it to encrypt data that is sent to the router. The private key is kept on the router and used both to decrypt the data sent by peers and to digitally sign transactions when negotiating with peers.

RSA key pairs contain a key modulus value. The modulus determines the size of the RSA key. The larger the modulus, the more secure the RSA key. However, keys with large modulus values take longer to generate, and encryption and decryption operations take longer with larger keys.

If you want a modulus value between 512 and 1024, enter an integer value that is a multiple of 64. If you want a value higher than 1024, enter 1536 or 2048. If you enter a value greater than 512, key generation may take a minute or longer.

**Note**

---

As of Cisco IOS Release 12.4(11)T, peer *public* RSA key modulus values up to 4096 bits are automatically supported.

The largest private RSA key modulus is 2048 bits. Therefore, the largest RSA private key a router may generate or import is 2048 bits.

The recommended modulus value for a CA is 2048 bits; the recommended modulus value for a client is 1024 bits.

---

## Usage RSA Keys Versus General-Purpose RSA Keys

There are two mutually exclusive types of RSA key pairs—usage keys and general-purpose keys. When you generate RSA key pairs (via the **crypto key generate rsa** command), you will be prompted to select either usage keys or general-purpose keys.

### Usage RSA Keys

Usage keys consist of two RSA key pairs—one RSA key pair is generated and used for encryption and one RSA key pair is generated and used for signatures. With usage keys, each key is not unnecessarily exposed. (Without usage keys, one key is used for both authentication methods, increasing the exposure of that key.)

### General-Purpose RSA Keys

General-purpose keys consist of only one RSA key pair that used for both encryption and signatures. General-purpose key pairs are used more frequently than usage key pairs.

## Reasons to Store Multiple RSA Keys on a Router

Configuring multiple RSA key pairs allows the Cisco IOS software to maintain a different key pair for each CA with which it is dealing or the software can maintain multiple key pairs and certificates with the same CA. Thus, the Cisco IOS software can match policy requirements for each CA without compromising the requirements specified by the other CAs, such as key length, key lifetime, and general-purpose versus usage keys.

Named key pairs (which are specified via the **label** *key-label* option) allow you to have multiple RSA key pairs, enabling the Cisco IOS software to maintain a different key pair for each identity certificate.

## Benefits of Exportable RSA Keys

### Caution

Exportable RSA keys should be carefully evaluated before use because using exportable RSA keys introduces the risk that these keys might be exposed.

Any existing RSA keys are *not* exportable. New keys are generated as nonexportable by default. It is not possible to convert an existing nonexportable key to an exportable key.

As of Cisco IOS Release 12.2(15)T, users can share the private RSA key pair of a router with standby routers, therefore transferring the security credentials between networking devices. The key pair that is shared between two routers will allow one router to immediately and transparently take over the functionality of the other router. If the main router were to fail, the standby router could be dropped into the network to replace the failed router without the need to regenerate keys, reenroll with the CA, or manually redistribute keys.

Exporting and importing an RSA key pair also enables users to place the same RSA key pair on multiple routers so that all management stations using Secure Shell (SSH) can be configured with a single public RSA key.

### Exportable RSA Keys in PEM-Formatted Files

Using privacy-enhanced mail (PEM)-formatted files to import or export RSA keys can be helpful for customers who are running Cisco IOS software Release 12.3(4)T or later and who are using secure socket layer (SSL) or secure shell (SSH) applications to manually generate RSA key pairs and import the keys back into their PKI applications. PEM-formatted files allow customers to directly use existing RSA key pairs on their Cisco IOS routers instead of generating new keys.

## Passphrase Protection While Importing and Exporting RSA Keys

You have to include a passphrase to encrypt the PKCS12 file or the PEM file that will be exported, and when the PKCS12 or PEM file is imported, the same passphrase has to be entered to decrypt it. Encrypting the PKCS12 or PEM file when it is being exported, deleted, or imported protects the file from unauthorized access and use while it is being transported or stored on an external device.

The passphrase can be any phrase that is at least eight characters in length; it can include spaces and punctuation, excluding the question mark (?), which has special meaning to the Cisco IOS parser.

### How to Convert an Exportable RSA Key Pair to a Nonexportable RSA Key Pair

Passphrase protection protects the external PKCS12 or PEM file from unauthorized access and use. To prevent an RSA key pair from being exported, it must be labeled “nonexportable.” To convert an exportable RSA key pair into a nonexportable key pair, the key pair must be exported and then reimported without specifying the “exportable” keyword.

## How to Set Up and Deploy RSA Keys Within a PKI

This section contains the following procedures:

- [Generating an RSA Key Pair, page 4](#)
- [Generating and Storing Multiple RSA Key Pairs, page 5](#)
- [Exporting and Importing RSA Keys, page 6](#)
- [Encrypting and Locking Private Keys on a Router, page 10](#)
- [Removing RSA Key Pair Settings, page 13](#)

## Generating an RSA Key Pair

Perform this task to manually generate an RSA key pair.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto key generate rsa {general-keys | usage-keys} [label key-label] [modulus modulus-size] [exportable]**
4. **exit**
5. **show crypto key mypubkey rsa**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                           | Purpose                                                                                                                                                                                                                |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                      | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                       |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                              | Enters global configuration mode.                                                                                                                                                                                      |
| Step 3 | <b>crypto key generate rsa {general-keys   usage-keys} [label key-label] [modulus modulus-size] [exportable]</b><br><br><b>Example:</b><br>Router(config)# crypto key generate rsa general-keys modulus 360 | Generates RSA key pairs. <ul style="list-style-type: none"> <li>If a <i>key-label</i> argument is not specified, the default value, which is the fully qualified domain name (FQDN) of the router, is used.</li> </ul> |
| Step 4 | <b>exit</b><br><br><b>Example:</b><br>Router(config)# exit                                                                                                                                                  | Exits global configuration mode.                                                                                                                                                                                       |
| Step 5 | <b>show crypto key mypubkey rsa</b><br><br><b>Example:</b><br>Router# show crypto key mypubkey rsa                                                                                                          | (Optional) Displays the RSA public keys of your router.<br><br>This step allows you to verify that the RSA key pair has been successfully generated.                                                                   |

## What to Do Next

After you have successfully generated an RSA key pair, you can proceed to any of the additional tasks in this module to generate additional RSA key pairs, perform export and import of RSA key pairs, or configure additional security parameters for the RSA key pair (such as encrypting or locking the private key).

## Generating and Storing Multiple RSA Key Pairs

Perform this task to configure the router to generate and store multiple RSA key pairs and associate the key pairs with a trustpoint.

A trustpoint (also known as a CA) manages certificate requests and issues certificates to participating network devices. These services provide centralized key management for the participating devices and are explicitly trusted by the receiver to validate identities and to create digital certificates. Before any PKI operations can begin, the CA generates its own public key pair and creates a self-signed CA certificate; thereafter, the CA can sign certificate requests and begin peer enrollment for the PKI.

## Prerequisites

You must have already generated an RSA key pair as shown in the task “[Generating an RSA Key Pair](#).”

## SUMMARY STEPS

1. **crypto pki trustpoint** *name*
2. **rsa***keypair* *key-label* [*key-size* [*encryption-key-size*]]
3. **exit**
4. **exit**
5. **show crypto key mypubkey** *rsa*

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                            |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <code>crypto pki trustpoint <i>name</i></code><br><br><b>Example:</b><br>Router(config)# <code>crypto pki trustpoint fancy-ca</code>                                                           | Creates a trustpoint and enters ca-trustpoint configuration mode.                                                                                                                                                                                                                                  |
| Step 2 | <code>rsa</code> <i>keypair</i> <i>key-label</i> [ <i>key-size</i> [ <i>encryption-key-size</i> ]]<br><br><b>Example:</b><br>Router(ca-trustpoint)# <code>rsa</code> <i>keypair</i> fancy-keys | Specifies the key pair that is to be used with the trustpoint. <ul style="list-style-type: none"> <li>Specify the <i>key-size</i> argument for generating the key and specify the <i>encryption-key-size</i> argument to request separate encryption, signature keys, and certificates.</li> </ul> |
| Step 3 | <code>exit</code><br><br><b>Example:</b><br>Router(ca-trustpoint)# <code>exit</code>                                                                                                           | Exits ca-trustpoint configuration mode.                                                                                                                                                                                                                                                            |
| Step 4 | <code>exit</code><br><br><b>Example:</b><br>Router(config)# <code>exit</code>                                                                                                                  | Exits global configuration mode.                                                                                                                                                                                                                                                                   |
| Step 5 | <code>show crypto key mypubkey</code> <i>rsa</i><br><br><b>Example:</b><br>Router# <code>show crypto key mypubkey</code> <i>rsa</i>                                                            | (Optional) Displays the RSA public keys of your router.<br><br>This step allows you to verify that the RSA key pair has been successfully generated.                                                                                                                                               |

## Exporting and Importing RSA Keys

This section contains the following tasks that can be used for exporting and importing RSA keys. Whether you are using PKCS12 files or PEM files, exportable RSA keys allow you to use existing RSA keys on Cisco IOS routers instead of having to generate new RSA keys if the main router were to fail.

- [Exporting and Importing RSA Keys in PKCS12 Files, page 7](#)
- [Exporting and Importing RSA Keys in PEM-Formatted Files, page 8](#)

## Exporting and Importing RSA Keys in PKCS12 Files

Exporting and importing RSA key pairs enables users to transfer security credentials between devices. The key pair that is shared between two devices allows one device to immediately and transparently take over the functionality of the other router.

### Prerequisites for Exporting and Importing RSA Key in PKCS12 Files

You must generate an RSA key pair and mark it “exportable” as specified in the task “[Generating an RSA Key Pair](#).”

### Restrictions for Exporting and Importing RSA Keys in PKCS12 Files

- You cannot export RSA keys that existed on the router before your system was upgraded to Cisco IOS Release 12.2(15)T or later. You have to generate new RSA keys and label them as “exportable” after you upgrade the Cisco IOS software.
- When you import a PKCS12 file that was generated by a third-party application, the PKCS12 file must include a CA certificate.
- If you want reexport an RSA key pair after you have already exported the key pair and imported them to a target router, you must specify the **exportable** keyword when you are importing the RSA key pair.
- The largest RSA key a router may import is 2048-bits.

### SUMMARY STEPS

1. **crypto pki trustpoint** *name*
2. **rsa****keypair** *key-label* [*key-size* [*encryption-key-size*]]
3. **exit**
4. **crypto pki export** *trustpointname* **pkcs12** *destination-url* *passphrase*
5. **crypto pki import** *trustpointname* **pkcs12** *source-url* *passphrase*
6. **exit**
7. **show crypto key mypubkey** *rsa*

## DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                        | Purpose                                                                                                                                                                                                                                          |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>crypto pki trustpoint</b> <i>name</i><br><br><b>Example:</b><br>Router(config)# <b>crypto pki trustpoint</b> my-ca                                                                                                    | Creates the trustpoint name that is to be associated with the RSA key pair and enters ca-trustpoint configuration mode.                                                                                                                          |
| <b>Step 2</b> | <b>rsa</b> keypair <i>key-label</i> [ <i>key-size</i> [ <i>encryption-key-size</i> ]]<br><br><b>Example:</b><br>Router(ca-trustpoint)# <b>rsa</b> keypair my-keys                                                        | Specifies the key pair that is to be used with the trustpoint.                                                                                                                                                                                   |
| <b>Step 3</b> | <b>exit</b><br><br><b>Example:</b><br>Router(ca-trustpoint)# <b>exit</b>                                                                                                                                                 | Exits ca-trustpoint configuration mode.                                                                                                                                                                                                          |
| <b>Step 4</b> | <b>crypto pki export</b> <i>trustpointname</i> <b>pkcs12</b> <i>destination-url</i> <i>passphrase</i><br><br><b>Example:</b><br>Router(config)# <b>crypto pki export</b> my-ca pkcs12 tftp://tftpserver/my-keys PASSWORD | Exports the RSA keys via the trustpoint name.<br><br><b>Note</b> You can export the trustpoint using any of the following file system types: flash, FTP, null, NVRAM, remote file copying (RCP), SCP, system, TFTP, Webflash, Xmodem, or Ymodem. |
| <b>Step 5</b> | <b>crypto pki import</b> <i>trustpointname</i> <b>pkcs12</b> <i>source-url</i> <i>passphrase</i><br><br><b>Example:</b><br>Router(config)# <b>crypto pki import</b> my-ca pkcs12 tftp://tftpserver/my-keys PASSWORD      | Imports the RSA keys to the target router.                                                                                                                                                                                                       |
| <b>Step 6</b> | <b>exit</b><br><br><b>Example:</b><br>Router(config)# <b>exit</b>                                                                                                                                                        | Exits global configuration mode.                                                                                                                                                                                                                 |
| <b>Step 7</b> | <b>show crypto key mypubkey</b> <i>rsa</i><br><br><b>Example:</b><br>Router# <b>show crypto key mypubkey</b> <i>rsa</i>                                                                                                  | (Optional) Displays the RSA public keys of your router.                                                                                                                                                                                          |

## Exporting and Importing RSA Keys in PEM-Formatted Files

Perform this task to export or import RSA key pairs in PEM files.

## Prerequisites for Exporting and Importing RSA Keys in PEM-Formatted Files

You must generate an RSA key pair and mark it “exportable” as specified in the task “[Generating an RSA Key Pair](#).”

## Restrictions for Exporting and Importing RSA Keys in PEM Formatted Files

- You cannot export and import RSA keys that were generated without an exportable flag before your system was upgraded to Cisco IOS Release 12.3(4)T or a later release. You have to generate new RSA keys after you upgrade the Cisco IOS software.
- The largest RSA key a router may import is 2048 bits.

## SUMMARY STEPS

1. **crypto key generate rsa** {usage-keys | general-keys} label *key-label* [exportable]
2. **crypto key export rsa** *key-label* **pem** {terminal | url *url*} {3des | des} *passphrase*
3. **crypto key import rsa** *key-label* **pem** [usage-keys] {terminal | url *url*} [exportable] *passphrase*

4. **exit**
5. **show crypto key mypubkey rsa**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                         | Purpose                                                                                                                                                                                                                                    |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>crypto key generate rsa</b> {usage-keys   general-keys} <b>label</b> key-label [ <b>exportable</b> ]<br><br><b>Example:</b><br>Router(config)# crypto key generate rsa general-keys label mykey exportable             | Generates RSA key pairs.<br><br>To use PEM files, the RSA key pair must be labeled exportable.                                                                                                                                             |
| Step 2 | <b>crypto key export rsa</b> key-label <b>pem</b> {terminal   url url} {3des   des} <b>passphrase</b><br><br><b>Example:</b><br>Router(config)# crypto key export rsa mycs pem url nvram: 3des PASSWORD                   | Exports the generated RSA key pair.<br><br><b>Tip</b> Be sure to keep the PEM file safe. For example, you may want to store it on another backup router.                                                                                   |
| Step 3 | <b>crypto key import rsa</b> key-label <b>pem</b> [usage-keys] {terminal   url url} [ <b>exportable</b> ] <b>passphrase</b><br><br><b>Example:</b><br>Router(config)# crypto key import rsa mycs2 pem url nvram: PASSWORD | Imports the generated RSA key pair.<br><br><b>Note</b> If you do not want the key to be exportable from your CA, import it back to the CA after it has been exported as a nonexportable key pair. Thus, the key cannot be taken off again. |
| Step 4 | <b>exit</b><br><br><b>Example:</b><br>Router(config)# exit                                                                                                                                                                | Exits global configuration mode.                                                                                                                                                                                                           |
| Step 5 | <b>show crypto key mypubkey rsa</b><br><br><b>Example:</b><br>Router# show crypto key mypubkey rsa                                                                                                                        | (Optional) Displays the RSA public keys of your router.                                                                                                                                                                                    |

## Encrypting and Locking Private Keys on a Router

Digital signatures are used to authenticate one device to another device. To use digital signatures, private information (the private key) must be stored on the device that is providing the signature. The stored private information may aid an attacker who steals the hardware device that contains the private key; for example, a thief might be able to use the stolen router to initiate a secure connection to another site by using the RSA private keys stored in the router.

### Note

RSA keys are lost during password recovery operations. If you lose your password, the RSA keys will be deleted when you perform the password recovery operation. (This function prevents an attacker from performing password recovery and then using the keys.)

To protect the private RSA key from an attacker, a user can encrypt the private key that is stored in NVRAM via a passphrase. Users can also “lock” the private key, which blocks new connection attempts from a running router and protects the key in the router if the router is stolen by an attempted attacker.

Perform this task to encrypt and lock the private key that is saved to NVRAM.

## Prerequisites

Before encrypting or locking a private key, you should perform the following tasks:

- Generate an RSA key pair as shown in the task “[Generating an RSA Key Pair](#).”
- Optionally, you can authenticate and enroll each router with the CA server.

**Note**

The RSA keys must be unlocked while enrolling the CA. The keys can be locked while authenticating the router with the CA because the private key of the router is not used during authentication.

## Restrictions for Encrypting and Locking Private Keys

### Backward Compatibility Restriction

Any image prior to Cisco IOS Release 12.3(7)T does not support encrypted keys. To prevent your router from losing all encrypted keys, ensure that only unencrypted keys are written to NVRAM before booting an image prior to Cisco IOS Release 12.3(7)T.

If you must download an image prior to Cisco IOS Release 12.3(7)T, decrypt the key and immediately save the configuration so the downloaded image does not overwrite the configuration.

### Interaction with Applications

An encrypted key is not effective after the router boots up until you manually unlock the key (via the **crypto key unlock rsa** command). Depending on which key pairs are encrypted, this functionality may adversely affect applications such as IP security (IPsec), SSH, and SSL; that is, management of the router over a secure channel may not be possible until the necessary key pair is unlocked.

## SUMMARY STEPS

1. **crypto key encrypt [write] rsa [name *key-name*] passphrase *passphrase***
2. **exit**
3. **show crypto key mypubkey rsa**
4. **crypto key lock rsa [name *key-name*] passphrase *passphrase***
5. **show crypto key mypubkey rsa**
6. **crypto key unlock rsa [name *key-name*] passphrase *passphrase***
7. **configure terminal**
8. **crypto key decrypt [write] rsa [name *key-name*] passphrase *passphrase***

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>crypto key encrypt [write] rsa [name key-name] passphrase passphrase</b><br><br><b>Example:</b><br>Router(config)# crypto key encrypt write rsa name pki.company.com passphrase password | Encrypts the RSA keys.<br><br>After this command is issued, the router can continue to use the key; the key remains unlocked.<br><br><b>Note</b> If the <b>write</b> keyword is not issued, the configuration must be manually written to NVRAM; otherwise, the encrypted key will be lost next time the router is reloaded.                                                                                            |
| Step 2 | <b>exit</b><br><br><b>Example:</b><br>Router(config)# exit                                                                                                                                  | Exits global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                        |
| Step 3 | <b>show crypto key mypubkey rsa</b><br><br><b>Example:</b><br>Router# show crypto key mypubkey rsa                                                                                          | (Optional) Shows that the private key is encrypted (protected) and unlocked.<br><br><b>Note</b> You can also use this command to verify that applications such as Internet Key Exchange (IKE) and SSH are properly working after the key has been encrypted.                                                                                                                                                            |
| Step 4 | <b>crypto key lock rsa [name key-name] passphrase passphrase</b><br><br><b>Example:</b><br>Router# crypto key lock rsa name pki.company.com passphrase password                             | (Optional) Locks the encrypted private key on a running router.<br><br><b>Note</b> After the key is locked, it cannot be used to authenticate the router to a peer device. This behavior disables any IPsec or SSL connections that use the locked key.<br><br>Any existing IPsec tunnels created on the basis of the locked key will be closed.<br><br>If all RSA keys are locked, SSH will automatically be disabled. |
| Step 5 | <b>show crypto key mypubkey rsa</b><br><br><b>Example:</b><br>Router# show crypto key mypubkey rsa                                                                                          | (Optional) Shows that the private key is protected and locked.<br><br>The output will also show failed connection attempts via applications such as IKE, SSH, and SSL.                                                                                                                                                                                                                                                  |
| Step 6 | <b>crypto key unlock rsa [name key-name] passphrase passphrase</b><br><br><b>Example:</b><br>Router# crypto key unlock rsa name pki.company.com passphrase password                         | (Optional) Unlocks the private key.<br><br><b>Note</b> After this command is issued, you can continue to establish IKE tunnels.                                                                                                                                                                                                                                                                                         |

|        | Command or Action                                                                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                              |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 7 | <code>configure terminal</code><br><br><b>Example:</b><br>Router# <code>configure terminal</code>                                                                                                              | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                    |
| Step 8 | <code>crypto key decrypt [write] rsa [name key-name] passphrase passphrase</code><br><br><b>Example:</b><br>Router(config)# <code>crypto key decrypt write rsa name pki.company.com passphrase password</code> | (Optional) Deletes the encrypted key and leaves only the unencrypted key.<br><br><b>Note</b> The <b>write</b> keyword immediately saves the unencrypted key to NVRAM. If the <b>write</b> keyword is not issued, the configuration must be manually written to NVRAM; otherwise, the key will remain encrypted the next time the router is reloaded. |

## Removing RSA Key Pair Settings

You might want to remove an RSA key pair for one of the following reasons:

- During manual PKI operations and maintenance, old RSA keys can be removed and replaced with new keys.
- An existing CA is replaced and the new CA requires newly generated keys; for example, the required key size might have changed in an organization so you would have to delete the old 1024-bit keys and generate new 2048-bit keys.

Perform this task to remove all RSA keys or the specified RSA key pair that has been generated by your router.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `crypto key zeroize rsa [key-pair-label]`
4. `exit`
5. `show crypto key mypubkey rsa`

## DETAILED STEPS

|        | Command or Action                                                                                                          | Purpose                                                                                                                                                                                                                 |
|--------|----------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                     | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                                                                                        |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                             | Enters global configuration mode.                                                                                                                                                                                       |
| Step 3 | <b>crypto key zeroize rsa [key-pair-label]</b><br><br><b>Example:</b><br>Router(config)# crypto key zeroize rsa fancy-keys | Deletes RSA key pairs from your router. <ul style="list-style-type: none"><li>• If the <i>key-pair-label</i> argument is not specified, all RSA keys that have been generated by your router will be deleted.</li></ul> |
| Step 4 | <b>exit</b><br><br><b>Example:</b><br>Router(config)# exit                                                                 | Exits global configuration mode.                                                                                                                                                                                        |
| Step 5 | <b>show crypto key mypubkey rsa</b><br><br><b>Example:</b><br>Router# show crypto key mypubkey rsa                         | (Optional) Displays the RSA public keys of your router. This step allows you to verify that the RSA key pair has been successfully generated.                                                                           |

## Configuration Examples for RSA Key Pair Deployment

This section contains the following configuration examples:

- [Generating and Specifying RSA Keys: Example, page 14](#)
- [Exporting and Importing RSA Keys: Examples, page 14](#)
- [Encrypting and Locking Private Keys on a Router: Examples, page 18](#)

### Generating and Specifying RSA Keys: Example

The following example is a sample trustpoint configuration that shows how to generate and specify the RSA key pair “exampleCAkeys”:

```
crypto key generate rsa general-purpose exampleCAkeys
crypto ca trustpoint exampleCAkeys
enroll url http://exampleCAkeys/certsrv/mscep/mscep.dll
rsakeypair exampleCAkeys 1024 1024
```

### Exporting and Importing RSA Keys: Examples

This section contains the following configuration examples:

- [Exporting and Importing RSA Keys in PKCS12 Files: Example, page 15](#)
- [Generating, Exporting, Importing, and Verifying RSA Keys in PEM Files: Example, page 15](#)
- [Exporting Router RSA Key Pairs and Certificates from PEM Files: Example, page 16](#)
- [Importing Router RSA Key Pairs and Certificate from PEM Files: Example, page 18](#)

## Exporting and Importing RSA Keys in PKCS12 Files: Example

In the following example, an RSA key pair “mynewkp” is generated on Router A, and a trustpoint name “mynewtp” is created and associated with the RSA key pair. The trustpoint is exported to a TFTP server, so that it can be imported on Router B. By importing the trustpoint “mynewtp” to Router B, the user has imported the RSA key pair “mynewkp” to Router B.

### Router A

```
crypto key generate rsa general label mykeys exportable
! The name for the keys will be:mynewkp
Choose the size of the key modulus in the range of 360 to 2048 for your
General Purpose Keys. Choosing a key modulus greater than 512 may take
a few minutes.
How many bits in the modulus [512]:
% Generating 512 bit RSA keys ...[OK]
!
crypto pki trustpoint mynewtp
 rsakeypair mykeys
 exit

crypto pki export mytp pkcs12 flash:myexport companyname
Destination filename [myexport]?
Writing pkcs12 file to tftp://mytftpserver/myexport
CRYPTO_PKI:Exported PKCS12 file successfully.
Verifying checksum... OK (0x3307)
!
Feb 18 17:30:09 GMT:%CRYPTO-6-PKCS12EXPORT_SUCCESS:PKCS #12 Successfully Exported.
```

### Router B

```
crypto pki import mynewtp pkcs12 flash:myexport companyname
Source filename [myexport]?
CRYPTO_PKI:Imported PKCS12 file successfully.

!
Feb 18 18:07:50 GMT:%CRYPTO-6-PKCS12IMPORT_SUCCESS:PKCS #12 Successfully Imported.
```

## Generating, Exporting, Importing, and Verifying RSA Keys in PEM Files: Example

The following example shows how to generate, export, bring the key back (import), and verify the status of the RSA key pair “mycs”:

```
! Generate the key pair
!
Router(config)# crypto key generate rsa general-purpose label mycs exportable
The name for the keys will be: mycs

Choose the size of the key modulus in the range of 360 to 2048 for your
General Purpose Keys. Choosing a key modulus greater than 512 may take a few minutes.

How many bits in the modulus [512]: 1024
% Generating 1024 bit RSA keys ...[OK]
!
```

```

! Archive the key pair to a remote location, and use a good password.
!
Router(config)# crypto key export rsa mycs pem url nvram:3des PASSWORD

% Key name:mycs
Usage:General Purpose Key
Exporting public key...
Destination filename [mycs.pub]?
Writing file to nvram:mycs.pub
Exporting private key...
Destination filename [mycs.prv]?
Writing file to nvram:mycs.prv
!
! Import the key as a different name.
!
Router(config)# crypto key import rsa mycs2 pem url nvram:mycs PASSWORD

% Importing public key or certificate PEM file...
Source filename [mycs.pub]?
Reading file from nvram:mycs.pub
% Importing private key PEM file...
Source filename [mycs.prv]?
Reading file from nvram:mycs.prv% Key pair import succeeded.
!
! After the key has been imported, it is no longer exportable.
!
! Verify the status of the key.
!
Router# show crypto key mypubkey rsa

% Key pair was generated at:18:04:56 GMT Jun 6 2003
Key name:mycs
Usage:General Purpose Key
Key is exportable.

```

## Exporting Router RSA Key Pairs and Certificates from PEM Files: Example

The following example shows how to generate and export the RSA key pair “aaa” and certificates of the router in PEM files that are associated with the trustpoint “mycs.” This example also shows PEM-formatted files, which include PEM boundaries before and after the base64-encoded data, that are used by other SSL and SSH applications.

```
Router(config)# crypto key generate rsa general-keys label aaa exportable
```

The name for the keys will be:aaa

Choose the size of the key modulus in the range of 360 to 2048 for your General Purpose Keys. Choosing a key modulus greater than 512 may take a few minutes.

```
!
How many bits in the modulus [512]:
% Generating 512 bit RSA keys ...[OK]
!
Router(config)# crypto pki trustpoint mycs
Router(ca-trustpoint)# enrollment url http://mycs
Router(ca-trustpoint)# rsakeypair aaa
Router(ca-trustpoint)# exit
Router(config)# crypto pki authenticate mycs
Certificate has the following attributes:
Fingerprint:C21514AC 12815946 09F635ED FBB6CF31
% Do you accept this certificate? [yes/no]: y
Trustpoint CA certificate accepted.
!
Router(config)# crypto pki enroll mycs
%
% Start certificate enrollment ..
% Create a challenge password. You will need to verbally provide this password to the CA
Administrator in order to revoke your certificate.
For security reasons your password will not be saved in the configuration.
Please make a note of it.
```

Password:

Re-enter password:

```
% The fully-qualified domain name in the certificate will be: Router
% The subject name in the certificate will be:host.company.com
% Include the router serial number in the subject name? [yes/no]: n
% Include an IP address in the subject name? [no]: n
Request certificate from CA? [yes/no]: y

## Importing Router RSA Key Pairs and Certificate from PEM Files: Example

The following example shows how to import the RSA key pairs and certificate to the trustpoint “ggg” from PEM files via TFTP:

```
Router(config)# crypto pki import ggg pem url tftp://10.1.1.2/username/msca password
% Importing CA certificate...
Address or name of remote host [10.1.1.2]?
Destination filename [username/msca.ca]?
Reading file from tftp://10.1.1.2/username/msca.ca
Loading username/msca.ca from 10.1.1.2 (via Ethernet0):!
[OK - 1082 bytes]

% Importing private key PEM file...
Address or name of remote host [10.1.1.2]?
Destination filename [username/msca.prv]?
Reading file from tftp://10.1.1.2/username/msca.prv
Loading username/msca.prv from 10.1.1.2 (via Ethernet0):!
[OK - 573 bytes]

% Importing certificate PEM file...
Address or name of remote host [10.1.1.2]?
Destination filename [username/msca.crt]?
Reading file from tftp://10.1.1.2/username/msca.crt
Loading username/msca.crt from 10.1.1.2 (via Ethernet0):!
[OK - 1289 bytes]
% PEM files import succeeded.
Router(config)#
```

## Encrypting and Locking Private Keys on a Router: Examples

This section contains the following configuration examples:

- [Configuring and Verifying an Encrypted Key: Example, page 18](#)
- [Configuring and Verifying a Locked Key: Example, page 19](#)

### Configuring and Verifying an Encrypted Key: Example

The following example shows how to encrypt the RSA key “pki-123.company.com.” Thereafter, the **show crypto key mypubkey rsa** command is issued to verify that the RSA key is encrypted (protected) and unlocked.

```
Router(config)# crypto key encrypt rsa name pki-123.company.com passphrase password
Router(config)# exit
Router# show crypto key mypubkey rsa
```

```
% Key pair was generated at:00:15:32 GMT Jun 25 2003
Key name:pki-123.company.com
Usage:General Purpose Key
*** The key is protected and UNLOCKED. ***
Key is not exportable.
Key Data:

Router#
```

## Configuring and Verifying a Locked Key: Example

The following example shows how to lock the key “pki-123.company.com.” Thereafter, the **show crypto key mypubkey rsa** command is issued to verify that the key is protected (encrypted) and locked.

```
Router# crypto key lock rsa name pki-123.company.com passphrase password
!
Router# show crypto key mypubkey rsa
```

```
% Key pair was generated at:20:29:41 GMT Jun 20 2003
Key name:pki-123.company.com
Usage:General Purpose Key
*** The key is protected and LOCKED. ***
Key is exportable.

## Where to Go Next

After you have generated an RSA key pair, you should set up the trustpoint. If you have already set up the trustpoint, you should authenticate and enroll the routers in a PKI. For information on enrollment, see the module “Configuring Certificate Enrollment for a PKI.”

## Additional References

The following sections provide references related to configuring RSA keys for a PKI.

## Feature Information for RSA Keys Within a PKI

Table 57 lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table.

For information on a feature in this technology that is not documented here, see the *“Implementing and Managing PKI Features Roadmap”*.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Note

Table 57 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 57**      **Feature Information for RSA Keys Within a PKI**

# Configuring Authorization and Revocation of Certificates in a PKI

---

**First Published: May 2, 2005**

Last Updated: June 19, 2006

This module describes how to configure authorization and revocation of certificates in a public key infrastructure (PKI).

## Finding Feature Information in This Module

*Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for Certificate Authorization and Revocation](#)” section on page 40.*

## Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

# Prerequisites for Authorization and Revocation of Certificates

## Plan Your PKI Strategy

### Tip

It is strongly recommended that you plan your entire PKI strategy before you begin to deploy actual certificates.

Authorization and revocation can occur only after you or a network administrator have completed the following tasks:

- Configured the CA.
- Enrolled peer devices with the CA.
- Identified and configured the protocol (such as IP Security [IPsec] or secure socket layer [SSL]) that is to be used for peer-to-peer communication.

You should decide which authorization and revocation strategy you are going to configure before enrolling peer devices because the peer device certificates might have to contain authorization and revocation-specific information.

### “crypto ca” to “crypto pki” CLI Change

As of Cisco IOS Release 12.3(7)T, all commands that begin as “crypto ca” have been changed to begin as “crypto pki.” Although the router will still accept crypto ca commands, all output will be read back as crypto pki.

## Information About Authorization and Revocation of Certificates

Before configuring certificate authorization and revocation, you should understand the following concepts:

- [PKI Authorization, page 2](#)
- [PKI and AAA Server Integration for Certificate Status, page 3](#)
- [CRLs or OCSP Server: Choosing a Certificate Revocation Mechanism, page 4](#)
- [When to Use Certificate-Based ACLs for Authorization or Revocation, page 7](#)
- [PKI Certificate Chain Validation, page 8](#)

## PKI Authorization

PKI authentication does not provide authorization. Current solutions for authorization are specific to the router that is being configured, although a centrally managed solution is often required.

There is not a standard mechanism by which certificates are defined as authorized for some tasks and not for others. This authorization information can be captured in the certificate itself if the application is aware of the certificate-based authorization information. But this solution does not provide a simple mechanism for real-time updates to the authorization information and forces each application to be aware of the specific authorization information embedded in the certificate.

When the certificate-based ACL mechanism is configured as part of the trustpoint authentication, the application is no longer responsible for determining this authorization information, and it is no longer possible to specify for which application the certificate is authorized. In some cases, the certificate-based ACL on the router gets so large that it cannot be managed. Additionally, it is beneficial to retrieve certificate-based ACL indications from an external server. (For more information on using certificate-based ACLs for authentication, see the section [“When to Use Certificate-Based ACLs for Authorization or Revocation.”](#))

Current solutions to the real-time authorization problem involve specifying a new protocol and building a new server (with associated tasks, such as management and data distribution).

## PKI and AAA Server Integration for Certificate Status

Integrating your PKI with an authentication, authorization, and accounting (AAA) server provides an alternative online certificate status solution that leverages the existing AAA infrastructure. Certificates can be listed in the AAA database with appropriate levels of authorization. For components that do not explicitly support PKI-AAA, a default label of “all” from the AAA server provides authorization. Likewise, a label of “none” from the AAA database indicates that the specified certificate is not valid. (The absence of any application label is equivalent, but “none” is included for completeness and clarity). If the application component does support PKI-AAA, the component may be specified directly; for example, the application component could be “ipsec,” “ssl,” or “osp.” (ipsec=IP Security, ssl=Secure Sockets Layer, and osp=Open Settlement Protocol.)

### Note

- Currently, no application component supports specification of the application label.
- There may be a time delay when accessing the AAA server. If the AAA server is not available, the authorization fails.

## RADIUS or TACACS+: Choosing a AAA Server Protocol

The AAA server can be configured to work with either the RADIUS or TACACS+ protocol. When you are configuring the AAA server for the PKI integration, you must set the RADIUS or TACACS attributes that are required for authorization.

If the RADIUS protocol is used, the password that is configured for the username in the AAA server should be set to “cisco,” which is acceptable because the certificate validation provides authentication and the AAA database is only being used for authorization. When the TACACS protocol is used, the password that is configured for the username in the AAA server is irrelevant because TACACS supports authorization without requiring authentication (the password is used for authentication).

In addition, if you are using TACACS, you must add a PKI service to the AAA server. The custom attribute “cert-application=all” is added under the PKI service for the particular user or usergroup to authorize the specific username.

## Attribute-Value Pairs for PKI and AAA Server Integration

[Table 1](#) lists the attribute-value (AV) pairs that are to be used when setting up PKI integration with a AAA server. (Note the values shown in the table are possible values.) The AV pairs must match the client configuration. If they do not match, the peer certificate is not authorized.

**Note**

Users can sometimes have AV pairs that are different from those of every other user. As a result, a unique username is required for each user. The **all** parameter (within the **authorization username** command) specifies that the entire subject name of the certificate will be used as the authorization username.

**Table 1** *AV Pairs That Must Match*

| AV Pair                                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cisco-avpair=pki:cert-application=all               | Valid values are “all” and “none.”                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| cisco-avpair=pki:cert-trustpoint=msca               | <p>The value is a Cisco IOS command-line interface (CLI) configuration trustpoint label.</p> <p><b>Note</b> The cert-trustpoint AV pair is normally optional. If more than three characters are entered for the month, the remaining characters are ignored (for example Janxxxx).</p> |

## CRLs or OCSP Server: Choosing a Certificate Revocation Mechanism

After a certificate is validated as a properly signed certificate, a certificate revocation method is performed to ensure that the certificate has not been revoked by the issuing CA. Cisco IOS software supports two revocation mechanisms—certificate revocation lists (CRLs) and Online Certificate Status Protocol (OCSP). (Cisco IOS software also supports AAA integration for certificate checking; however, additional authorization functionality is included. For more information on PKI and AAA certificate authorization and status check, see the section “[PKI and AAA Server Integration for Certificate Status.](#)”)

The following sections explain how each revocation mechanism works:

- [What Is a CRL?, page 5](#)
- [What Is OCSP?, page 6](#)

## What Is a CRL?

A certificate revocation list (CRL) contains a list of revoked certificates. The CRL is created and digitally signed by the CA that originally issued the certificates. The CRL contains dates for when each certificate was issued and when it expires.

CAs publish new CRLs periodically or when a certificate for which the CA is responsible has been revoked. By default, a new CRL will be downloaded after the currently cached CRL expires. An administrator may also configure the duration for which CRLs are cached in router memory or disable CRL caching completely. The CRL caching configuration will apply to all CRLs associated with a trustpoint.

When the CRL expires, the router deletes it from its cache. A new CRL is downloaded when a certificate is presented for verification; however, if a newer version of the CRL that lists the certificate under examination is on the server but the router is still using the CRL in its cache, the router will not know that the certificate has been revoked. The certificate will pass the revocation check even though it should have been denied.

When a CA issues a certificate, the CA can include in the certificate the CRL distribution point (CDP) for that certificate. Cisco IOS client devices use CDPs to locate and load the correct CRL. The Cisco IOS client supports multiple CDPs, but the Cisco IOS CA currently supports only one CDP; however, third-party vendor CAs may support multiple CDPs or different CDPs per certificate. If a CDP is not specified in the certificate, the client device will use the default Simple Certificate Enrollment Protocol (SCEP) method to retrieve the CRL. (The CDP location can be specified via the **cdp-url** command.)

When implementing CRLs, you should consider the following design considerations:

- CRL lifetimes and the security association (SA) and Internet Key Exchange (IKE) lifetimes  
The CRL lifetime determines the length of time between CA-issued updates to the CRL. (The default CRL lifetime value, which is 168 hours [1 week], can be changed via the **lifetime crl** command.)
- The method and location of the CDP
  - The method determines how the CRL is retrieved; some possible choices include HTTP, Lightweight Directory Access Protocol (LDAP), SCEP, or TFTP.  
HTTP, TFTP, and LDAP are the most commonly used methods. Although Cisco IOS software defaults to SCEP, an HTTP CDP is recommended for large installations using CRLs because HTTP can be made highly scalable.
  - The location determines from where the CRL is retrieved; for example, you can specify the server and file path from which to retrieve the CRL.

## Querying All CDPs During Revocation Check

When a CDP server does not respond to a request, the Cisco IOS software reports an error, which may result in the peer's certificate being rejected. To prevent a possible certificate rejection and if there are multiple CDPs in a certificate, the Cisco IOS software will attempt to use the CDPs in the order in which they appear in the certificate. The router will attempt to retrieve a CRL using each CDP URL or directory specification. If an error occurs using a CDP, an attempt will be made using the next CDP.

**Note**

Prior to Cisco IOS Release 12.3(7)T, the Cisco IOS software makes only one attempt to retrieve the CRL, even when the certificate contains more than one CDP.

**Tip**

Although the Cisco IOS software will make every attempt to obtain the CRL from one of the indicated CDPs, it is recommended that you use an HTTP CDP server with high-speed redundant HTTP servers to avoid application timeouts because of slow CDP responses.

## What Is OCSP?

OCSP is an online mechanism that is used to determine certificate validity and provides the following flexibility as a revocation mechanism:

- OCSP can provide real-time certificate status checking.
- OCSP allows the network administrator to specify a central OCSP server, which can service all devices within a network.
- OCSP also allows the network administrator the flexibility to specify multiple OCSP servers, either per client certificate or per group of client certificates.
- OCSP server validation is usually based on the root CA certificate or a valid subordinate CA certificate, but may also be configured so that external CA certificates or self-signed certificates may be used. Using external CA certificates or self-signed certificates allows the OCSP servers certificate to be issued and validated from an alternative PKI hierarchy.

A network administrator can configure an OCSP server to collect and update CRLs from different CA servers. The devices within the network can rely on the OCSP server to check the certificate status without retrieving and caching each CRL for every peer. When peers have to check the revocation status of a certificate, they send a query to the OCSP server that includes the serial number of the certificate in question and an optional unique identifier for the OCSP request, or a nonce. The OCSP server holds a copy of the CRL to determine if the CA has listed the certificate as being revoked; the server then responds to the peer including the nonce. If the nonce in the response from the OCSP server does not match the original nonce sent by the peer, the response is considered invalid and certificate verification fails. The dialog between the OCSP server and the peer consumes less bandwidth than most CRL downloads.

If the OCSP server is using a CRL, CRL time limitations will be applicable; that is, a CRL that is still valid might be used by the OCSP server although a new CRL has been issued by the CRL containing additional certificate revocation information. Because fewer devices are downloading the CRL information on a regular basis, you can decrease the CRL lifetime value or configure the OCSP server not to cache the CRL. For more information, check your OCSP server documentation.

## When to Use an OCSP Server

OCSP may be more appropriate than CRLs if your PKI has any of the following characteristics:

- Real-time certificate revocation status is necessary. CRLs are updated only periodically and the latest CRL may not always be cached by the client device. For example, if a client does not yet have the latest CRL cached and a newly revoked certificate is being checked, that revoked certificate will successfully pass the revocation check.

- There are a large number of revoked certificates or multiple CRLs. Caching a large CRL consumes large portions of Cisco IOS memory and may reduce resources available to other processes.
- CRLs expire frequently, causing the CDP to handle a larger load of CRLs.

**Note**

As of Cisco IOS Release 12.4(9)T or later, an administrator may configure CRL caching, either by disabling CRL caching completely or setting a maximum lifetime for a cached CRL per trustpoint.

## When to Use Certificate-Based ACLs for Authorization or Revocation

Certificates contain several fields that are used to determine whether a device or user is authorized to perform a specified action.

Because certificate-based ACLs are configured on the device, they do not scale well for large numbers of ACLs; however, certificate-based ACLs do provide very granular control of specific device behavior. Certificate-based ACLs are also leveraged by additional features to help determine when PKI components such as revocation, authorization, or a trustpoint should be used. They provide a general mechanism allowing users to select a specific certificate or a group of certificates that are being validated for either authorization or additional processing.

Certificate-based ACLs specify one or more fields within the certificate and an acceptable value for each specified field. You can specify which fields within a certificate should be checked and which values those fields may or may not have.

There are six logical tests for comparing the field with the value—equal, not equal, contains, does not contain, less than, and greater than or equal. If more than one field is specified within a single certificate-based ACL, the tests of all of the fields within the ACL must succeed to match the ACL. The same field may be specified multiple times within the same ACL. More than one ACL may be specified, and ACL will be processed in turn until a match is found or all of the ACLs have been processed.

## Ignore Revocation Checks Using a Certificate-Based ACL

Certificate-based ACLs can be configured to instruct your router to ignore the revocation check and expired certificates of a valid peer. Thus, a certificate that meets the specified criteria can be accepted regardless of the validity period of the certificate, or if the certificate meets the specified criteria, revocation checking does not have to be performed. You can also use a certificate-based ACL to ignore the revocation check when the communication with a AAA server is protected with a certificate.

### Ignoring Revocation Lists

To allow a trustpoint to enforce CRLs except for specific certificates, enter the **match certificate** command with the **skip revocation-check** keyword. This type of enforcement is most useful in a hub-and-spoke configuration in which you also want to allow direct spoke-to-spoke connections. In pure hub-and-spoke configurations, all spokes connect only to the hub, so CRL checking is necessary only on the hub. For one spoke to communicate directly with another spoke, the **match certificate** command with the **skip revocation-check** keyword can be used for neighboring peer certificates instead of requiring a CRL on each spoke.

### Ignoring Expired Certificates

To configure your router to ignore expired certificates, enter the **match certificate** command with the **allow expired-certificate** keyword. This command has the following purposes:

- If the certificate of a peer has expired, this command may be used to “allow” the expired certificate until the peer can obtain a new certificate.
- If your router clock has not yet been set to the correct time, the certificate of a peer will appear to be not yet valid until the clock is set. This command may be used to allow the certificate of the peer even though your router clock is not set.

**Note**

- If Network Time Protocol (NTP) is available only via the IPsec connection (usually via the hub in a hub-and-spoke configuration), the router clock can never be set. The tunnel to the hub cannot be “brought up” because the certificate of the hub is not yet valid.
- “Expired” is a generic term for a certificate that is expired or that is not yet valid. The certificate has a start and end time. An expired certificate, for purposes of the ACL, is one for which the current time of the router is outside the start and end times specified in the certificate.

**Skipping the AAA Check of the Certificate**

If the communication with an AAA server is protected with a certificate, and you want to skip the AAA check of the certificate, use the **match certificate** command with the **skip authorization-check** keyword. For example, if a virtual private network (VPN) tunnel is configured so that all AAA traffic goes over that tunnel, and the tunnel is protected with a certificate, you can use the **match certificate** command with the **skip authorization-check** keyword to skip the certificate check so that the tunnel can be established.

The **match certificate** command and the **skip authorization-check** keyword should be configured after PKI integration with an AAA server is configured.

**Note**

If the AAA server is available only via an IPsec connection, the AAA server cannot be contacted until after the IPsec connection is established. The IPsec connection cannot be “brought up” because the certificate of the AAA server is not yet valid.

## PKI Certificate Chain Validation

A certificate chain establishes a sequence of trusted certificates—from a peer certificate to the root CA certificate. Within a PKI hierarchy, all enrolled peers can validate the certificate of one another if the peers share a trusted root CA certificate or a common subordinate CA. Each CA corresponds to a trustpoint.

When a certificate chain is received from a peer, the default processing of a certificate chain path continues until the first trusted certificate, or trustpoint, is reached. In Cisco IOS Release 12.4(6)T and later releases, an administrator may configure the level to which a certificate chain is processed on all certificates including subordinate CA certificates.

Configuring the level to which a certificate chain is processed allows for the reauthentication of trusted certificates, the extension of a trusted certificate chain, and the completion of a certificate chain that contains a gap.

**Reauthentication of Trusted Certificates**

The default behavior is for the router to remove any trusted certificates from the certificate chain sent by the peer before the chain is validated. An administrator may configure certificate chain path processing so that the router does not remove CA certificates that are already trusted before chain validation, so that all certificates in the chain are re-authenticated for the current session.

### Extending the Trusted Certificate Chain

The default behavior is for the router to use its trusted certificates to extend the certificate chain if there are any missing certificates in the certificate chain sent by the peer. The router will validate only certificates in the chain sent by the peer. An administrator may configure certificate chain path processing so that the certificates in the peer's certificate chain and the router's trusted certificates are validated to a specified point.

### Completing Gaps in a Certificate Chain

An administrator may configure certificate chain processing so that if there is a gap in the configured Cisco IOS trustpoint hierarchy, certificates sent by the peer can be used to complete the set of certificates to be validated.

**Note**

If the trustpoint is configured to require parent validation and the peer does not provide the full certificate chain, the gap cannot be completed and the certificate chain is rejected and invalid.

**Note**

It is a configuration error if the trustpoint is configured to require parent validation and there is no parent trustpoint configured. The resulting certificate chain gap cannot be completed and the subordinate CA certificate cannot be validated. The certificate chain is invalid.

## How to Configure Authorization and Revocation of Certificates for Your PKI

This section contains the following procedures:

- [Configuring PKI Integration with a AAA Server, page 9](#)
- [Configuring a Revocation Mechanism for PKI Certificate Status Checking, page 13](#)
- [Configuring Certificate Authorization and Revocation Settings, page 16](#)
- [Configuring Certificate Chain Validation, page 25](#)

## Configuring PKI Integration with a AAA Server

Perform this task to generate a AAA username from the certificate presented by the peer and specify which fields within a certificate should be used to build the AAA database username.

### Restrictions When Using the Entire Subject Name for PKI Authorization

The following restrictions should be considered when using the **all** keyword as the subject name for the **authorization username** command:

- Some AAA servers limit the length of the username (for example, to 64 characters). As a result, the entire certificate subject name cannot be longer than the limitation of the server.
- Some AAA servers limit the available character set that may be used for the username (for example, a space [ ] and an equal sign [=] may not be acceptable). You cannot use the **all** keyword for a AAA server having such a character-set limitation.

- The **subject-name** command in the trustpoint configuration may not always be the final AAA subject name. If the fully qualified domain name (FQDN), serial number, or IP address of the router are included in a certificate request, the subject name field of the issued certificate will also have these components. To turn off the components, use the **fqdn**, **serial-number**, and **ip-address** commands with the **none** keyword.
- CA servers sometimes change the requested subject name field when they issue a certificate. For example, CA servers of some vendors switch the relative distinguished names (RDNs) in the requested subject names to the following order: CN, OU, O, L, ST, and C. However, another CA server might append the configured LDAP directory root (for example, O=cisco.com) to the end of the requested subject name.
- Depending on the tools you choose for displaying a certificate, the printed order of the RDNs in the subject name could be different. Cisco IOS software always displays the least significant RDN first, but other software, such as Open Source Secure Socket Layer (OpenSSL), does the opposite. Therefore, if you are configuring a AAA server with a full distinguished name (DN) (subject name) as the corresponding username, ensure that the Cisco IOS software style (that is, with the least significant RDN first) is used.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa new-model**
4. **aaa authorization network** *listname* [*method*]
5. **crypto pki trustpoint** *name*
6. **enrollment url** *url*
7. **revocation-check** *method*
8. **exit**
9. **authorization username** {*subjectname* *subjectname*}
10. **authorization list** *listname*
11. **tacacs-server host** *hostname* [**key** *string*]  
or  
**radius-server host** *hostname* [**key** *string*]

## DETAILED STEPS

|        | Command or Action                             | Purpose                                                                                                            |
|--------|-----------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b>                                 | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
|        | <b>Example:</b><br>Router> enable             |                                                                                                                    |
| Step 2 | <b>configure terminal</b>                     | Enters global configuration mode.                                                                                  |
|        | <b>Example:</b><br>Router# configure terminal |                                                                                                                    |

|        | Command or Action                                                                                                                               | Purpose                                                                                                                                                                                                   |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <b>aaa new-model</b><br><br><b>Example:</b><br>Router(config)# aaa new-model                                                                    | Enables the AAA access control model.                                                                                                                                                                     |
| Step 4 | <b>aaa authorization network listname [method]</b><br><br><b>Example:</b><br>Router (config)# aaa authorization network<br>maxaaa group tacacs+ | Sets the parameters that restrict user access to a network. <ul style="list-style-type: none"> <li><i>method</i>—Can be <b>group radius</b>, <b>group tacacs+</b>, or <b>group group-name</b>.</li> </ul> |
| Step 5 | <b>crypto pki trustpoint name</b><br><br><b>Example:</b><br>Route (config)# crypto pki trustpoint msca                                          | Declares the trustpoint and a given name and enters ca-trustpoint configuration mode.                                                                                                                     |
| Step 6 | <b>enrollment url url</b><br><br><b>Example:</b><br>Router (ca-trustpoint)# enrollment url<br>http://caserver.mycompany.com                     | Specifies the enrollment parameters of your CA. <ul style="list-style-type: none"> <li>The <i>url</i> argument is the URL of the CA to which your router should send certificate requests.</li> </ul>     |
| Step 7 | <b>revocation-check method</b><br><br><b>Example:</b><br>Router (ca-trustpoint)# revocation-check crl                                           | (Optional) Checks the revocation status of a certificate.                                                                                                                                                 |
| Step 8 | <b>exit</b><br><br><b>Example:</b><br>Router (ca-trustpoint)# exit                                                                              | Exits ca-trustpoint configuration mode and returns to global configuration mode.                                                                                                                          |

|         | Command or Action                                                                                                                                                                                                                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Step 9  | <p><b>authorization username</b> {<b>subjectname</b> <i>subjectname</i>}</p> <p><b>Example:</b><br/>Router (config)# authorization username <i>subjectname</i> <i>serialnumber</i></p>                                                                                                                                                                            | <p>Sets parameters for the different certificate fields that are used to build the AAA username.</p> <p>The <i>subjectname</i> argument can be any of the following:</p> <ul style="list-style-type: none"> <li>• <b>all</b>—Entire distinguished name (subject name) of the certificate.</li> <li>• <b>commonname</b>—Certification common name.</li> <li>• <b>country</b>—Certificate country.</li> <li>• <b>email</b>—Certificate e-mail.</li> <li>• <b>ipaddress</b>—Certificate IP address.</li> <li>• <b>locality</b>—Certificate locality.</li> <li>• <b>organization</b>—Certificate organization.</li> <li>• <b>organizationalunit</b>—Certificate organizational unit.</li> <li>• <b>postalcode</b>—Certificate postal code.</li> <li>• <b>serialnumber</b>—Certificate serial number.</li> <li>• <b>state</b>—Certificate state field.</li> <li>• <b>streetaddress</b>—Certificate street address.</li> <li>• <b>title</b>—Certificate title.</li> <li>• <b>unstructuredname</b>—Certificate unstructured name.</li> </ul> |
| Step 10 | <p><b>authorization list</b> <i>listname</i></p> <p><b>Example:</b><br/>Route (config)# authorization list maxaaa</p>                                                                                                                                                                                                                                             | Specifies the AAA authorization list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Step 11 | <p><b>tacacs-server host</b> <i>hostname</i> [<b>key string</b>]</p> <p><b>Example:</b><br/>Router(config)# tacacs-server host 192.0.2.2<br/>key <i>a_secret_key</i></p> <p>or</p> <p><b>radius-server host</b> <i>hostname</i> [<b>key string</b>]</p> <p><b>Example:</b><br/>Router(config)# radius-server host 192.0.2.1<br/>key <i>another_secret_key</i></p> | <p>Specifies a TACACS+ host.</p> <p>or</p> <p>Specifies a RADIUS host.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Troubleshooting Tips

To display debug messages for the trace of interaction (message type) between the CA and the router, use the **debug crypto pki transactions** command. (See the sample output, which shows a successful PKI integration with AAA server exchange and a failed PKI integration with AAA server exchange.)

**Successful Exchange**

```
Router# debug crypto pki transactions
```

```
Apr 22 23:15:03.695: CRYPTO_PKI: Found a issuer match
Apr 22 23:15:03.955: CRYPTO_PKI: cert revocation status unknown.
Apr 22 23:15:03.955: CRYPTO_PKI: Certificate validated without revocation check
```

Each line that shows “CRYPTO\_PKI\_AAA” indicates the state of the AAA authorization checks. Each of the AAA AV pairs is indicated, and then the results of the authorization check are shown.

```
Apr 22 23:15:04.019: CRYPTO_PKI_AAA: checking AAA authorization (ipsecca_script_aalist,
PKIAAA-L, <all>)
Apr 22 23:15:04.503: CRYPTO_PKI_AAA: reply attribute ("cert-application" = "all")
Apr 22 23:15:04.503: CRYPTO_PKI_AAA: reply attribute ("cert-trustpoint" = "CA1")
Apr 22 23:15:04.503: CRYPTO_PKI_AAA: reply attribute ("cert-serial" = "15DE")
Apr 22 23:15:04.503: CRYPTO_PKI_AAA: authorization passed
Apr 22 23:12:30.327: CRYPTO_PKI: Found a issuer match
```

**Failed Exchange**

```
Router# debug crypto pki transactions
```

```
Apr 22 23:11:13.703: CRYPTO_PKI_AAA: checking AAA authorization =
Apr 22 23:11:14.203: CRYPTO_PKI_AAA: reply attribute ("cert-application" = "all")
Apr 22 23:11:14.203: CRYPTO_PKI_AAA: reply attribute ("cert-trustpoint" = "CA1")
Apr 22 23:11:14.203: CRYPTO_PKI_AAA: reply attribute ("cert-serial" = "233D")
Apr 22 23:11:14.203: CRYPTO_PKI_AAA: parsed cert-lifetime-end as: 21:30:00
Apr 22 23:11:14.203: CRYPTO_PKI_AAA: timezone specific extended
Apr 22 23:11:14.203: CRYPTO_PKI_AAA: cert-lifetime-end is expired
Apr 22 23:11:14.203: CRYPTO_PKI_AAA: cert-lifetime-end check failed.
Apr 22 23:11:14.203: CRYPTO_PKI_AAA: authorization failed
```

In the above failed exchange, the certificate has expired.

## Configuring a Revocation Mechanism for PKI Certificate Status Checking

Perform this task to set up a CRL as the certificate revocation mechanism—CRLs or OCSP—that is used to check the status of certificates in a PKI.

### The revocation-check Command

Use the **revocation-check** command to specify at least one method (OCSP, CRL, or skip the revocation check) that is to be used to ensure that the certificate of a peer has not been revoked. For multiple methods, the order in which the methods are applied is determined by the order specified via this command.

If your router does not have the applicable CRL and is unable to obtain one or if the OCSP server returns an error, your router will reject the peer’s certificate—unless you include the **none** keyword in your configuration. If the **none** keyword is configured, a revocation check will not be performed and the certificate will always be accepted.

### Nonces and Peer Communications with OCSP Servers

When using OCSP, nonces, unique identifiers for OCSP requests, are sent by default during peer communications with your OCSP server. The use of nonces offers a more secure and reliable communication channel between the peer and OCSP server.

If your OCSP server does not support nonces, you may disable the sending of nonces. For more information, check your OCSP server documentation.

## Prerequisites

- Before issuing any client certificates, the appropriate settings on the server (such as setting the CDP) should be configured.
- When configuring an OCSP server to return the revocation status for a CA server, the OCSP server must be configured with an OCSP response signing certificate that is issued by that CA server. Ensure that the signing certificate is in the correct format, or the router will not accept the OCSP response. See your OCSP manual for additional information.

## Restrictions

- OCSP transports messages over HTTP, so there may be a time delay when you access the OCSP server.
- If the OCSP server depends on normal CRL processing to check revocation status, the same time delay that affects CRLs will also apply to OCSP.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto pki trustpoint *name***
4. **ocsp url *url***
5. **revocation-check *method1* [*method2* [*method3*]]**
6. **ocsp disable-nonce**
7. **exit**
8. **exit**
9. **show crypto pki certificates**
10. **show crypto pki trustpoints [*status* | *label* [*status*]]**

| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                  | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                    |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                          | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Step 3 | <b>crypto pki trustpoint <i>name</i></b><br><br><b>Example:</b><br>Router(config)# crypto pki trustpoint hazel                                          | Declares the trustpoint and a given name and enters ca-trustpoint configuration mode.                                                                                                                                                                                                                                                                                                                                                                               |
| Step 4 | <b>ocsp url <i>url</i></b><br><br><b>Example:</b><br>Router(ca-trustpoint)# ocsp url<br>http://ocsp-server                                              | (Optional) Specifies the URL of an OCSP server so that the trustpoint can check the certificate status. This URL will override the URL of the OCSP server (if one exists) in the Authority Info Access (AIA) extension of the certificate.                                                                                                                                                                                                                          |
| Step 5 | <b>revocation-check <i>method1</i> [<i>method2</i> [<i>method3</i>]]</b><br><br><b>Example:</b><br>Router(ca-trustpoint)# revocation-check ocsp<br>none | Checks the revocation status of a certificate. <ul style="list-style-type: none"> <li><b>crl</b>—Certificate checking is performed by a CRL. This is the default option.</li> <li><b>none</b>—Certificate checking is ignored.</li> <li><b>ocsp</b>—Certificate checking is performed by an OCSP server.</li> </ul> If a second and third method are specified, each method will be used only if the previous method returns an error, such as a server being down. |
| Step 6 | <b>ocsp disable-nonce</b><br><br><b>Example:</b><br>Router(ca-trustpoint)# ocsp disable-nonce                                                           | (Optional) Specifies that a nonce, or an OCSP request unique identifier, will not be sent during peer communications with the OCSP server.                                                                                                                                                                                                                                                                                                                          |
| Step 7 | <b>exit</b><br><br><b>Example:</b><br>Router(ca-trustpoint)# exit                                                                                       | Returns to global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Step 8 | <b>exit</b><br><br><b>Example:</b><br>Router(config)# exit                                                                                              | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|         | Command or Action                                                                                                                | Purpose                                                         |
|---------|----------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|
| Step 9  | <code>show crypto pki certificates</code><br><br><b>Example:</b><br>Router# show crypto pki certificates                         | (Optional) Displays information about your certificates.        |
| Step 10 | <code>show crypto pki trustpoints [status   label [status]]</code><br><br><b>Example:</b><br>Router# show crypto pki trustpoints | Displays information about the trustpoint configured in router. |

## Configuring Certificate Authorization and Revocation Settings

Perform this task to specify a certificate-based ACL, to ignore revocation checks or expired certificates, to manually override the default CDP location, to manually override the OCSP server setting, to configure CRL caching, or to set session acceptance or rejection based on a certificate serial number, as appropriate.

### Configuring Certificate-Based ACLs to Ignore Revocation Checks

To configure your router to use certificate-based ACLs to ignore revocation checks and expired certificates, perform the following steps:

- Identify an existing trustpoint or create a new trustpoint to be used when verifying the certificate of the peer. Authenticate the trustpoint if it has not already been authenticated. The router may enroll with this trustpoint if you want. Do not set optional CRLs for the trustpoint if you plan to use the **match certificate** command and **skip revocation-check** keyword.
- Determine the unique characteristics of the certificates that should not have their CRL checked and of the expired certificates that should be allowed.
- Define a certificate map to match the characteristics identified in the prior step.
- You can add the **match certificate** command and **skip revocation-check** keyword and the **match certificate command** and **allow expired-certificate** keyword to the trustpoint that was created or identified in the first step.

### Manually Overriding CDPs in a Certificate

Users can override the CDPs in a certificate with a manually configured CDP. Manually overriding the CDPs in a certificate can be advantageous when a particular server is unavailable for an extended period of time. The certificate's CDPs can be replaced with a URL or directory specification without reissuing all of the certificates that contain the original CDP.

### Manually Overriding the OCSP Server Setting in a Certificate

Administrators can override the OCSP server setting specified in the Authority Information Access (AIA) field of the client certificate or set by the issuing the **ocsp url** command. One or more OCSP servers may be manually specified, either per client certificate or per group of client certificates by the

**match certificate override ocs**p command. The **match certificate override ocs**p command overrides the client certificate AIA field or the **ocs url** command setting if a client certificate is successfully matched to a certificate map during the revocation check.

**Note**

Only one OCSF server can be specified per client certificate.

## Configuring CRL Cache Control

By default, a new CRL will be downloaded after the currently cached CRL expires. Administrators can either configure the maximum amount of time in minutes a CRL remains in the cache by issuing the **crl cache delete-after** command or disable CRL caching by issuing the **crl cache none** command. Only the **crl-cache delete-after** command or the **crl-cache none** command may be specified. If both commands are entered for a trustpoint, the last command executed will take effect and a message will be displayed.

Neither the **crl-cache none** command nor the **crl-cache delete-after** command affects the currently cached CRL. If you configure the **crl-cache none** command, all CRLs downloaded after this command is issued will not be cached. If you configure the **crl-cache delete-after** command, the configured lifetime will only affect CRLs downloaded after this command is issued.

This functionality is useful is when a CA issues CRLs with no expiration date or with expiration dates days or weeks ahead.

## Configuring Certificate Serial Number Session Control

A certificate serial number can be specified to allow a certificate validation request to be accepted or rejected by the trustpoint for a session. A session may be rejected, depending on certificate serial number session control, even if a certificate is still valid. Certificate serial number session control may be configured by using either a certificate map with the **serial-number** field or an AAA attribute, with the **cert-serial-not** command.

Using certificate maps for session control allows an administrator to specify a single certificate serial number. Using the AAA attribute allows an administrator to specify one or more certificate serial numbers for session control.

## Prerequisites

- The trustpoint should be defined and authenticated before attaching certificate maps to the trustpoint.
- The certificate map must be configured before the CDP override feature can be enabled or the **serial-number** command is issued.
- The PKI and AAA server integration must be successfully completed to use AAA attributes as described in [“PKI and AAA Server Integration for Certificate Status.”](#)

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto pki certificate map** *label sequence-number*
4. *field-name match-criteria match-value*

5. **exit**
6. **crypto pki trustpoint** *name*
7. **crl-cache none**
8. **crl-cache delete-after** *time*
9. **match certificate** *certificate-map-label* [**allow expired-certificate** | **skip revocation-check** | **skip authorization-check**]
10. **match certificate** *certificate-map-label* **override cdp** {**url** | **directory**} *string*
11. **match certificate** *certificate-map-label* **override ocsp** [**trustpoint** *trustpoint-label*] *sequence-number* **url** *ocsp-url*
12. **exit**
13. **aaa new-model**
14. **aaa attribute list** *list-name*
15. **attribute type** {*name*} {*label*}
16. **exit**
17. **exit**
18. **show crypto pki certificates**

## DETAILED STEPS

|        | Command or Action                                                                                                                                      | Purpose                                                                                                                 |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                 | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>        |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                         | Enters global configuration mode.                                                                                       |
| Step 3 | <b>crypto pki certificate map</b> <i>label</i> <i>sequence-number</i><br><br><b>Example:</b><br>Router(config)# crypto pki certificate map<br>Group 10 | Defines values in a certificate that should be matched or not matched and enters ca-certificate-map configuration mode. |

|        | Command or Action                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Step 11 | <p><b>match certificate</b> <i>certificate-map-label</i><br/> <b>override ocs</b> [<i>trustpoint trustpoint-label</i>]<br/> <i>sequence-number url ocs-url</i></p> <p><b>Example:</b><br/> Router(ca-trustpoint)# match certificate<br/> mycertmapname override ocs trustpoint mytp 15<br/> url http://192.0.2.2</p> | <p>(Optional) Specifies an OCS server, either per client certificate or per group of client certificates, and may be issued more than once to specify additional OCS servers and client certificate settings including alternative PKI hierarchies.</p> <ul style="list-style-type: none"> <li>• <i>certificate-map-label</i>—The name of an existing certificate map.</li> <li>• <b>trustpoint</b>—The trustpoint to be used when validating the OCS server certificate.</li> <li>• <i>sequence-number</i>—The order the <b>match certificate override ocs</b> command statements apply to the certificate being verified. Matches are performed from the lowest sequence number to the highest sequence number. If more than one command is issued with the same sequence number, it overwrites the previous OCS server override setting.</li> <li>• <b>url</b>—The URL of the OCS server.</li> </ul> <p>When the certificate matches a configured certificate map, the AIA field of the client certificate and any previously issued <b>ocs url</b> command settings are overwritten with the specified OCS server.</p> <p>If no map-based match occurs, one of the following two cases will continue to apply to the client certificate.</p> <ul style="list-style-type: none"> <li>• If OCS is specified as the revocation method, the AIA field value will continue to apply to the client certificate.</li> <li>• If the <b>ocs url</b> configuration exists, the <b>ocs url</b> configuration settings will continue to apply to the client certificates.</li> </ul> |
| Step 12 | <p><b>exit</b></p> <p><b>Example:</b><br/> Router(ca-trustpoint)# exit</p>                                                                                                                                                                                                                                           | Returns to global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Step 13 | <p><b>aaa new-model</b></p> <p><b>Example:</b><br/> Router(config)# aaa new-model</p>                                                                                                                                                                                                                                | (Optional) Enables the AAA access control model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Step 14 | <p><b>aaa attribute list</b> <i>list-name</i></p> <p><b>Example:</b><br/> Router(config)# aaa attribute list crl</p>                                                                                                                                                                                                 | (Optional) Defines an AAA attribute list locally on a router and enters config-attr-list configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|         | Command or Action                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|-----------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 15 | <b>attribute type</b> {name}{value}<br><br><b>Example:</b><br>Router(config-attr-list)# attribute type cert-serial-not 6C4A | (Optional) Defines an AAA attribute type that is to be added to an AAA attribute list locally on a router.<br><br>To configure certificate serial number session control, an administrator may specify a specific certificate in the <i>value</i> field to be accepted or rejected based on its serial number where <i>name</i> is set to <b>cert-serial-not</b> . If the serial number of the certificate matches the serial number specified by the attribute type setting, the certificate will be rejected.<br><br>For a full list of available AAA attribute types, execute the <b>show aaa attributes</b> command. |
| Step 16 | <b>exit</b><br><br><b>Example:</b><br>Router(ca-trustpoint)# exit<br><br><b>Example:</b><br>Router(config-attr-list)# exit  | Returns to global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Step 17 | <b>exit</b><br><br><b>Example:</b><br>Router(config)# exit                                                                  | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 18 | <b>show crypto pki certificates</b><br><br><b>Example:</b><br>Router# show crypto pki certificates                          | (Optional) Displays the components of the certificates installed on the router if the CA certificate has been authenticated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Examples

The following is a sample OCSP response when signing a certificate. The OCSP-related extensions are in bold.

```
Certificate:
 Data:
 Version: v3
 Serial Number:0x14
 Signature Algorithm:MD5withRSA - 1.2.840.113549.1.1.4
 Issuer:CN=CA server,OU=PKI,O=Cisco Systems
 Validity:
 Not Before:Thursday, August 8, 2002 4:38:05 PM PST
 Not After:Tuesday, August 7, 2003 4:38:05 PM PST
 Subject:CN=OCSP server,OU=PKI,O=Cisco Systems
 Subject Public Key Info:
 Algorithm:RSA - 1.2.840.113549.1.1.1
 Public Key:
 Exponent:65537
 Public Key Modulus:(1024 bits) :
 <snip>

 Extensions:
 Identifier:Subject Key Identifier - 2.5.29.14
 Critical:no
```

```

Key Identifier:
 <snip>
Identifier:Authority Key Identifier - 2.5.29.35
Critical:no
Key Identifier:
 <snip>

Identifier:OCSP NoCheck:- 1.3.6.1.5.5.7.48.1.5
Critical:no
Identifier:Extended Key Usage:- 2.5.29.37
Critical:no
Extended Key Usage:
 OCSPSigning
Identifier:CRL Distribution Points - 2.5.29.31
Critical:no
Number of Points:1
Point 0
 Distribution Point:
[URIName:ldap://CA-server/CN=CA server,OU=PKI,O=Cisco Systems]
Signature:
 Algorithm:MD5withRSA - 1.2.840.113549.1.1.4
Signature:
 <snip>

```

The following example shows an excerpt of the running configuration output when adding a **match certificate override ocs** command to the beginning of an existing sequence:

```

match certificate map3 override ocs 5 url http://192.0.2.3/
show running-configuration
.
.
.
 match certificate map3 override ocs 5 url http://192.0.2.3/
 match certificate map1 override ocs 10 url http://192.0.2.1/
 match certificate map2 override ocs 15 url http://192.0.2.2/

```

The following example shows an excerpt of the running configuration output when an existing **match certificate override ocs** command is replaced and a trustpoint is specified to use an alternative PKI hierarchy:

```

match certificate map4 override ocs trustpoint tp4 10 url http://192.0.2.4/newvalue
show running-configuration
.
.
.
 match certificate map3 override ocs trustpoint tp3 5 url http://192.0.2.3/
 match certificate map1 override ocs trustpoint tp1 10 url http://192.0.2.1/
 match certificate map4 override ocs trustpoint tp4 10 url
 http://192.0.2.4/newvalue
 match certificate map2 override ocs trustpoint tp2 15 url http://192.0.2.2/

```

## Troubleshooting Tips

If you ignored revocation check or expired certificates, you should carefully check your configuration. Verify that the certificate map properly matches either the certificate or certificates that should be allowed or the AAA checks that should be skipped. In a controlled environment, try modifying the certificate map and determine what is not working as expected.

## Configuring Certificate Chain Validation

Perform this task to configure the processing level for the certificate chain path of your peer certificates.

### Prerequisites

- The device must be enrolled in your PKI hierarchy.
- The appropriate key pair must be associated with the certificate.

### Restrictions

- A trustpoint associated with the root CA cannot be configured to be validated to the next level.

The **chain-validation** command is configured with the **continue** keyword for the trustpoint associated with the root CA, an error message will be displayed and the chain validation will revert to the default **chain-validation** command setting.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto pki trustpoint** *name*
4. **chain-validation** [{**stop** | **continue**} [*parent-trustpoint*]]
5. **exit**

## DETAILED STEPS

|        | Command or Action                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                             | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                     | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 3 | <b>crypto pki trustpoint name</b><br><br><b>Example:</b><br>Router(config)# crypto pki trustpoint ca-sub1                                          | Declares the trustpoint and a given name and enters ca-trustpoint configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Step 4 | <b>chain-validation [{stop   continue} [parent-trustpoint]]</b><br><br><b>Example:</b><br>Router(ca-trustpoint)# chain-validation continue ca-sub1 | Configures the level to which a certificate chain is processed on all certificates including subordinate CA certificates. <ul style="list-style-type: none"><li>• Use the <b>stop</b> keyword to specify that the certificate is already trusted. This is the default setting.</li><li>• Use the <b>continue</b> keyword to specify that the subordinate CA certificate associated with the trustpoint must be validated.</li><li>• The <i>parent-trustpoint</i> argument specifies the name of the parent trustpoint the certificate must be validated against.</li></ul> |
| Step 5 | <b>exit</b><br><br><b>Example:</b><br>Router(ca-trustpoint)# exit                                                                                  | Returns to global configuration mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Configuration Examples for Setting Up Authorization and Revocation of Certificates

This section contains the following configuration examples:

- [Configuring and Verifying PKI AAA Authorization: Examples, page 27](#)
- [Configuring a Revocation Mechanism: Examples, page 31](#)
- [Configuring a Hub Router at a Central Site for Certificate Revocation Checks: Example, page 32](#)
- [Configuring Certificate Authorization and Revocation Settings: Examples, page 36](#)
- [Configuring Certificate Chain Validation: Examples, page 38](#)

## Configuring and Verifying PKI AAA Authorization: Examples

This section provides configuration examples of PKI AAA authorizations:

- [Router Configuration: Example, page 27](#)
- [Debug of a Successful PKI AAA Authorization: Example, page 29](#)
- [Debugs of a Failed PKI AAA Authorization: Example, page 30](#)

### Router Configuration: Example

The following **show running-config** command output shows the working configuration of a router that is set up to authorize VPN connections using the PKI Integration with AAA Server feature:

Router# **show running-config**

## Debug of a Successful PKI AAA Authorization: Example

The following **show debugging** command output shows a successful authorization using the PKI Integration with AAA Server feature:

Router# **show debugging**

General OS:

```

TACACS access control debugging is on
AAA Authentication debugging is on
AAA Authorization debugging is on

```

Cryptographic Subsystem:

```

Crypto PKI Trans debugging is on

```

Router#

```

## Debugs of a Failed PKI AAA Authorization: Example

The following **show debugging** command output shows that the router is not authorized to connect using VPN. The messages are typical of those that you might see in such a situation.

In this example, the peer username was configured as not authorized, by moving the username to a Cisco Secure ACS group called VPN\_Router\_Disabled in Cisco Secure ACS. The router, router7200.company.com, has been configured to check with a Cisco Secure ACS AAA server prior to establishing a VPN connection to any peer.

Router# **show debugging**

General OS:

TACACS access control debugging is on

AAA Authentication debugging is on

AAA Authorization debugging is on

Cryptographic Subsystem:

Crypto PKI Trans debugging is on

## Configuring a Revocation Mechanism: Examples

This section contains the following configuration examples that can be used when specifying a revocation mechanism for your PKI:

- [Configuring an OCSP Server: Example, page 31](#)
- [Specifying a CRL and Then an OCSP Server: Example, page 31](#)
- [Specifying an OCSP Server: Example, page 31](#)
- [Disabling Nonces in Communications with the OCSP Server: Example, page 32](#)

### Configuring an OCSP Server: Example

The following example shows how to configure the router to use the OCSP server that is specified in the AIA extension of the certificate:

```
Router(config)# crypto pki trustpoint mytp
Router(ca-trustpoint)# revocation-check ocsp
```

### Specifying a CRL and Then an OCSP Server: Example

The following example shows how to configure the router to download the CRL from the CDP. If the CRL is unavailable, the OCSP server that is specified in the AIA extension of the certificate will be used. If both options fail, certificate verification will also fail.

```
Router(config)# crypto pki trustpoint mytp
Router(ca-trustpoint)# revocation-check crl ocsp
```

### Specifying an OCSP Server: Example

The following example shows how to configure your router to use the OCSP server at the HTTP URL “http://myocspserver:81.” If the server is down, the revocation check will be ignored.

```
Router(config)# crypto pki trustpoint mytp
Router(ca-trustpoint)# ocsf url http://myocspserver:81
Router(ca-trustpoint)# revocation-check ocsf none
```

## Disabling Nonces in Communications with the OCSP Server: Example

The following example shows communications when a nonce, or a unique identifier for the OCSP request, is disabled for communications with the OCSP server:

```
Router(config)# crypto pki trustpoint mytp
Router(ca-trustpoint)# ocsf url http://myocspserver:81
Router(ca-trustpoint)# revocation-check ocsf none
Router(ca-trustpoint)# ocsf disable-nonce
```

## Configuring a Hub Router at a Central Site for Certificate Revocation Checks: Example

The following example shows a hub router at a central site that is providing connectivity for several branch offices to the central site.

The branch offices are also able to communicate directly with each other using additional IPsec tunnels between the branch offices.

The CA publishes CRLs on an HTTP server at the central site. The central site checks CRLs for each peer when setting up an IPsec tunnel with that peer.

The example does not show the IPsec configuration—only the PKI-related configuration is shown.

### Home Office Hub Configuration

```
crypto pki trustpoint VPN-GW
enrollment url http://ca.home-office.com:80/certsrv/mscep/mscep.dll
serial-number none
fqdn none
ip-address none
subject-name o=Home Office Inc,cn=Central VPN Gateway
revocation-check crl
```

### Central Site Hub Router

```
Router# show crypto ca certificate
```

```
Certificate
 Status: Available
 Certificate Serial Number: 2F62BE140000000000CA0
 Certificate Usage: General Purpose
 Issuer:
 cn=Central Certificate Authority
 o=Home Office Inc
 Subject:
 Name: Central VPN Gateway
 cn=Central VPN Gateway
 o=Home Office Inc
 CRL Distribution Points:
 http://ca.home-office.com/CertEnroll/home-office.crl
 Validity Date:
 start date: 00:43:26 GMT Sep 26 2003
 end date: 00:53:26 GMT Sep 26 2004
 renew date: 00:00:00 GMT Jan 1 1970
 Associated Trustpoints: VPN-GW
```

```

CA Certificate
 Status: Available
 Certificate Serial Number: 1244325DE0369880465F977A18F61CA8
 Certificate Usage: Signature
 Issuer:
 cn=Central Certificate Authority
 o=Home Office Inc
 Subject:
 cn=Central Certificate Authority
 o=Home Office Inc
 CRL Distribution Points:
 http://ca.home-office.com/CertEnroll/home-office.crl
 Validity Date:
 start date: 22:19:29 GMT Oct 31 2002
 end date: 22:27:27 GMT Oct 31 2017
 Associated Trustpoints: VPN-GW

```

### Trustpoint on the Branch Office Router

```

crypto pki trustpoint home-office
 enrollment url http://ca.home-office.com:80/certsrv/mscep/mscep.dll
 serial-number none
 fqdn none

ip-address none
 subject-name o=Home Office Inc,cn=Branch 1
 revocation-check crl

```

A certificate map is entered on the branch office router.

#### Router# configure terminal

Enter configuration commands, one per line. End with CNTL/Z.

```

branch1(config)# crypto pki certificate map central-site 10
branch1(ca-certificate-map)#

```

The output from the **show certificate** command on the central site hub router shows that the certificate was issued by the following:

```

cn=Central Certificate Authority
o=Home Office Inc

```

These two lines are combined into one line using a comma (,) to separate them, and the original lines are added as the first criteria for a match.

```

Router (ca-certificate-map)# issuer-name co cn=Central Certificate Authority, ou=Home Office Inc

```

!The above line wrapped but should be shown on one line with the line above it.

The same combination is done for the subject name from the certificate on the central site router (note that the line that begins with "Name:" is not part of the subject name and must be ignored when creating the certificate map criteria). This is the subject name to be used in the certificate map.

```

cn=Central VPN Gateway

```

```

o=Home Office Inc

```

```

Router (ca-certificate-map)# subject-name eq cn=central vpn gateway, o=home office inc

```

Now the certificate map is added to the trustpoint that was configured earlier.

```

Router (ca-certificate-map)# crypto pki trustpoint home-office
Router (ca-trustpoint)# match certificate central-site skip revocation-check
Router (ca-trustpoint)# exit
Router (config)# exit

```

The configuration is checked (most of configuration is not shown).

```
Router# write term
!Many lines left out
.
.
.
crypto pki trustpoint home-office
 enrollment url http://ca.home-office.com:80/certsrv/mscep/mscep.dll
 serial-number none
 fqdn none
 ip-address none
 subject-name o=Home Office Inc,cn=Branch 1
 revocation-check crl
 match certificate central-site skip revocation-check
!
!
crypto pki certificate map central-site 10
 issuer-name co cn = Central Certificate Authority, ou = Home Office Inc
 subject-name eq cn = central vpn gateway, o = home office inc
!many lines left out
```

Note that the issuer-name and subject-name lines have been reformatted to make them consistent for later matching with the certificate of the peer.

If the branch office is checking the AAA, the trustpoint will have lines similar to the following:

```
crypto pki trustpoint home-office
 auth list allow_list
 auth user subj commonname
```

After the certificate map has been defined as was done above, the following command is added to the trustpoint to skip AAA checking for the central site hub.

```
match certificate central-site skip authorization-check
```

In both cases, the branch site router has to establish an IPSec tunnel to the central site to check CRLs or to contact the AAA server. However, without the **match certificate** command and **central-site skip authorization-check (argument and keyword)**, the branch office cannot establish the tunnel until it has checked the CRL or the AAA server. (The tunnel will not be established unless the **match certificate** command and **central-site skip authorization-check** argument and keyword are used.)

The **match certificate** command and **allow expired-certificate** keyword would be used at the central site if the router at a branch site had an expired certificate and it had to establish a tunnel to the central site to renew its certificate.

#### Trustpoint on the Central Site Router

```
crypto pki trustpoint VPN-GW
 enrollment url http://ca.home-office.com:80/certsrv/mscep/mscep.dll
 serial-number none
 fqdn none
 ip-address none
 subject-name o=Home Office Inc,cn=Central VPN Gateway
 revocation-check crl
```

#### Trustpoint on the Branch 1 Site Router

```
Router# show crypto ca certificate
```

```
Certificate
 Status: Available
 Certificate Serial Number: 2F62BE1400000000CA0
```

```

Certificate Usage: General Purpose
Issuer:
 cn=Central Certificate Authority
 o=Home Office Inc
Subject:
 Name: Branch 1 Site
 cn=Branch 1 Site
 o=Home Office Inc
CRL Distribution Points:
 http://ca.home-office.com/CertEnroll/home-office.crl
Validity Date:
 start date: 00:43:26 GMT Sep 26 2003
 end date: 00:53:26 GMT Oct 3 2003
 renew date: 00:00:00 GMT Jan 1 1970
Associated Trustpoints: home-office
CA Certificate
Status: Available
Certificate Serial Number: 1244325DE0369880465F977A18F61CA8
Certificate Usage: Signature
Issuer:
 cn=Central Certificate Authority
 o=Home Office Inc
Subject:
 cn=Central Certificate Authority
 o=Home Office Inc
CRL Distribution Points:
 http://ca.home-office.com/CertEnroll/home-office.crl
Validity Date:
 start date: 22:19:29 GMT Oct 31 2002
 end date: 22:27:27 GMT Oct 31 2017
Associated Trustpoints: home-office

```

A certificate map is entered on the central site router.

```

Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router (config)# crypto pki certificate map branch1 10
Router (ca-certificate-map)# issuer-name co cn=Central Certificate Authority, ou=Home Office Inc
!The above line wrapped but should be part of the line above it.
Router (ca-certificate-map)# subject-name eq cn=Branch 1 Site,o=home office inc

```

The certificate map is added to the trustpoint.

```

Router (ca-certificate-map)# crypto pki trustpoint VPN-GW
Router (ca-trustpoint)# match certificate branch1 allow expired-certificate
Router (ca-trustpoint)# exit
Router (config) #exit

```

The configuration should be checked (most of the configuration is not shown).

```

Router# write term

```

```

!many lines left out

```

```

crypto pki trustpoint VPN-GW
 enrollment url http://ca.home-office.com:80/certsrv/mscep/mscep.dll
 serial-number none
 fqdn none
 ip-address none
 subject-name o=Home Office Inc,cn=Central VPN Gateway
 revocation-check crl
 match certificate branch1 allow expired-certificate
!
!

```

```
crypto pki certificate map central-site 10
 issuer-name co cn = Central Certificate Authority, ou = Home Office Inc
 subject-name eq cn = central vpn gateway, o = home office inc
! many lines left out
```

The **match certificate** command and **branch1 allow expired-certificate** (argument and keyword) and the certificate map should be removed as soon as the branch router has a new certificate.

## Configuring Certificate Authorization and Revocation Settings: Examples

This section contains the following configuration examples that can be used when specifying a CRL cache control setting or certificate serial number session control:

- [Configuring CRL Cache Control, page 36](#)
- [Configuring Certificate Serial Number Session Control, page 37](#)

### Configuring CRL Cache Control

The following example shows how to disable CRL caching for all CRLs associated with the CA1 trustpoint:

```
crypto pki trustpoint CA1
 enrollment url http://CA1:80
 ip-address FastEthernet0/0
 crl query ldap://ldap_CA1
 revocation-check crl
 crl-cache none
```

The current CRL is still cached immediately after executing the example configuration shown above:

```
Router# show crypto pki crls
CRL Issuer Name:
 cn=name Cert Manager,ou=pki,o=company.com,c=US
 LastUpdate: 18:57:42 GMT Nov 26 2005
 NextUpdate: 22:57:42 GMT Nov 26 2005
 Retrieved from CRL Distribution Point:
 ldap://ldap.company.com/CN=name Cert Manager,O=company.com
```

When the current CRL expires, a new CRL is then downloaded to the router at the next update. The **crl-cache none** command takes effect and all CRLs for the trustpoint are no longer cached; caching is disabled. You can verify that no CRL is cached by executing the **show crypto pki crls** command. No output will be shown because there are no CRLs cached.

The following example shows how to configure the maximum lifetime of 2 minutes for all CRLs associated with the CA1 trustpoint:

```
crypto pki trustpoint CA1
 enrollment url http://CA1:80
 ip-address FastEthernet0/0
 crl query ldap://ldap_CA1
 revocation-check crl
 crl-cache delete-after 2
```

The current CRL is still cached immediately after executing the example configuration above for setting the maximum lifetime of a CRL:

```
Router# show crypto pki crls
CRL Issuer Name:
 cn=name Cert Manager,ou=pki,o=company.com,c=US
```

```
LastUpdate: 18:57:42 GMT Nov 26 2005
NextUpdate: 22:57:42 GMT Nov 26 2005
Retrieved from CRL Distribution Point:
 ldap://ldap.company.com/CN=name Cert Manager,O=company.com
```

When the current CRL expires, a new CRL is downloaded to the router at the next update and the **crl-cache delete-after** command takes effect. This newly cached CRL and all subsequent CRLs will be deleted after a maximum lifetime of 2 minutes.

You can verify that the CRL will be cached for 2 minutes by executing the **show crypto pki crls** command. Note that the NextUpdate time is 2 minutes after the LastUpdate time.

```
Router# show crypto pki crls
CRL Issuer Name:
 cn=name Cert Manager,ou=pki,o=company.com,c=US
 LastUpdate: 22:57:42 GMT Nov 26 2005

 NextUpdate: 22:59:42 GMT Nov 26 2005
 Retrieved from CRL Distribution Point:
 ldap://ldap.company.com/CN=name Cert Manager,O=company.com
```

## Configuring Certificate Serial Number Session Control

The following example shows the configuration of certificate serial number session control using a certificate map for the CA1 trustpoint:

```
crypto pki trustpoint CA1
 enrollment url http://CA1
 chain-validation stop
 crl query ldap://ldap_server
 revocation-check crl
 match certificate crl
!
crypto pki certificate map crl 10
 serial-number co 279d
```

### Note

If the *match-criteria* value is set to **eq** (equal) instead of **co** (contains), the serial number must match the certificate map serial number *exactly*, including any spaces.

The following example shows the configuration of certificate serial number session control using AAA attributes. In this case, all valid certificates will be accepted if the certificate does not have the serial number “4ACA.”

```
crypto pki trustpoint CA1
 enrollment url http://CA1
 ip-address FastEthernet0/0
 crl query ldap://ldap_CA1
 revocation-check crl
 aaa new-model
!
aaa attribute list crl
attribute-type aaa-cert-serial-not 4ACA
```

The server log shows that the certificate with the serial number “4ACA” was rejected. The certificate rejection is shown in bold.

```
.
.
.
```

```

```

## Configuring Certificate Chain Validation: Examples

This section contains the following configuration examples that can be used to specify the level of certificate chain processing for your device certificates:

- [Configuring Certificate Chain Validation from Peer to Root CA, page 38](#)
- [Configuring Certificate Chain Validation from Peer to Subordinate CA, page 39](#)
- [Configuring Certificate Chain Validation Through a Gap, page 39](#)

### Configuring Certificate Chain Validation from Peer to Root CA

In the following configuration example, all of the certificates will be validated—the peer, SubCA11, SubCA1, and RootCA certificates.

```

crypto pki trustpoint RootCA
 enrollment terminal
 chain-validation stop
 revocation-check none
 rsakeypair RootCA

crypto pki trustpoint SubCA1
 enrollment terminal
 chain-validation continue RootCA
 revocation-check none

```

```
rsa keypair SubCA1

crypto pki trustpoint SubCA11
 enrollment terminal
 chain-validation continue SubCA1
 revocation-check none
 rsa keypair SubCA11
```

## Configuring Certificate Chain Validation from Peer to Subordinate CA

In the following configuration example, the following certificates will be validated—the peer and SubCA1 certificates.

```
crypto pki trustpoint RootCA
 enrollment terminal
 chain-validation stop
 revocation-check none
 rsa keypair RootCA

crypto pki trustpoint SubCA1
 enrollment terminal
 chain-validation continue RootCA
 revocation-check none
 rsa keypair SubCA1

crypto pki trustpoint SubCA11
 enrollment terminal
 chain-validation continue SubCA1
 revocation-check none
 rsa keypair SubCA11
```

## Configuring Certificate Chain Validation Through a Gap

In the following configuration example, SubCA1 is not in the configured Cisco IOS hierarchy but is expected to have been supplied in the certificate chain presented by the peer.

If the peer supplies the SubCA1 certificate in the presented certificate chain, the following certificates will be validated—the peer, SubCA11, and SubCA1 certificates.

If the peer does not supply the SubCA1 certificate in the presented certificate chain, the chain validation will fail.

```
crypto pki trustpoint RootCA
 enrollment terminal
 chain-validation stop
 revocation-check none
 rsa keypair RootCA

crypto pki trustpoint SubCA11
 enrollment terminal
 chain-validation continue RootCA
 revocation-check none
 rsa keypair SubCA11
```

## Additional References

## Feature Information for Certificate Authorization and Revocation

Table 2 lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table.

Not all commands may be available in your Cisco IOS software release. For details on when support for a specific command was introduced, see the command reference documentation. For information on a feature in this technology that is not documented here, see the Implementing and Managing PKI Features Roadmap.

Cisco IOS software images are specific to a Cisco IOS software release, a feature set, and a platform. Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

### Note

Table 2 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 2**      **Feature Information for PKI Certificate Authorization and Revocation**

| Feature Name                                                  | Software Releases | Feature Configuration Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------------------------|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cache Control Enhancements for Certification Revocation Lists | 12.4(9)T          | <p>This feature provides users the ability to disable CRL caching or to specify the maximum lifetime for which a CRL will be cached in router memory. It also provides functionality to configure certificate serial number session control.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">What Is a CRL?</a></li> <li>• <a href="#">Configuring Certificate Authorization and Revocation Settings</a></li> <li>• <a href="#">Configuring Certificate Authorization and Revocation Settings: Examples</a></li> </ul> <p>The following commands were introduced or modified by this feature: <b>crl-cache delete-after</b>, <b>crl-cache none</b>, <b>crypto pki certificate map</b></p> |
| Certificate-Complete Chain Validation                         | 12.4(6)T          | <p>This feature provides users the ability to configure the level to which a certificate chain is processed on all certificates including subordinate CA certificates.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">PKI Certificate Chain Validation</a></li> <li>• <a href="#">Configuring Certificate Chain Validation</a></li> <li>• <a href="#">Configuring Certificate Chain Validation: Examples</a></li> </ul> <p>The following command was introduced by this feature: <b>chain-validation</b></p>                                                                                                                                                                             |
| OCSP - Server Certification from Alternate Hierarchy          | 12.4(6)T          | <p>This feature provides users with the flexibility to specify multiple OCSP servers, either per client certificate or per group of client certificates, and provides the capability for OCSP server validation based on external CA certificates or self-signed certificates.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">What Is OCSP?</a></li> <li>• <a href="#">Configuring Certificate Authorization and Revocation Settings</a></li> </ul> <p>The following command was introduced by this feature: <b>match certificate override ocsp</b></p>                                                                                                                                  |

**Table 2** *Feature Information for PKI Certificate Authorization and Revocation (continued)*

| Feature Name                                        | Software Releases      | Feature Configuration Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------------------|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Optional OCSP Nonce                                 | 12.2(33)SR<br>12.4(4)T | <p>This feature provides users with the ability to configure the sending of a nonce, or unique identifier for an OCSP request, during OCSP communications.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">What Is OCSP?</a></li> <li>• <a href="#">Configuring a Revocation Mechanism for PKI Certificate Status Checking</a></li> <li>• <a href="#">Disabling Nonces in Communications with the OCSP Server: Example</a></li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                 |
| Certificate Security Attribute-Based Access Control | 12.2(15)T              | <p>Under the IPsec protocol, CA interoperability permits Cisco IOS devices and a CA to communicate so that the Cisco IOS device can obtain and use digital certificates from the CA. Certificates contain several fields that are used to determine whether a device or user is authorized to perform a specified action. This feature adds fields to the certificate that allow specifying an ACL, creating a certificate-based ACL.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">When to Use Certificate-Based ACLs for Authorization or Revocation</a></li> <li>• <a href="#">Configuring Certificate Authorization and Revocation Settings</a></li> </ul> <p>The following commands were introduced or modified by this feature: <b>crypto pki certificate map</b>, <b>crypto pki trustpoint</b>, <b>match certificate</b></p> |
| Online Certificate Status Protocol (OCSP)           | 12.3(2)T               | <p>This feature allows users to enable OCSP instead of CRLs to check certificate status. Unlike CRLs, which provide only periodic certificate status, OCSP can provide timely information regarding the status of a certificate.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">CRLs or OCSP Server: Choosing a Certificate Revocation Mechanism</a></li> <li>• <a href="#">Configuring a Revocation Mechanism for PKI Certificate Status Checking</a></li> </ul> <p>The following commands were introduced by this feature: <b>ocsp url</b>, <b>revocation-check</b></p>                                                                                                                                                                                                                                                            |

**Table 2**      **Feature Information for PKI Certificate Authorization and Revocation (continued)**

| Feature Name                                                    | Software Releases | Feature Configuration Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------------------------|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PKI AAA Authorization Using the Entire Subject Name             | 12.3(11)T         | <p>This feature provides users with the ability to query the AAA server using the entire subject name from the certificate as a unique AAA username.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">Attribute-Value Pairs for PKI and AAA Server Integration</a></li> <li>• <a href="#">Configuring PKI Integration with a AAA Server</a></li> </ul> <p>The following command was modified by this feature:<br/><b>authorization username</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PKI Integration with AAA Server                                 | 12.3(1)           | <p>This feature provides additional scalability for authorization by generating a AAA username from the certificate presented by the peer. A AAA server is queried to determine whether the certificate is authorized for use by the internal component. The authorization is indicated by a component-specified label that must be present in the AV pair for the user.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">PKI and AAA Server Integration for Certificate Status</a></li> <li>• <a href="#">Configuring PKI Integration with a AAA Server</a></li> </ul> <p>The following commands were introduced by this feature:<br/><b>authorization list, authorization username</b></p>                                                                                                                                                                                                     |
| PKI: Query Multiple Servers During Certificate Revocation Check | 12.3(7)T          | <p>This feature introduces the ability for Cisco IOS software to make multiple attempts to retrieve the CRL, allowing operations to continue when a particular server is not available. In addition, the ability to override the CDPs in a certificate with a manually configured CDP has been introduced. Manually overriding the CDPs in a certificate can be advantageous when a particular server is unavailable for an extended period of time. The certificate's CDPs can be replaced with a URL or directory specification without reissuing all of the certificates that contain the original CDP.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">Querying All CDPs During Revocation Check</a></li> <li>• <a href="#">Manually Overriding CDPs in a Certificate</a></li> </ul> <p>The following command was introduced by this feature:<br/><b>match certificate override cdp</b></p> |

**Table 2** *Feature Information for PKI Certificate Authorization and Revocation (continued)*

| Feature Name                                                               | Software Releases        | Feature Configuration Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| PKI: Query Multiple Servers During Certificate Revocation Check            | 12.3(7)T                 | <p>This feature introduces the ability for Cisco IOS software to make multiple attempts to retrieve the CRL, allowing operations to continue when a particular server is not available. In addition, the ability to override the CDPs in a certificate with a manually configured CDP has been introduced. Manually overriding the CDPs in a certificate can be advantageous when a particular server is unavailable for an extended period of time. The certificate's CDPs can be replaced with a URL or directory specification without reissuing all of the certificates that contain the original CDP.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li><a href="#">Querying All CDPs During Revocation Check</a></li> <li><a href="#">Manually Overriding CDPs in a Certificate</a></li> </ul> <p>The following command was introduced by this feature:<br/><b>match certificate override cdp</b></p> |
| Using Certificate ACLs to Ignore Revocation Check and Expired Certificates | 12.3(4)T                 | <p>This feature allows a certificate that meets specified criteria to be accepted regardless of the validity period of the certificate, or if the certificate meets the specified criteria, revocation checking does not have to be performed. Certificate ACLs are used to specify the criteria that the certificate must meet to be accepted or to avoid revocation checking. In addition, if AAA communication is protected by a certificate, this feature provides for the AAA checking of the certificate to be ignored.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li><a href="#">Ignore Revocation Checks Using a Certificate-Based ACL</a></li> <li><a href="#">Configuring Certificate-Based ACLs to Ignore Revocation Checks</a></li> </ul> <p>The following command was modified by this feature:<br/><b>match certificate</b></p>                                                           |
| Certificate - Security Attribute-Based Access Control                      | Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| OCSP (Online Certificate Status Protocol)                                  | Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Optional OCSP Nonce                                                        | Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Table 2**      **Feature Information for PKI Certificate Authorization and Revocation (continued)**

| Feature Name                                               | Software Releases        | Feature Configuration Information                             |
|------------------------------------------------------------|--------------------------|---------------------------------------------------------------|
| PKI AAA Authorization Using the Entire Subject Name        | Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers. |
| PKI Integration with AAA Server                            | Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers. |
| Query Mode Definition Per Trustpoint                       | Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers. |
| Query Multiple Servers during Certificate Revocation Check | Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers. |

# Configuring Certificate Enrollment for a PKI

---

**First Published: May 2, 2005**

**Last Updated: August 21, 2007**

Certificate enrollment, which is the process of obtaining a certificate from a certification authority (CA), occurs between the end host that requests the certificate and the CA. Each peer that participates in the public key infrastructure (PKI) must enroll with a CA. This module describes the different methods available for certificate enrollment and how to set up each method for a participating PKI peer.

## **Finding Feature Information in This Module**

*Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for PKI Certificate Enrollment](#)” section on page 34.*

## **Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images**

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

# Prerequisites for PKI Certificate Enrollment

Before configuring peers for certificate enrollment, you should have the following items:

- A generated Rivest, Shamir, and Adelman (RSA) key pair to enroll and a PKI in which to enroll.
- Your CA should be authenticated.
- Familiarity with the module “Cisco IOS PKI Overview: Understanding and Planning a PKI.”

**Note**

As of Cisco IOS Release 12.3(7)T, all commands that begin with “**crypto ca**” have been changed to begin with “**crypto pki**.” Although the router will still accept **crypto ca** commands, all output will be read back as **crypto pki**.

## Information About Certificate Enrollment for a PKI

Before configuring peers to request a certificate and enroll in the PKI, you should understand the following concepts:

- [What Are CAs?, page 2](#)
- [Authentication of the CA, page 3](#)
- [Supported Certificate Enrollment Methods, page 3](#)
- [Registration Authorities \(RA\), page 4](#)
- [Automatic Certificate Enrollment, page 4](#)
- [Certificate Enrollment Profiles, page 5](#)

## What Are CAs?

A CA manages certificate requests and issues certificates to participating network devices. These services (managing certificate requests and issuing certificates) provide centralized key management for the participating devices to validate identities and to create digital certificates. Before any PKI operations can begin, the CA generates its own public key pair and creates a self-signed CA certificate; thereafter, the CA can sign certificate requests and begin peer enrollment for the PKI.

You can use the Cisco IOS certificate server or a CA provided by a third-party CA vendor.

## Hierarchical PKI: Multiple CAs

A PKI can be set up in a hierarchical framework to support multiple CAs. At the top of the hierarchy is a root CA, which holds a self-signed certificate. The trust within the entire hierarchy is derived from the RSA key pair of the root CA. The subordinate CAs within the hierarchy can be enrolled with either the root CA or with another subordinate CA. Multiple tiers of CAs are configured by either the root CA or with another subordinate CA. Within a hierarchical PKI, all enrolled peers, can validate the certificate of one another if the peers share a trusted root CA certificate or a common subordinate CA.

### When to Use Multiple CAs

Multiple CAs provide users with added flexibility and reliability. For example, subordinate CAs can be placed in branch offices while the root CA is at the office headquarters. Also, different granting policies can be implemented per CA, so you can set up one CA to automatically grant certificate requests while another CA within the hierarchy requires each certificate request to be manually granted.

Scenarios in which at least a two-tier CA is recommended are as follows:

- Large and very active networks in which a large number of certificates are revoked and reissued. A multiple tier CA helps to control the size of the certificate revocation lists (CRLs).
- When online enrollment protocols are used, the root CA can be kept offline except to issue subordinate CA certificates. This scenario provides added security for the root CA.

## Authentication of the CA

The certificate of the CA must be authenticated before the device will be issued its own certificate and before certificate enrollment can occur. Authentication of the CA typically occurs only when you initially configure PKI support at your router. To authenticate the CA, issue the **crypto pki authenticate** command, which authenticates the CA to your router by obtaining the self-signed certificate of the CA that contains the public key of the CA.

### Authentication via the fingerprint Command

After Cisco IOS Release 12.3(12), you can issue the **fingerprint** command to preenter a fingerprint that can be matched against the fingerprint of a CA certificate during authentication.

If a fingerprint is not preentered for a trustpoint, and if the authentication request is interactive, you must verify the fingerprint that is displayed during authentication of the CA certificate. If the authentication request is noninteractive, the certificate will be rejected without a preentered fingerprint.

#### Note

If the authentication request is made using the command-line interface (CLI), the request is an interactive request. If the authentication request is made using HTTP or another management tool, the request is a noninteractive request.

## Supported Certificate Enrollment Methods

Cisco IOS software supports the following methods to obtain a certificate from a CA:

- Simple Certificate Enrollment Protocol (SCEP)—A Cisco developed enrollment protocol that uses HTTP to communicate with the CA or registration authority (RA). SCEP is the most commonly used method for sending and receiving requests and certificates.

#### Note

To take advantage of automated certificate and key rollover functionality, you must be running a CA that supports rollover and SCEP must be used as your client enrollment method.

If you are running a Cisco IOS CA, you must be running Cisco IOS Release 12.4(2)T or a later release for rollover support.

- PKCS12—The router imports certificates in PKCS12 format from an external server.
- IOS File System (IFS)—The router uses any file system that is supported by Cisco IOS software (such as TFTP, FTP, flash, and NVRAM) to send a certificate request and to receive the issued certificate. Users may enable IFS certificate enrollment when their CA does not support SCEP.

**Note** Prior to Cisco IOS Release 12.3(4)T, only the TFTP file system is supported within IFS.

- Manual cut-and-paste—The router displays the certificate request on the console terminal, allowing the user to enter the issued certificate on the console terminal. A user may manually cut-and-paste certificate requests and certificates when there is no network connection between the router and CA.
- Enrollment profiles—The router sends HTTP-based enrollment requests directly to the CA server instead of to the RA-mode CS. Enrollment profiles can be used if a CA server does not support SCEP.
- Self-signed certificate enrollment for a trustpoint—The secure HTTP (HTTPS) server generates a self-signed certificate that is to be used during the secure socket layer (SSL) handshake, establishing a secure connection between the HTTPS server and the client. The self-signed certificate is then saved in the router's startup configuration (NVRAM). The saved, self-signed certificate can then be used for future SSL handshakes, eliminating the user intervention that was necessary to accept the certificate every time the router reloaded.

**Note**

To take advantage of autoenrollment and auto reenrollment, do not use either TFTP or manual cut-and-paste enrollment as your enrollment method. Both TFTP and manual cut-and-paste enrollment methods are manual enrollment processes, requiring user input.

## Registration Authorities (RA)

A Cisco IOS certificate server can be configured to run in RA mode. An RA offloads authentication and authorization responsibilities from a CA. When the RA receives a SCEP or manual enrollment request, the administrator can either reject or grant it on the basis of local policy. If the request is granted, it will be forwarded to the issuing CA, and the CA can be configured to automatically generate the certificate and return it to the RA. The client can later retrieve the granted certificate from the RA.

## Automatic Certificate Enrollment

Certificate autoenrollment allows the CA client to automatically request a certificate from its CA server. This automatic router request eliminates the need for operator intervention when the enrollment request is sent to the CA server. Automatic enrollment is performed on startup for any trustpoint CA that is configured and that does not have a valid client certificate. When the certificate expires, a new certificate is automatically requested.

**Note**

When automatic enrollment is configured, clients automatically request client certificates. The CA server performs its own authorization checks; if these checks include a policy to automatically issue certificates, all clients will automatically receive certificates, which is not very secure. Thus, automatic certificate enrollment should be combined with additional authentication and authorization mechanisms (such as Secure Device Provisioning (SDP), leveraging existing certificates, and one-time passwords).

### Automated Client Certificate and Key Rollover

By default, the automatic certificate enrollment function requests a new client certificate and keys from the CS before the client's current certificate expires. Certificate and key rollover allows the certificate renewal rollover request to be made before the certificate expires by retaining the current key and certificate until the new, or rollover, certificate is available. After a specified amount of time, the rollover certificate and keys will become the active certificate and keys. The expired certificate and keys are immediately deleted upon rollover and removed from the certificate chain and CRL.

The setup for automatic rollover is twofold: CA clients must be automatically enrolled and the client's CAs must be automatically enrolled and have the **auto-rollover** command enabled. For more information on configuring your CA servers for automatic certificate rollover see the section "Automatic CA Certificate and Key Rollover" in the chapter "[Configuring and Managing a Cisco IOS Certificate Server for PKI Deployment](#)."

An optional renewal percentage parameter can be used with the **auto-enroll** command to allow a new certificate to be requested when a specified percentage of the lifetime of the certificate has passed. For example, if the renewal percentage is configured as 90 and the certificate has a lifetime of one year, a new certificate is requested 36.5 days before the old certificate expires. In order for automatic rollover to occur, the renewal percentage must be less than 100.

#### Tip

If CA autoenrollment is not enabled, you may manually initiate rollover on an existing client with the **crypto pki enroll** command if the expiration time of the current client certificate is equal to or greater than the expiration time of the corresponding CA certificate.

The client will initiate the rollover process, which only occurs if the server is configured for automated rollover and has an available rollover server certificate.

#### Note

A key pair is also sent if configured by the **auto-enroll re-generate** command and keyword. It is recommended that a new key pair be issued for security reasons.

## Certificate Enrollment Profiles

Enrollment profiles allow users to specify certificate authentication, enrollment, and reenrollment parameters when prompted. The values for these parameters are referenced by two templates that make up the profile. One template contains parameters for the HTTP request that is sent to the CA server to obtain the certificate of the CA (also known as certificate authentication); the other template contains parameters for the HTTP request that is sent to the CA for certificate enrollment.

Configuring two templates enables users to specify different URLs or methods for certificate authentication and enrollment; for example, authentication (getting the certificate of the CA) can be performed via TFTP (using the **authentication url** command) while enrollment can be performed manually (using the **enrollment terminal** command).

Prior to Cisco IOS Release 12.3(11)T, certificate requests could be sent only in a PKCS10 format; however, an additional parameter has now been added to the profile, allowing users to specify the PKCS7 format for certificate renewal requests.

#### Note

A single enrollment profile can have up to three separate sections for each task—certificate authentication, enrollment, and reenrollment.

# How to Configure Certificate Enrollment for a PKI

This section contains the following enrollment option procedures. If you configure enrollment or autoenrollment (the first task), you cannot configure manual certificate enrollment. Also, if you configure TFTP or manual cut-and-paste certificate enrollment, you cannot configure autoenrollment, auto reenrollment, an enrollment profile, nor can you utilize the automated CA certificate rollover capability.

## Configuring Certificate Enrollment or Autoenrollment

Perform this task to configure certificate enrollment for clients participating in your PKI.

### Prerequisites for Autoenrollment

Before configuring automatic certificate enrollment requests, you should ensure that all necessary enrollment information is configured.

#### Prerequisites for Enabling Automated Client Certificate and Key Rollover

CA client support for certificate rollover is automatically enabled when using autoenrollment. For automatic CA certificate rollover to run successfully, the following prerequisites are applicable:

- Your network devices must support shadow PKI.
- Your clients must be running Cisco IOS Release 12.4(2)T or a later release.
- The client's CS must support automatic rollover. See the section "Automatic CA Certificate and Key Rollover" in the chapter "[Configuring and Managing a Cisco IOS Certificate Server for PKI Deployment](#)" for more information on CA server automatic rollover configuration.

#### Prerequisites for Specifying Autoenrollment Initial Key Generation Location

To specify the location of the autoenrollment initial key generation, you must be running Cisco IOS Release 12.4(11)T or a later release.

### Restrictions for Autoenrollment

#### RSA Key Pair Restriction for Autoenrollment

Trustpoints configured to generate a new key pair using the **regenerate** command or the **regenerate** keyword of the **auto-enroll** command must not share key pairs with other trustpoints. To give each trustpoint its own key pair, use the **rsakeypair** command in ca-trustpoint configuration mode. Sharing key pairs among regenerating trustpoints is not supported and will cause loss of service on some of the trustpoints because of key and certificate mismatches.

#### Restrictions for Automated Client Certificate and Key Rollover

In order for clients to run automatic CA certificate rollover successfully, the following restrictions are applicable:

- SCEP must be used to support rollover. Any device that enrolls with the PKI using an alternative to SCEP as the certificate management protocol or mechanism (such as enrollment profiles, manual enrollment, or TFTP enrollment) will not be able to take advantage of the rollover functionality provided by SCEP.
- If the configuration cannot be saved to the startup configuration after a shadow certificate is generated, rollover will not occur.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto pki trustpoint** *name*
4. **enrollment** [**mode**] [**retry period** *minutes*] [**retry count** *number*] **url** *url* [**pem**]
5. **subject-name** [*x.500-name*]
6. **ip address** {*ip address* | *interface* | **none**}
7. **serial-number** [**none**]
8. **auto-enroll** [*percent*] [**regenerate**]
9. **usage** *method1* [*method2* [*method3*]]
10. **password** *string*
11. **rsa****keypair** *key-label* [*key-size* [*encryption-key-size*]]
12. **fingerprint** *ca-fingerprint*
13. **on** *devicename*:
14. **exit**
15. **crypto pki authenticate** *name*
16. **exit**
17. **copy system:running-config nvram:startup-config**
18. **show crypto pki certificates**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                    | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                            | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 3 | <b>crypto pki trustpoint name</b><br><br><b>Example:</b><br>Router(config)# crypto pki trustpoint mytp                                                                    | Declares the trustpoint and a given name and enters ca-trustpoint configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Step 4 | <b>enrollment [mode] [retry period minutes] [retry count number] url url [pem]</b><br><br><b>Example:</b><br>Router(ca-trustpoint)# enrollment url http://cat.example.com | Specifies the URL of the CA on which your router should send certificate requests. <ul style="list-style-type: none"> <li><b>mode</b>—Specifies RA mode if your CA system provides an RA.</li> <li><b>retry period minutes</b>—Specifies the wait period between certificate request retries. The default is 1 minute between retries.</li> <li><b>retry count number</b>— Specifies the number of times a router will resend a certificate request when it does not receive a response from the previous request. (Specify from 1 to 100 retries.)</li> <li><b>url url</b>—URL of the file system where your router should send certificate requests. For enrollment method options, see the <b>enrollment</b> command in the <a href="#">Cisco IOS Security Command Reference</a>.</li> <li><b>pem</b>—Adds privacy-enhanced mail (PEM) boundaries to the certificate request.</li> </ul> <p><b>Note</b> An enrollment method other than TFTP or manual cut-and-paste must be configured to support autoenrollment.</p> |
| Step 5 | <b>subject-name [x.500-name]</b><br><br><b>Example:</b><br>Router(ca-trustpoint)# subject-name cat                                                                        | (Optional) Specifies the requested subject name that will be used in the certificate request. <ul style="list-style-type: none"> <li><b>x.500-name</b>—If it is not specified, the fully qualified domain name (FQDN), which is the default subject name, will be used.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Step 6 | <b>ip address {ip address   interface   none}</b><br><br><b>Example:</b><br>Router(ca-trustpoint)# ip address 192.168.1.66                                                | (Optional) Includes the IP address of the specified interface in the certificate request. <p>Issue the <b>none</b> keyword if no IP address should be included.</p> <p><b>Note</b> If this command is enabled, you will not be prompted for an IP address during enrollment for this trustpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|         | Command or Action                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 7  | <b>serial-number</b> [none]<br><br><b>Example:</b><br>Router(ca-trustpoint)# serial-number                                   | (Optional) Specifies the router serial number in the certificate request, unless the <b>none</b> keyword is issued.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Step 8  | <b>auto-enroll</b> [percent] [regenerate]<br><br><b>Example:</b><br>Router(ca-trustpoint)# auto-enroll regenerate            | <p>(Optional) Enables autoenrollment, allowing the client to automatically request a rollover certificate from the CA. If autoenrollment is not enabled, the client must be manually reenrolled in your PKI upon certificate expiration.</p> <ul style="list-style-type: none"> <li>By default, only the Domain Name System (DNS) name of the router is included in the certificate.</li> <li>Use the <i>percent</i> argument to specify that a new certificate will be requested after the percentage of the lifetime of the current certificate is reached.</li> <li>Use the <b>regenerate</b> keyword to generate a new key for the certificate even if a named key already exists.</li> </ul> <p><b>Note</b> If the key pair being rolled over is exportable, the new key pair will also be exportable. The following comment will appear in the trustpoint configuration to indicate whether the key pair is exportable: “! RSA key pair associated with trustpoint is exportable.”</p> <p><b>Note</b> It is recommended that a new key pair be generated for security reasons.</p> |
| Step 9  | <b>usage</b> method1 [method2 [method3]]<br><br><b>Example:</b><br>Router(ca-trustpoint)# usage ssl-client                   | <p>(Optional) Specifies the intended use for the certificate. Available options are <b>ike</b>, <b>ssl-client</b>, and <b>ssl-server</b>; the default is <b>ike</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Step 10 | <b>password</b> string<br><br><b>Example:</b><br>Router(ca-trustpoint)# password meow                                        | <p>(Optional) Specifies the revocation password for the certificate. If this command is enabled, you will not be prompted for a password during enrollment for this trustpoint.</p> <p><b>Note</b> When SCEP is used, this password can be used to authorize the certificate request—often via a one-time password or similar mechanism.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Step 11 | <b>rsakeypair</b> key-label [key-size [encryption-key-size]]<br><br><b>Example:</b><br>Router(ca-trustpoint)# rsakeypair cat | <p>(Optional) Specifies which key pair to associate with the certificate.</p> <ul style="list-style-type: none"> <li>A key pair with <i>key-label</i> will be generated during enrollment if it does not already exist or if the <b>auto-enroll regenerate</b> command was issued.</li> <li>Specify the <i>key-size</i> argument for generating the key, and specify the <i>encryption-key-size</i> argument to request separate encryption, signature keys, and certificates.</li> </ul> <p><b>Note</b> If this command is not enabled, the FQDN key pair is used.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                | Command or Action                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 12</b> | <pre>fingerprint ca-fingerprint</pre> <p><b>Example:</b><br/>Router(ca-trustpoint)# fingerprint 12EF53FA 355CD23E 12EF53FA 355CD23E</p>       | <p>(Optional) Specifies a fingerprint that can be matched against the fingerprint of a CA certificate during authentication.</p> <p><b>Note</b> If the fingerprint is not provided and authentication of the CA certificate is interactive, the fingerprint will be displayed for verification.</p>                                                                                                                                                 |
| <b>Step 13</b> | <pre>on devicename:</pre> <p><b>Example:</b><br/>Router(ca-trustpoint)# on usbtokent0:</p>                                                    | <p>(Optional) Specifies that RSA keys will be created on the specified device upon autoenrollment initial key generation.</p> <p>Devices that may be specified include NVRAM, local disks, and USB tokens. USB tokens may be used as cryptographic devices in addition to a storage device. Using a USB token as a cryptographic device allows RSA operations such as key generation, signing, and authentication to be performed on the token.</p> |
| <b>Step 14</b> | <pre>exit</pre> <p><b>Example:</b><br/>Router(ca-trustpoint)# exit</p>                                                                        | Exits ca-trustpoint configuration mode and returns to global configuration mode.                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 15</b> | <pre>crypto pki authenticate name</pre> <p><b>Example:</b><br/>Router(config)# crypto pki authenticate mytp</p>                               | <p>Retrieves the CA certificate and authenticates it.</p> <ul style="list-style-type: none"> <li>Check the certificate fingerprint if prompted.</li> </ul> <p><b>Note</b> This command is optional if the CA certificate is already loaded into the configuration.</p>                                                                                                                                                                              |
| <b>Step 16</b> | <pre>exit</pre> <p><b>Example:</b><br/>Router(config)# exit</p>                                                                               | Exits global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 17</b> | <pre>copy system:running-config nvram:startup-config</pre> <p><b>Example:</b><br/>Router# copy system:running-config nvram:startup-config</p> | <p>(Optional) Copies the running configuration to the NVRAM startup configuration.</p> <p><b>Note</b> Autoenrollment will not update NVRAM if the running configuration has been modified but not written to NVRAM.</p>                                                                                                                                                                                                                             |
| <b>Step 18</b> | <pre>show crypto pki certificates</pre> <p><b>Example:</b><br/>Router# show crypto pki certificates</p>                                       | (Optional) Displays information about your certificates, including any rollover certificates.                                                                                                                                                                                                                                                                                                                                                       |

## Examples

The following example shows the configuration for the “mytp-A” certificate server and its associated trustpoint, where RSA keys generated by the initial autoenrollment for the trustpoint will be stored on a USB token, “usbtokent0”:

```
crypto pki server mytp-A
 database level complete
 issuer-name CN=company, L=city, C=country
 grant auto
! Specifies that certificate requests will be granted automatically.
```

```

!
crypto pki trustpoint mytp-A
 revocation-check none
 rsakeypair myTP-A
 storage usbtoken0:
! Specifies that keys will be stored on usbtoken0:.
 on usbtoken0:
! Specifies that keys generated on initial auto enroll will be generated on and stored on ! usbtoken0:

```

## Configuring Manual Certificate Enrollment

Manual certificate enrollment can be set up via TFTP or the manual cut-and-paste method. Both options can be used if your CA does not support SCEP or if a network connection between the router and CA is not possible. Perform one of the following tasks to set up manual certificate enrollment:

- [Configuring Cut-and-Paste Certificate Enrollment, page 11](#)
- [Configuring TFTP Certificate Enrollment, page 14](#)

## PEM-Formatted Files for Certificate Enrollment Request

Using PEM-formatted files for certificate requests can be helpful for customers who are using terminal or profile-based enrollment to request certificates from their CA server. Customers using PEM-formatted files can directly use existing certificates on their Cisco IOS routers.

## Restrictions for Manual Certificate Enrollment

### Switching Enrollment URLs When Using SCEP

We do not recommend switching URLs if SCEP is used; that is, if the enrollment URL is “http://myca,” do not change the enrollment URL after getting the CA certificate and before enrolling the certificate. A user can switch between TFTP and manual cut-and-paste

### Key Regeneration Restriction

Do not regenerate the keys manually using the **crypto key generate** command; key regeneration will occur when the **crypto pki enroll** command is issued if the **regenerate** keyword is specified.

## Configuring Cut-and-Paste Certificate Enrollment

Perform this task to configure manual certificate enrollment via the cut-and-paste method for peers participating in your PKI.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto pki trustpoint** *name*
4. **enrollment terminal** [*pem*]
5. **fingerprint** *ca-fingerprint*
6. **exit**

7. **crypto pki authenticate** *name*
8. **crypto pki enroll** *name*
9. **crypto pki import** *name* **certificate**
10. **exit**
11. **show crypto pki certificates**

## DETAILED STEPS

|        | Command or Action                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------|------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                             | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                    |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                     | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Step 3 | <b>crypto pki trustpoint name</b><br><br><b>Example:</b><br>Router(config)# crypto pki trustpoint mytp                             | Declares the trustpoint and a given name and enters ca-trustpoint configuration mode.                                                                                                                                                                                                                                                                                                                                                               |
| Step 4 | <b>enrollment terminal [pem]</b><br><br><b>Example:</b><br>Router(ca-trustpoint)# enrollment terminal                              | Specifies manual cut-and-paste certificate enrollment method. The certificate request will be displayed on the console terminal so that you may manually copied (or cut). <ul style="list-style-type: none"> <li><b>pem</b>—Configures the trustpoint to generate PEM-formatted certificate requests to the console terminal.</li> </ul>                                                                                                            |
| Step 5 | <b>fingerprint ca-fingerprint</b><br><br><b>Example:</b><br>Router(ca-trustpoint)# fingerprint 12EF53FA 355CD23E 12EF53FA 355CD23E | (Optional) Specifies a fingerprint that can be matched against the fingerprint of a CA certificate during authentication.<br><br><b>Note</b> If the fingerprint is not provided, it will be displayed for verification.                                                                                                                                                                                                                             |
| Step 6 | <b>exit</b><br><br><b>Example:</b><br>Router(config)# exit                                                                         | Exits ca-trustpoint configuration mode and returns to global configuration mode.                                                                                                                                                                                                                                                                                                                                                                    |
| Step 7 | <b>crypto pki authenticate name</b><br><br><b>Example:</b><br>Router(config)# crypto pki authenticate mytp                         | Retrieves the CA certificate and authenticates it.                                                                                                                                                                                                                                                                                                                                                                                                  |
| Step 8 | <b>crypto pki enroll name</b><br><br><b>Example:</b><br>Router(config)# crypto pki enroll mytp                                     | Generates certificate request and displays the request for copying and pasting into the certificate server.<br><br>You are prompted for enrollment information, such as whether to include the router FQDN and IP address in the certificate request. You are also given the choice about displaying the certificate request to the console terminal.<br><br>The base-64 encoded certificate with or without PEM headers as requested is displayed. |

|         | Command or Action                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 9  | <b>crypto pki import</b> <i>name</i> <b>certificate</b><br><br><b>Example:</b><br>Router(config)# crypto pki import mytp<br>certificate | Imports a certificate manually at the console terminal (pasting).<br><br>The base-64 encoded certificate is accepted from the console terminal and inserted into the internal certificate database.<br><br><b>Note</b> You must enter this command twice if usage keys, a signature key and an encryption key, are used. The first time the command is entered, one of the certificates is pasted into the router. The second time the command is entered, the other certificate is pasted into the router. It does not matter which certificate is pasted first.<br><br><b>Note</b> Some CAs ignore the usage key information in the certificate request and issue general purpose usage certificates. If this applies to the certificate authority you are using, import the general purpose certificate. The router will not use one of the two key pairs generated. |
| Step 10 | <b>exit</b><br><br><b>Example:</b><br>Router(config)# exit                                                                              | Exits global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Step 11 | <b>show crypto pki certificates</b><br><br><b>Example:</b><br>Router# show crypto pki certificates                                      | (Optional) Displays information about your certificates, the certificates of the CA, and RA certificates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Configuring TFTP Certificate Enrollment

Perform this task to configure manual certificate enrollment using a TFTP server.

### Prerequisites for TFTP Certificate Enrollment

- You must know the correct URL to use if you are configuring certificate enrollment via TFTP.
- The router must be able to write a file to the TFTP server for the **crypto pki enroll** command.
- If using a file specification with the **enrollment** command, the file must contain the CA certificate either in binary format or be base-64 encoded.
- You must know if your CA ignores key usage information in a certificate request and issues only a general purpose usage certificate.

#### Caution

Some TFTP servers require that the file must exist on the server before it can be written.

Most TFTP servers require that the file be “write-able” by the world. This requirement may pose a risk

because any router or other device may write or overwrite the certificate request; thus, the replacement certificate request will not be used by the CA administrator, who must first check the enrollment request fingerprint before granting the certificate request.

---

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto pki trustpoint** *name*
4. **enrollment** [**mode**] [**retry period** *minutes*] [**retry count** *number*] **url** *url* [**pem**]
5. **fingerprint** *ca-fingerprint*
6. **exit**
7. **crypto pki authenticate** *name*
8. **crypto pki enroll** *name*
9. **crypto pki import** *name* **certificate**
10. **exit**
11. **show crypto pki certificates**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                       | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                               | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Step 3 | <b>crypto pki trustpoint <i>name</i></b><br><br><b>Example:</b><br>Router(config)# crypto pki trustpoint mytp                                                                                                | Declares the trustpoint and a given name and enters ca-trustpoint configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Step 4 | <b>enrollment [mode] [retry period <i>minutes</i>] [retry count <i>number</i>] url <i>url</i> [pem]</b><br><br><b>Example:</b><br>Router(ca-trustpoint)# enrollment url tftp://certserver/file_specification | Specifies TFTP as the enrollment method to send the enrollment request and to retrieve the CA certificate and router certificate and any optional parameters.<br><br><b>Note</b> For TFTP enrollment, the url must be configured as a TFTP url, tftp://example_tftp_url.<br><br>An optional file specification filename may be included in the TFTP url. If the file specification is not included, the FQDN will be used. If the file specification is included, the router will append the extension “.ca” to the specified file name. |
| Step 5 | <b>fingerprint <i>ca-fingerprint</i></b><br><br><b>Example:</b><br>Router(ca-trustpoint)# fingerprint 12EF53FA 355CD23E 12EF53FA 355CD23E                                                                    | (Optional) Specifies the fingerprint of the CA certificate received via an out-of-band method from the CA administrator.<br><br><b>Note</b> If the fingerprint is not provided, it will be displayed for verification.                                                                                                                                                                                                                                                                                                                   |
| Step 6 | <b>exit</b><br><br><b>Example:</b><br>Router(config)# exit                                                                                                                                                   | Exits ca-trustpoint configuration mode and returns to global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 7 | <b>crypto pki authenticate <i>name</i></b><br><br><b>Example:</b><br>Router(config)# crypto pki authenticate mytp                                                                                            | Retrieves the CA certificate and authenticates it from the specified TFTP server.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|                | Command or Action                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 8</b>  | <b>crypto pki enroll</b> <i>name</i><br><br><b>Example:</b><br>Router(config)# crypto pki enroll mytp                                | Generates certificate request and writes the request out to the TFTP server.<br><br>You are prompted for enrollment information, such as whether to include the router FQDN and IP address in the certificate request. You are queried about whether or not to display the certificate request to the console terminal.<br><br>The filename to be written is appended with the extension “.req”. For usage keys, a signature key and an encryption key, two requests are generated and sent. The usage key request filenames are appended with the extensions “-sign.req” and “-encr.req” respectively.                                                                                                                                                                                                                                                   |
| <b>Step 9</b>  | <b>crypto pki import</b> <i>name</i> <b>certificate</b><br><br><b>Example:</b><br>Router(config)# crypto pki import mytp certificate | Imports a certificate via TFTP at the console terminal, which retrieves the granted certificate.<br><br>The router will attempt to retrieve the granted certificate via TFTP using the same filename used to send the request, except the extension is changed from “.req” to “.crt”. For usage key certificates, the extensions “-sign.crt” and “-encr.crt” are used.<br><br>The router will parse the received files, verify the certificates, and insert the certificates into the internal certificate database on the router.<br><br><b>Note</b> Some CAs ignore the usage key information in the certificate request and issue general purpose usage certificates. If your CA ignores the usage key information in the certificate request, only import the general purpose certificate. The router will not use one of the two keypairs generated. |
| <b>Step 10</b> | <b>exit</b><br><br><b>Example:</b><br>Router(config)# exit                                                                           | Exits global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Step 11</b> | <b>show crypto pki certificates</b><br><br><b>Example:</b><br>Router# show crypto pki certificates                                   | (Optional) Displays information about your certificates, the certificates of the CA, and RA certificates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Configuring a Persistent Self-Signed Certificate for Enrollment via SSL

This section contains the following tasks:

- [Configuring a Trustpoint and Specifying Self-Signed Certificate Parameters, page 18](#)
- [Enabling the HTTPS Server, page 20](#)

### Note

These tasks are optional because if you enable the HTTPS server, it generates a self-signed certificate automatically using default values.

## Persistent Self-Signed Certificates Overview

The SSL protocol can be used to establish a secure connection between an HTTPS server and a client (web browser). During the SSL handshake, the client expects the SSL server's certificate to be verifiable using a certificate the client already possesses.

If Cisco IOS software does not have a certificate that the HTTPS server can use, the server generates a self-signed certificate by calling a PKI application programming interface (API). When the client receives this self-signed certificate and is unable to verify it, intervention is needed. The client asks you if the certificate should be accepted and saved for future use. If you accept the certificate, the SSL handshake continues.

Future SSL handshakes between the same client and the server use the same certificate. However, if the router is reloaded, the self-signed certificate is lost. The HTTPS server must then create a new self-signed certificate. This new self-signed certificate does not match the previous certificate so you are once again asked to accept it.

Requesting acceptance of the router's certificate each time that the router reloads may present an opportunity for an attacker to substitute an unauthorized certificate when you are being asked to accept the certificate. Persistent self-signed certificates overcome all these limitations by saving a certificate in the router's startup configuration.

## Restrictions

You can configure only one trustpoint for a persistent self-signed certificate.

## Configuring a Trustpoint and Specifying Self-Signed Certificate Parameters

Perform the following task to configure a trustpoint and specify self-signed certificate parameters.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto pki trustpoint** *name*
4. **enrollment selfsigned**
5. **subject-name** [*x.500-name*]
6. **rsa** *key-label* [*key-size* [*encryption-key-size*]]
7. **crypto pki enroll** *name*
8. **end**
9. **show crypto pki certificates** [*trustpoint-name* [*verbose*]]
10. **show crypto pki trustpoints** [*status* | *label* [*status*]]

## DETAILED STEPS

|        | Command or Action                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p><b>enable</b></p> <p><b>Example:</b><br/>Router&gt; enable</p>                                                                                                             | <p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Step 2 | <p><b>configure terminal</b></p> <p><b>Example:</b><br/>Router# configure terminal</p>                                                                                        | <p>Enters global configuration mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Step 3 | <p><b>crypto pki trustpoint <i>name</i></b></p> <p><b>Example:</b><br/>Router(config)# crypto pki trustpoint local</p>                                                        | <p>Declares the CA that your router should use and enters ca-trustpoint configuration mode.</p> <p><b>Note</b> Effective with Cisco IOS Release 12.3(8)T, the <b>crypto pki trustpoint</b> command replaced the <b>crypto ca trustpoint</b> command.</p>                                                                                                                                                                                                                                                                                                             |
| Step 4 | <p><b>enrollment selfsigned</b></p> <p><b>Example:</b><br/>Router(ca-trustpoint)# enrollment selfsigned</p>                                                                   | <p>Specifies self-signed enrollment.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Step 5 | <p><b>subject-name [<i>x.500-name</i>]</b></p> <p><b>Example:</b><br/>Router(ca-trustpoint)# subject-name</p>                                                                 | <p>(Optional) Specifies the requested subject name to be used in the certificate request.</p> <ul style="list-style-type: none"> <li>If the <i>x-500-name</i> argument is not specified, the FQDN, which is the default subject name, is used.</li> </ul>                                                                                                                                                                                                                                                                                                            |
| Step 6 | <p><b>rsa keypair <i>key-label</i> [<i>key-size</i> [<i>encryption-key-size</i>]]</b></p> <p><b>Example:</b><br/>Router(ca-trustpoint)# rsa keypair examplekeys 1024 1024</p> | <p>(Optional) Specifies which key pair to associate with the certificate.</p> <ul style="list-style-type: none"> <li>The <i>key-label</i> argument will be generated during enrollment if it does not already exist or if the <b>auto-enroll regenerate</b> command was issued.</li> <li>Specify the <i>key-size</i> argument for generating the key, and specify the <i>encryption-key-size</i> argument to request separate encryption, signature keys, and certificates.</li> </ul> <p><b>Note</b> If this command is not enabled, the FQDN key pair is used.</p> |
| Step 7 | <p><b>crypto pki enroll <i>name</i></b></p> <p><b>Example:</b><br/>Router(ca-trustpoint)# crypto pki enroll local</p>                                                         | <p>Tells the router to generate the persistent self-signed certificate.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 8 | <p><b>end</b></p> <p><b>Example:</b><br/>Router(ca-trustpoint)# end</p> <p><b>Example:</b><br/>Router(config)# end</p>                                                        | <p>(Optional) Exits ca-trustpoint configuration mode and global configuration mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|         | Command or Action                                                                                                                                                     | Purpose                                                                                                                            |

## Enabling the HTTPS Server

Perform the following task to enable the HTTPS server.

### Prerequisites

To specify parameters, you must create a trustpoint and configure it. To use default values, delete any existing self-signed trustpoints. Deleting all self-signed trustpoints causes the HTTPS server to generate a persistent self-signed certificate using default values as soon as the server is enabled.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip http secure-server**
4. **end**
5. **copy system:running-config nvram: startup-config**

## DETAILED STEPS

|        | Command or Action                                                                                                                          | Purpose                                                                                                           |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                     | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>  |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                             | Enters global configuration mode.                                                                                 |
| Step 3 | <b>ip http secure-server</b><br><br><b>Example:</b><br>Router(config)# ip http secure-server                                               | Enables the secure HTTP web server. <p><b>Note</b> A key pair (modulus 1024) and a certificate are generated.</p> |
| Step 4 | <b>end</b><br><br><b>Example:</b><br>Router(config)# end                                                                                   | Exits global configuration mode.                                                                                  |
| Step 5 | <b>copy system:running-config nvram: startup-config</b><br><br><b>Example:</b><br>Router# copy system:running-config nvram: startup-config | Saves the self-signed certificate and the HTTPS server in enabled mode.                                           |

## Configuring a Certificate Enrollment Profile for Enrollment or Reenrollment

Perform this task to configure an enrollment profile for certificate enrollment or reenrollment of a router with a Cisco IOS CA that is already enrolled with a third-party vendor CA.

Enable a router that is enrolled with a third-party vendor CA to use its existing certificate to enroll with the Cisco IOS certificate server so the enrollment request is automatically granted. To enable this functionality, you must issue the **enrollment credential** command. Also, you cannot configure manual certificate enrollment.

### Prerequisites

Before configuring a certificate enrollment profile for the client router that is already enrolled with a third party vendor CA so that the router can reenroll with a Cisco IOS certificate server, you should have already performed the following tasks at the client router:

- Defined a trustpoint that points to the third-party vendor CA.
- Authenticated and enrolled the client router with the third-party vendor CA.

### Restrictions

- To use certificate profiles, your network must have an HTTP interface to the CA.

- If an enrollment profile is specified, an enrollment URL may not be specified in the trustpoint configuration. Although both commands are supported, only one command can be used at a time in a trustpoint.
- Because there is no standard for the HTTP commands used by various CAs, the user is required to enter the command that is appropriate to the CA that is being used.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto pki trustpoint** *name*
4. **enrollment profile** *label*
5. **exit**
6. **crypto pki profile enrollment** *label*
7. **authentication url** *url*  
or  
**authentication terminal**
8. **authentication command**
9. **enrollment url** *url*  
or  
**enrollment terminal**
10. **enrollment credential** *label*
11. **enrollment command**
12. **parameter** *number* {**value** *value* | **prompt** *string*}
13. **exit**
14. **show crypto pki certificates**

| Step 9  | <b>enrollment url url</b><br><br><b>Example:</b><br>Router(ca-profile-enroll)# enrollment url http://entrust:81/cda-cgi/clientcgi.exe or<br><br><b>enrollment terminal</b><br><br><b>Example:</b><br>Router(ca-profile-enroll)# enrollment terminal | Specifies the URL of the CA server to which to send certificate enrollment requests via HTTP or TFTP.<br><br><br><br>Specifies manual cut-and-paste certificate enrollment.                              |
| Step 10 | <b>enrollment credential label</b><br><br><b>Example:</b><br>Router(ca-profile-enroll)# enrollment credential Entrust                                                                                                                               | (Optional) Specifies the third-party vendor CA trustpoint that is to be enrolled with the Cisco IOS CA.<br><br><b>Note</b> This command cannot be issued if manual certificate enrollment is being used. |
| Step 11 | <b>enrollment command</b><br><br><b>Example:</b><br>Router(ca-profile-enroll)# enrollment command                                                                                                                                                   | (Optional) Specifies the HTTP command that is sent to the CA for enrollment.                                                                                                                             |
| Step 12 | <b>parameter number {value value   prompt string}</b><br><br><b>Example:</b><br>Router(ca-profile-enroll)# parameter 1 value aaaa-bbbb-cccc                                                                                                         | (Optional) Specifies parameters for an enrollment profile.<br><br>This command can be used multiple times to specify multiple values.                                                                    |
| Step 13 | <b>exit</b><br><br><b>Example:</b><br>Router(ca-profile-enroll)# exit<br>Router(config)# exit                                                                                                                                                       | Enter this command two times—one time to exit ca-profile-enroll configuration mode and the second time to exit global configuration mode.                                                                |
| Step 14 | <b>show crypto pki certificates</b><br><br><b>Example:</b><br>Router# show crypto pki certificates                                                                                                                                                  | (Optional) Displays information about your certificates, the certificates of the CA, and RA certificates.                                                                                                |

## What to Do Next

If you configured the router to reenroll with a Cisco IOS CA, you should configure the Cisco IOS certificate server to accept enrollment requests only from clients already enrolled with the specified third-party vendor CA trustpoint to take advantage of this functionality. For more information, see the module “Configuring and Managing a Cisco IOS Certificate Server for PKI Deployment.”

# Configuration Examples for PKI Certificate Enrollment Requests

This section contains the following configuration examples:

- [Configuring Autoenrollment: Example, page 25](#)
- [Configuring Certificate Autoenrollment with Key Regeneration: Example, page 26](#)
- [Configuring Cut-and-Paste Certificate Enrollment: Example, page 27](#)
- [Configuring Manual Certificate Enrollment with Key Regeneration: Example, page 30](#)
- [Creating and Verifying a Persistent Self-Signed Certificate: Example, page 30](#)
- [Configuring Direct HTTP Enrollment: Example, page 32](#)

## Configuring Autoenrollment: Example

The following example shows how to configure the router to automatically enroll with a CA on startup, enabling automatic rollover, and how to specify all necessary enrollment information in the configuration:

```
crypto pki trustpoint frog

quit
```

### Note

In this example, keys are neither regenerated nor rolled over.

## Configuring Certificate Autoenrollment with Key Regeneration: Example

The following example shows how to configure the router to automatically enroll with the CA named “trustme1” on startup and enable automatic rollover. The **regenerate** keyword is issued, so a new key will be generated for the certificate and reissued when the automatic rollover process is initiated. The renewal percentage is configured as 90 so if the certificate has a lifetime of one year, a new certificate is requested 36.5 days before the old certificate expires. The changes made to the running configuration are saved to the NVRAM startup configuration because autoenrollment will not update NVRAM if the running configuration has been modified but not written to NVRAM.

```
crypto pki trustpoint trustme1
 enrollment url http://trustme1.company.com/
 subject-name OU=Spiral Dept., O=tiedye.com
 ip-address ethernet0
 serial-number none
 auto-enroll 90 regenerate
 password revokeme
 rsakeypair trustme1 2048
exit
crypto pki authenticate trustme1
copy system:running-config nvram:startup-config
```

```

## Configuring Manual Certificate Enrollment with Key Regeneration: Example

The following example shows how to regenerate new keys with a manual certificate enrollment from the CA named “trustme2”:

```
crypto pki trustpoint trustme2
 enrollment url http://trustme2.company.com/
 subject-name OU=Spiral Dept., O=tiedye.com
 ip-address ethernet0
 serial-number none
 regenerate
 password revokeme
 rsakeypair trustme2 2048s
 exit
crypto pki authenticate trustme2
crypto pki enroll trustme2
```

## Creating and Verifying a Persistent Self-Signed Certificate: Example

The following example shows how to declare and enroll a trustpoint named “local” and generate a self-signed certificate with an IP address:

```
crypto pki trustpoint local
 enrollment selfsigned
 end
configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

crypto pki enroll local
Nov 29 20:51:13.067: %SSH-5-ENABLED: SSH 1.99 has been enabled
Nov 29 20:51:13.267: %CRYPTO-6-AUTOGEN: Generated new 512 bit key pair
% Include the router serial number in the subject name? [yes/no]: yes
% Include an IP address in the subject name? [no]: yes
Enter Interface name or IP Address[]: ethernet 0
Generate Self Signed Router Certificate? [yes/no]: yes
Router Self Signed Certificate successfully created
```

### Note

A router can have only one self-signed certificate. If you attempt to enroll a trustpoint configured for a self-signed certificate and one already exists, you receive a notification and are asked if you want to replace it. If so, a new self-signed certificate is generated to replace the existing one.

### Enabling the HTTPS Server: Example

The following example shows how to enable the HTTPS server and generate a default trustpoint because one was not previously configured:

```
configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

ip http secure-server
% Generating 1024 bit RSA keys ...[OK]
*Dec 21 19:14:15.421:%PKI-4-NOAUTOSAVE:Configuration was modified. Issue "write memory"
to save new certificate
Router(config)#
```

### Note

You need to save the configuration to NVRAM if you want to keep the self-signed certificate and have the HTTPS server enabled following router reloads.

The following message also appears:

```
*Dec 21 19:14:10.441:%SSH-5-ENABLED:SSH 1.99 has been enabled
```

#### Note

Creation of the key pair used with the self-signed certificate causes the Secure Shell (SSH) server to start. This behavior cannot be suppressed. You may want to modify your access control lists (ACLs) to permit or deny SSH access to the router.

### Verifying the Self-Signed Certificate Configuration: Example

The following example displays information about the self-signed certificate that you just created:

```
Router# show crypto pki certificates
```

```
Router Self-Signed Certificate
 Status: Available
 Certificate Serial Number: 01
 Certificate Usage: General Purpose
 Issuer:
 cn=IOS-Self-Signed-Certificate-3326000105
 Subject:
 Name: IOS-Self-Signed-Certificate-3326000105
 cn=IOS-Self-Signed-Certificate-3326000105
 Validity Date:
 start date: 19:14:14 GMT Dec 21 2004
 end date: 00:00:00 GMT Jan 1 2020
 Associated Trustpoints: TP-self-signed-3326000105
```

#### Note

The number 3326000105 above is the router's serial number and varies depending on the router's actual serial number.

The following example displays information about the key pair corresponding to the self-signed certificate:

```
Router# show crypto key mypubkey rsa
```

```
% Key pair was generated at: 19:14:10 GMT Dec 21 2004
Key name: TP-self-signed-3326000105
Usage: General Purpose Key
Key is not exportable.

```

#### Note

The second key pair with the name TP-self-signed-3326000105.server is the SSH key pair and is generated when any key pair is created on the router and SSH starts up.

The following example displays information about the trustpoint named “local”:

```
Router# show crypto pki trustpoints
```

```
Trustpoint local:
 Subject Name:
 serialNumber=C63EBBE9+ipaddress=10.3.0.18+hostname=test.company.com
 Serial Number: 01
 Persistent self-signed certificate trust point
```

## Configuring Direct HTTP Enrollment: Example

The following example show how to configure an enrollment profile for direct HTTP enrollment with a CA server:

```
crypto pki trustpoint Entrust
 enrollment profile E
 serial

crypto pki profile enrollment E
 authentication url http://entrust:81
 authentication command GET /certs/cacert.der
 enrollment url http://entrust:81/cda-cgi/clientcgi.exe
 enrollment command POST reference_number=$P2&authcode=$P1
 &retrievedAs=rawDER&action=getServerCert&pkcs10Request=$REQ
 parameter 1 value aaaa-bbbb-cccc
 parameter 2 value 5001
```

## Additional References

The following sections provide references related to certificate enrollment for a PKI.

## Feature Information for PKI Certificate Enrollment

[Table 1](#) lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table.

For information on a feature in this technology that is not documented here, see the “[Implementing and Managing PKI Features Roadmap](#).”

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

**Note**

---

[Table 1](#) lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

---

**Table 1** *Feature Information for PKI Certificate Enrollment*

| Feature Name                                 | Releases  | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cisco IOS USB Token PKI Enhancements—Phase 2 | 12.4(11)T | <p>This feature enhances USB token functionality by using the USB token as a cryptographic device. USB tokens may be used for RSA operations such as key generation, signing, and authentication.</p> <p>The following sections in this document provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">Configuring Certificate Enrollment or Autoenrollment</a></li> </ul> <p><b>Note</b> This document covers the use of utilizing USB tokens for RSA operations during initial autoenrollment for a trustpoint. For other documents on this topic, see the “<a href="#">Related Documents</a>” section.</p>                                                                                                                                                  |
| Certificate Authority (CA) Key Rollover      | 12.4(2)T  | <p>This feature introduces the ability for root CAs to roll over expiring CA certificates and keys and to have these changes propagate through the PKI network without manual intervention.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">Automatic Certificate Enrollment</a></li> <li>• <a href="#">Configuring Certificate Enrollment or Autoenrollment</a></li> </ul> <p>The following commands were introduced or modified by this feature: <b>auto-rollover</b>, <b>crypto pki certificate chain</b>, <b>crypto pki export pem</b>, <b>crypto pki server</b>, <b>crypto pki server info request</b>, <b>show crypto pki certificates</b>, <b>show crypto pki server</b>, and <b>show crypto pki trustpoint</b></p> |
| Certificate Autoenrollment                   | 12.2(8)T  | <p>This feature introduces certificate autoenrollment, which allows the router to automatically request a certificate from the CA that is using the parameters in the configuration.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">Automatic Certificate Enrollment</a></li> <li>• <a href="#">Configuring Certificate Enrollment or Autoenrollment</a></li> </ul> <p>The following commands were introduced by this feature: <b>auto-enroll</b>, <b>rsa keypair</b>, <b>show crypto ca timers</b></p>                                                                                                                                                                                                                   |

**Table 1** *Feature Information for PKI Certificate Enrollment (continued)*

| Feature Name                                          | Releases | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------------------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Certificate Enrollment Enhancements                   | 12.2(8)T | <p>This feature introduces five new <b>crypto ca trustpoint</b> subcommands that provide new options for certificate requests and allow users to specify fields in the configuration instead of having to go through prompts.</p> <p>The following section provides information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">Configuring Certificate Enrollment or Autoenrollment</a></li> </ul> <p>The following commands were introduced by this feature:<br/> <b>ip-address (ca-trustpoint), password (ca-trustpoint), serial-number, subject-name, usage</b></p>                                                                                                                                                                                                                           |
| Direct HTTP Enrollment with CA Servers                | 12.3(4)T | <p>This feature allows users to configure an enrollment profile if their CA server does not support SCEP and they do not want to use an RA-mode CS. The enrollment profile allows users to send HTTP requests directly to the CA server instead of to an RA-mode CS.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">Certificate Enrollment Profiles</a></li> <li>• <a href="#">Configuring a Certificate Enrollment Profile for Enrollment or Reenrollment</a></li> </ul> <p>The following commands were introduced by this feature:<br/> <b>authentication command, authentication terminal, authentication url, crypto ca profile enrollment, enrollment command, enrollment profile, enrollment terminal, enrollment url, parameter</b></p> |
| Import of RSA Key Pair and Certificates in PEM Format | 12.3(4)T | <p>This feature allows customers to issue certificate requests and receive issued certificates in PEM-formatted files.</p> <p>The following section provides information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">Configuring Manual Certificate Enrollment</a></li> </ul> <p>The following commands were modified by this feature:<br/> <b>enrollment, enrollment terminal</b></p>                                                                                                                                                                                                                                                                                                                                                                                                        |

# Configuring and Managing a Cisco IOS Certificate Server for PKI Deployment

---

**First Published: May 2, 2005**

**Last Updated: November 17, 2006**

This module describes how to set up and manage a Cisco IOS certificate server for public key infrastructure (PKI) deployment. A certificate server embeds a simple certificate server, with limited certification authority (CA) functionality, into the Cisco IOS software. Thus, the following benefits are provided to the user:

- Easier PKI deployment by defining default behavior. The user interface is simpler because default behaviors are predefined. That is, you can leverage the scaling advantages of PKI without all of the certificate extensions that a CA provides, thereby allowing you to easily enable a basic PKI-secured network.
- Direct integration with Cisco IOS software.

## Finding Feature Information in This Module

*Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for the Cisco IOS Certificate Server](#)” section on page 50.*

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

- [Where to Go Next, page 48](#)
- [Additional References, page 48](#)
- [Feature Information for the Cisco IOS Certificate Server, page 50](#)

## Prerequisites for Configuring a Cisco IOS Certificate Server

### Planning Your PKI Before Configuring the Certificate Server

Before configuring a Cisco IOS certificate server, it is important that you have planned for and chosen appropriate values for the settings you intend to use within your PKI (such as certificate lifetimes and certificate revocation list (CRL) lifetimes). After the settings have been configured in the certificate server and certificates have been granted, settings cannot be changed without having to reconfigure the certificate server and reenrolling the peers. For information on certificate server default settings and recommended settings, see the section “[Certificate Server Default Values and Recommended Values](#).”

### Enabling an HTTP Server

The certificate server supports Simple Certificate Enrollment Protocol (SCEP) over HTTP. The HTTP server must be enabled on the router for the certificate server to use SCEP. (To enable the HTTP server, use the **ip http server** command.) The certificate server will automatically enable or disable SCEP services after the HTTP server is enabled or disabled. If the HTTP server is not enabled, only manual PKCS10 enrollment is supported.

#### Note

To take advantage of automatic CA certificate and key pair rollover functionality for all types of certificate servers, Cisco IOS Release 12.4(4)T or a later release must be used and SCEP must be used as the enrollment method.

### Configuring Reliable Time Services

Time services must be running on the router because the certificate server must have reliable time knowledge. If a hardware clock is unavailable, the certificate server will depend on manually configured clock settings, such as Network Time Protocol (NTP). If there is not a hardware clock or the clock is invalid, the following message will be displayed at bootup:

```
% Time has not been set. Cannot start the Certificate server.
```

After the clock has been set, the certificate server will automatically switch to running status.

For information on manually configuring clock settings, see the section “Setting Time and Calendar Services” in the chapter “Performing Basic System Management” of the *Cisco IOS Network Management Configuration Guide*.

### “crypto ca” to “crypto pki” CLI Change

As of Cisco IOS Release 12.3(7)T, all commands that begin as “crypto ca” have been changed to begin as “crypto pki.” Although the router will still accept crypto ca commands, all output will be read back as crypto pki.

# Restrictions for Configuring a Cisco IOS Certificate Server

The certificate server does not provide a mechanism for modifying the certificate request that is received from the client; that is, the certificate that is issued from the certificate server matches the requested certificate without modifications. If a specific certificate policy, such as name constraints, must be issued, the policy must be reflected in the certificate request.

## Information About Cisco IOS Certificate Servers

Before setting up and deploying a certificate server in your PKI, you should understand the following concepts:

- [RSA Key Pair and Certificate of the Certificate Server, page 3](#)
- [Certificate Server Database, page 4](#)
- [Trustpoint of the Certificate Server, page 6](#)
- [Certificate Revocation Lists \(CRLs\), page 6](#)
- [Certificate Server Error Conditions, page 7](#)
- [Certificate Enrollment Using a Certificate Server, page 8](#)
- [Types of CA Servers: Subordinate and Registration Authorities \(RAs\), page 8](#)
- [Automatic CA Certificate and Key Rollover, page 9](#)

## RSA Key Pair and Certificate of the Certificate Server

The certificate server automatically generates a 1024-bit Rivest, Shamir, and Adelman (RSA) key pair. You must manually generate an RSA key pair if you prefer a different key pair modulus. For information on completing this task, see the section “[Generating a Certificate Server RSA Key Pair.](#)”

**Note**

---

The recommended modulus for a certificate server key pair is 2048 bits.

---

The certificate server will use a regular Cisco IOS RSA key pair as its CA key. This key pair must have the same name as the certificate server. If you do not generate the key pair before the certificate server is created on the router, a general-purpose key pair will be automatically generated during the configuration of the certificate server.

As of Cisco IOS Release 12.3(11)T and later releases, the CA certificate and CA key can be backed up automatically one time after they are generated by the certificate server. As a result, it is not necessary to generate an exportable CA key for backup purposes.

**What to Do with Automatically Generated Key Pairs in Cisco IOS Software Prior to Release 12.3(11)T**

If the key pair is automatically generated, it will not be marked as exportable. Thus, you must manually generate the key pair as exportable if you want to back up the CA key. For information on how to complete this task, see the section “[Generating a Certificate Server RSA Key Pair.](#)”

## How the CA Certificate and CA Key Are Automatically Archived

At initial certificate server setup, you can enable the CA certificate and the CA key to be automatically archived so that they may be restored later if either the original copy or the original configuration is lost.

When the certificate server is turned on the first time, the CA certificate and CA key will be generated. If automatic archive is also enabled, the CA certificate and the CA key will be exported (archived) to the server database. The archive can be in PKCS12 or privacy-enhanced mail (PEM) format.

**Note**

- This CA key backup file is extremely important and should be moved immediately to another secured place.
- This archiving action occurs only one time. Only the CA key that is (1) manually generated and marked exportable or (2) automatically generated by the certificate server will be archived (this key will be marked nonexportable).
- Autoarchiving will not occur if you generate the CA key manually and mark it “nonexportable.”
- In addition to the CA certificate and CA key archive file, you should also regularly back up the serial number file (.ser) and the CRL file (.crl). The serial file and the CRL file are both critical for CA operation if you need to restore your certificate server.
- It is not possible to manually back up a server that uses nonexportable RSA keys or manually generated, nonexportable RSA keys. Although automatically generated RSA keys are marked as nonexportable, they are automatically archived once.

## Certificate Server Database

The Cisco IOS certificate server stores files for its own use and may publish files for other processes to use. Critical files generated by the certificate server that are needed for its ongoing operation are stored to only one location per file type for its exclusive use. The certificate server reads from and writes to these files. The critical certificate server files are the serial number file (.ser) and the CRL storage location file (.crl). Files that the certificate server writes to, but does not read from again, may be published and available for use by other processes. An example of a file that may be published is the issued certificates file (.crt).

Performance of your certificate server may be affected by the following factors, which should be considered when you choose storage options and publication options for your certificate server files.

- The storage or publish locations you choose may affect your certificate server performance. Reading from a network location takes more time than reading directly from a router’s local storage device.
- The number of files you choose to store or publish to a specific location may affect your certificate server performance. The local Cisco IOS file system may not always be suitable for a large number of files.
- The file types you choose to store or publish may affect your certificate server performance. Certain files, such as the .crl files, can become very large.

**Note**

It is recommended that you store .ser and .crl files to your local Cisco IOS file system and publish your .crt files to a remote file system.

## Certificate Server Database File Storage

The certificate server allows the flexibility to store different critical file types to different storage locations depending on the database level set (see the **database level** command for more information). When choosing storage locations, consider the file security needed and server performance. For instance, serial number files and archive files (.p12 or .pem) might have greater security restrictions than the issued certificates file storage location (.crt) or the name file storage location (.cnm).

Table 1 shows the critical certificate server file types by file extension that may be stored to a specific location.

**Table 1** Certificate Server Storage Critical File Types

| File Extension | File Type                                                                  |
|----------------|----------------------------------------------------------------------------|
| .ser           | The main certificate server database file.                                 |
| .crl           | The CRL storage location.                                                  |
| .crt           | The issued certificates storage location.                                  |
| .cnm           | The certificate name and expiration file storage location.                 |
| .p12           | The certificate server certificate archive file location in PKCS12 format. |
| .pem           | The certificate server certificate archive file location in PEM format.    |

Cisco IOS certificate server files may be stored to three levels of specificity:

- Default location, NVRAM
- Specified primary storage location for all critical files
- Specified storage location for specific critical file(s).

A more specific storage location setting overrides a more general storage location setting. For instance, if you have not specified any certificate server file storage locations, all certificate server files will be stored to NVRAM. If you specify a storage location for the name file, only the name file will be stored there; all other files will still be stored to NVRAM. If you then specify a primary location, all files except the name file will now be stored to this location, instead of NVRAM.

**Note**

You may specify either .p12 or .pem; you cannot specify both types of archive files.

## Certificate Server Database File Publication

A publish file is a copy of the original file and is available for other processes to use or for your use. If the certificate server fails to publish a file, it does cause the server to shut down. You may specify one publish location for the issued certificates file and name file and multiple publish locations for the CRL file. See Table 2 for files types available for publication. You may publish files regardless of the database level that is set.

Table 2 Certificate Server Publish File Types

| File Extension | File Type                                                  |
|----------------|------------------------------------------------------------|
| .crl           | The CRL publish location.                                  |
| .crt           | The issued certificates publish location.                  |
| .cnm           | The certificate name and expiration file publish location. |

## Trustpoint of the Certificate Server

The certificate server will also have an automatically generated trustpoint of the same name; the trustpoint will store the certificate of the certificate server. After the router detects that a trustpoint is being used to store the certificate of the certificate server, the trustpoint will be locked so that it cannot be modified.

Before configuring the certificate server you can perform the following:

- Manually create and set up this trustpoint (using the **crypto pki trustpoint** command), which allows you to specify an alternative RSA key pair (using the **rsa keypair** command).
- Specify that the initial autoenrollment key pair will be generated on a specific device, such as a configured and available USB token, using the **on** command.

### Note

The automatically generated trustpoint and the certificate server certificate are not available for the certificate server device identity. Thus, any command-line interface (CLI) (such as the **ip http secure-trustpoint** command) that is used to specify the CA trustpoint to obtain certificates and authenticate the connecting client's certificate must point to an additional trustpoint configured on the certificate server device.

If the server is a root certificate server, it will use the RSA key pairs and several other attributes to generate a self-signed certificate. The associated CA certificate will have the following key usage extensions—Digital Signature, Certificate Sign, and CRL Sign.

After the CA certificate is generated, attributes can be changed only if the certificate server is destroyed.

### Note

A certificate server trustpoint must not be automatically enrolled using the **auto-enroll** command. Initial enrollment of the certificate server must be initiated manually and ongoing automatic rollover functionality may be configured with the **auto-rollover** command. For more information on automatic rollover functionality, see the section [“Automatic CA Certificate and Key Rollover.”](#)

## Certificate Revocation Lists (CRLs)

By default, CRLs are issued once every 168 hours (1 calendar week). To specify a value other than the default value for issuing the CRL, execute the **lifetime crl** command. After the CRL is issued, it is written to the specified database location as *ca-label.crl*, where *ca-label* is the name of the certificate server.

CRLs can be distributed via SCEP, which is the default method, or a CRL distribution point (CDP), if configured and available. If you set up a CDP, use the **cdp-url** command to specify the CDP location. If the **cdp-url** command is not specified, the CDP certificate extension will not be included in the

certificates that are issued by the certificate server. If the CDP location is not specified, Cisco IOS PKI clients will automatically request a CRL from the certificate server with a SCEP GetCRL message. The CA then returns the CRL in a SCEP CertRep message to the client. Because all SCEP messages are enveloped and signed PKCS#7 data, the SCEP retrieval of the CRL from the certificate server is costly and not highly scalable. In very large networks, an HTTP CDP provides better scalability and is recommended if you have many peer devices that will be checking CRLs. You may specify the CDP location by a simple HTTP URL string for example,

```
cdp-url http://my-cdp.company.com/filename.crl
```

The certificate server supports only one CDP; thus, all certificates that are issued include the same CDP.

If you have PKI clients that are not running Cisco IOS software and that do not support a SCEP GetCRL request and wish to use a CDP you may set up an external server to distribute CRLs and configure the CDP to point to that server. Or, you can specify a non-SCEP request for the retrieval of the CRL from the certificate server by specifying the **cdp-url** command with the URL in the following format where *cs-addr* is the location of the certificate server:

```
cdp-url http://cs-addr/cgi-bin/pkiclient.exe?operation=GetCRL
```

**Note**

If your Cisco IOS CA is also configured as your HTTP CDP server, specify your CDP with the **cdp-url** `http://cs-addr/cgi-bin/pkiclient.exe?operation=GetCRL` command syntax.

It is the responsibility of the network administrator to ensure that the CRL is available from the location that is specified via the **cdp-url** command.

The CDP location may be changed after the certificate server is running via the **cdp-url** command. New certificates will contain the updated CDP location, but existing certificates will not be reissued with the newly specified CDP location. When a new CRL is issued, the certificate server uses its current cached CRL to generate a new CRL. (When the certificate server is rebooted, it reloads the current CRL from the database.) A new CRL cannot be issued unless the current CRL has expired. After the current CRL expires, a new CRL is issued only after a certificate is revoked from the CLI.

## Certificate Server Error Conditions

At startup, the certificate server checks the current configuration before issuing any certificates. It reports the last known error conditions via the **show crypto pki server** command output. Example errors can include any of the following conditions:

- Storage inaccessible
- Waiting for HTTP server
- Waiting for time setting

If the certificate server experiences a critical failure at any time, such as failing to publish a CRL, the certificate server will automatically enter a disabled state. This state allows the network administrator to fix the condition; thereafter, the certificate server will return to the previous normal state.

## Certificate Enrollment Using a Certificate Server

A certificate enrollment request functions as follows:

- The certificate server receives the enrollment request from an end user, and the following actions occur:
  - A request entry is created in the enrollment request database with the initial state. (See [Table 3](#) for a complete list of certificate enrollment request states.)
  - The certificate server refers to the CLI configuration (or the default behavior any time a parameter is not specified) to determine the authorization of the request. Thereafter, the state of the enrollment request is updated in the enrollment request database.
- At each SCEP query for a response, the certificate server examines the current request and performs one of the following actions:
  - Responds to the end user with a “pending” or “denied” state.
  - Generates and signs the appropriate certificate and stores the certificate in the enrollment request database.

If the connection of the client has closed, the certificate server will wait for the client to request another certificate.

All enrollment requests transition through the certificate enrollment states that are defined in [Table 3](#). To see current enrollment requests, use the **crypto pki server request pkcs10** command.

**Table 3** *Certificate Enrollment Request State Descriptions*

| Certificate Enrollment State | Description                                                                                  |
|------------------------------|----------------------------------------------------------------------------------------------|
| authorized                   | The certificate server has authorized the request.                                           |
| denied                       | The certificate server has denied the request for policy reasons.                            |
| granted                      | The CA core has generated the appropriate certificate for the certificate request.           |
| initial                      | The request has been created by the SCEP server.                                             |
| malformed                    | The certificate server has determined that the request is invalid for cryptographic reasons. |
| pending                      | The enrollment request must be manually accepted by the network administrator.               |

### SCEP Enrollment

All SCEP requests are treated as new certificate enrollment requests, even if the request specifies a duplicate subject name or public key pair as a previous certificate request.

## Types of CA Servers: Subordinate and Registration Authorities (RAs)

CA servers have the flexibility to be configured as a subordinate certificate server or an RA-mode certificate server.

### Why Configure a Subordinate CA?

A subordinate certificate server provides all the same features as a root certificate server. The root RSA key pairs are extremely important in a PKI hierarchy, and it is often advantageous to keep them offline or archived. To support this requirement, PKI hierarchies allow for subordinate CAs that have been signed by the root authority. In this way, the root authority can be kept offline (except to issue occasional CRL updates), and the subordinate CA can be used during normal operation.

### Why Configure an RA-Mode Certificate Server?

A Cisco IOS certificate server can be configured to run in RA mode. An RA offloads authentication and authorization responsibilities from a CA. When the RA receives a SCEP or manual enrollment request, the administrator can either reject or grant it on the basis of local policy. If the request is granted, it will be forwarded to the issuing CA, and the CA will automatically generate the certificate and return it to the RA. The client can later retrieve the granted certificate from the RA.

An RA is the authority charged with recording or verifying some or all of the data required for the CA to issue certificates. In many cases the CA will undertake all of the RA functions itself, but where a CA operates over a wide geographical area or when there is security concern over exposing the CA to direct network access, it may be administratively advisable to delegate some of the tasks to an RA and leave the CA to concentrate on its primary tasks of signing certificates and CRLs.

## Automatic CA Certificate and Key Rollover

CAs—root CAs, subordinate CAs, and RA-mode CAs—like their clients, have certificates and key pairs with expiration dates that need to be reissued when the current certificate and key pair are about to expire. When a root CA's certificate and key pair are expiring it must generate a self-signed rollover certificate and key pair. If a subordinate CA or an RA-mode CA's certificate and key pair are expiring, it will request a rollover certificate and key pair from its superior CA, obtaining the superior CA's new self-signed rollover certificates at the same time. The CA must distribute the new CA rollover certificate and keys too all its peers. This process, called rollover, allows for continuous operation of the network while the CAs and their clients are switching from an expiring CA certificate and key pair to a new CA certificate and key pair.

Rollover relies on the PKI infrastructure requirements of trust relationships and synchronized clocks. The PKI trust relationships allow (1) the new CA certificate to be authenticated, and (2) the rollover to be accomplished automatically without the loss of security. Synchronized clocks allow the rollover to be coordinated throughout your network.

### Automatic CA Certificate Rollover: How It Works

The CA server must have rollover configured. All levels of CAs must be automatically enrolled and have **auto-rollover** enabled. CA clients support rollover automatically when automatically enrolled. For more information about clients and automatic rollover, see the section "[Automatic Certificate Enrollment](#)" in the chapter "Configuring Certificate Enrollment for a PKI".

After CAs have rollover enabled and their clients are automatically enrolled, there are three stages to the automatic CA certificate rollover process.

#### Stage One: Active CA Certificate and Key Pair Only

In stage one, there is an active CA certificate and key pair only.

**Stage Two: Rollover CA Certificate and Key Pair Generation and Distribution**

In stage two, the rollover CA certificate and key pair are generated and distributed. The superior CA generates a rollover certificate and key pair. After the CA successfully saves its active configuration, the CA is ready to respond to client requests for the rollover certificate and key pair. When the superior CA receives a request for the new CA certificate and key pair from a client, the CA responds by sending the the new rollover CA certificate and key pair to the requesting client. The clients store the rollover CA certificate and key pair.

**Note**

When a CA generates its rollover certificate and key pair, it must be able to save its active configuration. If the current configuration has been altered, saving of the rollover certificate and key pair will not happen automatically. In this case, the administrator must save the configuration manually or rollover information will be lost.

**Stage Three: Rollover CA Certificate and Key Pair Become the Active CA Certificate and Key Pair**

In stage three, the rollover CA certificate and key pair become the active CA certificate and key pair. All devices that have stored a valid rollover CA certificate rename the rollover certificate to the active certificate and the once-active certificate and key pair are deleted.

## How to Set Up and Deploy a Cisco IOS Certificate Server

This section contains the following procedures:

- [Generating a Certificate Server RSA Key Pair, page 10](#)
- [Configuring Certificate Servers, page 13](#)
- [Configuring Certificate Server Functionality, page 24](#)
- [Working with Automatic CA Certificate Rollover, page 28](#)
- [Maintaining, Verifying, and Troubleshooting the Certificate Server, Certificates, and the CA, page 30](#)

### Generating a Certificate Server RSA Key Pair

Perform this task to manually generate an RSA key pair for the certificate server. Manually generating a certificate server RSA key pair allows you to specify the type of key pair you want to generate, to create an exportable key pair for backup purposes, to specify the key pair storage location, or to specify the key generation location.

If you are running Cisco IOS Release 12.3(8)T or earlier releases, you may want to create an exportable certificate server key pair for backup, or archive purposes. If this task is not performed, the certificate server will automatically generate a key pair, which will not be marked as exportable. Automatic CA certificate archiving was introduced in Cisco IOS Release 12.3(11)T.

As of Cisco IOS Release 12.4(11)T and later releases, if your router has a USB token configured and available, the USB token can be used as cryptographic device in addition to a storage device. Using a USB token as a cryptographic device allows RSA operations such as key generation, signing, and authentication of credentials to be performed on a USB token. The private key never leaves the USB token and is not exportable. The public key is exportable. For titles of specific documents about configuring a USB token and making it available to use as a cryptographic device, see the [“The following sections provide references related to Cisco IOS certificate server.Related Documents”](#) section.

**Note**

It is recommended that the private key be kept in a secure location and that you regularly archive the certificate server database.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto key generate rsa** [**general-keys** | **usage-keys** | **signature** | **encryption**] [**label** *key-label*] [**exportable**] [**modulus** *modulus-size*] [**storage** *devicename:*] [**on** *devicename:*]
4. **crypto key export rsa** *key-label* **pem** {**terminal** | **url** *url*} {**3des** | **des**} *passphrase*
5. **crypto key import rsa** *key-label* **pem** [**usage-keys** | **signature** | **encryption**] {**terminal** | **url** *url*} [**exportable**] [**on** *devicename:*] *passphrase*
6. **exit**
7. **show crypto key mypubkey rsa**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                                                                                                                                                                                                        | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                                                                                                                                                                                                                | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Step 3 | <b>crypto key generate rsa</b> [ <b>general-keys</b>   <b>usage-keys</b>   <b>signature</b>   <b>encryption</b> ] [ <b>label</b> <i>key-label</i> ] [ <b>exportable</b> ] [ <b>modulus</b> <i>modulus-size</i> ] [ <b>storage</b> <i>devicename:</i> ] [ <b>on</b> <i>devicename:</i> ]<br><br><b>Example:</b><br>Router (config)# crypto key generate rsa label mycs exportable modulus 2048 | Generates the RSA key pair for the certificate server.<br><br>When specifying a label name, you must use the same name for the label that you plan to use for the certificate server (via the <b>crypto pki server cs-label</b> command). By default, the fully qualified domain name (FQDN) of the router is used for the key label.<br><br>If you manually generate the exportable RSA key pair but wait until after the CA certificate has been generated before issuing the <b>no shutdown</b> command, you can use the <b>crypto ca export pkcs12</b> command to export a PKCS12 file that contains the certificate server certificate and the private key.<br><br>By default, the modulus size of a CA key is 1024 bits. The recommended modulus for a CA key is 2048 bits. The range for a CA key is from 350 to 2048 bits. |

|        | Command or Action                                                                                                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 4 | <b>crypto key export rsa key-label pem {terminal   url url} {3des   des} passphrase</b><br><br><b>Example:</b><br>Router (config)# crypto key export rsa mycs pem url nvram: 3des PASSWORD                                                        | (Optional) Exports the generated RSA key pair.<br><br>Allows you to export the generated keys.                                                                                                                                                                                                                                                                                                                      |
| Step 5 | <b>crypto key import rsa key-label pem [usage-keys   signature   encryption] {terminal   url url} [exportable] [on devicename:] passphrase</b><br><br><b>Example:</b><br>Router (config)# crypto key import rsa mycs2 pem url nvram:mycs PASSWORD | (Optional) Imports RSA key pair.<br><br>To create the imported keys on a USB token, use the <b>on</b> keyword and specify the appropriate device location.<br><br>If you exported the RSA keys using the <b>exportable</b> keyword and you want to change the RSA key pair to nonexportable, import the key back to the certificate server without the <b>exportable</b> keyword. The key cannot be exported again. |
| Step 6 | <b>exit</b><br><br><b>Example:</b><br>Router (config)# exit                                                                                                                                                                                       | Exits global configuration.                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 7 | <b>show crypto key mypubkey rsa</b><br><br><b>Example:</b><br>Router# show crypto key mypubkey rsa                                                                                                                                                | Displays the RSA public keys of your router.                                                                                                                                                                                                                                                                                                                                                                        |

## Examples

The following example generates a general usage 1024-bit RSA key pair on a USB token with the label “ms2” with crypto engine debugging messages shown:

```
Router(config)# crypto key generate rsa on usbtok0 label ms2 modulus 1024
The name for the keys will be: ms2
% The key modulus size is 1024 bits
% Generating 1024 bit RSA keys, keys will be on-token, non-exportable...
Jan 7 02:41:40.895: crypto_engine: Generate public/private keypair [OK]
Jan 7 02:44:09.623: crypto_engine: Create signature
Jan 7 02:44:10.467: crypto_engine: Verify signature
Jan 7 02:44:10.467: CryptoEngine0: CRYPTO_ISA_RSA_CREATE_PUBKEY(hw)(ipsec)
Jan 7 02:44:10.467: CryptoEngine0: CRYPTO_ISA_RSA_PUB_DECRYPT(hw)(ipsec)
```

Now, the on-token keys labeled “ms2” may be used for enrollment.

The following example shows the successful import of an encryption key to a configured and available USB tokens:

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# crypto key import rsa encryption on usbtok0 url nvram:e password
% Importing public Encryption key or certificate PEM file...
filename [e-encr.pub]?
Reading file from nvram:e-encr.pub
% Importing private Encryption key PEM file...
Source filename [e-encr.prv]?
Reading file from nvram:e-encr.prv
% Key pair import succeeded.
```

## Configuring Certificate Servers

The following tasks explain how to configure a certificate server, a subordinate certificate server, or an RA-mode certificate server, and how to enable automatic rollover.

- [Configuring a Certificate Server, page 13](#)
- [Configuring a Subordinate Certificate Server, page 15](#)
- [Configuring a Certificate Server to Run in RA Mode, page 21](#)
- [Configuring the Root Certificate Server to Delegate Enrollment Tasks to the RA Mode Certificate Server, page 23](#)

### Prerequisites for Automatic CA Certificate Rollover

When configuring a certificate server, for automatic CA certificate rollover to run successfully, the following prerequisites are applicable for your CA servers:

- You must be running Cisco IOS Release 12.4(2)T or a later release on your CA servers.
- Your CA server must be enabled and fully configured with a reliable time of day, an available key pair, a self-signed, valid CA certificate associated with the key pair, a CRL, an accessible storage device, and an active HTTP/SCEP server.
- CA clients must have successfully completed automatic enrollment and have autoenrollment enabled with the same certificate server.

**Note**

If you are running Cisco IOS 12.4(2)T or earlier releases, only your root CA will support automatic CA certificate rollover functionality. Cisco IOS 12.4(4)T or later releases support all CAs—root CAs, subordinate CAs, and RA-mode CAs.

### Restrictions for Automatic CA Certificate Rollover

When configuring a certificate server, in order for automatic CA certificate rollover to run successfully, the following restrictions are applicable:

- SCEP must be used to support rollover. Any device that enrolls with the PKI using an alternative to SCEP as the certificate management protocol or mechanism (such as enrollment profiles, manual enrollment, or TFTP enrollment) will not be able to take advantage of the rollover functionality provided by SCEP.
- If you have automatic archive configured on your network and the archive fails, rollover will not occur because the certificate server will not enter the rollover state, and the rollover certificate and key pair will not be automatically saved.

### Configuring a Certificate Server

Perform this task to configure a Cisco IOS certificate server and enable automatic rollover.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**

3. **ip http server**
4. **crypto pki server** *cs-label*
5. **no shutdown**
6. **auto-rollover** [*time-period*]

## DETAILED STEPS

|        | Command or Action                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                          |
|--------|-----------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                          | Enables privileged EXEC mode.<br><ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                              |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                  | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                |
| Step 3 | <b>ip http server</b><br><br><b>Example:</b><br>Router(config)# ip http server                                  | Enables the HTTP server on your system.                                                                                                                                                                                                                                                                                                          |
| Step 4 | <b>crypto pki server</b> <i>cs-label</i><br><br><b>Example:</b><br>Router(config)# crypto pki server server-pki | Defines a label for the certificate server and enters certificate server configuration mode.<br><br><b>Note</b> If you manually generated an RSA key pair, the <i>cs-label</i> argument must match the name of the key pair.                                                                                                                     |
| Step 5 | <b>no shutdown</b><br><br><b>Example:</b><br>Router(cs-server)# no shutdown                                     | (Optional) Enables the certificate server.<br><br><b>Note</b> Only use this command at this point if you want to use the preconfigured default functionality. That is, do not issue this command just yet if you plan to change any of the default settings as shown in the task <a href="#">“Configuring Certificate Server Functionality.”</a> |
| Step 6 | <b>auto-rollover</b> [ <i>time-period</i> ]<br><br><b>Example:</b><br>Router(cs-server)# auto-rollover 90       | (Optional) Enables the automated CA certificate rollover functionality.<br><ul style="list-style-type: none"> <li><i>time-period</i>—default is 30 days.</li> </ul>                                                                                                                                                                              |

## Examples

The following example shows how to configure the certificate server “ca”:

```
Router(config)# crypto pki server ca
Router(cs-server)# no shutdown
```

```
% Once you start the server, you can no longer change some of
% the configuration.
Are you sure you want to do this? [yes/no]: yes
% Generating 1024 bit RSA keys ...[OK]
```

```
% Certificate Server enabled.
Router(cs-server)# end
!
Router# show crypto pki server

Certificate Server ca:
 Status: enabled, configured
 CA cert fingerprint: 5A856122 4051347F 55E8C246 866D0AC3
 Granting mode is: manual
 Last certificate issued serial number: 0x1
 CA certificate expiration timer: 19:44:57 GMT Oct 14 2006
 CRL NextUpdate timer: 19:45:25 GMT Oct 22 2003
 Current storage dir: nvram:
 Database Level: Complete - all issued certs written as <serialnum>.cer
```

The following example shows how to enable automated CA certificate rollover on the server mycs with the **auto-rollover** command. The **show crypto pki server** command shows that the automatic rollover has been configured on the server mycs with an overlap period of 25 days.

```
Router(config)# crypto pki server mycs
Router(cs-server)# auto-rollover 25
Router(cs-server)# no shut

%Some server settings cannot be changed after CA certificate generation.
% Generating 1024 bit RSA keys, keys will be non-exportable...[OK]
% Exporting Certificate Server signing certificate and keys...

% Certificate Server enabled.
Router(cs-server)#

Router# show crypto pki server

Certificate Server mycs:
 Status:enabled
 Server's configuration is locked (enter "shut" to unlock it)
 Issuer name:CN=mycs
 CA cert fingerprint:70AFECA9 211CDDCC 6AA9D7FF 3ADB03AE
 Granting mode is:manual
 Last certificate issued serial number:0x1
 CA certificate expiration timer:00:49:26 PDT Jun 20 2008
 CRL NextUpdate timer:00:49:29 PDT Jun 28 2005
 Current storage dir:nvram:
 Database Level:Minimum - no cert data written to storage
 Auto-Rollover configured, overlap period 25 days
 Autorollover timer:00:49:26 PDT May 26 2008
```

## Configuring a Subordinate Certificate Server

Perform this task to configure a subordinate certificate server to grant all or certain SCEP or manual certificate requests and to enable automatic rollover.

### Restrictions

- You must be running Cisco IOS Release 12.3(14)T or a later release. (Versions prior to Cisco IOS software Release 12.3(14)T support only one certificate server and no hierarchy; that is, subordinate certificate servers are not supported.)
- The root certificate server should be a Cisco IOS certificate server.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto pki trustpoint** *name*
4. **enrollment url** *url*
5. **exit**
6. **crypto pki server** *cs-label*
7. **issuer name** *DN-string*
8. **mode sub-cs**
9. **auto-rollover** [*time-period*]
10. **grant auto rollover** {*ca-cert* | *ra-cert*}
11. **no shutdown**

## DETAILED STEPS

|        | Command or Action                                                                                                     | Purpose                                                                                                                                                                                               |
|--------|-----------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>Enter your password if prompted.</li></ul>                                                                                     |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                        | Enters global configuration mode.                                                                                                                                                                     |
| Step 3 | <b>crypto pki trustpoint</b> <i>name</i><br><br><b>Example:</b><br>Router (config)# crypto pki trustpoint sub         | Declares the trustpoint that your subordinate certificate server should use and enters ca-trustpoint configuration mode.                                                                              |
| Step 4 | <b>enrollment url</b> <i>url</i><br><br><b>Example:</b><br>Router (ca-trustpoint)# enrollment url<br>http://192.0.2.6 | Specifies the enrollment URL of the issuing CA certificate server (root certificate server).                                                                                                          |
| Step 5 | <b>exit</b><br><br><b>Example:</b><br>Router (ca-trustpoint)# exit                                                    | Exits ca-trustpoint configuration mode.                                                                                                                                                               |
| Step 6 | <b>crypto pki server</b> <i>cs-label</i><br><br><b>Example:</b><br>Router(config)# crypto pki server sub              | Enables a Cisco IOS certificate server and enters cs-server configuration mode.<br><br><b>Note</b> The subordinate server must have the same name as the trustpoint that was created in Step 3 above. |

|         | Command or Action                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 7  | <b>issuer name</b> <i>DN-string</i><br><br><b>Example:</b><br>Router(cs-server)# issuer-name CN=sub CA,<br>O=Cisco, C=us                | (Optional) Specifies the DN as the CA issuer name for the certificate server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Step 8  | <b>mode sub-cs</b><br><br><b>Example:</b><br>Router(cs-server)# mode sub-cs                                                             | Places the PKI server into sub-certificate server mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 9  | <b>auto-rollover</b> [ <i>time-period</i> ]<br><br><b>Example:</b><br>Router(cs-server)# auto-rollover 90                               | (Optional) Enables the automated CA certificate rollover functionality. <ul style="list-style-type: none"> <li><i>time-period</i>—default is 30 days.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                 |
| Step 10 | <b>grant auto rollover</b> { <i>ca-cert</i>   <i>ra-cert</i> }<br><br><b>Example:</b><br>Router(cs-server)# grant auto rollover ca-cert | (Optional) Automatically grants reenrollment requests for subordinate CAs and RA-mode CAs without operator intervention. <ul style="list-style-type: none"> <li><b>ca-cert</b>—Specifies that the subordinate CA rollover certificate will be automatically granted.</li> <li><b>ra-cert</b>—Specifies that the RA-mode CA rollover certificate will be automatically granted.</li> </ul> <b>Note</b> If this is the first time that a subordinate certificate server is enabled and enrolled, the certificate request must be manually granted. |
| Step 11 | <b>no shutdown</b><br><br><b>Example:</b><br>Router(cs-server)# no shutdown                                                             | Enables or reenables the certificate server.<br><br>If this is the first time that a subordinate certificate server is enabled, the certificate server will generate the key and obtain its signing certificate from the root certificate server.                                                                                                                                                                                                                                                                                                |

## Examples

If the certificate server fails to enable or if the certificate server has trouble handling the request that has been configured, you can use the **debug crypto pki server** command to troubleshoot your configuration as shown in the following examples (Clock Not Set and Trustpoint Not Configured):

```
Router# debug crypto pki server
```

### Clock Not Set

```
Router (config)# crypto pki server sub
Router (cs-server)# mode sub-cs
Router (cs-server)# no shutdown
%Some server settings cannot be changed after CA certificate generation.
% Please enter a passphrase to protect the private key % or type Return to exit
Password:
*Jan 6 20:57:37.667: CRYPTO_CS: enter FSM: input state initial, input signal no shut

Re-enter password:
% Generating 1024 bit RSA keys ...
```

```
*Jan 6 20:57:45.303: CRYPTO_CS: starting enabling checks
*Jan 6 20:57:45.303: CRYPTO_CS: key 'sub' does not exist; generated automatically[OK]
% Time has not been set. Cannot start the Certificate server
```

### Trustpoint Not Configured

```
Router (config)# crypto pki server sub
Router (cs-server)# mode sub-cs
Router (cs-server)# no shutdown
```

```
%Some server settings cannot be changed after CA certificate generation.
% Please enter a passphrase to protect the private key or type Return to exit
Password:
Jan 6 21:00:15.961: CRYPTO_CS: enter FSM: input state initial, input signal no shut.
Jan 6 21:03:34.309: CRYPTO_CS: enter FSM: input state initial, input signal time set.
Jan 6 21:03:34.313: CRYPTO_CS: exit FSM: new state initial.
Jan 6 21:03:34.313: CRYPTO_CS: cs config has been unlocked
Re-enter password:
% Generating 1024 bit RSA keys ...
Jan 6 21:03:44.413: CRYPTO_CS: starting enabling checks
Jan 6 21:03:44.413: CRYPTO_CS: associated trust point 'sub' does not exist; generated
automatically
Jan 6 21:03:44.417: CRYPTO_CS: key 'sub' does not exist; generated automatically[OK]

Jan 6 21:04:03.993: CRYPTO_CS: nvram filesystem

You must specify an enrollment URL for this CA before you can authenticate it.
% Failed to authenticate the Certificate Authority
```

If the certificate server fails to obtain its signing certificate from the root certificate server, you can use the **debug crypto pki transactions** command to troubleshoot your configuration as shown in the following example:

```
Router# debug crypto pki transactions
```

```

```

If the certificate server fails to enable or if the certificate server has trouble handling the request that has been configured, you can use the **debug crypto pki server** command to troubleshoot the progress of an enrollment. This command can also be used to debug the root CA (turn it on at the root CA).

## Configuring a Certificate Server to Run in RA Mode

### Restrictions for Configuring a Certificate Server for RA Mode

When the Cisco IOS certificate server is acting as an RA, the issuing CA should be a Cisco IOS certificate server.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto pki trustpoint** *name*
4. **enrollment url** *url*
5. **subject-name** *x.500-name*
6. **exit**
7. **crypto pki server** *cs-label*
8. **mode ra**
9. **auto-rollover** [*time-period*]
10. **grant auto rollover** {*ca-cert* | *ra-cert*}
11. **no shutdown**
12. **no shutdown**

### DETAILED STEPS

|        | Command or Action                             | Purpose                                                                            |
|--------|-----------------------------------------------|------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b>                                 | Enables privileged EXEC mode.                                                      |
|        | <b>Example:</b><br>Router> enable             | <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b>                     | Enters global configuration mode.                                                  |
|        | <b>Example:</b><br>Router# configure terminal |                                                                                    |

|         | Command or Action                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3  | <b>crypto pki trustpoint</b> <i>name</i><br><br><b>Example:</b><br>Router (config)# crypto pki trustpoint ra-server                     | Declares the trustpoint that your RA mode certificate server should use and enters ca-trustpoint configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Step 4  | <b>enrollment url</b> <i>url</i><br><br><b>Example:</b><br>Router (ca-trustpoint)# enrollment url http://ca-server.company.com          | Specifies the enrollment URL of the issuing CA certificate server (root certificate server).                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 5  | <b>subject-name</b> <i>x.500-name</i><br><br><b>Example:</b><br>Router (ca-trustpoint)# subject-name cn=ioscs RA                        | (Optional) Specifies the subject name the RA will use.<br><br><b>Note</b> Include “cn=ioscs RA” or “ou=ioscs RA” in the subject name so that the issuing CA certificate server can recognize the RA (see Step 7 below).                                                                                                                                                                                                                                                                                                              |
| Step 6  | <b>exit</b><br><br><b>Example:</b><br>Router (ca-trustpoint)# exit                                                                      | Exits ca-trustpoint configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Step 7  | <b>crypto pki server</b> <i>cs-label</i><br><br><b>Example:</b><br>Router(config)# crypto pki server ra-server                          | Enables a Cisco IOS certificate server and enters cs-server configuration mode.<br><br><b>Note</b> The certificate server must have the same name as the trustpoint that was created in Step 3 above.                                                                                                                                                                                                                                                                                                                                |
| Step 8  | <b>mode ra</b><br><br><b>Example:</b><br>Router(cs-server)# mode ra                                                                     | Places the PKI server into RA certificate server mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Step 9  | <b>auto-rollover</b> [ <i>time-period</i> ]<br><br><b>Example:</b><br>Router(cs-server)# auto-rollover 90                               | (Optional) Enables the automatic CA certificate rollover functionality. <ul style="list-style-type: none"> <li><i>time-period</i>—default is 30 days.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                     |
| Step 10 | <b>grant auto rollover</b> { <i>ca-cert</i>   <i>ra-cert</i> }<br><br><b>Example:</b><br>Router(cs-server)# grant auto rollover ra-cert | (Optional) Automatically grants reenrollment requests for subordinate CAs and RA-mode CAs without operator intervention. <ul style="list-style-type: none"> <li><b>ca-cert</b>—Specifies that the subordinate CA rollover certificate will be automatically granted.</li> <li><b>ra-cert</b>—Specifies that the RA-mode CA rollover certificate will be automatically granted.</li> </ul> If this is the first time that a subordinate certificate server is enabled and enrolled, the certificate request must be manually granted. |

|         | Command or Action                                 | Purpose                                                                                                                                                                                                                                                                   |
|---------|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 11 | <b>no shutdown</b>                                | Enables the certificate server.                                                                                                                                                                                                                                           |
|         | <b>Example:</b><br>Router(cs-server)# no shutdown | <b>Note</b> After this command is issued, the RA will automatically enroll with the root certificate server.<br><br>After the RA certificate has been successfully received, you must issue the <b>no shutdown</b> command again, which reenables the certificate server. |
| Step 12 | <b>no shutdown</b>                                | Reenables the certificate server.                                                                                                                                                                                                                                         |
|         | <b>Example:</b><br>Router(cs-server)# no shutdown |                                                                                                                                                                                                                                                                           |

## Configuring the Root Certificate Server to Delegate Enrollment Tasks to the RA Mode Certificate Server

Perform the following steps on the router that is running the issuing certificate server; that is, configure the root certificate server that is delegating enrollment tasks to the RA mode certificate server.

### Note

Granting enrollment requests for an RA is essentially the same process as granting enrollment requests for client devices—except that enrollment requests for an RA are displayed in the section “RA certificate requests” of the command output for the **crypto pki server info-requests** command.

## SUMMARY STEPS

1. **enable**
2. **crypto pki server** *cs-label* **info requests**
3. **crypto pki server** *cs-label* **grant** *req-id*
4. **configure terminal**
5. **crypto pki server** *cs-label*
6. **grant ra-auto**

## DETAILED STEPS

|        | Command or Action                                                      | Purpose                                                                                          |
|--------|------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b>                                                          | Enables privileged EXEC mode.                                                                    |
|        | <b>Example:</b><br>Router> enable                                      | <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>             |
| Step 2 | <b>crypto pki server</b> <i>cs-label</i> <b>info requests</b>          | Displays the outstanding RA certificate request.                                                 |
|        | <b>Example:</b><br>Router# crypto pki server root-server info requests | <b>Note</b> This command is issued on the router that is running the issuing certificate server. |

|        | Command or Action                                                                                                                                         | Purpose                                                                                                                                                                                                                                                                          |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <b>crypto pki server</b> <i>cs-label</i> <b>grant</b> <i>req-id</i><br><br><b>Example:</b><br>Router# <b>crypto pki server</b> root-server <b>grant</b> 9 | Grants the pending RA certificate request.<br><br><b>Note</b> Because the issuing certificate server will delegate the enrollment request verification task to the RA, you must pay extra attention to the RA certificate request before granting it.                            |
| Step 4 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# <b>configure terminal</b>                                                                     | Enters global configuration mode.                                                                                                                                                                                                                                                |
| Step 5 | <b>crypto pki server</b> <i>cs-label</i><br><br><b>Example:</b><br>Router (config)# <b>crypto pki server</b> root-server                                  | Enables a Cisco IOS certificate server and enters cs-server configuration mode.                                                                                                                                                                                                  |
| Step 6 | <b>grant ra-auto</b><br><br><b>Example:</b><br>Router(cs-server)# <b>grant ra-auto</b>                                                                    | (Optional) Specifies that all enrollment requests from an RA are to be granted automatically.<br><br><b>Note</b> For the <b>grant ra-auto</b> command to work, you have to include “cn=ioscs RA” or “ou=ioscs RA” in the subject name of the RA certificate. (See Step 2 above.) |

## What to Do Next

After you have configured a certificate server, you can use the preconfigured default values or specify values via the CLI for the functionality of the certificate server. If you choose to specify values other than the defaults, see the following section, [“Configuring Certificate Server Functionality.”](#)

## Configuring Certificate Server Functionality

After you have enabled a certificate server and are in certificate server configuration mode, use any of the steps in this task to configure basic certificate server functionality values other than the default values.

### Certificate Server Default Values and Recommended Values

The default values for a certificate server are intended to address a relatively small network (of about ten devices). For example, the database settings are minimal (via the **database level minimal** command) and the certificate server handles all CRL requests via SCEP. For larger networks, it is recommended that you use either the database setting “names” or “complete” (as described in the **database level** command) for possible audit and revocation purposes. Depending on the CRL checking policy, you should also use an external CDP in a larger network.

## Certificate Server File Storage and Publication Locations

You have the flexibility to store file types to different storage and publication locations.

### SUMMARY STEPS

1. **database url** *root-url*
2. **database url** {*cnm* | *crl* | *crt* | **p12** | **pem** | **ser**} *root-url*
3. **database url** {*cnm* | *crl* | *crt*} **publish** *root-url*
4. **database level** {*minimal* | *names* | **complete**}
5. **database username** *username* [**password** [*encr-type*] *password*]
6. **database archive** {**pkcs12** | **pem**} [**password** [*encr-type*] *password*]
7. **issuer-name** *DN-string*
8. **lifetime** {*ca-certificate* | *certificate*} *time*
9. **lifetime crl** *time*
10. **lifetime enrollment-request** *time*
11. **cdp-url** *url*
12. **no shutdown**

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                      |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>database url</b> <i>root-url</i><br><br><b>Example:</b><br>Router (cs-server)# database url<br>tftp://cert-svr-db.company.com                                                                                 | Specifies the primary location where database entries for the certificate server will be written out.<br><br>If this command is not specified, all database entries will be written to NVRAM.                                                                                                |
| Step 2 | <b>database url</b> { <i>cnm</i>   <i>crl</i>   <i>crt</i>   <b>p12</b>   <b>pem</b>   <b>ser</b> } <i>root-url</i><br><br><b>Example:</b><br>Router (cs-server)# database url ser nvram:                        | Specifies certificate server critical file storage location by file type.<br><br><b>Note</b> If this command is not specified, all critical files will be stored to the primary location if specified. If the primary location is not specified, all critical files will be stored to NVRAM. |
| Step 3 | <b>database url</b> { <i>cnm</i>   <i>crl</i>   <i>crt</i> } <b>publish</b> <i>root-url</i><br><br><b>Example:</b><br>Router (cs-server)# database url crl publish<br>tftp://csdb_specific_crl_files.company.com | Specifies certificate server publish location by file type.<br><br><b>Note</b> If this command is not specified, all publish files will be stored to the primary location if specified. If the primary location is not specified, all publish files will be stored to NVRAM.                 |

|        | Command or Action                                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 4 | <p><b>database level</b> {<i>minimal</i>   <i>names</i>   <i>complete</i>}</p> <p><b>Example:</b><br/>Router (cs-server)# database level complete</p>                                        | <p>Controls what type of data is stored in the certificate enrollment database.</p> <ul style="list-style-type: none"> <li><b>minimal</b>—Enough information is stored only to continue issuing new certificates without conflict; the default value.</li> <li><b>names</b>—In addition to the information given in the minimal level, the serial number and subject name of each certificate.</li> <li><b>complete</b>—In addition to the information given in the minimal and names levels, each issued certificate is written to the database.</li> </ul> <p><b>Note</b> The <b>complete</b> keyword produces a large amount of information; if it is issued, you should also specify an external TFTP server in which to store the data via the <b>database url</b> command.</p> |
| Step 5 | <p><b>database username</b> <i>username</i> [<b>password</b> [<i>encr-type</i>] <i>password</i>]</p> <p><b>Example:</b><br/>Router (cs-server)# database username user password PASSWORD</p> | <p>(Optional) Sets a username and password when a user is required to access a primary certificate enrollment database storage location.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 6 | <p><b>database archive</b> {<i>pkcs12</i>   <i>pem</i>} [<b>password</b> [<i>encr-type</i>] <i>password</i>]</p> <p><b>Example:</b><br/>Router (cs-server)# database archive pem</p>         | <p>(Optional) Sets the CA key and CA certificate archive format and password to encrypt the file.</p> <p>The default value is <b>pkcs12</b>, so if this subcommand is not configured, autoarchiving will still be done, and the PKCS12 format will be used.</p> <ul style="list-style-type: none"> <li>The password is optional. If it is not configured, you will be prompted for the password when the server is turned on for the first time.</li> </ul> <p><b>Note</b> It is recommended that you remove the password from the configuration after the archive is finished.</p>                                                                                                                                                                                                  |
| Step 7 | <p><b>issuer-name</b> <i>DN-string</i></p> <p><b>Example:</b><br/>Router (cs-server)# issuer-name my-server</p>                                                                              | <p>(Optional) Sets the CA issuer name to the specified distinguished name (<i>DN-string</i>). The default value is as follows: <b>issuer-name cn={cs-label}</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Step 8 | <p><b>lifetime</b> {<i>ca-certificate</i>   <i>certificate</i>} <i>time</i></p> <p><b>Example:</b><br/>Router (cs-server)# lifetime certificate 888</p>                                      | <p>(Optional) Specifies the lifetime, in days, of a CA certificate or a certificate.</p> <p>Valid values range from 1 day to 1825 days. The default CA certificate lifetime is 3 years; the default certificate lifetime is 1 year. The maximum certificate lifetime is 1 month less than the lifetime of the CA certificate.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Step 9 | <p><b>lifetime crl</b> <i>time</i></p> <p><b>Example:</b><br/>Router (cs-server)# lifetime crl 333</p>                                                                                       | <p>(Optional) Defines the lifetime, in hours, of the CRL that is used by the certificate server.</p> <p>Maximum lifetime value is 336 hours (2 weeks). The default value is 168 hours (1 week).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|         | Command or Action                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------|------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 10 | <b>lifetime enrollment-request</b> <i>time</i><br><br><b>Example:</b><br>Router (cs-server)# lifetime enrollment-request 888 | (Optional) Specifies how long an enrollment request should stay in the enrollment database before being removed.<br><br>Maximum lifetime is 1000 hours.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Step 11 | <b>cdp-url</b> <i>url</i><br><br><b>Example:</b><br>Router (cs-server)# cdp-url http://my-cdp.company.com                    | (Optional) Defines the CDP location to be used in the certificates that are issued by the certificate server. <ul style="list-style-type: none"> <li>The URL must be an HTTP URL.</li> </ul> If you have PKI clients that are not running Cisco IOS software and that do not support a SCEP GetCRL request, use the following URL format:<br>http://server.company.com/certEnroll/filename.crl<br>Or, if your Cisco IOS certificate server is also configured as your CDP, use the following URL format<br>http://cs-addr/cgi-bin/pkiclient.exe?operation=GetCRL<br>where <i>cs-addr</i> is the location of the certificate server.<br><br><b>Note</b> Although this command is optional, it is strongly recommended for any deployment scenario. |
| Step 12 | <b>no shutdown</b><br><br><b>Example:</b><br>Router (cs-server)# no shutdown                                                 | Enables the certificate server.<br><br>You should issue this command only after you have completely configured your certificate server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Examples

The following example shows how to configure a CDP location where the PKI clients do not support SCEP GetCRL requests:

```
Router(config)# crypto pki server aaa
Router(cs-server)# database level minimum
Router(cs-server)# database url tftp://10.1.1.1/username1/
Router(cs-server)# issuer-name CN=aaa
Router(cs-server)# cdp-url http://server.company.com/certEnroll/aaa.crl
```

After a certificate server has been enabled on a router, the **show crypto pki server** command displays the following output:

```
Router# show crypto pki server

Certificate Server status:enabled, configured
Granting mode is:manual
Last certificate issued serial number:0x1
CA certificate expiration timer:19:31:15 PST Nov 17 2006
CRL NextUpdate timer:19:31:15 PST Nov 25 2003
Current storage dir:nvram:
Database Level:Minimum - no cert data written to storage
```

## Working with Automatic CA Certificate Rollover

This section describes different methods of initiating automatic CA certificate rollover on the server and obtaining rollover certificates. Use the following tasks as appropriate:

- [Starting Automated CA Certificate Rollover Immediately, page 28](#)
- [Requesting a Certificate Server Client's Rollover Certificate, page 28](#)
- [Exporting a CA Rollover Certificate, page 29](#)

### Starting Automated CA Certificate Rollover Immediately

Use this task to initiate the automated CA certificate rollover process immediately on your root CA server.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto pki server *cs-label* [rollover [cancel]]**

#### DETAILED STEPS

|--------|----------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                 | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                                                             |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                         | Enters global configuration mode.                                                                                                                                                               |
| Step 3 | <b>crypto pki server <i>cs-label</i> [rollover [cancel]]</b><br><br><b>Example:</b><br>Router(config)# crypto pki server mycs rollover | Immediately starts the CA certificate rollover process by generating a shadow CA certificate.<br><br>To delete the CA certificate rollover certificate and keys, use the <b>cancel</b> keyword. |

### Requesting a Certificate Server Client's Rollover Certificate

Use this task to request a certificate server client's rollover certificate.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto pki server *cs-label* [rollover request pkcs10 terminal]**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                      | Purpose                                                                                                          |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                 | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                         | Enters global configuration mode.                                                                                |
| Step 3 | <b>crypto pki server cs-label [rollover request pkcs10 terminal]</b><br><br><b>Example:</b><br>Router(config)# crypto pki server mycs rollover request pkcs10 terminal | Requests a client rollover certificate from the server.                                                          |

## Examples

The following example shows a rollover certificate request being inputted into the server:

```
Router# crypto pki server mycs rollover request pkcs10 terminal

% Enter Base64 encoded or PEM formatted PKCS10 enrollment request.

% End with a blank line or "quit" on a line by itself.

## Maintaining, Verifying, and Troubleshooting the Certificate Server, Certificates, and the CA

Use the tasks in this section to help maintain, verify, and troubleshoot the certificate server, certificates and the CA as appropriate:

- [Managing the Enrollment Request Database, page 30](#)
- [Removing Enrollment Requests from the Enrollment Request Database: Examples, page 38](#)
- [Deleting a Certificate Server, page 33](#)
- [Verifying and Troubleshooting Certificate Server and CA Status, page 34](#)
- [Verifying CA Certificate Information, page 34](#)

### Managing the Enrollment Request Database

SCEP supports two client authentication mechanisms—manual and preshared key. Manual enrollment requires the administrator at the CA server to specifically authorize the enrollment requests; enrollment using preshared keys allows the administrator to preauthorize enrollment requests by generating a one-time password (OTP).

Use any of the optional steps within this task to help manage the enrollment request database by performing functions such as specifying enrollment processing parameters that are to be used by SCEP and by controlling the run-time behavior of the certificate server.

## SUMMARY STEPS

1. **enable**
2. **crypto pki server cs-label grant {all | req-id}**
3. **crypto pki server cs-label reject {all | req-id}**
4. **crypto pki server cs-label password generate [minutes]**

5. **crypto pki server** *cs-label* **revoke** *certificate-serial-number*
6. **crypto pki server** *cs-label* **request pkcs10** {*url* | **terminal**} [**base64** | **pem**]
7. **crypto pki server** *cs-label* **info** **crl**
8. **crypto pki server** *cs-label* **info** **requests**

| Step 6 | <b>crypto pki server <i>cs-label</i> request pkcs10 {url   terminal} [base64   pem]</b><br><br><b>Example:</b><br>Router# crypto pki server mycs request pkcs10 terminal pem | Manually adds either a base64-encoded or PEM-formatted PKCS10 certificate enrollment request to the request database.<br><br>After the certificate is granted, it will be displayed on the console terminal using base64 encoding. <ul style="list-style-type: none"> <li>• <b>pem</b>—Specifies the certificate will be returned <i>with</i> PEM headers automatically added to the certificate after the certificate is granted, regardless of whether PEM headers were used in the request.</li> <li>• <b>base64</b>—Specifies the certificate will be returned <i>without</i> privacy-enhanced mail (PEM) headers, regardless of whether PEM headers were used in the request.</li> </ul> |
| Step 7 | <b>crypto pki server <i>cs-label</i> info crl</b><br><br><b>Example:</b><br>Router# crypto pki server mycs info crl                                                          | Displays information regarding the status of the current CRL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Step 8 | <b>crypto pki server <i>cs-label</i> info requests</b><br><br><b>Example:</b><br>Router# crypto pki server mycs info requests                                                | Displays all outstanding certificate enrollment requests.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Removing Requests from the Enrollment Request Database

After the certificate server receives an enrollment request, the server can leave the request in a pending state, reject it, or grant it. The request stays in the enrollment request database for 1 week until the client polls the certificate server for the result of the request. If the client exits and never polls the certificate server, you can remove either individual requests or all requests from the database.

Use this task to remove requests from the database and allow the server to be returned to a clean slate with respect to the keys and transaction IDs. Also, you can use this task to help troubleshoot a SCEP client that may not be behaving properly.

### SUMMARY STEPS

1. **enable**
2. **crypto pki server *cs-label* remove {all | req-id}**

## DETAILED STEPS

|        | Command or Action                                                                                                          | Purpose                                                                                                          |
|--------|----------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                     | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>crypto pki server cs-label remove {all   req-id}</b><br><br><b>Example:</b><br>Router# crypto pki server mycs remove 15 | Removes enrollment requests from the enrollment request database.                                                |

## Deleting a Certificate Server

Users can delete a certificate server from the PKI configuration if they no longer want it on the configuration. Typically, a subordinate certificate server or an RA is being deleted. However, users may delete a root certificate server if they are moving it to another device via the archived RSA keys.

Perform this task to delete a certificate server from your PKI configuration.

### Note

When a certificate server is deleted, the associated trustpoint and key are also deleted.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no crypto pki server cs-label**

## DETAILED STEPS

|        | Command or Action                                                                                         | Purpose                                                                                                          |
|--------|-----------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                    | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                            | Enters global configuration mode.                                                                                |
| Step 3 | <b>no crypto pki server cs-label</b><br><br><b>Example:</b><br>Router (config)# no crypto pki server mycs | Deletes a certificate server and associated trustpoint and key.                                                  |

## Verifying and Troubleshooting Certificate Server and CA Status

Use any of the following optional steps to verify the status of the certificate server or the CA.

### SUMMARY STEPS

1. **enable**
2. **debug crypto pki server**
3. **dir filesystem:**

### DETAILED STEPS

|        | Command or Action                                                                        | Purpose                                                                                                                                                                                                                                                                                                                                                 |
|--------|------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                   | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                                                                                                                                                                                                                     |
| Step 2 | <b>debug crypto pki server</b><br><br><b>Example:</b><br>Router# debug crypto pki server | Enables debugging for a crypto PKI certificate server.<br><ul style="list-style-type: none"><li>• This command can be used for monitoring the progress of an enrollment and for troubleshooting if the certificate server fails to respond or if the certificate server has trouble handling the request that has been configured.</li></ul>            |
| Step 3 | <b>dir filesystem:</b><br><br><b>Example:</b><br>Router# dir slot0:                      | Displays a list of files on a file system.<br><ul style="list-style-type: none"><li>• This command can be used to verify the certificate server autoarchived file if the <b>database url</b> command was entered to point to a local file system. You should be able to at least see “cs-label.ser” and “cs-label.crl” files in the database.</li></ul> |

## Verifying CA Certificate Information

To obtain information relating to the CA certificates including the certificate server rollover process, rollover certificates, and timers, you may use any of the following commands.

#### Note

These commands are not exclusive to shadow certificate information. If no shadow certificate exists, the following commands will simply display the active certificate information.

### SUMMARY STEPS

1. **crypto pki certificate chain name**
2. **crypto pki server cs-label info requests**
3. **show crypto pki certificates**
4. **show crypto pki server**
5. **show crypto pki trustpoints**

## DETAILED STEPS

- Step 1** The **crypto pki certificate chain** command can be used to view the certificate chain details and to distinguish the current active certificate from the rollover certificate in the certificate chain. The following example shows a certificate chain with an active CA certificate and a shadow, or rollover, certificate:

```
Router(config)# crypto pki certificate chain mica

certificate 06
certificate ca 01
! This is the peer's shadow PKI certificate.
certificate rollover 0B
! This is the CA shadow PKI certificate
certificate rollover ca 0A
```

- Step 2** The **crypto pki server info requests** command displays all outstanding certificate enrollment requests. The following example shows the output for shadow PKI certificate information requests:

```
Router# crypto pki server myca info requests

Enrollment Request Database:
RA certificate requests:

 ReqID State Fingerprint SubjectName

RA rollover certificate requests:

 ReqID State Fingerprint SubjectName

Router certificates requests:

 ReqID State Fingerprint SubjectName

1 pending A426AF07FE3A4BB69062E0E47198E5BF hostname=client

Router rollover certificates requests:

 ReqID State Fingerprint SubjectName

2 pending B69062E0E47198E5BFA426AF07FE3A4B hostname=client
```

- Step 3** The **show crypto pki certificates** command displays information about your certificate, the certification authority certificate, shadow certificates, and any registration authority certificates. The following example displays the certificate of the router and the certificate of the CA. There is no shadow certificate available. A single, general-purpose RSA key pair was previously generated, and a certificate was requested but not received for that key pair. Note that the certificate status of the router shows “Pending.” After the router receives its certificate from the CA, the Status field changes to “Available” in the **show** output.

```
Router# show crypto pki certificates

Certificate
Subject Name
 Name: myrouter.example.com
 IP Address: 192.0.2.1
 Serial Number: 04806682
Status: Pending
Key Usage: General Purpose
```

```

Fingerprint: 428125BD A3419600 3F6C7831 6CD8FA95 00000000
CA Certificate
Status: Available
Certificate Serial Number: 3051DF7123BEE31B8341DFE4B3A338E5F
Key Usage: Not Set

```

- Step 4** The **show crypto pki server** command displays the current state and configuration of the certificate server. The following example shows that the certificate server “routercs” has rollover configured. The CA auto-rollover time has occurred and the rollover, or shadow, PKI certificate is available. The status shows the rollover certificate fingerprint and rollover CA certificate expiration timer information.

```
Router# show crypto pki server
```

```

Certificate Server routercs:
 Status: enabled, configured
 Issuer name: CN=walnutcs
 CA cert fingerprint: 800F5944 74337E5B C2DF6C52 9A7B1BDB
 Granting mode is: auto
 Last certificate issued serial number: 0x7
 CA certificate expiration timer: 22:10:29 GMT Jan 29 2007
 CRL NextUpdate timer: 21:50:56 GMT Mar 5 2004
 Current storage dir: nvram:
 Database Level: Minimum - no cert data written to storage
Rollover status: available for rollover
 Rollover CA cert fingerprint: 6AAF5944 74227A5B 23DF3E52 9A7F1FEF
 Rollover CA certificate expiration timer: 22:10:29 GMT Jan 29 2017

```

- Step 5** The **show crypto pki trustpoints** command displays the trustpoints that are configured in the router. The following output shows that a shadow CA certificate is available and shows the SCEP capabilities reported during the last enrollment operation:

```
Router# show crypto pki trustpoints
```

```

Trustpoint vpn:
 Subject Name:
 cn=Cisco SSL CA
 o=Cisco Systems
 Serial Number: 0FFEBCDC1B6F6D9D0EA7875875E4C695
 Certificate configured.
 Rollover certificate configured.
 Enrollment Protocol:
 SCEPv1, PKI Rollover

```

## Configuration Examples for Using a Certificate Server

This section contains the following configuration examples:

- [Configuring Specific Storage and Publication Locations: Examples, page 37](#)
- [Removing Enrollment Requests from the Enrollment Request Database: Examples, page 38](#)
- [Autoarchiving the Certificate Server Root Keys: Examples, page 39](#)
- [Restoring a Certificate Server from Certificate Server Backup Files: Examples, page 41](#)
- [Subordinate Certificate Server: Example, page 43](#)
- [RA Mode Certificate Server: Example, page 45](#)
- [Enabling CA Certificate Rollover to Start Immediately: Example, page 47](#)

## Configuring Specific Storage and Publication Locations: Examples

The following example shows the configuration of a minimal local file system, so that the certificate server can respond quickly to certificate requests. The .ser and .crl files are stored on the local Cisco IOS file system for fast access, and a copy of all of the .crt files are published to a remote location for long-term logging.

```
crypto pki server myserver
 !Pick your database level.
 database level minimum
 !Specify a location for the .crt files that is different than the default local
 !Cisco IOS file system.
 database url crt publish http://url username user1 password secret
```

### Note

Free space on the local file system should be monitored, in case the .crl file becomes too large.

The following example shows the configuration of a primary storage location for critical files, a specific storage location for the critical file serial number file, the main certificate server database file, and a password protected file publication location for the CRL file:

```
Router(config)# crypto pki server mycs
Router(cs-server)# database url ftp://cs-db.company.com
!
% Server database url was changed. You need to move the
% existing database to the new location.
!
Router(cs-server)# database url ser nvram:
Router(cs-server)# database url crt publish ftp://crl.company.com username myname password
mypassword
Router(cs-server)# end
```

The following output displays the specified primary storage location and critical file storage locations specified:

```
Router# show
```

```
Sep 3 20:19:34.216: %SYS-5-CONFIG_I: Configured from console by user on console
```

```
Router# show crypto pki server
```

```
Certificate Server mycs:
 Status: disabled
 Server's configuration is unlocked (enter "no shut" to lock it)
 Issuer name: CN=mycs
 CA cert fingerprint: -Not found-
 Granting mode is: manual
 Last certificate issued serial number: 0x0
 CA certificate expiration timer: 00:00:00 GMT Jan 1 1970
 CRL not present.
 Current primary storage dir: ftp://cs-db.company.com
 Current storage dir for .ser files: nvram:
 Database Level: Minimum - no cert data written to storage
The following output displays all storage and publication locations. The serial number file (.ser) is stored in NVRAM. The CRL file will be published to ftp://crl.company.com with a username and password. All other critical files will be stored to the primary location, ftp://cs-db.company.com.
```

```
Router# show running-config
```

```
section crypto pki server
crypto pki server mycs shutdown database url ftp://cs-db.company.com
```

```

database url crl publish ftp://crl.company.com username myname password 7
12141C0713181F13253920
database url ser nvram:
Router#

```

## Removing Enrollment Requests from the Enrollment Request Database: Examples

The following examples show both the enrollment requests that are currently in the enrollment request database and the result after one of the enrollment requests has been removed from the database.

### Enrollment Request Currently in the Enrollment Request Database

The following example shows that the **crypto pki server info requests** command has been used to display the enrollment requests that are currently in the Enrollment Request Database:

```
Router# crypto pki server myserver info requests
```

Enrollment Request Database:

```

RA certificate requests:
ReqID State Fingerprint SubjectName

```

```

Router certificates requests:
ReqID State Fingerprint SubjectName

2 pending 1B07F3021DAAB0F19F35DA25D01D8567 hostname=host1.company.com
1 denied 5322459D2DC70B3F8EF3D03A795CF636 hostname=host2.company.com

```

### crypto pki server remove Command Used to Remove One Enrollment Request

The following example shows that the **crypto pki server remove** command has been used to remove Enrollment Request 1:

```
Router# crypto pki server myserver remove 1
```

### Enrollment Request Database After the Removal of One Enrollment Request

The following example shows the result of the removal of Enrollment Request 1 from the Enrollment Request Database:

```
Router# crypto pki server mycs info requests
```

Enrollment Request Database:

```

RA certificate requests:
ReqID State Fingerprint SubjectName

```

```

Router certificates requests:
ReqID State Fingerprint SubjectName

2 pending 1B07F3021DAAB0F19F35DA25D01D8567 hostname=host1.company.com

```

## Autoarchiving the Certificate Server Root Keys: Examples

The following output configurations and examples show what you might see if the **database archive** command has not been configured (that is, configured using the default value); if the **database archive** command has been configured to set the CA certificate and CA key archive format as PEM, without configuring a password; and if the **database archive** command has been configured to set the CA certificate and CA key archive format as PKCS12, with a password configured. The last example is sample content of a PEM-formatted archive file.

### database archive Command Not Configured

#### Note

The default is PKCS12, and the prompt for the password appears after the **no shutdown** command has been issued.

```
Router (config)# crypto pki server myserver
Router (cs-server)# no shutdown

% Generating 1024 bit RSA keys ...[OK]
% Ready to generate the CA certificate.
%Some server settings cannot be changed after CA certificate generation.

Are you sure you want to do this? [yes/no]: y
% Exporting Certificate Server signing certificate and keys...
! Note the next two lines, which are asking for a password.
% Please enter a passphrase to protect the private key.
Password:
% Certificate Server enabled.
Router (cs-server)# end

Router# dir nvram:

Directory of nvram:/

 125 -rw- 1693 <no date> startup-config
 126 --- 5 <no date> private-config
 1 -rw- 32 <no date> myserver.ser
 2 -rw- 214 <no date> myserver.crl
! Note the next line, which indicates PKCS12 format.
 3 -rw- 1499 <no date> myserver.p12
```

### database archive Command and pem Keyword Configured

#### Note

The prompt for the password appears after the **no shutdown** command has been issued.

```
Router (config)# crypto pki server myserver
Router (cs-server)# database archive pem
Router (cs-server)# no shutdown

% Generating 1024 bit RSA keys ...[OK]
% Ready to generate the CA certificate.
%Some server settings cannot be changed after CA certificate generation.

Are you sure you want to do this? [yes/no]: y
% Exporting Certificate Server signing certificate and keys...
!Note the next two lines, which are asking for a password.
% Please enter a passphrase to protect the private key.
Password:
```

```
% Certificate Server enabled.
Router (cs-server)# end

Router# dir nvram

Directory of nvram:/

 125 -rw- 1693 <no date> startup-config
 126 ---- 5 <no date> private-config
 1 -rw- 32 <no date> myserver.ser
 2 -rw- 214 <no date> myserver.crl
! Note the next line showing that the format is PEM.
 3 -rw- 1705 <no date> myserver.pem
```

### database archive Command and pkcs12 Keyword (and Password) Configured

#### Note

When the password is entered, it will be encrypted. However, it is recommended that you remove the password from the configuration after the archive has finished.

```
Router (config)# crypto pki server myserver
Router (cs-server)# database archive pkcs12 password cisco123
Router (cs-server)# no shutdown

% Generating 1024 bit RSA keys ...[OK]
% Ready to generate the CA certificate.
% Some server settings cannot be changed after CA certificate generation.

Are you sure you want to do this? [yes/no]: y
% Exporting Certificate Server signing certificate and keys...
! Note that you are not being prompted for a password.
% Certificate Server enabled.
Router (cs-server)# end
Router# dir nvram:
Directory of nvram:/

 125 -rw- 1693 <no date> startup-config
 126 ---- 5 <no date> private-config
 1 -rw- 32 <no date> myserver.ser
 2 -rw- 214 <no date> myserver.crl
! Note that the next line indicates that the format is PKCS12.
 3 -rw- 1499 <no date> myserver.p12
```

### PEM-Formatted Archive

The following sample output shows that autoarchiving has been configured in PEM file format. The archive consists of the CA certificate and the CA private key. To restore the certificate server using the backup, you would have to import the PEM-formatted CA certificate and CA key individually.

#### Note

In addition to the CA certificate and CA key archive files, you should also back up the serial file (.ser) and the CRL file (.crl) regularly. The serial file and the CRL file are both critical for CA operation if you need to restore your certificate server.

```
Router# more nvram:mycs.pem

```

## Restoring a Certificate Server from Certificate Server Backup Files: Examples

The following example shows that restoration is from a PKCS12 archive and that the database URL is NVRAM (the default).

```
Router# copy tftp://192.0.2.71/backup.ser nvram:mycs.ser
Destination filename [mycs.ser]?
```

32 bytes copied in 1.320 secs (24 bytes/sec)

```
Router# copy tftp://192.0.2.71/backup.crl nvram:mycs.crl
Destination filename [mycs.crl]?
```

214 bytes copied in 1.324 secs (162 bytes/sec)

```
Router# configure terminal
```

```
Router (config)# crypto pki import mycs pkcs12 tftp://192.0.2.71/backup.p12 cisco123
```

```
Source filename [backup.p12]?
```

```
CRYPTO_PKI: Imported PKCS12 file successfully.
```

```
Router (config)# crypto pki server mycs
```

```
! fill in any certificate server configuration here
```

```
Router (cs-server)# no shutdown
```

```
% Certificate Server enabled.
```

```
Router (cs-server)# end
```

```
Router# show crypto pki server
```

```
Certificate Server mycs:
```

```
Status: enabled
```

```
Server's current state: enabled
```

```
Issuer name: CN=mycs
```

```
CA cert fingerprint: 34885330 B13EAD45 196DA461 B43E813F
```

```
Granting mode is: manual
```

```
Last certificate issued serial number: 0x1
```

```

CA certificate expiration timer: 01:49:13 GMT Aug 28 2007
CRL NextUpdate timer: 01:49:16 GMT Sep 4 2004
Current storage dir: nvram:
Database Level: Minimum - no cert data written to storage

```

The following example shows that restoration is from a PEM archive and that the database URL is flash:

```

Router# copy tftp://192.0.2.71/backup.ser flash:mycs.ser
Destination filename [mycs.ser]?
32 bytes copied in 1.320 secs (24 bytes/sec)
Router# copy tftp://192.0.2.71/backup.crl flash:mycs.crl
Destination filename [mycs.crl]?
214 bytes copied in 1.324 secs (162 bytes/sec)
Router# configure terminal
! Because CA cert has Digital Signature usage, you need to import using the "usage-keys"
keyword
Router (config)# crypto ca import mycs pem usage-keys terminal cisco123
% Enter PEM-formatted CA certificate.
% End with a blank line or "quit" on a line by itself.
! Paste the CA cert from .pem archive.

```

## Root Certificate Server Differentiation: Example

When issuing certificates, the root certificate server (or parent subordinate certificate server) will differentiate the certificate request from “Sub CA,” “RA,” and peer requests, as shown in the following sample output:

```
Router# crypto pki server server1 info req
```

```
Enrollment Request Database:
```

```
RA certificate requests:
```

| ReqID | State | Fingerprint | SubjectName |
|-------|-------|-------------|-------------|
| ----- |       |             |             |

```
Subordinate CS certificate requests:
```

| ReqID | State   | Fingerprint                      | SubjectName                     |
|-------|---------|----------------------------------|---------------------------------|
| ----- |         |                                  |                                 |
| 1     | pending | CB9977AD8A73B146D3221749999B0F66 | hostname=host-subcs.company.com |

```

RA certificate requests:
ReqID State Fingerprint SubjectName

Router certificate requests:
ReqID State Fingerprint SubjectName

```

## Show Output for a Subordinate Certificate Server: Example

The following **show crypto pki server** command output indicates that a subordinate certificate server has been configured:

```

Router# show crypto pki server

Certificate Server sub:
 Status: enabled
 Server's configuration is locked (enter "shut" to unlock it)
 Issuer name: CN=sub
 CA cert fingerprint: 11B586EE 3B354F33 14A25DDD 7BD39187
 Server configured in subordinate server mode
 Upper CA cert fingerprint: 328ACC02 52B25DB8 22F8F104 B6055B5B
 Granting mode is: manual
 Last certificate issued serial number: 0x1
 CA certificate expiration timer: 22:33:44 GMT Jan 6 2006
 CRL NextUpdate timer: 22:33:29 GMT Jan 13 2005
 Current storage dir: nvram:
 Database Level: Minimum - no cert data written to storage

```

## RA Mode Certificate Server: Example

The following output is typical of what you might see after having configured an RA mode certificate server:

```

Router-ra (config)# crypto pki trustpoint myra
Router-ra (ca-trustpoint)# enrollment url http://192.0.2.17
! Include "cn=ioscs RA" or "ou=ioscs RA" in the subject-name.
Router-ra (ca-trustpoint)# subject-name cn=myra, ou=ioscs RA, o=company, c=us
Router-ra (ca-trustpoint)# exit
Router-ra (config)# crypto pki server myra
Router-ra (cs-server)# mode ra
Router-ra (cs-server)# no shutdown
% Generating 1024 bit RSA keys ...[OK]

Certificate has the following attributes:
Fingerprint MD5: 32661452 0DDA3CE5 8723B469 09AB9E85
Fingerprint SHA1: 9785BB CD 6C67D27C C950E8D0 718C7A14 C0FE9C38
% Do you accept this certificate? [yes/no]: yes
Trustpoint CA certificate accepted.
% Ready to request the CA certificate.
%Some server settings cannot be changed after the CA certificate has been requested.

Are you sure you want to do this? [yes/no]: yes
%
% Start certificate enrollment ..
% Create a challenge password. You will need to verbally provide this
 password to the CA administrator in order to revoke your certificate.
 For security reasons your password will not be saved in the configuration.
 Please make a note of it.

```

```

Password:
Re-enter password:

% The subject name in the certificate will include: cn=myra, ou=ioscs RA, o=company, c=us
% The subject name in the certificate will include: Router-ra.company.com
% Include the router serial number in the subject name? [yes/no]: no
% Include an IP address in the subject name? [no]: no
Request certificate from CA? [yes/no]: yes
% Certificate request sent to Certificate Authority
% The certificate request fingerprint will be displayed.
% The 'show crypto pki certificate' command will also show the fingerprint.

% Enrollment in progress...
Router-ra (cs-server)#
Sep 15 22:32:40.197: CRYPTO_PKI: Certificate Request Fingerprint MD5: 82B41A76 AF4EC87D
AAF093CD 07747D3A
Sep 15 22:32:40.201: CRYPTO_PKI: Certificate Request Fingerprint SHA1: 897CDF40 C6563EAA
0FED05F7 0115FD3A 4FFC5231
Sep 15 22:34:00.366: %PKI-6-CERTRET: Certificate received from Certificate Authority
Router-ra (cs-server)#
Router-ra(cs-server)# end

```

```
Router-ra# show crypto pki server
```

```

Certificate Server myra:
 Status: enabled
 Issuer name: CN=myra
 CA cert fingerprint: 32661452 0DDA3CE5 8723B469 09AB9E85
 ! Note that the certificate server is running in RA mode
 Server configured in RA mode
 RA cert fingerprint: C65F5724 0E63B3CC BE7AE016 BE0D34FE
 Granting mode is: manual
 Current storage dir: nvram:
 Database Level: Minimum - no cert data written to storage

```

The following output shows the enrollment request database of the issuing certificate server after the RA has been enabled:

#### Note

The RA certificate request is recognized by the issuing certificate server because "ou=ioscs RA" is listed in the subject name.

```

Router-ca# crypto pki server mycs info request
Enrollment Request Database:

Subordinate CA certificate requests:
ReqID State Fingerprint SubjectName

! The request is identified as RA certificate request.
RA certificate requests:
ReqID State Fingerprint SubjectName

12 pending 88F547A407FA0C90F97CDE8900A30CB0
hostname=Router-ra.company.com,cn=myra,ou=ioscs RA,o=company,c=us

```

```
Router certificates requests:
ReqID State Fingerprint SubjectName

```

```
! Issue the RA certificate.
Router-ca# crypto pki server mycs grant 12
```

The following output shows that the issuing certificate server is configured to issue a certificate automatically if the request comes from an RA:

```
Router-ca(config)# crypto pki server mycs
Router-ca (cs-server)# grant ra-auto
% This will cause all certificate requests already authorized by known RAs to be
automatically granted.

Are you sure you want to do this? [yes/no]: yes
Router-ca (cs-server)# end
Router-ca# show crypto pki server

Certificate Server mycs:
 Status: enabled
 Server's current state: enabled
 Issuer name: CN=mycs
 CA cert fingerprint: 32661452 0DDA3CE5 8723B469 09AB9E85
 ! Note that the certificate server will issue certificate for requests from the RA.
 Granting mode is: auto for RA-authorized requests, manual otherwise
 Last certificate issued serial number: 0x2
 CA certificate expiration timer: 22:29:37 GMT Sep 15 2007
 CRL NextUpdate timer: 22:29:39 GMT Sep 22 2004
 Current storage dir: nvram:
 Database Level: Minimum - no cert data written to storage
```

The following example shows the configuration of “myra”, an RA server, configured to support automatic rollover from “myca”, the CA. After the RA server is configured, automatic granting of certificate reenrollment requests is enabled:

```
crypto pki trustpoint myra
 enrollment url http://myca
 subject-name ou=iosca RA
 rsa-keypair myra
crypto pki server myra
 mode ra
 auto-rollover

crypto pki server mycs
 grant auto rollover ra-cert
 auto-rollover 25
```

## Enabling CA Certificate Rollover to Start Immediately: Example

The following example shows how to enable automated CA certificate rollover on the server mycs with the **crypto pki server** command. The **show crypto pki server** command then shows the current state of the mycs server and that the rollover certificate is currently available for rollover.

```
Router(config)# crypto pki server mycs rollover

Jun 20 23:51:21.211:%PKI-4-NOSHADOWAUTOSAVE:Configuration was
modified. Issue "write memory" to save new IOS CA certificate
```

```
! The config has not been automatically saved because the config has been changed.
```

```
Router# show crypto pki server
```

```
Certificate Server mycs:
 Status:enabled
 Server's configuration is locked (enter "shut" to unlock it)
 Issuer name:CN=mycs
 CA cert fingerprint:E7A5FABA 5D7AA26C F2A9F7B3 03CE229A
 Granting mode is:manual
 Last certificate issued serial number:0x2
 CA certificate expiration timer:00:49:26 PDT Jun 20 2008
 CRL NextUpdate timer:00:49:29 PDT Jun 28 2005
 Current storage dir:nvram:
 Database Level:Minimum - no cert data written to storage
 Rollover status:available for rollover
 ! Rollover certificate is available for rollover.
 Rollover CA certificate fingerprint:9BD7A443 00A6DD74 E4D9ED5F B7931BE0
 Rollover CA certificate expiration time:00:49:26 PDT Jun 20 2011
 Auto-Rollover configured, overlap period 25 days
```

## Where to Go Next

After the certificate server is successfully running, you can either begin enrolling clients via manual mechanisms (as explained in the module “Configuring Certificate Enrollment for a PKI”) or begin configuring SDP, which is a web-based enrollment interface, (as explained in the module “Setting Up Secure Device Provisioning (SDP) for Enrollment in a PKI.”)

## Additional References

The following sections provide references related to Cisco IOS certificate server.

# Feature Information for the Cisco IOS Certificate Server

Table 4 lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table.

For information on a feature in this technology that is not documented here, see the “[Implementing and Managing PKI Features Roadmap](#).”

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

**Note**

Table 4 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 4** Feature Information for the Cisco IOS Certificate Server

| Feature Name                                 | Releases  | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Cisco IOS USB Token PKI Enhancements—Phase 2 | 12.4(11)T | <p>This feature enhances USB token functionality by using the USB token as a cryptographic device. USB tokens may be used for RSA operations such as key generation, signing, and authentication.</p> <p>The following sections in this document provide information about this feature:</p> <ul style="list-style-type: none"> <li><a href="#">RSA Key Pair and Certificate of the Certificate Server</a></li> <li><a href="#">Trustpoint of the Certificate Server</a></li> <li><a href="#">Generating a Certificate Server RSA Key Pair</a></li> </ul> <p><b>Note</b> This document covers the use of using USB tokens for RSA operations during certificate server configuration. For other documents on this topic, see the “<a href="#">The following sections provide references related to Cisco IOS certificate server.Related Documents</a>” section.</p> |
| IOS Certificate Server (CS) Split Database   | 12.4(4)T  | <p>This feature allows the user to set storage locations and publish locations for specific certificate server file types.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li><a href="#">Certificate Server Database</a></li> <li><a href="#">Configuring Certificate Server Functionality</a></li> <li><a href="#">Configuring Specific Storage and Publication Locations: Examples</a></li> </ul> <p>The following command was modified by this feature:<br/><b>database url</b></p>                                                                                                                                                                                                                                                                                                               |

**Table 4** *Feature Information for the Cisco IOS Certificate Server (continued)*

| Feature Name                                             | Releases | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------------------------------------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Subordinate/RA Mode IOS Certificate Server (CS) Rollover | 12.4(4)T | <p>This feature expands on Certificate Authority (CA) Key Rollover introduced in 12.4(2)T to allow CA certificate rollover for subordinate CAs and RA-mode CAs. This functionality allows the rollover expiring CA certificates and keys and to have these changes propagate through the PKI network without manual intervention.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">Automatic CA Certificate and Key Rollover</a></li> <li>• <a href="#">Configuring Certificate Servers</a></li> <li>• <a href="#">RA Mode Certificate Server: Example</a></li> </ul> <p>The following command was modified by this feature:<br/><b>grant auto rollover</b></p>                                                                                                                                                                                                                                    |
| Certificate Authority (CA) Key Rollover                  | 12.4(2)T | <p>This feature introduces the ability for root or subordinate CAs to roll over expiring CA certificates and keys and to have these changes propagate through the PKI network without manual intervention.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">Automatic CA Certificate and Key Rollover</a></li> <li>• <a href="#">Configuring Certificate Servers</a></li> <li>• <a href="#">Working with Automatic CA Certificate Rollover</a></li> <li>• <a href="#">Enabling CA Certificate Rollover to Start Immediately: Example</a></li> </ul> <p>The following commands were introduced or modified by this feature: <b>auto-rollover</b>, <b>crypto pki certificate chain</b>, <b>crypto pki export pem</b>, <b>crypto pki server info request</b>, <b>crypto pki server</b>, <b>show crypto pki certificates</b>, <b>show crypto pki server</b>, and <b>show crypto pki trustpoint</b></p> |
| Cisco IOS Certificate Server                             | 12.3(8)T | <p>This feature introduces support for the Cisco IOS certificate server, which offers users a CA that is directly integrated with Cisco IOS software to more easily deploy basic PKI networks.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">Information About Cisco IOS Certificate Servers</a></li> <li>• <a href="#">How to Set Up and Deploy a Cisco IOS Certificate Server</a></li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Table 4** *Feature Information for the Cisco IOS Certificate Server (continued)*

| Feature Name                                                        | Releases                 | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| The Certificate Server Auto Archive Enhancement <sup>1</sup>        | 12.3(11)T                | <p>This enhancement enables the CA certificate and CA key to be backed up automatically just once after they are generated by the certificate server. As a result, it is not necessary to generate an exportable CA key if CA backup is desirable.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li><a href="#">Certificate Enrollment Using a Certificate Server</a></li> <li><a href="#">Configuring Certificate Server Functionality</a></li> </ul> <p>The following commands were introduced by this feature:<br/><b>crypto pki server remote, database archive</b></p> |
| The Certificate Server Registration Authority (RA) Mode enhancement | 12.3(7)T                 | <p>A certificate server can be configured to run in RA mode.</p> <p>The following section provides information about this feature:</p> <ul style="list-style-type: none"> <li><a href="#">Configuring a Certificate Server to Run in RA Mode</a></li> </ul> <p>The following commands were introduced by this feature:<br/><b>grant ra-auto, lifetime enrollment-requests</b></p>                                                                                                                                                                                                                                                           |
| PKI Status <sup>1</sup>                                             | 12.3(11)T                | <p>This enhancement provides a quick snapshot of current trustpoint status.</p> <p>The following section provides information about this enhancement:</p> <ul style="list-style-type: none"> <li><a href="#">Maintaining, Verifying, and Troubleshooting the Certificate Server, Certificates, and the CA</a></li> </ul> <p>The following command was modified by this enhancement: <b>show crypto pki trustpoints</b></p>                                                                                                                                                                                                                  |
| Subordinate Certificate Server <sup>1</sup>                         | 12.3(14)T                | <p>This enhancement allows you to configure a subordinate certificate server to grant all or certain SCEP or manual certificate requests.</p> <p>The following section provides information about this enhancement:</p> <ul style="list-style-type: none"> <li><a href="#">Configuring a Subordinate Certificate Server</a></li> </ul> <p>The following command was introduced by this enhancement: <b>mode sub-cs</b></p>                                                                                                                                                                                                                  |
| Cisco IOS Certificate Server                                        | Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Trustpoint CLI                                                      | Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

1. This is a minor enhancement. Minor enhancements are not typically listed in Feature Navigator.

# Storing PKI Credentials

---

**First Published: May 2, 2005**

**Last Updated: August 21, 2007**

This module explains how to store public key infrastructure (PKI) credentials, such as Rivest, Shamir, and Adelman (RSA) keys and certificates in a specific location.

An example of a certificate storage location includes NVRAM, which is the default location, and other local storage locations, such as flash, as supported by your platform.

An example of an RSA key and certificate storage location includes a USB token. Selected Cisco platforms support smart card technology in a USB key form factor (such as an Aladdin USB eToken key). USB tokens provide secure configuration distribution, provide RSA operations such as on-token key generation, signing, and authentication, and allow users to store Virtual Private Network (VPN) credentials for deployment.

## Finding Feature Information in This Module

*Your Cisco IOS software release may not support all of the features documented in this module.* To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for Storing PKI Credentials](#)” section on page 25.

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

- [Feature Information for Storing PKI Credentials, page 25](#)

## Prerequisites for Storing PKI Credentials

### Prerequisites for Specifying a Local Certificate Storage Location

Before you can specify the local certificate storage location, your system should meet the following requirements:

- A Cisco IOS Release 12.4(2)T PKI-enabled image or a later image
- A platform that supports storing PKI credentials as separate files
- A configuration that contains at least one certificate
- An accessible local file system

### Prerequisites for Specifying USB Token Storage for PKI Credentials

Before you can use a USB token, your system should meet the following requirements:

- A Cisco 871 router, Cisco 1800 series, Cisco 2800 series, a Cisco 3800 series router, or a Cisco 7200VXR NPE-G2 platform
- At least a Cisco IOS Release 12.3(14)T image running on any of the supported platforms
- A Cisco supported USB token
- A k9 image

## Restrictions for Storing PKI Credentials

### Restrictions for Specifying a Local Certificate Storage Location

When storing certificates to a local storage location, the following restrictions are applicable:

- Only local file systems may be used. An error message will be displayed if a remote file system is selected, and the command will not take effect.
- A subdirectory may be specified if supported by the local file system. NVRAM does not support subdirectories.

### Restrictions for Specifying USB Token Storage

When using a USB token to store PKI data, the following restrictions are applicable:

- USB token support requires a 3DES (k9) Cisco IOS software image, which provides secure file storage.
- You cannot boot an image from a USB token. (However, you can boot a configuration from a USB token.)
- USB hubs are currently not supported. Thus, the number of supported devices is limited to the number of available USB ports.

# Information About Storing PKI Credentials

To determine where to store PKI credentials, you should understand the following concepts:

- [Storing Certificates to a Local Storage Location, page 3](#)
- [PKI Credentials and USB Tokens, page 3](#)

## Storing Certificates to a Local Storage Location

Certificates are stored to NVRAM by default, however some routers do not have the required amount of NVRAM to successfully store certificates. Introduced in Cisco IOS Release 12.4(2)T is the ability to specify where certificates are stored on a local file system.

All Cisco platforms support NVRAM and flash local storage. Depending on your platform, you may have other supported local storage options including bootflash, slot, disk, USB flash, or USB token.

During run time, you can specify what active local storage device you would like to use to store certificates.

## PKI Credentials and USB Tokens

To use a secure USB token on your router, you should understand the following concepts:

- [How a USB Token Works, page 3](#)
- [Benefits of USB Tokens, page 4](#)

### How a USB Token Works

A smart card is a small plastic card, containing a microprocessor and memory that allows you to store and process data. A USB token is a smart card with a USB interface. The token can securely store any type of file within its available storage space (32 KB). Configuration files that are stored on the USB token can be encrypted and accessed only via a user PIN. The router will not load the configuration file unless the proper PIN has been configured for secure deployment of router configuration files.

After you plug the USB token into the router, you must log into the USB token; thereafter, you can change default settings, such as the user PIN (default: 1234567890) and the allowed number of failed login attempts (default: 15 attempts) before future logins are refused. For more information on accessing and configuring the USB token, see the section “[Logging Into and Setting Up the USB Token.](#)”

After you have successfully logged into the USB token, you can copy files from the router on to the USB token via the **copy** command. USB token RSA keys and associated IPsec tunnels remain available until the router is reloaded. To specify the length of time before the keys are removed and the IPsec tunnels are torn down, issue the **crypto pki token removal timeout** command.

[Table 1](#) highlights the capabilities of the USB token.

**Table 1**      **Functionality Highlights for USB Tokens**

| Function      | USB Token                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------|
| Accessibility | Used to securely store and transfer digital certificates, preshared keys, and router configurations from the USB token to the router. |
| Storage Size  | 32 KB                                                                                                                                 |

**Table 1**      **Functionality Highlights for USB Tokens (continued)**

| Function                   | USB Token                                                                                                                                                                                                                                                                                                      |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>File Types</b>          | <ul style="list-style-type: none"> <li>Typically used to store digital certificates, preshared keys, and router configurations for IPsec VPNs.</li> <li>USB tokens cannot store Cisco IOS images.</li> </ul>                                                                                                   |
| <b>Security</b>            | <ul style="list-style-type: none"> <li>Files can be encrypted and accessed only with a user PIN.</li> <li>Files can also be stored in a nonsecure format.</li> </ul>                                                                                                                                           |
| <b>Boot Configurations</b> | <ul style="list-style-type: none"> <li>The router can use the configuration stored in the USB token during boot time.</li> <li>The router can use the secondary configuration stored in the USB token during boot time. (A secondary configuration allows users to load their IPsec configuration.)</li> </ul> |

## Benefits of USB Tokens

USB token support on a Cisco router provides the following application benefits:

### **Removable Credentials: Provide or Store VPN Credentials on an External Device for Deployment**

A USB token can use smart card technology to store a digital certificate and configuration for IPsec VPN deployment. This ability enhances the capability of the router to generate RSA public keys to authenticate at least one IPsec tunnel. (Because a router can initiate multiple IPsec tunnels, the USB token can contain several certificates, as appropriate.)

Storing VPN credentials on an external device reduces the threat of compromising secure data.

### **PIN Configuration for Secure File Deployment**

A USB token can store a configuration file that can be used for enabling encryption on the router via a user-configured PIN. (That is, no digital certificates, preshared keys, or VPNs are used.)

### **Touchless or Low Touch Configuration**

The USB token can provide remote software configuration and provisioning with little or no human interaction. Configuration is set up as an automated process. That is, the USB token can store a bootstrap configuration that the router can use to boot from after the USB token has been inserted into the router. The bootstrap configuration connects the router to a TFTP server, which contains a configuration that completely configures the router.

### **RSA Operations**

As of Cisco IOS Release 12.4(11)T and later releases, a USB token may be used as a cryptographic device in addition to a storage device. Using a USB token as a cryptographic device allows RSA operations such as key generation, signing, and authentication to be performed on the token.

General-purpose, special-usage, encryption, or signature RSA key pairs with a modulus of 2048 bits or less may be generated from credentials located on your token storage device. Private keys are not distributed and remain on the token by default, however you may configure the private key storage location.

Keys that reside on a USB token are saved to persistent token storage when they are generated. Key deletion will remove the keys stored on the token from persistent storage immediately. (Keys that do not reside on a token are saved to or deleted from nontoken storage locations when the **write memory** or a similar command is issued.)

Remote Device Configuration and Provisioning in a Secure Device Provisioning (SDP) Environment

As of Cisco IOS Release 12.4(15)T and later releases, SDP may be used to configure a USB token. The configured USB token may be transported to provision a device at a remote location. That is, a USB token may be used to transfer cryptographic information from one network device to another remote network device providing a solution for a staged USB token deployment.

For information about using USB tokens with SDP, see document titles in the “[Related Documents](#)” section.

## How to Configure PKI Storage

This section contains the following configuration tasks:

- [Specifying a Local Storage Location for Certificates, page 5](#)
- [Setting Up and Using USB Tokens on Cisco Routers, page 6](#)
- [Troubleshooting USB Tokens, page 16](#)

### Specifying a Local Storage Location for Certificates

The following procedure allows you to specify the local storage location for certificates.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. `crypto pki certificate storage location-name`
4. `exit`
5. **copy** *source-url destination-url*
6. `show crypto pki certificates storage`

## DETAILED STEPS

|        | Command or Action                                                                                                                                   | Purpose                                                                                                                                                                                          |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                              | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>Enter your password if prompted.</li></ul>                                                                                |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                      | Enters global configuration mode.                                                                                                                                                                |
| Step 3 | <b>crypto pki certificate storage</b> <i>location-name</i><br><br><b>Example:</b><br>Router(config)# crypto pki certificate storage<br>flash:/certs | Specifies the local storage location for certificates.                                                                                                                                           |
| Step 4 | <b>exit</b><br><br><b>Example:</b><br>Router(config)# exit                                                                                          | Exits global configuration mode.                                                                                                                                                                 |
| Step 5 | <b>copy</b> <i>source-url destination-url</i><br><br><b>Example:</b><br>Router# copy system:running-config<br>nvram:startup-config                  | (Optional) Saves the running configuration to the startup configuration.<br><br><b>Note</b> Settings will only take effect when the running configuration is saved to the startup configuration. |
| Step 6 | <b>show crypto pki certificates storage</b><br><br><b>Example:</b><br>Router# show crypto pki certificates storage                                  | (Optional) Displays the current setting for the PKI certificate storage location.                                                                                                                |

## Examples

The following is sample output for the **show crypto pki certificates storage** command where the certificates are stored in the certs subdirectory of disk0:

```
Router# show crypto pki certificates storage
```

```
Certificates will be stored in disk0:/certs/
```

## Setting Up and Using USB Tokens on Cisco Routers

This section contains the following procedures that allow you to configure a router to support USB tokens:

- [Storing the Configuration on a USB Token, page 7](#)
- [Logging Into and Setting Up the USB Token, page 7](#)
- [Configuring the USB Token, page 10](#)
- [Setting Administrative Functions on the USB Token, page 13](#)

## Storing the Configuration on a USB Token

Perform this task to store the configuration file in a USB token.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **boot config usbtoken[0-9]:filename**

### DETAILED STEPS

|        | Command or Action                                                                                              | Purpose                                                                                                          |
|--------|----------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                         | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                 | Enters global configuration mode.                                                                                |
| Step 3 | <b>boot config usbtoken[0-9]:filename</b><br><br><b>Example:</b><br>Router(config)# boot config usbtoken0:file | Specifies that the startup configuration file is stored in a secure USB token.                                   |

## Logging Into and Setting Up the USB Token

Perform this task to log into and to perform the initial set up of a USB token.

### Use of RSA Keys with a USB Token

- RSA keys are loaded after the USB token is successfully logged into the router.
- By default, newly generated RSA keys are stored on the most recently inserted USB token. Regenerated keys should be stored in the same location where the original RSA key was generated.

### Automatic Login

Automatic login allows the router to completely come back up without any user or operator intervention. The PIN is stored in the private NVRAM, so it is not visible in the startup or running configuration.

#### Note

A hand-generated startup configuration can contain the automatic login command for deployment purposes, but the **copy system:running-config nvram: startup-config** command must be issued to put the hand-generated configuration in the private configuration.

### Manual Login

Unlike automatic login, manual login requires that the user know the actual USB token PIN.

Manual login can be used when storing a PIN on the router is not desirable. Manual login may also be suitable for some initial deployment or hardware replacement scenarios for which the router is obtained from the local supplier or drop-shipped to the remote site. Manual login can be executed with or without privileges, and it will make files and RSA keys on the USB token available to the Cisco IOS software. If a secondary configuration file is configured, it will be executed only with the privileges of the user who is performing the login. Thus, if you want to use manual login and set up the secondary configuration on the USB token to perform anything useful, you need to enable privileges.

Manual login can also be used in recovery scenarios for which the router configuration has been lost. If the scenario contains a remote site that normally connects to the core network with a VPN, the loss of the configuration and RSA keys requires out-of-band services that the USB token can provide. The USB token can contain a boot configuration, a secondary configuration, or both, and RSA keys to authenticate the connection.

## SUMMARY STEPS

1. **enable**
2. **crypto pki token** *token-name* [**admin**] **login** [*pin*]  
or  
**configure terminal**
3. **crypto pki token** *token-name* **user-pin** [*pin*]
4. **exit**
5. **show usbtokens** [*0-9*]:*filename*

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                                            |

## What to Do Next

After you have logged into the USB token, it is available for use.

- To further configure the USB token, see the “[Configuring the USB Token](#)” section.
- To perform USB token administrative tasks, such as changing the user PIN, copying files from the router to the USB token set key storage location, and changing USB tokens, see the “[Setting Administrative Functions on the USB Token](#)” section.
- To utilize the USB token as a cryptographic device to perform RSA operations, see the document titles in the “[Related Documents](#)” section.
- To specify that the USB token be used for RSA operations during initial autoenrollment, see the document titles in the “[Related Documents](#)” section.

## Configuring the USB Token

After you have set up automatic login, you may perform this task to further configure the USB token.

### PINs and Passphrases

For additional PIN security with automatic login, you may encrypt your PIN stored in NVRAM and set up a passphrase for your USB token. Establishing a passphrase allows you to keep your PIN secure; another user needs only to know the passphrase, not the PIN.

When the USB token is inserted into the router, the passphrase is needed to decrypt the PIN. Once the PIN is decrypted, the router can then use the PIN to login the USB token.

**Note**

---

The user has only the access they would normally have and needs only privilege level 1 to log in.

---

### Unlocking and Locking the USB Token

The USB token itself can be locked (encrypted) or unlocked (decrypted).

Unlocking the USB token allows it to be used. Once unlocked, Cisco IOS treats the token as if it were automatically logged in. Any keys on the USB token are loaded, and if a secondary configuration file is on the token, it is executed with full user privileges (privilege level 15) independent of the privilege level of the logged-in user.

Locking the token, unlike logging out of the token, deletes any RSA keys loaded from the token and runs the secondary unconfiguration file, if configured.

### Secondary Configuration and Unconfiguration Files

Configuration files that exist on a USB token are called secondary configuration files. If you create and configure a secondary configuration file, it is executed after the token is logged in. The existence of a secondary configuration file is determined by the presence of a secondary configuration file option in the Cisco IOS configuration stored in NVRAM. When the token is removed or logged out and the removal timer expires, a separate secondary unconfiguration file is processed to remove all secondary configuration elements from the running configuration. Secondary configuration and secondary unconfiguration files are executed at privilege level 15 and are not dependent on the level of the user logged in.

### SUMMARY STEPS

1. **enable**
2. **crypto pki token *token-name* unlock [*pin*]**
3. **configure terminal**
4. **crypto pki token *token-name* encrypted-user-pin [write]**
5. **crypto pki token *token-name* secondary unconfig *file***
6. **exit**
7. **crypto pki token *token-name* lock [*pin*]**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                           | Purpose                                                                                                                                                                                                                                                             |

| Step 4 | <b>crypto pki token token-name encrypted-user-pin [write]</b><br><br><b>Example:</b><br>Router(config)# crypto pki token mytoken encrypted-user-pin write                   | (Optional) Encrypts the stored PIN in NVRAM.                                                                                                                                                                                                                        |
| Step 5 | <b>crypto pki token token-name secondary unconfig file</b><br><br><b>Example:</b><br>Router(config)# crypto pki token mytoken secondary unconfig configs/myunconfigfile.cfg | (Optional) Specifies the secondary configuration file and its location.                                                                                                                                                                                             |
| Step 6 | <b>exit</b><br><br><b>Example:</b><br>Router(config)# exit                                                                                                                  | Enters privileged EXEC mode.                                                                                                                                                                                                                                        |
| Step 7 | <b>crypto pki token token-name lock [pin]</b><br><br><b>Example:</b><br>Router# crypto pki token mytoken lock mypin                                                         | (Optional) Deletes any RSA keys loaded from the token and runs the secondary unconfiguration file, if it exists.                                                                                                                                                    |

## Examples

The following example shows both the configuration and encryption of a user PIN and then the router reloading and the user PIN being unlocked:

! Configuring the user PIN

Enter configuration commands, one per line. End with CNTL/Z.

Router(config)# **crypto pki token usbtoken0: user-pin**

Enter password:

! Encrypt the user PIN

```

Router (config)# crypto pki token usbtoken0: encrypted-user-pin
 Enter passphrase:
Router(config)# exit
Router#
Sep 20 21:51:38.076: %SYS-5-CONFIG_I: Configured from console by console
!

Router# show running config
.
.
.
crypto pki token usbtoken0 user-pin *encrypted*
.
.
.

! Reloading the router.
!
Router> enable
Password:
!
! Decrypting the user pin.
!
Router# crypto pki token usbtoken0: unlock
Token eToken is usbtoken0
!
Enter passphrase:
Token login to usbtoken0(eToken) successful
Router#
Sep 20 22:31:13.128: %CRYPTO-6-TOKENLOGIN: Cryptographic Token eToken
Login Successful

```

The following example shows how a secondary unconfiguration file might be used to remove secondary configuration elements from the running configuration. For example, a secondary configuration file might be used to set up a PKI trustpoint. A corresponding unconfiguration file, named `mysecondaryunconfigfile.cfg`, might contain this command line:

```
no crypto pki trustpoint token-tp
```

If the token were removed and the following commands executed, the trustpoint and associated certificates would be removed from the router's running configuration:

```

Router# configure terminal
Router(config)# no crypto pki token mytoken secondary unconfig mysecondaryunconfigfile.cfg

```

## What to Do Next

After you have logged into and configured the USB token, it is available for use.

- To perform USB token administrative tasks, such as changing the user PIN, copying files from the router to the USB token set key storage location, and changing USB tokens, see the “[Setting Administrative Functions on the USB Token](#)” section.
- To utilize the USB token as a cryptographic device to perform RSA operations, see the document titles in the “[Related Documents](#)” section.

- To specify that the USB token be used for RSA operations during initial autoenrollment, see the document titles in the “[Related Documents](#)” section.

## Setting Administrative Functions on the USB Token

Perform this task to change default settings, such as the user PIN, the maximum number of failed attempts on the USB token, or the credential storage location.

### SUMMARY STEPS

1. **enable**
2. **crypto pki token** *token-name* [**admin**] **change-pin** [*pin*]
3. **crypto pki token** *token-name* **device: label** *token-label*
4. **configure terminal**
5. **crypto key storage** *device:*
6. **crypto key generate rsa** [**general-keys** | **usage-keys** | **signature** | **encryption**] [**label** *key-label*] [**exportable**] [**modulus** *modulus-size*] [**storage** *devicename:*] [**on** *devicename:*]
7. **crypto key move rsa** *keylabel* [**non-exportable**] [**on** | **storage**] *location*
8. **crypto pki token** {*token-name* | **default**} **removal timeout** [*seconds*]
9. **crypto pki token** {*token-name* | **default**} **max-retries** [*number*]
10. **exit**
11. **copy usbflash**[0-9]:*filename* *destination-url*
12. **show usbtok**[0-9]:*filename*
13. **crypto pki token** *token-name* **logout**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                                                                                                 | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                           |
| Step 2 | <b>crypto pki token token-name [admin] change-pin [pin]</b><br><br><b>Example:</b><br>Router# crypto pki token usbtokens0 admin change-pin                                                                                                                                             | (Optional) Changes the user PIN number on the USB token. <ul style="list-style-type: none"> <li>If the PIN is not changed, the default PIN—1234567890—will be used.</li> </ul> <b>Note</b> After the PIN has been changed, you must reset the login failure count to zero (via the <b>crypto pki token max-retries</b> command). The maximum number of allowable login failures is set (by default) to 15. |
| Step 3 | <b>crypto pki token token-name device: label token-label</b><br><br><b>Example:</b><br>Router# crypto pki token my token usb0: label newlabel                                                                                                                                          | (Optional) Sets or changes the name of the USB token. <ul style="list-style-type: none"> <li>The value of the <i>token-label</i> argument may be up to 31 alphanumeric characters in length including dashes and underscores.</li> </ul> <b>Tip</b> This command is useful when configuring multiple USB tokens for automatic login, secondary configuration files, or other token specific settings.      |
| Step 4 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                                                                                                         | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                          |
| Step 5 | <b>crypto key storage device:</b><br><br><b>Example:</b><br>Router(config)# crypto key storage usbtokens0:                                                                                                                                                                             | (Optional) Sets the default RSA key storage location for newly created keys. <b>Note</b> Regardless of configuration settings, existing keys are stored on the device from where they were originally loaded.                                                                                                                                                                                              |
| Step 6 | <b>crypto key generate rsa [general-keys   usage-keys   signature   encryption] [label key-label] [exportable] [modulus modulus-size] [storage devicename:] [on devicename:]</b><br><br><b>Example:</b><br>Router(config)# crypto key generate rsa label tokenkey1 storage usbtokens0: | (Optional) Generates the RSA key pair. <ul style="list-style-type: none"> <li>The <b>storage</b> keyword specifies the key storage location.</li> <li>The <b>on</b> keyword specifies that the keys will be generated on the designated device.</li> </ul>                                                                                                                                                 |

|         | Command or Action                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 7  | <p><b>crypto key move rsa keylabel [non-exportable] [on   storage] location</b></p> <p><b>Example:</b><br/>Router(config)# crypto key move rsa keypairname non-exportable on token</p> | <p>(Optional) Moves existing Cisco IOS credentials from the current storage location to the specified storage location.</p> <p>By default, the RSA key pair remains stored on the current device.</p> <p>Generating the key on the router and moving it to the token takes less than a minute. Generating a key on the token, using the <b>on</b> keyword could take five to ten minutes, and is dependent on hardware key generation routines available on the USB token.</p> <p>When an existing RSA key pair is generated in Cisco IOS, stored on a USB token, and used for an enrollment, it may be necessary to move those existing RSA key pairs to an alternate location for permanent storage.</p> <p>This command is useful when using SDP with USB tokens to deploy credentials.</p> |
| Step 8  | <p><b>crypto pki token {token-name   default} removal timeout [seconds]</b></p> <p><b>Example:</b><br/>Router(config)# crypto pki token usbtoken0 removal timeout 60</p>               | <p>(Optional) Sets the time interval, in seconds, that the router will wait before removing the RSA keys that are stored in the USB token after the USB token has been removed from the router.</p> <p><b>Note</b> If this command is not issued, all RSA keys and IPsec tunnels associated with the USB token are torn down immediately after the USB token is removed from the router.</p>                                                                                                                                                                                                                                                                                                                                                                                                   |
| Step 9  | <p><b>crypto pki token {token-name   default} max-retries [number]</b></p> <p><b>Example:</b><br/>Router(config)# crypto pki token usbtoken0 max-retries 20</p>                        | <p>(Optional) Sets the maximum number of consecutive failed login attempts allowed before access to the USB token is denied.</p> <ul style="list-style-type: none"> <li>By default, the value is set at 15.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 10 | <p><b>exit</b></p> <p><b>Example:</b><br/>Router(config)# exit</p>                                                                                                                     | Exits global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Step 11 | <p><b>copy usbflash[0-9]:filename destination-url</b></p> <p><b>Example:</b><br/>Router# copy usbflash0:file1 nvram:</p>                                                               | <p>Copies files from USB token to the router.</p> <ul style="list-style-type: none"> <li><i>destination-url</i>—See the <b>copy</b> command page documentation for a list of supported options.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Step 12 | <p><b>show usbtoken[0-9]:filename</b></p> <p><b>Example:</b><br/>Router# show usbtoken:usbfile</p>                                                                                     | (Optional) Displays information about the USB token. You can use this command to verify whether the USB token has been logged onto the router.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Step 13 | <p><b>crypto pki token token-name logout</b></p> <p><b>Example:</b><br/>Router# crypto pki token usbtoken0 logout</p>                                                                  | <p>Logs the router out of the USB token.</p> <p><b>Note</b> If you want to save any data to the USB token, you must log back into the token.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Troubleshooting USB Tokens

This section contains descriptions of the following Cisco IOS commands that can be used to help troubleshoot possible problems that may arise while using a USB token:

- [The show file systems Command, page 16](#)
- [The show usb device Command, page 17](#)
- [The show usb controllers Command, page 17](#)
- [The dir Command, page 19](#)

### The show file systems Command

Use the **show file systems** command to determine whether the router recognizes that there is a USB module plugged into a USB port. The USB module should appear on the list of file systems. If the module does not appear on the list, it can indicate any of the following problems:

- A connection problem with the USB module.
- The Cisco IOS image running on the router does not support a USB module.
- A hardware problem with the USB module itself.

### SUMMARY STEPS

1. **show file systems**

### DETAILED STEPS

- Step 1** Sample output from the **show file systems** command showing a USB token appears below. The USB module listing appears in the last line of the examples.

```
Router# show file systems
```

```
File Systems:
```

|   | Size(b)   | Free(b)  | Type     | Flags | Prefixes   |
|---|-----------|----------|----------|-------|------------|
|   | -         | -        | opaque   | rw    | archive:   |
|   | -         | -        | opaque   | rw    | system:    |
|   | -         | -        | opaque   | rw    | null:      |
|   | -         | -        | network  | rw    | tftp:      |
| * | 129880064 | 69414912 | disk     | rw    | flash:#    |
|   | 491512    | 486395   | nvr      | rw    | nvr        |
|   | -         | -        | opaque   | wo    | syslog:    |
|   | -         | -        | opaque   | rw    | xmodem:    |
|   | -         | -        | opaque   | rw    | ymodem:    |
|   | -         | -        | network  | rw    | rcp:       |
|   | -         | -        | network  | rw    | pram:      |
|   | -         | -        | network  | rw    | ftp:       |
|   | -         | -        | network  | rw    | http:      |
|   | -         | -        | network  | rw    | scp:       |
|   | -         | -        | network  | rw    | https:     |
|   | -         | -        | opaque   | ro    | cns:       |
|   | 63158272  | 33037312 | usbflash | rw    | usbflash0: |
|   | 32768     | 858      | usbtoken | rw    | usbtoken1: |

## The show usb device Command

Use the **show usb device** command to determine if a USB token is supported by Cisco.

### SUMMARY STEPS

1. **show usb device**

### DETAILED STEPS

- Step 1** The following sample output for the **show usb device** command indicates whether or not the module is supported is bold in the sample output below:

```
Router# show usb device

Host Controller:1
Address:0x11
Device Configured:YES
Device Supported:YES
Description:eToken Pro 4254
Manufacturer:AKS
Version:1.0
Serial Number:
Device Handle:0x1010000
USB Version Compliance:1.0
Class Code:0xFF
Subclass Code:0x0
Protocol:0x0
Vendor ID:0x529
Product ID:0x514
Max. Packet Size of Endpoint Zero:8
Number of Configurations:1
Speed:Low
Selected Configuration:1
Selected Interface:0

Configuration:
 Number:1
 Number of Interfaces:1
 Description:
 Attributes:None
 Max Power:60 mA

 Interface:
 Number:0
 Description:
 Class Code:255
 Subclass:0
 Protocol:0
 Number of Endpoints:0
```

## The show usb controllers Command

Use the **show usb controllers** command to determine if there is a hardware problem with a USB flash module. If the **show usb controllers** command displays an error, the error indicates a hardware problem in the USB module.

You can also use the **show usb controllers** command to verify that copy operations onto a USB flash module are occurring successfully. Issuing the **show usb controllers** command after performing a file copy should display successful data transfers.

## SUMMARY STEPS

### 1. show usb controllers

## DETAILED STEPS

- Step 1** The following sample output for the **show usb controllers** command displays a working USB flash module:

Router# **show usb controllers**

```

## The dir Command

Use the **dir** command with the **filesystem** keyword option **usbtoken[0-9]**: to display all files, directories, and their permission strings on the USB token.

### SUMMARY STEPS

1. **dir [filesystem:]**

## DETAILED STEPS

**Step 1** The following sample output displays directory information for the USB token:

```
Router# dir usbtoken1:
```

```
Directory of usbtoken1:/
```

```

 2 d--- 64 Dec 22 2032 05:23:40 +00:00 1000
 5 d--- 4096 Dec 22 2032 05:23:40 +00:00 1001
 8 d--- 0 Dec 22 2032 05:23:40 +00:00 1002
10 d--- 512 Dec 22 2032 05:23:42 +00:00 1003
12 d--- 0 Dec 22 2032 05:23:42 +00:00 5000
13 d--- 0 Dec 22 2032 05:23:42 +00:00 6000
14 d--- 0 Dec 22 2032 05:23:42 +00:00 7000
15 ---- 940 Jun 27 1992 12:50:42 +00:00 mystartup-config

## Configuration Examples for PKI Storage

This section contains the following configuration examples:

- [Storing Certificates to a Specific Local Storage Location: Example, page 21](#)
- [Logging Into a USB Token and Saving RSA Keys to the USB Token: Example, page 22](#)

### Storing Certificates to a Specific Local Storage Location: Example

The following configuration example shows how to store certificates to the certs subdirectory. The certs subdirectory does not exist and is automatically created.

Router# **dir nvram:**

```

114 -rw- 4687 <no date> startup-config
115 ---- 5545 <no date> private-config
116 -rw- 4687 <no date> underlying-config
 1 ---- 34 <no date> persistent-data
 3 -rw- 707 <no date> ioscaroot#7401CA.cer
 9 -rw- 863 <no date> msca-root#826E.cer
10 -rw- 759 <no date> msca-root#1BA8CA.cer
11 -rw- 863 <no date> msca-root#75B8.cer
24 -rw- 1149 <no date> storagename#6500CA.cer
26 -rw- 863 <no date> msca-root#83EE.cer

```

129016 bytes total (92108 bytes free)

Router# **configure terminal**

Enter configuration commands, one per line. End with CNTL/Z.

Router(config)# **crypto pki certificate storage disk0:/certs**

Requested directory does not exist -- created

Certificates will be stored in disk0:/certs/

Router(config)# **end**

Router# **write**

\*May 27 02:09:00: %SYS-5-CONFIG\_I: Configured from console by consolemem

Building configuration...

[OK]

Router# **directory disk0:/certs**

Directory of disk0:/certs/

```

14 -rw- 707 May 27 2005 02:09:02 +00:00 ioscaroot#7401CA.cer
15 -rw- 863 May 27 2005 02:09:02 +00:00 msca-root#826E.cer
16 -rw- 759 May 27 2005 02:09:02 +00:00 msca-root#1BA8CA.cer
17 -rw- 863 May 27 2005 02:09:02 +00:00 msca-root#75B8.cer
18 -rw- 1149 May 27 2005 02:09:02 +00:00 storagename#6500CA.cer

```

```

19 -rw- 863 May 27 2005 02:09:02 +00:00 msca-root#83EE.cer
47894528 bytes total (20934656 bytes free)

```

! The certificate files are now on disk0/certs:

## Logging Into a USB Token and Saving RSA Keys to the USB Token: Example

The following configuration example shows to how log into the USB token, generate RSA keys, and store the RSA keys onto the USB token:

```

! Configure the router to automatically log into the eToken
configure terminal
 crypto pki token default user-pin 0 1234567890
! Generate RSA keys and enroll certificates with the CA.
crypto pki trustpoint IOSCA
 enrollment url http://10.23.2.2
 exit
crypto ca authenticate IOSCA
Certificate has the following attributes:
 Fingerprint MD5:23272BD4 37E3D9A4 236F7E1A F534444E
 Fingerprint SHA1:D1B4D9F8 D603249A 793B3CAF 8342E1FE 3934EB7A

% Do you accept this certificate? [yes/no]:yes
Trustpoint CA certificate accepted.
crypto pki enroll
crypto pki enroll IOSCA
%
% Start certificate enrollment ..
% Create a challenge password. You will need to verbally provide this
password to the CA Administrator in order to revoke your certificate.
For security reasons your password will not be saved in the configuration.
Please make a note of it.

Password:
Re-enter password:

% The subject name in the certificate will include:c2851-27.cisco.com
% Include the router serial number in the subject name? [yes/no]:no
% Include an IP address in the subject name? [no]:no
Request certificate from CA? [yes/no]:yes
% Certificate request sent to Certificate Authority
% The 'show crypto ca certificate IOSCA verbose' command will show the fingerprint.

*Jan 13 06:47:19.413:CRYPTO_PKI: Certificate Request Fingerprint MD5:E6DDAB1B
0E30EFE6 54529D8A DA787DBA
*Jan 13 06:47:19.413:CRYPTO_PKI: Certificate Request Fingerprint SHA1:3B0F33B

*Jan 13 06:47:21.021:%PKI-6-CERTRET:Certificate received from Certificate Authority
! Issue the write memory command, which will automatically save the RSA keys to the eToken
! instead of private NVRAM.
Router# write memory
Building configuration...
[OK]

*Jan 13 06:47:29.481:%CRYPTO-6-TOKENSTOREKEY:Key c2851-27.cisco.com stored on
Cryptographic Token eToken Successfully

```

The following sample output from the **show crypto key mypubkey rsa** command displays stored credentials after they are successfully loaded from the USB token. Credentials that are stored on the USB token are in the protected area. When storing the credentials on the USB token, the files are stored in a directory called /keystore. However, the key files are hidden from the command-line interface (CLI).

Router# **show crypto key mypubkey rsa**

# Feature Information for Storing PKI Credentials

Table 2 lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table.

For information on a feature in this technology that is not documented here, see the “[Implementing and Managing PKI Features Roadmap](#).”

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

**Note**

Table 2 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 2**      **Feature Information for Storing PKI Credentials**

| Feature Name                                               | Releases  | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

# Source Interface Selection for Outgoing Traffic with Certificate Authority

The Source Interface Selection for Outgoing Traffic with Certificate Authority feature allows you to specify that the address of an interface be used as the source address for all outgoing TCP connections associated with that trustpoint when a designated trustpoint has been configured.

## Feature Specifications for Source Interface Selection for Outgoing Traffic with Certificate Authority

### Feature History

| Release                  | Modification                                                  |
|--------------------------|---------------------------------------------------------------|
| 12.2(15)T                | This feature was introduced.                                  |
| Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers. |

### Supported Platforms

Cisco 1600, Cisco 1600R, Cisco 1710, Cisco 1720, Cisco 1750, Cisco 1751, Cisco 1760, Cisco 2400, Cisco 2610–2613, Cisco 2610XM–2611XM, Cisco 2620–2621, Cisco 2620XM–2621XM, Cisco 2650–2651, Cisco 2650XM–2651XM, Cisco 2691, Cisco 3620, Cisco 3631, Cisco 3640, Cisco 3660, Cisco 3725, Cisco 3745, Cisco 7100, Cisco 7200, Cisco 7400, Cisco 7500, Cisco 801–Cisco 806, Cisco 811, Cisco 813, Cisco 828, Cisco 8850-RPM, Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, Cisco MC3810, Cisco ubr7200, Cisco ubr905, Cisco ubr925

## Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

## Information About Source Interface Selection for Outgoing Traffic with Certificate Authority

To configure the Source Interface Selection for Outgoing Traffic with Certificate Authority feature, you must understand the following concepts:

- [Certificates That Identify an Entity, page 2](#)
- [Source Interface for Outgoing TCP Connections Associated with a Trustpoint, page 2](#)

### Certificates That Identify an Entity

Certificates can be used to identify an entity. A trusted server, known as the certification authority (CA), issues the certificate to the entity after determining the identity of the entity. A router that is running Cisco IOS software obtains its certificate by making a network connection to the CA. Using the Simple Certificate Enrollment Protocol (SCEP), the router transmits its certificate request to the CA and receives the granted certificate. The router obtains the certificate of the CA in the same manner using SCEP. When validating a certificate from a remote device, the router may again contact the CA or a Lightweight Directory Access Protocol (LDAP) or HTTP server to determine whether the certificate of the remote device has been revoked. (This process is known as checking the certificate revocation list [CRL].)

In some configurations, the router may make the outgoing TCP connection using an interface that does not have a valid or routable IP address. The user must specify that the address of a different interface be used as the source IP address for the outgoing connection. Cable modems are a specific example of this requirement because the outgoing cable interface (the RF interface) usually does not have a routable address. However, the user interface (usually Ethernet) does have a valid IP address.

### Source Interface for Outgoing TCP Connections Associated with a Trustpoint

The **crypto ca trustpoint** command is used to specify a trustpoint. The **source interface** command is used along with the **crypto ca trustpoint** command to specify the address of the interface that is to be used as the source address for all outgoing TCP connections associated with that trustpoint.

#### Note

If the interface address is not specified using the **source interface** command, the address of the outgoing interface is used.

# How to Configure Source Interface Selection for Outgoing Traffic with Certificate Authority

This section includes the following procedure:

- [Configuring the Interface for All Outgoing TCP Connections Associated with a Trustpoint, page 3](#)

## Configuring the Interface for All Outgoing TCP Connections Associated with a Trustpoint

Perform this task to configure the interface that you want to use as the source address for all outgoing TCP connections associated with a trustpoint.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ca trustpoint** *name*
4. **enrollment url** *url*
5. **source interface** *interface-address*
6. **interface** *type slot/port*
7. **description** *string*
8. **ip address** *ip-address mask*
9. **interface** *type slot/port*
10. **description** *string*
11. **ip address** *ip-address mask*
12. **crypto map** *map-name*

### DETAILED STEPS

|        | Command or Action                                                              | Purpose                                                                                                          |
|--------|--------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                         | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal | Enters global configuration mode.                                                                                |

|         | Command or Action                                                                                                                               | Purpose                                                                                                          |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 3  | <b>crypto ca trustpoint</b> <i>name</i><br><br><b>Example:</b><br>Router (config)# crypto ca trustpoint ms-ca                                   | Declares the Certificate Authority (CA) that your router should use and enters ca-trustpoint configuration mode. |
| Step 4  | <b>enrollment url</b> <i>url</i><br><br><b>Example:</b><br>Router (ca-trustpoint)# enrollment url<br>http://yourname:80/certsrv/mscep/mscep.dll | Specifies the enrollment parameters of your CA.                                                                  |
| Step 5  | <b>source interface</b> <i>interface-address</i><br><br><b>Example:</b><br>Router (ca-trustpoint)# interface ethernet 0                         | Interface to be used as the source address for all outgoing TCP connections associated with that trustpoint.     |
| Step 6  | <b>interface type slot/port</b><br><br><b>Example:</b><br>Router (ca-trustpoint)# interface ethernet 1                                          | Configures an interface type and enters interface configuration mode.                                            |
| Step 7  | <b>description</b> <i>string</i><br><br><b>Example:</b><br>Router (config-if)# description inside interface                                     | Adds a description to an interface configuration.                                                                |
| Step 8  | <b>ip address</b> <i>ip-address mask</i><br><br><b>Example:</b><br>Router (config-if)# ip address 10.1.1.1 255.255.255.0                        | Sets a primary or secondary IP address for an interface.                                                         |
| Step 9  | <b>interface type slot/port</b><br><br><b>Example:</b><br>Router (config-if)# interface ethernet1/0                                             | Configures an interface type.                                                                                    |
| Step 10 | <b>description</b> <i>string</i><br><br><b>Example:</b><br>Router (config-if)# description outside interface 10.1.1.205 255.255.255.0           | Adds a description to an interface configuration.                                                                |
| Step 11 | <b>ip address</b> <i>ip-address mask</i><br><br><b>Example:</b><br>Router (config-if)# ip address 10.2.2.205 255.255.255.0                      | Sets a primary or secondary IP address for an interface.                                                         |
| Step 12 | <b>crypto map</b> <i>map-name</i><br><br><b>Example:</b><br>Router (config-if)# crypto map mymap                                                | Applies a previously defined crypto map set to an interface.                                                     |

## Troubleshooting Tips

Ensure that the interface specified in the command has a valid address. Attempt to ping the router using the address of the specified interface from another device (possibly the HTTP or LDAP server that is serving the CRL). You can do the same thing by using a traceroute to the router from the external device.

You can also test connectivity between the router and the CA or LDAP server by using Cisco IOS command-line interface (CLI). Enter the **ping ip** command and respond to the prompts. If you answer “yes” to the “Extended commands [n]:” prompt, you will be able to specify the source address or interface.

In addition, you can use Cisco IOS CLI to input a traceroute command. If you enter the **traceroute ip** command (in EXEC mode), you will be prompted for the destination and source address. You should specify the CA or LDAP server as the destination and the address of the interface that you specified in the “source interface” as the source address.

## Configuration Examples for Source Interface Selection for Outgoing Traffic with Certificate Authority

This section includes the following example:

- [Source Interface Selection for Outgoing Traffic with Certificate Authority Example, page 5](#)

### Source Interface Selection for Outgoing Traffic with Certificate Authority Example

In the following example, the router is located in a branch office. The router uses IP Security (IPSec) to communicate with the main office. Ethernet 1 is the “outside” interface that connects to the Internet Service Provider (ISP). Ethernet 0 is the interface connected to the LAN of the branch office. To access the CA server located in the main office, the router must send its IP datagrams out interface Ethernet 1 (address 10.2.2.205) using the IPSec tunnel. Address 10.2.2.205 is assigned by the ISP. Address 10.2.2.205 is not a part of the branch office or main office.

The CA cannot access any address outside the company because of a firewall. The CA sees a message coming from 10.2.2.205 and cannot respond (that is, the CA does not know that the router is located in a branch office at address 10.1.1.1, which it is able to reach).

Adding the **source interface** command tells the router to use address 10.1.1.1 as the source address of the IP datagram that it sends to the CA. The CA is able to respond to 10.1.1.1.

This scenario is configured using the **source interface** command and the interface addresses as described above.

```
crypto ca trustpoint ms-ca
 enrollment url http://ms-ca:80/certsrv/mscep/mscep.dll
 source interface ethernet0
!
interface ethernet 0
 description inside interface
 ip address 10.1.1.1 255.255.255.0
!
interface ethernet 1
 description outside interface
 ip address 10.2.2.205 255.255.255.0
 crypto map main-office
```

## Command Reference

The following commands are introduced or modified in the feature or features

- **source interface**

For information about these commands, see the Cisco IOS Security Command Reference at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html).

For information about all Cisco IOS commands, see the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the Master Command List.

# Glossary

**authenticate**—To prove the identity of an entity using the certificate of an identity and a secret that the identity poses (usually the private key corresponding to the public key in the certificate).

**CA**—Certificate Authority. A CA is an entity that issues digital certificates (especially X.509 certificates) and vouches for the binding between the data items in a certificate.

**CA authentication**—The user manually approves a certificate from a root CA. Usually a fingerprint of the certificate is presented to the user, and the user is asked to accept the certificate based on the fingerprint. The certificate of a root CA is signed by itself (self-signed) so that it cannot be automatically authenticated using the normal certificate verification process.

**CRL**—certificate revocation list. A CRL is a data structure that enumerates digital certificates that have been invalidated by their issuer prior to when they were scheduled to expire.

**enrollment**—A router receives its certificate via the enrollment process. The router generates a request for a certificate in a specific format (known as PKCS #10). The request is transmitted to a CA, which grants the request and generates a certificate encoded in the same format as the request. The router receives the granted certificate and stores it in an internal database for use during normal operations.

**certificate**—A data structure defined in International Organization for Standardization (ISO) standard X.509 to associate an entity (machine or human) with the public key of that entity. The certificate contains specific fields, including the name of the entity. The certificate is normally issued by a CA on behalf of the entity. In this case the router will act as its own CA. Common fields within a certificate include the distinguished name (DN) of the entity, the DN of the authority issuing the certificate, and the public key of the entity.

**LDAP**—Lightweight Directory Access Protocol. A LDAP is a protocol that provides access for management and browser applications that provide read-and-write interactive access to the X.500 directory.

| Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers.                             |

This chapter describes the Unicast Reverse Path Forwarding (Unicast RPF) feature. The Unicast RPF feature helps to mitigate problems that are caused by malformed or forged IP source addresses that are passing through a router.

For a complete description of the Unicast RPF commands in this chapter, refer to the chapter “Unicast Reverse Path Forwarding Commands” of the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the “Identifying Supported Platforms” section in the chapter “Using Cisco IOS Software.”

## In This Chapter

This chapter has the following sections:

- [About Unicast Reverse Path Forwarding](#)
- [Unicast RPF Configuration Task List](#)
- [Troubleshooting Tips](#)
- [Monitoring and Maintaining Unicast RPF](#)
- [Unicast RPF Configuration Examples](#)

# About Unicast Reverse Path Forwarding

The Unicast RPF feature helps to mitigate problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network by discarding IP packets that lack a verifiable IP source address. For example, a number of common types of denial-of-service (DoS) attacks, including Smurf and Tribal Flood Network (TFN), can take advantage of forged or rapidly changing source IP addresses to allow attackers to thwart efforts to locate or filter the attacks. For Internet service providers (ISPs) that provide public access, Unicast RPF deflects such attacks by forwarding only packets that have source addresses that are valid and consistent with the IP routing table. This action protects the network of the ISP, its customer, and the rest of the Internet.

This section covers the following information:

- [How Unicast RPF Works](#)
- [Implementing Unicast RPF](#)
- [Restrictions](#)
- [Related Features and Technologies](#)
- [Prerequisites to Configuring Unicast RPF](#)

## How Unicast RPF Works

When Unicast RPF is enabled on an interface, the router examines all packets received as input on that interface to make sure that the source address and source interface appear in the routing table and match the interface on which the packet was received. This “look backwards” ability is available only when Cisco express forwarding (CEF) is enabled on the router, because the lookup relies on the presence of the Forwarding Information Base (FIB). CEF generates the FIB as part of its operation.

**Note**

Unicast RPF is an input function and is applied only on the input interface of a router at the upstream end of a connection.

Unicast RPF checks to see if any packet received at a router interface arrives on the best return path (return route) to the source of the packet. Unicast RPF does this by doing a reverse lookup in the CEF table. If the packet was received from one of the best reverse path routes, the packet is forwarded as normal. If there is no reverse path route on the same interface from which the packet was received, it might mean that the source address was modified. If Unicast RPF does not find a reverse path for the packet, the packet is dropped or forwarded, depending on whether an access control list (ACL) is specified in the **ip verify unicast reverse-path** interface configuration command.

**Note**

With Unicast RPF, all equal-cost “best” return paths are considered valid. This means that Unicast RPF works in cases where multiple return paths exist, provided that each path is equal to the others in terms of the routing cost (number of hops, weights, and so on) and as long as the route is in the FIB. Unicast RPF also functions where EIGRP variants are being used and unequal candidate paths back to the source IP address exist.

When a packet is received at the interface where Unicast RPF and ACLs have been configured, the following actions occur:

**Step 1** Input ACLs configured on the inbound interface are checked.

- Step 2** Unicast RPF checks to see if the packet has arrived on the best return path to the source, which it does by doing a reverse lookup in the FIB table.
- Step 3** CEF table (FIB) lookup is carried out for packet forwarding.
- Step 4** Output ACLs are checked on the outbound interface.
- Step 5** The packet is forwarded.
- 

This section provides information about Unicast RPF enhancements:

- [Access Control Lists and Logging](#)
- [Per-Interface Statistics](#)

## Access Control Lists and Logging

If an ACL is specified in the command, then when (and only when) a packet fails the Unicast RPF check, the ACL is checked to see if the packet should be dropped (using a deny statement in the ACL) or forwarded (using a permit statement in the ACL). Whether a packet is dropped or forwarded, the packet is counted in the global IP traffic statistics for Unicast RPF drops and in the interface statistics for Unicast RPF.

If no ACL is specified in the Unicast RPF command, the router drops the forged or malformed packet immediately and no ACL logging occurs. The router and interface Unicast RPF counters are updated.

Unicast RPF events can be logged by specifying the logging option for the ACL entries used by the Unicast RPF command. Using the log information, administrators can see what source addresses are being used in the attack, the time the packets arrived at the interface, and so on.

### Caution

Logging requires CPU and memory resources. Logging Unicast RPF events for attacks having a high rate of forged packets can degrade the performance of the router.

---

## Per-Interface Statistics

Each time a packet is dropped or forwarded at an interface, that information is counted two ways: globally on the router and at each interface where you have applied Unicast RPF. Global statistics on dropped packets provide information about potential attacks on the network; however, these global statistics do not help to specify which interface is the source of the attack.

Per-interface statistics allow network administrators to track two types of information about malformed packets: Unicast RPF drops and Unicast RPF suppressed drops. Statistics on the number of packets that Unicast RPF drops help to identify the interface that is the entry point of the attack. The Unicast RPF drop count tracks the number of drops at the interface. The Unicast RPF suppressed drop count tracks the number of packets that failed the Unicast RPF check but were forwarded because of the permit permission set up in the ACL. Using the drop count and suppressed drop count statistics, a network administrator can take steps to isolate the attack at a specific interface.

### Note

Judicious use of ACL logging can further identify the address or addresses that are being dropped by Unicast RPF.

---

Figure 38 illustrates how Unicast RPF and CEF work together to validate IP source addresses by verifying packet return paths. In this example, a customer has sent a packet having a source address of 192.168.1.1 from interface FDDI 2/0/0. Unicast RPF checks the FIB to see if 192.168.1.1 has a path to FDDI 2/0/0. If there is a matching path, the packet is forwarded. If there is no matching path, the packet is dropped.

**Figure 38** *Unicast RPF Validating IP Source Addresses*

33402

Figure 39 illustrates how Unicast RPF drops packets that fail validation. In this example, a customer has sent a packet having a source address of 209.165.200.225, which is received at interface FDDI 2/0/0. Unicast RPF checks the FIB to see if 209.165.200.225 has a return path to FDDI 2/0/0. If there is a matching path, the packet is forwarded. In this case, there is no reverse entry in the routing table that routes the customer packet back to source address 209.165.200.225 on interface FDDI 2/0/0, and so the packet is dropped.

**Figure 39 Unicast RPF Dropping Packets That Fail Verification**

## Implementing Unicast RPF

Unicast RPF has several key implementation principles:

- The packet must be received at an interface that has the best return path (route) to the packet source (a process called *symmetric routing*). There must be a route in the FIB matching the route to the receiving interface. Adding a route in the FIB can be done via static route, network statement, or dynamic routing. (ACLs permit Unicast RPF to be used when packets are known to be arriving by specific, less optimal asymmetric input paths.)
- IP source addresses at the receiving interface must match the routing entry for the interface.
- Unicast RPF is an input function and is applied only on the input interface of a router at the upstream end of a connection.

Given these implementation principles, Unicast RPF becomes a tool that network administrators can use not only for their customers but also for their downstream network or ISP, even if the downstream network or ISP has other connections to the Internet.

### Caution

Using optional BGP attributes such as weight and local preference, the best path back to the source address can be modified. Modification would affect the operation of Unicast RPF.

This section provides information about the implementation of Unicast RPF:

- [Security Policy and Unicast RPF](#)
- [Where to Use Unicast RPF](#)
- [Routing Table Requirements](#)
- [Where Not to Use Unicast RPF](#)
- [Unicast RPF with BOOTP and DHCP](#)

## Security Policy and Unicast RPF

Consider the following points in determining your policy for deploying Unicast RPF:

- Unicast RPF must be applied at the interface downstream from the larger portion of the network, preferably at the edges of your network.
- The further downstream you apply Unicast RPF, the finer the granularity you have in mitigating address spoofing and in identifying the sources of spoofed addresses. For example, applying Unicast RPF on an aggregation router helps mitigate attacks from many downstream networks or clients and is simple to administer, but it does not help identify the source of the attack. Applying Unicast RPF at the network access server helps limit the scope of the attack and trace the source of the attack; however, deploying Unicast RPF across many sites does add to the administration cost of operating the network.
- The more entities that deploy Unicast RPF across Internet, intranet, and extranet resources, the better the chances of mitigating large-scale network disruptions throughout the Internet community, and the better the chances of tracing the source of an attack.
- Unicast RPF will not inspect IP packets encapsulated in tunnels, such as GRE, LT2P, or PPTP. Unicast RPF must be configured at a home gateway so that Unicast RPF processes network traffic only after the tunneling and encryption layers have been stripped off the packets.

## Where to Use Unicast RPF

Unicast RPF can be used in any “single-homed” environment where there is essentially only one access point out of the network; that is, one upstream connection. Networks having one access point offer the best example of symmetric routing, which means that the interface where a packet enters the network is also the best return path to the source of the IP packet. Unicast RPF is best used at the network perimeter for Internet, intranet, or extranet environments, or in ISP environments for customer network terminations.

The following sections provide a look at implementing Unicast RPF in two network environments:

- [Enterprise Networks with a Single Connection to an ISP](#)
- [Network Access Server Application \(Applying Unicast RPF in PSTN/ISDN PoP Aggregation Routers\)](#)

### Enterprise Networks with a Single Connection to an ISP

In enterprise networks, one objective of using Unicast RPF for filtering traffic at the input interface (a process called *ingress filtering*) is for protection from malformed packets arriving from the Internet. Traditionally, local networks that have one connection to the Internet would use ACLs at the receiving interface to prevent spoofed packets from the Internet from entering their local network.

ACLs work well for many single-homed customers; however, there are trade-offs when ACLs are used as ingress filters, including two commonly referenced limitations:

- Packet per second (PPS) performance at very high packet rates
- Maintenance of the ACL (whenever there are new addresses added to the network)

Unicast RPF is one tool that addresses both of these limitations. With Unicast RPF, ingress filtering is done at CEF PPS rates. This processing speed makes a difference when the link is more than 1 Mbps. Additionally, since Unicast RPF uses the FIB, no ACL maintenance is necessary, and thus the administration overhead of traditional ACLs is reduced. The following figure and example demonstrate how Unicast RPF is configured for ingress filtering.

Figure 40 illustrates an enterprise network that has a single link to an upstream ISP. In this example, Unicast RPF is applied at interface S0 on the enterprise router for protection from malformed packets arriving from the Internet. Unicast RPF is also applied at interface S5/0 on the ISP router for protection from malformed packets arriving from the enterprise network.

**Figure 40** Enterprise Network Using Unicast RPF for Ingress Filtering

Using the topography in Figure 40, a typical configuration (assuming that CEF is turned on) on the ISP router would be as follows:

```

ip cef
interface loopback 0
 description Loopback interface on Gateway Router 2
 ip address 192.168.3.1 255.255.255.255
 no ip redirects
 no ip directed-broadcast
 no ip proxy-arp
interface Serial 5/0
 description 128K HDLC link to ExampleCorp WT50314E R5-0
 bandwidth 128
 ip unnumbered loopback 0
 ip verify unicast reverse-path
 no ip redirects
 no ip directed-broadcast
 no ip proxy-arp
ip route 192.168.10.0 255.255.252.0 Serial 5/0

```

The gateway router configuration of the enterprise network (assuming that CEF is turned on) would look similar to the following:

```

ip cef
interface Ethernet 0
 description ExampleCorp LAN
 ip address 192.168.10.1 255.255.252.0
 no ip redirects
 no ip directed-broadcast
 no ip proxy-arp
interface Serial 0

```

```

description 128K HDLC link to ExampleCorp Internet Inc WT50314E C0
bandwidth 128
ip unnumbered ethernet 0
ip verify unicast reverse-path
no ip redirects
no ip directed-broadcast
no ip proxy-arp
ip route 0.0.0.0 0.0.0.0 Serial 0

```

Notice that Unicast RPF works with a single default route. There are no additional routes or routing protocols. Network 192.168.10.0/22 is a connected network. Hence, packets coming from the Internet with a source address in the range 192.168.10.0/22 will be dropped by Unicast RPF.

### Network Access Server Application (Applying Unicast RPF in PSTN/ISDN PoP Aggregation Routers)

Aggregation routers are ideal places to use Unicast RPF with single-homed clients. Unicast RPF works equally well on leased-line or PSTN/ISDN/xDSL customer connections into the Internet. In fact, dialup connections are reputed to be the greatest source of DoS attacks using forged IP addresses. As long as the network access server supports CEF, Unicast RPF will work. In this topology, the customer aggregation routers need not have the full Internet routing table. Aggregation routers need the routing prefixes information (IP address block); hence, information configured or redistributed in the Interior Gateway Protocol (IGP) or Internal Border Gateway Protocol (IBGP) (depending on the way that you add customer routes into your network) would be enough for Unicast RPF to do its job.

Figure 41 illustrates the application of Unicast RPF to the aggregation and access routers for an Internet service provider (ISP) point of presence (POP), with the ISP routers providing dialup customer connections. In this example, Unicast RPF is applied upstream from the customer dialup connection router on the receiving (input) interfaces of the ISP aggregation routers.

**Figure 41** Unicast RPF Applied to PSTN/ISDN Customer Connections

## Routing Table Requirements

To work correctly, Unicast RPF needs proper information in the CEF tables. This requirement does not mean that the router must have the entire Internet routing table. The amount of routing information needed in the CEF tables depends on where Unicast RPF is configured and what functions the router performs in the network. For example, in an ISP environment, a router that is a leased-line aggregation router for customers needs only the information based on the static routes redistributed into the IGP or IBGP (depending on which technique is used in the network). Unicast RPF would be configured on the customer interfaces—hence the requirement for minimal routing information. In another scenario, a single-homed ISP could place Unicast RPF on the gateway link to the Internet. The full Internet routing table would be required. Requiring the full routing table would help protect the ISP from external DoS attacks that use addresses that are not in the Internet routing table.

## Where Not to Use Unicast RPF

Unicast RPF should not be used on interfaces that are internal to the network. Internal interfaces are likely to have routing asymmetry (see [Figure 42](#)), meaning multiple routes to the source of a packet. Unicast RPF should be applied only where there is natural or configured symmetry. As long as administrators carefully plan which interfaces they activate Unicast RPF on, routing asymmetry is not a serious problem.

For example, routers at the edge of the network of an ISP are more likely to have symmetrical reverse paths than routers that are in the core of the ISP network. Routers that are in the core of the ISP network have no guarantee that the best forwarding path out of the router will be the path selected for packets returning to the router. Hence, it is not recommended that you apply Unicast RPF where there is a chance of asymmetric routing, unless you use ACLs to allow the router to accept incoming packets. ACLs permit Unicast RPF to be used when packets are known to be arriving by specific, less optimal asymmetric input paths. However, it is simplest to place Unicast RPF only at the edge of a network or, for an ISP, at the customer edge of the network.

[Figure 42](#) illustrates how Unicast RPF can block legitimate traffic in an asymmetrical routing environment.

**Figure 42** Unicast RPF Blocking Traffic in an Asymmetrical Routing Environment

## Unicast RPF with BOOTP and DHCP

Unicast RPF will allow packets with 0.0.0.0 source and 255.255.255.255 destination to pass so that Bootstrap Protocol (BOOTP) and Dynamic Host Configuration Protocol (DHCP) functions work properly. This enhancement was added in Cisco IOS Release 12.0 and later, but it is not in Cisco IOS Release 11.1CC.

## Restrictions

There are some basic restrictions to applying Unicast RPF to multihomed clients:

- Clients should not be multihomed to the same router because multihoming defeats the purpose of building a redundant service for the client.
- Customers must ensure that the packets flowing up the link (out to the Internet) match the route advertised out the link. Otherwise, Unicast RPF filters those packets as malformed packets.
- Unicast RPF is available only for platform images that support CEF. Unicast RPF is supported in Cisco IOS Releases 11.1(17)CC and 12.0 and later. It is not available in Cisco IOS Release 11.2 or 11.3.

## Related Features and Technologies

For more information about Unicast RPF-related features and technologies, review the following:

- Unicast RPF requires Cisco express forwarding (CEF) to function properly on the router. For more information about CEF, refer to the *Cisco IOS Switching Services Configuration Guide*.
- Unicast RPF can be more effective at mitigating spoofing attacks when combined with a policy of *ingress* and *egress* filtering using Cisco IOS access control lists (ACLs).
  - Ingress filtering applies filters to traffic received at a network interface from either internal or external networks. With ingress filtering, packets that arrive from other networks or the Internet and that have a source address that matches a local network, private, or broadcast address are dropped. In ISP environments, for example, ingress filtering can apply to traffic received at the router from either the client (customer) or the Internet.
  - Egress filtering applies filters to traffic exiting a network interface (the sending interface). By filtering packets on routers that connect your network to the Internet or to other networks, you can permit only packets with valid source IP addresses to leave your network.

For more information on network filtering, refer to RFC 2267 and to the *Cisco IOS IP Configuration Guide*.

- Cisco IOS software provides additional features that can help mitigate DoS attacks:
  - Committed Access Rate (CAR). CAR allows you to enforce a bandwidth policy against network traffic that matches an access list. For example, CAR allows you to rate-limit what should be low-volume traffic, such as ICMP traffic. To find out more about CAR, refer to the *Cisco IOS Quality of Service Solutions Configuration Guide*.
  - Context-based Access Control (CBAC). CBAC selectively blocks any network traffic not originated by a protected network. CBAC uses timeout and threshold values to manage session state information, helping to determine when to drop sessions that do not become fully established. Setting timeout values for network sessions helps mitigate DoS attacks by freeing up system resources, dropping sessions after a specified amount of time. For more information on CBAC, refer to the *Cisco IOS Security Configuration Guide*.

- TCP Intercept. The TCP Intercept feature implements software to protect TCP servers from TCP SYN-flooding attacks, which are a type of DoS attack. A SYN-flooding attack occurs when a hacker floods a server with a barrage of requests for connection. Like CBAC, the TCP Intercept feature also uses timeout and threshold values to manage session state information, helping to determine when to drop sessions that do not become fully established. For more information on TCP Intercept, refer to the *Cisco IOS Security Configuration Guide*.

## Prerequisites to Configuring Unicast RPF

Prior to configuring Unicast RPF, configure ACLs:

- Configure standard or extended ACLs to mitigate transmission of invalid IP addresses (perform egress filtering). Permit only valid source addresses to leave your network and get onto the Internet. Prevent all other source addresses from leaving your network for the Internet.
- Configure standard or extended ACLs entries to drop (deny) packets that have invalid source IP addresses (perform ingress filtering). Invalid source IP addresses include the following types:
  - Reserved addresses
  - Loopback addresses
  - Private addresses (RFC 1918, *Address Allocation for Private Internets*)
  - Broadcast addresses (including multicast addresses)
  - Source addresses that fall outside the range of valid addresses associated with the protected network
- Configure standard or extended ACL entries to forward (permit) packets that fail the Unicast RPF checks to allow specific traffic from known asymmetric routed sources.
- Configure ACLs to track Unicast RPF events by adding the logging option into the ACL command. During network attacks, judicious logging of dropped or forwarded packets (suppressed drops) can provide additional information about network attacks.

## Unicast RPF Configuration Task List

The following sections describe the configuration tasks for Unicast RPF. Each task in the list is identified as either optional or required.

- [Configuring Unicast RPF](#) (Required)
- [Verifying Unicast RPF](#) (Optional)

See the section “[Unicast RPF Configuration Examples](#)” at the end of this chapter.

## Configuring Unicast RPF

To use Unicast RPF, you must configure the router for CEF switching or CEF distributed switching. There is no need to configure the input interface for CEF switching because Unicast RPF has been implemented as a search through the FIB using the source IP address. As long as CEF is running on the router, individual interfaces can be configured with other switching modes. Unicast RPF is an input-side function that is enabled on an interface or subinterface that supports any type of encapsulation and operates on IP packets received by the router. It is very important that CEF be turned on globally in the router—Unicast RPF will not work without CEF.

To configure Unicast RPF, use the following commands beginning in global configuration mode:

|        | Command                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------|---------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | Router(config)# <b>ip cef</b>                                 | Enables CEF or distributed CEF on the router. Distributed CEF is required for routers that use a Route Switch Processor (RSP) and Versatile Interface Processor (VIP), which includes Unicast RPF.<br><br>You might want to disable CEF or distributed CEF (dCEF) on a particular interface if that interface is configured with a feature that CEF or dCEF does not support. In this case, you would enable CEF globally, but disable CEF on a specific interface using the <b>no ip route-cache cef</b> interface command, which enables all but that specific interface to use express forwarding. If you have disabled CEF or dCEF operation on an interface and want to reenabling it, you can do so by using the <b>ip route-cache cef</b> command in interface configuration mode. |
|        | or<br>Router(config)# <b>ip cef distributed</b>               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Step 2 | Router(config-if)# <b>interface type</b>                      | Selects the input interface on which you want to apply Unicast RPF. This is the receiving interface, which allows Unicast RPF to verify the best return path before forwarding the packet on to the next destination.<br><br>The interface type is specific to your router and the types of interface cards installed on the router. To display a list of available interface types, enter the <b>interface ?</b> command.                                                                                                                                                                                                                                                                                                                                                                |
| Step 3 | Router(config-if)# <b>ip verify unicast reverse-path list</b> | Enables Unicast RPF on the interface. Use the <i>list</i> option to identify an access list. If the access list denies network access, spoofed packets are dropped at the interface. If the access list permits network access, spoofed packets are forwarded to the destination address. Forwarded packets are counted in the interface statistics. If the access list includes the logging option, information about the spoofed packets is logged to the log server.<br><br>Repeat this step for each access list that you want specify.                                                                                                                                                                                                                                               |
| Step 4 | Router(config-if)# <b>exit</b>                                | Exits interface configuration mode. Repeat Steps 2 and 3 for each interface on which you want to apply Unicast RPF.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Verifying Unicast RPF

To verify that Unicast RPF is operational, use the **show cef interface** command. The following example shows that Unicast RPF is enabled at interface serial2/0/0.

```
Router-3# show cef interface serial 2/0/0
```

```
Serial2/0/0 is up (if_number 8)
Internet address is 192.168.10.2/30
ICMP redirects are never sent
Per packet loadbalancing is disabled
!The next line displays Unicast RPF packet dropping information.
IP unicast RPF check is enabled
Inbound access list is not set
Outbound access list is not set
Interface is marked as point to point interface
Packets switched to this interface on linecard are dropped to next slow path
Hardware idb is Serial2/0/0
Fast switching type 4, interface type 6
!The next line displays Unicast RPF packet dropping information.
IP Distributed CEF switching enabled
IP LES Feature Fast switching turbo vector
IP Feature CEF switching turbo vector
Input fast flags 0x40, Output fast flags 0x0, ifindex 7(7)
Slot 2 Slot unit 0 VC -1
Transmit limit accumulator 0x48001A02 (0x48001A02)
IP MTU 1500
```

## Troubleshooting Tips

If you experience problems while using Unicast RPF, check the following items.

### HSRP Failure

Failure to disable Unicast RPF before disabling CEF can cause Hot Standby Router Protocol (HSRP) failure. If you want to disable CEF on the router, you must first disable Unicast RPF. To disable Unicast RPF, see the section “[Monitoring and Maintaining Unicast RPF](#).”

### Dropped Boot Requests

In Cisco IOS Release 11.1(17)CC, Unicast RPF can drop BOOTP request packets that have a source address of 0.0.0.0 due to source address verification at the interface. To enable boot requests to work on the interface, you must use ACLs instead of Unicast RPF.

# Monitoring and Maintaining Unicast RPF

This section describes commands used to monitor and maintain Unicast RPF.

| Command                                                          | Purpose                                                                                                                       |
|------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| Router# <b>show ip traffic</b>                                   | Displays global router statistics about Unicast RPF drops and suppressed drops.                                               |
| Router# <b>show ip interface type</b>                            | Displays per-interface statistics about Unicast RPF drops and suppressed drops.                                               |
| Router# <b>show access-lists</b>                                 | Displays the number of matches to a specific ACL.                                                                             |
| Router(config-if)# <b>no ip verify unicast reverse-path list</b> | Disables Unicast RPF at the interface. Use the <i>list</i> option to disable Unicast RPF for a specific ACL at the interface. |

## Caution

To disable CEF, you must first disable Unicast RPF. Failure to disable Unicast RPF before disabling CEF can cause HSRP failure. If you want to disable CEF on the router, you must first disable Unicast RPF.

Unicast RPF counts the number of packets dropped or suppressed because of malformed or forged source addresses. Unicast RPF counts dropped or forwarded packets that include the following global and per-interface information:

- Global Unicast RPF drops
- Per-interface Unicast RPF drops
- Per-interface Unicast RPF suppressed drops

The **show ip traffic** command shows the total number (global count) of dropped or suppressed packets for all interfaces on the router. The Unicast RPF drop count is included in the IP statistics section.

Router# **show ip traffic**

IP statistics:

```
Rcvd: 1471590 total, 887368 local destination
 0 format errors, 0 checksum errors, 301274 bad hop count
 0 unknown protocol, 0 not a gateway
 0 security failures, 0 bad options, 0 with options
Opts: 0 end, 0 nop, 0 basic security, 0 loose source route
 0 timestamp, 0 extended security, 0 record route
 0 stream ID, 0 strict source route, 0 alert, 0 other
Frgs: 0 reassembled, 0 timeouts, 0 couldn't reassemble
 0 fragmented, 0 couldn't fragment
Bcast: 205233 received, 0 sent
Mcast: 463292 received, 462118 sent
Sent: 990158 generated, 282938 forwarded
! The second line below ("0 unicast RPF") displays Unicast RPF packet dropping
information.
Drop: 3 encapsulation failed, 0 unresolved, 0 no adjacency
 0 no route, 0 unicast RPF, 0 forced drop
```

A nonzero value for the count of dropped or suppressed packets can mean one of two things:

- Unicast RPF is dropping or suppressing packets that have a bad source address (normal operation).

- Unicast RPF is dropping or suppressing legitimate packets because the route is misconfigured to use Unicast RPF in environments where asymmetric routing exists; that is, where multiple paths can exist as the best return path for a source address.

The **show ip interface** command shows the total of dropped or suppressed packets at a specific interface. If Unicast RPF is configured to use a specific ACL, that ACL information is displayed along with the drop statistics.

```
Router> show ip interface ethernet0/1/1
```

```
Unicast RPF ACL 197
1 unicast RPF drop
1 unicast RPF suppressed drop
```

The **show access-lists** command displays the number of matches found for a specific entry in a specific access list.

```
Router> show access-lists
```

```
Extended IP access list 197
deny ip 192.168.201.0 0.0.0.63 any log-input (1 match)
permit ip 192.168.201.64 0.0.0.63 any log-input (1 match)
deny ip 192.168.201.128 0.0.0.63 any log-input
permit ip 192.168.201.192 0.0.0.63 any log-input
```

## Unicast RPF Configuration Examples

This section provides the following configuration examples:

- [Unicast RPF on a Leased-Line Aggregation Router Example](#)
- [Unicast RPF on the Cisco AS5800 Using Dialup Ports Example](#)
- [Unicast RPF with Inbound and Outbound Filters Example](#)
- [Unicast RPF with ACLs and Logging Example](#)

### Unicast RPF on a Leased-Line Aggregation Router Example

The following commands enable Unicast RPF on a serial interface:

```
ip cef
! or "ip cef distributed" for RSP+VIP based routers
!
interface serial 5/0/0
ip verify unicast reverse-path
```

### Unicast RPF on the Cisco AS5800 Using Dialup Ports Example

The following example enables Unicast RPF on a Cisco AS5800. The **interface Group-Async** command makes it easy to apply Unicast RPF on all the dialup ports.

```
ip cef
!
interface Group-Async1
ip verify unicast reverse-path
```

## Unicast RPF with Inbound and Outbound Filters Example

The following example uses a very simple single-homed ISP to demonstrate the concepts of ingress and egress filters used in conjunction with Unicast RPF. The example illustrates an ISP-allocated classless interdomain routing (CIDR) block 209.165.202.128/28 that has both inbound and outbound filters on the upstream interface. Be aware that ISPs are usually not single-homed. Hence, provisions for asymmetrical flows (when outbound traffic goes out one link and returns via a different link) need to be designed into the filters on the border routers of the ISP.

```
ip cef distributed
!
interface Serial 5/0/0
 description Connection to Upstream ISP
 ip address 209.165.200.225 255.255.255.252
 no ip redirects
 no ip directed-broadcast
 no ip proxy-arp
 ip verify unicast reverse-path
 ip access-group 111 in
 ip access-group 110 out
!
access-list 110 permit ip 209.165.202.128 0.0.0.31 any
access-list 110 deny ip any any log
access-list 111 deny ip host 0.0.0.0 any log
access-list 111 deny ip 127.0.0.0 0.255.255.255 any log
access-list 111 deny ip 10.0.0.0 0.255.255.255 any log
access-list 111 deny ip 172.16.0.0 0.15.255.255 any log
access-list 111 deny ip 192.168.0.0 0.0.255.255 any log
access-list 111 deny ip 209.165.202.128 0.0.0.31 any log
access-list 111 permit ip any any
```

## Unicast RPF with ACLs and Logging Example

The following example demonstrates the use of ACLs and logging with Unicast RPF. In this example, extended ACL 197 provides entries that deny or permit network traffic for specific address ranges. Unicast RPF is configured on interface Ethernet0 to check packets arriving at that interface.

For example, packets with a source address of 192.168.201.10 arriving at interface Ethernet0 are dropped because of the deny statement in ACL 197. In this case, the ACL information is logged (the logging option is turned on for the ACL entry) and dropped packets are counted per interface and globally. Packets with a source address of 192.168.201.100 arriving at interface Ethernet0 are forwarded because of the permit statement in ACL 197. ACL information about dropped or suppressed packets is logged (logging option turned on for the ACL entry) to the log server.

```
ip cef distributed
!
int eth0/1/1
 ip address 192.168.200.1 255.255.255.0
 ip verify unicast reverse-path 197
!
int eth0/1/2
 ip address 192.168.201.1 255.255.255.0
!
access-list 197 deny ip 192.168.201.0 0.0.0.63 any log-input
access-list 197 permit ip 192.168.201.64 0.0.0.63 any log-input
access-list 197 deny ip 192.168.201.128 0.0.0.63 any log-input
access-list 197 permit ip 192.168.201.192 0.0.0.63 any log-input
access-list 197 deny ip host 0.0.0.0 any log
```

# Unicast Reverse Path Forwarding Loose Mode

The Unicast Reverse Path Forwarding Loose Mode feature creates a new option for Unicast Reverse Path Forwarding (Unicast RPF), providing a scalable anti-spoofing mechanism suitable for use in multihome network scenarios. This mechanism is especially relevant for Internet Service Providers (ISPs), specifically on routers that have multiple links to multiple ISPs. In addition, Unicast RPF (strict or loose mode), when used in conjunction with a Border Gateway Protocol (BGP) “trigger,” provides an excellent quick reaction mechanism that allows network traffic to be dropped on the basis of either the source or destination IP address, giving network administrators an efficient tool for mitigating denial of service (DoS) and distributed denial of service (DDoS) attacks.

## History for the Unicast Reverse Path Forwarding Loose Mode Feature

| Release   | Modification                                                  |
|-----------|---------------------------------------------------------------|
| 12.0(15)S | This feature was introduced.                                  |
| 12.1(8a)E | This feature was integrated into Cisco IOS Release 12.1(8a)E. |
| 12.2(13)T | This feature was integrated into Cisco IOS Release 12.2(13)T. |

## Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

## Prerequisites for Unicast Reverse Path Forwarding Loose Mode

- To use Unicast RPF, you must enable Cisco Express Forwarding (CEF) switching or distributed CEF (dCEF) switching in the router. There is no need to configure the input interface for CEF switching. As long as CEF is running on the router, individual interfaces can be configured for other switching modes.

## Information About Unicast Reverse Path Forwarding Loose Mode

Before configuring Unicast Reverse Path Forwarding Loose Check, you should understand the following concepts:

- [Unicast Reverse Path Forwarding: Background, page 2](#)
- [Loose Mode, page 3](#)

## Unicast Reverse Path Forwarding: Background

A number of common types of DoS attacks take advantage of forged or rapidly changing source IP addresses, allowing attackers to thwart efforts by ISPs to locate or filter these attacks. Unicast RPF was originally created to help mitigate such attacks by providing an automated, scalable mechanism to implement the Internet Engineering Task Force (IETF) Best Common Practices 38/Request for Comments 2827 (BCP 38/RFC 2827) anti-spoofing filtering on the customer-to-ISP network edge. By taking advantage of the information stored in the Forwarding Information Base (FIB) that is created by the CEF switching process, Unicast RPF can determine whether IP packets are spoofed or malformed by matching the IP source address and ingress interface against the FIB entry that reaches “back” to this source (a so-called “reverse lookup”). Packets that are received from one of the best reverse path routes back out of the same interface are forwarded as normal. If there is no reverse path route on the same interface from which the packet was received, it might mean that the source address was modified, and the packet is dropped (by default).

This original implementation of Unicast RPF, known as “strict mode,” required a match between the ingress interface and the reverse path FIB entry. With Unicast RPF, all equal-cost “best” return paths are considered valid, meaning that it works for cases in which multiple return paths exist, provided that each path is equal in routing cost to the others (number of hops, weights, and so on), and as long as the route is in the FIB. Unicast RPF also functions when Enhanced Interior Gateway Routing Protocol (EIGRP) variants are being used and unequal candidate paths back to the source IP address exist. The strict mode works well for customer-to-ISP network edge configurations that have symmetrical flows (including some multihomed configurations in which symmetrical flows can be enforced).

However, some customer-to-ISP network edges and nearly all ISP-to-ISP network edges use multihomed configurations in which routing asymmetry is typical. When traffic flows are asymmetrical, that is, those in which traffic from Network A to Network B would normally take a different path from traffic flowing from Network B to Network A, the Unicast RPF check will always fail the strict mode test. Because this type of asymmetric routing is common among ISPs and in the Internet core, the original implementation of Unicast RPF was not available for use by ISPs on their core routers and ISP-to-ISP links.

Over time and with an increase in DDoS attacks on the Internet, the functionality of Unicast RPF was reviewed as a tool that ISPs can use on the ISP-to-ISP network edge (an ISP router “peered” with another ISP router) to enable dynamic BGP, triggered black-hole filtering. To provide this functionality, however, the mechanisms used with Unicast RPF had to be modified to permit its deployment on the ISP-to-ISP network edge so that asymmetrical routing is not an issue.

## Loose Mode

To provide ISPs with a DDoS resistance tool on the ISP-to-ISP edge of a network, Unicast RPF was modified from its original strict mode implementation to check the source addresses of each ingress packet without regard for the specific interface on which it was received. This modification is known as “loose mode.” Loose mode allows Unicast RPF to automatically detect and drop packets such as the following:

- IETF RFC 1918 source addresses
- Other Documenting Special Use Addresses (DUSA) that should not appear in the source
- Unallocated addresses that have not been allocated by the Regional Internet Registries (RIRs)
- Source addresses that are routed to a null interface on the router

Loose mode removes the match requirement on the specific ingress interface, allowing Unicast RPF to loose-check packets. This packet checking allows the “peering” router of an ISP having multiple links to multiple ISPs to check the source IP address of ingress packets to determine whether they exist in the FIB. If they exist, the packets are forwarded. If they do not exist in the FIB, the packets fail and are dropped. This checking increases resistance against DoS and DDoS attacks that use spoofed source addresses and unallocated IP addresses.

## How to Configure Unicast Reverse Path Forwarding Loose Mode

This section contains the following procedure:

- [Configuring Unicast Reverse Path Forwarding Loose Mode, page 3](#)

### Configuring Unicast Reverse Path Forwarding Loose Mode

To configure Unicast RPF loose mode, perform the following steps.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef**
4. **interface** *type slot/port-adapter/port*
5. **ip verify unicast source reachable-via any**

## DETAILED STEPS

|        | Command or Action                                                                                                   | Purpose                                                                                                          |
|--------|---------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                              | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                      | Enters global configuration mode.                                                                                |
| Step 3 | <b>ip cef</b><br><br><b>Example:</b><br>Router (config)# ip cef                                                     | Enables CEF on the route processor card.                                                                         |
| Step 4 | <b>interface type slot/port-adapter/port</b><br><br><b>Example:</b><br>Router (config)# interface serial5/0/0       | Configures an interface type and enters interface configuration mode.                                            |
| Step 5 | <b>ip verify unicast source reachable-via any</b><br>Router (config-if)# ip verify unicast source reachable-via any | Enables Unicast RPF using loose mode.                                                                            |

## Troubleshooting Tips

### CEF Not Enabled

If CEF is not enabled on your device and an attempt is made to deploy Unicast RPF, the following error message is generated:

```
Router(config-if)# ip verify unicast source reachable-via any
% CEF not enabled. Enable first.
```

### Dropped Packets

If it is believed that Unicast RPF is dropping packets that are deemed valid, it may be necessary to configure an access list within Unicast RPF to pass these specific packets.

- Check to see if Unicast RPF is dropping packets using the following **show** commands.

```
Router# show ip traffic | include unicast RPF
```

The above command output displays the global counter for packets dropped by Unicast RPF. If the packet drop counter is increasing, Unicast RPF is dropping packets.

```
Router# show ip interface {type/slot/port} | include verif
```

The above command output displays drop counters on a per-interface basis. If the packet drop counter is increasing, Unicast RPF is dropping packets on the referenced interface.

- Configure a “classification” access list (one that is used to identify traffic types) and add it to the Unicast RPF configuration on the interface or interfaces that are in question.

In this case, the most prudent classification access list would be one that includes a series of “deny” statements covering the traffic types in question (instead of the more traditional “permit” statements that would be used, for example, in a typical classification access list that would be applied directly to an interface). The **logging** keyword may be useful for this access list as well.

- Apply the above access list to Unicast RPF on the interface in question using the following command:

```
Router (config-if)# ip verify unicast source reachable-via any 199
```

- Periodically check the counters on the above access list using the following **show** command:

```
Router# show ip access-list 199
```

If the access list hit counters are increasing for the packet type in question, Unicast RPF is dropping the packets in question. To permit them, configure an access list using a “permit” statement for the packet type in question and apply it to Unicast RPF.

## Configuration Examples for Unicast Reverse Path Forwarding Loose Mode

This section includes the following configuration example:

- [Configuring Unicast RPF Using Loose Mode: Example, page 5](#)

### Configuring Unicast RPF Using Loose Mode: Example

The following example (see [Figure 1](#)) uses a simple dual-homed ISP to demonstrate the concept of Unicast RPF loose mode. The example illustrates an ISP (A) peering router that is connected to two different upstream ISPs (B and C) and shows that traffic flows into and out of ISP A may be asymmetric given this dual-homed configuration. Hence, provisions for asymmetrical flows (when outbound traffic goes out one link and returns via a different link) must be accounted for by the Unicast RPF deployment. In this case, it is appropriate to use the loose-mode configuration of Unicast RPF because this configuration alleviates the interface dependency of strict mode.

**Figure 1**      **Unicast RPF Loose Mode**

```

interface Serial4/0/0
description - link to ISP B
ip address 192.168.200.225 255.255.255.252
no ip redirects
no ip directed-broadcasts
no ip proxy-arp
ip verify unicast source reachable-via any
!
interface Serial5/0/0
description - link to ISP C
ip address 172.16.100.9 255.255.255.252
no ip redirects
no ip directed-broadcasts
no ip proxy-arp
ip verify unicast source reachable-via any
!

```

# CISCO-IP-URPF-MIB Support

---

**First Published: December 4, 2006**

**Last Updated: July 11, 2008**

Customers use the IP Unicast Reverse Path Forwarding (URPF) feature to avert denial of service (DoS) attacks by verifying the validity of the source IP of an incoming packet. The CISCO-IP-URPF-MIB has been defined to provide Simple Network Management Protocol (SNMP) notification when a specified URPF drop-rate threshold on a managed device is exceeded. The URPF drop-rate threshold can be configured globally for a device, or per interface.

## Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for CISCO-IP-URPF-MIB Support” section on page 13](#).

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for CISCO-IP-URPF-MIB Support

Cisco IOS support for the CISCO-IP-URPF-MIB requires the following to be configured on the device:

- URPF
- Cisco Express Forwarding (CEF)
- IP Routing
- SNMP

## Restrictions for CISCO-IP-URPF-MIB Support

- Because Cisco IOS does not support Virtual Private Network (VPN) routing and forwarding- (VRF)-specific URPF counters, the following MIB objects related to VRF are not supported:
  - cipUrpIfVrfName
  - cipUrpVrfName
  - cipUrpVrfIfDrops
  - cipUrpVrfIfDiscontinuityTime
- This implementation of the CISCO-IP-URPF MIB supports IPv4 only.

## Information About CISCO-IP-URPF-MIB Support

To configure a notification threshold for URPF dropped packets, you should understand the following concepts:

- [Implementing URPF Notification, page 2](#)
- [Software Basis for URPF Notification, page 3](#)

## Implementing URPF Notification

URPF is a security feature that verifies the validity of the source IP of an incoming packet. When a packet arrives at an interface and its source IP is unknown in the routing table or is a known bad source address, URPF drops the packet. Source IP verification is done to prevent denial of service (DoS) attacks by detecting problems with the incoming packets on an interface. However, URPF is challenging to deploy without some automated monitoring capability.

The CISCO-IP-URPF-MIB allows users to specify a URPF drop-rate threshold on interfaces of a managed device, which when exceeded causes an SNMP notification to be sent. This MIB includes objects for specifying global and per-interface drop counts and drop rates, as well as a means of generating SNMP traps when the drop rate exceeds a configurable per-interface threshold.

Although some parameters can be configured globally, this feature must be configured on individual interfaces.

## Software Basis for URPF Notification

The following elements make URPF drop-rate notification work:

- [Global Scalars](#)
- [Global Tables](#)
- [Per-interface Statistics](#)
- [Per-interface Configuration](#)
- [Drop-Rate Computation](#)

### Global Scalars

The following global scalars affect the behavior of the MIB agent in computing all drop rates and controlling notification generation:

- `cipUrpDropRateWindow`  
This object specifies the window of time in the recent past over which the computation takes place. If there were no window (that is, the window is the epoch since booting up), an identical drop count burst at a later time would produce a smaller drop rate than one occurring earlier.
- `cipUrpComputeInterval`  
This object specifies how often the drop-rate computation occurs.
- `cipUrpDropNotifyHoldDownTime`  
This object specifies the minimum time between notifications for a particular packet flow on an interface.

### Global Tables

The CISCO-IP-URPF-MIB includes the following global tables:

- `cipUrpTable`  
This table contains global drop count and drop-rate objects per packet flow (for both IPv4 and IPv6). These global rates are useful for determining quickly whether there is URPF activity on the managed device at a specific time.
- `cipUrpVrfTable`  
This table allows users to index drop counters by VRF, if a VRF routing table is used to determine URPF checking. The table provides a means to index all the URPF-enabled interfaces by VRF.

### Per-interface Statistics

The following MIB objects track per-interface statistics:

- `cipUrpIfMonTable`  
This table contains the statistics for a particular packet flow on an interface.
- `cipUrpIfDrops`  
This object accumulates URPF drops on an interface. Snapshots of this value are used in the drop-rate computation. Computed drop rate is specified in the **`cipUrpIfDropRate` object**. If URPF is configured on a subinterface, drop rates are computed.

## Per-interface Configuration

The following MIB objects enable per-interface configuration.

- **cipUrpIfDropRateNotifyEnable**

This object specifies whether the system produces the **cipUrpIfDropRateNotify** notification because URPF has dropped of version **cipUrpIfIpVersion** IP packets on the specified interface.

- **cipUrpIfNotifyDropRateThreshold**

This object specifies the drop-rate threshold value above which a notification is generated.

## Drop-Rate Computation

Whenever URPF is configured on an interface, the drop-rate calculation is performed periodically (at intervals specified by the **cipUrpComputeInterval** object). Drop rates are computed over a constantly sliding window, covering the period ending with the performance of the calculation and starting the configured number of seconds before the calculation.

# How to Configure URPF Drop-Rate Notification

This section contains the following tasks:

- [Configuring URPF Drop-Rate Notification via Syslog, page 4](#)
- [Configuring URPF Drop-Rate Notification via SNMP, page 6](#)
- [Verifying the URPF Configuration, page 7](#)

## Configuring URPF Drop-Rate Notification via Syslog

This task describes how to configure the URPF drop-rate threshold and computation parameters for notification via syslog.

## Prerequisites

You must have URPF configured on the router before configuring this feature. For information about configuring URPF, see [Configuring Unicast Reverse Path Forwarding](#).

## Restrictions

This feature can be configured only with IPv4.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip verify drop-rate compute window *seconds***
4. **ip verify drop-rate compute interval *seconds***
5. **ip verify drop-rate notify hold-down *seconds***

6. **configure interface** *type number*
7. **ip verify unicast notification threshold** *rate-val*

## DETAILED STEPS

|        | Command or Action                                                                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                                  |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b>                                                                                                                                              | Enables privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                            |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                             | Enters global configuration mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                                                                                                                                                                                                                                  |
| Step 3 | <b>ip verify drop-rate compute window</b> <i>seconds</i><br><br><b>Example:</b><br>Router <config># ip verify drop-rate compute window 60                  | Configures the period of time, in seconds, over which the URPF drop count used in the drop-rate computation is collected.<br><br>The range of the seconds argument is from 30 to 300. The default is 300.<br><br><b>Note</b> The value for the compute window must be greater than or equal to that entered for the <b>ip verify drop-rate compute interval</b> command. |
| Step 4 | <b>ip verify drop-rate compute interval</b> <i>seconds</i><br><br><b>Example:</b><br>Router <config># ip verify drop-rate compute interval 60              | Configures the interval of time, in seconds, between URPF drop-rate computations.<br><br>The range of the seconds argument is from 30 to 300. The default is 30.<br><br><b>Note</b> The value for the compute interval must be less than or equal to that entered for the <b>ip verify drop-rate compute window</b> command.                                             |
| Step 5 | <b>ip verify drop-rate notify hold-down</b> <i>seconds</i><br><br><b>Example:</b><br>Router <config># ip verify drop-rate notify hold-down 60              | Configures the minimum time, in seconds, between URPF drop-rate notifications.<br><br>The range of the seconds argument is from 30 to 300. The default is 300.                                                                                                                                                                                                           |
| Step 6 | <b>configure interface</b> <i>type number</i><br><br><b>Example:</b><br>Router# configure interface ethernet 3/0                                           | Enters privileged EXEC mode.<br><br>Enters interface configuration mode.                                                                                                                                                                                                                                                                                                 |
| Step 7 | <b>ip verify unicast notification threshold</b> <i>rate-val</i><br><br><b>Example:</b><br>Router (config-if)# ip verify unicast notification threshold 750 | Configures the threshold value, in packets per second, used to determine whether to send a URPF drop-rate notification.<br><br>The range is from 0 to the maximum number of packets the interface can process in 1 second. The default is 1000.<br><br><b>Note</b> If you configure the threshold to be 0, every packet drop will trigger a notification.                |

## Configuring URPF Drop-Rate Notification via SNMP

This task describes how to configure the URPF drop-rate threshold and computation parameters for notification via SNMP.

### Prerequisites

You must have URPF configured on the router before configuring this feature. For information about configuring URPF, see [Configuring Unicast Reverse Path Forwarding](#).

You must enable SNMP on the router to use this feature. For information about enabling SNMP, see [Configuring SNMP Support](#).

### Restrictions

This feature can be configured only with IPv4.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip verify drop-rate compute window *seconds***
4. **ip verify drop-rate compute interval *seconds***
5. **ip verify drop-rate notify hold-down *seconds***
6. **configure interface *type number***
7. **ip verify unicast notification threshold *rate-val***
8. **snmp trap ip verify drop-rate**

### DETAILED STEPS

|        | Command or Action                                                         | Purpose                                                                                                                                                 |
|--------|---------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b>                                                             | Enables privileged EXEC mode.                                                                                                                           |
| Step 2 | <b>configure terminal</b>                                                 | Enters global configuration mode.                                                                                                                       |
|        | <b>Example:</b><br>Router# configure terminal                             |                                                                                                                                                         |
| Step 3 | <b>ip verify drop-rate compute window <i>seconds</i></b>                  | Configures the period of time, in seconds, over which the URPF drop count used in the drop-rate computation is collected.                               |
|        | <b>Example:</b><br>Router <config># ip verify drop-rate compute window 60 | The range is from 30 to 300. The default is 300.                                                                                                        |
|        |                                                                           | <b>Note</b> The value for the compute window must be greater than or equal to that entered for the <b>ip verify drop-rate compute interval</b> command. |

|        | Command or Action                                                                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                   |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 4 | <b>ip verify drop-rate compute interval <i>seconds</i></b><br><br><b>Example:</b><br>Router <config># ip verify drop-rate compute interval 60              | Configures the interval of time, in seconds, between URPF drop-rate computations.<br><br>The range is from 30 to 300. The default is 30.<br><br><b>Note</b> The value for the compute interval must be less than or equal to that entered for the <b>ip verify drop-rate compute window</b> command                                                       |
| Step 5 | <b>ip verify drop-rate notify hold-down <i>seconds</i></b><br><br><b>Example:</b><br>Router <config># ip verify drop-rate notify hold-down 60              | Configures the minimum time, in seconds, between URPF drop-rate notifications.<br><br>The range is from 30 to 300. The default is 300.<br><br>Enters privileged EXEC mode.                                                                                                                                                                                |
| Step 6 | <b>configure interface <i>type number</i></b><br><br><b>Example:</b><br>Router# configure interface ethernet 3/0                                           | Enters interface configuration mode.                                                                                                                                                                                                                                                                                                                      |
| Step 7 | <b>ip verify unicast notification threshold <i>rate-val</i></b><br><br><b>Example:</b><br>Router (config-if)# ip verify unicast notification threshold 750 | Configures the threshold value, in packets per second, used to determine whether to send a URPF drop-rate notification.<br><br>The range is from 0 to the maximum number of packets the interface can process in 1 second. The default is 1000.<br><br><b>Note</b> If you configure the threshold to be 0, every packet drop will trigger a notification. |
| Step 8 | <b>snmp trap ip verify drop-rate</b><br><br><b>Example:</b><br>Router (config-if)# snmp trap ip verify drop-rate                                           | Configures the router to send an SNMP notification when the URPF drop rate exceeds the configured threshold.                                                                                                                                                                                                                                              |

## Verifying the URPF Configuration

You can use the following two commands to verify the URPF configuration and troubleshoot the operation of URPF drop-rate notification.

### SUMMARY STEPS

1. **enable**
2. **show ip interface *type number***
3. **debug ip verify mib**

## DETAILED STEPS

|        | Command or Action                                                                                     | Purpose                                                                                                                       |
|--------|-------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>              |
| Step 2 | <b>show ip interface type number</b><br><br><b>Example:</b><br>Router# show ip interface ethernet 3/0 | Displays the verification drop rate and the number of verification drops when URPF is configured for the specified interface. |
| Step 3 | <b>debug ip verify mib</b><br><br><b>Example:</b><br>Router# debug ip verify mib                      | Displays output useful for troubleshooting URPF notification.                                                                 |

## Examples

The last five lines in following example shows the output of the **show ip interface** command when URPF is configured:

Router# **show ip interface ethernet 2/3**

```

Ethernet2/3 is up, line protocol is up
 Internet address is 10.10.5.4/16
 Broadcast address is 255.255.255.255
 Address determined by non-volatile memory
 MTU is 1500 bytes
 Helper address is not set
 Directed broadcast forwarding is disabled
 Outgoing access list is not set
 Inbound access list is not set
 Proxy ARP is enabled
 Local Proxy ARP is disabled
 Security level is default
 Split horizon is enabled
 ICMP redirects are always sent
 ICMP unreachable are always sent
 ICMP mask replies are never sent
 IP fast switching is disabled
 IP Flow switching is disabled
 IP CEF switching is disabled
 IP Null turbo vector
 IP Null turbo vector
 IP multicast fast switching is disabled
 IP multicast distributed fast switching is disabled
 IP route-cache flags are No CEF
 Router Discovery is disabled
 IP output packet accounting is disabled
 IP access violation accounting is disabled
 TCP/IP header compression is disabled
 RTP/IP header compression is disabled
 Probe proxy name replies are disabled
 Policy routing is disabled
 Network address translation is disabled
 WCCP Redirect outbound is disabled
 WCCP Redirect inbound is disabled

```

The following example shows the output of the **debug ip verify mib** command:

```

## Configuring URPF Drop-Rate Notification via Syslog: Example

The following example shows how to configure URPF drop-rate notification via syslog:

```
configure terminal
ip verify drop-rate compute window 60
ip verify drop-rate compute interval 60
ip verify drop-rate hold-down 60
configure interface ethernet 3/0
interface ethernet 3/0
ip verify unicast notification threshold 750
```

## Configuring URPF Drop-Rate Notification via SNMP: Example

The following example shows how to configure URPF drop-rate notification via SNMP:

```
configure terminal
ip verify drop-rate compute window 60
ip verify drop-rate compute interval 60
ip verify drop-rate hold-down 60
configure interface ethernet 3/0
interface ethernet 3/0
ip verify unicast notification threshold 750
snmp trap ip verify drop-rate
```

## Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Security Command Reference* at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html). For information about all Cisco IOS commands, use the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or a Cisco IOS master commands list.

- **debug ip verify mib**
- **ip verify drop-rate compute interval**
- **ip verify drop-rate compute window**
- **ip verify drop-rate notify hold-down**
- **ip verify unicast notification threshold**
- **show ip interface**
- **snmp trap ip verify drop-rate**

# Feature Information for CISCO-IP-URPF-MIB Support

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1** Feature Information for CISCO-IP-URPF-MIB Support

| Feature Name              | Releases                                | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## **Secure Shell**

# Secure Copy

---

The Secure Copy (SCP) feature provides a secure and authenticated method for copying router configuration or router image files. SCP relies on Secure Shell (SSH), an application and a protocol that provide a secure replacement for the Berkeley r-tools.

## Feature History for Secure Copy

| Release                  | Modification                                                  |
|--------------------------|---------------------------------------------------------------|
| 12.2(2)T                 | This feature was introduced.                                  |
| 12.0(21)S                | This feature was integrated into Cisco IOS 12.0(21)S.         |
| 12.2(25)S                | This feature was integrated into Cisco IOS 12.2(25)S.         |
| Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers. |

## Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

## Prerequisites for Secure Copy

- Before enabling SCP, you must correctly configure SSH, authentication, and authorization on the router.
- Because SCP relies on SSH for its secure transport, the router must have an Rivest, Shamir, and Adelman (RSA) key pair.

## Information About Secure Copy

To configure Secure Copy feature, you should understand the following concepts.

- [How SCP Works, page 2](#)

## How SCP Works

The behavior of SCP is similar to that of remote copy (rcp), which comes from the Berkeley r-tools suite, except that SCP relies on SSH for security. In addition, SCP requires that authentication, authorization, and accounting (AAA) authorization be configured so the router can determine whether the user has the correct privilege level.

SCP allows a user who has appropriate authorization to copy any file that exists in the Cisco IOS File System (IFS) to and from a router by using the **copy** command. An authorized administrator may also perform this action from a workstation.

## How to Configure SCP

This section contains the following procedures:

- [Configuring SCP, page 2](#)
- [Verifying SCP, page 3](#)
- [Troubleshooting SCP, page 4](#)

## Configuring SCP

To enable and configure a Cisco router for SCP server-side functionality, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa new-model**
4. **aaa authentication login** {default | list-name} method1 [method2...]
5. **aaa authorization** {network | exec | commands level | reverse-access | configuration} {default | list-name} [method1 [method2...]]
6. **username** name [privilege level] {password encryption-type encrypted-password}

## 7. ip scp server enable

### DETAILED STEPS

|        | Command                                                                                                                                                                                                                   | Purpose                                                                                                                                                                                                                            |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | enable<br><br><b>Example:</b><br>Router> enable                                                                                                                                                                           | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>Enter your password if prompted.</li></ul>                                                                                                                  |
| Step 2 | configure terminal<br><br><b>Example:</b><br>Router# configure terminal                                                                                                                                                   | Enters global configuration mode.                                                                                                                                                                                                  |
| Step 3 | aaa new-model<br><br><b>Example:</b><br>Router (config)# aaa new-model                                                                                                                                                    | Sets AAA authentication at login.                                                                                                                                                                                                  |
| Step 4 | aaa authentication login {default   list-name} method1 [method2...]<br><br><b>Example:</b><br>Router (config)# aaa authentication login default group tacacs+                                                             | Enables the AAA access control system.                                                                                                                                                                                             |
| Step 5 | aaa authorization {network   exec   commands level   reverse-access   configuration} {default   list-name} [method1 [method2...]]<br><br><b>Example:</b><br>Router (config)# aaa authorization exec default group tacacs+ | Sets parameters that restrict user access to a network.<br><br><b>Note</b> The <b>exec</b> keyword runs authorization to determine if the user is allowed to run an EXEC shell; therefore, you must use it when you configure SCP. |
| Step 6 | username name [privilege level] {password encryption-type encrypted-password}<br><br><b>Example:</b><br>Router (config)# username superuser privilege 2 password 0 superpassword                                          | Establishes a username-based authentication system.<br><br><b>Note</b> You may skip this step if a network-based authentication mechanism—such as TACACS+ or RADIUS—has been configured.                                           |
| Step 7 | ip scp server enable<br><br><b>Example:</b><br>Router (config)# ip scp server enable                                                                                                                                      | Enables SCP server-side functionality.                                                                                                                                                                                             |

## Verifying SCP

To verify SCP server-side functionality, perform the following steps.

**SUMMARY STEPS**

1. **enable**
2. **show running-config**

**DETAILED STEPS**

|        | Command or Action                                                                | Purpose                                                                                                            |
|--------|----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                           | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>show running-config</b><br><br><b>Example:</b><br>Router# show running-config | Verifies the SCP server-side functionality.                                                                        |

**Troubleshooting SCP**

To troubleshoot SCP authentication problems, perform the following steps.

**SUMMARY STEPS**

1. **enable**
2. **debug ip scp**

**DETAILED STEPS**

|        | Command or Action                                                  | Purpose                                                                                                            |
|--------|--------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable             | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>debug ip scp</b><br><br><b>Example:</b><br>Router# debug ip scp | Troubleshoots SCP authentication problems.                                                                         |

**Configuration Examples for Secure Copy**

This section provides the following configuration examples:

- [SCP Server-Side Configuration Using Local Authentication: Example, page 5](#)
- [SCP Server-Side Configuration Using Network-Based Authentication: Example, page 5](#)

## SCP Server-Side Configuration Using Local Authentication: Example

The following example shows how to configure the server-side functionality of SCP. This example uses a locally defined username and password.

```
! AAA authentication and authorization must be configured properly for SCP to work.
aaa new-model
aaa authentication login default local
aaa authorization exec default local
username tiger privilege 15 password 0 lab
! SSH must be configured and functioning properly.
ip ssh time-out 120
ip ssh authentication-retries 3
ip scp server enable
```

## SCP Server-Side Configuration Using Network-Based Authentication: Example

The following example shows how to configure the server-side functionality of SCP using a network-based authentication mechanism:

```
! AAA authentication and authorization must be configured properly for SCP to work.
aaa new-model
aaa authentication login default group tacacs+
aaa authorization exec default group tacacs+
! SSH must be configured and functioning properly.
ip ssh time-out 120
ip ssh authentication-retries 3
ip scp server enable
```

## Additional References

The following sections provide references related to Secure Copy.

## Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Security Command Reference* at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html). For information about all Cisco IOS commands, go to the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or to the *Cisco IOS Master Commands List*.

- **debug ip scp**
- **ip scp server enable**

# Glossary

**AAA**—authentication, authorization, and accounting. Framework of security services that provide the method for identifying users (authentication), for remote access control (authorization), and for collecting and sending security server information used for billing, auditing, and reporting (accounting).

**rcp**—remote copy. Relying on Remote Shell (Berkeley r-tools suite) for security, rcp copies files, such as router images and startup configurations, to and from routers.

**SCP**—secure copy. Relying on SSH for security, SCP support allows the secure and authenticated copying of anything that exists in the Cisco IOS File Systems. SCP is derived from rcp.

**SSH**—Secure Shell. Application and a protocol that provide a secure replacement for the Berkeley r-tools. The protocol secures the sessions using standard cryptographic mechanisms, and the application can be used similarly to the Berkeley rexec and rsh tools. SSH Version 1 is implemented in the Cisco IOS software.

# Secure Shell Version 2 Support

---

**First Published: November 3, 2003**

**Last Updated: July 11, 2008**

The Secure Shell Version 2 Support feature allows you to configure Secure Shell (SSH) Version 2 (SSH Version 1 support was implemented in an earlier Cisco IOS software release). SSH runs on top of a reliable transport layer and provides strong authentication and encryption capabilities. Currently, the only reliable transport that is defined for SSH is TCP. SSH provides a means to securely access and securely execute commands on another computer over a network. The Secure Copy Protocol (SCP) feature that is provided with SSH also allows for the secure transfer of files.

## Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for Secure Shell Version 2 Support” section on page 20](#).

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

---

**Americas Headquarters:**

**Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA**

## Prerequisites for Secure Shell Version 2 Support

Prior to configuring SSH, perform the following task:

- Download the required image on your router. The SSH server requires you to have a k9 (Triple Data Encryption Standard [3DES]) software image from Cisco IOS Release 12.3(4)T, 12.2(25)S, or 12.3(7)JA downloaded on your router.

**Note**

The SSH Version 2 server is supported in Cisco IOS Release 12.3(4)T, 12.3(2)XE, 12.2(25)S, and 12.3(7)JA; the SSH Version 2 client is supported beginning with Cisco IOS Release 12.3(7)T and is supported in Cisco IOS Release 12.3(7)JA. (The SSH client runs both the SSH Version 1 and Version 2 protocol and is supported in both k8 and k9 images in Cisco IOS Release 12.3(4)T.)

For more information on downloading a software image, refer to [Cisco IOS Configuration Fundamentals and Network Management Configuration Guide](#).

## Restrictions for Secure Shell Version 2 Support

- Rivest, Shamir, and Adelman (RSA) user authentication is not supported in the SSH server or SSH client for Cisco IOS software.
- SSH servers and SSH clients are supported in 3DES software images.
- Execution Shell, remote command execution, and Secure Copy Protocol (SCP) are the only applications supported.
- Compression is not supported.
- The RSA key-pair size must be greater than or equal to 768.

## Information About Secure Shell Version 2 Support

To configure SSH Version 2, you should understand the following concept:

- [Secure Shell Version 2, page 2](#)
- [SNMP Trap Generation, page 3](#)
- [SSH Keyboard Interactive Authentication, page 4](#)

## Secure Shell Version 2

The Secure Shell Version 2 Support feature allows you to configure SSH Version 2.

The configuration for the SSH Version 2 server is similar to the configuration for SSH Version 1. The command **ip ssh version** has been introduced so that you may define which version of SSH that you want to configure. If you do not configure this command, SSH by default runs in compatibility mode; that is, both SSH Version 1 and SSH Version 2 connections are honored.

**Note**

SSH Version 1 is a protocol that has never been defined in a standard. If you do not want your router to fall back to the undefined protocol (Version 1), you should use the **ip ssh version** command and specify Version 2.

The **ip ssh rsa keypair-name** command was also introduced in Cisco IOS Release 12.3(4)T so that you can enable a SSH connection using RSA keys that you have configured. Previously, SSH was linked to the first RSA keys that were generated (that is, SSH was enabled when the first RSA key pair was generated). The behavior still exists, but by using the **ip ssh rsa keypair-name** command, you can overcome that behavior. If you configure the **ip ssh rsa keypair-name** command with a key-pair name, SSH is enabled if the key pair exists, or SSH will be enabled if the key pair is generated later. If you use this command to enable SSH, you are not forced to configure a host name and a domain name, which was required in SSH Version 1 of the Cisco IOS software.

**Note**

The login banner is supported in Secure Shell Version 2, but it is not supported in Secure Shell Version 1.

## Secure Shell Version 2 Enhancements

The Secure Shell Version 2 Enhancements include a number of additional capabilities such as supporting VRF aware SSH, SSH debug enhancements, and Diffie-Hellman group exchange support.

The Cisco IOS SSH implementation has traditionally used 768 bit modulus but with an increasing need for higher key sizes to accommodate Diffie-Hellman (DH) Group 14 (2048 bits) and Group 16 (4096 bits) cryptographic applications a message exchange between the client and server to establish the favored DH group becomes necessary. The **ip ssh dh min size** command was introduced in Cisco IOS Release 12.4(20)T so you can configure modulus size on the SSH server. In addition to this the **ssh** command was extended to add VRF awareness to SSH client side functionality through which the VRF instance name in the client is provided with the IP address to look up the correct routing table and establish a connection.

Debugging has been enhanced by modifying SSH debug commands. The **debug ip ssh** command has been extended to allow you to simplify the debugging process. Previously this command printed all debug messages related to SSH regardless of what was specifically required. The behavior still exists, but if you configure the **debug ip ssh** command with a keyword messages are limited to information specified by the keyword.

## SNMP Trap Generation

Effective with Cisco IOS Release 12.4(17), Simple Network Management Protocol (SNMP) traps will be generated automatically when an SSH session terminates if the traps have been enabled and SNMP debugging has been turned on. For information about enabling SNMP traps, see the chapter “[Configuring SNMP Support](#)” in the *Cisco IOS Network Management Configuration Guide*.

**Note**

When configuring the **snmp-server host** command, the IP address must be the address of the PC that has the SSH (telnet) client and that has IP connectivity to the SSH server. For an example of an SNMP trap generation configuration, see the section “[Setting an SNMP Trap: Example](#).”

You must also turn on SNMP debugging using the **debug snmp packet** command to display the traps. The trap information includes information such as the number of bytes sent and the protocol that was used for the SSH session. For an example of SNMP debugging, see the section “[SNMP Debugging: Example](#).”

## SSH Keyboard Interactive Authentication

The SSH Keyboard Interactive Authentication feature, also known as Generic Message Authentication for SSH, is a method that can be used to implement different types of authentication mechanisms. Basically, any currently supported authentication method that requires only user input can be performed with this feature. The feature is automatically deployed.

The following methods are currently supported:

- Password
- SecurID and hardware tokens printing a number or a string in response to a challenge sent by the server
- Pluggable Authentication Module (PAM)
- S/KEY (and other One-Time-Pads)

For examples of various scenarios in which the SSH Keyboard Interactive Authentication feature has been automatically deployed, see the chapter “[SSH Keyboard Interactive Authentication: Examples](#).”

## How to Configure Secure Shell Version 2 Support

This section contains the following procedures:

- [Configuring a Router for SSH Version 2 Using a Host Name and Domain Name, page 4](#) (required)
- [Configuring a Router for SSH Version 2 Using RSA Key Pairs, page 5](#) (optional)
- [Starting an Encrypted Session with a Remote Device, page 7](#) (optional)
- [Verifying the Status of the Secure Shell Connection Using the show ssh Command, page 7](#) (optional)
- [Verifying the Secure Shell Status Using the show ip ssh Command, page 9](#) (optional)
- [Monitoring and Maintaining Secure Shell Version 2, page 10](#) (optional)

## Configuring a Router for SSH Version 2 Using a Host Name and Domain Name

To configure your router for SSH Version 2 using a host name and domain name, perform the following steps. You may also configure SSH Version 2 by using the RSA key pair configuration (See the section “[Configuring a Router for SSH Version 2 Using RSA Key Pairs](#)”).

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **hostname** *hostname*
4. **ip domain-name** *name*

5. `crypto key generate rsa`
6. `ip ssh [timeout seconds | authentication-retries integer]`
7. `ip ssh version [1 | 2]`

## DETAILED STEPS

|        | Command or Action                                                                                                                            | Purpose                                                                                                          |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                       | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                               | Enters global configuration mode.                                                                                |
| Step 3 | <b>hostname <i>hostname</i></b><br><br><b>Example:</b><br>Router (config)# hostname cisco 7200                                               | Configures a host name for your router.                                                                          |
| Step 4 | <b>ip domain-name <i>name</i></b><br><br><b>Example:</b><br>Router (config)# ip domain-name cisco.com                                        | Configures a domain name for your router.                                                                        |
| Step 5 | <b>crypto key generate rsa</b><br><br><b>Example:</b><br>Router (config)# crypto key generate rsa                                            | Enables the SSH server for local and remote authentication.                                                      |
| Step 6 | <b>ip ssh [timeout <i>seconds</i>   authentication-retries <i>integer</i>]</b><br><br><b>Example:</b><br>Router (config)# ip ssh timeout 120 | (Optional) Configures SSH control variables on your router.                                                      |
| Step 7 | <b>ip ssh version [1   2]</b><br><br><b>Example:</b><br>Router (config)# ip ssh version 1                                                    | (Optional) Specifies the version of SSH to be run on your router.                                                |

## Configuring a Router for SSH Version 2 Using RSA Key Pairs

To enable SSH Version 2 without configuring a host name or domain name, perform the following steps. SSH Version 2 will be enabled if the key pair that you configure already exists or if it is generated later. You may also configure SSH Version 2 by using the host name and domain name configuration (See the section “[Configuring a Router for SSH Version 2 Using a Host Name and Domain Name](#)”).

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip ssh rsa keypair-name** *keypair-name*
4. **crypto key generate rsa usage-keys label** *key-label* **modulus** *modulus-size*
5. **ip ssh [timeout** *seconds* **| authentication-retries** *integer*]
6. **ip ssh version 2**

## DETAILED STEPS

|        |                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                  |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                         | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                 |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                                 | Enters global configuration mode.                                                                                                                                                                                                                                                                                                |
| Step 3 | <b>ip ssh rsa keypair-name</b> <i>keypair-name</i><br><br><b>Example:</b><br>Router (config)# ip ssh rsa keypair-name<br>sshkeys                                                                               | Specifies which RSA keypair to use for SSH usage.<br><br><b>Note</b> A Cisco IOS router can have many RSA key pairs.                                                                                                                                                                                                             |
| Step 4 | <b>crypto key generate rsa usage-keys label</b> <i>key-label</i> <b>modulus</b> <i>modulus-size</i><br><br><b>Example:</b><br>Router (config)# crypto key generate rsa<br>usage-keys label sshkeys modulus 768 | Enables the SSH server for local and remote authentication on the router.<br><br>For SSH Version 2, the modulus size must be at least 768 bits.<br><br><b>Note</b> To delete the RSA key-pair, use the <b>crypto key zeroize rsa</b> command. After you have deleted the RSA key-pair, you automatically disable the SSH server. |
| Step 5 | <b>ip ssh [timeout</b> <i>seconds</i> <b>  authentication-retries</b> <i>integer</i> ]<br><br><b>Example:</b><br>Router (config)# ip ssh timeout 120                                                           | Configures SSH control variables on your router.                                                                                                                                                                                                                                                                                 |
| Step 6 | <b>ip ssh version 2</b><br><br><b>Example:</b><br>Router (config)# ip ssh version 2                                                                                                                            | Specifies the version of SSH to be run on a router.                                                                                                                                                                                                                                                                              |

## Starting an Encrypted Session with a Remote Device

To start an encrypted session with a remote networking device, perform the following step. (You do not have to enable your router. SSH can be run in disabled mode.)

### Note

The device you wish to connect with must support a SSH server that has an encryption algorithm that is supported in Cisco IOS software.

### SUMMARY STEPS

1. `ssh [-v {1 | 2}] [-c {3des | aes128-cbc | aes192-cbc | aes256-cbc}] [-m {hmac-md5 | hmac-md5-96 | hmac-sha1 | hmac-sha1-96}] [l userid] [-o numberofpasswordprompts n] [-p port-num] {ip-addr | hostname} [command]`

### DETAILED STEPS

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                     |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| <p><b>Step 1</b></p> <pre>ssh [-v {1   2}] [-c {3des   aes128-cbc   aes192-cbc   aes256-cbc}] [-m {hmac-md5   hmac-md5-96   hmac-sha1   hmac-sha1-96}] [l <i>userid</i>] [-o <i>numberofpasswordprompts n</i>] [-p <i>port-num</i>] {<i>ip-addr</i>   <i>hostname</i>} [<i>command</i>]</pre> <p><b>Example:</b></p> <pre>Router# ssh -v 2 -c aes256-cbc -m hmac-sha1-96 -l user2 10.76.82.24</pre> <p>Or</p> <p>The above example adheres to the SSH Version 2 conventions. A more natural and common way to start a session is by linking the username with the hostname. For example, the following configuration example provides an end result that is identical to that of the above example:</p> <pre>Router# ssh -v 2 -c aes256-cbc -m hmac-sha1-96 user2@10.76.82.24</pre> | <p>Starts an encrypted session with a remote networking device.</p> |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|

### Troubleshooting Tips

The **ip ssh version** command can be used for troubleshooting your SSH configuration. By changing versions, you can determine which SSH version has a problem.

## Verifying the Status of the Secure Shell Connection Using the show ssh Command

To display the status of the SSH connection on your router, use the **show ssh** command.

## SUMMARY STEPS

1. **enable**
2. **show ssh**

## DETAILED STEPS

|        |                                                            |                                                                                                                  |
|--------|------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable     | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>show ssh</b><br><br><b>Example:</b><br>Router# show ssh | Displays the status of SSH server connections.                                                                   |

## Examples

The following output examples from the **show ssh** command display status about various SSH Version 1 and Version 2 connections.

## Version 1 and Version 2 Connections

```
Router# show ssh
```

```

Connection Version Encryption State Username
0 1.5 3DES Session started lab
Connection Version Mode Encryption Hmac State
Username
1 2.0 IN aes128-cbc hmac-md5 Session started lab
1 2.0 OUT aes128-cbc hmac-md5 Session started lab

```

## Version 2 Connection with No Version 1

```
Router# show ssh
```

```

Connection Version Mode Encryption Hmac State
Username
1 2.0 IN aes128-cbc hmac-md5 Session started lab
1 2.0 OUT aes128-cbc hmac-md5 Session started lab
%No SSHv1 server connections running.

```

## Version 1 Connection with No Version 2

```
Router# show ssh
```

```

Connection Version Encryption State Username
0 1.5 3DES Session started lab
%No SSHv2 server connections running.

```

## Verifying the Secure Shell Status Using the show ip ssh Command

To verify your SSH configuration, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **show ip ssh**

### DETAILED STEPS

|        |                                                                  |                                                                                                                  |
|--------|------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable           | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>show ip ssh</b><br><br><b>Example:</b><br>Router# show ip ssh | Displays the version and configuration data for SSH.                                                             |

### Examples

The following examples from the **show ip ssh** command display the version of SSH that is enabled, the authentication timeout values, and the number of authentication retries.

#### Version 1 and Version 2 Connections

```

router# show ip ssh

3d06h: %SYS-5-CONFIG_I: Configured from console by consoleh
SSH Enabled - version 1.99
Authentication timeout: 120 secs; Authentication retries: 3

```

#### Version 2 Connection with No Version 1

```

Router# show ip ssh

SSH Enabled - version 2.0
Authentication timeout: 120 secs; Authentication retries: 3

```

#### Version 1 Connection with No Version 2

```

Router# show ip ssh

3d06h: %SYS-5-CONFIG_I: Configured from console by console
SSH Enabled - version 1.5
Authentication timeout: 120 secs; Authentication retries: 3

```

## Monitoring and Maintaining Secure Shell Version 2

To display debug messages about the SSH connections, use the **debug ip ssh** command.

### SUMMARY STEPS

1. **enable**
2. **debug ip ssh**
3. **debug snmp packet**

### DETAILED STEPS

|        |                                                                              |                                                                                                                  |
|--------|------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                       | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>debug ip ssh</b><br><br><b>Example:</b><br>Router# debug ip ssh           | Displays debugging messages for SSH.                                                                             |
| Step 3 | <b>debug snmp packet</b><br><br><b>Example:</b><br>Router# debug snmp packet | Displays information about every SNMP packet sent or received by the router.                                     |

### Example

The following output from the **debug ip ssh** command shows that the digit 2 keyword has been assigned, signifying that it is an SSH Version 2 connection.

Router# **debug ip ssh**

```
00:33:55: SSH1: starting SSH control process
00:33:55: SSH1: sent protocol version id SSH-1.99-Cisco-1.25
00:33:55: SSH1: protocol version id is - SSH-2.0-OpenSSH_2.5.2p2
00:33:55: SSH2 1: send: len 280 (includes padlen 4)

00:34:08: SSH1: Session terminated normally

```

# Configuration Examples for Secure Shell Version 2 Support

This section provides the following configuration examples:

- [Configuring Secure Shell Version 1: Example, page 13](#)
- [Configuring Secure Shell Version 2: Example, page 13](#)
- [Configuring Secure Shell Versions 1 and 2: Example, page 13](#)
- [Starting an Encrypted Session with a Remote Device: Example, page 13](#)
- [Setting an SNMP Trap: Example, page 13](#)
- [SSH Keyboard Interactive Authentication: Examples, page 14](#)
- [SNMP Debugging: Example, page 16](#)
- [SSH Debugging Enhancements: Examples, page 16](#)

## Configuring Secure Shell Version 1: Example

```
Router# configure terminal
Router (config)# ip ssh version 1
c7200-25-2013(config)# end
```

## Configuring Secure Shell Version 2: Example

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# ip ssh version 2
Router(config)# end
```

## Configuring Secure Shell Versions 1 and 2: Example

```
Router# configure terminal
Router (config)# no ip ssh version
Router (config)# end
```

## Starting an Encrypted Session with a Remote Device: Example

```
Router# ssh -v 2 -c aes256-cbc -m hmac-sha1-160 -l shaship 10.76.82.24
```

## Setting an SNMP Trap: Example

The following shows that an SNMP trap has been set. The trap notification is generated automatically when the SSH session terminates. For an example of SNMP trap debug output, see the section “[SNMP Debugging: Example](#).”

```
snmp-server
snmp-server host a.b.c.d public tty
```

Where a.b.c.d is the IP address of the SSH client.

## SSH Keyboard Interactive Authentication: Examples

The following are examples of various scenarios in which the SSH Keyboard Interactive Authentication feature has been automatically deployed:

### Client-Side Debugs

In the following example, client-side debugs are turned on and the maximum number of prompts = six, (three each for the SSH Keyboard Interactive Authentication method and for the password method of authentication).

```
Password:
Password:
Password:
Password:
Password:
Password: cisco123
Last login: Tue Dec 6 13:15:21 2005 from 10.76.248.213
user1@courier:~> exit
logout
[Connection to 10.76.248.200 closed by foreign host]
```

```
Router1# debug ip ssh client
```

SSH Client debugging is on

```
Router1# ssh -l lab 10.1.1.3

### TACACS+ ACS Is the Backend AAA Server, ChPass Is Enabled, and a Blank Password Change Is Made

In the following example, a TACACS+ access control server (ACS) is the backend Accounting, Authentication, and Authorization (AAA) server; the ChPass feature is enabled; and a blank password change is accomplished using the SSH Keyboard Interactive Authentication method:

```
Router1# ssh -l cisco 10.1.1.3
Password:
Old Password: cisco
New Password: cisco123
Re-enter New password: cisco123

Router2> exit
[Connection to 10.1.1.3 closed by foreign host]
```

**TACACS+ ACS Is the Backend AAA Server, ChPass Is Enabled, and the Password Is Changed on First Login**

In the following example, a TACACS+ ACS is the backend server, and the ChPass feature is enabled. The password is changed on the first login using the SSH Keyboard Interactive Authentication method:

```
Router1# ssh -l cisco 10.1.1.3
Password: cisco
Your password has expired.
Enter a new one now.
New Password: cisco123
Re-enter New password: cisco123

Router2> exit
[Connection to 10.1.1.3 closed by foreign host]
```

```
Router1# ssh -l cisco 10.1.1.3
Password:cisco1
Your password has expired.
Enter a new one now.
New Password: cisco
Re-enter New password: cisco12
The New and Re-entered passwords have to be the same.
Try again.
New Password: cisco
Re-enter New password: cisco
```

Router2>

**TACACS+ ACS Is the Backend AAA Server, ChPass Is Enabled, and the Password Expires After Three Logins**

In the following example, a TACACS+ ACS is the backend AAA server, and the ChPass feature is enabled. The password expires after three logins using the SSH Keyboard Interactive Authentication method:

```
Router# ssh -l cisco. 10.1.1.3
Password: cisco

Router2> exit
[Connection to 10.1.1.3 closed by foreign host]

Router1# ssh -l cisco 10.1.1.3
Password: cisco

Router2> exit

Router1# ssh -l cisco 10.1.1.3
Password: cisco

Router2> exit
[Connection to 10.1.1.3 closed by foreign host]

Router1# ssh -l cisco 10.1.1.3
Password: cisco
Your password has expired.
Enter a new one now.
New Password: cisco123
Re-enter New password: cisco123

Router2>
```

## SNMP Debugging: Example

The following is sample output using the **debug snmp packet** command. The output provides SNMP trap information for an SSH session.

```
Router1# debug snmp packet
```

```
SNMP packet debugging is on
```

```
Router1# ssh -l lab 10.0.0.2
```

```
Password:
```

```
Router2# exit
```

```
[Connection to 10.0.0.2 closed by foreign host]
```

```
Router1#
```

```
*Jul 18 10:18:42.619: SNMP: Queuing packet to 10.0.0.2
```

```
*Jul 18 10:18:42.619: SNMP: V1 Trap, ent cisco, addr 10.0.0.1, gentrap 6, spectrap 1
local.9.3.1.1.2.1 = 6
```

```
tcpConnEntry.1.10.0.0.1.22.10.0.0.2.55246 = 4
```

```
ltcpConnEntry.5.10.0.0.1.22.10.0.0.2.55246 = 1015
```

```
ltcpConnEntry.1.10.0.0.1.22.10.0.0.2.55246 = 1056
```

```
ltcpConnEntry.2.10.0.0.1.22.10.0.0.2.55246 = 1392
```

```
local.9.2.1.18.2 = lab
```

```
*Jul 18 10:18:42.879: SNMP: Packet sent via UDP to 10.0.0.2
```

```
Router1#
```

## SSH Debugging Enhancements: Examples

The following is sample output from the **debug ip ssh detail** command. The output provides debugging information regarding the SSH protocol and channel requests.

```
Router# debug ip ssh detail
```

```
00:04:22: SSH0: starting SSH control process
```

```
00:04:22: SSH0: sent protocol version id SSH-1.99-Cisco-1.25
```

```
00:04:22: SSH0: protocol version id is - SSH-1.99-Cisco-1.25
```

```
00:04:22: SSH2 0: SSH2_MSG_KEXINIT sent
```

```
00:04:22: SSH2 0: SSH2_MSG_KEXINIT received
```

```
00:04:22: SSH2:kex: client->server enc:aes128-cbc mac:hmac-sha1
```

```
00:04:22: SSH2:kex: server->client enc:aes128-cbc mac:hmac-sha1
```

```
00:04:22: SSH2 0: expecting SSH2_MSG_KEXDH_INIT
```

```
00:04:22: SSH2 0: SSH2_MSG_KEXDH_INIT received
```

```
00:04:22: SSH2: kex_derive_keys complete
```

```
00:04:22: SSH2 0: SSH2_MSG_NEWKEYS sent
```

```
00:04:22: SSH2 0: waiting for SSH2_MSG_NEWKEYS
```

```
00:04:22: SSH2 0: SSH2_MSG_NEWKEYS received
```

```
00:04:24: SSH2 0: authentication successful for lab
```

```
00:04:24: SSH2 0: channel open request
```

```
00:04:24: SSH2 0: pty-req request
```

```
00:04:24: SSH2 0: setting TTY - requested: height 24, width 80; set: height 24, width 80
```

```
00:04:24: SSH2 0: shell request
```

```
00:04:24: SSH2 0: shell message received
```

```
00:04:24: SSH2 0: starting shell for vty
```

```
00:04:38: SSH0: Session terminated normally
```

The following is sample output from the **debug ip ssh packet** command. The output provides debugging information regarding the ssh packet.

```
Router# debug ip ssh packet
```

```
00:05:43: SSH2 0: send:packet of length 280 (length also includes padlen of 4)
00:05:43: SSH2 0: ssh_receive: 64 bytes received
00:05:43: SSH2 0: input: total packet length of 280 bytes
00:05:43: SSH2 0: partial packet length(block size)8 bytes,needed 272 bytes, maclen 0
00:05:43: SSH2 0: ssh_receive: 64 bytes received
00:05:43: SSH2 0: partial packet length(block size)8 bytes,needed 272 bytes, maclen 0
00:05:43: SSH2 0: ssh_receive: 64 bytes received
00:05:43: SSH2 0: partial packet length(block size)8 bytes,needed 272 bytes, maclen 0
00:05:43: SSH2 0: ssh_receive: 64 bytes received
00:05:43: SSH2 0: partial packet length(block size)8 bytes,needed 272 bytes, maclen 0
00:05:43: SSH2 0: ssh_receive: 24 bytes received
00:05:43: SSH2 0: partial packet length(block size)8 bytes,needed 272 bytes, maclen 0
00:05:43: SSH2 0: input: padlength 4 bytes
00:05:43: SSH2 0: ssh_receive: 64 bytes received
00:05:43: SSH2 0: input: total packet length of 144 bytes
00:05:43: SSH2 0: partial packet length(block size)8 bytes,needed 136 bytes, maclen 0
00:05:43: SSH2 0: ssh_receive: 64 bytes received
00:05:43: SSH2 0: partial packet length(block size)8 bytes,needed 136 bytes, maclen 0
00:05:43: SSH2 0: ssh_receive: 16 bytes received
00:05:43: SSH2 0: partial packet length(block size)8 bytes,needed 136 bytes, maclen 0
00:05:43: SSH2 0: input: padlength 6 bytes
00:05:43: SSH2 0: signature length 143
00:05:43: SSH2 0: send:packet of length 448 (length also includes padlen of 7)
00:05:43: SSH2 0: send:packet of length 16 (length also includes padlen of 10)
00:05:43: SSH2 0: newkeys: mode 1
00:05:43: SSH2 0: ssh_receive: 16 bytes received
00:05:43: SSH2 0: input: total packet length of 16 bytes
00:05:43: SSH2 0: partial packet length(block size)8 bytes,needed 8 bytes, maclen 0
00:05:43: SSH2 0: input: padlength 10 bytes
00:05:43: SSH2 0: newkeys: mode 0
00:05:43: SSH2 0: ssh_receive: 52 bytes received
00:05:43: SSH2 0: input: total packet length of 32 bytes
00:05:43: SSH2 0: partial packet length(block size)16 bytes,needed 16 bytes, maclen 20
00:05:43: SSH2 0: MAC compared for #3 :ok
```

## Where to Go Next

You have to use a SSH remote device that supports SSH Version 2, and you have to connect to a Cisco IOS router.

## Additional References

The following sections provide references related to Secure Shell Version 2.

## Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Security Command Reference* at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html). For information about all Cisco IOS commands, use the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the *Cisco IOS Master Command List, All Releases*, at [http://www.cisco.com/en/US/docs/ios/mcl/allreleasemcl/all\\_book.html](http://www.cisco.com/en/US/docs/ios/mcl/allreleasemcl/all_book.html).

- **debug ip ssh**
- **ip ssh min dh size**
- **ip ssh rsa keypair-name**
- **ip ssh version**
- **ssh**

# Feature Information for Secure Shell Version 2 Support

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1** Feature Information for Secure Shell Version 2 Support

| Feature Name                                     | Releases                 | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Secure Shell Version 2 Support                   | 12.3(4)T<br>12.2(25)S    | The Secure Shell Version 2 Support feature allows you to configure Secure Shell (SSH) Version 2 (SSH Version 1 support was implemented in an earlier Cisco IOS software release). SSH runs on top of a reliable transport layer and provides strong authentication and encryption capabilities.                                                                                                                                                                                                                                                                       |
| Secure Shell Version 2 Client and Server Support | 12.3(7)JA<br>12.0(32)SY  | This feature was integrated into Cisco IOS Release 12.3(7)JA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Secure Shell Version 2 Client and Server Support | 12.4(17)                 | <p>The Cisco IOS image was updated to provide for the automatic generation of SNMP traps when an SSH session terminates.</p> <p>For information about this feature, see the following section:</p> <ul style="list-style-type: none"> <li>• “SNMP Trap Generation” section on page 3</li> <li>• “SNMP Debugging: Example” section on page 16</li> </ul>                                                                                                                                                                                                               |

## **Secure Infrastructure**

# AutoSecure

---

By using a single command-line interface (CLI), the AutoSecure feature allows a user to perform the following functions:

- Disable common IP services that can be exploited for network attacks
- Enable IP services and features that can aid in the defense of a network when under attack.

This feature also simplifies the security configuration of a router and hardens the router configuration.

## Feature History for AutoSecure

| Release     | Modification                                                                                                  |
|-------------|---------------------------------------------------------------------------------------------------------------|
| 12.3(1)     | This feature was introduced.                                                                                  |
| 12.2(18)S   | This feature was integrated into Cisco IOS Release 12.2(18)S.                                                 |
| 12.3(8)T    | Support for the roll-back functionality and system logging messages were added to Cisco IOS Release 12.3(8)T. |
| 12.2(27)SBC | This feature was integrated into Cisco IOS Release 12.(27)SBC.                                                |

## Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

# Information About AutoSecure

To configure the AutoSecure feature, you should understand the following concepts:

- [Benefits of AutoSecure, page 2](#)
- [Secure Management Plane, page 3](#)
- [Secure Forwarding Plane, page 5](#)

## Benefits of AutoSecure

### Simplified Router Security Configuration

AutoSecure is valuable to customers without special Security Operations Applications because it allows them to quickly secure their network without thorough knowledge of all the Cisco IOS features.

This feature eliminates the complexity of securing a router by creating a new CLI that automates the configuration of security features and disables certain features enabled by default that could be exploited for security holes.

### Enhanced Password Security

AutoSecure provides the following mechanisms to enhance security access to the router:

- The ability to configure a required minimum password length, which can eliminate common passwords that are prevalent on most networks, such as “lab” and “cisco.”

To configure a minimum password length, use the [security passwords min-length](#) command.

- Syslog messages are generated after the number of unsuccessful attempts exceeds the configured threshold.

To configure the number of allowable unsuccessful login attempts (the threshold rate), use the [security passwords min-length](#) command.

### Roll-Back and System Logging Message Support

In Cisco IOS Release 12.3(8)T, support for roll-back of the AutoSecure configuration is introduced. Roll-back enables a router to revert back to its preautosecure configuration state if the AutoSecure configuration fails.

#### Note

---

Prior to Cisco IOS Release 12.3(8)T, roll-back of the AutoSecure configuration is unavailable; thus, you should always save the running configuration before configuring AutoSecure.

---

System Logging Messages capture any changes or tampering of the AutoSecure configuration that were applied on the running configuration. That is, more detailed audit trail information is provided when autosecure is executed.

## Secure Management Plane

Securing the management plane is one of two focus areas for the AutoSecure feature. (The other focus area is described in the following section, “[Secure Forwarding Plane](#).”) Securing the management plane is done by turning off certain global and interface services that can be potentially exploited for security attacks and turning on global services that help mitigate the threat of attacks. Secure access and secure logging are also configured for the router.

**Caution**

If your device is managed by a network management (NM) application, securing the management plane could turn off some services like HTTP server and disrupt the NM application support.

The following subsections define how AutoSecure helps to secure the management plane:

- [Disable Global Services](#)
- [Disable Per Interface Services](#)
- [Enable Global Services](#)
- [Secure Access to the Router](#)
- [Log for Security](#)

### Disable Global Services

After enabling this feature (via the [auto secure](#) command), the following global services will be disabled on the router without prompting the user:

- Finger—Collects information about the system (reconnaissance) before an attack. If enabled, the information can leave your device vulnerable to attacks.
- PAD—Enables all packet assembler and disassembler (PAD) commands and connections between PAD devices and access servers. If enabled, it can leave your device vulnerable to attacks.
- Small Servers—Causes TCP and User Datagram Protocol (UDP) diagnostic port attacks: a sender transmits a volume of fake requests for UDP diagnostic services on the router, consuming all CPU resources.
- Bootp Server—Bootp is an insecure protocol that can be exploited for an attack.
- HTTP Server—Without secure-http or authentication embedded in the HTTP server with an associated ACL, the HTTP server is insecure and can be exploited for an attack. (If you must enable the HTTP server, you will be prompted for the proper authentication or access list.)

**Note**

If you are using Security Device Manager (SDM), you must manually enable the HTTP server via the **ip http server** command.

- Identification Service—An unsecure protocol, defined in RFC 1413, that allows one to query a TCP port for identification. An attacker can access private information about the user from the ID server.
- CDP—If a large number of Cisco Discovery Protocol (CDP) packets are sent to the router, the available memory of the router can be consumed, causing the router to crash.

**Caution**

NM applications that use CDP to discover network topology will not be able to perform discovery.

- **NTP**—Without authentication or access-control, Network Time Protocol (NTP) is insecure and can be used by an attacker to send NTP packets to crash or overload the router. (If you want to turn on NTP, you must configure NTP authentication using Message Digest 5 (MD5) and the **ntp access-group** command. If NTP is enabled globally, disable it on all interfaces on which it is not needed.)
- **Source Routing**—Provided only for debugging purposes, so source routing should be disabled in all other cases. Otherwise, packets may slip away from some of the access control mechanisms that they should have gone through.

### Disable Per Interface Services

After enabling this feature, the following per interface services will be disabled on the router without prompting the user:

- **ICMP redirects**—Disabled on all interfaces. Does not add a useful functionality to a correctly configured to network, but it could be used by attackers to exploit security holes.
- **ICMP unreachable**s—Disabled on all interfaces. Internet Control Management Protocol (ICMP) unreachable are a known cause for some ICMP-based denial of service (DoS) attacks.
- **ICMP mask reply** messages—Disabled on all interfaces. ICMP mask reply messages can give an attacker the subnet mask for a particular subnetwork in the internetwork.
- **Proxy-Arp**—Disabled on all interfaces. Proxy-Arp requests are a known cause for DoS attacks because the available bandwidth and resources of the router can be consumed in an attempt to respond to the repeated requests that are sent by an attacker.
- **Directed Broadcast**—Disabled on all interfaces. Potential cause of SMURF attacks for DoS.
- **Maintenance Operations Protocol (MOP) service**—Disabled on all interfaces.

### Enable Global Services

After enabling this feature, the following global services will be enabled on the router without prompting the user:

- The **service password-encryption** command—Prevents passwords from being visible in the configuration.
- The **service tcp-keepalives-in** and **service tcp-keepalives-out** commands—Ensures that abnormally terminated TCP sessions are removed.

### Secure Access to the Router

#### Caution

If your device is managed by an NM application, securing access to the router could turn off vital services and may disrupt the NM application support.

After enabling this feature, the following options in which to secure access to the router are available to the user:

- If a text banner does not exist, users will be prompted to add a banner. This feature provides the following sample banner:

#### Authorized access only

```
This system is the property of ABC Enterprise
Disconnect IMMEDIATELY if you are not an authorized user!
Contact abc@xyz.com +99 876 543210 for help.
```

- The login and password (preferably a secret password, if supported) are configured on the console, AUX, vty, and tty lines. The **transport input** and **transport output** commands are also configured on all of these lines. (Telnet and secure shell (SSH) are the only valid transport methods.) The **exec-timeout** command is configured on the console and AUX as 10.
- When the image on the device is a crypto image, AutoSecure enables SSH and secure copy (SCP) for access and file transfer to and from the router. The **timeout seconds** and **authentication-retries integer** options for the **ip ssh** command are configured to a minimum number. (Telnet and FTP are not affected by this operation and remain operational.)
- If the AutoSecure user specifies that their device does not use Simple Network Management Protocol (SNMP), one of the following functionalities will occur:
  - In interactive mode, the user is asked whether to disable SNMP regardless of the values of the community strings, which act like passwords to regulate access to the agent on the router.
  - In non-interact mode, SNMP will be disabled if the community string is “public” or “private.”

**Note**

After AutoSecure has been enabled, tools that use SNMP to monitor or configure a device will be unable to communicate with the device via SNMP.

- If authentication, authorization, and accounting (AAA) is not configured, configure local AAA. AutoSecure will prompt users to configure a local username and password on the router.

**Log for Security**

After this feature is enabled, the following logging options, which allow you to identify and respond to security incidents, are available:

- Sequence numbers and time stamps for all debug and log messages. This option is useful when auditing logging messages.
- Logging messages can be generated for login-related events; for example, the message “Blocking Period when Login Attack Detected” will be displayed when a login attack is detected and the router enters “quiet mode.” (Quiet mode means that the router will not allow any login attempts via Telnet, HTTP, or SSH.)

For more information on login system messages, see the Cisco IOS Release 12.3(4)T feature module *Cisco IOS Login Enhancements*.

- The **logging console critical** command, which sends system logging (syslog) messages to all available TTY lines and limits messages based on severity.
- The **logging buffered** command, which copies logging messages to an internal buffer and limits messages logged to the buffer based on severity.
- The **logging trap debugging** command, which allows all commands with a severity higher than debugging to be sent to the logging server.

## Secure Forwarding Plane

To minimize the risk of attacks on the router forward plane, AutoSecure provides the following functions:

- Cisco Express Forwarding (CEF)—AutoSecure enables CEF or distributed CEF (dCEF) on the router whenever possible. Because there is no need to build cache entries when traffic starts arriving for new destinations, CEF behaves more predictably than other modes when presented with large volumes of traffic addressed to many destinations. Thus, routers configured for CEF perform better under SYN attacks than routers using the traditional cache.

---

**Note** CEF consumes more memory than a traditional cache.

---

- If the TCP intercept feature is available, it can be configured on the router for connection timeout.
- If strict Unicast Reverse Path Forwarding (uRPF) is available, it can be configured on the router to help mitigate problems that are caused by the introduction of forged (spoofed) IP source addresses. uRPF discards IP packets that lack a verifiable IP source address.
- If the router is being used as a firewall, it can be configured for context-based access control (CBAC) on public interfaces that are facing the Internet.

---

**Note** At the beginning of the AutoSecure dialogue, you will be prompted for a list of public interfaces.

---

## How to Configure AutoSecure

This section contains the following procedures:

- [Configuring AutoSecure, page 6](#) (required)
- [Configuring Additional Security, page 7](#) (required)
- [Verifying AutoSecure, page 8](#) (optional)

## Configuring AutoSecure

To configure AutoSecure, you must perform the following tasks.

### The auto secure Command

The **auto secure** command takes you through a semi-interactive session (also known as the AutoSecure dialogue) to secure the management and forwarding planes. This command gives you the option to secure just the management or the forwarding plane; if neither option is selected, the dialogue will ask you to configure both planes.

This command also allows you to go through all noninteractive configuration portions of the dialogue before the interactive portions. The noninteractive portions of the dialogue can be enabled by selecting the optional **no-interact** keyword.

**Caution**

---

Although the **auto secure** command helps to secure a router, it does not guarantee the complete security of the router.

---

## Restrictions

The AutoSecure configuration can be configured at run time or setup time. If any related configuration is modified after AutoSecure has been enabled, the AutoSecure configuration may not be fully effective.

### SUMMARY STEPS

1. **enable**
2. **auto secure** [**management** | **forwarding**] [**no-interact** | **full**] [**ntp** | **login** | **ssh** | **firewall** | **tcp-intercept**]

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                                              | Enables higher privilege levels, such as privileged EXEC mode.<br><br>Enter your password if prompted.                                                                                                                                                                                                                                                                                                                                                           |
| Step 2 | <b>auto secure</b> [ <b>management</b>   <b>forwarding</b> ] [ <b>no-interact</b>   <b>full</b> ] [ <b>ntp</b>   <b>login</b>   <b>ssh</b>   <b>firewall</b>   <b>tcp-intercept</b> ]<br><br><b>Example:</b><br>Router# auto secure | Secures the management and forwarding planes of the router.<br><br><ul style="list-style-type: none"> <li>• <b>management</b>—Only the management plane will be secured.</li> <li>• <b>forwarding</b>—Only the forwarding plane will be secured.</li> <li>• <b>no-interact</b>—The user will not be prompted for any interactive configurations.</li> <li>• <b>full</b>—The user will be prompted for all interactive questions. This is the default.</li> </ul> |

## Configuring Additional Security

To enable enhanced security access to your router, perform the following steps:

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **security passwords min-length** *length*
4. **enable password** {*password* | [*encryption-type*] *encrypted-password*}
5. **security authentication failure rate** *threshold-rate* **log**

## DETAILED STEPS

|        | Command or Action                                                                             | Purpose                                                                                                                                                                                                        |
|--------|-----------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b>                                                                                 | Enables higher privilege levels, such as privileged EXEC mode.                                                                                                                                                 |
|        | <b>Example:</b><br>Router> enable                                                             | Enter your password if prompted.                                                                                                                                                                               |
| Step 2 | <b>configure terminal</b>                                                                     | Enters global configuration mode.                                                                                                                                                                              |
|        | <b>Example:</b><br>Router# configure terminal                                                 |                                                                                                                                                                                                                |
| Step 3 | <b>security passwords min-length <i>length</i></b>                                            | Ensures that all configured passwords are at least a specified length.                                                                                                                                         |
|        | <b>Example:</b><br>Router(config)# security passwords min-length 6                            | <ul style="list-style-type: none"> <li><i>length</i>—Minimum length of a configured password.</li> </ul>                                                                                                       |
| Step 4 | <b>enable password {<i>password</i>   [<i>encryption-type</i>] <i>encrypted-password</i>}</b> | Sets a local password to control access to various privilege levels.                                                                                                                                           |
|        | <b>Example:</b><br>Router(config)# enable password elephant                                   |                                                                                                                                                                                                                |
| Step 5 | <b>security authentication failure rate <i>threshold-rate</i> log</b>                         | Configures the number of allowable unsuccessful login attempts.                                                                                                                                                |
|        | <b>Example:</b><br>Router(config)# security authentication failure rate 10 log                | <ul style="list-style-type: none"> <li><i>threshold-rate</i>—Number of allowable unsuccessful login attempts.</li> <li><b>log</b>—Syslog authentication failures if the rate exceeds the threshold.</li> </ul> |

## Verifying AutoSecure

To verify that the AutoSecure feature is working successfully, perform the following optional steps:

### SUMMARY STEPS

1. **enable**
2. **show auto secure config**

## DETAILED STEPS

|        | Command or Action                                  | Purpose                                                                                                      |
|--------|----------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b>                                      | Enables higher privilege levels, such as privileged EXEC mode.                                               |
|        | <b>Example:</b><br>Router> enable                  | Enter your password if prompted.                                                                             |
| Step 2 | <b>show auto secure config</b>                     | (Optional) Displays all configuration commands that have been added as part of the AutoSecure configuration. |
|        | <b>Example:</b><br>Router# show auto secure config |                                                                                                              |

## Configuration Examples for AutoSecure

This section provides the following configuration example:

- [AutoSecure Configuration Dialogue: Example, page 9](#)

### AutoSecure Configuration Dialogue: Example

The following example is a sample AutoSecure dialogue. After you enable the **auto secure** command, the feature will automatically prompt you with a similar dialogue unless you enable the **no-interact** keyword. (For information on which features are disabled and which features are enabled, see the sections, “[Secure Management Plane](#)” and “[Secure Forwarding Plane](#)” earlier in this document.)

```
Router# auto secure
```

```
--- AutoSecure Configuration ---
```

```
*** AutoSecure configuration enhances the security of the router but it will not make
router absolutely secure from all security attacks ***
```

```
All the configuration done as part of AutoSecure will be shown here. For more details of
why and how this configuration is useful, and any possible side effects, please refer to
Cisco documentation of AutoSecure.
```

```
At any prompt you may enter '?' for help.
```

```
Use ctrl-c to abort this session at any prompt.
```

```
Gathering information about the router for AutoSecure
```

```
Is this router connected to internet? [no]:y
```

```
Enter the number of interfaces facing internet [1]:
```

```
Interface IP-Address OK? Method Status
Protocol
```

```
FastEthernet0/1 10.1.1.1 YES NVRAM up down
```

```
FastEthernet1/0 10.2.2.2 YES NVRAM up down
```

```
FastEthernet1/1 10.0.0.1 YES NVRAM up up
```

```
Loopback0 unassigned YES NVRAM up up
```

```
FastEthernet0/0 10.0.0.2 YES NVRAM up down
```

```
Enter the interface name that is facing internet:FastEthernet0/0
```

Securing Management plane services..

```
Disabling service finger
Disabling service pad
Disabling udp & tcp small servers
Enabling service password encryption
Enabling service tcp-keepalives-in
Enabling service tcp-keepalives-out
Disabling the cdp protocol
```

```
Disabling the bootp server
Disabling the http server
Disabling the finger service
Disabling source routing
Disabling gratuitous arp
Enable secret is either not configured or is same as enable password
Enter the new enable secret:abc123
Configuring aaa local authentication
Configuring console, Aux and vty lines for
local authentication, exec-timeout, transport
```

```
Configure SSH server? [yes]:
Enter the domain-name:cisco.com
```

Configuring interface specific AutoSecure services  
Disabling the following ip services on all interfaces:

```
no ip redirects
no ip proxy-arp
no ip unreachable
no ip directed-broadcast
no ip mask-reply
Disabling mop on Ethernet interfaces
```

Securing Forwarding plane services..

Enabling CEF (it might have more memory requirements on some low end platforms)

Enabling unicast rpf on all interfaces connected to internet

```
Configure CBAC Firewall feature? [yes/no]:yes
```

This is the configuration generated:

```
no service finger
no service pad
no service udp-small-servers
no service tcp-small-servers
service password-encryption

# Cisco IOS Login Enhancements (Login Block)

**Document First Published: August 2005**

**Last Updated: October 2007**

The Cisco IOS Login Enhancements (Login Block) feature allows users to enhance the security of a router by configuring options to automatically block further login attempts when a possible denial-of-service (DoS) attack is detected.

The login block and login delay options introduced by this feature can be configured for Telnet or SSH virtual connections. By enabling this feature, you can slow down “dictionary attacks” by enforcing a “quiet period” if multiple failed connection attempts are detected, thereby protecting the routing device from a type of denial-of-service attack.

## Feature History for Cisco IOS Login Enhancements

| Release                                    | Modification                                                  |
|--------------------------------------------|---------------------------------------------------------------|
| 12.3(4)T                                   | This feature was introduced.                                  |
| 12.2(25)S                                  | This feature was integrated into Cisco IOS Release 12.2 S.    |
| 12.2(33)SRA                                | This feature was integrated into Cisco IOS Release 12.2 SR.   |
| 12.2(33)SRB,<br>12.2(33)SXH,<br>12.4(15)T1 | Support for HTTP login blocking was added.                    |
| Cisco IOS XE<br>Release 2.1                | This feature was introduced on Cisco ASR 1000 Series Routers. |

## Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

## Information About Cisco IOS Login Enhancements

To use login enhancements, you should understand the following concepts:

- [Protecting Against Denial of Service and Dictionary Login Attacks](#)
- [Login Enhancements Functionality Overview, page 3](#)

## Protecting Against Denial of Service and Dictionary Login Attacks

Connecting to a routing device for the purposes of administering (managing) the device, at either the User or Executive level, is most frequently performed using Telnet or SSH (secure shell) from a remote console (such as a PC). SSH provides a more secure connection option because communication traffic between the user's device and the managed device are encrypted. The Login Block capability, when enabled, applies to both Telnet connections and SSH connections. Beginning in Release versions 12.3(33)SRB2, 12.2(33)SXH2, and 12.4(15)T1, the Login Block capability also applies to HTTP connections."

The automated activation and logging of the Login Block and Quiet Period capabilities introduced by this feature are designed to further enhance the security of your devices by specifically addressing two well known methods that individuals use to attempt to disrupt or compromise networked devices.

If the connection address of a device is discovered and is reachable, a malicious user may attempt to interfere with the normal operations of the device by flooding it with connection requests. This type of attack is referred to as an attempted Denial-of-Service, because it is possible that the device may become too busy trying to process the repeated login connection attempts to properly handle normal routing services or will not be able to provide the normal login service to legitimate system administrators.

The primary intention of a dictionary attack, unlike a typical DoS attack, is to actually gain administrative access to the device. A dictionary attack is an automated process to attempt to login by attempting thousands, or even millions, of username/password combinations. (This type of attack is called a "dictionary attack" because it typically uses, as a start, every word found in a typical dictionary as a possible password.) As scripts or programs are used to attempt this access, the profile for such attempts is typically the same as for DoS attempts; multiple login attempts in a short period of time.

By enabling a detection profile, the routing device can be configured to react to repeated failed login attempts by refusing further connection request (login blocking). This block can be configured for a period of time, called a "quiet period". Legitimate connection attempts can still be permitted during a quiet period by configuring an access-list (ACL) with the addresses that you know to be associated with system administrators.

## Login Enhancements Functionality Overview

To better configure security for virtual login connections, the following requirements have been added to the login process:

- [Delays Between Successive Login Attempts](#)
- [Login Shutdown If DoS Attacks Are Suspected](#)
- [Generation of System Logging Messages for Login Detection](#)

### Delays Between Successive Login Attempts

A Cisco IOS device can accept virtual connections as fast as they can be processed. Introducing a delay between login attempts helps to protect the Cisco IOS software-based device against malicious login connections such as dictionary attacks and DoS attacks. Delays can be enabled in one of the following ways:

- Via the **auto secure** command. If you enable the AutoSecure feature, the default login delay time of one second is automatically enforced.
- Via the **login block-for** command. You must enter this command before issuing the **login delay** command. If you enter only the **login block-for** command, the default login delay time of one second is automatically enforced.
- Via the new global configuration mode command, **login delay**, which allows you to specify a the login delay time to be enforced, in seconds.

### Login Shutdown If DoS Attacks Are Suspected

If the configured number of connection attempts fail within a specified time period, the Cisco IOS device will not accept any additional connections for a “quiet period.” (Hosts that are permitted by a predefined access-control list [ACL] are excluded from the quiet period.)

The number of failed connection attempts that trigger the quiet period can be specified via the new global configuration mode command **login block-for**. The predefined ACL that is excluded from the quiet period can be specified via the new global configuration mode command **login quiet-mode access-class**.

This functionality is disabled by default, and it is not enabled if autosecure is enabled.

### Generation of System Logging Messages for Login Detection

After the router switches to and from quiet mode, logging messages are generated. Also, if configured, logging messages are generated upon every successful or failed login request.

Logging messages can be generated for successful login requests via the new global configuration command **login on-success**; the **login on-failure** command generates logs for failed login requests.

Logging messages for failed login attempts are automatically enabled when the **auto secure** command is issued; they are not automatically enabled for successful login attempts via autosecure.

#### Note

Currently, only system logging (syslog) messages can be generated for login-related events. Support for SNMP notifications (traps) will be added in a later release.

**System Logging Messages for a Quiet Period**

The following logging message is generated after the router switches to quiet-mode:

```
00:04:07:%SEC_LOGIN-1-QUIET_MODE_ON:Still timeleft for watching failures is 158 seconds,
[user:sfd] [Source:10.4.2.11] [localport:23] [Reason:Invalid login], [ACL:22] at 16:17:23
UTC Wed Feb 26 2003
```

The following logging message is generated after the router switches from quiet mode back to normal mode:

```
00:09:07:%SEC_LOGIN-5-QUIET_MODE_OFF:Quiet Mode is OFF, because block period timed out at
16:22:23 UTC Wed Feb 26 2003
```

**System Logging Messages for Successful and Failed Login Requests**

The following logging message is generated upon a successful login request:

```
00:04:32:%SEC_LOGIN-5-LOGIN_SUCCESS>Login Success [user:test] [Source:10.4.2.11]
[localport:23] at 20:55:40 UTC Fri Feb 28 2003
```

The following logging message is generated upon a failed login request:

```
00:03:34:%SEC_LOGIN-4-LOGIN_FAILED>Login failed [user:sdfs] [Source:10.4.2.11]
[localport:23] [Reason:Invalid login] at 20:54:42 UTC Fri Feb 28 2003
```

# How to Configure Cisco IOS Login Enhancements

This section contains the following procedures:

- [Configuring Login Parameters, page 4](#) (Required)
- [Verifying Login Parameters, page 6](#) (Optional)

## Configuring Login Parameters

Use this task to configure your Cisco IOS device for login parameters that help detect suspected DoS attacks and slow down dictionary attacks.

### Login Parameter Defaults

All login parameters are disabled by default. You must issue the **login block-for** command, which enables default login functionality, before using any other login commands. After the **login block-for** command is enabled, the following defaults are enforced:

- A default login delay of one second
- All login attempts made via Telnet or SSH are denied during the quiet period; that is, no ACLs are exempt from the login period until the **login quiet-mode access-class** command is issued.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **login block-for** *seconds* **attempts** *tries* **within** *seconds*
4. **login quiet-mode access-class** {*acl-name* | *acl-number*}

5. **login delay** *seconds*
6. **login on-failure log** [*every login*]
7. **login on-success log** [*every login*]

## DETAILED STEPS

|        | Command or Action                                                                                                                                       | Purpose                                                                                                                                                                                     |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                  | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                            |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                          | Enters global configuration mode.                                                                                                                                                           |
| Step 3 | <b>login block-for</b> <i>seconds attempts tries within seconds</i><br><br><b>Example:</b><br>Router(config)# login block-for 100 attempts 2 within 100 | Configures your Cisco IOS device for login parameters that help provide DoS detection.<br><br><b>Note</b> This command must be issued before any other login command can be used.           |
| Step 4 | <b>login quiet-mode access-class</b> { <i>acl-name   acl-number</i> }<br><br><b>Example:</b><br>Router(config)# login quiet-mode access-class myacl     | (Optional) Specifies an ACL that is to be applied to the router when it switches to quiet mode.<br><br>If this command is not enabled, all login requests will be denied during quiet mode. |
| Step 5 | <b>login delay</b> <i>seconds</i><br><br><b>Example:</b><br>Router(config)# login delay 10                                                              | (Optional) Configures a delay between successive login attempts.                                                                                                                            |
| Step 6 | <b>login on-failure log</b> [ <i>every login</i> ]<br><br><b>Example:</b><br>Router(config)# login on-failure log                                       | (Optional) Generates logging messages for failed login attempts.                                                                                                                            |
| Step 7 | <b>login on-success log</b> [ <i>every login</i> ]<br><br><b>Example:</b><br>Router(config)# login on-success log every 5                               | (Optional) Generates logging messages for successful login attempts.                                                                                                                        |

## What to Do Next

After you have configured login parameters on your router, you may wish to verify the settings. To complete this task, see the following section [“Verifying Login Parameters.”](#)

# Verifying Login Parameters

Use this task to verify the applied login configuration and present login status on your router.

## SUMMARY STEPS

- 1. `enable`
- 2. `show login [failures]`

## DETAILED STEPS

|        | Command or Action                                                        | Purpose                                                                                                                                                  |
|--------|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <code>enable</code><br><br>Example:<br>Router> enable                    | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                         |
| Step 2 | <code>show login [failures]</code><br><br>Example:<br>Router# show login | Displays login parameters. <ul style="list-style-type: none"><li>• <b>failures</b>—Displays information related only to failed login attempts.</li></ul> |

## Examples

The following sample output from the `show login` command verifies that no login parameters have been specified:

```
Router# show login

No login delay has been applied.
No Quiet-Mode access list has been configured.
All successful login is logged and generate SNMP traps.
All failed login is logged and generate SNMP traps

Router NOT enabled to watch for login Attacks
```

The following sample output from the `show login` command verifies that the `login block-for` command is issued. In this example, the command is configured to block login hosts for 100 seconds if 16 or more login requests fail within 100 seconds; five login requests have already failed.

```
Router# show login

A default login delay of 1 seconds is applied.
No Quiet-Mode access list has been configured.
All successful login is logged and generate SNMP traps.
All failed login is logged and generate SNMP traps.

Router enabled to watch for login Attacks.
If more than 15 login failures occur in 100 seconds or less, logins will be disabled for 100 seconds.

Router presently in Watch-Mode, will remain in Watch-Mode for 95 seconds.
Present login failure count 5.
```

The following sample output from the **show login** command verifies that the router is in quiet mode. In this example, the **login block-for** command was configured to block login hosts for 100 seconds if 3 or more login requests fail within 100 seconds.

```
Router# show login
```

```
A default login delay of 1 seconds is applied.
No Quiet-Mode access list has been configured.
All successful login is logged and generate SNMP traps.
All failed login is logged and generate SNMP traps.
```

```
Router enabled to watch for login Attacks.
If more than 2 login failures occur in 100 seconds or less, logins will be disabled for
100 seconds.
```

```
Router presently in Quiet-Mode, will remain in Quiet-Mode for 93 seconds.
Denying logins from all sources.
```

The following sample output from **show login failures** command shows all failed login attempts on the router:

```
Router# show login failures
```

```
Information about login failure's with the device
```

| Username | Source IPAddr | lPort | Count | TimeStamp                   |
|----------|---------------|-------|-------|-----------------------------|
| try1     | 10.1.1.1      | 23    | 1     | 21:52:49 UTC Sun Mar 9 2003 |
| try2     | 10.1.1.2      | 23    | 1     | 21:52:52 UTC Sun Mar 9 2003 |

The following sample output from **show login failures** command verifies that no information is presently logged:

```
Router# show login failures
```

```
*** No logged failed login attempts with the device.***
```

## Configuration Examples for Login Parameters

This section includes the following example:

- [Setting Login Parameters: Example, page 7](#)

### Setting Login Parameters: Example

The following example shows how to configure your router to enter a 100 second quiet period if 15 failed login attempts is exceeded within 100 seconds; all login requests will be denied during the quiet period except hosts from the ACL "myacl." Also, logging messages will be generated for every 10th failed login and every 15th successful login.

```
Router(config)# login block-for 100 attempts 15 within 100
Router(config)# login quiet-mode access-class myacl
Router(config)# login on-failure log every 10
Router(config)# login on-success log every 15
```

# Image Verification

---

The Image Verification feature allows users to automatically verify the integrity of Cisco IOS images. Thus, users can be sure that the image is protected from accidental corruption, which can occur at any time during transit, starting from the moment the files are generated by Cisco until they reach the user.

## Feature History for Image Verification

| Release                  | Modification                                                  |
|--------------------------|---------------------------------------------------------------|
| 12.2(18)S                | This feature was introduced.                                  |
| 12.0(26)S                | This feature was integrated into Cisco IOS Release 12.0(26)S. |
| 12.3(4)T                 | This feature was integrated in Cisco IOS Release 12.3(4)T.    |
| Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers. |

## Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

# Restrictions for Image Verification

## Cisco IOS Release 12.2(18)S and 12.0(26)S Only

Image Verification is applied to and attempted on any file; however, if the file is not an image file, image verification will not occur and you will see the following error, “SIGNATURE-NOT-FOUND.”

## Cisco IOS Release 12.3(4)T Only

Image Verification is applied only to image files. If any other file type is copied or verified, you will not receive a warning that image verification did occur, and the command (copy or verify) will silently succeed.

# Information About Image Verification

To use image authentication for your Cisco IOS images, you should understand the following concepts:

- [Benefit of Image Verification, page 2](#)
- [How Image Verification Works, page 2](#)

## Benefit of Image Verification

The efficiency of Cisco IOS routers is improved because the routers can now automatically detect when the integrity of an image is accidentally corrupted as a result of transmission errors or disk corruption.

## How Image Verification Works

Because a production image undergoes a sequence of transfers before it is copied into the memory of a router, the integrity of the image is at risk of accidental corruption every time a transfer occurs. When downloading an image from Cisco.com, a user can run a message-digest5 (MD5) hash on the downloaded image and verify that the MD5 digest posted on Cisco.com is the same as the MD5 digest that is computed on the user's server. However, many users choose not to run an MD5 digest because it is 128-bits long and the verification is manual. Image verification allows the user to automatically validate the integrity of all downloaded images, thereby, significantly reducing user interaction.

# How to Use Image Verification

This section contains the following procedures:

- [Globally Verifying the Integrity of an Image, page 3](#)
- [Verifying the Integrity of an Image That Is About to Be Copied, page 4](#)
- [Verifying the Integrity of an Image That Is About to Be Reloaded, page 4](#)

## Globally Verifying the Integrity of an Image

The **file verify auto** command enables image verification globally; that is, all images that are to be copied (via the **copy** command) or reloaded (via the **reload** command) are automatically verified. Although both the **copy** and **reload** commands have a **/verify** keyword that enables image verification, you must issue the keyword each time you want to copy or reload an image. The **file verify auto** command enables image verification by default, so you no longer have to specify image verification multiple times.

If you have enabled image verification by default but prefer to disable verification for a specific image copy or reload, the **/noverify** keyword, along with either the **copy** or the **reload** command, will override the **file verify auto** command.

Use this task to enable automatic image verification.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **file verify auto**
4. **exit**

### DETAILED STEPS

|        | Command or Action                                                                  | Purpose                                                                                                                      |
|--------|------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                             | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>             |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal     | Enters global configuration mode.                                                                                            |
| Step 3 | <b>file verify auto</b><br><br><b>Example:</b><br>Router(config)# file verify auto | Enables automatic image verification.                                                                                        |
| Step 4 | <b>exit</b><br><br><b>Example:</b><br>Router(config)# exit                         | Exits global configuration mode.<br><br>You must exit global configuration mode if you are going to copy or reload an image. |

### What to Do Next

After issuing the **file verify auto** command, you do not have to issue the **/verify** keyword with the **copy** or the **reload** command because each image that is copied or reloaded will be automatically verified.

## Verifying the Integrity of an Image That Is About to Be Copied

When issuing the **copy** command, you can verify the integrity of the copied file by entering the **/verify** keyword. If the integrity check fails, the copied file will be deleted. If the file that is about to be copied does not have an embedded hash (an old image), you will be prompted whether or not to continue with the copying process. If you choose to continue, the file will be successfully copied; if you choose not to continue, the copied file will be deleted.

Without the **/verify** keyword, the **copy** command could copy a file that is not valid. Thus, after the **copy** command has been successfully executed, you can issue the **verify** command at any time to check the integrity of the files that are in the storage of the router.

Use this task to verify the integrity of an image before it is copied onto a router.

### SUMMARY STEPS

1. **enable**
2. **copy** [/erase] [/verify | /noverify] *source-url destination-url*
3. **verify** [/md5 [md5-value]] *filesystem:[file-url]*

|        | Command or Action                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                 | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                 |
| Step 2 | <b>copy</b> [/erase] [/verify   /noverify] <i>source-url destination-url</i><br><br><b>Example:</b><br>Router# copy /verify<br>tftp://10.1.1.1/jdoe/c7200-js-mz disk0: | Copies any file from a source to a destination. <ul style="list-style-type: none"> <li>• <b>/verify</b>—Verifies the signature of the destination file. If verification fails, the file will be deleted.</li> <li>• <b>/noverify</b>—Does not verify the signature of the destination file before the image is copied.</li> </ul> <p><b>Note</b> <b>/noverify</b> is often issued if the <b>file verify auto</b> command is enabled, which automatically verifies the signature of all images that are copied.</p> |
| Step 3 | <b>verify</b> [/md5 [md5-value]] <i>filesystem:[file-url]</i><br><br><b>Example:</b><br>Router# verify bootflash://c7200-kboot-mz.121-8a.E                             | (Optional) Verifies the integrity of the images in the router's storage.                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Verifying the Integrity of an Image That Is About to Be Reloaded

By issuing the **reload** command with the **/verify** keyword, the image that is about to be loaded onto your system will be checked for integrity. If the **/verify** keyword is specified, image verification will occur before the system initiates the reboot. Thus, if verification fails, the image will not be loaded.

**Note**

Because different platforms obtain the file that is to be loaded in various ways, the file specified in BOOTVAR will be verified. If a file is not specified, the first file on each subsystem will be verified.

On certain platforms, because of variables such as the configuration register, the file that is verified may not be the file that is loaded.

Use this task to verify the integrity of an image before it is reloaded onto a router.

**SUMMARY STEPS**

1. **enable**
2. **reload** [
  - [warm] [/verify | /noverify] text |
  - [warm] [/verify | /noverify] in [hh:]mm [text] |
  - [warm] [/verify | /noverify] at hh:mm [month day | day month] [text] |
  - [warm] [/verify | /noverify] cancel]

**DETAILED STEPS**

|        | Command or Action                                                                                                                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                                                                                       | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                   |
| Step 2 | <b>reload</b> [[warm] [/verify   /noverify] text  <br>[warm] [/verify   /noverify] in [hh:]mm [text]  <br>[warm] [/verify   /noverify] at hh:mm [month day  <br>day month] [text]  <br>[warm] [/verify   /noverify] cancel]<br><br><b>Example:</b><br>Router# reload /verify | Reloads the operating system. <ul style="list-style-type: none"> <li>• <b>/verify</b>—Verifies the signature of the destination file. If verification fails, the file will be deleted.</li> <li>• <b>/noverify</b>—Does not verify the signature of the destination file before the image is reloaded.</li> </ul> <b>Note</b> /noverify is often issued if the <b>file verify auto</b> command is enabled, which automatically verifies the signature of all images that are copied. |

## Configuration Examples for Image Verification

This section contains the following configuration examples:

- [Global Image Verification: Example, page 6](#)
- [Image Verification via the copy Command: Example, page 6](#)
- [Image Verification via the reload Command: Example, page 6](#)
- [verify Command Sample Output: Example, page 7](#)

## Global Image Verification: Example

The following example shows how to enable automatic image verification. After enabling this command, image verification will automatically occur for all images that are either copied (via the **copy** command) or reloaded (via the **reload** command).

```
Router(config)# file verify auto
```

## Image Verification via the copy Command: Example

The following example shows how to specify image verification before copying an image:

```
Router# copy /verify tftp://10.1.1.1/jdoe/c7200-js-mz disk0:
```

```
Destination filename [c7200-js-mz]?
Accessing tftp://10.1.1.1/jdoe/c7200-js-mz...
Loading jdoe/c7200-js-mz from 10.1.1.1 (via FastEthernet0/0):!!!!!!!!!!!!!!
!!
!!
[OK - 19879944 bytes]

19879944 bytes copied in 108.632 secs (183003 bytes/sec)
Verifying file integrity of disk0:/c7200-js-mz
.....
.....
.....Done!
Embedded Hash MD5 :CFA258948C4ECE52085DCF428A426DCD
Computed Hash MD5 :CFA258948C4ECE52085DCF428A426DCD
CCO Hash MD5 :44A7B9BDDD9638128C35528466318183

Signature Verified
```

## Image Verification via the reload Command: Example

The following example shows how to specify image verification before reloading an image onto the router:

```
Router# reload /verify
```

```
Verifying file integrity of bootflash:c7200-kboot-mz.121-8a.E
%ERROR:Signature not found in file bootflash:c7200-kboot-mz.121-8a.E.
Signature not present. Proceed with verify? [confirm]
Verifying file disk0:c7200-js-mz
.....
.....Done!
Embedded Hash MD5 :CFA258948C4ECE52085DCF428A426DCD
Computed Hash MD5 :CFA258948C4ECE52085DCF428A426DCD
CCO Hash MD5 :44A7B9BDDD9638128C35528466318183
Signature Verified

Proceed with reload? [confirm]n
```

## verify Command Sample Output: Example

The following example shows how to specify image verification via the **verify** command:

```
Router# verify disk0:c7200-js-mz
```

```
%Filesystem does not support verify operations
Verifying file integrity of disk0:c7200-js-mz.....
.....Done!
Embedded Hash MD5 :CFA258948C4ECE52085DCF428A426DCD
Computed Hash MD5 :CFA258948C4ECE52085DCF428A426DCD
CCO Hash MD5 :44A7B9BDDD9638128C35528466318183

Signature Verified
```

## Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Security Command Reference* at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html). For information

about all Cisco IOS commands, go to the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or to the *Cisco IOS Master Commands List*.

#### New Command

- **file verify auto**

#### Modified Commands

- **copy**
- **reload**
- **verify**

## Role-Based CLI Access

---

The Role-Based CLI Access feature allows the network administrator to define “views,” which are a set of operational commands and configuration capabilities that provide selective or partial access to Cisco IOS EXEC and configuration (Config) mode commands. Views restrict user access to Cisco IOS command-line interface (CLI) and configuration information; that is, a view can define what commands are accepted and what configuration information is visible. Thus, network administrators can exercise better control over access to Cisco networking devices.

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the [“Feature Information for Role-Based CLI Access” section on page 14](#).

Use Cisco Feature Navigator to find information about platform support and Cisco IOS, Catalyst OS, and Cisco IOS XE software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

# Prerequisites for Role-Based CLI Access

Your image must support CLI views.

## Restrictions for Role-Based CLI Access

### Lawful Intercept Images Limitation

Because CLI views are a part of the Cisco IOS parser, CLI views are a part of all platforms and Cisco IOS images. However, the lawful intercept view is available only in images that contain the lawful intercept subsystem.

### Maximum Number of Allowed Views

The maximum number of CLI views and superviews, including one lawful intercept view, that can be configured is 15. (This does not include the root view.)

## Information About Role-Based CLI Access

To create and use views, you should understand the following concepts:

- [Benefits of Using CLI Views, page 2](#)
- [Root View, page 2](#)
- [View Authentication via a New AAA Attribute, page 3](#)

## Benefits of Using CLI Views

### Views: Detailed Access Control

Although users can control CLI access via both privilege levels and enable mode passwords, these functions do not provide network administrators with the necessary level of detail needed when working with Cisco IOS routers and switches. CLI views provide a more detailed access control capability for network administrators, thereby, improving the overall security and accountability of Cisco IOS software.

As of Cisco IOS Release 12.3(11)T, network administrators can also specify an interface or a group of interfaces to a view; thereby, allowing access on the basis of specified interfaces.

## Root View

When a system is in “root view,” it has all of the access privileges as a user who has level 15 privileges. If the administrator wishes to configure any view to the system (such as a CLI view, a superview, or a lawful intercept view), the system must be in root view.

The difference between a user who has level 15 privileges and a root view user is that a root view user can configure a new view and add or remove commands from the view. Also, when you are in a CLI view, you have access only to the commands that have been added to that view by the root view user.

## View Authentication via a New AAA Attribute

View authentication is performed by an external authentication, authorization, and accounting (AAA) server via the new attribute “cli-view-name.”

AAA authentication associates only one view name to a particular user; that is, only one view name can be configured for a user in an authentication server.

## How to Use Role-Based CLI Access

This section contains the following procedures:

- [Configuring a CLI View, page 3](#) (required)
- [Configuring a Lawful Intercept View, page 5](#) (optional)
- [Configuring a Superview, page 7](#) (optional)
- [Monitoring Views and View Users, page 9](#) (optional)

## Configuring a CLI View

Use this task to create a CLI view and add commands or interfaces to the view, as appropriate.

### Prerequisites

Before you create a view, you must perform the following tasks:

- Enable AAA via the **aaa new-model** command.
- Ensure that your system is in root view—not privilege level 15.

### SUMMARY STEPS

1. **enable view**
2. **configure terminal**
3. **parser view** *view-name*
4. **secret 5** *encrypted-password*
5. **commands** *parser-mode* {**include** | **include-exclusive** | **exclude**} [**all**] [**interface** *interface-name* | *command*]
6. **exit**
7. **exit**
8. **enable** [*privilege-level*] [**view** *view-name*]
9. **show parser view** [**all**]

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable view</b><br><br><b>Example:</b><br>Router> enable view                                                                                                                                 | Enables root view. <ul style="list-style-type: none"> <li>Enter your privilege level 15 password (for example, root password) if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                   | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Step 3 | <b>parser view view-name</b><br><br><b>Example:</b><br>Router(config)# parser view first                                                                                                         | Creates a view and enters view configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Step 4 | <b>secret 5 encrypted-password</b><br><br><b>Example:</b><br>Router(config-view)# secret 5 secret                                                                                                | Associates a command-line interface (CLI) view or superview with a password. <p><b>Note</b> You must issue this command before you can configure additional attributes for the view.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Step 5 | <b>commands parser-mode {include   include-exclusive   exclude} [all] [interface interface-name   command]</b><br><br><b>Example:</b><br>Router(config-view)# commands exec include show version | Adds commands or interfaces to a view. <ul style="list-style-type: none"> <li><i>parser-mode</i>—The mode in which the specified command exists.</li> <li><b>include</b>—Adds a command or an interface to the view and allows the same command or interface to be added to an additional view.</li> <li><b>include-exclusive</b>—Adds a command or an interface to the view and excludes the same command or interface from being added to all other views.</li> <li><b>exclude</b>—Excludes a command or an interface from the view; that is, customers cannot access a command or an interface.</li> <li><b>all</b>—A “wildcard” that allows every command in a specified configuration mode that begins with the same keyword or every subinterface for a specified interface to be part of the view.</li> <li><b>interface interface-name</b>—Interface that is added to the view.</li> <li><i>command</i>—Command that is added to the view.</li> </ul> |
| Step 6 | <b>exit</b><br><br><b>Example:</b><br>Router(config-view)# exit                                                                                                                                  | Exits view configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|        | Command or Action                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------|-------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 7 | <code>exit</code><br><br><b>Example:</b><br>Router(config)# <code>exit</code>                                           | Exits global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Step 8 | <code>enable [privilege-level] [view view-name]</code><br><br><b>Example:</b><br>Router# <code>enable view first</code> | Prompts the user for a password, which allows the user to access a configured CLI view, and is used to switch from one view to another view.<br><br>After the correct password is given, the user can access the view.                                                                                                                                                                                                                                                                                       |
| Step 9 | <code>show parser view [all]</code><br><br><b>Example:</b><br>Router# <code>show parser view</code>                     | (Optional) Displays information about the view that the user is currently in.<br><ul style="list-style-type: none"><li><b>all</b>—Displays information for all views that are configured on the router.</li></ul> <b>Note</b> Although this command is available for both root and lawful intercept users, the <b>all</b> keyword is available only to root users. However, the <b>all</b> keyword can be configured by a user in root view to be available for users in lawful intercept view and CLI view. |

## Troubleshooting Tips

After you have successfully created a view, a system message such as the following will be displayed:

```
%PARSER-6-VIEW_CREATED: view 'first' successfully created.
```

After you have successfully deleted a view, a system message such as the following will be displayed:

```
%PARSER-6-VIEW_DELETED: view 'first' successfully deleted.
```

You must associate a password with a view. If you do not associate a password, and you attempt to add commands to the view via the **commands** command, a system message such as the following will be displayed:

```
%Password not set for view <viewname>.
```

## Configuring a Lawful Intercept View

Use this task to initialize and configure a view for lawful-intercept-specific commands and configuration information. (Only an administrator or a user who has level 15 privileges can initialize a lawful intercept view.)

## About Lawful Intercept Views

Like a CLI view, a lawful intercept view restricts access to specified commands and configuration information. Specifically, a lawful intercept view allows a user to secure access to lawful intercept commands that are held within the TAP-MIB, which is a special set of simple network management protocol (SNMP) commands that store information about calls and users.

Commands available in lawful intercept view belong to one of the following categories:

- Lawful intercept commands that should not be made available to any other view or privilege level
- CLI views that are useful for lawful intercept users but do not have to be excluded from other views or privilege levels

## Prerequisites

Before you initialize a lawful intercept view, ensure that the privilege level is set to 15 via the **privilege** command.

## SUMMARY STEPS

1. **enable view**
2. **configure terminal**
3. **li-view** *li-password* **user** *username* **password** *password*
4. **username** [**lawful-intercept**] *name* [**privilege** *privilege-level* | **view** *view-name*] **password** *password*
5. **parser view** *view-name*
6. **secret** 5 *encrypted-password*
7. **name** *new-name*

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                                         | Purpose                                                                                                                                                                                   |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable view</b><br><br><b>Example:</b><br>Router> enable view                                                                                                                                                                                                          | Enables root view.<br><br><ul style="list-style-type: none"> <li>• Enter your privilege level 15 password (for example, root password) if prompted.</li> </ul>                            |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                                                                                            | Enters global configuration mode.                                                                                                                                                         |
| Step 3 | <b>li-view</b> <i>li-password</i> <b>user</b> <i>username</i> <b>password</b> <i>password</i><br><br><b>Example:</b><br>Router(config)# li-view lipass user li_admin password li_adminpass                                                                                | Initializes a lawful intercept view.<br><br>After the li-view is initialized, you must specify at least one user via <b>user</b> <i>username</i> <b>password</b> <i>password</i> options. |
| Step 4 | <b>username</b> [ <b>lawful-intercept</b> ] [ <i>name</i> ] [ <b>privilege</b> <i>privilege-level</i>   <b>view</b> <i>view-name</i> ] <b>password</b> <i>password</i><br><br><b>Example:</b><br>Router(config)# username lawful-intercept li-user1 password li-user1pass | Configures lawful intercept users on a Cisco device.                                                                                                                                      |

|        | Command or Action                                                                                       | Purpose                                                                                                                                                   |
|--------|---------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 5 | <code>parser view view-name</code><br><br><b>Example:</b><br>Router(config)# parser view li view name   | (Optional) Enters view configuration mode, which allows you to change the lawful intercept view password or the lawful intercept view name.               |
| Step 6 | <code>secret 5 encrypted-password</code><br><br><b>Example:</b><br>Router(config-view)# secret 5 secret | (Optional) Changes an existing password for a lawful intercept view.                                                                                      |
| Step 7 | <code>name new-name</code><br><br><b>Example:</b><br>Router(config-view)# name second                   | (Optional) Changes the name of a lawful intercept view.<br><br>If this command is not issued, the default name of the lawful intercept view is “li-view.” |

## Troubleshooting Tips

To display information for all users who have access to a lawful intercept view, issue the **show users lawful-intercept** command. (This command is available only to authorized lawful intercept view users.)

## Configuring a Superview

Use this task to create a superview and add at least one CLI view to the superview.

### About Superviews

A superview consists of one or more CLI views, which allow users to define what commands are accepted and what configuration information is visible. Superviews allow a network administrator to easily assign all users within configured CLI views to a superview instead of having to assign multiple CLI views to a group of users.

Superviews contain the following characteristics:

- A CLI view can be shared among multiple superviews.
- Commands cannot be configured for a superview; that is, you must add commands to the CLI view and add that CLI view to the superview.
- Users who are logged into a superview can access all of the commands that are configured for any of the CLI views that are part of the superview.
- Each superview has a password that is used to switch between superviews or from a CLI view to a superview.
- If a superview is deleted, all CLI views associated with that superview will not be deleted too.

#### Adding CLI Views to a Superview

You can add a view to a superview only after a password has been configured for the superview (via the **secret 5** command). Thereafter, issue the **view** command in view configuration mode to add at least one CLI view to the superview.

**Note**

Before adding a CLI view to a superview, ensure that the CLI views that are added to the superview are valid views in the system; that is, the views have been successfully created via the **parser view** command.

**SUMMARY STEPS**

1. **enable view**
2. **configure terminal**
3. **parser view** *superview-name* **superview**
4. **secret 5** *encrypted-password*
5. **view** *view-name*
6. **exit**
7. **exit**
8. **show parser view** [**all**]

**DETAILED STEPS**

|        | Command or Action                                                                                                                  | Purpose                                                                                                                                                         |
|--------|------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable view</b><br><br><b>Example:</b><br>Router> enable view                                                                   | Enables root view.<br><br><ul style="list-style-type: none"> <li>Enter your privilege level 15 password (for example, root password) if prompted.</li> </ul>    |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                     | Enters global configuration mode.                                                                                                                               |
| Step 3 | <b>parser view</b> <i>superview-name</i> <b>superview</b><br><br><b>Example:</b><br>Router(config)# parser view su_view1 superview | Creates a superview and enters view configuration mode.                                                                                                         |
| Step 4 | <b>secret 5</b> <i>encrypted-password</i><br><br><b>Example:</b><br>Router(config-view)# secret 5 secret                           | Associates a CLI view or superview with a password.<br><br><b>Note</b> You must issue this command before you can configure additional attributes for the view. |
| Step 5 | <b>view</b> <i>view-name</i><br><br><b>Example:</b><br>Router(config-view)# view view_three                                        | Adds a normal CLI view to a superview.<br><br>Issue this command for each CLI view that is to be added to a given superview.                                    |
| Step 6 | <b>exit</b><br><br><b>Example:</b><br>Router(config-view)# exit                                                                    | Exits view configuration mode.                                                                                                                                  |

|        | Command or Action                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------|-----------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 7 | <code>exit</code><br><br><b>Example:</b><br>Router(config)# <code>exit</code>                       | Exits global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 8 | <code>show parser view [all]</code><br><br><b>Example:</b><br>Router# <code>show parser view</code> | <p>(Optional) Displays information about the view that the user is currently in.</p> <ul style="list-style-type: none"> <li><b>all</b>—Displays information for all views that are configured on the router.</li> </ul> <p><b>Note</b> Although this command is available for both root and lawful intercept users, the <b>all</b> keyword is available only to root users. However, the <b>all</b> keyword can be configured by a user in root view to be available for users in lawful intercept view and CLI view.</p> |

## Monitoring Views and View Users

To display debug messages for all views—root, CLI, lawful intercept, and super, use the **debug parser view** command in privileged EXEC mode.

## Configuration Examples for Role-Based CLI Access

This section contains the following configuration examples:

- [Configuring a CLI View: Example, page 9](#)
- [Verifying a CLI View: Example, page 10](#)
- [Configuring a Lawful Intercept View: Example, page 11](#)
- [Configuring a Superview: Example, page 12](#)

### Configuring a CLI View: Example

The following example shows how to configure two CLI views, “first” and “second.” Thereafter, you can verify the CLI view in the running configuration.

```
Router(config)# parser view first
00:11:40:%PARSER-6-VIEW_CREATED:view 'first' successfully created.
Router(config-view)# secret 5 firstpass
Router(config-view)# command exec include show version
Router(config-view)# command exec include configure terminal
Router(config-view)# command exec include all show ip
Router(config-view)# exit
Router(config)# parser view second
00:13:42:%PARSER-6-VIEW_CREATED:view 'second' successfully created.
Router(config-view)# secret 5 secondpass
Router(config-view)# command exec include-exclusive show ip interface
Router(config-view)# command exec include logout
Router(config-view)# exit
!
```

```

!
Router(config-view)# do show run | beg view
parser view first
secret 5 1MCMh$QuZaU8PIMPlff9sFCZvgW/
commands exec include configure terminal
commands exec include configure
commands exec include all show ip
commands exec include show version
commands exec include show
!
parser view second
secret 5 1iP2M$R16BXKecMEiQesxLyqygW.
commands exec include-exclusive show ip interface
commands exec include show ip
commands exec include show
commands exec include logout
!

```

## Verifying a CLI View: Example

After you have configured the CLI views “first” and “second,” you can issue the **enable view** command to verify which commands are available in each view. The following example shows which commands are available inside the CLI view “first” after the user has logged into this view. (Because the **show ip** command is configured with the all option, a complete set of suboptions is shown, except the **show ip interface** command, which is using the include-exclusive keyword in the second view.)

```

Router# enable view first
Password:

00:28:23:%PARSER-6-VIEW_SWITCH:successfully set to view 'first'.
Router# ?
Exec commands:
 configure Enter configuration mode
 enable Turn on privileged commands
 exit Exit from the EXEC
 show Show running system information

Router# show ?

 ip IP information
 parser Display parser information
 version System hardware and software status

Router# show ip ?

 access-lists List IP access lists
 accounting The active IP accounting database
 aliases IP alias table
 arp IP ARP table
 as-path-access-list List AS path access lists
 bgp BGP information
 cache IP fast-switching route cache
 casa display casa information
 cef Cisco Express Forwarding
 community-list List community-list
 dfp DFP information
 dhcp Show items in the DHCP database
 drp Director response protocol
 dvmrp DVMRP information
 eigrp IP-EIGRP show commands
 extcommunity-list List extended-community list

```

```

flow NetFlow switching
helper-address helper-address table
http HTTP information
igmp IGMP information
irdp ICMP Router Discovery Protocol

```

```

.
.
.

```

## Configuring a Lawful Intercept View: Example

The following example shows how to configure a lawful intercept view, add users to the view, and verify the users that were added:

```

!Initialize the LI-View.
Router(config-view)# li-view lipass user li_admin password li_adminpass
00:19:25:%PARSER-6-LI_VIEW_INIT:LI-View initialized.
Router(config-view)# end

! Enter the LI-View; that is, check to see what commands are available within the view.
Router# enable view li-view
Password:

Router#
00:22:57:%PARSER-6-VIEW_SWITCH:successfully set to view 'li-view'.
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# parser view li-view
Router(config-view)# ?
View commands:
 commands Configure commands for a view
 default Set a command to its defaults
 exit Exit from view configuration mode
 name New LI-View name ===This option only resides in LI View.
 no Negate a command or set its defaults
 password Set a password associated with CLI views

Router(config-view)#

! NOTE:LI View configurations are never shown as part of 'running-configuration'.

! Configure LI Users.
Router(config)# username lawful-intercept li-user1 password li-user1pass
Router(config)# username lawful-intercept li-user2 password li-user2pass

! Displaying LI User information.
Router# show users lawful-intercept

li_admin
li-user1
li-user2
Router#

```

## Configuring a Superview: Example

The following sample output from the **show running-config** command shows that “view\_one” and “view\_two” have been added to superview “su\_view1,” and “view\_three” and “view\_four” have been added to superview “su\_view2”:

```
!
parser view su_view1 superview
 secret 5 <encoded password>
 view view_one
 view view_two
!
parser view su_view2 superview
 secret 5 <encoded password>
 view view_three
 view view_four
!
```

# Feature Information for Role-Based CLI Access

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS, Catalyst OS, and Cisco IOS XE software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1** Feature Information for Role-Based CLI Access

| Feature Name          | Releases                 | Feature Information                                                                                                                                                                                                                                                 |
|-----------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Role-Based CLI Access | 12.3(7)T                 | This feature enables network administrators to restrict user access to CLI and configuration information.                                                                                                                                                           |

# Router Security Audit Logs

---

The Router Security Audit Logs feature allows users to configure audit trails, which track changes that have been made to a router that is running Cisco IOS software.

## History for Router Security Audit Logs Feature

| Release     | Modification                                                                                                                                                                                              |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 12.2(18)S   | This feature was introduced.                                                                                                                                                                              |
| 12.0(27)S   | This feature was integrated into Cisco IOS Release 12.0(27)S.                                                                                                                                             |
| 12.2(25)S   | The <b>show audit</b> command was extended to support the <b>filestat</b> keyword, which displays the statistics of the audit logs and helps customers choose the filesize appropriate for their network. |
| 12.2(27)SBC | This feature was integrated into Cisco IOS Release 12.2(27)SBC.                                                                                                                                           |

## Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

# Restrictions for Router Security Audit Logs

## Default Functionality

The Router Security Audit Logs feature is enabled by default and cannot be disabled. (This restriction will be lifted in a future release.)

## Disk File System Requirement

The disk file system is supported only on high-end routers; audit files are created only for platforms that support the disk file system. For platforms that do not support the disk file system, audit files are not generated and persistent-data files are lost.

## Cisco IOS Release 12.0(27)S Platform Restriction

Software images for Cisco 12000 series Internet routers have been deferred to Cisco IOS Release 12.0(27)S1.

# Information About Router Security Audit Logs

To use router security audit logs, you should understand the following concept:

- [How Router Security Audit Logs Work, page 2](#)

## How Router Security Audit Logs Work

Audit logs (also known as audit files) allow you to track changes that have been made to your router. Each change is logged as a syslog message, and all syslog messages are kept in the audit file, which is kept in the audit subsystem. Hashes are used to monitor changes in your router. A separate hash is maintained for each of the following areas:

- Running version—A hash of the information that is provided in the output of the **show version** command—running version, ROM information, BOOTLDR information, system image file, system and processor information, and configuration register contents.
- Hardware configuration—A hash of platform-specific information that is generally provided in the output of the **show diag** command.
- File system—A hash of the dir information on all of the flash file systems, which includes bootflash and any other flash file systems on the router.
- Running configuration—A hash of the running configuration.
- Startup configuration—A hash of the contents of the files on NVRAM, which includes the startup-config, private-config, underlying-config, and persistent-data files.

By default, the hashes are calculated every 5 minutes to see if any changes (events) have been made to the router. The time interval prevents a large number of hashes from being generated.

Because the audit file that is stored on the disk is circular, the number of messages that can be stored is dependent on the size of the selected file.

# How to Use Router Security Audit Logs

This section contains the following procedures:

- [Specifying and Viewing Audit File Parameters, page 3](#)
- [Monitoring the Audit Subsystem, page 5](#)

## Specifying and Viewing Audit File Parameters

Use this task to change the default parameters of the audit file.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **audit filesize** *size*
4. **audit interval** *seconds*
5. **exit**
6. **show audit** [*filestat*]

### DETAILED STEPS

|        | Command or Action                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                                                   |
|--------|---------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                            | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                                                                                                                                                                                                                                          |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                    | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                         |
| Step 3 | <b>audit filesize</b> <i>size</i><br><br><b>Example:</b><br>Router(config)# audit filesize 128    | (Optional) Changes the size of the audit file. <ul style="list-style-type: none"><li>• <i>size</i>—Size of the audit file in KB. Valid values range from 32 KB to 128 KB. 32 KB is the default size.</li></ul> <b>Note</b> Because the audit file is circular, this command determines the number of messages that can be stored on the disk before a wrap around occurs. |
| Step 4 | <b>audit interval</b> <i>seconds</i><br><br><b>Example:</b><br>Router(config)# audit interval 120 | (Optional) Changes the time interval that is used for calculating hashes. <ul style="list-style-type: none"><li>• <i>seconds</i>—Time interval, in seconds, between hash calculations. Valid values range from 120 seconds to 3600 seconds. The default value is 300 seconds (5 minutes).</li></ul>                                                                       |

|        | Command or Action                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------|---------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 5 | <b>exit</b><br><br><b>Example:</b><br>Router(config)# exit                | (Optional) Exits global configuration mode.                                                                                                                                                                                                                                                                                                                                                                          |
| Step 6 | <b>show audit [filestat]</b><br><br><b>Example:</b><br>Router# show audit | (Optional) Displays the contents of an audit file. <ul style="list-style-type: none"> <li><b>filestat</b>—Displays the rollover counter for the circular buffer and the number of messages that are received.</li> </ul> <p>The rollover counter, which indicates the number of times circular buffer has been overwritten, is reset when the audit filesize is changed (via the <b>audit filesize</b> command).</p> |

## Example

The following example is sample output from the **show audit** command:

Router# **show audit**

```

**Table 1** *show audit Field Descriptions (continued)*

| Field                                                                   | Description                                                                                                                                                    |
|-------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AUDIT-1-FILESYSTEM:Hash:<br>330E7111F2B526F0B850C24ED5774EDE<br>User:   | File system, which is a hash of the dir information on all of the flash file systems, which includes bootflash and any other flash file systems on the router. |
| AUDIT-1-HARDWARE_CONFIG:Hash:32F6646<br>3DDA802CC9171AF6386663D20 User: | Hardware configuration, which is a hash of platform-specific information that is generally provided in the output of the <b>show diag</b> command.             |

## Troubleshooting Tips

Although the **show audit** command displays audit file information such as the timestamp and what area is being hashed (such as the file system or hardware configuration), a description of what changes were attempted is not available. To view more detailed information regarding the hashes, use the **debug audit** command.

## Monitoring the Audit Subsystem

The audit subsystem contains the audit file, which contains syslog messages that monitor changes that have been made to your system. Use this optional task to monitor audit file updates.

### SUMMARY STEPS

1. **enable**
2. **debug audit**

### DETAILED STEPS

|        | Command or Action                                                | Purpose                                                                                                          |
|--------|------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable           | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul> |
| Step 2 | <b>debug audit</b><br><br><b>Example:</b><br>Router# debug audit | Displays debug messages for the audit subsystem.                                                                 |

## Examples

The following example is sample output from the **debug audit** command:

```
Router# debug audit
```

```
*Sep 14 18:37:31.535:disk0:/forensics.log -> File not found
```

```
*Sep 14 18:37:31.535:%AUDIT-1-RUN_VERSION:Hash:
```

```

## Configuration Examples for Using Router Security Audit Logs

This section contains the following configuration example:

- [Specifying Audit Log Parameters: Example, page 7](#)

## Specifying Audit Log Parameters: Example

The following example shows how to specify an audit file size of 128kb and that hashes should be calculated every 2 minutes:

```
Router(config)# audit filesize 128
Router(config) audit interval 120
```

## Command Reference

The following commands are introduced or modified in the feature or features

- **audit filesize**
- **audit interval**

- **debug audit**
- **show audit**

For information about these commands, see the Cisco IOS Security Command Reference at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html).

For information about all Cisco IOS commands, see the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the Master Command List.

# Control Plane Policing

---

Part Number OL-8695-01 (Rev A0), January 19, 2006

The Control Plane Policing feature allows users to configure a quality of service (QoS) filter that manages the traffic flow of control plane packets to protect the control plane of Cisco IOS routers and switches against reconnaissance and denial-of-service (DoS) attacks. In this way, the control plane (CP) can help maintain packet forwarding and protocol states despite an attack or heavy traffic load on the router or switch.

## History for the Control Plane Policing Feature

| Release                  | Modification                                                                                                                                                                                                             |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 12.2(18)S                | This feature was introduced.                                                                                                                                                                                             |
| 12.3(4)T                 | Control Plane Policing was integrated into Cisco IOS Release 12.3(4)T, and the output rate-limiting (silent mode operation) feature was added.                                                                           |
| 12.3(7)T                 | CISCO-CLASS-BASED-QOS-MIB was extended to manage control plane QoS policies, and the <b>police rate</b> command was introduced to support traffic policing on the basis of packets per second for control plane traffic. |
| 12.0(29)S                | The Control Plane Policing feature was integrated into Cisco IOS Release 12.0(29)S.                                                                                                                                      |
| 12.2(18)SXD1             | The Control Plane Policing feature was integrated into Cisco IOS Release 12.2(18)SXD1.                                                                                                                                   |
| 12.0(30)S                | Support for distributed control plane services on the Cisco 12000 series Internet router was added.                                                                                                                      |
| 12.2(27)SBC              | This feature was integrated into Cisco IOS Release 12.2(27)SBC.                                                                                                                                                          |
| 12.0(32)S                | Support for aggregate control plane services on the Cisco 10720 Internet router was added.                                                                                                                               |
| Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers.                                                                                                                                                            |

- [Information About Control Plane Policing, page 4](#)
- [How to Use the Control Plane Policing Feature, page 10](#)
- [Configuration Examples for Control Plane Policing, page 16](#)
- [Additional References, page 17](#)
- [Command Reference, page 18](#)

## Prerequisites for Control Plane Policing

- Understanding the concepts and general configuration procedure (class map and policy map) for applying quality-of-service (QoS) policies on a router

For information about Cisco IOS QoS and the procedure for configuring QoS in your network using the modular QoS command-line interface (MQC), refer to [Cisco IOS Quality of Service Solutions Configuration Guide](#), Release 12.3.

## Restrictions for Control Plane Policing

### Aggregate and Distributed Control Plane Policing

Aggregate policing is supported in Cisco IOS Release 12.0(29)S, Cisco IOS Release 12.2(18)S, and Cisco IOS Release 12.3(4)T and later releases.

Distributed policing is supported only in Cisco IOS Release 12.0(30)S and later Cisco IOS 12.0S releases.

### Output Rate-Limiting Support

Output rate-limiting is performed in silent (packet discard) mode. Silent mode enables a router to silently discard packets using policy maps applied to output control plane traffic with the **service-policy output** command. For more information, see [Output Rate-Limiting and Silent Mode Operation, page 10](#).

Output rate-limiting (policing) in silent mode is supported only in:

- Cisco IOS Release 12.2(25)S and later Cisco IOS 12.2S releases
- Cisco IOS Release 12.3(4)T and later Cisco IOS 12.3T releases

Output rate-limiting is not supported for distributed control plane services in Cisco IOS 12.0S releases or in Cisco IOS 12.2SX releases.

Output rate-limiting is not supported on the Cisco 7500 series and Cisco 10720 Internet router.

### Modular QoS Restrictions

The Control Plane Policing feature requires the modular QoS command-line interface (CLI) (MQC) to configure packet classification and policing. All restrictions that apply when you use the MQC to configure policing also apply when you configure control plane policing. Only two MQC actions are supported in policy maps—**police** and **drop**.

#### Note

On the Cisco 10720 Internet router, only the **police** command, not the **drop** command, is supported in policy maps. In addition, in a QoS service policy attached to the 10720 control plane, the **police** command does not support **set** actions as arguments in **conform-action**, **exceed-action**, and **violate-action** parameters.

Features that require network-based application recognition (NBAR) classification may not work well at the control plane level. The following classification (match) criteria are supported on all platforms:

- Standard and extended IP access lists (ACLs)
- In class-map configuration mode: **match ip dscp**, **match ip precedence**, and **match protocol arp** commands.

#### Note

In the Cisco IOS 12.2SX release, the **match protocol arp** command is not supported.

On the Cisco 10720 Internet router, the following MQC commands are also supported in class-map configuration mode: **match input-interface**, **match mpls experimental**, **match protocol ipv6**, and **match qos-group**. When using these commands for control plane policing on the Cisco 10720 Internet router, note the following restrictions:

- Packet classification using match criteria is not supported for packets that cannot be classified in the 10720 data path, such as unknown Layer 2 encapsulation and IP options.
- The following IPv6 fields are not supported in packet classification for IPv6 QoS on the Cisco 10720 Internet router and are, therefore, not supported for control plane policing:
  - IPv6 source and destination addresses
  - Layer 2 class of service (CoS)
  - IPv6 routing header flag
  - IPv6 undetermined transport flag
  - IPv6 flow label
  - IP Real-Time transport Protocol (RTP)

#### Note

Packets that are not supported for QoS packet classification on the Cisco 10720 Internet router are not policed in the default traffic class for control plane policing.

### CISCO-CLASS-BASED-QOS-MIB Control Plane Support

In Cisco IOS Release 12.3(7)T and later Cisco IOS 12.3T releases, the CISCO-CLASS-BASED-QOS-MIB is extended to manage control plane QoS policies and provide information about the control plane.

**Cisco IOS Release 12.2(18)SXD1**

In Cisco IOS Release 12.2(18)SXD1 and later releases, Hardware Control Plane Interface for Control Plane Policing has the following restrictions:

- Supported only with Supervisor Engine 720. Not supported with Supervisor Engine 2.
- Does not support CoPP output rate limiting (policing).
- Does not support the CoPP silent operation mode.
- Cisco IOS Release 12.2(18)SXD1 and later releases automatically install the CoPP service policy on all DFC-equipped switching modules.

For more information about Control Plane Policing in Cisco IOS Release 12.2(18)SXD1 and later releases, see either of these publications:

- For Control Plane Policing on Catalyst 6500 series switches:  
<http://www.cisco.com/univercd/cc/td/doc/product/lan/cat6000/122sx/swcg/dos.htm>
- For Control Plane Policing on Cisco 7600 series routers:  
<http://www.cisco.com/univercd/cc/td/doc/product/core/cis7600/software/122sx/swcg/dos.htm>

## Information About Control Plane Policing

To configure the Control Plane Policing feature, you should understand the following concepts:

- [Benefits of Control Plane Policing, page 4](#)
- [Terms to Understand, page 4](#)
- [Control Plane Security and Packet QoS Overview, page 6](#)
- [Aggregate Control Plane Services, page 7](#)
- [Distributed Control Plane Services, page 8](#)
- [Using Distributed CP Services, page 9](#)
- [Output Rate-Limiting and Silent Mode Operation, page 10](#)

## Benefits of Control Plane Policing

Configuring the Control Plane Policing feature on your Cisco router or switch provides the following benefits:

- Protection against DoS attacks at infrastructure routers and switches
- QoS control for packets that are destined to the control plane of Cisco routers or switches
- Ease of configuration for control plane policies
- Better platform reliability and availability

## Terms to Understand

Because different platforms can have different architectures, the following set of terms is defined. [Figure 1](#) illustrates how control plane policing works.

**Figure 1**      **Layout of Control Plane, Central Switch Engine, Distributed Switch Engines, and Line Cards on a Router**

- Control plane (CP)—A collection of processes that run at the process level on the route processor (RP). These processes collectively provide high-level control for most Cisco IOS functions.
- Central switch engine—A device that is responsible for high-speed routing of IP packets. It also typically performs high-speed input and output services for nondistributed interfaces. (See nondistributed line cards.) The central switch engine is used to implement aggregate CP protection for all interfaces on the router.

**Note**

All IP packets that are destined for the CP should pass through the central switch engine before they are forwarded to the process level.

On the Cisco 10720 Internet router, control plane policing is implemented on Cisco Parallel eXpress Forwarding (PXF) in a Toaster-based architecture. PXF is a hardware-based central switch engine that can filter traffic at a higher rate than the route processor. PXF switches all data traffic separately from the route processor. PXF packet processing occurs at an intermediate step between the nondistributed line cards and route processor shown in [Figure 1](#). In addition to the regular punting, PXF also punts certain types of packets (such as unknown Layer 2 encapsulation and packets with IP options) to the RP for further processing at interrupt level. For more information, refer to [Queueing Architecture and Modular Quality of Service \(QoS\) on the Cisco 10720 Internet Router](#).

**Note**

On the Cisco 10720 Internet router, you can configure enhanced RP protection by using the **ip option drop** command to drop IPv4 packets with IP options that are punted to the RP by PXF. Tunneled IPv4 packets and IPv4 packets with an unsupported encapsulation method are not dropped. For more information, refer to [ACL IP Options Selective Drop](#).

- Distributed switch engine—A device that is responsible for high-speed switching of IP packets on distributed line cards without using resources from the central switch engine. It also typically performs input and output services for the line card. Each distributed switch engine is used to

implement distributed CP services for all ports on a line card. Input CP services distribute the processing load across multiple line cards and conserve vital central switch engine resources. Distributed CP services are optional; however, they provide a more refined level of service than aggregate services.

- Nondistributed line cards—Line cards that are responsible for receiving packets and occasionally performing input and output services. All packets must be forwarded to the central switch engine for a routing or switching decision. Aggregate CP services provide coverage for nondistributed line cards.

---

**Note** Distributed CP services are supported only in 12.0(30)S and later 12.0S releases.

---

## Control Plane Security and Packet QoS Overview

To protect the CP on a router from DoS attacks and to provide packet QoS, the Control Plane Policing feature treats the CP as a separate entity with its own ingress (input) and egress (output) ports, which are like ports on a router and switch. Because the Control Plane Policing feature treats the CP as a separate entity, a set of rules can be established and associated with the ingress and egress port of the CP.

These rules are applied only after the packet has been determined to have the CP as its destination or when a packet exits from the CP. Thereafter, you can configure a service policy to prevent unwanted packets from progressing after a specified rate limit has been reached; for example, a system administrator can limit all TCP/SYN packets that are destined for the CP to a maximum rate of 1 megabit per second.

Input CP services are executed after router input port services and a routing decision on the input path have been made. As shown in [Figure 2](#), CP security and packet QoS are applied on:

- An aggregate level by the central switch engine and applied to all CP packets received from all line cards on the router (see [Aggregate Control Plane Services, page 7](#))
- A distributed level by the distributed switch engine of a line card and applied to all CP packets received from all interfaces on the line card (see [Distributed Control Plane Services, page 8](#))

**Figure 2** *Input Control Plane Services: Aggregate and Distributed Services*

The following types of Layer 3 packets are forwarded to the control plane and processed by aggregate and distributed control plane policing:

- Routing protocol control packets
- Packets destined for the local IP address of the router
- Packets from management protocols (such as Simple Network Management Protocol [SNMP], Telnet, and secure shell [SSH])

**Note**

Ensure that Layer 3 control packets have priority over other packet types that are destined for the control plane.

## Aggregate Control Plane Services

Aggregate control plane services provide control plane policing for all CP packets received from all line-card interfaces on the router.

The central switch engine executes normal input port services and makes routing decisions for an incoming packet: if the packet is destined for the CP, aggregate services are performed. Because CP traffic from all line cards must pass through aggregate CP services, these services manage the cumulative amount of CP traffic that reaches the CP.

Aggregate CP service steps are as follows:

1. The line card receives a packet and delivers it to the central switch engine.

**Note**

Before the packet is sent to the central switch engine, additional processing may be necessary for platforms that support hardware-level policing or platform-specific aggregate policing. It is possible that the packet may undergo multiple checks before it undergoes the generic Cisco IOS check.

2. The interfaces perform normal (interface-level) input port services and QoS.
3. The central switch engine performs Layer 3 switching or makes a routing decision, determining whether or not the packet is destined for the CP.
4. The central switch engine performs aggregate CP services for all CP packets.
5. On the basis of the results of the aggregate CP services, the central switch engine either drops the packet or delivers the packet to the CP for final processing.

**Functionality Highlights of Aggregate CP Services**

The following list highlights the functionality of aggregate CP services:

- Defined for a single input interface, such as the CP, and represents an aggregate for all ports on a router.
- Modular QoS is used to define CP services. Class maps and policy maps for both DoS protection and packet QoS are defined for a single aggregate CP service policy.
- Modular QoS does not prevent a single bad port from consuming all allocated bandwidth. Class maps that match an interface or subinterface may be able to constrain the contribution of each interface through an interface-specific policy map.

## Distributed Control Plane Services

Distributed control plane services provide control plane policing for all CP packets received from the interfaces on a line card.

A distributed switch engine executes normal input port services and makes routing decisions for a packet: if the packet is destined for the CP, distributed CP services are performed. Afterwards, CP traffic from each line card is forwarded to the central switch engine where aggregate CP services are applied.

**Note**

Distributed CP services may also forward conditioned packets to the central switch engine. In this case, aggregate CP services are also performed on the conditioned CP traffic.

Distributed CP service steps are as follows:

1. A line card receives a packet and delivers it to the distributed switch engine.
2. The distributed switch engine performs normal (interface-level) input port services and QoS.
3. The distributed switch engine performs Layer 2 or Layer 3 switching, or makes a routing decision, determining whether or not the packet is destined for the CP.
4. The distributed switch engine performs distributed CP services for all CP packets.
5. On the basis of the results of the distributed CP services, the distributed switch engine either drops the packet or marks the packet and delivers it to the central switch engine for further processing.
6. The central switch engine performs aggregate CP services and delivers the packet to the CP for final processing.

### Functionality Highlights of Distributed CP Services

The following list highlights the functionality of distributed CP services:

- Distributed CP services are defined for a single input interface, such as the distributed CP, and represent an aggregate for all ports on a line card.
- Modular QoS is used to define CP services. Class maps and policy maps for both DoS protection and packet QoS are defined for a single distributed CP service policy. Each line card may have a unique CP service policy that applies traffic classifications, QoS policies and DoS services to packets received from all ports on the line card in an aggregate way.
- Modular QoS does not prevent one bad port from consuming all allocated bandwidth on a line card. Class maps that match an interface or subinterface may be able to constrain the contribution of each interface through an interface-specific policy map.

Distributed CP services allow you to limit the number of CP packets forwarded from a line card to the central switch engine. The total amount of CP packets received from all line cards on a router may exceed aggregate CP levels.

## Using Distributed CP Services

The purpose of CP protection and packet QoS is to apply sufficient control to the packets that reach the control plane. To successfully configure this level of CP protection, you must:

- Apply traditional QoS services using the modular QoS command-line interface to CP packets.
- Protect the path to the control plane against indiscriminate packet dropping due to resource exhaustion. If packets are not dropped according to user-defined QoS policies, but are dropped due to a resource limitation, the QoS policy is not maintained.

Distributed CP services allow you to configure specific CP services that are enforced at the line card level and required for the following reasons:

- While under a DoS attack, line card resources may be consumed. In this case, you must configure a drop policy to identify important packets. The drop policy ensures that all important packets arrive to the central switch engine for aggregate CP protection and later to the CP. Distributed CP services allow routers to apply the appropriate drop policy when resources are consumed, and therefore maintain the desired QoS priorities. If a line card indiscriminately drops packets, the aggregate CP filter becomes ineffective and the QoS priorities are no longer maintained.
- It is not possible to prevent one interface from consuming all aggregate CP resources. A DoS attack on one port may negatively impact CP processing of traffic from other ports. Distributed CP services allow you to limit the amount of important traffic forwarded by a line card to the CP. For example, you can configure a layered approach in which the combined rates of all line cards is over-subscribed compared to the aggregate rate. The rate of each individual line card would be below the aggregate rate, but combined together, the rates of all line cards exceed it. This over-subscription model is commonly used for other resource-related functions and helps limit the contribution of CP packets from any one line card.
- Distributed CP services provide for slot-level (line card) filtering. Customer-facing interfaces may have greater security requirements (with more restrictions or for billing reasons) than network-facing interfaces to backbone devices.
- Because distributed CP protection allows you to configure packet filters on a per-line card basis, processing cycles on line cards may offload aggregate level processing. You can configure Border Gateway Protocol (BGP) filtering at the distributed level for interfaces that use BGP, allowing the aggregate level to filter packets with the remaining filter requirements. Or you can configure identical filters for distributed and aggregate CP services with a distributed packet marking scheme.

that informs the aggregate filter that a packet has already been checked. Distributed CP service processing further reduces aggregate processing and can significantly reduce the load on aggregate CP services.

## Output Rate-Limiting and Silent Mode Operation

A router is automatically enabled to silently discard packets when you configure output policing on control plane traffic, using the **service-policy output** *policy-map-name* command.

Rate-limiting (policing) of output traffic from the CP is performed in silent mode. In silent mode, a router that is running Cisco IOS software operates without sending any system messages. If a packet that is exiting from the control plane is discarded for output policing, you do not receive an error message.

When control plane policing is configured for output traffic, error messages are not generated in the following cases:

- Traffic that is being transmitted to a port to which the router is not listening
- A connection to a legitimate address and port that is rejected because of a malformed request

### Note

The silent mode functionality and output policing on CP traffic are supported only in:

- Cisco IOS Release 12.2(25)S and later Cisco IOS 12.2S releases.
- Cisco IOS Release 12.3(4)T and later Cisco IOS 12.3T releases.

Silent mode and output policing on CP traffic are not supported for distributed control plane services.

## How to Use the Control Plane Policing Feature

This section documents the following procedures:

- [Defining Aggregate Control Plane Services, page 10](#)
- [Defining Distributed Control Plane Services, page 11](#)
- [Verifying Aggregate CP Services, page 13](#)
- [Verifying Distributed CP Services, page 14](#)

## Defining Aggregate Control Plane Services

Perform this task to configure aggregate CP services, such as packet rate control and silent packet discard, for the active route processor.

### Prerequisites

Before you enter control-plane configuration mode to attach an existing QoS policy to the control plane, you must first create the policy using MQC to define a class map and policy map for control plane traffic.

For information about how to classify traffic and create a QoS policy, refer to the “[Modular Quality of Service Command-Line Interface](#)” chapter in the *Cisco IOS Quality of Service Solutions Configuration Guide*.

## Restrictions

- Platform-specific restrictions, if any, are checked when the service policy is applied to the control plane interface.
- Support for output policing is available only in Cisco IOS Release 12.3(4)T and later T-train releases. (Note that output policing does not provide any performance benefits. It simply controls the information that is leaving the device.)

## SUMMARY STEPS

- enable**
- configure terminal**
- control-plane**
- service-policy {input | output} *policy-map-name***

## DETAILED STEPS

|        | Command or Action                                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> <b>enable</b>                                                                                               | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# <b>configure terminal</b>                                                                       | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 3 | <b>control-plane</b><br><br><b>Example:</b><br>Router(config)# <b>control-plane</b>                                                                         | Enters control-plane configuration mode to attach a QoS policy that manages CP traffic.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Step 4 | <b>service-policy {input   output} <i>policy-map-name</i></b><br><br><b>Example:</b><br>Router(config-cp)# <b>service-policy input control-plane-policy</b> | Attaches a QoS service policy to the control plane. <ul style="list-style-type: none"> <li><b>input</b>—Applies the specified service policy to packets received on the control plane.</li> <li><b>output</b>—Applies the specified service policy to packets transmitted from the control plane and enables the router to silently discard packets.</li> <li><b><i>policy-map-name</i></b>—Name of a service policy map (created using the <b>policy-map</b> command) to be attached. The name can be a maximum of 40 alphanumeric characters.</li> </ul> |

## Defining Distributed Control Plane Services

Perform this task to configure distributed CP services, such as packet rate control, for packets that are destined for the CP and sent from the interfaces on a line card.

## Prerequisites

Before you enter control-plane configuration mode to attach an existing QoS policy for performing distributed control-plane services, you must first create the policy using MQC to define a class map and policy map for control-plane traffic.

For information about how to classify traffic and create a QoS policy, refer to the “[Modular Quality of Service Command-Line Interface](#)” chapter in the *Cisco IOS Quality of Service Solutions Configuration Guide*.

## Restrictions

- Platform-specific restrictions, if any, are checked when the service policy is applied to the control plane interface.
- Support for output policing is available only in Cisco IOS Release 12.3(4)T and later T-train releases. (Note that output policing does not provide any performance benefits. It simply controls the information that is leaving the device.)
- With Cisco IOS 12.2SX releases, Supervisor Engine 720 automatically installs the service policy on all DFC-equipped switching modules.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **control-plane** [slot *slot-number*]
4. **service-policy input** *policy-map-name*

## DETAILED STEPS

|        | Command or Action                                    | Purpose                                                                                                          |
|--------|------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b>                                        | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul> |
|        | <b>Example:</b><br>Router> <b>enable</b>             |                                                                                                                  |
| Step 2 | <b>configure terminal</b>                            | Enters global configuration mode.                                                                                |
|        | <b>Example:</b><br>Router# <b>configure terminal</b> |                                                                                                                  |

|        | Command or Action                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <b>control-plane</b> [ <i>slot slot-number</i> ]<br><br><b>Example:</b><br>Router(config)# <b>control-plane slot 3</b>                           | Enters control-plane configuration mode to attach a QoS policy to manage CP traffic on the line card in the specified slot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Step 4 | <b>service-policy input</b> <i>policy-map-name</i><br><br><b>Example:</b><br>Router(config-cp)# <b>service-policy input control-plane-policy</b> | Attaches a QoS service policy to filter and manage CP traffic on a specified line card before the aggregate CP policy is applied. <ul style="list-style-type: none"> <li><b>input</b>—Applies the specified service policy using the distributed switch engine to CP packets received from all interfaces on the line card.</li> <li><b>policy-map-name</b>—Name of a service policy map (created using the <b>policy-map</b> command) to be attached. The name can be a maximum of 40 alphanumeric characters.</li> </ul> <p><b>Note</b> The <b>service-policy output</b> <i>policy-map-name</i> command is not supported for applying a QoS policy for distributed control plane services.</p> |

## Verifying Aggregate CP Services

To display information about the service policy attached to the control plane for aggregate CP services, perform the following optional steps.

### SUMMARY STEPS

1. **enable**
2. **show policy-map control-plane** [*all*] [*input* [*class class-name*] | *output* [*class class-name*]]

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> <b>enable</b>                                                                                                                                                          | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                           |
| Step 2 | <b>show policy-map control-plane</b> [ <i>all</i> ] [ <i>input</i> [ <i>class class-name</i> ]   <i>output</i> [ <i>class class-name</i> ]]<br><br><b>Example:</b><br>Router# <b>show policy-map control-plane all</b> | Displays information about the control plane. <ul style="list-style-type: none"> <li><b>all</b>—Service policy information about all QoS policies used in aggregate and distributed CP services.</li> <li><b>input</b>—Statistics for the attached input policy.</li> <li><b>output</b>—Statistics for the attached output policy.</li> <li><b>class class-name</b>—Name of the traffic class whose configuration and statistics are displayed.</li> </ul> |

## Examples

The following example shows that the policy map TEST is associated with the control plane. This policy map polices traffic that matches the class map TEST, while allowing all other traffic (that matches the class map “class-default”) to go through as is. (Table 1 describes the significant fields shown in the display.)

```
Router# show policy-map control-plane

Control Plane

Service-policy input:TEST

Class-map:TEST (match-all)
 20 packets, 11280 bytes
 5 minute offered rate 0 bps, drop rate 0 bps
 Match:access-group 101
 police:
 8000 bps, 1500 limit, 1500 extended limit
 conformed 15 packets, 6210 bytes; action:transmit
 exceeded 5 packets, 5070 bytes; action:drop
 violated 0 packets, 0 bytes; action:drop
 conformed 0 bps, exceed 0 bps, violate 0 bps

Class-map:class-default (match-any)
 105325 packets, 11415151 bytes
 5 minute offered rate 0 bps, drop rate 0 bps
 Match:any
```

## Verifying Distributed CP Services

To display information about the service policy attached to the control plane to perform distributed CP services, perform the following optional steps.

### SUMMARY STEPS

1. **enable**
2. **show policy-map control-plane** [**all** | **slot** *slot-number*] [**input** [**class** *class-name*] | **output** [**class** *class-name*]]

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> <b>enable</b>                                                                                                                                      | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Step 2 | <b>show policy-map control-plane [all] [slot slot-number] [input [class class-name]   output [class class-name]]</b><br><br><b>Example:</b><br>Router# <b>show policy-map control-plane slot 2</b> | Displays information about the service policy used to apply distributed CP services on the router. <ul style="list-style-type: none"> <li><b>all</b>—Service policy information about all QoS policies used in aggregate and distributed CP services.</li> <li><b>slot slot-number</b>—Service policy information about the QoS policy used to perform distributed CP services on the specified line card.</li> <li><b>input</b>—Statistics for the attached input policy.</li> <li><b>output</b>—Statistics for the attached output policy.</li> <li><b>class class-name</b>—Name of the traffic class whose configuration and statistics are displayed.</li> </ul> |

## Examples

The following example shows how to display information about the classes of CP traffic received from all interfaces on the line card in slot 1 to which the policy map TESTII is applied for distributed CP services. This policy map polices traffic that matches the traffic class TESTII, while allowing all other traffic (that matches the class map “class-default”) to go through as is. (Table 1 describes the significant fields shown in the display.)

```
Router# show policy-map control-plane slot 1

Control Plane - slot 1

Service-policy input: TESTII (1048)

Class-map: TESTII (match-all) (1049/4)
 0 packets, 0 bytes
 5 minute offered rate 0 bps, drop rate 0 bps
 Match: protocol arp (1050)
 police:
 cir 8000 bps, bc 4470 bytes, be 4470 bytes
 conformed 0 packets, 0 bytes; actions:
 transmit
 exceeded 0 packets, 0 bytes; actions:
 drop
 violated 0 packets, 0 bytes; actions:
 drop
 conformed 0 bps, exceed 0 bps, violate 0 bps

Class-map: class-default (match-any) (1052/0)
 0 packets, 0 bytes
 5 minute offered rate 0 bps, drop rate 0 bps
 Match: any (1053)
```

# Configuration Examples for Control Plane Policing

This section contains examples that shows how to configure aggregate control plane services on both an input and an output interface:

- [Configuring Control Plane Policing on Input Telnet Traffic: Example, page 16](#)
- [Configuring Control Plane Policing on Output ICMP Traffic: Example, page 16](#)

## Configuring Control Plane Policing on Input Telnet Traffic: Example

The following example shows how to apply a QoS policy for aggregate CP services to Telnet traffic received on the control plane. Trusted hosts with source addresses 10.1.1.1 and 10.1.1.2 forward Telnet packets to the control plane without constraint, while allowing all remaining Telnet packets to be policed at the specified rate:

```
! Allow 10.1.1.1 trusted host traffic.
Router(config)# access-list 140 deny tcp host 10.1.1.1 any eq telnet
! Allow 10.1.1.2 trusted host traffic.
Router(config)# access-list 140 deny tcp host 10.1.1.2 any eq telnet
! Rate limit all other Telnet traffic.
Router(config)# access-list 140 permit tcp any any eq telnet
! Define class-map "telnet-class."
Router(config)# class-map telnet-class
Router(config-cmap)# match access-group 140
Router(config-cmap)# exit
Router(config)# policy-map control-plane-in
Router(config-pmap)# class telnet-class
Router(config-pmap-c)# police 80000 conform transmit exceed drop
Router(config-pmap-c)# exit
Router(config-pmap)# exit
! Define aggregate control plane service for the active Route Processor.
Router(config)# control-plane
Router(config-cp)# service-policy input control-plane-in
Router(config-cp)# exit
```

## Configuring Control Plane Policing on Output ICMP Traffic: Example

The following example shows how to apply a QoS policy for aggregate CP services to Telnet traffic transmitted from the control plane. Trusted networks with source addresses 3.3.3.0 and 4.4.4.0 receive Internet Control Management Protocol (ICMP) port-unreachable responses without constraint, while allowing all remaining ICMP port-unreachable responses to be dropped:

```
! Allow 3.3.3.0 trusted network traffic.
Router(config)# access-list 141 deny icmp 3.3.3.0 0.0.0.255 any port-unreachable
! Allow 4.4.4.0 trusted network traffic.
Router(config)# access-list 141 deny icmp 4.4.4.0 0.0.0.255 any port-unreachable
! Rate limit all other ICMP traffic.
Router(config)# access-list 141 permit icmp any any port-unreachable
Router(config)# class-map icmp-class
Router(config-cmap)# match access-group 141
Router(config-cmap)# exit
Router(config)# policy-map control-plane-out
! Drop all traffic that matches the class "icmp-class."
Router(config-pmap)# class icmp-class
Router(config-pmap-c)# drop
Router(config-pmap-c)# exit
Router(config-pmap)# exit
```

```
Router(config)# control-plane
! Define aggregate control plane service for the active route processor.
Router(config-cp)# service-policy output control-plane-out
Router(config-cp)# exit
```

# IP Traffic Export

---

The IP Traffic Export feature allows users to configure their router to export IP packets that are received on multiple, simultaneous WAN or LAN interfaces. The unaltered IP packets are exported on a single LAN or VLAN interface, thereby, easing deployment of protocol analyzers and monitoring devices.

## Feature History for IP Traffic Export

| Release   | Modification                                                  |
|-----------|---------------------------------------------------------------|
| 12.3(4)T  | This feature was introduced.                                  |
| 12.2(25)S | This feature was integrated into Cisco IOS Release 12.2(25)S. |

## Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

# Restrictions for IP Traffic Export

## Platform Restriction

IP traffic export is intended only for software switching platforms; distributed architectures are not supported.

## IP Packet Forwarding Performance Impact

When IP traffic export is enabled, a delay is incurred on the outbound interface when packets are captured and transmitted across the interface. Performance delays increase with the increased number of interfaces that are monitored and the increased number of destination hosts.

## Exported Traffic Limitation

- The MAC address of the device that is receiving the exported traffic must be on the same VLAN or directly connected to one of the router interfaces. (Use the **show arp** command to determine the MAC address of device that is directly connected to an interface.)
- The outgoing interface for exported traffic must be Ethernet (10/100/1000). (Incoming (monitored) traffic can traverse any interface.)

# Information About IP Traffic Export

To use the IP traffic export, you should understand the following concept:

- [Benefits of IP Traffic Export, page 2](#)

# Benefits of IP Traffic Export

## Simplified IDS Deployment

Without the ability to export IP traffic, the Intrusion Detection System (IDS) probe must be inline with the network device to monitor traffic flow. IP traffic export eliminates the probe placement limitation, allowing users to place an IDS probe in any location within their network or direct all exported traffic to a VLAN that is dedicated for network monitoring. Allowing users to choose the optimal location of their IDS probe reduces processing burdens.

Also, because packet processing that was once performed on the network device can now be performed away from the network device, the need to enable IDS with the Cisco IOS software can be eliminated.

## IP Traffic Export Functionality Benefits

Users can configure their router to perform the following tasks:

- Filter copied packets via an access control list (ACL)
- Filter copied packets via sampling, which allows you to export one in every few packets in which you are interested. Use this option when it is not necessary to export all incoming traffic. Also, sampling is useful when a monitored ingress interface can send traffic faster than the egress interface can transmit it.
- Configure bidirectional traffic on an interface. (By default, only incoming traffic is exported.)

# How to Use IP Traffic Export

This section contains the following procedures:

- [Configuring IP Traffic Export, page 3](#)
- [Displaying IP Traffic Export Configuration Data, page 5](#)

## Configuring IP Traffic Export

Use this task to configure IP traffic export profiles, which enable IP traffic to be exported on an ingress interface and allow you to specify profile attributes, such as the outgoing interface for exporting traffic.

**Note**

Packet exporting is performed before packet switching or filtering.

## IP Traffic Export Profiles Overview

All packet export configurations are specified via IP traffic export profiles, which consist of IP-traffic-export-related command-line interfaces (CLIs) that control various attributes for both incoming and outgoing exported IP traffic. You can configure a router with multiple IP traffic export profiles. (Each profile must have a different name.) You can apply different profiles on different interfaces.

The two different IP traffic export profiles are as follows:

- The global configuration profile, which is configured via the **ip traffic-export profile** command.
- The IP traffic export submode configuration profile, which is configured via any of the following router IP Traffic Export (RITE) commands—**bidirectional**, **incoming**, **interface**, **mac-address**, and **outgoing**.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip traffic-export profile** *profile-name*
4. **interface** *interface-name*
5. **bidirectional**
6. **mac-address** *H.H.H*
7. **incoming** {**access-list** {*standard* | *extended* | *named*} | **sample one-in-every** *packet-number*}
8. **outgoing** {**access-list** {*standard* | *extended* | *named*} | **sample one-in-every** *packet-number*}
9. **exit**
10. **interface** *type number*
11. **ip traffic-export apply** *profile-name*

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                           |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                                       | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                  |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                                               | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                 |
| Step 3 | <b>ip traffic-export profile</b> <i>profile-name</i><br><br><b>Example:</b><br>Router(config)# ip traffic-export profile my_rite                                                                                             | Creates or edits an IP traffic export profile, enables the profile on an ingress interface, and enters RITE configuration mode.                                                                                                                                                                                                                                   |
| Step 4 | <b>interface</b> <i>interface-name</i><br><br><b>Example:</b><br>Router(config-rite)# interface FastEthernet 0/1                                                                                                             | Specifies the outgoing (monitored) interface for exported traffic.<br><br><b>Note</b> If you do not issue this command, the profile will not recognize an interface in which to send the captured IP traffic.                                                                                                                                                     |
| Step 5 | <b>bidirectional</b><br><br><b>Example:</b><br>Router(config-rite)# bidirectional                                                                                                                                            | (Optional) Exports incoming and outgoing IP traffic on the monitored interface.<br><br><b>Note</b> If this command is not enabled, only incoming traffic is exported.                                                                                                                                                                                             |
| Step 6 | <b>mac-address</b> <i>H.H.H</i><br><br><b>Example:</b><br>Router(config-rite)# mac-address 00a.8aab.90a0                                                                                                                     | Specifies the 48-bit address of the destination host that is receiving the exported traffic.<br><br><b>Note</b> If you do not issue this command, the profile will not recognize a destination host in which to send the exported packets.                                                                                                                        |
| Step 7 | <b>incoming</b> { <b>access-list</b> { <i>standard</i>   <i>extended</i>   <i>named</i> }   <b>sample one-in-every</b> <i>packet-number</i> }<br><br><b>Example:</b><br>Router(config-rite)# incoming access-list my_acl     | (Optional) Configures filtering for incoming traffic.<br>After you have created a profile via the <b>ip traffic-export profile</b> , this functionality is enabled by default.                                                                                                                                                                                    |
| Step 8 | <b>outgoing</b> { <b>access-list</b> { <i>standard</i>   <i>extended</i>   <i>named</i> }   <b>sample one-in-every</b> <i>packet-number</i> }<br><br><b>Example:</b><br>Router(config-rite)# outgoing sample one-in-every 50 | (Optional) Configures filtering for outgoing export traffic.<br><br><b>Note</b> If you issue this command, you must also issue the <b>bidirectional</b> command, which enables outgoing traffic to be exported. However, only routed traffic (such as passthrough traffic) is exported; that is, traffic that originates from the network device is not exported. |
| Step 9 | <b>exit</b>                                                                                                                                                                                                                  | Exits RITE configuration mode.                                                                                                                                                                                                                                                                                                                                    |

|         | Command or Action                                                                                                              | Purpose                                                               |
|---------|--------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------|
| Step 10 | <code>interface type number</code><br><br><b>Example:</b><br>Router(config)# interface FastEthernet0/0                         | Configures an interface type and enters interface configuration mode. |
| Step 11 | <code>ip traffic-export apply profile-name</code><br><br><b>Example:</b><br>Router(config-if)# ip traffic-export apply my_rite | Enables IP traffic export on an ingress interface.                    |

## Troubleshooting Tips

### Creating an IP Traffic Export Profile

The **interface** and **mac-address** commands are required to successfully create a profile. If these commands are not issued, you will receive the following profile incomplete message if the **show running config** command is issued:

```
ip traffic-export profile newone
! No outgoing interface configured
! No destination mac-address configured
```

### Applying an IP Traffic Export Profile to an interface

The following system logging messages should appear immediately after you activate and deactivate a profile from an interface (via the **ip traffic-export apply profile** command):

- Activated profile:  
%RITE-5-ACTIVATE: Activated IP traffic export on interface FastEthernet 0/0.
- Deactivated profile:  
%RITE-5-DEACTIVATE: Deactivated IP traffic export on interface FastEthernet 0/0.

If you attempt to apply an incomplete profile to an interface, you will receive the following message:

```
Router(config-if)# ip traffic-export apply newone
RITE: profile newone has missing outgoing interface
```

## What to Do Next

After you have configured a profile and enabled the profile on an ingress interface, you can monitor IP traffic exporting events and verify your profile configurations. To complete these steps, refer to the following task “[Displaying IP Traffic Export Configuration Data](#).”

## Displaying IP Traffic Export Configuration Data

This task allows you to verify IP traffic export parameters such as the monitored ingress interface, which is where the IP traffic is exported, and outgoing and incoming IP packet information, such as configured ACLs. You can also use this task to monitor packets that are captured and then transmitted across an interface to a destination host. Use this optional task to help you troubleshoot any problems with your exported IP traffic configurations.

## SUMMARY STEPS

1. **enable**
2. **debug ip traffic-export events**
3. **show ip traffic-export** [**interface** *interface-name* | **profile** *profile-name*]

## DETAILED STEPS

|        | Command or Action                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                     |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                 | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                                                                                                                                                                                                                         |
| Step 2 | <b>debug ip traffic-export events</b><br><br><b>Example:</b><br>Router# debug ip traffic-export events                                                                 | Enables debugging messages for exported IP traffic packets events.                                                                                                                                                                                                                                                                                          |
| Step 3 | <b>show ip traffic-export</b> [ <b>interface</b> <i>interface-name</i>   <b>profile</b> <i>profile-name</i> ]<br><br><b>Example:</b><br>Router# show ip traffic-export | Displays information related to exported IP traffic events.<br><ul style="list-style-type: none"><li>• <b>interface</b> <i>interface-name</i>—Only data associated with the monitored ingress interface is shown.</li><li>• <b>profile</b> <i>profile-name</i>—Only flow statistics, such as exported packets and the number of bytes, are shown.</li></ul> |

## Examples

The following sample output from the **show ip traffic-export** command is for the profile “one.” This example is for a single, configured interface. If multiple interfaces are configured, the information shown below is displayed for each interface.

Router# **show ip traffic-export**

```
Router IP Traffic Export Parameters
Monitored Interface FastEthernet0/0
Export Interface FastEthernet0/1
Destination MAC address 0030.7131.abfc
bi-directional traffic export is off
Input IP Traffic Export Information Packets/Bytes Exported 0/0
Packets Dropped 0
Sampling Rate one-in-every 1 packets
No Access List configured
Profile one is Active
```

# Configuration Examples for IP Traffic Export

This section includes the following configuration example:

- [Exporting IP Traffic Configuration: Example, page 7](#)

## Exporting IP Traffic Configuration: Example

Figure 1 and the following sample output from the **show running-config** command illustrate how to configure Router 2 to export the incoming traffic from Router 1 to IDS:

Router2# **show running-config**

Building configuration...

Current configuration :2349 bytes

# Command Reference

The following commands are introduced or modified in the feature or features

- **bidirectional**
- **debug ip traffic-export events**
- **incoming**
- **interface (RITE)**
- **ip traffic-export apply**
- **ip traffic-export profile**
- **mac-address (RITE)**
- **outgoing**
- **show ip traffic-export**

For information about these commands, see the Cisco IOS Security Command Reference at

[http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html).

For information about all Cisco IOS commands, see the Command Lookup Tool at

<http://tools.cisco.com/Support/CLILookup> or the Master Command List.

## **Security with Passwords, Privilege Levels, and Login Usernames for CLI Sessions on Networking Devices**

# Configuring Security with Passwords, Privilege Levels, and Login Usernames for CLI Sessions on Networking Devices

---

Cisco IOS based networking devices provide several features that can be used to implement basic security for CLI sessions using only the operating system running on the device. These features include the following:

- Different levels of authorization for CLI sessions to control access to commands that can modify the status of the networking device versus commands that are used to monitor the device
- Assigning passwords to CLI sessions
- Requiring users log in to a networking device with a username
- Changing the privilege levels of commands to create new authorization levels for CLI sessions.

This module is a guide to implementing a baseline level of security for your networking devices. It focuses on the least complex options available for implementing a baseline level of security. If you have networking devices installed in your network with no security options configured, or you are about to install a networking device and you need help understanding the how to implement a baseline of security, this document will help you.

## Module History

This module was first published on May 2nd, 2005, and last updated on May 2nd, 2005.

## Finding Feature Information in This Module

*Your Cisco IOS software release may not support all features.* To find information about feature support and configuration, use the [“Feature Information for Configuring Security with Passwords, Privilege Levels and, Login Usernames for CLI Sessions on Networking Devices”](#) section on page 42.

## Restrictions for Configuring Security with Passwords, Privilege Levels and, Login Usernames for CLI Sessions on Networking Devices

Your networking device must not be configured to use any local or remote authentication, authorization, and accounting (AAA) security features. This document describes only the non-AAA security features that can be configured locally on the networking device.

For information how to configure AAA security features that can be run locally on a networking device, or for information on how to configure remote AAA security using TACACS+ or RADIUS servers, see the [Cisco IOS Security Configuration Guide](#), Release 12.4.

## Information About Configuring Security with Passwords, Privilege Levels and, Login Usernames for CLI Sessions on Networking Devices

To configure router security with passwords, CLI privilege levels and usernames, you should understand the following concepts:

- [Benefits of Creating a Security Scheme for Your Networking Device, page 3](#)
- [Cisco IOS CLI Modes, page 3](#)
- [Cisco IOS CLI Sessions, page 10](#)
- [Protect Access to Cisco IOS EXEC Modes, page 11](#)
- [Cisco IOS Password Encryption Levels, page 11](#)
- [Cisco IOS CLI Session Usernames, page 13](#)
- [Cisco IOS Privilege Levels, page 13](#)
- [Cisco IOS Password Configuration, page 14](#)

## Benefits of Creating a Security Scheme for Your Networking Device

The foundation of a good security scheme in the network is the protection of the user interfaces of the networking devices from unauthorized access. Protecting access to the user interfaces on your networking devices prevents unauthorized users from making configuration changes that can disrupt the stability of your network or compromise your network security.

The Cisco IOS features described in this document can be combined in many different ways to create a unique security scheme for each of your networking devices. Here are some possible examples that you can configure:

- You can enable non administrative users to run a subset of the administrative commands available on the networking device by lowering the entitlement level for the commands to the non administrative privilege level. This can be useful for the following scenarios:
  - ISPs that want their first-line technical support staff to perform tasks such as enabling new interfaces for new customers or resetting the connection for a customer whose connection has stopped passing traffic. See the [“Configuring and Verifying a Networking Device to Allow Non Administrative Users to Shutdown and Enable Interfaces: Example”](#) section on page 38 section for an example of how to do this.
  - When you want your first-line technical support staff to have the ability to clear console port sessions that were disconnected improperly from a terminal server. See the [“Configuring and Verifying a Networking Device to Allow Non Administrative Users to Clear Remote CLI Sessions: Example”](#) section on page 37 section for an example of how to do this.
  - When you want your first-line technical support staff to have the ability to view, but not change, the configuration of a networking device to facilitate troubleshooting a networking problem. See the [“Configuring and Verifying a Networking Device to Allow Non Administrative Users to View the Running Configuration Automatically: Example”](#) section on page 38 section for an example of how to do this.

## Cisco IOS CLI Modes

To aid in the configuration of Cisco devices, the Cisco IOS command-line interface is divided into different command modes. Each command mode has its own set of commands available for the configuration, maintenance, and monitoring of router and network operations. The commands available to you at any given time depend on the mode you are in. Entering a question mark (?) at the system prompt (router prompt) allows you to obtain a list of commands available for each command mode.

The use of specific commands allows you to navigate from one command mode to another. The standard order in which a user would access the modes is as follows: user EXEC mode; privileged EXEC mode; global configuration mode; specific configuration modes; configuration submodes; and configuration subsubmodes.

### Note

The default configuration of a Cisco IOS software based networking device only allows you to configure passwords to protect access to user EXEC mode (for local, and remote CLI sessions) and privileged EXEC mode. This document describes how you can provide additional levels of security by protecting access to other modes, and commands, using a combination of usernames, passwords and the **privilege** command.

Most EXEC mode commands are one-time commands, such as **show** or **more** commands, which show the current configuration status, and **clear** commands, which clear counters or interfaces. EXEC mode commands are not saved across reboots of the router.

From privileged EXEC mode, you can enter *global configuration mode*. In this mode, you can enter commands that configure general system characteristics. You also can use global configuration mode to enter specific configuration modes. Configuration modes, including global configuration mode, allow you to make changes to the running configuration. If you later save the configuration, these commands are stored across router reboots.

From global configuration mode you can enter a variety of protocol-specific or feature-specific configuration modes. The CLI hierarchy requires that you enter these specific configuration modes only through global configuration mode. For example, *interface configuration mode*, is a commonly used configuration mode.

From configuration modes, you can enter configuration submodes. Configuration submodes are used for the configuration of specific features within the scope of a given configuration mode. As an example, this chapter describes the *subinterface configuration mode*, a submode of the interface configuration mode.

*ROM monitor mode* is a separate mode used when the router cannot boot properly. If your system (router, switch, or access server) does not find a valid system image to load when it is booting, the system will enter ROM monitor mode. ROM monitor (ROMMON) mode can also be accessed by interrupting the boot sequence during startup. ROMMON is not covered in this document because it does not have any security features available in it.

The following sections contain detailed information on these command modes:

- [User EXEC Mode](#)
- [Privileged EXEC Mode](#)
- [Global Configuration Mode](#)
- [Interface Configuration Mode](#)
- [Subinterface Configuration Mode](#)

## User EXEC Mode

When you start a session on a router, you generally begin in *user EXEC mode*, which is one of two access levels of the EXEC mode. For security purposes, only a limited subset of EXEC commands are available in user EXEC mode. This level of access is reserved for tasks that do not change the configuration of the router, such as determining the router status.

If your device is configured to require users to log-in the log-in process will require a username and a password. You may try three times to enter a password before the connection attempt is refused.

User EXEC mode is set by default to privilege level 1. Privileged EXEC mode is set by default to privilege level 15. For more information see the [“Privileged EXEC Mode” section on page 6](#). When you are logged into a networking device in user EXEC mode your session is running at privilege level 1. By default the EXEC commands at privilege level 1 are a subset of those available at privilege level 15. When you are logged into a networking device in privileged EXEC mode your session is running at privilege level 15. You can move commands to any privilege level between 1 and 15 using the **privilege** command. See the [“Cisco IOS Privilege Levels” section on page 13](#) for more information on privilege levels and the **privilege** command.

In general, the user EXEC commands allow you to connect to remote devices, change terminal line settings on a temporary basis, perform basic tests, and list system information.

To list the available user EXEC commands, use the following command:

| Command           | Purpose                           |
|-------------------|-----------------------------------|
| Router(config)# ? | Lists the user EXEC mode commands |

The user EXEC mode prompt consists of the host name of the device followed by an angle bracket (>), as shown in the following example:

```
Router>
```

The default host name is generally Router, unless it has been changed during initial configuration using the **setup** EXEC command. You also change the host name using the **hostname** global configuration command.

#### Note

Examples in Cisco IOS documentation assume the use of the default name of “Router.” Different devices (for example, access servers) may use a different default name. If the routing device (router, access server, or switch) has been named with the **hostname** command, that name will appear as the prompt instead of the default name.

To list the commands available in user EXEC mode, enter a question mark (?) as shown in the following example:

```
Router> ?
Exec commands:
<1-99> Session number to resume
connect Open a terminal connection
disconnect Disconnect an existing telnet session
enable Turn on privileged commands
exit Exit from Exec mode
help Description of the interactive help system
lat Open a lat connection
lock Lock the terminal
login Log in as a particular user
logout Exit from Exec mode and log out
menu Start a menu-based user interface
mbranch Trace multicast route for branch of tree
mrbranch Trace reverse multicast route to branch of tree
mtrace Trace multicast route to group
name-connection Name an existing telnet connection
pad Open a X.29 PAD connection
ping Send echo messages
resume Resume an active telnet connection
show Show running system information
systat Display information about terminal lines
telnet Open a telnet connection
terminal Set terminal line parameters
tn3270 Open a tn3270 connection
trace Trace route to destination
where List active telnet connections
x3 Set X.3 parameters on PAD
```

The list of commands will vary depending on the software feature set and router platform you are using.

#### Note

You can enter commands in uppercase, lowercase, or mixed case. Only passwords are case sensitive. However, Cisco IOS documentation convention is to always present commands in lowercase.

## Privileged EXEC Mode

In order to have access to all commands, you must enter *privileged EXEC mode*, which is the second level of access for the EXEC mode. Normally, you must enter a password to enter privileged EXEC mode. In privileged EXEC mode, you can enter any EXEC command, because privileged EXEC mode is a superset of the user EXEC mode commands.

Because many privileged EXEC mode commands set operating parameters, privileged EXEC level access should be password protected to prevent unauthorized use. The privileged EXEC command set includes those commands contained in user EXEC mode. Privileged EXEC mode also provides access to configuration modes through the **configure** command, and includes advanced testing commands, such as **debug**.

Privileged EXEC mode is set by default to privilege level 15. User EXEC mode is set by default to privilege level 1. For more information see the [“User EXEC Mode” section on page 4](#). When you are logged into a networking device in privileged EXEC mode your session is running at privilege level 15. When you are logged into a networking device in user EXEC mode your session is running at privilege level 1. By default the EXEC commands at privilege level 15 are a superset of those available at privilege level 1. You can move commands to any privilege level between 1 and 15 using the **privilege** command. See the [“Cisco IOS Privilege Levels” section on page 13](#) for more information on privilege levels and the **privilege** command.

The privileged EXEC mode prompt consists of the host name of the device followed by a pound sign(#), as shown in the following example:

```
Router#
```

To access privileged EXEC mode, use the following command:

| Command                                                             | Purpose                                                                                                                                                                                                                                                                           |
|---------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router> <b>enable</b><br>Password<br>Router# <b>exit</b><br>Router> | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>If a privileged EXEC mode password has been configured the system will prompt you for a password after you issue the enable command.</li> <li>Use the exit command to leave privileged EXEC mode.</li> </ul> |

### Note

Privileged EXEC mode is sometimes referred to as “enable mode,” because the **enable** command is used to enter the mode.

If a password has been configured on the system, you will be prompted to enter it before being allowed access to privileged EXEC mode. The password is not displayed on the screen and is case sensitive. If an enable password has not been set, privileged EXEC mode can be accessed only by a local CLI session (terminal connected to the console port).

If you attempt to access privileged EXEC mode on a router over a remote connection, such as a telnet connection, and you have not configured a password for privileged EXEC mode you will see the **% No password set** error message. For more information on remote connections see the [“Remote CLI Sessions” section on page 10](#). The system administrator uses the **enable secret** or **enable password** global configuration commands to set the password that restricts access to privileged EXEC mode. For information on configuring a password for privileged EXEC mode, see the [“Protecting Access to Privileged Exec Mode” section on page 20](#).

To return to user EXEC mode, use the following command:

| Command                | Purpose                                            |
|------------------------|----------------------------------------------------|
| Router# <b>disable</b> | Exits from privileged EXEC mode to user EXEC mode. |

The following example shows the process of accessing privileged EXEC mode:

```
Router> enable
Password:<letmein>
Router#
```

Note that the password will not be displayed as you type, but is shown here for illustrational purposes. To list the commands available in privileged EXEC mode, issue the **?** command at the prompt. From privileged EXEC mode you can access global configuration mode, which is described in the following section.

**Note**

Because the privileged EXEC command set contains all of the commands available in user EXEC mode, some commands can be entered in either mode. In Cisco IOS documentation, commands that can be entered in either user EXEC mode or privileged EXEC mode are referred to as EXEC mode commands. If user or privileged is not specified in the documentation, assume that you can enter the referenced commands in either mode.

## Global Configuration Mode

The term “global” is used to indicate characteristics or features that affect the system as a whole. Global configuration mode is used to configure your system globally, or to enter specific configuration modes to configure specific elements such as interfaces or protocols. Use the **configure terminal** privileged EXEC command to enter global configuration mode.

To access global configuration mode, use the following command in privileged EXEC mode:

| Command                           | Purpose                                                      |
|-----------------------------------|--------------------------------------------------------------|
| Router# <b>configure terminal</b> | From privileged EXEC mode, enters global configuration mode. |

The following example shows the process of entering global configuration mode from privileged EXEC mode:

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)#
```

Note that the system prompt changes to indicate that you are now in global configuration mode. The prompt for global configuration mode consists of the host-name of the device followed by (config) and the pound sign (#). To list the commands available in privileged EXEC mode, issue the **?** command at the prompt.

Commands entered in global configuration mode update the running configuration file as soon as they are entered. In other words, changes to the configuration take effect each time you press the Enter or Return key at the end of a valid command. However, these changes are not saved into the startup configuration file until you issue the **copy running-config startup-config** EXEC mode command. This behavior is explained in more detail later in this document.

As shown in the example above, the system dialogue prompts you to end your configuration session (exit configuration mode) by pressing the Control (Ctrl) and “z” keys simultaneously; when you press these keys, ^Z is printed to the screen. You can actually end your configuration session by entering the Ctrl-Z key combination, using the **end** command, using the Ctrl-C key combination. The **end** command is the recommended way to indicate to the system that you are done with the current configuration session.

#### Caution

If you use Ctrl-Z at the end of a command line in which a valid command has been typed, that command will be added to the running configuration file. In other words, using Ctrl-Z is equivalent to hitting the Enter (Carriage Return) key before exiting. For this reason, it is safer to end your configuration session using the **end** command. Alternatively, you can use the Ctrl-C key combination to end your configuration session without sending a Carriage Return signal.

You can also use the **exit** command to return from global configuration mode to EXEC mode, but this only works in global configuration mode. Pressing Ctrl-Z or entering the **end** command will always take you back to EXEC mode regardless of which configuration mode or configuration submode you are in.

To exit global configuration command mode and return to privileged EXEC mode, use one of the following commands:

| Command                                                | Purpose                                                                                                                                      |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>end</b><br>or<br>Router(config)# ^Z | Ends the current configuration session and returns to privileged EXEC mode.                                                                  |
| Router(config)# <b>exit</b>                            | Exits the current command mode and returns to the preceding mode. For example, exits from global configuration mode to privileged EXEC mode. |

From global configuration mode, you can enter a number of protocol-specific, platform-specific, and feature-specific configuration modes.

Interface configuration mode, described in the following section, is an example of a configuration mode you can enter from global configuration mode.

## Interface Configuration Mode

One example of a specific configuration mode you enter from global configuration mode is interface configuration mode.

Many features are enabled on a per-interface basis. Interface configuration commands modify the operation of an interface such as an Ethernet, FDDI, or serial port. Interface configuration commands always follow an **interface** global configuration command, which defines the interface type.

For details on interface configuration commands that affect general interface parameters, such as bandwidth or clock rate, refer to the Release 12.2 *Cisco IOS Interface Configuration Guide*. For protocol-specific commands, refer to the appropriate Cisco IOS software command reference.

To access and list the interface configuration commands, use the following command:

| Command                                      | Purpose                                                                            |
|----------------------------------------------|------------------------------------------------------------------------------------|
| Router(config)# <b>interface</b> type number | Specifies the interface to be configured, and enters interface configuration mode. |

In the following example, the user enters interface configuration mode for serial interface 0. The new prompt, *hostname(config-if)#*, indicates interface configuration mode.

```
Router(config)# interface serial 0
Router(config-if)#
```

To exit interface configuration mode and return to global configuration mode, enter the **exit** command. Configuration submodes are configuration modes entered from other configuration modes (besides global configuration mode). Configuration submodes are for the configuration of specific elements within the configuration mode. One example of a configuration submode is subinterface configuration mode, described in the following section.

## Subinterface Configuration Mode

From interface configuration mode, you can enter subinterface configuration mode. Subinterface configuration mode is a submode of interface configuration mode. In subinterface configuration mode you can configure multiple virtual interfaces (called subinterfaces) on a single physical interface. Subinterfaces appear to be distinct physical interfaces to the various protocols.

For detailed information on how to configure subinterfaces, refer to the appropriate documentation module for a specific protocol in the Cisco IOS software documentation set.

To access subinterface configuration mode, use the following command in interface configuration mode:

| Command                                         | Purpose                                                                                      |
|-------------------------------------------------|----------------------------------------------------------------------------------------------|
| Router(config-if)# <b>interface type number</b> | Specifies the virtual interface to be configured and enters subinterface configuration mode. |

In the following example, a subinterface is configured for serial line 2, which is configured for Frame Relay encapsulation. The subinterface is identified as “2.1” to indicate that it is subinterface 1 of serial interface 2. The new prompt *hostname(config-subif)#* indicates subinterface configuration mode. The subinterface can be configured to support one or more Frame Relay PVCs.

```
Router(config)# interface serial 2
Router(config-if)# encapsulation frame-relay
Router(config-if)# interface serial 2.1
Router(config-subif)#
```

To exit subinterface configuration mode and return to interface configuration mode, use the **exit** command. To end your configuration session and return to privileged EXEC mode, press Ctrl-Z or enter the **end** command.

## Cisco IOS CLI Sessions

This section describes the following concepts:

- [Local CLI Sessions, page 10](#)
- [Remote CLI Sessions, page 10](#)
- [Terminal Lines are Used for Local and Remote CLI Sessions, page 10](#)

### Local CLI Sessions

Local CLI sessions require direct access to the console port of the networking device. Local CLI sessions start in user EXEC mode. See the [“Cisco IOS CLI Modes” section on page 3](#) for more information on the different modes that are supported on your networking device. All of the tasks required to configure and manage a networking device can be done using a local CLI session. The most common method for establishing a local CLI session is to connect the serial port on a PC to the console port of the networking device and then to launch a terminal emulation application on the PC. The type of cable and connectors required and the settings for the terminal emulation application on the PC are dependant on the type of networking device that you are configuring. See to the documentation for your networking device for more information on setting it up for a local CLI session.

### Remote CLI Sessions

Remote CLI sessions are created between a host such as a PC and a networking device such as a router over a network using a remote terminal access application such as Telnet and Secure Shell (SSH). Local CLI sessions start in user EXEC mode. See the [“Cisco IOS CLI Modes” section on page 3](#) for more information on the different modes that are supported on your networking device. Most of the tasks required to configure and manage a networking device can be done using a remote CLI session. The exceptions are tasks that interact directly with the console port (such as recovering from a corrupted operating system (OS) by uploading a new OS image over the console port) and interacting with the networking device when it is in ROM Monitor Mode.

This document explains how to configure security for remote Telnet sessions. Telnet is the most common method for accessing a remote CLI session on a networking device.

#### Note

SSH is a more secure alternative to Telnet. SSH provides encryption for the session traffic between your local management device such as a PC and the networking device that you are managing. Encrypting the session traffic with SSH prevents hackers that might intercept the traffic from being able to decode it. See [Secure Shell Version 2 Support](#) ([http://www.cisco.com/en/US/products/sw/iosswrel/ps5207/products\\_feature\\_guide09186a00802045dc.html](http://www.cisco.com/en/US/products/sw/iosswrel/ps5207/products_feature_guide09186a00802045dc.html)) for more information on using SSH.

### Terminal Lines are Used for Local and Remote CLI Sessions

Cisco networking devices use the word lines to refer to the software components that manage local and remote CLI sessions. You use the **line console 0** global configuration command to enter line configuration mode to configure options, such as a password, for the console port.

```
Router# configure terminal
Router(config)# line console 0
Router(config-line)# password password-string
```

Remote CLI sessions use lines that are referred to virtual teletypewriter (VTY) lines. You use the **line vty line-number [ending-line-number]** global configuration command to enter line configuration mode to configure options, such as a password, for remote CLI sessions.

```
Router# configure terminal
Router(config)# line vty 0 4
Router(config-line)# password password-string
```

## Protect Access to Cisco IOS EXEC Modes

Cisco IOS provides the ability to configure passwords that protect access to the following:

- [Protecting Access to User EXEC Mode, page 11](#)
- [Protecting Access to Privileged EXEC mode, page 11](#)

### Protecting Access to User EXEC Mode

The first step in creating a secure environment for your networking device is protecting access to user EXEC mode by configuring passwords for local and remote CLI sessions.

You protect access to user EXEC mode for local CLI sessions by configuring a password on the console port. See the [“Configuring and Verifying a Password for Local CLI Sessions” section on page 18](#).

You protect access to user EXEC mode for remote CLI sessions by configuring a password on the virtual terminal lines (VTYs). See the [“Configuring and Verifying a Password for Remote CLI Sessions” section on page 15](#) for instructions on how to configure passwords for remote CLI sessions.

### Protecting Access to Privileged EXEC mode

The second step in creating a secure environment for your networking device is protecting access to privileged EXEC mode with a password. The method for protecting access to privileged EXEC mode is the same for local and remote CLI sessions.

You protect access to privileged EXEC mode by configuring a password for it. This is sometimes referred to as the enable password because the command to enter privileged EXEC mode is **enable**.

| Command                                                                       | Purpose                                                                                                                                                                                                                                                                                            |
|-------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>enable</b><br><br><b>Example:</b><br>Router> enable<br>Password<br>Router# | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted. The password will not be shown in the terminal window.</li><li>• The “&gt;” at the end of the prompt string is changed to a “#” to indicate that you are in privileged EXEC mode.</li></ul> |

## Cisco IOS Password Encryption Levels

Some of the passwords that you configure on your networking device are saved in the configuration in plain text. This means that if you store a copy of the configuration file on a disk, anybody with access to the disk can discover the passwords by reading the configuration file. The following password types are stored as plain text in the configuration by default:

- Console passwords for local CLI sessions
- Virtual terminal line passwords for remote CLI sessions
- Username passwords using the default method for configuring the password
- Privileged EXEC mode password when it is configured with the **enable password** *password* command
- Authentication key chain passwords used by RIPv2 and EIGRP
- BGP passwords for authenticating BGP neighbors
- OSPF authentication keys for authenticating OSPF neighbors
- ISIS passwords for authenticating ISIS neighbors

This excerpt from a router configuration file shows examples of passwords and authentication keys that are stored as clear text.

```
!
enable password 09Jb6D
!
username gjones password 0 kV9sIj3
!
key chain trees
 key 1
 key-string willow
!
interface Ethernet1/0.1
 ip address 172.16.6.1 255.255.255.0
 ip router isis
 ip rip authentication key-chain trees
 ip authentication key-chain eigrp 1 trees
 ip ospf authentication-key j7876
 no snmp trap link-status
 isis password u7865k
!
line vty 0 4
 password V9jA5M
!
```

You can encrypt these clear text passwords in the configuration file by using the **service password-encryption** command. This should be considered only a minimal level of security because the encryption algorithm used by the **service password-encryption** command to encrypt passwords creates text strings that be decrypted using tools that are publicly available. You should still protect access to any electronic or paper copies of your configuration files after you use the **service password-encryption** command.

The **service password-encryption** command does not encrypt the passwords when they are sent to the remote device. Anybody with a network traffic analyzer who has access to you network can capture these passwords from the packets as they are transmitted between the devices. See the [“Configuring Password Encryption for Clear Text Passwords”](#) section on page 22 for more information on encrypting clear text passwords in configuration files.

Many of the Cisco IOS features that use clear text passwords can also be configured to use the more secure MD5 algorithm. The MD5 algorithm creates a text string in the configuration file that is much more difficult to decrypt. The MD5 algorithm does not send the password to the remote device. This prevents people using a traffic analyzer to capture traffic on your network from being able to discover your passwords.

You can determine the type of password encryption that has been used by the number that is stored with the password string in the configuration file of the networking device. The number 5 in the configuration excerpt below indicates that the enable secret password has been encrypted using the MD5 algorithm.

```
!
enable secret 5 1fGCS$rkYbR6.Z8xo4qCl3vghWQ0
!
```

The number 7 in the excerpt below indicates that the enable password has been encrypted using the less secure algorithm used by the **service password-encryption** command.

```
!
enable password 7 00081204
!
```

## Cisco IOS CLI Session Usernames

After you have protected access to user EXEC mode and privileged EXEC mode by configuring passwords for them you can further increase the level of security on your networking device by configuring usernames to limit access to CLI sessions to your networking device to specific users.

Usernames that are intended to be used for managing a networking device can be modified with additional options such as:

- Automatically starting a CLI session at a specific privilege level. See [“Configuring and Verifying the Networking Device to Require a Username for the First-Line Technical Support Staff”](#) section on page 30.
- Running a CLI command automatically. See [“Configuring and Verifying a Networking Device to Allow Non Administrative Users to View the Running Configuration Automatically: Example”](#) section on page 38.

See the [Cisco IOS Security Command Reference](#), Release, 12.4

([http://www.cisco.com/univercd/cc/td/doc/product/software/ios124/124cr/hsec\\_r/index.htm](http://www.cisco.com/univercd/cc/td/doc/product/software/ios124/124cr/hsec_r/index.htm)) for more information on how to configure the **username** command.

## Cisco IOS Privilege Levels

The default configuration for Cisco IOS based networking devices uses privilege level 1 for user EXEC mode and privilege level 15 for privileged EXEC. The commands that can be run in user EXEC mode at privilege level 1 are a subset of the commands that can be run in privileged EXEC mode at privilege 15.

The **privilege** command is used to move commands from one privilege level to another. For example, some ISPs allow their first level technical support staff to enable and disable interfaces to activate new customer connections or to restart a connection that has stopped transmitting traffic. See the [“Configuring and Verifying a Networking Device to Allow Non Administrative Users to Shutdown and Enable Interfaces: Example”](#) section on page 38 for an example of how to configure this option.

The **privilege** command can also be used to assign a privilege level to a username so that when a user logs in with the username, the session will run at the privilege level specified by the **privilege** command. For example if you want your technical support staff to view the configuration on a networking device to help them troubleshoot network problems without being able to modify the configuration, you can create a username, configure it with privilege level 15, and configure it to run the **show running-config** command automatically. When a user logs in with the username the running configuration will be displayed automatically. The user’s session will be logged out automatically after the user has viewed the last line of the configuration. See the [“Configuring and Verifying a Networking Device to Allow Non Administrative Users to View the Running Configuration Automatically: Example”](#) section on page 38 for an example of how to configure this option.

These command privileges can also be implemented when using AAA with TACACS+ and RADIUS. For example, TACACS+ provides two ways to control the authorization of router commands on a per-user or per-group basis. The first way is to assign privilege levels to commands and have the router verify with the TACACS+ server whether or not the user is authorized at the specified privilege level. The second way is to explicitly specify in the TACACS+ server, on a per-user or per-group basis, the commands that are allowed. For more information about implementing AAA with TACACS+ and RADIUS, see the technical note [How to Assign Privilege Levels with TACACS+ and RADIUS](#).

## Cisco IOS Password Configuration

Cisco IOS software does not prompt you to repeat any passwords that you configure to verify that you have entered the passwords exactly as you intended. New passwords, and changes to existing passwords, go into effect immediately after you press the Enter key at the end of a password configuration command string. If you make a mistake when you enter a new password and have saved the configuration on the networking device to its startup configuration file and exited privileged EXEC mode before you realize that you made a mistake, you may find that you are no longer able to manage the device.

The following are common situations that can happen:

- You make a mistake configuring a password for local CLI sessions on the console port.
  - If you have properly configured access to your networking device for remote CLI sessions, you can Telnet to it and reconfigure the password on the console port.
- You make a mistake configuring a password for remote Telnet or SSH sessions.
  - If you have properly configured access to your networking device for local CLI sessions, you can connect a terminal to it and reconfigure the password for the remote CLI sessions.
- You make a mistake configuring a password for privileged EXEC mode (enable password or enable secret password).
  - You will have to perform a lost password recovery procedure.
- You make a mistake configuring your username password, and the networking device requires that you log into it with your username.
  - If you do not have access to another account name, you will have to perform a lost password recovery procedure.

To protect yourself from having to perform a lost password recovery procedure open two CLI sessions to the networking device and keep one of them in privilege EXEC mode while you reset the passwords using the other session. You can use the same device (PC or terminal) to run the two CLI sessions or two different devices. You can use a local CLI session and a remote CLI session or two remote CLI sessions for this procedure. The CLI session that you use to configure the password can also be used to verify that the password was changed properly. The other CLI session that you keep in privileged EXEC mode can be used to change the password again if you made a mistake the first time you configured it.

You should not save password changes that you have made in the running configuration to the startup configuration until you have verified that your password was changed successfully. If you discover that you made a mistake configuring a password, and you were not able to correct the problem using the second CLI session technique described above, you can power cycle the networking device so that it returns to the previous passwords that are stored in the startup configuration.

# How To Configure Security with Passwords, Privilege Levels and, Login Usernames for CLI Sessions on Networking Devices

This section contains the following procedures:

- [Protecting Access to User Exec Mode, page 15](#)
- [Protecting Access to Privileged Exec Mode, page 20](#)
- [Configuring Security Options with Passwords, Privilege Levels and usernames to Manage Access to CLI Sessions and CLI Commands, page 25](#)
- [Recovering from a Lost or Misconfigured Password for Local CLI Sessions, page 33](#)
- [Recovering from a Lost or Misconfigured Password for Remote CLI Sessions, page 34](#)
- [Recovering from a Lost or Misconfigured Passwords for Privileged EXEC Mode, page 35](#)

## Protecting Access to User Exec Mode

This section contains the following procedures:

- [Configuring and Verifying a Password for Remote CLI Sessions, page 15](#)
- [Configuring and Verifying a Password for Local CLI Sessions, page 18](#)

## Configuring and Verifying a Password for Remote CLI Sessions

This task will assign a password for remote CLI sessions. After you have completed this task the networking device will prompt you for a password the next time that you start a remote CLI session with it.

Cisco IOS based networking devices require that you have a password configured for remote CLI sessions. If you attempt to start a remote CLI session with a device that doesn't have a password configured for remote CLI sessions you will see a message that a password is required and has not been set. The remote CLI session will be terminated by the remote host.

### Prerequisites

If you have not previously configured a password for remote CLI sessions, you must perform this task over a local CLI session using a terminal or a PC running a terminal emulation application, attached to the console port.

Your terminal, or terminal emulation application, must be configured with the settings that are used by the console port on the networking device. The console ports on most Cisco networking devices require the following settings: 9600 baud, 8 data bits, 1 stop bit, no parity, and flow control is set to "none." See the documentation for your networking device if these settings do not work for your terminal.

To perform the verification step (Step 6) for this task, your networking device must have an interface that is in an operational state. The interface must have a valid IP address.

### Restrictions

If you have not previously configured a password for remote CLI sessions, you must perform this task over a local CLI session using a terminal attached to the console port.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **line vty** *line-number* [*ending-line-number*]
4. **password** *password*
5. **end**
6. telnet ip-address
7. exit

## DETAILED STEPS

|        | Command or Action                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------|---------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                  | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                          | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Step 3 | <b>line vty line-number [ending-line-number]</b><br><br><b>Example:</b><br>Router(config)# line vty 0 4 | Enters line configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Step 4 | <b>password password</b><br><br><b>Example:</b><br>Router(config-line)# password H7x3U8                 | The argument <i>password</i> is a character string that specifies the line password. The following rules apply to the <i>password</i> argument: <ul style="list-style-type: none"> <li>The first character cannot be a number.</li> <li>The string can contain any alphanumeric characters, including spaces, up to 80 characters. You cannot specify the password in the format number-space-anything.</li> <li>Passwords are case sensitive.</li> </ul>                                                                                            |
| Step 5 | <b>end</b><br><br><b>Example:</b><br>Router(config-line)# end                                           | Exits the current configuration mode and returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Step 6 | <b>telnet ip-address</b><br><br><b>Example:</b><br>Router# telnet 172.16.1.1                            | Start a remote CLI session with the networking device from your current CLI session using the IP address of an interface in the networking device that is in an operational state (interface up, line protocol up). <ul style="list-style-type: none"> <li>Enter the password that you configured in step 4 when prompted.</li> </ul> <p><b>Note</b> This procedure is often referred to as starting a recursive Telnet session because you are initiating a remote Telnet session with the networking device from the networking device itself.</p> |
| Step 7 | <b>exit</b>                                                                                             | Terminates the remote CLI session (recursive Telnet session) with the networking device.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Troubleshooting Tips

Repeat this task if you made a mistake configuring the remote CLI session password.

## What to Do Next

Proceed to the [“Configuring and Verifying a Password for Local CLI Sessions”](#) section on page 18 .

## Configuring and Verifying a Password for Local CLI Sessions

This task will assign a password for local CLI sessions over the console port. After you have completed this task, the networking device will prompt you for a password the next time that you start a local CLI session on the console port.

This task can be performed over a local CLI session using the console port or a remote CLI session. If you want to perform the optional step of verifying that you configured the password correctly you should perform this task using a local CLI session using the console port.

## Prerequisites

If you want to perform the optional step of verifying the local CLI session password, you must perform this task using a local CLI session. You must have a terminal or a PC running a terminal emulation program, connected to the console port of the networking device. Your terminal must be configured with the settings that are used by the console port on the networking device. The console ports on most Cisco networking devices require the following settings: 9600 baud, 8 data bits, 1 stop bit, no parity, and flow control is set to "none." See the documentation for your networking device if these settings do not work for your terminal.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **line console 0**
4. **password *password***
5. **end**
6. **exit**
7. Press the Enter key, and enter the password from Step 4 when prompted.

## DETAILED STEPS

|        | Command or Action                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------|------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <code>enable</code><br><br><b>Example:</b><br>Router> <code>enable</code>                                  | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>Enter your password if prompted.</li></ul>                                                                                                                                                                                                                                                                                                                                                     |
| Step 2 | <code>configure terminal</code><br><br><b>Example:</b><br>Router# <code>configure terminal</code>          | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Step 3 | <code>line console 0</code><br><br><b>Example:</b><br>Router(config)# <code>line console 0</code>          | Enters line configuration mode and selects the console port as the line that you are configuring.                                                                                                                                                                                                                                                                                                                                                                  |
| Step 4 | <code>password password</code><br><br><b>Example:</b><br>Router(config-line)# <code>password Ji8F5Z</code> | The argument <i>password</i> is a character string that specifies the line password. The following rules apply to the <i>password</i> argument: <ul style="list-style-type: none"><li>The first character cannot be a number.</li><li>The string can contain any alphanumeric characters, including spaces, up to 80 characters. You cannot specify the password in the format <code>number-space-anything</code>.</li><li>Passwords are case sensitive.</li></ul> |
| Step 5 | <code>end</code><br><br><b>Example:</b><br>Router(config-line)# <code>end</code>                           | Exits the current configuration mode and returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 6 | <code>exit</code><br><br><b>Example:</b><br>Router# <code>exit</code>                                      | Exits privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Step 7 | Press the Enter key.                                                                                       | (Optional) Initiates the local CLI session on the console port. <ul style="list-style-type: none"><li>Enter the password that you configured in step 4 when prompted to verify that it was configured correctly.</li></ul> <b>Note</b> This step can be performed only if you are using a local CLI session to perform this task.                                                                                                                                  |

## Troubleshooting Tips

If your new password is not accepted proceed to the [“Recovering from a Lost or Misconfigured Password for Local CLI Sessions”](#) section on page 33 for instructions on what to do next.

## What to Do Next

Proceed to the [“Protecting Access to Privileged Exec Mode”](#) section on page 20.

## Protecting Access to Privileged Exec Mode

This section contains the following procedures:

- [Configuring and Verifying the Enable Password, page 20](#) (optional)
- [Configuring Password Encryption for Clear Text Passwords, page 22](#) (optional)
- [Configuring and Verifying the Enable Secret Password, page 23](#) (recommended)

### Configuring and Verifying the Enable Password

Cisco no longer recommends that you use the **enable password** command to configure a password for privileged EXEC mode. The password that you enter with the **enable password** command is stored as plain text in the configuration file of the networking device. You can encrypt the password for the **enable password** command in the configuration file of the networking device using the **service password-encryption** command. However the encryption level used by the **service password-encryption** command can be decrypted using tools available on the Internet.

Instead of using the **enable password** command, Cisco recommends using the **enable secret** command because it encrypts the password that you configure with it with strong encryption. For more information on password encryption issues see the [“Cisco IOS Password Encryption Levels” section on page 11](#). For information on configuring the **enable secret** command see the [“Configuring and Verifying the Enable Secret Password” section on page 23](#).

#### Restrictions

The networking device must not have a password configured by the **enable secret** command in order to perform this task successfully. If you have already configured a password for privileged EXEC mode using the **enable secret** command, the password configured takes precedences over the password that you configure in this task using the **enable password** command.

You cannot use the same password for the **enable secret** command and the **enable password** command.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **enable password *password***
4. **end**
5. **exit**
6. **enable**

|        | Command or Action                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                              | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                      | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Step 3 | <b>enable password password</b><br><br><b>Example:</b><br>Router(config)# enable password t6D77CdKq | The argument <i>password</i> is a character string that specifies the enable password. The following rules apply to the <i>password</i> argument: <ul style="list-style-type: none"> <li>Must contain from 1 to 25 uppercase and lowercase alphanumeric characters.</li> <li>Must not have a number as the first character.</li> <li>Can have leading spaces, but they are ignored. However, intermediate and trailing spaces are recognized.</li> <li>Can contain the question mark (?) character if you precede the question mark with the key combination Crtl-v when you create the password; for example, to create the password abc?123, do the following: <ul style="list-style-type: none"> <li>Enter abc</li> <li>Type Crtl-v</li> <li>Enter ?123</li> </ul> </li> </ul> |
| Step 4 | <b>end</b><br><br><b>Example:</b><br>Router(config)# end                                            | Exits the current configuration mode and returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 5 | <b>exit</b><br><br><b>Example:</b><br>Router# exit                                                  | Exits privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Step 6 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                              | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter the password you configured in step 3.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Troubleshooting Tips

If your new password is not accepted, proceed to the [“Recovering from a Lost or Misconfigured Passwords for Privileged EXEC Mode”](#) section on page 35 for instructions on what to do next.

## What to Do Next

Encrypt the clear text enable password in the configuration file of the networking device using the procedure described in [“Configuring Password Encryption for Clear Text Passwords” section on page 22](#).

## Configuring Password Encryption for Clear Text Passwords

Cisco IOS stores passwords in clear text in network device configuration files for several features such as passwords for local and remote CLI sessions, and passwords for neighbor authentication for routing protocols. Clear text passwords are a security risk because anybody with access to archived copies of the configuration files can discover the passwords that are stored as clear text. The **service password-encryption** command can be used to encrypt clear text commands in the configuration files of networking devices. See the [“Cisco IOS Password Encryption Levels” section on page 11](#) for more information.

Perform the following steps to configure password encryption for passwords that are stored as clear text in the configuration files of your networking device.

## Prerequisites

You must have at least one feature that uses clear text passwords configured on your networking device for this command to have any immediate effect.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **service password-encryption**
4. **end**

## DETAILED STEPS

|        | Command or Action                                                                                        | Purpose                                                                                                                                                                                                                                                              |
|--------|----------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                   | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>Enter your password if prompted.</li></ul>                                                                                                                                                    |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                           | Enters global configuration mode.                                                                                                                                                                                                                                    |
| Step 3 | <b>service password-encryption</b><br><br><b>Example:</b><br>Router(config)# service password-encryption | Enables Password encryption for all passwords clear text passwords, including username passwords, authentication key passwords, the privileged command password, console and virtual terminal line access passwords, and Border Gateway Protocol neighbor passwords. |
| Step 4 | <b>end</b><br><br><b>Example:</b><br>Router(config)# end                                                 | Exits the current configuration mode and returns to privileged EXEC mode.                                                                                                                                                                                            |

## Configuring and Verifying the Enable Secret Password

Cisco recommends that you use the **enable secret** command, instead of the **enable password** command to configure a password for privileged EXEC mode. The password created by the **enable secret** command is encrypted with the more secure MD5 algorithm.

## Restrictions

You cannot use the same password for the **enable secret** command and the **enable password** command.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **enable secret password**  
or  
**enable secret 5 previously-encrypted-password**
4. **end**
5. **exit**
6. **enable**

|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                                                                             | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                                                                                     | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Step 3 | <b>enable secret password</b><br>or<br><b>enable secret 5 previously-encrypted-password</b><br><br><b>Example:</b><br>Router(config)# enable secret t6D77CdKq<br>or<br><br><b>Example:</b><br>Router(config)# enable secret 5<br>\$1\$/x6H\$RhndI3yLC4GA01aJnHLQ4/ | <p>The argument <i>password</i> is a character string that specifies the <b>enable secret</b> password. The following rules apply to the <i>password</i> argument:</p> <ul style="list-style-type: none"> <li>Must contain from 1 to 25 uppercase and lowercase alphanumeric characters.</li> <li>Must not have a number as the first character.</li> <li>Can have leading spaces, but they are ignored. However, intermediate and trailing spaces are recognized.</li> <li>Can contain the question mark (?) character if you precede the question mark with the key combination Crtl-v when you create the password; for example, to create the password abc?123, do the following: <ul style="list-style-type: none"> <li>Enter abc</li> <li>Type Crtl-v</li> <li>Enter ?123</li> </ul> </li> </ul> <p>or</p> <p>Sets a previously encrypted password for privileged EXEC mode by entering the number 5 before the previously encrypted string. You must enter an exact copy of a password from a configuration file that was previously encrypted by the <b>enable secret</b> command to use this method.</p> |
| Step 4 | <b>end</b><br><br><b>Example:</b><br>Router(config)# end                                                                                                                                                                                                           | Exits the current configuration mode and returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|        | Command or Action                                                         | Purpose                                                                                                                           |
|--------|---------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| Step 5 | <code>exit</code><br><br><b>Example:</b><br>Router# <code>exit</code>     | Exits privileged EXEC mode.                                                                                                       |
| Step 6 | <code>enable</code><br><br><b>Example:</b><br>Router> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter the password that you configured in Step 3.</li> </ul> |

### Troubleshooting Tips

If your new password is not accepted proceed to the [“Recovering from a Lost or Misconfigured Passwords for Privileged EXEC Mode”](#) section on page 35 for instructions on what to do next.

### What to Do Next

If you have finished configuring passwords for local and remote CLI sessions and you want to configure additional security features, such as usernames, and privilege levels proceed to the [“Configuring Security Options with Passwords, Privilege Levels and usernames to Manage Access to CLI Sessions and CLI Commands”](#) section on page 25.

## Configuring Security Options with Passwords, Privilege Levels and usernames to Manage Access to CLI Sessions and CLI Commands

The tasks in this section describe how to configure your networking device to permit the use of a subset of privileged EXEC mode commands by users who should not have access to all of the commands available in privileged EXEC mode.

These tasks are beneficial for companies that have multiple levels of network support staff and the company wants the staff at each level to have access to a different subset of the privileged EXEC mode commands.

In this task the users who should not have access to all of the commands available in privileged EXEC mode are referred to as the first-line technical support staff.

This section contains the following procedures:

- [Configuring the Networking Device for the First-Line Technical Support Staff, page 25](#)
- [Verifying the Configuration for the First-Line Technical Support Staff, page 28](#)
- [Configuring and Verifying the Networking Device to Require a Username for the First-Line Technical Support Staff, page 30](#)

### Configuring the Networking Device for the First-Line Technical Support Staff

This task describes how to configure the networking device for first-line technical support users. First-line technical support staff are usually not allowed to run all of the commands available in privileged EXEC mode (privilege level 15) on a networking device. They are prevented from running commands that they are not authorized for by not being granted access to the password assigned to privileged EXEC mode or to other roles that have been configured on the networking device.

The **privilege** command is used to move commands from one privilege level to another in order to create the additional levels of administration of a networking device that is required by companies that have different levels of network support staff with different skill levels.

The default configuration of a Cisco IOS device permits two types of users to access the CLI. The first type of user is a person who is only allowed to access user EXEC mode. The second type of user is a person who is allowed access to privileged EXEC mode. A user who is only allowed to access user EXEC mode is not allowed to view or change the configuration of the networking device, or to make any changes to the operational status of the networking device. On the other hand, a user who is allowed access to privileged EXEC mode can make any change to a networking device that is allowed by the CLI.

In this task the two commands that normally run at privilege level 15 are reset to privilege level 7 using the **privilege** command in order that first-line technical support users will be allowed to run the two commands. The two commands for which the privilege levels will be reset are the **clear counters** command and **reload** command.

- The **clear counters** command is used to reset the counter fields on interfaces for statistics such as packets received, packets transmitted, and errors. When a first-line technical support user is troubleshooting an interface related connectivity issue between networking devices, or with remote users connecting to the network, it is useful to reset the interface statistics to zero and then monitor the interfaces for a period of time to see if the values in the interface statistics counters change.
- The **reload** command is used to initiate a reboot sequence for the networking device. One common use of the **reload** command by first-line technical support staff is to cause the networking device to reboot during a maintenance window so that it loads a new operating system that was previously copied onto the networking device's file system by a user with a higher level of authority.

Any user that is permitted to know the **enable secret** password that is assigned to the first-line technical support user role privilege level can access the networking device as a first-line technical support user. You can add an additional level of security by configuring a username on the networking device and requiring that the users know the username and the password. Configuring a username as an additional level of security is described in the [“Configuring and Verifying the Networking Device to Require a Username for the First-Line Technical Support Staff” section on page 30.](#)

## Privilege Command Enhancement

Before Cisco IOS Releases 12.0(22)S and 12.2(13)T, each command in a privilege level had to be specified with a separate **privilege** command. In Cisco IOS Releases 12.0(22)S, 12.2(13)T, and later releases, a “wildcard” option specified by the new keyword **all** was introduced that allows you to configure access to multiple commands with only one **privilege** command. By using the new **all** keyword, you can specify a privilege level for all commands which begin with the string you enter. In other words, the **all** keyword allows you to grant access to all command-line options and suboptions for a specified command.

For example, if you wanted to create a privilege level to allow users to configure all commands which begin with **service-module t1** (such as **service-module t1 linecode** or **service-module t1 clock source**) you can use the **privilege interface all level 2 service-module t1** command instead of having to specify each **service-module t1** command separately.

If the command specified in the privilege command (used with the **all** keyword) enables a configuration submode, all commands in the submode of that command will also be set to the specified privilege level.

## Restrictions

The **all** “wildcard” keyword option for the **privilege** command is not supported in versions of Cisco IOS software prior to Cisco IOS Releases 12.0(22)S and, 12.2(13)T.

You must not have the **aaa new-model** command enabled on the networking device. You must not have the **login local** command configured for the local CLI sessions over the console port or the remote CLI sessions.

**Note**

For clarity, only the arguments and keywords that are relevant for each step are shown in the syntax for the steps in this task. See the Cisco IOS command reference book for your Cisco IOS release for further information on the additional arguments and keywords that can be used with these commands.

**Caution**

Do not use the no form of the **privilege** command to reset the privilege level of a command to its default because it might not return the configuration to the correct default state. Use the **reset** keyword for the **privilege** command instead to return a command to its default privilege level. For example, to remove the **privilege exec level reload** command from the configuration and return the **reload** command to its default privilege of 15, use the **privilege exec reset reload** command.

## SUMMARY STEPS

1. **enable password**
2. **configure terminal**
3. **enable secret level level password**
4. **privilege exec level level command-string**
5. **privilege exec all level level command-string**
6. **end**

## DETAILED STEPS

- |               |                                                                                                                                                                                                                                    |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable password</b><br>Enters privileged EXEC mode. Enter the password when prompted.<br>Router> <b>enable</b>                                                                                                                  |
| <b>Step 2</b> | <b>configure terminal</b><br>Enters global configuration mode.<br>Router# <b>configure terminal</b>                                                                                                                                |
| <b>Step 3</b> | <b>enable secret level level password</b><br>Configures a new enable secret password for privilege level 7.<br>Router(config)# <b>enable secret level 7 Zy72sKj</b>                                                                |
| <b>Step 4</b> | <b>privilege exec level level command-string</b><br>Changes the privilege level of the <b>clear counters</b> command from privilege level 15 to privilege level 7.<br>Router(config)# <b>privilege exec level 7 clear counters</b> |
| <b>Step 5</b> | <b>privilege exec all level level command-string</b><br>Changes the privilege level of the <b>reload</b> command from privilege level 15 to privilege level 7.<br>Router(config)# <b>privilege exec all level 7 reload</b>         |

**Step 6**    **end**

Exits global configuration mode.

```
Router(config)# end
```

---

## Verifying the Configuration for the First-Line Technical Support Staff

This task describes how to verify that the network device is configured correctly for the first-line technical support staff.

### Prerequisites

The following commands must have been modified to run at privilege level 7 for this task:

- **clear counters**
- **reload**

### SUMMARY STEPS

1. **enable level password**
2. **show privilege**
3. **clear counters**
4. **clear ip route \***
5. **reload in time**
6. **reload cancel**
7. **disable**
8. **show privilege**

### DETAILED STEPS

---

**Step 1**    **enable level password**

Logs the user into the networking device at the privilege level specified for the level argument.

```
Router> enable 7 Zy72sKj
```

**Step 2**    **show privilege**

Displays the privilege level of the current CLI session

```
Router# show privilege
Current privilege level is 7
```

**Step 3**    **clear counters**

The clear counters command clears the interface counters. This command has been changed from privilege level 15 to privilege level 7.

```
Router# clear counters
Clear "show interface" counters on all interfaces [confirm]
Router#
02:41:37: %CLEAR-5-COUNTERS: Clear counter on all interfaces by console
```

**Step 4 clear ip route \***

The *ip route* argument string for the **clear** command should not be allowed because it was not changed from privilege level 15 to privilege level 7.

```
Router# clear ip route *
 ^
% Invalid input detected at '^' marker.

Router#
```

**Step 5 reload in time**

The **reload** command causes the networking device to reboot.

```
Router# reload in 10
Reload scheduled in 10 minutes by console
Proceed with reload? [confirm]
Router#
```

```

*** --- SHUTDOWN in 0:10:00 ---

```

```
02:59:50: %SYS-5-SCHEDULED_RELOAD: Reload requested for 23:08:30 PST Sun Mar 20
```

**Step 6 reload cancel**

The **reload cancel** terminates a reload that was previously setup with the the **reload in time** command.

```
Router# reload cancel
```

```

*** --- SHUTDOWN ABORTED ---

```

```
04:34:08: %SYS-5-SCHEDULED_RELOAD_CANCELLED: Scheduled reload cancelled at 15:38:46 PST
Sun Mar 27 2005
```

**Step 7 disable**

Exits the current privilege level and returns to privilege level 1.

```
Router# disable
```

**Step 8 show privilege**

Displays the privilege level of the current CLI session

```
Router> show privilege
Current privilege level is 1
```

**Troubleshooting Tips**

If your configuration does not work the way that you want it to and you want to remove the privilege commands from the configuration, use the **reset** keyword for the **privilege** command to return the commands to their default privilege level. For example, to remove the command **privilege exec level reload** command from the configuration and return the **reload** command to its default privilege of 15 use the **privilege exec reset reload** command.

## What to Do Next

If you want to add an additional level of security by requiring that the first level technical staff use a login name, proceed to the [“Configuring and Verifying the Networking Device to Require a Username for the First-Line Technical Support Staff”](#) section on page 30.

## Configuring and Verifying the Networking Device to Require a Username for the First-Line Technical Support Staff

This task configures the networking device to require that the first-line technical support staff login to the networking device with a login name of admin. The admin username configured in this task is assigned the privilege level 0f 7 which will allow users who log in with this name to run the commands that were reassigned to privilege level 7 in the previous task. When a user successfully logs in with the admin username, the CLI session will automatically enter privilege level 7.

### Enhanced Username Password Security

Before Cisco IOS Releases 12.0(18)S and 12.2(8)T, two types of passwords were associated with usernames: Type 0, which is a clear text password visible to any user who has access to privileged mode on the router, and type 7, which has a password encrypted by the **service password encryption** command.

In Cisco IOS Releases 12.0(18)S, 12.2(8)T, and later releases, the new **secret** keyword for the **username** command allows you to configure Message Digest 5 (MD5) encryption for username passwords.

### Prerequisites

The following commands must have been modified to run at privilege level 7 for this task:

- **clear counters**
- **reload**

See the [“Configuring the Networking Device for the First-Line Technical Support Staff”](#) section on page 25 for instructions on how to change the privilege level for a command.

### Restrictions

MD5 encryption for the **username** command is not supported in versions of Cisco IOS software prior to Cisco IOS Releases 12.0(18)S and 12.2(8)T.

You must not have the **aaa-new model** command enabled on the networking device. You must not have the **login local** command configured for the local CLI sessions over the console port or the remote CLI sessions.

#### Note

For clarity, only the arguments and keywords that are relevant for each step are shown in the syntax for the steps in this task. Refer to the Cisco IOS command reference book for your Cisco IOS release for further information on the additional arguments and keywords that can be used with these commands.

## SUMMARY STEPS

1. **enable password**
2. **configure terminal**

3. **username *username* privilege *level* secret *password***
4. **end**
5. **disable**
6. **login username *password***
7. **show privilege**
8. **clear counters**
9. **clear ip route \***
10. **reload in 10**
11. **reload cancel**
12. **disable**
13. **show privilege**

## DETAILED STEPS

---

**Step 1** **enable *t6D77CdKq***

Enters privileged EXEC mode. Enter the password when prompted.

Router> **enable**

**Step 2** **configure terminal**

Enters global configuration mode.

Router# **configure terminal**

**Step 3** **username *username* privilege *level* secret *password***

Creates a username and applies MD5 encryption to the *password* text string.

Router(config)# **username *admin* privilege 7 secret *Kd65xZa***

**Step 4** **end**

Exits global configuration mode.

Router(config)# **end**

**Step 5** **disable**

Exits the current privilege level and returns to user EXEC mode.

Router# **disable**

**Step 6** **login *username***

Logs in the user. Enter the username and password you configured in step 3 when prompted.

Router> **login *admin***

**Step 7** **show privilege**

The **show privilege** command displays the privilege level of the CLI session.

Router# **show privilege**

Current privilege level is 7

**Step 8** **clear counters**

The **clear counters** command clears the interface counters. This command has been changed from privilege level 15 to privilege level 7.

```
Router# clear counters
Clear "show interface" counters on all interfaces [confirm]
Router#
02:41:37: %CLEAR-5-COUNTERS: Clear counter on all interfaces by console
```

#### Step 9 **clear ip route \***

The *ip route* argument string for the **clear** command is not allowed because it was not changed from privilege level 15 to privilege level 7.

```
Router# clear ip route *
 ^
% Invalid input detected at '^' marker.

Router#
```

#### Step 10 **reload in time**

The reload command causes the networking device to reboot.

```
Router# reload in 10
Reload scheduled in 10 minutes by console
Proceed with reload? [confirm]
Router#
```

```

*** --- SHUTDOWN in 0:10:00 ---

```

```
02:59:50: %SYS-5-SCHEDULED_RELOAD: Reload requested for 23:08:30 PST Sun Mar 20
```

#### Step 11 **reload cancel**

The **reload cancel** command terminates a reload that was previously setup with the the **reload in time** command.

```
Router# reload cancel
```

```

*** --- SHUTDOWN ABORTED ---

```

```
04:34:08: %SYS-5-SCHEDULED_RELOAD_CANCELLED: Scheduled reload cancelled at 15:38:46 PST
Sun Mar 27 2005
```

#### Step 12 **disable**

Exits the current privilege level and returns to user EXEC mode.

```
Router# disable
```

#### Step 13 **show privilege**

Displays the privilege level of the current CLI session

```
Router> show privilege
Current privilege level is 1
```

## Recovering from a Lost or Misconfigured Password for Local CLI Sessions

There are three methods that can be used to recover from a lost or misconfigured password for local CLI sessions over console port. The method that you will use depends on the current configuration of your networking device.

- [Networking Device Is Configured to Allow Remote CLI Sessions, page 33](#)
- [Networking Device Is Not Configured to Allow Remote CLI Sessions and the Local CLI Session Password Has Not Been Saved to the Startup Configuration File, page 33](#)
- [Networking Device is not Configured to Allow Remote CLI Sessions and the Local CLI Session Password Has Been Saved to the Startup Configuration File, page 33](#)

### Networking Device Is Configured to Allow Remote CLI Sessions

The fastest method to recover from a lost, or misconfigured password for local CLI sessions is to establish a remote CLI session with the networking device and repeat the “[Configuring and Verifying a Password for Local CLI Sessions](#)” section on [page 18](#). Your networking device must be configured to allow remote CLI sessions and you must know the remote CLI session password to perform this procedure.

### Networking Device Is Not Configured to Allow Remote CLI Sessions and the Local CLI Session Password Has Not Been Saved to the Startup Configuration File

If you cannot establish a remote session to your networking device, and you have not saved the misconfigured local CLI session password to the startup configuration, you can restart the networking device. When the networking device starts up again it will read the startup configuration file. The previous local CLI session password is restored.

**Caution**

Restarting a networking device will cause it to stop forwarding traffic. This will also cause an interruption in any services that are running on the networking device, such as a DHCP server service, to stop. You should only restart a networking device during a period of time that has been allocated for network maintenance.

### Networking Device is not Configured to Allow Remote CLI Sessions and the Local CLI Session Password Has Been Saved to the Startup Configuration File

If you can not establish a remote CLI session with the networking device, and you have saved the misconfigured local CLI session password to the startup configuration, or you have lost the local CLI session password, you must perform a password recovery procedure. Password recovery procedures are device specific. You must locate the document that describes the procedure for your type of networking device.

There are three methods for locating a password recovery procedure document for your networking device:

- Many networking devices have a Password Recovery subsection in the Troubleshoot and Alerts section of their product support page on Cisco’s Technical Support website (<http://www.cisco.com/tac>). Navigate to the Troubleshoot and Alerts section of the product support page for your networking device and look for the Password Recovery subsection.

- If you do not find the password recovery document for your networking device on its product support page try searching for the text string **“password recovery”** on Cisco’s Technical Support website (<http://www.cisco.com/tac>). Enclose the text string in double quotes. You can improve the search results by adding an additional text string that matches the model number, series number or platform name for your networking device, For example searching on the string **“password recovery” 12000** will provide search results that give documents with the words **password**, **recovery** and **12000** in the title a higher ranking.
- If the product support page for your networking device does not have a password recovery document, and you can not find the correct document by searching for it, you can try the Cisco’s Network Professionals Connection (<http://www.cisco.com/go/netpro>).

## Recovering from a Lost or Misconfigured Password for Remote CLI Sessions

There are three methods that can be used to recover from a lost, or misconfigured remote CLI session password. The method that you will use depends on the current configuration of your networking device.

- [Networking Device Is Configured to Allow Local CLI Sessions, page 34](#)
- [Networking Device Is Not Configured to Allow Local CLI Sessions and the Remote CLI Session Password Has Not Been Saved to the Startup Configuration File, page 34](#)
- [Networking Device Is Not Configured to Allow Local CLI Sessions and the Remote CLI Session Password Has Been Saved to the Startup Configuration File, page 35](#)

### Networking Device Is Configured to Allow Local CLI Sessions

The fastest method to recover from a lost, or misconfigured password for remote CLI sessions is to establish a local CLI session with the networking device and repeat the [“Configuring and Verifying a Password for Remote CLI Sessions” section on page 15](#). Your networking device must be configured to allow local CLI sessions and you must know the local CLI session password to perform this procedure.

### Networking Device Is Not Configured to Allow Local CLI Sessions and the Remote CLI Session Password Has Not Been Saved to the Startup Configuration File

If you cannot establish a local CLI session to your networking device, and you have not saved the misconfigured remote CLI session password to the startup configuration, you can restart the networking device. When the networking device starts up again it will read the startup configuration file. The previous remote CLI session password is restored.

#### Caution

---

Restarting a networking device will cause it to stop forwarding traffic. This will also cause an interruption in any services that are running on the networking device, such as a DHCP server service, to stop. You should only restart a networking device during a period of time that has been allocated for network maintenance.

---

## Networking Device Is Not Configured to Allow Local CLI Sessions and the Remote CLI Session Password Has Been Saved to the Startup Configuration File

If you can not establish a local CLI session with the networking device, and you have saved the misconfigured remote CLI session password to the startup configuration, or you have lost the remote CLI session password, you must perform a password recovery procedure. Password recovery procedures are device specific. You must locate the document that describes the procedure for your type of networking device.

There are three methods for locating a password recovery procedure document for your networking device:

- Many networking devices have a Password Recovery subsection in the Troubleshoot and Alerts section of their product support page on Cisco's Technical Support website (<http://www.cisco.com/tac>). Navigate to the Troubleshoot and Alerts section of the product support page for your networking device and look for the Password Recovery subsection.
- If you do not find the password recovery document for your networking device on its product support page try searching for the text string **"password recovery"** on Cisco's Technical Support website (<http://www.cisco.com/tac>). Enclose the text string in double quotes. You can improve the search results by adding an additional text string that matches the model number, series number or platform name for your networking device. For example searching on the string **"password recovery" 12000** will provide search results that give documents with the words **password**, **recovery** and **12000** in the title a higher ranking.
- If the product support page for your networking device does not have a password recovery document, and you can not find the correct document by searching for it, you can try the Cisco's Network Professionals Connection (<http://www.cisco.com/go/netpro>).

## Recovering from a Lost or Misconfigured Passwords for Privileged EXEC Mode

There are two methods that can be used to recover from a lost, or misconfigured Privileged EXEC Mode password. The method that you will use depends on the current configuration of your networking device.

- [A Misconfigured Privileged EXEC Mode Password Has Not Been Saved to the Startup Configuration File, page 35](#)
- [A Misconfigured Privileged EXEC Mode Password Has Been Saved to the Startup Configuration File, or the Privileged EXEC Mode Password Has Been Lost, page 36](#)

### A Misconfigured Privileged EXEC Mode Password Has Not Been Saved to the Startup Configuration File

If you have not saved the misconfigured privileged EXEC mode password to the startup configuration, you can restart the networking device. When the networking device starts up again it will read the startup configuration file. The previous privileged EXEC mode password is restored.

#### Caution

Restarting a networking device will cause it to stop forwarding traffic. This will also cause an interruption in any services that are running on the networking device, such as a DHCP server service, to stop. You should only restart a networking device during a period of time that has been allocated for network maintenance.

## A Misconfigured Privileged EXEC Mode Password Has Been Saved to the Startup Configuration File, or the Privileged EXEC Mode Password Has Been Lost

If you have saved the misconfigured privileged EXEC mode password to the startup configuration, or you have lost the privileged EXEC mode password, you must perform a password recovery procedure. Password recovery procedures are device specific. You must locate the document that describes the procedure for your type of networking device.

There are three methods for locating a password recovery procedure document for your networking device:

- Many networking devices have a Password Recovery subsection in the Troubleshoot and Alerts section of their product support page on Cisco's Technical Support website (<http://www.cisco.com/tac>). Navigate to the Troubleshoot and Alerts section of the product support page for your networking device and look for the Password Recovery subsection.
- If you do not find the password recovery document for your networking device on its product support page try searching for the text string **"password recovery"** on Cisco's Technical Support website (<http://www.cisco.com/tac>). Enclose the text string in double quotes. You can improve the search results by adding an additional text string that matches the model number, series number or platform name for your networking device, For example searching on the string **"password recovery" 12000** will provide search results that give documents with the words **password, recovery** and **12000** in the title a higher ranking.
- If the product support page for your networking device does not have a password recovery document, and you can not find the correct document by searching for it, you can try the Cisco's Network Professionals Connection (<http://www.cisco.com/go/netpro>).

## Configuration Examples for Configuring Security with Passwords, Privilege Levels and, Login Usernames for CLI Sessions on Networking Devices

This section contains the following configuration examples:

- [Configuring and Verifying a Networking Device to Allow Non Administrative Users to Clear Remote CLI Sessions: Example, page 37](#)
- [Configuring and Verifying a Networking Device to Allow Non Administrative Users to View the Running Configuration Automatically: Example, page 38](#)
- [Configuring and Verifying a Networking Device to Allow Non Administrative Users to Shutdown and Enable Interfaces: Example, page 38](#)

## Configuring and Verifying a Networking Device to Allow Non Administrative Users to Clear Remote CLI Sessions: Example

The following example shows how to configure a networking device to allow a non administrative user to clear remote CLI session virtual terminal (VTY) lines.

The first section is an excerpt of the running configuration for this example. The following sections show you how this example is used.

The following section is an excerpt of the running-configuration:

```
!
privilege exec level 7 clear line
!
no aaa new-model
!
!
username admin privilege 7 secret 5 1tmIw$1aM7sadKhWmpkVTzxNw1J.
!
privilege exec level 7 clear line
!
! the privilege exec level 7 clear command below is entered automatically
! when you enter the privilege exec level 7 clear line command above, do
! not enter it again
!
privilege exec level 7 clear
!
```

The following section using the **login** command shows the user logging in to the networking device with the username of admin:

```
R1> login
Username: admin
Password:
```

The following section using the **show privilege** command shows that the current privilege level is 7:

```
R1# show privilege
Current privilege level is 7
R1#
```

The following section using the **show user** command shows that two users (admin and root) are currently logged in to the networking device:

```
R1# show user
```

| Line      | User  | Host(s) | Idle     | Location   |
|-----------|-------|---------|----------|------------|
| * 0 con 0 | admin | idle    | 00:00:00 |            |
| 2 vty 0   | root  | idle    | 00:00:17 | 172.16.6.2 |

| Interface | User | Mode | Idle | Peer Address |
|-----------|------|------|------|--------------|
|-----------|------|------|------|--------------|

The following section using the **clear line 2** command terminates the remote CLI session in use by the username root:

```
R1# clear line 2
[confirm]
[OK]
```

The following section using the **show user** command shows that admin is the only user currently logged in to the networking device:

```

R1# show user
 Line User Host(s) Idle Location
* 0 con 0 admin idle 00:00:00

 Interface User Mode Idle Peer Address

```

## Configuring and Verifying a Networking Device to Allow Non Administrative Users to View the Running Configuration Automatically: Example

The following example shows how to configure the networking device to allow a non administrative users (no access to privileged EXEC mode) to view the running configuration automatically. This example requires that the username is configured for privilege level 15 because many of the commands in the configuration file can be viewed only by users who have access to privilege level 15.

The solution is to temporarily allow the user access to privilege level 15 while running the **show running-config** command and then terminating the CLI session when the end of the configuration file has been viewed. In this example the networking device will automatically terminate the CLI session when the end of the configuration file has been viewed. No further configuration steps are required.

### Caution

You must include the **noescape** keyword for the **username** command to prevent the user from entering an escape character that will terminate viewing the configuration file and leave the session running at privilege level 15.

```

!
!
username viewconf privilege 15 noescape secret 5 1zA9C$TDWD/Q0zwp/5xRwRqdgC/.
username viewconf autocommand show running-config
!

```

## Configuring and Verifying a Networking Device to Allow Non Administrative Users to Shutdown and Enable Interfaces: Example

The following example shows how to configure a networking device to allow non administrative users to shutdown and enable interfaces.

The first section is an excerpt of the running configuration for this example. The following sections show you how this example is used.

The following section is an excerpt of the running-configuration:

```

!
no aaa new-model
!
username admin privilege 7 secret 5 1tmiw$1aM7sadKhWmpkVTzxNw1J.
!
privilege interface all level 7 shutdown
privilege interface all level 7 no shutdown
privilege configure level 7 interface
privilege exec level 7 configure terminal
!
! the privilege exec level 7 configure command below is entered automatically
! when you enter the privilege exec level 7 configure terminal command above, do
! not enter it again
!

```

```
privilege exec level 7 configure
!
```

The following section using the **login** command shows the user logging in to the networking device with the username of admin:

```
R1> login
Username: admin
Password:
```

The following section using the **show privilege** command shows that the current privilege level is 7:

```
R1# show privilege
Current privilege level is 7
R1#
```

The following section using the **show user** command shows that admin is the only user currently logged in to the networking device:

```
R1# show user
```

| Line      | User  | Host(s) | Idle     | Location |
|-----------|-------|---------|----------|----------|
| * 0 con 0 | admin | idle    | 00:00:00 |          |

| Interface | User | Mode | Idle | Peer Address |
|-----------|------|------|------|--------------|
|-----------|------|------|------|--------------|

The following section shows that the admin user is permitted to shutdown and enable an interface:

```
R1# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
R1(config)# interface ethernet 1/0
R1(config-if)# shutdown
R1(config-if)# no shutdown
R1(config-if)# exit
R1#
```

## Where to Go Next

Once you have established a baseline of security for your networking devices you can consider more advanced options such as:

- **Role-Based CLI Access**—The role-based CLI access feature offers a more comprehensive set of options than the **privilege** command (described in this document) for network managers who want to allow different levels of technical support staff to have different levels of access to CLI commands.
- **AAA Security**—Many Cisco networking devices offer an advanced level of security using authentication, authorization and accounting (AAA) features. All of the tasks described in this document, and other - more advanced security features - can be implemented using AAA on the networking device in conjunction with a remote TACACS+ or RADIUS server. For information how to configure AAA security features that can be run locally on a networking device, or for information on how to configure remote AAA security using TACACS+ or RADIUS servers, see the [Cisco IOS Security Configuration Guide](#), Release 12.4.

## Additional References

The following sections provide references related to Configuring Security with Passwords and, Login Usernames for CLI Sessions on Networking Devices.

# Feature Information for Configuring Security with Passwords, Privilege Levels and, Login Usernames for CLI Sessions on Networking Devices

Table 70 lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Releases 12.2(1) or 12.0(3)S or a later release appear in the table.

Not all commands may be available in your Cisco IOS software release. For details on when support for specific command was introduced, see the command reference documentation.

Cisco IOS software images are specific to a Cisco IOS software release, a feature set, and a platform. Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

## Note

Table 70 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 70** *Feature Information for Configuring Security with Passwords, Privilege Levels and, Login Usernames for CLI Sessions on Networking Devices*

| Feature Name                  | Releases               | Feature Configuration Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enhanced Password Security    | 12.0(18)S<br>12.2(8)T  | <p>Using the Enhanced Password Security feature, you can configure MD5 encryption for username passwords. MD5 encryption is a one-way hash function that makes reversal of an encrypted password impossible, providing strong encryption protection. Using MD5 encryption, you cannot retrieve clear text passwords. MD5 encrypted passwords cannot be used with protocols that require that the clear text password be retrievable, such as Challenge Handshake Authentication Protocol (CHAP).</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">Configuring and Verifying the Networking Device to Require a Username for the First-Line Technical Support Staff, page 30</a></li> </ul> |
| Privilege Command Enhancement | 12.0(22)S<br>12.2(13)T | <p>The keyword <b>all</b> was added to the <b>privilege</b> command as a wild card to reduce the number of times you need to enter the <b>privilege</b> command when you are changing the privilege level of several keywords for the same command.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> <li>• <a href="#">Privilege Command Enhancement, page 26</a></li> </ul>                                                                                                                                                                                                                                                                                                                                 |

Remote Authentication Dial-In User Service (RADIUS) attributes are used to define specific authentication, authorization, and accounting (AAA) elements in a user profile, which is stored on the RADIUS daemon. This appendix lists the RADIUS attributes currently supported.

## In This Appendix

This appendix contains the following sections:

- [RADIUS Attributes Overview](#)
- [RADIUS IETF Attributes](#)
- [RADIUS Vendor-Proprietary Attributes](#)
- [RADIUS Vendor-Specific Attributes \(VSA\) and RADIUS Disconnect-Cause Attribute Values](#)
- [RADIUS Disconnect-Cause Attribute Values](#)

## RADIUS Attributes Overview

This section contains information important to understanding how RADIUS attributes exchange AAA information between a client and server and includes the following sections:

- [IETF Attributes Versus VSAs](#)
- [RADIUS Packet Format](#)

## IETF Attributes Versus VSAs

RADIUS Internet Engineering Task Force (IETF) attributes are the original set of 255 standard attributes that are used to communicate AAA information between a client and a server. Because IETF attributes are standard, the attribute data is predefined and well known; thus all clients and servers who exchange AAA information via IETF attributes must agree on attribute data such as the exact meaning of the attributes and the general bounds of the values for each attribute.

RADIUS vendor-specific attributes (VSAs) derived from one IETF attribute—vendor-specific (attribute 26). Attribute 26 allows a vendor to create an additional 255 attributes however they wish. That is, a vendor can create an attribute that does not match the data of any IETF attribute and encapsulate it behind attribute 26; thus, the newly created attribute is accepted if the user accepts attribute 26.

For more information on VSAs, refer to the section “[RADIUS Vendor-Specific Attributes \(VSA\) and RADIUS Disconnect-Cause Attribute Values](#)” later in this appendix.

## RADIUS Packet Format

The data between a RADIUS server and a RADIUS client is exchanged in RADIUS packets. The data fields are transmitted from left to right.

[Figure 125](#) shows the fields within a RADIUS packet.

Note

For a diagram of VSAs, which is an extension of [Figure 125](#), refer to [Figure 1](#).

**Figure 125**      **RADIUS Packet Diagram**

Each RADIUS packet contains the following information:

- Code—The code field is one octet; it identifies one of the following types of RADIUS packets:
  - Access-Request (1)
  - Access-Accept (2)
  - Access-Reject (3)
  - Accounting-Request (4)
  - Accounting-Response (5)

- Identifier—The identifier field is one octet; it helps the RADIUS server match requests and responses and detect duplicate requests.
- Length—The length field is two octets; it specifies the length of the entire packet.
- Authenticator—The authenticator field is 16 octets. The most significant octet is transmitted first; it is used to authenticate the reply from the RADIUS server. Two types of authenticators are as follows:
  - Request-Authentication: Available in Access-Request and Accounting-Request packets
  - Response-Authenticator: Available in Access-Accept, Access-Reject, Access-Challenge, and Accounting-Response packets

## RADIUS Packet Types

The following list defines the various types of RADIUS packet types that can contain attribute information:

**Access-Request**—Sent from a client to a RADIUS server. The packet contains information that allows the RADIUS server to determine whether to allow access to a specific network access server (NAS), which will allow access to the user. Any user performing authentication *must* submit an Access-Request packet. Once an Access-Request packet is received, the RADIUS server *must* forward a reply.

**Access-Accept**—Once a RADIUS server receives an Access-Request packet, it must send an Access-Accept packet if all attribute values in the Access-Request packet are acceptable. Access-Accept packets provide the configuration information necessary for the client to provide service to the user.

**Access-Reject**—Once a RADIUS server receives an Access-Request packet, it must send an Access-Reject packet if any of the attribute values are not acceptable.

**Access-Challenge**—Once the RADIUS server receives an Access-Accept packet, it can send the client an Access-Challenge packet, which requires a response. If the client does not know how to respond or if the packets are invalid, the RADIUS server discards the packets. If the client responds to the packet, a new Access-Request packet should be sent with the original Access-Request packet.

**Accounting-Request**—Sent from a client to a RADIUS accounting server, which provides accounting information. If the RADIUS server successfully records the Accounting-Request packet, it must submit an Accounting Response packet.

**Accounting-Response**—Sent by the RADIUS accounting server to the client to acknowledge that the Accounting-Request has been received and recorded successfully.

## RADIUS Files

Understanding the types of files used by RADIUS is important for communicating AAA information from a client to a server. Each file defines a level of authentication or authorization for the user: The dictionary file defines which attributes the user's NAS can implement; the clients file defines which users are allowed to make requests to the RADIUS server; the users file defines which user requests the RADIUS server will authenticate based on security and configuration data.

- [Dictionary File](#)
- [Clients File](#)
- [Users File](#)

## Dictionary File

A dictionary file provides a list of attributes that are dependent upon which attributes your NAS supports. However, you can add your own set of attributes to your dictionary for custom solutions. It defines attribute values, thereby allowing you to interpret attribute output such as parsing requests. A dictionary file contains the following information:

- Name—The ASCII string “name” of the attribute, such as User-Name.
- ID—The numerical “name” of the attribute; for example, User-Name attribute is attribute 1.
- Value type—Each attribute can be specified as one of the following five value types:
  - binary—0 to 254 octets.
  - date—32-bit value in big endian order. For example, seconds since 00:00:00 GMT, JAN. 1, 1970.
  - ipaddr—4 octets in network byte order.
  - integer—32-bit value in big endian order (high byte first).
  - string—0 to 253 octets.

When the data type for a particular attribute is an integer, you can optionally expand the integer to equate to some string. The follow sample dictionary includes an integer-based attribute and its corresponding values:

```
dictionary sample of integer entry
#
ATTRIBUTE Service-Type 6 integer
VALUE Service-Type Login 1
VALUE Service-Type Framed 2
VALUE Service-Type Callback-Login 3
VALUE Service-Type Callback-Framed 4
VALUE Service-Type Outbound 5
VALUE Service-Type Administrative 6
VALUE Service-Type NAS-Prompt 7
VALUE Service-Type Authenticate-Only 8
VALUE Service-Type Callback-NAS-Prompt 9
VALUE Service-Type Call-Check 10
VALUE Service-Type Callback-Administrative 11
```

## Clients File

A clients file is important because it contains a list of RADIUS clients that are allowed to send authentication and accounting requests to the RADIUS server. To receive authentication, the name and authentication key the client sends the server must be an exact match with the data contained in clients file.

The following is an example of a clients file. The key, as shown in this example, must be the same as the **radius-server key** *SomeSecret* command.

```
#Client Name Key
#-----
10.1.1.2.3:256 test
nas01 bananas
nas02 MoNkEys
nas07.foo.com SomeSecret
```

## Users File

A RADIUS users file contains an entry for each user that the RADIUS server will authenticate; each entry, which is also referred to as a user profile, establishes an attribute the user can access.

The first line in any user profile is always a “user access” line; that is, the server must check the attributes on the first line before it can grant access to the user. The first line contains the name of the user, which can be up to 252 characters, followed by authentication information such as the password of the user.

Additional lines, which are associated with the user access line, indicate the attribute reply that is sent to the requesting client or server. The attributes sent in the reply must be defined in the dictionary file.

When looking at a user file, please note the the data to the left of the equal (=) character is an attribute defined in the dictionary file, and the data to the right of the equal character is the configuration data.

**Note**

A blank line cannot appear anywhere within a user profile.

The following is an example of a RADIUS user profile (Merit Daemon format). In this example, the user name is cisco.com, the password is cisco, and the user can access five tunnel attributes.

```
This user profile includes RADIUS tunneling attributes
cisco.com Password="cisco" Service-Type=Outbound
 Tunnel-Type = :1:L2TP
 Tunnel-Medium-Type = :1:IP
 Tunnel-Server-Endpoint = :1:10.0.0.1
 Tunnel-Password = :1:"welcome"
 Tunnel-Assignment-ID = :1:"nas"
```

## Supporting Documentation

For more information on RADIUS IETF and Vendor-Proprietary Attributes, refer to the following documents:

- Cisco AAA Implementation Case Study
- “[Configuring RADIUS](#)” “[Configuring Authentication](#),” “[Configuring Authorization](#)” and “[Configuring Accounting](#)” chapters in this book.

Refer to these chapters for information on how RADIUS is used with AAA.

- IETF RADIUS RFCs
  - RFC 2865, *Remote Authentication Dial In User Service (RADIUS)*
  - RFC 2866, *RADIUS Accounting*
  - RFC 2867, *RADIUS Accounting Modifications for Tunnel Protocol Support*
  - RFC 2868, *RADIUS Attributes for Tunnel Protocol Support*
  - RFC 2869, *RADIUS Extensions*
- RADIUS Vendor-Specific Attributes Voice Implementation Guide

# RADIUS IETF Attributes

## Note

In the Cisco IOS Release 12.2 for RADIUS tunnel attributes, 32 tagged tunnel sets are supported for L2TP.

This section contains the following sections:

- [Supported RADIUS IETF Attributes](#)
- [Comprehensive List of RADIUS Attribute Descriptions](#)

## Supported RADIUS IETF Attributes

[Table 71](#) lists Cisco-supported IETF RADIUS attributes and the Cisco IOS release in which they are implemented. In cases where the attribute has a security server-specific format, the format is specified.

Refer to [Table 72](#) for a description of each listed attribute.

## Note

Attributes implemented in special (AA) or early development (T) releases will be added to the next mainline image.

**Table 71** *Supported RADIUS IETF Attributes*

| Number | IETF Attribute     | 11.1 | 11.2 | 11.3 | 11.3 AA | 11.3T | 12.0 | 12.1 | 12.2 |
|--------|--------------------|------|------|------|---------|-------|------|------|------|
| 1      | User-Name          | yes  | yes  | yes  | yes     | yes   | yes  | yes  | yes  |

1. This RADIUS attribute complies with the following two draft IETF documents: RFC 2868 *RADIUS Attributes for Tunnel Protocol Support* and RFC 2867 *RADIUS Accounting Modifications for Tunnel Protocol Support*.
2. This RADIUS attribute complies with RFC 2865 and RFC 2868.

## Comprehensive List of RADIUS Attribute Descriptions

Table 72 lists and describes IETF RADIUS attributes. In cases where the attribute has a security server-specific format, the format is specified.

**Table 72**      **RADIUS IETF Attributes**

| Number | IETF Attribute | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1      | User-Name      | Indicates the name of the user being authenticated by the RADIUS server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 2      | User-Password  | Indicates the user's password or the user's input following an Access-Challenge. Passwords longer than 16 characters are encrypted using RFC 2865 specifications.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 3      | CHAP-Password  | Indicates the response value provided by a PPP Challenge-Handshake Authentication Protocol (CHAP) user in response to an Access-Challenge.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 4      | NAS-IP Address | Specifies the IP address of the network access server that is requesting authentication. The default value is 0.0.0.0/0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 5      | NAS-Port       | <p>Indicates the physical port number of the network access server that is authenticating the user. The NAS-Port value (32 bits) consists of one or two 16-bit values (depending on the setting of the <b>radius-server extended-portnames</b> command). Each 16-bit number should be viewed as a 5-digit decimal integer for interpretation as follows:</p> <p>For asynchronous terminal lines, async network interfaces, and virtual async interfaces, the value is <b>00ttt</b>, where <b>ttt</b> is the line number or async interface unit number.</p> <p>For ordinary synchronous network interface, the value is <b>10xxx</b>.</p> <p>For channels on a primary rate ISDN interface, the value is <b>2ppcc</b>.</p> <p>For channels on a basic rate ISDN interface, the value is <b>3bb0c</b>.</p> <p>For other types of interfaces, the value is <b>6nnss</b>.</p> |

Table 72 RADIUS IETF Attributes (continued)

| Number | IETF Attribute    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6      | Service-Type      | <p>Indicates the type of service requested or the type of service to be provided.</p> <ul style="list-style-type: none"> <li>In a request: <ul style="list-style-type: none"> <li>Framed for known PPP or SLIP connection.</li> <li>Administrative-user for <b>enable</b> command.</li> </ul> </li> <li>In response: <ul style="list-style-type: none"> <li>Login—Make a connection.</li> <li>Framed—Start SLIP or PPP.</li> <li>Administrative User—Start an EXEC or <b>enable ok</b>.</li> <li>Exec User—Start an EXEC session.</li> </ul> </li> </ul> <p>Service type is indicated by a particular numeric value as follows:</p> <ul style="list-style-type: none"> <li>1: Login</li> <li>2: Framed</li> <li>3: Callback-Login</li> <li>4: Callback-Framed</li> <li>5: Outbound</li> <li>6: Administrative</li> <li>7: NAS-Prompt</li> <li>8: Authenticate Only</li> <li>9: Callback-NAS-Prompt</li> </ul> |
| 7      | Framed-Protocol   | <p>Indicates the framing to be used for framed access. No other framing is allowed.</p> <p>Framing is indicated by a numeric value as follows:</p> <ul style="list-style-type: none"> <li>1: PPP</li> <li>2: SLIP</li> <li>3: ARA</li> <li>4: Gandalf-proprietary single-link/multilink protocol</li> <li>5: Xylogics-proprietary IPX/SLIP</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 8      | Framed-IP-Address | <p>Indicates the IP address to be configured for the user, by sending the IP address of a user to the RADIUS server in the access-request. To enable this command, use the <b>radius-server attribute 8 include-in-access-req</b> command in global configuration mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 9      | Framed-IP-Netmask | <p>Indicates the IP netmask to be configured for the user when the user is a router to a network. This attribute value results in a static route being added for Framed-IP-Address with the mask specified.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Table 72**      **RADIUS IETF Attributes (continued)**

| Number | IETF Attribute     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10     | Framed-Routing     | <p>Indicates the routing method for the user when the user is a router to a network. Only “None” and “Send and Listen” values are supported for this attribute.</p> <p>Routing method is indicated by a numeric value as follows:</p> <ul style="list-style-type: none"> <li>• 0: None</li> <li>• 1: Send routing packets</li> <li>• 2: Listen for routing packets</li> <li>• 3: Send routing packets and listen for routing packets</li> </ul>              |
| 11     | Filter-Id          | <p>Indicates the name of the filter list for the user and is formatted as follows: %d, %d.in, or %d.out. This attribute is associated with the most recent service-type command. For login and EXEC, use %d or %d.out as the line access list value from 0 to 199. For Framed service, use %d or %d.out as interface output access list, and %d.in for input access list. The numbers are self-encoding to the protocol to which they refer.</p>             |
| 12     | Framed-MTU         | <p>Indicates the maximum transmission unit (MTU) that can be configured for the user when the MTU is not negotiated by PPP or some other means.</p>                                                                                                                                                                                                                                                                                                          |
| 13     | Framed-Compression | <p>Indicates a compression protocol used for the link. This attribute results in a “/compress” being added to the PPP or SLIP autocommand generated during EXEC authorization. Not currently implemented for non-EXEC authorization.</p> <p>Compression protocol is indicated by a numeric value as follows:</p> <ul style="list-style-type: none"> <li>• 0: None</li> <li>• 1: VJ-TCP/IP header compression</li> <li>• 2: IPX header compression</li> </ul> |
| 14     | Login-IP-Host      | <p>Indicates the host to which the user will connect when the Login-Service attribute is included. (This begins immediately after login.)</p>                                                                                                                                                                                                                                                                                                                |
| 15     | Login-Service      | <p>Indicates the service that should be used to connect the user to the login host.</p> <p>Service is indicated by a numeric value as follows:</p> <ul style="list-style-type: none"> <li>• 0: Telnet</li> <li>• 1: Rlogin</li> <li>• 2: TCP-Clear</li> <li>• 3: PortMaster</li> <li>• 4: LAT</li> </ul>                                                                                                                                                     |
| 16     | Login-TCP-Port     | <p>Defines the TCP port with which the user is to be connected when the Login-Service attribute is also present.</p>                                                                                                                                                                                                                                                                                                                                         |
| 18     | Reply-Message      | <p>Indicates text that might be displayed to the user via the RADIUS server. You can include this attribute in user files; however, you cannot exceed a maximum of 16 Reply-Message entries per profile.</p>                                                                                                                                                                                                                                                 |
| 19     | Callback-Number    | <p>Defines a dialing string to be used for callback.</p>                                                                                                                                                                                                                                                                                                                                                                                                     |
| 20     | Callback-ID        | <p>Defines the name (consisting of one or more octets) of a place to be called, to be interpreted by the network access server.</p>                                                                                                                                                                                                                                                                                                                          |

**Table 72** *RADIUS IETF Attributes (continued)*

| Number | IETF Attribute     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 22     | Framed-Route       | Provides routing information to be configured for the user on this network access server. The RADIUS RFC format (net/bits [router [metric]]) and the old style dotted mask (net mask [router [metric]]) are supported. If the router field is omitted or 0, the peer IP address is used. Metrics are currently ignored. This attribute is access-request packets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 23     | Framed-IPX-Network | Defines the IPX network number configured for the user.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 24     | State              | Allows state information to be maintained between the network access server and the RADIUS server. This attribute is applicable only to CHAP challenges.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 25     | Class              | (Accounting) Arbitrary value that the network access server includes in all accounting packets for this user if supplied by the RADIUS server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 26     | Vendor-Specific    | <p>Allows vendors to support their own extended attributes not suitable for general use. The Cisco RADIUS implementation supports one vendor-specific option using the format recommended in the specification. Cisco's vendor-ID is 9, and the supported option has vendor-type 1, which is named "cisco-avpair." The value is a string of the format:</p> <pre>protocol : attribute sep value</pre> <p>"Protocol" is a value of the Cisco "protocol" attribute for a particular type of authorization. "Attribute" and "value" are an appropriate AV pair defined in the Cisco TACACS+ specification, and "sep" is "=" for mandatory attributes and "*" for optional attributes. This allows the full set of features available for TACACS+ authorization to also be used for RADIUS. For example:</p> <pre>cisco-avpair= "ip:addr-pool=first" cisco-avpair= "shell:priv-lvl=15"</pre> <p>The first example causes Cisco's "multiple named ip address pools" feature to be activated during IP authorization (during PPP's IPCP address assignment). The second example causes a user logging in from a network access server to have immediate access to EXEC commands.</p> <p><a href="#">Table 71</a> lists supported vendor-specific RADIUS attributes (IETF attribute 26). The "TACACS+ Attribute-Value Pairs" appendix provides a complete list of supported TACACS+ attribute-value (AV) pairs that can be used with IETF attribute 26. (RFC 2865)</p> |
| 27     | Session-Timeout    | Sets the maximum number of seconds of service to be provided to the user before the session terminates. This attribute value becomes the per-user "absolute timeout."                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 28     | Idle-Timeout       | Sets the maximum number of consecutive seconds of idle connection allowed to the user before the session terminates. This attribute value becomes the per-user "session-timeout."                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 29     | Termination-Action | Termination is indicated by a numeric value as follows: <ul style="list-style-type: none"> <li>0: Default</li> <li>1: RADIUS request</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 30     | Called-Station-Id  | (Accounting) Allows the network access server to send the telephone number the user called as part of the Access-Request packet (using Dialed Number Identification Service [DNIS] or similar technology). This attribute is only supported on ISDN, and modem calls on the Cisco AS5200 if used with PRI.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Table 72 RADIUS IETF Attributes (continued)

| Number | IETF Attribute           | Description                                                                                                                                                                                                                                                                                                                                                                  |
|--------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31     | Calling-Station-Id       | (Accounting) Allows the network access server to send the telephone number the call came from as part of the Access-Request packet (using Automatic Number Identification or similar technology). This attribute has the same value as “remote-addr” from TACACS+. This attribute is only supported on ISDN, and modem calls on the Cisco AS5200 if used with PRI.           |
| 32     | NAS-Identifier           | String identifying the network access server originating the Access-Request. Use the <b>radius-server attribute 32 include-in-access-req</b> global configuration command to send RADIUS attribute 32 in an Access-Request or Accounting-Request. By default, the FQDN is sent in the attribute when the format is not specified.                                            |
| 33     | Proxy-State              | Attribute that can be sent by a proxy server to another server when forwarding Access-Requests; this must be returned unmodified in the Access-Accept, Access-Reject or Access-Challenge and removed by the proxy server before sending the response to the network access server.                                                                                           |
| 34     | Login-LAT-Service        | Indicates the system with which the user is to be connected by LAT. This attribute is only available in the EXEC mode.                                                                                                                                                                                                                                                       |
| 35     | Login-LAT-Node           | Indicates the node with which the user is to be automatically connected by LAT.                                                                                                                                                                                                                                                                                              |
| 36     | Login-LAT-Group          | Identifies the LAT group codes that this user is authorized to use.                                                                                                                                                                                                                                                                                                          |
| 37     | Framed-AppleTalk-Link    | Indicates the AppleTalk network number that should be used for serial links to the user, which is another AppleTalk router.                                                                                                                                                                                                                                                  |
| 38     | Framed-AppleTalk-Network | Indicates the AppleTalk network number that the network access server uses to allocate an AppleTalk node for the user.                                                                                                                                                                                                                                                       |
| 39     | Framed-AppleTalk-Zone    | Indicates the AppleTalk Default Zone to be used for this user.                                                                                                                                                                                                                                                                                                               |
| 40     | Acct-Status-Type         | (Accounting) Indicates whether this Accounting-Request marks the beginning of the user service (start) or the end (stop).                                                                                                                                                                                                                                                    |
| 41     | Acct-Delay-Time          | (Accounting) Indicates how many seconds the client has been trying to send a particular record.                                                                                                                                                                                                                                                                              |
| 42     | Acct-Input-Octets        | (Accounting) Indicates how many octets have been received from the port over the course of this service being provided.                                                                                                                                                                                                                                                      |
| 43     | Acct-Output-Octets       | (Accounting) Indicates how many octets have been sent to the port in the course of delivering this service.                                                                                                                                                                                                                                                                  |
| 44     | Acct-Session-Id          | (Accounting) A unique accounting identifier that makes it easy to match start and stop records in a log file. Acct-Session ID numbers restart at 1 each time the router is power cycled or the software is reloaded. To send this attribute in access-request packets, use the <b>radius-server attribute 44 include-in-access-req</b> command in global configuration mode. |
| 45     | Acct-Authentic           | (Accounting) Indicates how the user was authenticated, whether by RADIUS, the network access server itself, or another remote authentication protocol. This attribute is set to “radius” for users authenticated by RADIUS; “remote” for TACACS+ and Kerberos; or “local” for local, enable, line, and if-needed methods. For all other methods, the attribute is omitted.   |
| 46     | Acct-Session-Time        | (Accounting) Indicates how long (in seconds) the user has received service.                                                                                                                                                                                                                                                                                                  |
| 47     | Acct-Input-Packets       | (Accounting) Indicates how many packets have been received from the port over the course of this service being provided to a framed user.                                                                                                                                                                                                                                    |

**Table 72**      **RADIUS IETF Attributes (continued)**

| Number | IETF Attribute        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 48     | Acct-Output-Packets   | (Accounting) Indicates how many packets have been sent to the port in the course of delivering this service to a framed user.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 49     | Acct-Terminate-Cause  | <p>(Accounting) Reports details on why the connection was terminated. Termination causes are indicated by a numeric value as follows:</p> <ol style="list-style-type: none"> <li>1. User request</li> <li>2. Lost carrier</li> <li>3. Lost service</li> <li>4. Idle timeout</li> <li>5. Session timeout</li> <li>6. Admin reset</li> <li>7. Admin reboot</li> <li>8. Port error</li> <li>9. NAS error</li> <li>10. NAS request</li> <li>11. NAS reboot</li> <li>12. Port unneeded</li> <li>13. Port pre-empted</li> <li>14. Port suspended</li> <li>15. Service unavailable</li> <li>16. Callback</li> <li>17. User error</li> <li>18. Host request</li> </ol> <p><b>Note</b> For attribute 49, Cisco IOS supports values 1 to 6, 9, 12, and 15 to 18.</p> |
| 50     | Acct-Multi-Session-Id | <p>(Accounting) A unique accounting identifier used to link multiple related sessions in a log file.</p> <p>Each linked session in a multilink session has a unique Acct-Session-Id value, but shares the same Acct-Multi-Session-Id.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 51     | Acct-Link-Count       | (Accounting) Indicates the number of links known in a given multilink session at the time an accounting record is generated. The network access server can include this attribute in any accounting request that might have multiple links.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 52     | Acct-Input-Gigawords  | Indicates how many times the Acct-Input-Octets counter has wrapped around 2 <sup>32</sup> over the course of the provided service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 53     | Acct-Output-Gigawords | Indicates how many times the Acct-Output-Octets counter has wrapped around 2 <sup>32</sup> while delivering service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Table 72 RADIUS IETF Attributes (continued)

| Number | IETF Attribute                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 55     | Event-Timestamp                 | <p>Records the time that the event occurred on the NAS; the timestamp sent in attribute 55 is in seconds since January 1, 1970 00:00 UTC. To send RADIUS attribute 55 in accounting packets, use the <b>radius-server attribute 55 include-in-acct-req</b> command.</p> <p><b>Note</b> Before the Event-Timestamp attribute can be sent in accounting packets, you <i>must</i> configure the clock on the router. (For information on setting the clock on your router, refer to section “Performing Basic System Management” in the chapter “System Management” of the <i>Cisco IOS Configuration Fundamentals Configuration Guide</i>.)</p> <p>To avoid configuring the clock on the router every time the router is reloaded, you can enable the <b>clock calendar-valid</b> command. (For information on this command, refer to the chapter “Basic System Management Commands” in the <i>Cisco IOS Configuration Fundamentals Command Reference</i>.)</p> |
| 60     | CHAP-Challenge                  | Contains the Challenge Handshake Authentication Protocol challenge sent by the network access server to a PPP CHAP user.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 61     | NAS-Port-Type                   | <p>Indicates the type of physical port the network access server is using to authenticate the user. Physical ports are indicated by a numeric value as follows:</p> <ul style="list-style-type: none"> <li>• 0: Asynchronous</li> <li>• 1: Synchronous</li> <li>• 2: ISDN-Synchronous</li> <li>• 3: ISDN-Asynchronous (V.120)</li> <li>• 4: ISDN-Asynchronous (V.110)</li> <li>• 5: Virtual</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 62     | Port-Limit                      | Sets the maximum number of ports provided to the user by the NAS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 63     | Login-LAT-Port                  | Defines the port with which the user is to be connected by LAT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 64     | Tunnel-Type <sup>1</sup>        | Indicates the tunneling protocol(s) used. Cisco IOS software supports two possible values for this attribute: L2TP and L2F. If this attribute is not set, L2F is used as a default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 65     | Tunnel-Medium-Type <sup>1</sup> | Indicates the transport medium type to use to create a tunnel. This attribute has only one available value for this release: IP. If no value is set for this attribute, IP is used as the default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

Table 72 RADIUS IETF Attributes (continued)

| Number | IETF Attribute                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 66     | Tunnel-Client-Endpoint              | <p>Contains the address of the initiator end of the tunnel. It <i>may</i> be included in both Access-Request and Access-Accept packets to indicate the address from which a new tunnel is to be initiated. If the Tunnel-Client-Endpoint attribute is included in an Access-Request packet, the RADIUS server should take the value as a hint; the server is not obligated to honor the hint, however. This attribute <i>should</i> be included in Accounting-Request packets that contain Acct-Status-Type attributes with values of either Start or Stop, in which case it indicates the address from which the tunnel was initiated. This attribute, along with the Tunnel-Server-Endpoint and Acct-Tunnel-Connection-ID attributes, may be used to provide a globally unique means to identify a tunnel for accounting and auditing purposes.</p> <p>An enhancement has been added for the network access server to accept a value of 127.0.0.X for this attribute such that:</p> <ul style="list-style-type: none"> <li>127.0.0.0 would indicate that loopback0 IP address is to be used</li> <li>127.0.0.1 would indicate that loopback1 IP address is to be used</li> <li>...</li> <li>127.0.0.X would indicate that loopbackX IP address is to be used</li> </ul> <p>for the actual tunnel client endpoint IP address. This enhancement adds scalability across multiple network access servers.</p> |
| 67     | Tunnel-Server-Endpoint <sup>1</sup> | Indicates the address of the server end of the tunnel. The format of this attribute varies depending on the value of Tunnel-Medium-Type. Because this release only supports IP as a tunnel medium type, the IP address or the host name of LNS is valid for this attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 68     | Acct-Tunnel-Connection-ID           | Indicates the identifier assigned to the tunnel session. This attribute <i>should</i> be included in Accounting-Request packets that contain an Acct-Status-Type attribute having the value Start, Stop, or any of the values described above. This attribute, along with the Tunnel-Client-Endpoint and Tunnel-Server-Endpoint attributes, may be used to provide a means to uniquely identify a tunnel session for auditing purposes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 69     | Tunnel-Password <sup>1</sup>        | <p>Defines the password to be used to authenticate to a remote server. This attribute is converted into different AAA attributes based on the value of Tunnel-Type: AAA_ATTR_l2tp_tunnel_pw (L2TP), AAA_ATTR_nas_password (L2F), and AAA_ATTR_gw_password (L2F).</p> <p>By default, all passwords received are encrypted, which can cause authorization failures when a NAS attempts to decrypt a non-encrypted password. To enable attribute 69 to receive non-encrypted passwords, use the <b>radius-server attribute 69 clear</b> global configuration command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 70     | ARAP-Password                       | Identifies an Access-Request packet containing a Framed-Protocol of ARAP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 71     | ARAP-Features                       | Includes password information that the NAS should send to the user in an ARAP "feature flags" packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 72     | ARAP-Zone-Access                    | Indicates how the ARAP zone list for the user should be used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 73     | ARAP-Security                       | Identifies the ARAP Security Module to be used in an Access-Challenge packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 74     | ARAP-Security-Data                  | Contains the actual security module challenge or response. It can be found in Access-Challenge and Access-Request packets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 75     | Password-Retry                      | Indicates how many times a user may attempt authentication before being disconnected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Table 72**      **RADIUS IETF Attributes (continued)**

| Number | IETF Attribute                    | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|--------|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 76     | Prompt                            | Indicates to the NAS whether it should echo the user's response as it is entered or not echo it. (0=no echo, 1=echo)                                                                                                                                                                                                                                                                                |
| 77     | Connect-Info                      | Provides additional call information for modem calls. This attribute is generated in start and stop accounting records.                                                                                                                                                                                                                                                                             |
| 78     | Configuration-Token               | Indicates a type of user profile to be used. This attribute should be used in large distributed authentication networks based on proxy. It is sent from a RADIUS Proxy Server to a RADIUS Proxy Client in an Access-Accept; it should not be sent to a NAS.                                                                                                                                         |
| 79     | EAP-Message                       | Encapsulates Extended Access Protocol (EAP) packets that allow the NAS to authenticate dial-in users via EAP without having to understand the EAP protocol.                                                                                                                                                                                                                                         |
| 80     | Message-Authenticator             | Prevents spoofing Access-Requests using CHAP, ARAP, or EAP authentication methods.                                                                                                                                                                                                                                                                                                                  |
| 81     | Tunnel-Private-Group-ID           | Indicates the group ID for a particular tunneled session.                                                                                                                                                                                                                                                                                                                                           |
| 82     | Tunnel-Assignment-ID <sup>1</sup> | Indicates to the tunnel initiator the particular tunnel to which a session is assigned.                                                                                                                                                                                                                                                                                                             |
| 83     | Tunnel-Preference                 | Indicates the relative preference assigned to each tunnel. This attribute should be included if more than one set of tunneling attributes is returned by the RADIUS server to the tunnel initiator.                                                                                                                                                                                                 |
| 84     | ARAP-Challenge-Response           | Contains the response to the challenge of the dial-in client.                                                                                                                                                                                                                                                                                                                                       |
| 85     | Acct-Interim-Interval             | Indicates the number of seconds between each interim update in seconds for this specific session. This value can only appear in the Access-Accept message.                                                                                                                                                                                                                                          |
| 86     | Acct-Tunnel-Packets-Lost          | Indicates the number of packets lost on a given link. This attribute should be included in Accounting-Request packets that contain an Acct-Status-Type attribute having the value Tunnel-Link-Stop.                                                                                                                                                                                                 |
| 87     | NAS-Port-ID                       | Contains a text string which identifies the port of the NAS that is authenticating the user.                                                                                                                                                                                                                                                                                                        |
| 88     | Framed-Pool                       | Contains the name of an assigned address pool that should be used to assign an address for the user. If a NAS does not support multiple address pools, the NAS should ignore this attribute.                                                                                                                                                                                                        |
| 90     | Tunnel-Client-Auth-ID             | Specifies the name used by the tunnel initiator (also known as the NAS) when authenticating tunnel setup with the tunnel terminator. Supports L2F and L2TP protocols.                                                                                                                                                                                                                               |
| 91     | Tunnel-Server-Auth-ID             | Specifies the name used by the tunnel terminator (also known as the Home Gateway) when authenticating tunnel setup with the tunnel initiator. Supports L2F and L2TP protocols.                                                                                                                                                                                                                      |
| 200    | IETF-Token-Immediate              | <p>Determines how RADIUS treats passwords received from login-users when their file entry specifies a hand-held security card server.</p> <p>The value for this attribute is indicated by a numeric value as follows:</p> <ul style="list-style-type: none"> <li>• 0: No, meaning that the password is ignored.</li> <li>• 1: Yes, meaning that the password is used for authentication.</li> </ul> |

1. This RADIUS attribute complies with the following two IETF documents: RFC 2868, *RADIUS Attributes for Tunnel Protocol Support* and RFC 2867, *RADIUS Accounting Modifications for Tunnel Protocol Support*.

# Per-User QoS via AAA Policy Name

---

**First Published: March 31, 2000**

**Last Updated: January 2, 2008**

The Per-User QoS via AAA Policy Name feature provides the ability to download a policy name that describes quality of service (QoS) parameters for a user session from a RADIUS server and apply them for the particular session.

## Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Command Reference” section on page 6](#).

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

# Prerequisites for Per-User QoS via AAA Policy Name

Before you configure the Per-User QoS via AAA Policy Name feature, you must locally define on your router the policy whose name is received from the RADIUS server.

## Information About Per-User QoS via AAA Policy Name

Effective with Cisco IOS Release 12.2(15)T, separate Cisco vendor-specific attributes (VSAs) are added for the service map.

To configure the Per-User QoS via AAA Policy Name feature, you must understand the following concept:

### VSAs Added for Per-User QoS via AAA Policy Name

Two new VSAs have been added for the service map, and the VSAs will bypass the parser while applying the policy for a particular user or session. The new VSAs are as follows:

- vendor-id=9 (Cisco) Vendor type 37 for upstream traffic to input policy name
- vendor-id+9 (Cisco) Vendor type 38 for downstream traffic to output policy name

## How to Configure Per-User QoS via AAA Policy Name

This section contains the following procedure:

- [Monitoring and Maintaining Per-User QoS via AAA Policy Name, page 2](#)

To configure per-user QoS, use the authentication, authorization, and accounting (AAA) policy name that you have received from the RADIUS server. To configure QoS policy, refer to the documents listed in the section [Related Documents](#).

### Monitoring and Maintaining Per-User QoS via AAA Policy Name

To monitor and maintain per-user QoS using the AAA policy name, use the following **debug** commands:

#### SUMMARY STEPS

1. **enable**
2. **debug aaa authorization**
3. **debug aaa per-user**

## DETAILED STEPS

|        | Command or Action                                                                        | Purpose                                                                                                          |
|--------|------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                   | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>debug aaa authorization</b><br><br><b>Example:</b><br>Router# debug aaa authorization | Displays information about AAA/TACACS+ authorization.                                                            |
| Step 3 | <b>debug aaa per-user</b><br><br><b>Example:</b><br>Router# debug aaa per-user           | Displays information about per-user QoS parameters.                                                              |

# Configuration Examples for Per-User QoS via AAA Policy Name

This section provides the following configuration example:

- [Per-User QoS Using the AAA Policy Name, page 3](#)

## Per-User QoS Using the AAA Policy Name

The following example shows that per-user QoS is being configured using the AAA policy name "policy\_class\_1\_2":

```
class-map match-all class1
 match access-group 101
class-map match-all class2
 match qos-group 4
 match access-group 101
```

```
policy-map policy_class_1_2
 class class1
 bandwidth 3000
 queue-limit 30
 class class2
 bandwidth 2000
 class class-default
 bandwidth 500
```

```
peruser_qos_1 Password = "lab"
 Service-Type = Framed,
 Framed-Protocol = PPP,
 Cisco:Cisco-avpair = "ip:sub-policy-In=ssspolicy"
!ssspolicy in the above line is the name of the policy.
```

```
peruser_qos_2 Password = "lab"
 Service-Type = Framed,
```

```
Framed-Protocol = PPP,
Cisco:Cisco-avpair = "ip:sub-policy-Out=ssspolicy"
```

# Additional References

## Command Reference

This feature uses no new or modified commands. To see the command pages for the commands used with this feature, see the *Cisco IOS Security Command Reference* at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html). For information about all Cisco IOS commands, use the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or a Cisco IOS master commands list.

## Feature Information for Per-User QoS via AAA Policy Name

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1** Feature Information for Per-User QoS via AAA Policy Name

| Feature Name                     | Releases                              | Feature Information                                                                                                                                                                               |

# Glossary

**RADIUS**—Remote Authentication Dial-In User Service. RADIUS is a database for authenticating modem and ISDN connections and for tracking connection time.

**VSA**—vendor-specific attribute. A VSA is an attribute that has been implemented by a particular vendor. It uses the attribute Vendor-Specific to encapsulate the resulting AV pair: essentially, Vendor-Specific = protocol:attribute = value.

**Note**

Refer to the [Internetworking Terms and Acronyms](#) for terms not included in this glossary.

# RADIUS Attribute 8 (Framed-IP-Address) in Access Requests

---

**First Published: August 12, 2002**

**Last Updated: January 10, 2008**

The RADIUS Attribute 8 (Framed-IP-Address) in Access Requests feature makes it possible for a network access server (NAS) to provide the RADIUS server with a hint of the user IP address in advance of user authentication. An application can be run on the RADIUS server to use this hint and build a table (map) of user names and addresses. Using the mapping information, service applications can begin preparing user login information to have available upon successful user authentication.

## Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for RADIUS Attribute 8 \(Framed-IP-Address\) in Access Requests”](#) section on page 7.

## Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

**Americas Headquarters:**

**Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA**

© 2002–2008 Cisco Systems, Inc. All rights reserved.

- [Command Reference, page 6](#)
- [Feature Information for RADIUS Attribute 8 \(Framed-IP-Address\) in Access Requests, page 7](#)

## Prerequisites for RADIUS Attribute 8 (Framed-IP-Address) in Access Requests

Sending RADIUS attribute 8 in the RADIUS access requests assumes that the login host has been configured to request its IP address from the NAS server. It also assumes that the login host has been configured to accept an IP address from the NAS.

The NAS must be configured with a pool of network addresses on the interface supporting the login hosts.

## Information About RADIUS Attribute 8 (Framed-IP-Address) in Access Requests

### How This Feature Works

When a network device dials in to a NAS that is configured for RADIUS authentication, the NAS begins the process of contacting the RADIUS server in preparation for user authentication. Typically, the IP address of the dial-in host is not communicated to the RADIUS server until after successful user authentication. Communicating the device IP address to the server in the RADIUS access request allows other applications to begin to take advantage of that information.

As the NAS is setting up communication with the RADIUS server, the NAS assigns an IP address to the dial-in host from a pool of IP addresses configured at the specific interface. The NAS sends the IP address of the dial-in host to the RADIUS server as attribute 8. At that time, the NAS sends other user information, such as the user name, to the RADIUS server.

After the RADIUS server receives the user information from the NAS, it has two options:

- If the user profile on the RADIUS server already includes attribute 8, the RADIUS server can override the IP address sent by the NAS with the IP address defined as attribute 8 in the user profile. The address defined in the user profile is returned to the NAS.
- If the user profile does not include attribute 8, the RADIUS server can accept attribute 8 from the NAS, and the same address is returned to the NAS.

The address returned by the RADIUS server is saved in memory on the NAS for the life of the session. If the NAS is configured for RADIUS accounting, the accounting start packet sent to the RADIUS server includes the same IP address as in attribute 8. All subsequent accounting packets, updates (if configured), and stop packets will also include the same IP address provided in attribute 8.

## Benefits

The RADIUS Attribute 8 (Framed-IP-Address) in Access Requests feature makes it possible to run applications on the RADIUS server that builds mapping tables of users and IP addresses. The server can then use the mapping table information in other applications, such as preparing customized user login pages in advance of a successful user authentication with the RADIUS server.

## How to Configure RADIUS Attribute 8 (Framed-IP-Address) in Access Requests

This section contains the following procedures:

- [Configuring RADIUS Attribute 8 in Access Requests, page 3](#) (required)
- [Verifying RADIUS Attribute 8 in Access Requests, page 4](#)

## Configuring RADIUS Attribute 8 in Access Requests

To send RADIUS attribute 8 in the access request, perform the following steps:

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **radius-server attribute 8 include-in-access-req**

### DETAILED STEPS

|        | Command or Action                                                                                                                                | Purpose                                                                                                             |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                           | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                   | Enters global configuration mode.                                                                                   |
| Step 3 | <b>radius-server attribute 8 include-in-access-req</b><br><br><b>Example:</b><br>Router(config)# radius-server attribute 8 include-in-access-req | Sends RADIUS attribute 8 in access-request packets.                                                                 |

## Verifying RADIUS Attribute 8 in Access Requests

To verify that RADIUS attribute 8 is being sent in access requests, perform the following steps. Attribute 8 should be present in all PPP access requests.

### SUMMARY STEPS

1. `enable`
2. `more system:running-config`
3. `debug radius`

### DETAILED STEPS

|        | Command or Action                                                  | Purpose                                                                                                                                                                         |
|--------|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <code>enable</code>                                                | Enables privileged EXEC mode. <ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                                                |
|        | <b>Example:</b><br><code>Router&gt; enable</code>                  |                                                                                                                                                                                 |
| Step 2 | <code>more system:running-config</code>                            | Displays the contents of the current running configuration file. (Note that the <b>more system:running-config</b> command has replaced the <b>show running-config</b> command.) |
|        | <b>Example:</b><br><code>Router# more system:running-config</code> |                                                                                                                                                                                 |
| Step 3 | <code>debug radius</code>                                          | Displays information associated with RADIUS. The output of this command shows whether attribute 8 is being sent in access requests.                                             |
|        | <b>Example:</b><br><code>Router# debug radius</code>               |                                                                                                                                                                                 |

## Configuration Examples for RADIUS Attribute 8 (Framed-IP-Address) in Access Requests

This section provides the following configuration example:

- [NAS Configuration That Sends the IP Address of the Dial-in Host to the RADIUS Server in the RADIUS Access Request](#)

### NAS Configuration That Sends the IP Address of the Dial-in Host to the RADIUS Server in the RADIUS Access Request

The following example shows a NAS configuration that sends the IP address of the dial-in host to the RADIUS server in the RADIUS access request. The NAS is configured for RADIUS authentication, authorization, and accounting (AAA). A pool of IP addresses (async1-pool) has been configured and applied at interface Async1.

```
aaa new-model
aaa authentication login default group radius
aaa authentication ppp default group radius
aaa authorization network default group radius
```

```

aaa accounting network default start-stop group radius
!
ip address-pool local
!
interface Async1
 peer default ip address pool async1-pool
!
ip local pool async1-pool 209.165.200.225 209.165.200.229
!
radius-server host 172.31.71.146 auth-port 1645 acct-port 1646
radius-server retransmit 3
radius-server attribute 8 include-in-access-req
radius-server key radhost<xxx>: Example

```

## Additional References

The following sections provide references related to the RADIUS Attribute 8 (Framed-IP-Address) in Access Requests feature.

## Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Security Command Reference* at [http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html). For information about all Cisco IOS commands, see the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the Cisco IOS Master Commands list.

- **radius-server attribute 8 include-in-access-req**

# Feature Information for RADIUS Attribute 8 (Framed-IP-Address) in Access Requests

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 1** Feature Information for RADIUS Attribute 8 (Framed-IP-Address) in Access Requests

| Feature Name                                              | Releases                               | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

# RADIUS Attribute 66 (Tunnel-Client-Endpoint) Enhancements

---

**First Published:** November 27, 2000  
**Last Updated:** February, 2006

## History for the RADIUS Attribute 66 (Tunnel-Client-Endpoint) Enhancements Feature

| Release                  | Modification                                                   |
|--------------------------|----------------------------------------------------------------|
| 12.1(5)T                 | This feature was introduced.                                   |
| 12.2(28)SB               | This feature was integrated into Cisco IOS Release 12.2(28)SB. |
| Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers.  |

## Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

## Feature Overview

Virtual Private Networks (VPNs) use Layer 2 Forwarding (L2F) or Layer 2 Tunnel Protocol (L2TP) tunnels to tunnel the link layer of high-level protocols (for example, PPP or asynchronous High-Level Data Link Control (HDLC)). Internet service providers (ISPs) configure their network access servers (NASs) to receive calls from users and forward the calls to the customer tunnel server. Usually, the ISP maintains only information about the tunnel server—the tunnel endpoint. The customer maintains the IP addresses, routing, and other user database functions of the tunnel server users.

The RADIUS Attribute 66 (Tunnel-Client-Endpoint) Enhancements feature adds the ability to specify the hostname of the NAS—rather than the IP address of the NAS—in RADIUS attribute 66 (Tunnel-Client-Endpoint).

## Benefits

The RADIUS Attribute 66 (Tunnel-Client-Endpoint) Enhancements feature allows the user to specify the hostname of the NAS, rather than the IP address. This feature prevents the user from having to remember the numerical IP address and may also provide a small measure of security by protecting the numerical IP address of the NAS.

## Restrictions

Your Cisco router or access server must be running a Cisco IOS software image that supports virtual private dialup networks (VPDNs).

## Related Features and Technologies

- L2TP
- PPP
- RADIUS
- VPDN

## Prerequisites

You must be using a Cisco platform that supports VPDN.

## Configuration Tasks

None

# Configuration Examples

This section provides the following configuration example:

- [Setting Up the RADIUS Profile for RADIUS Attribute 66 \(Tunnel-Client-Endpoint\) Enhancements, page 3](#)

## Setting Up the RADIUS Profile for RADIUS Attribute 66 (Tunnel-Client-Endpoint) Enhancements

The following example shows a configuration that allows the user to specify the hostname of the NAS using RADIUS attribute 66 (Tunnel-Client-Endpoint):

```
cisco.com Password = "cisco"
Service-Type = Outbound-User,
Tunnel-Type = :1:L2F,
Tunnel-Medium-Type = :1:IP,
Tunnel-Client-Endpoint = :1:"cisco2"
Tunnel-Server-Endpoint = :1:"172.21.135.4",
Tunnel-Assignment-Id = :1:"nas1",
Tunnel-Password = :1:"cisco"
```

## Additional References

The following sections provide references related to RADIUS Attribute 66 (Tunnel-Client-Endpoint) Enhancements feature.

# Glossary

**L2F**—Layer 2 Forwarding Protocol. Protocol that supports the creation of secure virtual private dialup networks over the Internet.

**L2TP**—Layer 2 Tunnel Protocol. Protocol that is one of the key building blocks for virtual private networks in the dial access space and is endorsed by Cisco and other internetworking industry leaders. This protocol combines the best of Cisco's Layer 2 Forwarding (L2F) protocol and Microsoft's Point-to-Point Tunneling Protocol (PPTP).

**Layer 2 Forwarding Protocol**—See L2F.

**Layer 2 Tunnel Protocol**—See L2TP.

**Point-to-Point Protocol**—See PPP.

**PPP**—Point-to-Point Protocol. Successor to SLIP that provides router-to-router and host-to-network connections over synchronous and asynchronous circuits. Whereas SLIP was designed to work with IP, PPP was designed to work with several network layer protocols, such as IP, IPX, and ARA. PPP also has built-in security mechanisms, such as CHAP and PAP. PPP relies on two protocols: LCP and NCP.

**RADIUS**—Remote Authentication Dial-In User Service. Database for authenticating modem and ISDN connections and for tracking connection time.

**Remote Authentication Dial-In User Service**—See RADIUS.

**virtual private dialup network**—See VPDN.

**VPDN**—virtual private dialup network. A system that permits dial-in networks to exist remotely to home networks, while giving the appearance of being directly connected. VPDNs use L2TP and L2F to terminate the Layer 2 and higher parts of the network connection at the L2TP network server (LNS), instead of the L2TP access concentrator (LAC).

# RADIUS Tunnel Attribute Extensions

## Feature History

| Release                  | Modification                                                  |
|--------------------------|---------------------------------------------------------------|
| 12.1(5)T                 | This feature was introduced.                                  |
| 12.2(4)B3                | This feature was integrated into Cisco IOS Release 12.2(4)B3. |
| 12.2(13)T                | This feature was integrated into Cisco IOS Release 12.2(13)T. |
| Cisco IOS XE Release 2.1 | This feature was introduced on Cisco ASR 1000 Series Routers. |

This feature module describes the RADIUS Tunnel Attribute Extensions feature. It includes the following sections:

- [Feature Overview, page 1](#)
- [Supported Platforms, page 3](#)
- [Supported Standards, MIBs, and RFCs, page 4](#)
- [Prerequisites, page 4](#)
- [Configuration Tasks, page 4](#)
- [Configuration Examples, page 5](#)
- [Command Reference, page 6](#)
- [Glossary, page 7](#)

## Feature Overview

The RADIUS Tunnel Attribute Extensions feature introduces RADIUS attribute 90 (Tunnel-Client-Auth-ID) and RADIUS attribute 91 (Tunnel-Server-Auth-ID). Both attributes help support the provision of compulsory tunneling in virtual private networks (VPNs) by allowing the user to specify authentication names for the network access server (NAS) and the RADIUS server.

**Americas Headquarters:**  
**Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA**

© 2007 Cisco Systems, Inc. All rights reserved.

## How It Works

Once a NAS has set up communication with a RADIUS server, you can enable a tunneling protocol. Some applications of tunneling protocols are voluntary, but others involve compulsory tunneling; that is, a tunnel is created without any action from the user and without allowing the user any choice in the matter. In those cases, new RADIUS attributes are needed to carry the tunneling information from the NAS to the RADIUS server to establish authentication. These new RADIUS attributes are listed in [Table 79](#).

**Note**

In compulsory tunneling, any security measures in place apply only to traffic between the tunnel endpoints. Encryption or integrity protection of tunneled traffic must not be considered as a replacement for end-to-end security.

**Table 79**      **RADIUS Tunnel Attributes**

| Number | IETF RADIUS Tunnel Attribute | Equivalent TACACS+ Attribute | Supported Protocols                                                                                                   | Description                                                                                                                                                 |
|--------|------------------------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 90     | Tunnel-Client-Auth-ID        | tunnel-id                    | <ul style="list-style-type: none"> <li>Layer 2 Forwarding (L2F)</li> <li>Layer 2 Tunneling Protocol (L2TP)</li> </ul> | Specifies the name used by the tunnel initiator (also known as the NAS <sup>1</sup> ) when authenticating tunnel setup with the tunnel terminator.          |
| 91     | Tunnel-Server-Auth-ID        | gw-name                      | <ul style="list-style-type: none"> <li>Layer 2 Forwarding (L2F)</li> <li>Layer 2 Tunneling Protocol (L2TP)</li> </ul> | Specifies the name used by the tunnel terminator (also known as the Home Gateway <sup>2</sup> ) when authenticating tunnel setup with the tunnel initiator. |

1. When L2TP is used, the NAS is referred to as an L2TP access concentrator (LAC).
2. When L2TP is used, the Home Gateway is referred to as an L2TP network server (LNS).

RADIUS attribute 90 and RADIUS attribute 91 are included in the following situations:

- If the RADIUS server accepts the request and the desired authentication name is different from the default, they must be included it.
- If an accounting request contains Acct-Status-Type attributes with values of either start or stop and pertains to a tunneled session, they should be included in.

## Benefits

The RADIUS Tunnel Attribute Extensions feature allows you to specify a name (other than the default) of the tunnel initiator and the tunnel terminator. Thus, you can establish a higher level of security when setting up VPN tunneling.

## Restrictions

Your RADIUS server must support tagged attributes to use RADIUS tunnel attributes 90 and 91.

## Related Documents

The following documents provide information related to the RADIUS Tunnel Attribute Extensions feature:

- The chapters “Configuring Authentication” and “Configuring RADIUS” in the *Cisco IOS Security Configuration Guide*, Release 12.2
- The appendix “RADIUS Attributes” in the *Cisco IOS Security Configuration Guide*, Release 12.2
- The chapter “Configuring Virtual Private Networks” in the *Cisco IOS Dial Technologies Configuration Guide*, Release 12.2
- RFC 2868, *RADIUS Attributes for Tunnel Protocol Support*

## Supported Platforms

### Cisco IOS Release 12.1(5)T Only

- AS5300
- AS5800

### Cisco IOS Releases 12.2(4)B3 and 12.2(13)T Only

Cisco 6400-NRP-1

Cisco 6400-NRP-2

Cisco 6400-NRP-2SV

### Determining Platform Support Through Cisco Feature Navigator

Cisco IOS software is packaged in feature sets that are supported on specific platforms. To get updated information regarding platform support for this feature, access Cisco Feature Navigator. Cisco Feature Navigator dynamically updates the list of supported platforms as new platform support is added for the feature.

Cisco Feature Navigator is a web-based tool that enables you to determine which Cisco IOS software images support a specific set of features and which features are supported in a specific Cisco IOS image. You can search by feature or release. Under the release section, you can compare releases side by side to display both the features unique to each software release and the features in common.

To access Cisco Feature Navigator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to [cco-locksmith@cisco.com](mailto:cco-locksmith@cisco.com). An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions found at this URL:

<http://www.cisco.com/register>

Cisco Feature Navigator is updated regularly when major Cisco IOS software releases and technology releases occur. For the most current information, go to the Cisco Feature Navigator home page at the following URL:

<http://www.cisco.com/go/fn>

**Availability of Cisco IOS Software Images**

Platform support for particular Cisco IOS software releases is dependent on the availability of the software images for those platforms. Software images for some platforms may be deferred, delayed, or changed without prior notice. For updated information about platform support and availability of software images for each Cisco IOS software release, refer to the online release notes or, if supported, Cisco Feature Navigator.

## Supported Standards, MIBs, and RFCs

**Standards**

None

**MIBs**

None

To locate and download MIBs for selected platforms, Cisco IOS releases, and feature sets, use Cisco MIB Locator found at the following URL:

<http://tools.cisco.com/ITDIT/MIBS/servlet/index>

If Cisco MIB Locator does not support the MIB information that you need, you can also obtain a list of supported MIBs and download MIBs from the Cisco MIBs page at the following URL:

<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>

To access Cisco MIB Locator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to [cco-locksmith@cisco.com](mailto:cco-locksmith@cisco.com). An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions found at this URL:

<http://www.cisco.com/register>

**RFCs**

- RFC 2868, *RADIUS Attributes for Tunnel Protocol Support*

## Prerequisites

To use RADIUS attributes 90 and 91, you must complete the following tasks:

- Configure your NAS to support AAA.
- Configure your NAS to support RADIUS.
- Configure your NAS to support VPN.

## Configuration Tasks

None

## Verifying RADIUS Attribute 90 and RADIUS Attribute 91

To verify that RADIUS attribute 90 and RADIUS attribute 91 are being sent in access accepts and accounting requests, use the following command in privileged EXEC mode:

| Command                     | Purpose                                                                                                                                                                       |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router# <b>debug radius</b> | Displays information associated with RADIUS. The output of this command shows whether attribute 90 and attribute 91 are being sent in access accepts and accounting requests. |

## Configuration Examples

This section provides the following configuration examples:

- [L2TP Network Server \(LNS\) Configuration Example](#)
- [RADIUS User Profile with RADIUS Tunneling Attributes 90 and 91 Example](#)

### L2TP Network Server (LNS) Configuration Example

The following example shows how to configure the LNS with a basic L2F and L2TP configuration using RADIUS tunneling attributes 90 and 91:

```
aaa new-model
aaa authentication login default none
aaa authentication login console none
aaa authentication ppp default local group radius
aaa authorization network default group radius if-authenticated
!
username l2f-cli-auth-id password 0 l2f-cli-pass
username l2f-svr-auth-id password 0 l2f-svr-pass
username l2tp-svr-auth-id password 0 l2tp-tnl-pass
!
vpdn enable
vpdn search-order domain
!
vpdn-group 1
accept-dialin
protocol l2f
virtual-template 1
terminate-from hostname l2f-cli-auth-id
local name l2f-svr-auth-id
!
vpdn-group 2
accept-dialin
protocol l2tp
virtual-template 2
terminate-from hostname l2tp-cli-auth-id
local name l2tp-svr-auth-id
!
interface Ethernet1/0
ip address 10.0.0.3 255.255.255.0
no ip route-cache
no ip mroute-cache
```

```

!
interface Virtual-Template1
ip unnumbered Ethernet1/0
ppp authentication pap
!
interface Virtual-Template2
ip unnumbered Ethernet1/0
ppp authentication pap
!
radius-server host 1.1.1.1 auth-port 1645 acct-port 1646
radius-server key <deleted>
!

```

## RADIUS User Profile with RADIUS Tunneling Attributes 90 and 91 Example

The following is an example of a RADIUS user profile that includes RADIUS tunneling attributes 90 and 91. This entry supports two tunnels, one for L2F and the other for L2TP. The tag entries with :1 support L2F tunnels, and the tag entries with :2 support L2TP tunnels.

```

cisco.com Password = "cisco", Service-Type = Outbound
 Service-Type = Outbound,
 Tunnel-Type = :1:L2F,
 Tunnel-Medium-Type = :1:IP,
 Tunnel-Client-Endpoint = :1:"10.0.0.2",
 Tunnel-Server-Endpoint = :1:"10.0.0.3",
 Tunnel-Client-Auth-Id = :1:"l2f-cli-auth-id",
 Tunnel-Server-Auth-Id = :1:"l2f-svr-auth-id",
 Tunnel-Assignment-Id = :1:"l2f-assignment-id",
 Cisco-Avpair = "vpdn:nas-password=l2f-cli-pass",
 Cisco-Avpair = "vpdn:gw-password=l2f-svr-pass",
 Tunnel-Preference = :1:1,
 Tunnel-Type = :2:L2TP,
 Tunnel-Medium-Type = :2:IP,
 Tunnel-Client-Endpoint = :2:"10.0.0.2",
 Tunnel-Server-Endpoint = :2:"10.0.0.3",
 Tunnel-Client-Auth-Id = :2:"l2tp-cli-auth-id",
 Tunnel-Server-Auth-Id = :2:"l2tp-svr-auth-id",
 Tunnel-Assignment-Id = :2:"l2tp-assignment-id",
 Cisco-Avpair = "vpdn:l2tp-tunnel-password=l2tp-tnl-pass",
 Tunnel-Preference = :2:2

```

## Command Reference

This feature uses no new or modified commands. To see the command pages for the commands used with this feature, see the Cisco IOS Security Command Reference at

[http://www.cisco.com/en/US/docs/ios/security/command/reference/sec\\_book.html](http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html).

For information about all Cisco IOS commands, see the Command Lookup Tool at

<http://tools.cisco.com/Support/CLILookup> or the Master Command List.

# Glossary

**Layer 2 Forwarding (L2F)**—A Layer 2 tunneling protocol that enables an ISP or other access service to create a virtual tunnel to link customer remote sites or remote users with corporate home networks. In particular, a network access server (NAS) at the ISP point of presence (POP) exchanges PPP messages with the remote users and communicates by L2F or L2TP requests and responses with the customer tunnel server to set up tunnels.

**Layer 2 Tunnel Protocol (L2TP)**—A Layer 2 tunneling protocol that enables an ISP or other access service to create a virtual tunnel to link customer remote sites or remote users with corporate home networks. In particular, a network access server (NAS) at the ISP point of presence (POP) exchanges PPP messages with the remote users and communicates by L2F or L2TP requests and responses with the customer tunnel server to set up tunnels.

**L2TP access concentrator (LAC)**—A network access server (NAS) to which the client directly connects and through which PPP frames are tunneled to the L2TP network server (LNS). The LAC need only implement the media over which L2TP is to operate to pass traffic to one or more LNSs. The LAC may tunnel any protocol carried within PPP. The LAC initiates incoming calls and receives outgoing calls. A LAC is analogous to an L2F network access server.

**L2TP network server (LNS)**—A termination point for L2TP tunnels, and an access point where PPP frames are processed and passed to higher-layer protocols. An LNS can operate on any platform that terminates PPP. The LNS handles the server side of the L2TP protocol. L2TP relies only on the single medium over which L2TP tunnels arrive. The LNS initiates outgoing calls and receives incoming calls. An LNS is analogous to a home gateway in L2F technology.

**network access server (NAS)**—A Cisco platform, or collection of platforms, such as an AccessPath system, that interfaces between the packet world (such as the Internet) and the circuit-switched world (such as the PSTN).

**tunnel**—A virtual pipe between the L2TP access concentrator (LAC) and L2TP network server (LNS) that can carry multiple PPP sessions.

**virtual private network (VPN)**—A system that permits dial-in networks to exist remotely to home networks, while giving the appearance of being directly connected. VPNs use L2TP and L2F to terminate the Layer 2 and higher parts of the network connection at the L2TP network server (LNS) instead of the L2TP access concentrator (LAC).

# RADIUS Vendor-Proprietary Attributes

---

**First Published: May 15, 2001**

**Last Updated: September 25, 2008**

The IETF draft standard for RADIUS specifies a method for communicating vendor-proprietary information between the network access server and the RADIUS server. However, some vendors have extended the RADIUS attribute set for specific applications. This document provides Cisco IOS support information for these vendor-proprietary RADIUS attributes.

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the [“Feature Information for RADIUS Vendor-Proprietary Attributes” section on page 13](#).

Use Cisco Feature Navigator to find information about platform support and Cisco IOS, Catalyst OS, and Cisco IOS XE software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Contents

- [Supported Vendor-Proprietary RADIUS Attributes](#)
- [Comprehensive List of Vendor-Proprietary RADIUS Attribute Descriptions](#)

## Supported Vendor-Proprietary RADIUS Attributes

[Table 73](#) lists Cisco-supported vendor-proprietary RADIUS attributes and the Cisco IOS release in which they are implemented. In cases where the attribute has a security server-specific format, the format is specified. Refer to [Table 74](#) for a list of descriptions.

---

**Americas Headquarters:**

**Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA**

**Note**

Attributes implemented in special (AA) or early development (T) releases will be added to the next mainline image.

**Table 73** *Supported Vendor-Proprietary RADIUS Attributes*

| Number | Vendor-Proprietary Attribute | 11.1 | 11.2 | 11.3 | 11.3AA | 11.3T | 12.0 | 12.1 | 12.2 | 12.3 | 12.4 |
|--------|------------------------------|------|------|------|--------|-------|------|------|------|------|------|
| 17     | Change-Password              | no   | no   | yes  | yes    | yes   | yes  | yes  | yes  | no   | no   |
| 21     | Password-Expiration          | no   | no   | yes  | yes    | yes   | yes  | yes  | yes  | no   | no   |

## Comprehensive List of Vendor-Proprietary RADIUS Attribute Descriptions

Table 74 lists and describes the known vendor-proprietary RADIUS attributes:

**Table 74**      **Vendor-Proprietary RADIUS Attributes**

| Number | Vendor-Proprietary Attribute | Description                                                                                                                                                          |
|--------|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 17     | Change-Password              | Specifies a request to change the password of a user.                                                                                                                |
| 21     | Password-Expiration          | Specifies an expiration date for a user's password in the user's file entry.                                                                                         |
| 68     | Tunnel-ID                    | (Ascend 5) Specifies the string assigned by RADIUS for each session using CLID or DNIS tunneling. When accounting is implemented, this value is used for accounting. |
| 108    | My-Endpoint-Disc-Alias       | (Ascend 5) No description available.                                                                                                                                 |
| 109    | My-Name-Alias                | (Ascend 5) No description available.                                                                                                                                 |
| 110    | Remote-FW                    | (Ascend 5) No description available.                                                                                                                                 |
| 111    | Multicast-GLeave-Delay       | (Ascend 5) No description available.                                                                                                                                 |
| 112    | CBCP-Enable                  | (Ascend 5) No description available.                                                                                                                                 |
| 113    | CBCP-Mode                    | (Ascend 5) No description available.                                                                                                                                 |
| 114    | CBCP-Delay                   | (Ascend 5) No description available.                                                                                                                                 |
| 115    | CBCP-Trunk-Group             | (Ascend 5) No description available.                                                                                                                                 |
| 116    | Appletalk-Route              | (Ascend 5) No description available.                                                                                                                                 |
| 117    | Appletalk-Peer-Mode          | (Ascend 5) No description available.                                                                                                                                 |
| 118    | Route-Appletalk              | (Ascend 5) No description available.                                                                                                                                 |
| 119    | FCP-Parameter                | (Ascend 5) No description available.                                                                                                                                 |
| 120    | Modem-PortNo                 | (Ascend 5) No description available.                                                                                                                                 |
| 121    | Modem-SlotNo                 | (Ascend 5) No description available.                                                                                                                                 |

**Table 74 Vendor-Proprietary RADIUS Attributes (continued)**

| Number | Vendor-Proprietary Attribute | Description                                                                                                                              |
|--------|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| 122    | Modem-ShelfNo                | (Ascend 5) No description available.                                                                                                     |
| 123    | Call-Attempt-Limit           | (Ascend 5) No description available.                                                                                                     |
| 124    | Call-Block-Duration          | (Ascend 5) No description available.                                                                                                     |
| 125    | Maximum-Call-Duration        | (Ascend 5) No description available.                                                                                                     |
| 126    | Router-Preference            | (Ascend 5) No description available.                                                                                                     |
| 127    | Tunneling-Protocol           | (Ascend 5) No description available.                                                                                                     |
| 128    | Shared-Profile-Enable        | (Ascend 5) No description available.                                                                                                     |
| 129    | Primary-Home-Agent           | (Ascend 5) No description available.                                                                                                     |
| 130    | Secondary-Home-Agent         | (Ascend 5) No description available.                                                                                                     |
| 131    | Dialout-Allowed              | (Ascend 5) No description available.                                                                                                     |
| 133    | BACP-Enable                  | (Ascend 5) No description available.                                                                                                     |
| 134    | DHCP-Maximum-Leases          | (Ascend 5) No description available.                                                                                                     |
| 135    | Primary-DNS-Server           | Identifies a primary DNS server that can be requested by Microsoft PPP clients from the network access server during IPCP negotiation.   |
| 136    | Secondary-DNS-Server         | Identifies a secondary DNS server that can be requested by Microsoft PPP clients from the network access server during IPCP negotiation. |
| 137    | Client-Assign-DNS            | No description available.                                                                                                                |
| 138    | User-Acct-Type               | No description available.                                                                                                                |
| 139    | User-Acct-Host               | No description available.                                                                                                                |
| 140    | User-Acct-Port               | No description available.                                                                                                                |
| 141    | User-Acct-Key                | No description available.                                                                                                                |
| 142    | User-Acct-Base               | No description available.                                                                                                                |

| 172    | Base-Channel-Count           | No description available.                                                                                             |
| 173    | Minimum-Channels             | No description available.                                                                                             |
| 174    | IPX-Route                    | No description available.                                                                                             |
| 175    | FT1-Caller                   | No description available.                                                                                             |
| 176    | Backup                       | No description available.                                                                                             |
| 177    | Call-Type                    | No description available.                                                                                             |
| 178    | Group                        | No description available.                                                                                             |
| 179    | FR-DLCI                      | No description available.                                                                                             |
| 180    | FR-Profile-Name              | No description available.                                                                                             |
| 181    | Ara-PW                       | No description available.                                                                                             |
| 182    | IPX-Node-Addr                | No description available.                                                                                             |
| 183    | Home-Agent-IP-Addr           | Indicates the home agent's IP address (in dotted decimal format) when using Ascend Tunnel Management Protocol (ATMP). |
| 184    | Home-Agent-Password          | With ATMP, specifies the password that the foreign agent uses to authenticate itself.                                 |
| 185    | Home-Network-Name            | With ATMP, indicates the name of the connection profile to which the home agent sends all packets.                    |
| 186    | Home-Agent-UDP-Port          | Indicates the UDP port number the foreign agent uses to send ATMP messages to the home agent.                         |

**Table 74**      **Vendor-Proprietary RADIUS Attributes (continued)**

| Number | Vendor-Proprietary Attribute | Description                                                                                                                                                                                                                                                                                                                                                                                          |
|--------|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 187    | Multilink-ID                 | Reports the identification number of the multilink bundle when the session closes. This attribute applies to sessions that are part of a multilink bundle. The Multilink-ID attribute is sent in authentication-response packets.                                                                                                                                                                    |
| 188    | Num-In-Multilink             | Reports the number of sessions remaining in a multilink bundle when the session reported in an accounting-stop packet closes. This attribute applies to sessions that are part of a multilink bundle. The Num-In-Multilink attribute is sent in authentication-response packets and in some accounting-request packets.                                                                              |
| 189    | First-Dest                   | Records the destination IP address of the first packet received after authentication.                                                                                                                                                                                                                                                                                                                |
| 190    | Pre-Input-Octets             | Records the number of input octets before authentication. The Pre-Input-Octets attribute is sent in accounting-stop records.                                                                                                                                                                                                                                                                         |
| 191    | Pre-Output-Octets            | Records the number of output octets before authentication. The Pre-Output-Octets attribute is sent in accounting-stop records.                                                                                                                                                                                                                                                                       |
| 192    | Pre-Input-Packets            | Records the number of input packets before authentication. The Pre-Input-Packets attribute is sent in accounting-stop records.                                                                                                                                                                                                                                                                       |
| 193    | Pre-Output-Packets           | Records the number of output packets before authentication. The Pre-Output-Packets attribute is sent in accounting-stop records.                                                                                                                                                                                                                                                                     |
| 194    | Maximum-Time                 | Specifies the maximum length of time (in seconds) allowed for any session. After the session reaches the time limit, its connection is dropped.                                                                                                                                                                                                                                                      |
| 195    | Disconnect-Cause             | Specifies the reason a connection was taken offline. The Disconnect-Cause attribute is sent in accounting-stop records. This attribute also causes stop records to be generated without first generating start records if disconnection occurs before authentication is performed. For more information, refer to the table of <a href="#">Disconnect-Cause Attribute Values</a> and their meanings. |
| 196    | Connect-Progress             | Indicates the connection state before the connection is disconnected.                                                                                                                                                                                                                                                                                                                                |
| 197    | Data-Rate                    | Specifies the average number of bits per second over the course of the connection's lifetime. The Data-Rate attribute is sent in accounting-stop records.                                                                                                                                                                                                                                            |
| 198    | PreSession-Time              | Specifies the length of time, in seconds, from when a call first connects to when it completes authentication. The PreSession-Time attribute is sent in accounting-stop records.                                                                                                                                                                                                                     |
| 199    | Token-Idle                   | Indicates the maximum amount of time (in minutes) a cached token can remain alive between authentications.                                                                                                                                                                                                                                                                                           |
| 201    | Require-Auth                 | Defines whether additional authentication is required for class that has been CLID authenticated.                                                                                                                                                                                                                                                                                                    |

**Table 74**      **Vendor-Proprietary RADIUS Attributes (continued)**

| Number | Vendor-Proprietary Attribute | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 202    | Number-Sessions              | Specifies the number of active sessions (per class) reported to the RADIUS accounting server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 203    | Authen-Alias                 | Defines the RADIUS server's login name during PPP authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 204    | Token-Expiry                 | Defines the lifetime of a cached token.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 205    | Menu-Selector                | Defines a string to be used to cue a user to input data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 206    | Menu-Item                    | Specifies a single menu-item for a user-profile. Up to 20 menu items can be assigned per profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 207    | PW-Warntime                  | (Ascend 5) No description available.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 208    | PW-Lifetime                  | Enables you to specify on a per-user basis the number of days that a password is valid.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 209    | IP-Direct                    | <p>When you include this attribute in a user's file entry, a framed route is installed to the routing and bridging tables.</p> <p><b>Note</b>    Packet routing is dependent upon the entire table, not just this newly installed entry. The inclusion of this attribute does not guarantee that all packets should be sent to the specified IP address; thus, this attribute is not fully supported.</p> <p>These attribute limitations occur because the Cisco router cannot bypass all internal routing and bridging tables and send packets to a specified IP address.</p> |
| 210    | PPP-VJ-Slot-Comp             | Instructs the Cisco router not to use slot compression when sending VJ-compressed packets over a PPP link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 211    | PPP-VJ-1172                  | Instructs PPP to use the 0x0037 value for VJ compression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 212    | PPP-Async-Map                | Gives the Cisco router the asynchronous control character map for the PPP session. The specified control characters are passed through the PPP link as data and used by applications running over the link.                                                                                                                                                                                                                                                                                                                                                                    |
| 213    | Third-Prompt                 | Defines a third prompt (after username and password) for additional user input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 214    | Send-Secret                  | Enables an encrypted password to be used in place of a regular password in outdial profiles.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 215    | Receive-Secret               | Enables an encrypted password to be verified by the RADIUS server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 216    | IPX-Peer-Mode                | (Ascend 5) No description available.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 217    | IP-Pool-Definition           | Defines a pool of addresses using the following format: X a.b.c Z; where X is the pool index number, a.b.c is the pool's starting IP address, and Z is the number of IP addresses in the pool. For example, 3 10.0.0.1 5 allocates 10.0.0.1 through 10.0.0.5 for dynamic assignment.                                                                                                                                                                                                                                                                                           |
| 218    | Assign-IP-Pool               | Tells the router to assign the user and IP address from the IP pool.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Table 74**      **Vendor-Proprietary RADIUS Attributes (continued)**

| Number | Vendor-Proprietary Attribute | Description                                                                                                                                                                                                                                                                         |
|--------|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 219    | FR-Direct                    | Defines whether the connection profile operates in Frame Relay redirect mode.                                                                                                                                                                                                       |
| 220    | FR-Direct-Profile            | Defines the name of the Frame Relay profile carrying this connection to the Frame Relay switch.                                                                                                                                                                                     |
| 221    | FR-Direct-DLCI               | Indicates the DLCI carrying this connection to the Frame Relay switch.                                                                                                                                                                                                              |
| 222    | Handle-IPX                   | Indicates how NCP watchdog requests will be handled.                                                                                                                                                                                                                                |
| 223    | Netware-Timeout              | Defines, in minutes, how long the RADIUS server responds to NCP watchdog packets.                                                                                                                                                                                                   |
| 224    | IPX-Alias                    | Allows you to define an alias for IPX routers requiring numbered interfaces.                                                                                                                                                                                                        |
| 225    | Metric                       | No description available.                                                                                                                                                                                                                                                           |
| 226    | PRI-Number-Type              | No description available.                                                                                                                                                                                                                                                           |
| 227    | Dial-Number                  | Defines the number to dial.                                                                                                                                                                                                                                                         |
| 228    | Route-IP                     | Indicates whether IP routing is allowed for the user's file entry.                                                                                                                                                                                                                  |
| 229    | Route-IPX                    | Allows you to enable IPX routing.                                                                                                                                                                                                                                                   |
| 230    | Bridge                       | No description available.                                                                                                                                                                                                                                                           |
| 231    | Send-Auth                    | Defines the protocol to use (PAP or CHAP) for username-password authentication following CLID authentication.                                                                                                                                                                       |
| 232    | Send-Passwd                  | Enables the RADIUS server to specify the password that is sent to the remote end of a connection on outgoing calls.                                                                                                                                                                 |
| 233    | Link-Compression             | <p>Defines whether to turn on or turn off "stac" compression over a PPP link.</p> <p>Link compression is defined as a numeric value as follows:</p> <ul style="list-style-type: none"> <li>• 0: None</li> <li>• 1: Stac</li> <li>• 2: Stac-Draft-9</li> <li>• 3: MS-Stac</li> </ul> |
| 234    | Target-Util                  | Specifies the load-threshold percentage value for bringing up an additional channel when PPP multilink is defined.                                                                                                                                                                  |
| 235    | Maximum-Channels             | Specifies allowed/allocatable maximum number of channels.                                                                                                                                                                                                                           |
| 236    | Inc-Channel-Count            | No description available.                                                                                                                                                                                                                                                           |
| 237    | Dec-Channel-Count            | No description available.                                                                                                                                                                                                                                                           |
| 238    | Seconds-of-History           | No description available.                                                                                                                                                                                                                                                           |
| 239    | History-Weigh-Type           | No description available.                                                                                                                                                                                                                                                           |
| 240    | Add-Seconds                  | No description available.                                                                                                                                                                                                                                                           |
| 241    | Remove-Seconds               | No description available.                                                                                                                                                                                                                                                           |

**Table 74**      **Vendor-Proprietary RADIUS Attributes (continued)**

| Number | Vendor-Proprietary Attribute | Description                                                                                                                                                                                                                                                                                     |
|--------|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 242    | Data-Filter                  | Defines per-user IP data filters. These filters are retrieved only when a call is placed using a RADIUS outgoing profile or answered using a RADIUS incoming profile. Filter entries are applied on a first-match basis; therefore, the order in which filter entries are entered is important. |
| 243    | Call-Filter                  | Defines per-user IP data filters. On a Cisco router, this attribute is identical to the Data-Filter attribute.                                                                                                                                                                                  |
| 244    | Idle-Limit                   | Specifies the maximum time (in seconds) that any session can be idle. When the session reaches the idle time limit, its connection is dropped.                                                                                                                                                  |
| 245    | Preempt-Limit                | No description available.                                                                                                                                                                                                                                                                       |
| 246    | Callback                     | Allows you to enable or disable callback.                                                                                                                                                                                                                                                       |
| 247    | Data-Svc                     | No description available.                                                                                                                                                                                                                                                                       |
| 248    | Force-56                     | Determines whether the network access server uses only the 56 K portion of a channel, even when all 64 K appear to be available.                                                                                                                                                                |
| 249    | Billing Number               | No description available.                                                                                                                                                                                                                                                                       |
| 250    | Call-By-Call                 | No description available.                                                                                                                                                                                                                                                                       |
| 251    | Transit-Number               | No description available.                                                                                                                                                                                                                                                                       |
| 252    | Host-Info                    | No description available.                                                                                                                                                                                                                                                                       |
| 253    | PPP-Address                  | Indicates the IP address reported to the calling unit during PPP IPCP negotiations.                                                                                                                                                                                                             |
| 254    | MPP-Idle-Percent             | No description available.                                                                                                                                                                                                                                                                       |
| 255    | Xmit-Rate                    | (Ascend 5) No description available.                                                                                                                                                                                                                                                            |

For more information on vendor-proprietary RADIUS attributes, refer to the section “[Configuring Router for Vendor-Proprietary RADIUS Server Communication](#)” in the chapter “[Configuring RADIUS](#).”

# Feature Information for RADIUS Vendor-Proprietary Attributes

Table 75 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Note

Table 75 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

**Table 75** Feature Information for RADIUS Vendor-Proprietary Attributes

| Feature Name                         | Releases  | Feature Information                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RADIUS Vendor-Proprietary Attributes | 12.2(1)XE | The IETF draft standard for RADIUS specifies a method for communicating vendor-proprietary information between the network access server and the RADIUS server. However, some vendors have extended the RADIUS attribute set for specific applications. This document provides Cisco IOS support information for these vendor-proprietary RADIUS attributes.<br><br>In 12.2(1) XE, this feature was introduced. |
